History of Education

Education can be thought of as the transmission of the values and accumulated knowledge of a society. In this sense, it is equivalent to what social scientists term socialization or enculturation. Children—whether conceived among New Guinea tribespeople, the Renaissance Florentines, or the middle classes of Manhattan—are born without culture. Education is designed to guide them in learning a culture, molding their behaviour in the ways of adulthood, and directing them toward their eventual role in society. In the most primitive cultures, there is often little formal learning, little of what one would ordinarily call school or classes or teachers; instead, frequently, the entire environment and all activities are viewed as school and classes, and many or all adults act as teachers. As societies grow more complex, however, the quantity of knowledge to be passed on from one generation to the next becomes more than any one person can know; and hence there must evolve more selective and efficient means of cultural transmission. The outcome is formal education—the school and the specialist called the teacher.

As society becomes ever more complex and schools become ever more institutionalized, educational experience becomes less directly related to daily life, less a matter of showing and learning in the context of the workaday world, and more abstracted from practice, more a matter of distilling, telling, and learning things out of context. This concentration of learning in a formal atmosphere allows children to learn far more of their culture than they are able to do by merely observing and imitating. As society gradually attaches more and more importance to education, it also tries to formulate the overall objectives, content, organization, and strategies of education. Literature becomes laden with advice on the rearing of the younger generation. In short, there develop philosophies and theories of education.

This article deals with the evolution of the formal teaching of knowledge and skills in all parts of the world and with the various philosophies that have inspired the resulting diverse systems. A further discussion of educational theory can be found in the article PHILOSOPHIES OF THE BRANCHES OF KNOWLEDGE. The teaching profession and the functions and methods of teachers are treated in TEACHING.

For coverage of related topics in the *Macropædia* and *Micropædia,* see the *Propædia,* sections 561 and 562, and the *Index.*

The article is divided into the following sections:

Education in primitive and early civilized cultures

PREHISTORIC AND PRIMITIVE CULTURES

The term education can be applied to primitive cultures only in the sense of enculturation, which is the process of cultural transmission. A primitive person, whose culture is the totality of his universe, has a relatively fixed sense of cultural continuity and timelessness. The model of life is relatively static and absolute, and it is transmitted from one generation to another with little deviation. As for prehistoric education, it can only be inferred from educational practices in surviving primitive cultures.

The purpose of primitive education is thus to guide children to becoming good members of their tribe or band. There is a marked emphasis upon training for citizenship, because primitive people are highly concerned with the growth of individuals as tribal members and the thorough comprehension of their way of life during passage from prepuberty to postpuberty.

Participatory learning in primitive societies

Because of the variety in the countless thousands of primitive cultures, it is difficult to describe any standard and uniform characteristics of prepuberty education. Nevertheless, certain things are practiced commonly within cultures. Children actually participate in the social processes of adult activities, and their participatory learning is based upon what the American anthropologist Margaret Mead has called empathy, identification, and imitation. Primitive children, before reaching puberty, learn by doing and observing basic technical practices. Their teachers are not strangers but, rather, their immediate community.

In contrast to the spontaneous and rather unregulated imitations in prepuberty education, postpuberty education in some cultures is strictly standardized and regulated. The teaching personnel may consist of fully initiated men, often unknown to the initiate though they are his relatives in other clans. The initiation may begin with the initiate being abruptly separated from his familial group and sent to a secluded camp where he joins other initiates. The purpose of this separation is to deflect the initiate's deep attachment away from his family and to establish his emotional and social anchorage in the wider web of his culture.

The initiation "curriculum" does not usually include practical subjects. Instead, it consists of a whole set of cultural values, tribal religion, myths, philosophy, history, rituals, and other knowledge. Primitive people in some cultures regard the body of knowledge constituting the initiation curriculum as most essential to their tribal membership. Within this essential curriculum, religious instruction takes the most prominent place.

EDUCATION IN THE EARLIEST CIVILIZATIONS

The Old World civilizations of Egypt, Mesopotamia, and North China. The history of civilization started in the Middle East about 3000 BC, whereas the North China civilization began about a millennium and a half later. The Mesopotamian and Egyptian civilizations flourished almost simultaneously during the first civilizational phase (3000–1500 BC). Although these civilizations differed, they shared monumental literary achievements. The need for the perpetuation of these highly developed civilizations made writing and formal education indispensable.

Egypt. Egyptian culture and education were preserved and controlled chiefly by the priests, a powerful intellectual elite in the Egyptian theocracy who also served as the political bulwarks by preventing cultural diversity. The humanities as well as such practical subjects as science, medicine, mathematics, and geometry were in the hands of the priests, who taught in formal schools. Vocational skills relating to such fields as architecture, engineering, and sculpture were generally transmitted outside the context of formal schooling.

Priestly control of Egyptian and Babylonian education

Egyptians developed two types of formal schools for privileged youth under the supervision of governmental officials and priests: one for scribes and the other for priest trainees. At the age of five, pupils entered the writing school and continued their studies in reading and writing until the age of 16 or 17. At the age of 13 or 14, the schoolboys were also given practical training in offices for which they were being prepared. Priesthood training began at the temple college, which boys entered at the age of 17, the length of training depending upon the requirements for various priestly offices. It is not clear whether or not the practical sciences constituted a part of the systematically organized curriculum of the temple college.

Rigid method and severe discipline were applied to achieve uniformity in cultural transmission, since deviation from the traditional pattern of thought was strictly prohibited. Drill and memorization were the typical methods employed. But, as noted, Egyptians also used a work-study method in the final phase of the training for scribes.

Mesopotamia. As a civilization contemporary with Egyptian civilization, Mesopotamia developed education quite similar to that of its counterpart with respect to its purpose and training. Formal education was practical and aimed to train scribes and priests. It was extended from basic reading, writing, and religion to higher learning in law, medicine, and astrology. Generally, youth of the upper classes were prepared to become scribes, who ranged from copyists to librarians and teachers. The schools for priests were said to be as numerous as temples. This in-

dicates not only the thoroughness but also the supremacy of priestly education. Very little is known about higher education, but the advancement of the priestly work sheds light upon the extensive nature of intellectual pursuit.

As in the case of Egypt, the priests in Mesopotamia dominated the intellectual and educational domain as well as the applied. The centre of intellectual activity and training was the library, which was usually housed in a temple under the supervision of influential priests. Methods of teaching and learning were memorization, oral repetition, copying of models, and individual instruction. It is believed that the exact copying of scripts was the hardest and most strenuous and served as the test of excellence in learning. The period of education was long and rigorous, and discipline was harsh.

North China. In North China, the civilization of which began with the emergence of the Shang era, complex educational practices were in effect at a very early date. In fact, every important foundation of the formation of modern Chinese character was already established, to a great extent, more than 3,000 years ago.

Moral emphases of Chinese education

Chinese ancient formal education was distinguished by its markedly secular and moral character. Its paramount purpose was to develop a sense of moral sensitivity and duty toward people and the state. Even in the early civilizational stage, harmonious human relations, rituals, and music formed the curriculum.

Formal colleges and schools probably antedate the Chou dynasty of the 1st millennium BC, at least in the imperial capitals. Local states probably had less-organized institutions, such as halls of study, village schools, and district schools. With regard to actual methods of education, ancient Chinese learned from bamboo books and obtained moral training and practice in rituals by word of mouth and example. Rigid rote learning, which typified later Chinese education, seems to have been rather condemned. Education was regarded as the process of individual development from within.

The New World civilizations of the Maya, Aztec, and Inca. The outstanding cultural achievements of the pre-Columbian civilizations are often compared with those of Old World civilizations. The ancient Mayan calendar, which surpassed Europe's Julian calendar in accuracy, was, for example, a great accomplishment demonstrating the extraordinary degree of knowledge of astronomy and mathematics possessed by the Maya. Equally impressive are the sophistication of the Inca's calendar and their highway construction, the development of the Maya's complex writing system, and the magnificent temples of the Aztec. It is unfortunate that archaeological findings and written documents hardly shed sufficient light upon education among the Maya, Aztec, and Inca. But from available documents it is evident that these pre-Columbian civilizations developed formal education for training the nobility and priests. The major purposes of education were cultural conservation, vocational training, moral and character training, and control of cultural deviation.

The Maya. Being a highly religious culture, the Maya regarded the priesthood as one of the most influential factors in the development of their society. The priest enjoyed high prestige by virtue of his extensive knowledge, literate skills, and religious and moral leadership, and high priests served as major advisers of the rulers and the nobility. To obtain a priesthood, which was usually inherited from his father or another close relative, the trainee had to receive rigorous education in the school, where priests taught history, writing, methods of divining, medicine, and the calendar system.

Priestly control of Maya and Aztec education

Character training was one of the salient features of Mayan education. The inculcation of self-restraint, cooperative work, and moderation was highly emphasized in various stages of socialization as well as on various occasions of religious festivals. In order to develop self-discipline, the future priest endured a long period of continence and abstinence, and, to develop a sense of loyalty to community, he engaged in group labour.

The Aztec. Among the Aztec, cultural preservation relied heavily upon oral transmission and rote memorization of important events, calendrical information, and religious knowledge. Priests and noble elders, who were called conservators, were in charge of education. Since one of the important responsibilities of the conservator was to censor new poems and songs, he took the greatest care in teaching poetry, particularly divine songs.

At the *calmecac,* the school for native learning where apprenticeship started at the age of 10, the history of Mexico and the content of the historical codices were systematically taught. The *calmecac* played the most vital role in ensuring oral transmission of history through oratory, poetry, and music, which were employed to make accurate memorization of events easier and to galvanize remembrance. Visual aids, such as simple graphic representations, were used to guide recitation phases, to sustain interest, and to increase comprehension of facts and dates.

The Inca. The Inca did not possess a written or recorded language as far as is known. Like the Aztec, they also depended largely on oral transmission as a means of maintaining the preservation of their culture. Inca education was divided into two distinct categories: vocational education for common Inca and highly formalized training for the nobility. As the Inca empire was a theocratic, imperial government based upon agrarian collectivism, the rulers were concerned about the vocational training of men and women in collective agriculture. Personal freedom, life, and work were subservient to the community. At birth an individual's place in the society was strictly ordained, and at five years of age every child was taken over by the government, and his socialization and vocational training were supervised by government surrogates.

Education for the nobility consisted of a four-year program that was clearly defined in terms of the curricula and rituals. In the first year the pupils learned the Quechua language, the language of the nobility. The second year was devoted to the study of religion and the third year to learning about the quipus, a complex system of knotted coloured strings or cords used for sending messages and recording historical events. In the fourth year major attention was given to the study of history, with additional instruction in sciences, geometry, geography, and astronomy. The instructors were highly respected encyclopaedic scholars known as *amautas.* After the completion of this education, the pupils were required to pass a series of rigorous examinations in order to attain full status in the life of the Inca nobility. (N.S.)

Education in classical cultures

ANCIENT INDIA

The Hindu tradition. India is the site of one of the most ancient civilizations in the world. About the 2nd millennium BC the Aryans entered the land and came into conflict with the *dāsa*s, or the non-Aryan tribes. They defeated them, spread far and wide in the country, established large-scale settlements, and founded powerful kingdoms. In the course of time, a section of the intellectuals, the Brahmans, became priests and men of learning; another group, nobles and soldiers, became Kṣatriyas; the agricultural and trading class was called Vaiśyas; and finally the *dāsa*s were absorbed as Śūdras, or domestic servants. Such was the origin of the division of the Hindus into four varnas, or "classes." By about 500 BC, the classes became hardened into castes.

Religion was the mainspring of all activities in ancient India. It was of an all-absorbing interest and embraced not only prayer and worship but philosophy, morality, law, and government as well. Religion saturated educational ideals, too, and the study of Vedic literature was indispensable to higher castes. The stages of instruction were very well defined. During the first period, the child received elementary education at home. The beginning of secondary education and formal schooling was marked by a ritual known as the *upanayana,* or thread ceremony, which was restricted to boys only and was more or less compulsory for boys of the three higher castes. The Brahman boys had this ceremony at the age of eight, the Kṣatriya boys at the age of 11, and the Vaiśya boys at the age of 12 years. The boy would leave his father's house and enter his preceptor's *āśrama,* or home, situated amid sylvan surroundings.

The Vedic tradition in Hindu education

The *ācārya* would treat him as his own child, give him free education, and not charge anything for his boarding and lodging. The pupil had to tend the sacrificial fires, do the household work of his preceptor, and look after his cattle.

The study at this stage consisted of the recitation of the Vedic mantras, or "hymns," and the auxiliary sciences—phonetics, the rules for the performance of the sacrifices, grammar, astronomy, prosody, and etymology. The character of education, however, differed according to the needs of the caste. For a child of the priestly class, there was a definite syllabus of studies. The *trayī-vidyā,* or the knowledge of the three Vedas, the most ancient of Hindu scriptures, was obligatory for him. During the whole course at school, as at college, the student had to observe brahmacharya—that is, wearing a simple dress, living on plain food, using a hard bed, and leading a celibate life.

The period of studentship normally extended to 12 years. For those who wanted to continue their studies, there was no age limit. After finishing their education at an *āśrama,* or forest school, they would join a higher centre of learning or a university presided over by a *kulapati* (a founder of a school of thought). Advanced students would also improve their knowledge by taking part in philosophical discussions at a *parisad,* or "academy." Education was not denied to women, but normally girls were instructed at home.

The method of instruction differed according to the nature of the subject. The first duty of the student was to memorize the particular Veda of his school, with special emphasis placed on correct pronunciation. In the study of such literary subjects as law, logic, rituals, and prosody, comprehension played a very important role. A third method was the use of parables, which were employed in the personal spiritual teaching relating to the Upanishads, or conclusion of the Vedas. In higher learning, such as in the teaching of dharmashastra ("righteousness science"), the most popular and useful method was catechism—the pupil asking questions and the teacher discoursing at length on the topics referred to him. Memorization, however, played the greatest role.

The introduction of Buddhist influences. By about the end of the 6th century BC, the Vedic rituals and sacrifices had gradually developed into a highly elaborate cult that profited the priests but antagonized an increasing section of the people. Education became generally confined to the Brahmans, and the *upanayana* was being gradually discarded by the non-Brahmans. The formalism and exclusiveness of the Brahmanic system was largely responsible for the rise of two new religious orders, Buddhism and Jainism. Neither of them recognized the authority of the Vedas, and both challenged the exclusive claims of the Brahmans to priesthood. They taught through the common language of the people and gave education to all, irrespective of caste, creed, or sex. Buddhism also introduced the monastic system of education. Monasteries attached to Buddhist temples served the double purpose of imparting education and of training persons for priesthood. A monastery, however, educated only those who were its members. It did not admit day scholars and thus did not cater to the needs of the entire population.

Buddhism and Jainism in Indian education

Meanwhile, significant developments were taking place in the political field that had repercussions on education. The establishment of the imperialistic Nanda dynasty in about 413 BC and then of the even stronger Mauryas some 40 years later shook the very foundations of the Vedic structure of life, culture, and polity. The Brahmans in large numbers gave up their ancient occupation of teaching in their forest retreats and took to all sorts of occupations; the Kṣatriyas also abandoned their ancient calling as warriors; and the Śūdras in their turn rose from their servile occupations. These forces produced revolutionary changes in education. Schools were established in growing towns, and even day scholars were admitted. Studies were chosen freely and not according to caste. Taxila had already acquired an international reputation in the 6th century BC as a centre of advanced studies and now improved upon it. It did not possess any college or university in the modern sense of the term, but it was a great centre of learning with a number of famous teachers, each having a school of his own.

In the 3rd century BC Buddhism received a great impetus under India's most celebrated ruler, Aśoka. After his death, Buddhism evoked resistance, and a counterreformation in Hinduism began in the country. About the 1st century AD there was also a widespread lay movement among both Buddhists and Hindus. As a result of these events, Buddhist monasteries began to undertake secular as well as religious education, and there began a large growth of popular elementary education along with secondary and higher learning.

Classical India. The 500 years from the 4th century AD to the close of the 8th, under the Guptas and Harṣa and their successors, is a remarkable period in Indian history. It was the age of the universities of Nālandā and Valabhī and of the rise of Indian sciences, mathematics, and astronomy. The university at Nālandā housed a population of several thousand teachers and students, who were maintained out of the revenues from more than 100 villages. Because of its fame, Nālandā attracted students from abroad, but the admission test was so strict that only two or three out of 10 attained admission. More than 1,500 teachers discussed over 100 different dissertations every day. These covered the Vedas, logic, grammar, Buddhist and Hindu philosophy (Sankhya, Nyaya, etc.), astronomy, and medicine. Other great centres of Buddhist learning of the post-Gupta era were Vikramaśīla, Odantapurī, and Jagaddala. The achievements in science were no less significant. Āryabhaṭa in the late 5th century was the greatest mathematician of his age. He introduced the concepts of zero and decimals. Varāhamihira of the Gupta age was a profound scholar of all the sciences and arts, from botany to astronomy and from military science to civil engineering. There was also considerable development of the medical sciences. According to contemporaries, more than eight branches of medical science, including surgery and pediatrics, were practiced by the physicians.

The university at Nālandā

These were the main developments in education prior to the Muslim invasions, beginning in the 10th century. Nearly every village had its schoolmaster, who was supported from local contributions. The Hindu schools of learning, known as *pathasala*s in western India and *tol*s in Bengal, were conducted by Brahman *ācārya*s at their residence. Each imparted instruction in an advanced branch of learning and had a student enrollment of not more than 30. Larger or smaller establishments, specially endowed by rajas and other donors for the promotion of learning, also grew in number. The usual centres of learning were either some king's capital, such as Kanauj, Dhār, Mithilā, or Ujjayinī, or a holy place, such as Vārānasi, Ayodhyā, Kāñchi, or Nasik. In addition to Buddhist viharas (monasteries), there sprang up Hindu *maṭha*s (monks' residences) and temple colleges in different parts of the country. There were also *agrahāra* villages, which were given in charity to the colonies of learned Brahmans in order to enable them to discharge their scriptural duties, including teaching. Girls were usually educated at home, and vocational education was imparted through a system of apprenticeship.

Indian influences on Asia. An account of Indian education during the ancient period would be incomplete without a discussion of the influence of Indian culture on Sri Lanka and Central and Southeast Asia. It was achieved partly through cultural or trade relations and partly through political influence. Khotān in Central Asia had a famous Buddhist vihara as early as in the 1st century AD. A number of Indian scholars lived there, and many Chinese pilgrims, instead of going to India, stayed there. Indian pandits (scholars) were also invited to China and Tibet, and many Chinese and Tibetan monks studied in Buddhist viharas in India.

The process of Indianization was at its highest in Southeast Asia. Beginning in the 2nd century AD Hindu rulers reigned in Indochina and in the numerous islands of the East Indian archipelago, from Sumatra to New Guinea, for a period of 1,500 years. These regions were peopled by primitive races, who adopted the civilization of their masters. A greater India was thus established by a general fusion of cultures. Some of the inscriptions of these countries, written in flawless Sanskrit, show the influence

Indianization of Southeast Asia

of Indian culture. There are references to Indian philosophical ideas, legends, and myths and to Indian astronomical systems and measurements. Hinduism continued to wield its influence on these lands so long as the Hindus ruled in India. This influence ceased by the 15th century AD. (S.N.M.)

ANCIENT CHINA

Ancient Chinese education served the needs of a simple agricultural society with the family as the basic social organization. Paper and the writing brush had not been invented, and the "bamboo books" then recorded to be in existence were of limited use at best. Oral instruction and teaching by example were the chief methods of education.

The molding of character was a primary aim of education. Ethical teachings stressed the importance of human relations and the family as the foundation of society. Filial piety, especially emphasizing respect for the elderly, was considered to be the most important virtue. It was the responsibility of government to provide instruction so that the talented would be able to enter government service and thus perpetuate the moral and ethical foundation of society.

Education and public service

The Chou period. *Western Chou (1111–771 BC).* This was the feudal age, when the feudal states were ruled by lords who paid homage to the king of Chou and recognized him as the "Son of Heaven."

Schools were established for the sons of the nobility in the capital city of Chou and the capital cities of the feudal states. Schools for the common people were provided within the feudal states in villages and hamlets and were attended, according to written records, by men and women after their work in the fields. There were elementary and advanced schools for both the ruling classes and the common people. Separate studies for girls were concerned chiefly with homemaking and the feminine virtues that assured the stability of the family system.

The content of education for the nobility consisted of the "six arts"—rituals, music, archery, charioteering, writing, and mathematics. They constituted what may be called the "liberal education" of the period. Mere memory work was condemned. As Confucius said of the ancient spirit of education, "learning without thought is labour lost."

Eastern Chou (770–255 BC). This was a period of social change brought about by the disintegration of the feudal order, the breakdown of traditional loyalties, the rise of cities and urban civilization, and the growth of commerce.

The instability and the perplexing problems of the times challenged scholars to propose various remedies. The absence of central control facilitated independent and creative thinking. Thus appeared one of the most creative periods in China's intellectual history, when a Hundred Schools of thought vied with one another to expound their views and proposals for attaining a happy social and political order. Some urged a return to the teachings of the sages of old, while others sought better conditions by radical change. Among the major "schools" of this age were Taoism, Confucianism, Mohism, and legalism. No one school was in the ascendancy. Each major school had its followers and disciples, among whom there was a vigorous program of instruction and intellectual discussion. Most active in the establishment of private schools were Confucius and his disciples, but the Taoists, the Mohists, and the legalists also maintained teaching institutions.

The Hundred Schools of thought

Another form of educational activity was the practice of the contending feudal states of luring to their domain a large number of scholars, partly to serve as a source of ideas for enhancing the prosperity of the state and partly to gain an aura of intellectual respectability in a land where the respect for scholars had already become an established tradition. The age of political instability and social disintegration was thus an age of free and creative intellectual activity. Conscious of their importance and responsibility, the scholars developed a tradition of self-respect and fearless criticism. It was this tradition that Confucius had in mind when he said that the educated person was not a utensil to be used, and it was this spirit that the Confucian philosopher Mencius described when he said that the great man was a man of principles whom riches and position could not corrupt, whom poverty and lowliness could not swerve, whom power and force could not bend.

The teachings of the Hundred Schools and the records of the feudal states meant a marked increase in literature and, consequently, in the materials for instruction. The classical age of China, the period of the Eastern Chou, left an intellectual and educational legacy of inestimable value. Its scholars propounded theories of government and of social and individual life that were as influential in China and East Asia as the Greek philosophers of almost contemporary age were in the Western world.

The Ch'in–Han period. *Ch'in autocracy (221–206 BC).* Of the various schools of thought that arose in China's classical age, legalism was the first to be accorded official favour. The policies of the Ch'in dynasty were based on legalist principles stressing a strong state with a centralized administration. Many of its policies were so different from past practices that they incurred the criticism of scholars, especially those who upheld the examples of the ancient sages. To stop the criticism, the ruler, who called himself the first emperor, acting upon the advice of a legalist minister, decreed a clean break with the past and a banning of books on history and of classics glorifying past rulers. Numerous books were collected and burned, and hundreds of scholars were put to death.

Though condemned for the burning of books and the persecution of scholars, the Ch'in dynasty laid the foundation for a unified empire and made it possible for the next dynasty to consolidate its power and position at home and abroad. In education, the unification efforts included a reform and simplification of the written script and the adoption of a standardized script intelligible throughout the country. First steps were taken toward uniform textbooks for the primary schools. The invention of the writing brush made of hair, as well as the making of ink, led to the replacement of the clumsy stylus and bamboo slips with writing on silk.

Scholarship under the Han (206 BC–AD 220). The Han dynasty reversed many of the policies of its short-lived predecessor. The most important change was a shift from legalism to Confucianism. The banned books were now highly regarded, and the classics became the core of education. An assiduous effort was made to recover the prohibited books and to discover books and manuscripts that scholars had concealed in secret places. Much painstaking work was done in copying and editing, and the textual and interpretative studies of the Han scholars accorded a new importance to the study of the classics. The making of paper further stimulated this revival of learning. Critical examination of old texts resulted in the practice of higher criticism long before it developed in the West.

Shift to Confucianism

There were historians, philosophers, poets, artists, and other scholars of renown in the Han dynasty. Deserving special mention is Ssu-ma Ch'ien, author of a monumental history of China from the earliest times to the 1st century BC, whose high level of scholarship earned him the title "Chinese Father of History." An illustrious woman of letters, Pan Chao, was named poet laureate. A bibliographer collected and edited ancient texts and designated them as classics. The first dictionary of the Chinese language was written. Since the discovery and interpretation of ancient texts had largely been the work of Confucian scholars, Chinese scholarship from now on became increasingly identified with Confucianism. Most of the Han rulers gave official sanction to Confucianism as a basis of conducting government and state affairs. There was, however, no action to exclude other schools of thought.

There were a variety of schools on the national and local levels. Increasing activity in private education continued, and much of the study of the classics and enriched literature was done in private schools. Of considerable influence in the country and abroad was a national university with an enrollment that soared to 30,000. The classics now became the core of the curriculum, but music, rituals, and archery were still included. The tradition of all-round education in the six arts had not vanished.

Introduction of Buddhism. The Han dynasty was a period of territorial expansion and growth in trade and cultural relations. Buddhism was introduced at this time.

Buddhist and Indian influences in China

Early information about Buddhism was probably brought into China by traders, envoys, and monks. By the 1st century AD an emperor became personally interested and sent a mission to India to seek more knowledge and bring back Buddhist literature. Thereafter, Indian missionaries as well as Chinese scholars translated Buddhist scriptures and other writings into Chinese.

Indian missionaries not only preached a new faith but also brought in new cultural influences. Indian mathematics and astronomical ideas enriched Chinese knowledge in these fields. Chinese medicine also benefited. Architectural and art forms reflected Buddhist and Indian influence. Hindu chants became a part of Chinese music.

For a couple of centuries after its introduction, however, Buddhism showed no signs of popular appeal. Han scholarship was engrossed in the study of ancient classics and was dominated by Confucian scholars who had scant interest in Buddhist teachings that were unconcerned with the practical issues of moral and political life. Moreover, the Buddhist view of evil and the Buddhist espousal of celibacy and escape from earthly existence were alien to China's traditions. Taoist scholars, finding in Buddhism much that seemed not too remote from their own spiritual message, were more inclined to study the new philosophy. Some of them aided in the translation of Buddhist texts, but they were not in the centre of the Han stage.

The fall of the Han dynasty was followed by a few hundred years of division, strife, and foreign invasions. China was not united again until the end of the 6th century. It was during this period that Buddhism gained a foothold in China. The literary efforts of Chinese monks produced a Chinese Buddhist literature, and this marked the beginning of a process that transformed an alien importation into a Chinese religion and system of thought.

(T.H.C.)

ANCIENT HEBREWS

Like all preindustrial societies, ancient Israel first experienced a type of education that was essentially familial; that is to say, the mother taught the very young and the girls, while the father assumed the responsibility of providing moral, religious, and handcraft instruction for the growing sons. This characteristic remained in Jewish education, for the relation of teacher to pupil was always expressed in terms of parenthood and filiation. Education, furthermore, was rigid and exacting; the Hebrew word *musar* signifies at the same time education and corporal punishment.

The education of scribes

Once they were established in Palestine—at the crossroads of the great literate civilizations of the Middle East, in the beginning of the 1st millennium BC—the Jewish people learned to develop a different type of education—one that involved training a specialized, professional class of scribes in a then rather esoteric art called writing, borrowed from the Phoenicians. Writing was at first practical: the scribe wrote letters and drew up contracts, kept accounts, maintained records, and prepared orders. Because he could receive written orders, he eventually became entrusted with their execution; hence the importance of scribes in the royal administration, well-attested since the times of David and Solomon. The training given these scribes, moreover, included training of character and instilling the high ideal of wisdom, as would befit the servants of the king.

Writing found another avenue of application in Israel—in religion. And the scribe again was the agent of education. He was the man who copied the sacred Law faithfully and established the canonical text. He was the one who read the Law to himself and to the people, taught it, and translated it when Hebrew ceased to be the vernacular or "living language" (into Greek in Alexandria, into Aramaic in Palestine); he explained it, commented on it, and studied its application in particular cases. After the downfall of Israel in 722–721 BC and Judah in 586 BC and their subjection to foreign rule, Jewish education became characterized more and more by this religious orientation. The synagogue in which the community assembled became not merely a house of prayer but also a school, with a "house of the book" (*bet ha-sefer*) and a "house of instruction" (*bet ha-midrash*) corresponding roughly to elementary and secondary or advanced levels of education. Girls, however, continued to be taught at home.

The role of writing in this Oriental world should not be exaggerated, of course; oral instruction still held first place by far. Although a pupil might learn to read aloud, or rather to intone his text, his main effort was to learn by heart fragment after fragment of the sacred Law. Alongside this written Law, however, there developed interpretations or exegeses of it, which at first were merely oral but which progressively were reduced to writing—first in the form of memoranda or aide-mémoire inscribed on tablets or notebooks, then in actual books. The diffusion of this religious literature called for an expansion of programs of instruction, evolving into diverse stages: elementary, intermediate, and advanced, the latter in several centres in Palestine, later in Babylonia. This religiously based education was to become one of the most important factors enabling Judaism to survive the national catastrophes of AD 70 and 135, involving the capture and subsequent destruction of Jerusalem. In their dispersion, the Jews clung to Hebrew, their only language for worship, for the study of the Law, for tradition, and consequently for instruction. From this evolved the respect with which the teacher was and is surrounded in Jewish communities.

ANCIENT GREEKS

Origins. The history of the Hellenic language and therewith of the Hellenic people goes back to the Mycenaean civilization of about 1400–1100 BC, which itself was the heir of the pre-Hellenic civilization of Minoan Crete. The Mycenaean civilization consisted of little monarchies of an Oriental type, with an administration operated by a bureaucracy, and it seems to have operated an educational system designed for the training of scribes, similar to those of the ancient civilizations of the Middle East. But continuity did not exist between this education and that which was to develop after a period of obscurity known as the Greek Dark Age, dating approximately from the 11th to the 8th century BC. When the Greek world reappeared in history, it was an entirely different society, one headed by a military aristocracy as idealized in Homer's *Iliad* and *Odyssey*.

Education in the Greek Archaic period

During this period, sons of the nobility received their education at the court of the prince in the setting of a guild companionship of warriors: the young nobleman was educated through the counsel and example of an older man to whom he had been entrusted or had entrusted himself, a senior admired and loved. It was in this atmosphere of virile camaraderie that there developed the characteristic ideal of Greek love that was enduringly to mark Hellenic civilization and to deeply influence its conception of education itself—for example, in the relation of master to pupil. Yet these warriors of the Archaic period were not coarse barbarians; by this time the Homerids (reciters of Homer) and the rhapsodists (singers-reciters and sometimes creative poets) were taking the great epics of Homer and Hesiod throughout the far-flung Greek settlements of the Mediterranean, and a new, cultivated civilization was already emerging. Dance, poetry, and instrumental music were well developed and provided an essential element in the educational formation of the dominant elites. In addition, the idea of *aretē* was becoming central to Greek life. The epics of Hesiod and Homer glorified physical and military prowess and promoted the ideal of the cultivated patriot-warrior who displayed this cardinal virtue of *aretē*, a concept difficult to translate but embodying the virtues of military skill, moral excellence, and educational cultivation. It was an ethic of honour, which made virtues of pride and of jealousy as the inspiration of great deeds and which accepted it as natural that one would be the object of jealousy or of enmity. Reverence for Homer, which until the end of antiquity (and in Byzantium even later) was to constitute the basis of Greek culture and therewith of Greek education, would maintain from generation to generation this "agonistic" ideal: the cult of the hero, of the champion, of high performance, which found an outlet outside the sphere of battles in games or contests (*agōnes*), particularly in the realm of athletics, the most celebrated being the Olympic Games, dating traditionally from 776 BC.

Profound changes were introduced into Greek education as a result of the political transformations involved in the maturing of the city-state. There developed a collective ideal of devotion to the community: the city-state (*polis*) was everything to its citizens; the city made its citizens what they were—mankind. This subordination of the individual exploit to collective discipline was reinforced by the strategic military revolution that saw the triumph of heavy infantry, the hoplites, foot soldiers heavily armed and in tight formation.

Sparta. It is in Sparta, the most flourishing city of the 8th and 7th centuries BC, that one sees to best advantage the richness and complexity of this archaic culture. Education was carried to a high level of artistic refinement, as evidenced by the events organized within the framework of the city's religious festivals. The young men and women engaged in processions, dances, and competitions in instrumental music and song. Physical education had a like part, equally for both sexes, given status by national or international contests (the Spartans regularly took more than half of the first places at the Olympic Games); but military and civic education dominated, as it was expected that the citizen-soldier be ready to fight and, if necessary, to die, for his country.

This last aspect became not merely dominant but exclusive from the time (about 550 BC) when a conservative reaction triumphed at Sparta, bringing to power a militarist and aristocratic regime. Arts and sports gave way completely to an education appropriate to men of a warrior caste. The education of girls was subordinated to their future function as mothers; a strict eugenic regime pitilessly eliminated sickly and deformed children. Up to the age of seven, children were brought up by the women, already in an atmosphere of severity and harshness. Education, properly speaking, *agōgē,* lasted from age seven to 20 and was entirely in the hands of the state.

Spartan education for a warrior caste

The male youth of Sparta were enrolled into formations corresponding to successive age classes, divided into smaller units under the authority of comrades of their own age or of young officers. It was a collective education, which progressively removed them from the family and subjected them to garrison life. Everything was organized with a view to preparation for military service: lightly clothed, bedded on the bare ground, the child was poorly fed, told to steal to supplement his rations, and subjected to rigorous discipline. His virility and combativeness were developed by hardening him to blows—thus the role of ritual brawls between groups of boys and of the institution of the *krypteia,* a nocturnal expedition designed both to terrify the lower classes of slaves (helots) and to train the future fighter in ambushes and the ruses of warfare. He was also, of course, directly apprenticed to the military craft, using arms and maneuvering in close formation. This puritanical education, proceeding in a climate of austerity, had as its sole norm the interests of the state, erected into a supreme category; the Spartan was trained under a strict discipline to obey blindly the orders of his superiors. Curiously, the child was at the same time trained to dissimulation, to lying, to theft—all virtues when directed toward the foreigner, toward whom distrust and Machiavellianism were encouraged.

This implacably logical education enabled Sparta to remain for long the most powerful city, militarily and diplomatically, of the entire Greek world and to triumph over its rival Athens after the long struggle of the Peloponnesian War (431–404 BC); but it did not prevent Sparta's decadence. Not that Sparta ever relaxed its tension: on the contrary, in the course of centuries, the rigour and ferocity were accentuated even as such behaviour became more and more anachronistic and without real use. Rites of initiation were transformed into barbarous tests of endurance, the boys undergoing flagellation and competing in enduring it, sometimes to the very death, under the eyes of tourists attracted by the sadistic spectacle. This occurred in times of complete peace when, under the Roman Empire, Sparta was nothing but a little provincial city with neither independence nor army.

Athens. Beginning at a date difficult to fix precisely (at the end of the 7th or during the 6th century), Athens, in contrast to Sparta, became the first to renounce education oriented toward the future duties of the soldier. The Athenian citizen, of course, was always obliged, when necessary and capable, to fight for the fatherland, but the civil aspect of life and culture was predominant: armed combat was only a sport. The evolution of Athenian education reflected that of the city itself, which was moving toward increasing democratization—though it should be noted that the slave and the resident alien always remained excluded from the body politic. The Athenian democracy, even in its most complete form, attained in the 4th century BC, was to remain always the way of life of a minority—about one-tenth, it is estimated, of the total population. Athenian culture continued to be oriented toward the noble life, that of the Homeric knight, minus the warrior aspect, and this orientation determined the practice of elegant sports. Some of these, such as horsemanship and hunting, always remained more or less the privilege of an aristocratic and wealthy elite; the various branches of athletics, however, originally reserved for the sons of the great families, became more and more widely practiced.

Athenian education for a democratic minority

Education of youth. Schools had begun to appear in those early centuries, probably on eastern Mediterranean models, run by private teachers. The earliest references are, however, more recent. Herodotus mentions schools dating from 496 BC and Pausanias from 491 BC. The term used is *didaskaleion* ("a place for instruction"), while the generic term *scholē,* meaning leisure—a reference to schooling being the preserve of the wealthier sector—was also coming into use. There was no single institution; rather, each activity was carried out in a separate place. The young boy of privileged rank would be taken by a kind of chaperon, the *paidagōgos,* who was generally a respected slave within the parents' household. The elements of literacy were taught by the writing master, known as a *grammatistes,* the child learning his letters and numbers by scratching them on a wax-coated wooden tablet with a stylus. More advanced formal literacy, chiefly in a study of the poets, playwrights, and historians, was given by the *grammatikos,* although this was restricted to the genuinely leisured. Supremely important was instruction in the mythopoeic legends of Hesiod and Homer, given by the lyre-playing *kitharistes.* In addition, all boys had to be instructed in physical and military activities in the wrestling school, known as the palaestra, itself part of the more comprehensive institution of the gymnasium.

The moral aspect of education was not neglected. The Athenian ideal was that of the *kalos k'agathos,* the "wise and good" man. The teachers were as much preoccupied with overseeing the child's good conduct and the formation of his character as with directing his progress in the various subjects taught him. Poetry served to transmit all the traditional wisdom, which combined two currents: the ethic of the citizen expressed in the moralizing elegies of the 6th-century lawmaker Solon and the old Homeric ideal of the value of competition and heroic exploit. But this ideal equilibrium between the education of the body and that of the mind was interrupted before long as a result on the one hand of the development of professional sports and the exigencies of its specialization and on the other by the development of the strictly intellectual disciplines, which had made great progress since the time of the first philosophers of the 5th century BC.

Higher education. A system of higher education open to all—to all, at any rate, who had the leisure and necessary money—emerged with the appearance of the Sophists, mostly foreign teachers who were contemporaries and adversaries of Socrates (*c.* 470–399 BC). Until then, the higher forms of culture had retained an esoteric character, being transmitted by the master to a few chosen disciples, as in the first schools of medicine at Cnidus and at Cos, or within the framework of a religious confraternity involving initiate status. The Sophists proposed to meet a new need that was generally felt in Greek society, particularly in the most active cities such as Athens, where political life had been intensively developed. Henceforth, participation in public affairs became the supreme occupation engaging the ambition of Greek man; it was no longer in athletics and elegant leisure activities that his valour, his desire to

Sophistic education

assert himself and to triumph, would find expression but rather in political action.

The Sophists, who were professional educators, introduced a form of higher education whose commercial success attested to and was promoted by its social utility and practical efficacy. They inaugurated the literary genre of the public lecture, which was to experience a long popularity. It was a teaching process that was oriented in an entirely realistic direction, education for political participation. The Sophists pretended neither to transmit nor to seek for the truth concerning man or existence; they offered simply an art of success in political life, which meant, above all, being able on every occasion to make one's point of view prevail. Two principal disciplines constituted the program: the art of logical argument, or dialectic, and the art of persuasive speaking, or rhetoric—the two most flourishing humanistic sciences of antiquity. These disciplines the Sophists founded by distilling from experience their general principles and logical structures, thus making possible their transmission on a theoretical basis from master to pupil.

To the pedagogy of the Sophists there was opposed the activity of Socrates, who, as inheritor of the earlier aristocratic tradition, was alarmed by this radical utilitarianism. He doubted that virtue could be taught, especially for money, a degrading substance. An heir also of the old sages of former times, Socrates held that the supreme ideal of man and hence of education was not the spirit of efficiency and power but the distinterested search for the absolute, for virtue—in short, for knowledge and understanding.

It was only at the beginning of the 4th century BC, however, that the principal types of classical Greek higher education became organized on definitive lines. This was the result of the joint and rival efforts of the two great educators, the philosopher Plato (*c.* 428–348/347), who opened his school, the Academy, probably in 387, and the orator Isocrates (436–338), who founded his school in about 390.

Platonic education

Plato was descended from a long line of aristocrats and became the most distinguished of Socrates' students. The indictment and execution of Socrates by what Plato considered an ignorant society turned him away from Athens and public life. After an absence of some 10 years, spent traveling the Mediterranean, he returned to Athens, where he founded a school of philosophy near the grove dedicated to the early hero Acadēmos and hence known as the Academy. The select band of scholars who gathered there engaged in philosophical disputations in preparation for their role as leaders. Good government, Plato believed, would only come from an educated society in which kings are philosophers, and philosophers, kings.

Plato's literary dialogues provide a comprehensive picture of his approach to education. Basically, it was built around the study of dialectic (the skill of accurate verbal reasoning), which, if pursued properly, he believed, enables misconceptions and confusions to be stripped away and the nature of underlying truth to be established. The ultimate educational quest, as revealed in the dialogues, is the search for the Good, that is, the ultimate idea that binds together all earthly existence.

Plato's educational program is set out in his most famous dialogue, *The Republic.* The world, he argued, has two aspects, the visible, or that which is perceived with the senses, and the non-visible, or the intelligible, which consists of universal, eternal forms or ideas that are apprehensible only by the mind. Furthermore, the visible realm itself is subdivided into two, the realm of appearances and that of beliefs. Human experiences of so-called reality, according to Plato, are only of visible "appearances" and from these can be derived only opinions and beliefs. Most people, he argued, remain locked in this visible world of opinion; only a select few can cross into the realm of the intelligible. Through a rigorous 15-year program of higher education devoted to the study of dialectics and mathematical reasoning, this elite ("persons of gold" was Plato's term) can attain an understanding of genuine reality, which is composed of such forms as goodness, truth, beauty, and justice. Plato maintained that only those individuals who survive this program are really fit for the highest offices of the state and capable of being entrusted with the noblest of all tasks, those of maintaining and dispensing justice.

The education of Isocrates

The rival school of Isocrates was much more down-to-earth and practical. It too aimed at a form of wisdom but of a much more practical order, based on working out commonsense solutions to life's problems. In contrast to Plato, Isocrates sought to develop the quality of grace, cleverness, or finesse rather than the spirit of geometry. The program of study that he enjoined upon his pupils was more literary than scientific. In addition to gymnastics and music, its basics included the study of the Homeric classics and an extensive study of rhetoric—consisting of five or six years of theory, analysis of the great classics, imitation of the classics, and finally practical exercises.

These two parallel forms of culture and of higher education were not totally in conflict: both opposed the cynical pragmatism of the Sophists; each influenced the other. Isocrates did promote elementary mathematics as a kind of mental training or mental gymnastics and did allow for a smattering of philosophy to illumine broad questions of human life. Plato, for his part, recognized the usefulness of the literary art and philosophical rhetoric. The two traditions appear as two species of one genus; their debate, continued in each generation, enriched classical culture without jeopardizing its unity.

Aristotelian education

Before leaving the Hellenic age, there is one other great figure to appraise—one who was a bridge to the next age since he was the tutor of the young prince who became Alexander the Great of Macedonia. Aristotle (384–322 BC), who was one of Plato's pupils and shared some of his opinions about education, believed that education should be controlled by the state and that it should have as a main objective the training of citizens. The last book of his *Politics* opens with these words:

> No one will doubt that the legislator should direct his attention above all to the education of youth.... The citizen should be moulded to suit the form of government under which he lives.

He shared some of Plato's misgivings about democracy; but, because he was no recluse but a man of the world acquainted with public affairs, he declared his preference for limited democracy, "polity," over other forms of government. His worldliness also led him to be less concerned with the search for ideas, in the Platonic mode, and more concerned with the observation of specific things. His urge for logical structure and classification, for systematization, was especially strong.

This systematization extended to a youth's education. In his first phase, from birth to age seven, he was to be physically developed, learning how to endure hardship. From age seven to puberty, his curriculum would include the fundamentals of gymnastics, music, reading, writing, and enumeration. During the next phase, from puberty to age 17, the student would be more concerned with exact knowledge, not only carrying on with music and mathematics but also exploring grammar, literature, and geography. Finally, in young manhood, only a few superior students would continue into higher education, developing encyclopaedic and intensely intellectual interests in the biological and physical sciences, ethics, and rhetoric, as well as philosophy. Aristotle's school, the Lyceum, was thus much more empirical than Plato's Academy.

The Hellenistic age. Alexander the Great's conquest of the Persian empire between 334 and 323 BC abruptly extended the area of Greek civilization by carrying its eastern frontier from the shores of the Aegean to the banks of the Syrdarya and Indus rivers in Central Asia. Its unity rested henceforward not so much on nationality (it incorporated and assimilated Persians, Semites, and Egyptians) nor on the political unity soon broken after the death of Alexander in 323 but on a common Greek way of life, the fact of sharing the same conception of man. This ideal was no longer social, communal in character, as had been that of the city-state; it now concerned man as an individual—or, better, as a person. This civilization of the Hellenistic age has been defined as a civilization of paideia—which eventually denoted the condition of a person achieving enlightened, mature self-fulfillment but which originally

The concept of paideia

signified education per se. The Greeks succeeded in preserving their distinctive national way of life amid this immense empire because, wherever numbers of them settled, they brought with them their own system of education for their youth, and they not only resisted being absorbed by the "barbarian" non-Hellenic peoples but succeeded somewhat in spreading Greek culture to many of the alien elite. It is important to note that, although Hellenism was finally to be swept away in the Middle East by the Persian national renaissance and the invasions originating from Central Asia beginning in the 2nd century BC, it continued to flourish and even expand in the Mediterranean world under Roman domination. Hellenistic civilization and its educational pattern were prolonged to the end of antiquity and even beyond; it was to be a slow metamorphosis and not a brutal revolution that would later give birth to the civilization and education strictly called Byzantine.

The institutions. Hellenistic education comprised an ensemble of studies occupying the young from age seven to age 19 or 20. To be sure, this entire program was completed only by a minority, recruited from the rich aristocratic and urban bourgeois classes. The students were mostly boys (girls occupied only a very modest place), and of course they were usually free citizens (masters, though some slaves were given a professional education occasionally reaching a high level).

As in the preceding era, education continued to be dependent upon the city, which remained the primary frame of Greek life. To facilitate control of his empire, Alexander had commenced the process of founding a network of cities or communities organized and administered in the Greek manner. In effect, the creation of vast kingdoms did not eliminate the role of the city, even if the latter was not altogether independent; the Hellenistic state was not at all totalitarian and sought to reduce its administrative machinery to a minimum. It relied upon the cities to assume responsibility for public services, that of education in particular. The city in turn looked to the contributions of the richest and most generous private individuals, either by requiring them to fill magistracies and supply costly services or by appealing to their voluntary generosity; the proper functioning of the Hellenistic city presupposed the willing contributions of "benefactors." Thus, certain educational institutions were supported—and in fact sometimes set up—by private foundations that specified exactly the use to be made of the income from their gift of capital. Many schools were private, the role of the city being limited to inspections and to the organization of athletic and musical competitions and festivals.

Physical education. The Hellenistic school par excellence was still the school of gymnastics, the practice of athletic sports and the nudity that they required being the most characteristic feature contrasting the Greek way of life with that of the barbarians. There were, at least in sufficiently large cities, several gymnasiums, separately for the different age classes and on occasion for the sexes. They were essentially palaestrae, or open-air, square-shaped sports grounds, surrounded by colonnades in which were set up the necessary services: cloakrooms, washstands, training rooms, massage rooms, and classrooms. Outside there was a track for footraces, the *stadion.*

The gymnasium

The foundation of the training always consisted of the sports properly called gymnastic and field. Horsemanship remained an aristocratic privilege. Nautical sports had a very modest role—a curious thing for a nation of sailors, but the fact is the Greeks were by origin Indo-Europeans from the interior of the Eurasian continent. The other sports—ball games, hockey—were considered merely diversions or at best preparatory exercises. As the competition of professional sports grew, however, education based on sports progressively, though no doubt very slowly, lost its preeminent position. The popularity of athletic sports as spectacle endured, but educational sports moved into the background, disappearing altogether in the Christian period (in the 4th century AD) in favour of literary studies.

There was a similar progressive decline, a similar final effacement, of artistic, particularly musical, education, the other survivor from the Archaic culture. The art of music continued to flourish, but like sports it became the concern of professional practitioners and a feature of public spectacles rather than an art generally practiced in cultivated circles.

The primary school. The child from seven to 14 years of age went to the school of letters, conducted thither, as in the classical period, by the *paidagōgos,* whose role was not limited to accompanying the child: he had also to educate him in good manners and morals and finally to act as a lesson coach. Literacy and numeration were taught in the private school conducted by the *grammatistes.* Class sizes varied considerably, from a few pupils to perhaps dozens. The teaching of reading involved an analytical method that made the process very slow. First the alphabet was taught from alpha to omega, and then backward, then from both ends at once—alpha–omega, beta–psi, and so on to mu–nu. (A comparable progression in the Latin alphabet would be *A–Z, B–Y,* and so on to *M–N.*) Then were taught simple syllables—*ba, be, bi, bo*—followed by more complex ones, and then by words, successively of one, two, and three syllables. The vocabulary list included rare words (*e.g.,* some of medical origin), chosen for their difficulty of reading and pronunciation. It took several years for the child to be able to read connected texts, which were anthologies of famous passages. With reading was associated recitation and, of course, practice in writing, which followed the same gradual plan.

The program in mathematics was very limited; rather than computation, the subject, strictly speaking, was numeration: learning the whole numbers and fractions, their names, their written notations, their representation in finger counting (in assorted bent positions of the fingers and assorted placements of either hand relative to the body). The general use of tokens and of the abacus made the teaching of methods of computation less necessary than it became in the modern world.

Secondary education. Between the primary school and the various types of higher education, the Hellenistic educational system introduced a program of intermediate, preparatory studies—a preliminary education, a kind of common trunk preparing for the different branches of higher culture, *enkyklios paideia* ("general, or common, education"). This general education, far from having "encyclopaedic" ambitions in the modern sense of the word, represented a reaction against the inordinate ambitions of philosophy and, more generally, of the Aristotelian ideals of culture, which had demanded the large accumulation of intellectual attainments. The program of the *enkyklios paideia* was limited to the common points on which, as noted earlier, the rival pedagogies of Plato and of Isocrates agreed, namely, the study of literature and mathematics. Specialized teachers taught each of these subjects. The mathematics program had not changed since the ancient Pythagoreans and comprised four disciplines—arithmetic, geometry, astronomy, and harmonics (not the art of music but the theory of the numerical laws regulating intervals and rhythm). The primary function of the *grammatikos,* or professor of letters, was to present and explicate the great classic authors: Homer first of all, of whom every cultivated man was expected to have a deep knowledge, and Euripides and Menander—the other poets being scarcely known except through anthologies. Although poetry remained the basis of literary culture, room was made for prose—for the great historians, for the orators, Demosthenes in particular, even for the philosophers. Along with these explications of texts, the students were introduced to exercises in literary composition of a very elementary character (for example, summarizing a story in a few lines).

The program of this intermediate education did not attain its definitive formulation until the second half of the 1st century BC, after the appearance of the first manual devoted to the theoretical elements of language, a slim grammatical treatise by Dionysius Thrax. The program then consisted of the seven liberal arts: the three literary arts of grammar, rhetoric, and dialectic and the four mathematical disciplines noted above. (These were, respectively, the trivium and the quadrivium of medieval education, though the latter term did not appear until the 6th century and the former not until the 9th century.) The long career of this program should not conceal the fact that in

The seven liberal arts

the course of the centuries it fell into disuse and became rather largely a theory or abstraction; in reality, literary studies gradually took over at the expense of the sciences. Of the four mathematical disciplines, only one remained in favour—astronomy. And this was not merely because of its connections with astrology but primarily because of the popularity of the basic textbook used to teach it—the *Phaenomena,* a poem in 1,154 hexameters by Aratus of Soli—whose predominantly literary quality was suited to textual explications. Not until about the 3rd and 4th centuries AD was the need of a sound preparatory mathematical education again recognized and put into practice.

Higher education. Higher education appeared in several forms, complementary or competitive. First was the *ephebeia* ("youth" culture), a kind of civic and military training that completed the education of the young Greek and prepared him to enter into life; it lasted two years (from 18 to 20) and corresponded quite closely to the obligatory military service of modern states. It was a survival from the regime of the old Greek city-states, but in the Hellenistic age the absence of national independence erased all reason for this military training; between the 3rd and 2nd centuries BC the Athenian *ephebeia* (eventually reduced to a single year) was transformed into a leisured civilian college where a minority of rich young men came to be initiated into the refinements of the elegant life. Military training came to play only a modest role and gave way to athletic competition. To this were added lectures on scientific and literary subjects, assuring the ephebe a polish of general culture. The same evolution took place in other cities: the *ephebeia* became everywhere more aristocratic than civic, more sporting than military. What the Greeks, especially those who had emigrated to the barbarian lands, demanded of it was above all that it initiate their sons into Greek life and its characteristic customs, beginning with athletic sports. Especially in Egypt, it was intended to legitimize the privileged status of the Hellene relative to the "native" Egyptian. In any event, the *ephebeia* no longer was the setting for the highest forms of education.

Education in science and medicine

Formal education in science also lacked any institutionalization. There were, however, some establishments having scientific staffs of high competence, of which the most important was the Mouseion (Museum) established at Alexandria, richly endowed by the Ptolemies; but, at least initially, it was an institute for advanced research. If the scholars endowed there were also teachers, this meant only that they dispensed instruction to a small circle of chosen disciples. The same informal character of personal training was to be seen in all the special disciplines—medicine, for example, which saw such a fine development between the time of Hippocrates (5th century BC) and that of Galen (2nd century AD). If there were in the Hellenistic era certain "schools" of medicine—old (Cnidus, Cos) and new (Pergamum, Alexandria)—these were less the equivalent of today's medical faculties than simply centres to which the presence of numerous qualified masters attracted a large number of aspirants. Whatever theory these "students" were able to learn, they learned largely through self-training and practice, by associating themselves with a practicing physician whom they accompanied to the bedsides of patients, taking part in his consultations, profiting by his experience and advice.

Philosophy and rhetoric were subjects of education most highly institutionalized. Although philosophy was taught privately by individual masters-lecturers, who could be either itinerants or residents of one place, these teachers were well organized and, in groups, possessed a kind of institutional character. On the model of Plato's Academy, the new Athenian schools of philosophy—Aristotle's Lyceum, Epicurus' Garden, the Porch (stoa), which gave its name to the Stoics—were brotherhoods in which the posts in both teaching and administration were passed from generation to generation as a kind of heritage. It was in philosophy that the personalistic character of the Hellenistic era most clearly asserted itself, in contrast to the more communal idea of the preceding period; when philosophy turned to the problem of politics, for instance, it dealt less with the citizens of a republic and more with the sovereign king, his duties and character. The central problem was henceforth that of wisdom, of the purpose that man should set for himself in order to attain happiness, the supreme ideal. The teaching of philosophy was not entirely contemplative: it involved the disciple in an experience analogous to a religious conversion, a decision implying a revision of his life and the adoption of a generally ascetic way of life. Such a vocation, however, could obviously appeal only to a moral, intellectual, and financially secure elite; philosophers were always quite a small number within the Hellenistic (and Roman) intelligentsia.

The prestige of rhetoric

The reigning discipline was always rhetoric. The prestige of the oratorical art outlived those social conditions that had inspired it; political eloquence operated only in the context of an embassy coming to plead the cause of a particular city or pressure group at the court of the sovereign. Legal eloquence maintained its function, and the profession of advocate retained its attractiveness; but it was above all the eloquence of showy set speeches, the art of the lecturer, that experienced a curious blossoming. Also, as a result of the customary habit of reading aloud, there was no sharp line between speech and the book; thus, eloquence imposed its rule upon all literary genres—poetry, history, philosophy. Even the astronomer and the physician became lecturers.

Hence, great importance was attached to the teaching of rhetoric, which developed from century to century with an ever more rigorous technicalism, precision, and systematization. The study of rhetoric had five parts: invention (the art of finding ideas, according to standard schemes), disposition (the arrangement of words and sentences), elocution, mnemonics (memory training), and action. Action was the art of self-presentation, the regulation of voice and delivery, and above all the art of reinforcing the word with the expressive power of gesture. Each of these parts, equally systematized to the tiniest detail, was taught with a technical vocabulary of extreme precision. Such an education, which in addition to theory comprised a study of the great examples to be imitated and exercises in practical application, required many years of study; in fact, even in maturity, the cultivated Hellene continued to deepen his knowledge of the art, to drill himself, to "declaim."

A rivalry existed between philosophy and rhetoric, each trying to draw into its orbit the best and the most students. Even in the time of Plato and Isocrates, this rivalry did not proceed without mutual concessions and reciprocal influences, but it remained one of the most constant characteristics of the classical tradition and continued until the end of antiquity and beyond. The long summer of Hellenic civilization was extended under the Roman domination; the great centres of learning also experienced a long prosperity. Athens in particular was the unchallenged capital of philosophy; its *ephebeia* welcomed foreigners to come to crown their culture in the "school of Greece." Its masters of eloquence also had a solid reputation, even though they had competition from such schools of Asia Minor as those of Rhodes (in the 1st century BC) and Smyrna (in the 2nd century AD). Under the later Roman Empire, Alexandria, already famous for medicine, competed with Athens for preeminence in philosophy. Other great centres developed: Beirut, Antioch, and the new capital Constantinople. The quality of the teachers and the number of students attending permits one to apply to these centres, without too much anachronism, the modern designation of "universities," or institutions of advanced learning.

ANCIENT ROMANS

Early Roman education. The quality of Latin education before the 6th century BC can only be conjectured. Rome and Roman civilization were then dominated by a rural aristocracy of landed proprietors directly engaged in exploiting their lands, even after the establishment of the republic. Their spirit was far removed from Greece and Homeric chivalry; ancient Roman education was instead an education suitable for a rural, traditional people—instilling in youth an unquestioned respect for the customs of the ancestors: the *mos maiorum.*

Education had a practical aspect, involving instruction in such farm management concerns as how to oversee the work of slaves and how to advise tenant farmers or one's

steward. It had a legal aspect; in contrast to Athenian law, which relied more on common law than on codified law, Roman justice was much more formalistic and technical and demanded much more study on the part of the citizen. Education also had a moral aspect, aiming at inculcating rural virtues, a respect for good management of one's patrimony, and a sense of austerity and frugality. Roman education, however, did not remain narrowly utilitarian; it broadened in urban Rome, where there developed the same ideal of communal devotion to the public weal that had existed in Greece—with the difference that in Rome such devotion would never be called into question. The interests of the state constituted the supreme law. The ideal set before youth was not that of the chivalrous hero in the Homeric manner but that of the great men of history who, in difficult situations, had by their courage and their wisdom saved the fatherland when it was in danger. A nation of small farmers, Rome was also a nation of soldiers. Physical education was oriented not toward self-realization or competitive sport but toward military preparedness: training in arms, toughening of the body, swimming across cold and rapid streams, and horsemanship, involving such performances as mounted acrobatics and cavalry parades under arms.

The familial character of Roman education

Differing from the Greeks, the Romans considered the family the natural milieu in which the child should grow up and be educated. The role of the mother as educator extended beyond the early years and often had lifelong influence. If, in contrast to the girl, the boy at seven years of age was allowed to move away from her exclusive direction, he came under the control of his father; the Roman father closely supervised the development and the studies of his son, giving him instruction in an atmosphere of severity and moral exigency, through precept but even more through example. The young Roman noble accompanied his father as a kind of young page in all his appearances, even within the Senate.

Familial education ended at 16, when the adolescent male was allowed to wear adult dress, the pure white woolen toga virilis. He devoted one year to an apprenticeship in public life, no longer at his father's side but placed in the care of some old friend of the family, a man of politics laden with years and honours. Then came military service, first as a simple soldier (it was well for the future leader to learn first to obey), encountering his first opportunity to distinguish himself by courage in battle, but soon thereafter as a staff officer under some distinguished commander. Civil and military, the education of the young Roman was thus completed in the entourage of some high personage whom he regarded with respect and veneration, without ceasing, however, to gravitate toward the family orbit. The young Roman was brought up not only to respect the national tradition embodied in the example of the illustrious men of the past but also, very specifically, to respect the particular traditions of his own family, which too had had its great men and which jealously transmitted a stereotype, a specific attitude toward life. If ancient Greek education can be defined as the imitation of the Homeric hero, that of ancient Rome took the form of imitation of one's ancestors.

Roman adoption of Hellenistic education. Something of these original characteristics was to survive always in Roman society, so ready to be conservative; but Latin civilization did not long develop autonomously.

It assimilated, with a remarkable faculty for adaptation, the structures and techniques of the much further evolved Hellenistic civilization. The Romans themselves were quite aware of this, as evidenced by the famous lines of Horace: "Captive Greece captivated her rude conqueror and introduced the arts to rustic Latium" ("Graecia capta ferum victorem cepit et artis intulit agresti Latio" [*Epistles,* II, i, 156]).

Greek influence was felt very early in Roman education and grew ever stronger after the long series of gains leading to the annexation of Macedonia (168 BC), of Greece proper (146 BC), of the kingdom of Pergamum (133 BC), and finally of the whole of the Hellenized Orient. The Romans quickly appreciated the advantages they could draw from this more mature civilization, richer than their own national culture. The practical Romans grasped the advantages to be drawn from a knowledge of Greek, an international language known to many of their adversaries, soon to be their Oriental subjects, and grasped the related importance of mastering the art of oratory so highly developed by the Greeks. Second-century Rome assigned to the spoken word, particularly in political and legal life, as great an importance as had Athens in the 5th century. The Roman aristocrats quickly understood what a weapon rhetoric could be for a statesman.

Rome doubly adopted Hellenistic education: on the one hand, it came to pass that a Roman was considered truly cultivated only if he had the same education, in Greek, as a native Greek acquired; on the other hand, there progressively developed a parallel system of instruction that transposed into Latin the institutions, programs, and methods of Hellenistic education. Naturally, only the children of the ruling class had the privilege of receiving the complete and bilingual education. From the earliest years, the child, boy or girl, was entrusted to a Greek servant or slave and thus learned to speak Greek fluently even before being able to speak Latin competently; the child also learned to read and write in both languages, with Greek again coming first. (Alongside this private tutoring there soon developed, from the 3rd century BC, a Greek public education in schools aimed at a socially broader clientele, but the results of this schooling were less satisfactory than the direct method enjoyed by the children of the aristocracy.) In following the normal course of studies, the young Roman was taught next by an instructor of Greek letters (*grammatikos*) and then by a Greek rhetorician. Those desiring more complete training did not content themselves with the numerous and often highly qualified Greeks to be found in Rome itself but went to Greece to participate in the higher studies of the Greeks themselves. From 119 or 118 BC onward, the Romans secured admission to the Ephebic College at Athens, and in the 1st century BC such young Latins as Cicero were attending the schools of the best philosophers and rhetoricians at Athens and Rhodes.

The tutoring of Roman children

Roman modifications. The adoption of Hellenistic education did not proceed, however, without a certain adaptation to the Latin temperament: the Romans showed a marked reserve toward Greek athleticism, which shocked both their morals and their sense of the deep seriousness of life. Although gymnastic exercises entered into their daily life, it was under the category of health and not that of sport; in Roman architecture, the palaestra or gymnasium was only an appendage of the public baths, which were exaggerations of their Greek models. There was the same reserve, on grounds of moral seriousness, toward music and dance, arts suitable for professional performers but not for freeborn young men and least of all for young aristocrats. The musical arts indeed became integrated into Latin culture as elements of the life of luxury and refinement, but as spectacle rather than as amateur participation; hence their disappearance from programs of education. It must be remembered, however, that athletics and music were in Greece itself survivals of archaic education and had already entered upon a process of decline.

This education in a foreign language was paralleled by a course of studies exactly patterned upon those of the Greek schools but transposed into the Latin language. The aristocracy was to remain always attached to the idea of private education conducted within the family, but social pressure brought about the gradual development of public education in schools, as in Greece, at three levels—elementary, secondary, and higher; they appeared at different dates and in various historical contexts.

Roman primary and secondary education

Education of youth. The appearance of the first primary schools is difficult to date; but the use of writing from the 7th century BC implies the early existence of some kind of appropriate primary instruction. The Romans took their alphabet from the Etruscans, who had taken theirs from the Greeks, who had taken theirs from the Phoenicians. The early Romans quite naturally copied the pedagogy of the Hellenistic world: the same ignorance of psychology, the same strict and brutal discipline, the same analytical method characterized by slow progress—the alphabet (forward, backward, from both ends toward the middle),

the syllabary, isolated words, then short sentences (one-line moral maxims), finally continuous texts—the same method for writing, and the same numeration, rather than computation.

It was only between the 3rd and the end of the 1st century BC that Latin secondary education developed, staffed by the *grammaticus Latinus,* corresponding to the Greek *grammatikos.* Since the principal object of this education was the explication of poetry, its rise was hindered by the slowness with which Latin literature developed. The first-known of these teachers, Livius Andronicus, took as his subject matter his own Latin translation of the *Odyssey;* two generations later, Ennius explicated his own poetic works. Only with the great poets of the age of Augustus could Latin literature provide classics able to rival Homer in educational value; they were adopted as basic texts almost immediately after their appearance. Thereafter, and until the end of antiquity, the program was not to undergo further change, the principal authors being first of all Virgil, the comic author Terence, the historian Sallust, and the unchallenged master of prose, Cicero. The methods of the Latin grammarian were copied directly from those of his Greek counterpart; the essential point was the explication of the classic authors, completed by a theoretical study of good language using a grammar textbook and by practical exercises in composition, graduated according to a minutely regulated progression and always remaining rather elementary. Theoretically, the curriculum remained that of the seven liberal arts, but, as in Greece, it practically neglected the study of the sciences in favour of that of letters.

Latin rhetoric

It was only in the 1st century BC that the teaching of rhetoric in Latin was established: the first recorded Latin rhetorician, Plotius Gallus, appeared in 93 BC in a political context, namely, as a democratic initiative to counter the aristocratic education given in Greek, and, as such, was soon prohibited by the conservative party in power. It was not until the end of the century and the appearance of the works of Cicero that this education would be revived and become normal practice; first, Cicero's discourses offered the young Latin the equivalent of those of the Greek Demosthenes, and, second, Cicero's theoretical treatises provided a technical vocabulary obviating the need for Greek manuals. But this instruction was to remain always very close to its Hellenistic origins: the terminology used by Rome's greatest educator, Quintilian (*c.* AD 35–*c.* 100), is much more impregnated with Hellenism, much less Latinized, than that which Cicero had proposed. At Rome, too, rhetoric became the form of higher education enjoying the greatest prestige; as in Greece, this popularity outlived the elimination of political eloquence. More than in Greece, legal eloquence continued to flourish (Quintilian had in mind particularly the training of future advocates), but, as in the Hellenic milieu, Latin culture became predominantly aesthetic: from the beginning of the empire, the public lecture was the most fashionable literary genre, and the teaching of rhetoric was very naturally oriented toward the art of the lecturer as the crowning achievement.

Higher education. Because the oratorical art was incontestably the most popular subject of higher education, the Romans did not feel the same urgency to Latinize the other rival branches of knowledge, which interested only a small number of specialists with unusual vocations. To be sure, the philosophical work of Cicero had the same ambition as his oratorical work and proved by its existence that it was possible to philosophize in Latin, but philosophy found no successors to Cicero as rhetoric did. There was never a Latin school for philosophy. Of course, Rome did not lack philosophers, but many used Greek as their means of expression (even the emperor Marcus Aurelius); those who, like Cicero, wrote in Latin—Seneca, for example—had taken their philosophy studies in Greek. It was the same in the sciences, particularly in the medical sciences; for long, there were no medical books in Latin except encyclopaedias on a popular level.

The innovation of legal education

On the other hand, Rome created in the school of law another type of higher education—the only one that had no equivalent in Hellenistic education. The position of law in Roman life and civilization is, of course, well known. Perhaps even more than rhetoric, it offered young Romans profitable careers; very naturally, there developed an appropriate education to prepare them. At first elementary in character and entirely practical, it was given within the framework of apprenticeship: the professor of law (*magister juris*) was primarily a practitioner, who initiated into his art the group of young disciples entrusted to him; these listened to his consultations and heard him plead or judge. Beginning in Cicero's time and undoubtedly under his influence, this instruction was paralleled by a systematic theoretical exposition. Roman law was thus promoted to the rank of a scientific discipline. True schools were progressively established and took on an official character; their existence is well attested beginning with the 2nd century AD. It was at this same time that legal education acquired its definitive tools, with the composition of systematic elementary treatises such as the *Institutiones* of Gaius, manuals of procedure, commentaries on the law, and systematic collections of jurisprudence. This creative period perhaps reached its peak at the beginning of the 3rd century AD. The works of the great legal authors of this time, which became classics, were offered by the law professor with much interpretation and explication—very similar to the way in which grammarians offered literature.

Rome, the capital, remained the great centre of this advanced study in law. At the beginning of the 3rd century, however, there appeared in the Roman Orient the school of Beirut. The teaching there was in Latin; and, to hear it and profit by the advantages that it offered for a high administrative or judicial career, many young Greeks enrolled at the school, in spite of the language obstacle. Only a legal career could persuade the Greeks to learn Latin, a language that they had always regarded as "barbarous."

The Roman world became covered with a network of schools concurrent with the Romanization of the provinces. The primary school always remained private; on the other hand, many schools of grammar or rhetoric acquired the character of public institutions supported (as in the Hellenic world) either by private foundations or by a municipal budget. In effect, it was always the city that was responsible for education. The liberal central government of the high empire, anxious to reduce its administrative apparatus to a minimum, made no pretense of assuming charge of it. It was content to encourage education and to favour teaching careers by fiscal exemptions; and only very exceptionally did an emperor create certain chairs of higher education and assign them a regular stipend. Vespasian (AD 69–79) created two chairs at Rome, one of Greek rhetoric and the other of Latin rhetoric. Marcus Aurelius (AD 161–180) similarly endowed, in Athens, a chair of rhetoric and four chairs of philosophy, one for each of the four great sects—Platonism, Aristotelianism, Epicureanism, and Stoicism.

The durable character of Greco-Roman education

Education in the later Roman Empire. The dominant fact is the extraordinary continuity of the methods of Roman education throughout such a long succession of centuries. Whatever the profound transformations in the Roman world politically, economically, and socially, the same educational institutions, the same pedagogical methods, the same curricula were perpetuated without great change for 1,000 years in Greek and six or seven centuries in Roman territory. At most, a few nuances of change need be noted. There was a measure of increasing intervention by the central government, but this was primarily to remind the municipalities of their educational duties, to fix the remuneration of teachers, and to supervise their selection. Only higher education received direct attention: in AD 425, Theodosius II created an institute of higher education in the new capital of Constantinople and endowed it with 31 chairs for the teaching of letters, rhetoric (both Greek and Latin), philosophy, and law. Another innovation was that the exuberant growth of the bureaucratic apparatus under the later empire favoured the rise of one branch of technical education, that of stenography.

The only evolution of any notable extent involves the use of Greek and Latin. There had never been more than a few Greeks who learned Latin, even though the growing machinery of administration and the increasing clientele drawn to the law schools of Beirut and Constantinople

tended to increase the numerical size of this tiny minority. On the other hand, in Latin territory, late antiquity exhibited a general recession in the use of Greek. Although the ideal remained unchanged and high culture always proposed to be bilingual, most people generally knew Greek less and less well. This retrogression need not be interpreted solely as a phenomenon of decadence: it had also a positive aspect, being an effect of the development of Latin culture itself. The richness and worth of the Latin classics explain why the youth of the West had less time than formerly to devote to the study of the Greek authors. Virgil and Cicero had replaced Homer and Demosthenes, just as in modern Europe the ancient languages have retreated before the progress of the national languages and literatures. Hence, in the later empire there appeared specialists in intercultural relations and translations from Greek into Latin. In the 4th and particularly in the 5th century, medical education in Latin became possible, thanks to the appearance of a whole medical (and veterinary) literature consisting essentially of translations of Greek manuals. It was the same with philosophy: resuming Cicero's enterprise at a distance of more than five centuries, Boethius (*c.* 480–524) in his turn sought with his manuals and his translations to make the study of that discipline available in Latin. Although the misfortunes of Italy in the 6th century, including the Lombardian invasion, did not permit this hope to be realized, the work of Boethius later nourished the medieval renaissance of philosophic thought.

Christian use of Greco-Roman education

Nothing better demonstrates the prestige and the allure of classical culture than the attitude taken toward it by the Christians. This new religion could have organized an original system of education analogous to that of the rabbinical school—that is, one in which children learned through study of the Holy Scriptures—but it did not do so. Usually, Christians were content to have both their special religious education, provided by the church and the family, and their classical instruction, received in the schools and shared with the pagans. Thus, they maintained the tradition of the empire after it had become Christian. Certainly, in their view, the education dispensed by these schools must have presented many dangers, inasmuch as classical culture was bound up with its pagan past (at the beginning of the 3rd century the profession of schoolteacher was among those that disqualified one from baptism); but the utility of classical culture was so evident that they considered it necessary to send their children to these same schools in which they barred themselves from teaching. From Tertullian to St. Basil the Great of Caesarea, Christian scholars were ever mindful of the dangers presented by the study of the classics, the idolatry and immorality that they promoted; nevertheless, they sought to show how the Christian could make good use of them.

With the passage of time and the general conversion of Roman society and particularly of its ruling class, Christianity, overcoming its reserve, completely assimilated and took over classical education. In the 4th century Christians were occupying teaching positions at all levels, from schoolmasters and grammarians to the highest chairs of eloquence. In his treatise *De doctrina Christiana* (426), St. Augustine formulated the theory of this new Christian culture: being a religion of the Book, Christianity required a certain level of literacy and literary understanding; the explication of the Bible required the methods of the grammarian; preaching a new field of action required rhetoric; theology required the equipment of philosophy. The synthesis of Christianity and classical education had become so intimate that, when the "barbarian" invasions swept away the traditional school along with many other imperial and Roman institutions, the church, needing a literary culture for the education of its clergy, kept alive the cultural tradition that Rome had received from the Hellenistic world. (H.-I.M./J.Bo.)

Education in Persian, Byzantine, early Russian, and Islāmic civilizations

ANCIENT PERSIA

The ancient Persian empire began when Cyrus II the Great initiated his conquests in 559 BC, and it ended when it was overrun by the Muslims in AD 651. Three elements dominated this ancient Persian civilization: (1) a rigorous and challenging physical environment, (2) the activist and positive Zoroastrian religion and ethics, and (3) a militant, expansionist people. These elements developed in the Persians an adventurous personality mingled with intense national feelings.

Zoroastrian influences

In the early period (559–330 BC), known as the Achaemenid period for the dynastic name of Cyrus and his successors, education, sustained by Zoroastrian ethics and the requirements of a military society, aimed at serving the needs of four social classes—priests, warriors, tillers of the soil, and merchants. Three principles sustained Zoroastrian ethics: the development of good thoughts, of good words, and of good actions (see ZOROASTRIANISM AND PARSIISM). Achaemenid-Zoroastrian education stressed strong family ties and community feelings, acceptance of imperial authority, religious indoctrination, and military discipline.

Education was a private enterprise. Formative education was carried on in the home and continued after the age of seven in court schools for children of the upper classes. Secondary and higher education included training in law to prepare for government service, as well as medicine, arithmetic, geography, music, and astronomy. There were also special military schools.

In 330 BC Persia was conquered by Alexander the Great, and native Persian or Zoroastrian education was largely eclipsed by Hellenistic. Greek practices continued during the Parthian empire (247 BC–AD 224), founded by seminomadic conquerors from the Caspian steppes. And, thus, truly Persian influences were not restored until the appearance of a new, more sophisticated and reform-minded dynasty, the Sāsānians, in the 3rd century AD. In what has been called the neo-Persian empire of the Sāsānians (AD 224–651), the Achaemenid social structure and education were revived and further developed and modified. Zoroastrian ethics, though more advanced than during the Achaemenid period, emphasized similar moral principles but with new stress upon the necessity for labour (particularly agriculture), upon the sanctity of marriage and family devotion, and upon the cultivation of respect for law and of intellectualism—all giving to education a strong moral, social, and national foundation. The subject matter of basic education included physical and military exercises, reading (Pahlavi alphabet), writing (on wooden tablets), arithmetic, and the fine arts.

The Academy of Gondēshāpūr

The greatest achievement of Sāsānian education was in higher education, particularly as it developed in the Academy of Gondēshāpūr. Here, Zoroastrian culture, Indian and Greek sciences, Alexandrian-Syrian thought, medical training, theology, philosophy, and other disciplines developed to a high degree, making Gondēshāpūr the most advanced academic centre of learning in the later period of Sāsānian civilization. The academy, to which came students from various parts of the world, advanced, among other subjects, Zoroastrian, Greek, and Indian philosophies; Persian, Hellenic, and Indian astronomy; Zoroastrian ethics, theology, and religion; law, government, and finance; and various branches of medicine.

It was partly through the Academy of Gondēshāpūr that important elements of classical Greek and Roman learning reached the Muslims during the 8th and 9th centuries AD and through them, in Latin translations of Arabic works, the Schoolmen of western Europe during the 12th and 13th centuries. (M.K.N.)

THE BYZANTINE EMPIRE

The Byzantine Empire was a continuation of the Roman Empire in the eastern Mediterranean area after the loss of the western provinces to Germanic kingdoms in the 5th century. Although it lost some of its eastern lands to the Muslims in the 7th century, the empire lasted until Constantinople—the new capital founded by the Roman emperor Constantine the Great in 330—fell to the Ottoman Turks in 1453. The empire was seriously weakened in 1204 when, as a result of the Fourth Crusade, its lands were partitioned and Constantinople captured; but until then it remained a powerful centralized state, with a

common Christian faith, an efficient administration, and a shared Greek culture. This culture, already Christianized in the 4th and 5th centuries, was maintained and transmitted by an educational system that was inherited from the Greco-Roman past and based on the study and imitation of classical Greek literature.

Stages of education. There were three stages of education. The basic skills of reading and writing were taught by the elementary-school master, or *grammatistes,* whose pupils generally ranged from six or seven to 10 years of age. The secondary-school master, or *grammatikos,* supervised the study and appreciation of classical literature and of literary Greek, from which the spoken Greek of everyday life differed more and more in the course of time, and Latin (until the 6th century). His pupils ranged in age from 10 to 15 or 16. Next, the rhetorician, or *rhētor,* taught pupils how to express themselves with clarity, elegance, and persuasiveness, in imitation of classical models. Speaking style was deemed more important than content or original thinking. An optional fourth stage was provided by the teacher of philosophy, who introduced pupils to some of the topics of ancient philosophy, often by reading and discussing works of Plato or Aristotle. Rhetoric and philosophy formed the main content of higher education.

Availability of education

Elementary education was widely available throughout most of the empire's existence, not only in towns but occasionally in the countryside as well. Literacy was therefore much more widespread than in western Europe, at least until the 12th century. Secondary education was confined to the larger cities. Pupils desiring higher education had almost always to go to Constantinople, which became the cultural centre of the empire after the loss to the Muslim Arabs of Syria, Palestine, and Egypt in the 7th century. Monasteries sometimes had schools in which young novices were educated, but they did not teach lay pupils. Girls did not normally attend schools, but the daughters of the upper classes were often educated by private tutors. Many women were literate, and some, such as the hymnographer Kasia (9th century) and the historian-princess Anna Comnena (1083–*c.* 1153), were recognized as writers of distinction.

Elementary education. Elementary-school pupils were taught to read and write individual letters first, then syllables, and finally short texts, often passages from the Psalms. They probably also learned simple arithmetic at this stage. Teachers had a humble social status and depended on the fees paid by parents for their livelihood. They usually held classes in their own homes or on church porches but were sometimes employed as private tutors by wealthy households. They had no assistants and used no textbooks. Teaching methods emphasized memorization and copying exercises, reinforced by rewards and punishments.

Secondary education. The secondary-school teacher taught the grammar and vocabulary of classical and ecclesiastical Greek literature from the Hellenistic and Roman periods and explained the elements of classical mythology and history that were necessary for the study of a limited selection of ancient Greek texts, mainly poetry, beginning with Homer. The most commonly used textbook was the brief grammar by Dionysius Thrax; numerous and repetitive later commentaries on the book were also frequently used. From the 9th century on, these books were sometimes supplemented with the *Canons* of Theognostos, a collection of brief rules of orthography and grammar. The *grammatikos* might also make use of anonymous texts dating from late antiquity, which offered word-by-word grammatical explanations of Homer's *Iliad,* or of similar texts on the Psalms by Georgius Choiroboscos (early 9th century). Pupils would not normally possess copies of these textbooks, since handwritten books were very expensive, but would learn the rules by rote from their teacher's dictation. Beginning in the 11th century, much use was made in secondary education of *schedē* (literally, "sketches" or "improvisations"), short prose texts that often ended in a few lines of verse. These were specially written by a teacher to illustrate points of grammar or style. From the early 14th century on, much use was also made of *erotemata,* systematic collections of questions and answers on grammar which the pupil learned by heart.

Secondary schools often had more than one teacher, and the older pupils were often expected to help teach their juniors. Schools of this kind had little institutional continuity, however. The most lasting schools were those conducted in churches.

Higher education. The rhetorician's textbooks included systematic handbooks of the art of rhetoric, model texts with detailed commentaries, and specimens of oratory by classical or postclassical Greek writers and by Church Fathers, in particular Gregory of Nazianzus. Many Byzantine handbooks of rhetoric survive from all periods. They are often anonymous and always derivative, mostly based directly or indirectly on the treatises of Hermogenes of Tarsus (late 2nd century AD). There is little innovation in the theory of rhetoric that they expound. After studying models, pupils went on to compose and deliver speeches on various general topics.

Until the early 6th century there was a flourishing school of Neoplatonic philosophy in Athens, but it was repressed or abolished in 529 because of the active paganism of its professors. A similar, but Christian, school in Alexandria survived until the Arab conquest of Egypt in 640. For the next five centuries philosophical teaching seems to have been limited to simple surveys of Aristotle's logic, but in the 11th century there was a renewal of interest in the Greek philosophical tradition and many commentaries on works of Aristotle were composed, evidently for use in teaching. In the early 15th century the philosopher George Gemistos Plethon revived interest in Plato, who until then had been neglected for Aristotle. All philosophical teaching in the Byzantine world was concerned with the explanation of texts rather than with the analysis of problems.

State and church patronage of education

Because higher education provided learned and articulate personnel for the sophisticated bureaucracies of state and church, it was often supported and controlled officially, although private education always existed as well. There were officially appointed teachers in Constantinople in the 4th century, and in 425 the emperor Theodosius II established professorships of Greek and Latin grammar, rhetoric, and philosophy, but these probably did not survive the great crisis of the Arab and Slav invasions of the 7th century. In the 9th century the School of Magnaura, an institution of higher learning, was founded by imperial decree. In the 11th century Constantine IX established new schools of philosophy and law at the Capitol School in Constantinople. Both survived until the 12th century, when the school under the control of the patriarch of Constantinople, with teachers of grammar, rhetoric, and biblical studies, gained predominance. After the interval of Western rule in Constantinople (1204–61), both emperors and patriarchs gave sporadic support to higher education in the capital. As the power, wealth, and territory of the empire were eroded in the 14th and 15th centuries, the church became the principal and ultimately the only patron of higher education.

Professional education. Teaching of such professional subjects as medicine, law, and architecture was largely a matter of apprenticeship, although at various times there was some imperially supported or institutionalized teaching.

Strangely, there is little sign of systematic teaching of theology, apart from that given by the professors of biblical studies in the 12th-century patriarchal school. Studious reading of works by the Church Fathers was the principal path to theological knowledge in Byzantium, both for clergy and for laymen. Nonetheless, religious orthodoxy, or faith, was Byzantium's greatest strength. It held the empire together for more than 1,000 years against eastern invaders. Faith was also the Byzantine culture's chief limitation, choking originality in the sciences and the practical arts. But within this limitation it preserved the literature, science, and philosophy of classical Greece in recopied texts, some of which escaped the plunders of the crusaders and were carried to southern Italy, restoring Greek learning there. Combined with the treasures of classical learning that reached Europe through the Muslims, this Byzantine heritage helped to initiate the beginnings of the European Renaissance. (M.K.N./R.B.)

EARLY RUSSIAN EDUCATION: KIEV AND MUSCOVY

Properly, the term Russia applies only to the empire that covered roughly the present area of the Soviet Union from the 18th to the early 20th century. It is sometimes less strictly employed, however, as in this section, to refer to that area from ancient times as well.

Early influences on Russian education and culture

The influences of the Byzantine Empire and of the Eastern Orthodox church made themselves strongly felt in Russia as early as the 10th century, when Kiev, the first East Slavic state, was firmly established. At that time Prince Svyatoslav, a determined pagan, failed to maintain control of the route "from the Varangians to the Greeks" (south from Novgorod through Kiev, along the Dnepr River) and the Byzantine Empire expelled him from its Balkan possessions, which he was attempting to conquer. After his death in 972 the way lay open for sustained penetration of cultural influences emanating from Byzantium into the Kievan state, although formal relations between the two powers were seldom harmonious. Byzantine cultural materials entering the Kievan state were translated into Old Church Slavonic; thus, there was no language barrier. A famous tale in an early chronicle recounts how Grand Prince Vladimir in 988 ordered the people of Kiev to receive baptism in the Orthodox Christian rite. It is, however, highly dubious to claim that this event, which established Christianity as the predominant cultural force in the Kievan state, also marked the beginning of an institutionalized system of education. A few sources of the time spoke of "book learning," but all this actually meant was that people were expected to be acquainted with the rudiments of Holy Writ.

The next epoch in Russian history is known as the appanage period. This period runs roughly from the decline of Kiev in the 11th century to the rise of the grand principality of Moscow (Muscovy) in the 14th century. It was characterized by the appearance of numerous autonomous fiefdoms and a population shift from southern plains to northern forests, brought about in large part by attacks from steppe nomads. Although the church and monasteries continued to acquire wealth and property, anarchic decentralization was not conducive to the development of any kind of widespread, uniform educational apparatus.

During this time of instability, in 1240, the Mongol (or Tatar) empire, known as the Golden Horde, sacked and devastated the European Russian Plain and imposed its control over the region, although with diminishing efficiency, until 1451. The Mongol rule had a debilitating effect on all phases of Russian culture, including the church, which became more formalistic and ritualistic. What little can be learned about education at this time must be culled from later biographies of contemporary saints. It is not clear who served as teachers, how many there were, where they taught, or how many and what kind of pupils they had. What instruction they gave was of an uncompromisingly religious nature: seven-year-olds did little more than read aloud and chant devotional materials or, very rarely, recite the numbers from one to 100. Because students uttered their assignments simultaneously, the result was often chaotic.

By the time the Mongol rule came to an end, the welter of independent Russian principalities had been united under the authority of the grand principality of Moscow, which began a successful program of territorial expansion. Controversies over religious issues, particularly the respective roles of church and state, flared up but failed to bring about any real improvement in education. The church's inability to provide adequate education was recognized, however, and in 1551 a church council known as the Hundred Chapters was convened at the initiative of the tsar Ivan IV the Terrible. The council heard many stories of clerical ignorance and licentiousness, and its deliberations made it clear that no effective system or institution existed to educate the clergy, the key class in the cultural establishment.

The familial character of Russian education

It is misleading to think of education solely in institutional terms, however. Another system existed in early Russia: the highly developed family system, within which from generation to generation parents handed on to their children skills and knowledge. Indeed, the very strength and tenacity of the family unit may well have retarded development of a more formal educational structure.

Things began to change in the 17th century. It is necessary to bear in mind that Kiev and much of the western Ukraine had for centuries been under the control of the Roman Catholic Polish-Lithuanian state, where intellectual achievement and ferment, especially during the Renaissance and Reformation, had been considerably greater than in Muscovite Russia. The people of the Ukraine were determined to preserve Orthodoxy from Catholic pressure, which grew intense when the Jesuits employed their excellent schools as one means to spearhead the Counter-Reformation. Different Orthodox groups responded to the challenge by forming schools at many levels, culminating in the foundation of the Kievan Academy by Peter Mogila, the energetic metropolitan of Kiev, who strove to adapt Western educational techniques to defend Orthodoxy. It should be noted, however, that, although these schools adopted portions of the broader Western curriculum, their goal continued to be what it always had been, the inculcation of traditional religious values.

By the mid-17th century much of the western Ukraine had come under Muscovite control, enabling a number of educated Ukrainians, some trained in Poland, a few even in Rome, to come to Moscow. They arrived under the auspices of Patriarch Nikon, who was then engaged in correcting what he saw as errors in Orthodox church books; but their appearance aroused deep suspicion on the part of the Orthodox establishment, many of whose members displayed little interest in or sympathy for the establishment of schools, an undertaking the newcomers considered to be of primary importance. Educational reforms nevertheless continued, albeit slowly.

The reign of Peter I the Great (1682–1725) ushered in a new and more dynamic age, although even this ruler's reforming zeal proved inadequate to the central task of creating a national school system, particularly at the elementary level. Religion was deemphasized as Peter strove to establish at least a few institutions that would provide graduates trained in practical subjects for government and military service. Church schools were brought under state control, and the Academy of Sciences was established. Nevertheless, the creation of a network of schools capable at all levels of responding to Russia's rapidly changing priorities was a task that awaited the future. (H.F.Gr.)

THE ISLĀMIC ERA

Influences on Muslim education and culture. The Greco-Byzantine heritage of learning that was preserved through the medium of Middle Eastern scholarship was combined with elements of Persian and Indian thought and taken over and enriched by the Muslims. It was initiated as early as the Umayyad caliphate (661–750), which allowed the sciences of the Hellenistic world to flourish in Syria and patronized Semitic and Persian schools in Alexandria, Beirut, Gondēshāpūr, Nisibis, Haran, and Antioch. But the largest share of Islām's preservation of classical culture was assumed by the ʿAbbāsid caliphate (750–*c.* 1100), which followed the Umayyad and encouraged and supported the translation of Greek works into Arabic, often by Nestorian, Hebrew, and Persian scholars. These translations included works by Plato and Aristotle, Hippocrates, Galen, Dioscorides, Alexander of Aphrodisias, Ptolemy, and others. The great mathematician al-Khwārizmī (flourished 9th century) compiled astronomical tables, introduced Hindu numerals (which became Arabic numerals), formulated the oldest known trigonometric tables, and prepared a geographic encyclopaedia in cooperation with 69 other scholars.

The Muslim blend of scholastic heritages

The transmission of classical culture through Muslim channels can be divided into seven basic types: works translated directly from Greek into Arabic; works translated into Pahlavi, including Indian, Greek, Syriac, Hellenistic, Hebrew, and Zoroastrian materials, with the Academy of Gondēshāpūr as the centre of such scholarship (the works then being translated from Pahlavi into Arabic); works translated from Hindi into Pahlavi, then into Syriac, Hebrew, and Arabic; works written by Muslim scholars from the 9th through the 11th centuries but borrowed, in effect,

from non-Muslim sources, with the line of transmission obscure; works that amounted to summaries and commentaries of Greco-Persian materials; works by Muslim scholars that were advances over pre-Islāmic learning but that might not have developed in Islām had there not been the stimulation from Hellenistic, Byzantine, Zoroastrian, and Hindu learning; and, finally, works that appear to have arisen from purely individual genius and national cultures and would likely have developed independent of Islām's classical heritage of learning.

Aims and purposes of Muslim education. Islām placed a high value on education, and, as the faith spread among diverse peoples, education became an important channel through which to create a universal and cohesive social order. By the middle of the 9th century knowledge was divided into three categories: the Islāmic sciences, the philosophical and natural sciences (Greek knowledge), and the literary arts. The Islāmic sciences, which emphasized the study of the Qur'ān (the Islāmic scripture) and the Ḥadīth (the sayings and traditions of the Prophet Muḥammad) and their interpretation by leading scholars and theologians, were valued the most highly, but Greek scholarship was considered equally important albeit less virtuous.

Early Muslim education emphasized practical studies, such as the application of technological expertise to the development of irrigation systems, architectural innovations, textiles, iron and steel products, earthenware, and leather products; the manufacture of paper and gunpowder; the advancement of commerce; and the maintenance of a merchant marine. After the 11th century, however, denominational interests dominated higher learning, and the Islāmic sciences achieved preeminence. Greek knowledge was studied in private, if at all, and the literary arts diminished in significance as educational policies encouraging academic freedom and new learning were replaced by a closed system characterized by an intolerance toward scientific innovations, secular subjects, and creative scholarship. This denominational system spread throughout eastern Islām from Transoxania (roughly modern Uzbek S.S.R.) to Egypt, with some 75 schools in existence between about 1050 and 1250.

Organization of education. The system of education in the Muslim world was unintegrated and undifferentiated. Learning took place in a variety of institutions, among them the *ḥalqah,* or study circle; the *maktab* (*kuttab*), or elementary school; the palace schools; bookshops and literary salons; and the various types of colleges, the *meshed,* the *masjid,* and the madrasah. All the schools taught essentially the same subjects.

Varieties of Islāmic schools

The simplest type of early Muslim education was offered in the mosques, where scholars who had congregated to discuss the Qur'ān began, before long, to teach the religious sciences to interested adults. Mosques increased in number under the caliphs, particularly the 'Abbāsids: 3,000 of them were reported in Baghdad alone in the first decades of the 10th century; as many as 12,000 were reported in Alexandria in the 14th century, most of them with schools attached. Some mosques, such as that of al-Manṣūr, built during the reign of Hārūn ar-Rashīd in Baghdad, or those in Isfahan, Mashhad, Ghom, Damascus, Cairo, and the Alhambra (Granada), became centres of learning for students from all over the Muslim world. Each mosque usually contained several study circles (*ḥalqah*), so named because the teacher was, as a rule, seated on a dais or cushion with the pupils gathered in a semicircle before him. The more advanced a student, the closer he was seated to the teacher. The mosque circles varied in approach, course content, size, and quality of teaching, but the method of instruction usually emphasized lectures and memorization. Teachers were as a rule looked upon as masters of scholarship, and their lectures were meticulously recorded in notebooks. Students often made long journeys to join the circle of a great teacher. Some circles, especially those in which the Ḥadīth was studied, were so large that it was necessary for assistants to repeat the lecture so that every student could hear and record it.

Elementary schools (*maktab,* or *kuttab*), in which pupils learned to read and write, date to the pre-Islāmic period in the Arab world. After the advent of Islām, these schools developed into centres for instruction in elementary Islāmic subjects. Students were expected to memorize the Qur'ān as perfectly as possible. Some schools also included in their curriculum the study of poetry, elementary arithmetic, penmanship, ethics (manners), and elementary grammar. *Maktab*s were quite common in almost every town or village in the Middle East, Africa, Sicily, and Spain.

Schools conducted in royal palaces taught not only the curriculum of the *maktab*s but also social and cultural studies designed to prepare the pupil for higher education, for service in the government of the caliphs, or for polite society. The instructors were called *mu'addib*s, or instructors in good manners. The exact content of the curriculum was specified by the ruler, but oratory, history, tradition, formal ethics, poetry, and the art of good conversation were often included. Instruction usually continued long after the pupils had passed elementary age.

The high degree of learning and scholarship in Islām, particularly during the 'Abbāsid period in eastern Islām and the later Umayyads in western Islām, encouraged the development of bookshops, copyists, and book dealers in large, important Islāmic cities such as Damascus, Baghdad, and Córdoba. Scholars and students spent many hours in these bookshop schools browsing, examining, and studying available books or purchasing favourite selections for their private libraries. Book dealers traveled to famous bookstores in search of rare manuscripts for purchase and resale to collectors and scholars and thus contributed to the spread of learning. Many such manuscripts found their way to private libraries of famous Muslim scholars such as Avicenna, al-Ghazālī, and al-Fārābī, who in turn made their homes centres of scholarly pursuits for their favourite students.

Fundamental to Muslim education as were the circle schools, the *maktab*s, and the palace schools, they embodied definite educational limitations. Their curricula were limited; they could not always attract well-trained teachers; physical facilities were not always conducive to a congenial educational environment; and conflicts between religious and secular aims in these schools were almost irreconcilable. Most importantly, these schools could not meet the growing need for trained personnel or provide sufficient educational opportunities for those who wished to continue their studies. These pressures led to the creation of a new type of school, the madrasah, which became the crown and glory of medieval Muslim education. The madrasah was an outgrowth of the *masjid,* a type of mosque college dating to the 8th century. The differences between these two institutions are still being studied, but most scholars believe that the *masjid* was also a place of worship and that, unlike the madrasah, its endowment supported only the faculty and not the students as well. A third type of college, the *meshed* (shrine college), was usually a madrasah built next to a pilgrimage centre. Whatever their particularities, all three types of college specialized in legal instruction, each turning out experts in one of the four schools of Sunnite, or orthodox, Islāmic law.

Madrasahs may have existed as early as the 9th century, but the most famous one was founded in 1057 by the vizier Niẓām al-Mulk in Baghdad. The Niẓāmīyah, devoted to Sunnite learning, served as a model for the establishment of an extensive network of such institutions throughout the eastern Islāmic world, especially in Cairo, which had 75 madrasahs, in Damascus, which had 51, and in Aleppo, where the number of madrasahs rose from six to 44 between 1155 and 1260.

The great Muslim institutions

Important institutions also developed in the Spanish cities of Córdoba, Seville, Toledo, Granada, Murcia, Almería, Valencia, and Cádiz, in western Islām, under the Umayyads. The madrasahs had no standard curriculum; the founder of each school determined the specific courses that would be taught, but they generally offered instruction in both the religious sciences and the physical sciences.

The contribution of these institutions to the advancement of knowledge was vast. Muslim scholars calculated the angle of the ecliptic; measured the size of the Earth; calculated the precession of the equinoxes; explained, in the field of optics and physics, such phenomena as refraction of light, gravity, capillary attraction, and twilight; and

developed observatories for the empirical study of heavenly bodies. They made advances in the uses of drugs, herbs, and foods for medication; established hospitals with a system of interns and externs; discovered causes of certain diseases and developed correct diagnoses of them; proposed new concepts of hygiene; made use of anesthetics in surgery with newly innovated surgical tools; and introduced the science of dissection in anatomy. They furthered the scientific breeding of horses and cattle; found new ways of grafting to produce new types of flowers and fruits; introduced new concepts of irrigation, fertilization, and soil cultivation; and improved upon the science of navigation. In the area of chemistry, Muslim scholarship led to the discovery of such substances as potash, alcohol, nitrate of silver, nitric acid, sulfuric acid, and mercury chloride. It also developed to a high degree of perfection the arts of textiles, ceramics, and metallurgy.

The Islāmic renaissance and medieval periods

Major periods of Muslim education and learning. The renaissance of Islāmic culture and scholarship developed largely under the ʿAbbāsid administration in eastern Islām and under the later Umayyads in western Islām, mainly in Spain, between 800 and 1000. This latter period, the golden age of Islāmic scholarship, was largely a period of translation and interpretation of classical thoughts and their adaptation to Islāmic theology and philosophy. The period also witnessed the introduction and assimilation of Hellenistic, Persian, and Hindu mathematics, astronomy, algebra, trigonometry, and medicine into Muslim culture.

Whereas the 8th and 9th centuries, mainly between 750 and 900, were characterized by the introduction of classical learning and its refinement and adaptation to Islāmic culture, the 10th and 11th were centuries of interpretation, criticism, and further adaptation. There followed a period of modification and significant additions to classical culture through Muslim scholarship. Then, during the 12th and 13th centuries, most of the works of classical learning and the creative Muslim additions were translated from Arabic into Hebrew and Latin. The decline of Muslim scholarship coincided with the early phases of the European intellectual awakening that these translations were partly instrumental in bringing about.

Creative scholarship in Islām from the 10th to the 12th century included works by such scholars as Omar Khayyam, al-Bīrūnī, Fakhr ad-Dīn ar-Rāzī, Avicenna (Ibn Sīnā), aṭ-Ṭabarī, Avempace (Ibn Bājjah), and Averroës (Ibn Rushd).

Influence of Islāmic learning on the West. The translation into Latin of most Islāmic works during the 12th and 13th centuries had a great impact upon the European Renaissance. As Islām was declining in scholarship and Europe was absorbing the fruits of Islām's centuries of creative productivity, signs of Latin Christian awakening were evident throughout the European continent.

The 12th century was one of intensified traffic of Muslim learning into the Western world through many hundreds of translations of Muslim works, which helped Europe seize the initiative from Islām when political conditions in Islām brought about a decline in Muslim scholarship. By 1300, when all that was worthwhile in Muslim scientific, philosophical, and social learning had been transmitted to European schoolmen through Latin translations, European scholars stood once again on the solid ground of Hellenistic thought, enriched or modified through Muslim and Byzantine efforts. (M.K.N./J.S.Sz.)

The European Middle Ages

THE BACKGROUND OF EARLY CHRISTIAN EDUCATION

From the beginnings to the 4th century. At first Christianity found most of its adherents among the poor and illiterate, making little headway, as St. Paul observed (1 Corinthians 1:26), among the worldly-wise, the mighty, and those of high rank. But during the 2nd century AD and afterward it appealed more and more to the educated class and to leading citizens. These naturally wanted their children to have at least as good an education as they themselves had had, but the only schools available were the grammar and rhetoric schools, with their Greco-Roman, non-Christian culture. There were different opinions among Christian leaders about the right attitude to this dilemma that confronted all Christians who sought a good education for their children. The Greek Fathers, especially the Christian Platonists Clement of Alexandria and Origen, sought to prove that the Christian view of the universe was compatible with Greek thought and even regarded Christianity as the culmination of philosophy, to which the way must be sought through liberal studies. Without a liberal education the Christian could live a life of faith and obedience but could not expect to attain an intellectual understanding of the mysteries of the faith or expect to appreciate the significance of the Gospel as the meeting ground of Hellenism and Judaism. St. Augustine and St. Basil also tolerated the use of the secular schools by Christians, maintaining that literary and rhetorical culture is valuable so long as it is kept subservient to the Christian life. The Roman theologian Tertullian, on the other hand, was suspicious of pagan culture, but he admitted the necessity, though deploring it, of making use of the educational facilities available.

Views of the early Christian Fathers

In any event, most Christians who wanted their children to have a good education appear to have sent their children to the secular schools; this practice continued even after 313, when the emperor Constantine, who had been converted to Christianity, stopped the persecution of Christians and gave them the same rights as other citizens. Christians also set up catechetical schools for the religious instruction of adults who wished to be baptized. Of these schools the most famous was the one at Alexandria in Egypt, which had a succession of outstanding heads, including Clement and Origen. Under their scholarly guidance, it developed a much wider curriculum than was usual in catechetical schools, including the best in Greek science and philosophy in addition to Christian studies. Other schools modeled on that at Alexandria developed in some parts of the Middle East, notably in Syria, and continued for some time after the collapse of the empire in the west.

From the 5th to the 8th century. The gradual subjugation of the Western Empire by the barbarian invaders during the 5th century eventually entailed the breakup of the educational system that the Romans had developed over the centuries. The barbarians, however, did not destroy the empire; in fact, their entry was really in the form of vast migrations that swamped the existing and rapidly weakening Roman culture. The position of the emperor remained, the barbarians exercising local control through smaller kingdoms. Roman learning continued, and there were notable examples in the writings of Boethius, chiefly his *Consolation of Philosophy.* Boethius composed most of these studies while acting as director of civil administration under the Ostrogoths. Equally famous was his contemporary Cassiodorus (*c.* 490–*c.* 585) who, as a minister under the Ostrogoths, worked energetically at his vision of *civilitas,* a program of educating the public and developing a sound administrative structure. Thus, despite the political and social upheavals, the methods and program of ancient education survived into the 6th century in the new barbarian Mediterranean kingdoms; indeed, the barbarians were frequently impressed and attracted by things Roman. In Ostrogothic Italy (Milan, Ravenna, Rome) and in Vandal Africa (Carthage), the schools of the grammarians and rhetoricians survived for a time, and, even in those places where such schools soon disappeared, as in Gaul and in Spain, private teachers or parents maintained the tradition of classical culture until the 7th century. As in previous centuries, the culture bestowed was essentially literary and oratorical: grammar and rhetoric constituted the basis of the studies. The pupils read, reread, and commented on the classical authors and imitated them by composing certain kinds of exercises (*dictiones*) with the aim of achieving a perfect mastery of their style. In fact, however, the practice was desultory, and the results were mechanical and poor. Greek was ignored more and more, and attempts to revive Hellenic studies were limited to a dwindling number of scholars.

Christianity, meanwhile, was becoming more formally organized, and in the Latin-speaking western division of the empire, the Catholic church (as it was beginning to

be called, from the Greek *katholikos,* the "whole") had developed an administrative pattern, based upon that of the empire itself, for which learning was essential for the proper discharge of its duties. Schools began to be formed in the rudimentary cathedrals, although the main centres of learning from the 5th century to the time of Charlemagne in the 8th century were in the monasteries. The prototype of Western monasticism was the great monastery founded at Monte Cassino in 529 by Benedict of Nursia (*c.* 480–*c.* 547), probably on the model of Vivarium, the scholarly monastery established by Cassiodorus. The rule developed by Benedict to guide monastic life stimulated many other foundations, and one result was the rapid spread of Benedictine monasteries and the establishment of an order. The Benedictine monasteries became the chief centres of learning and the source of the many literate scribes needed for the civil administration.

Monastic and episcopal schools

The monastic schools, however, are no more significant in the history of education than the schools founded by bishops, usually in connection with a cathedral. These episcopal schools are sometimes looked upon as successors of the grammar schools of the Roman Empire. First specializing in the development of the clergy, they later admitted young lay people when the small Roman schools had disappeared. At the same time there were bishops who organized a kind of boarding school where the aspiring clergyman, living in a community, participated in duties of a monastic character and learned his clerical trade.

The influence of monasticism affected the content of instruction and the method of presenting it. Children were to be dutiful, as the Celtic and English monks Columban and Bede were to remark: "A child does not remain angry, he is not spiteful, does not contradict the professors, but receives with confidence what is taught him." In the case of the adolescent destined for a religious profession, the monastic lawgiver was severe. The teacher must know and teach the doctrine, reprimand the undisciplined, and adapt his method to the different temperaments of the young monks. The education of young girls destined for monastic life was similar: the mistress of the novices recommended prayer, manual work, and study.

Education of the laity

Between the 5th and 8th centuries the principles of education of the laity likewise evolved. The treatises on education, later called the "mirrors," pointed to the importance of the four moral virtues—prudence, courage, justice, and temperance. The *Institutionum disciplinae* of an anonymous Visigoth pedagogue expressed the desire that all young men "quench their thirst at the quadruple fountain of the virtues." In the 7th and 8th centuries the moral concepts of antiquity completely surrendered to religious principles. The Christian Bible was more and more considered as the only source of moral life, as the mirror in which men must learn to see themselves. A bishop addressing himself to a son of the Frankish king Dagobert (died 639) drew his examples from the books of the Old Testament. The mother of Didier of Cahors addressed to her son letters of edification on the fear of God, on the horror of vice, and on penitence.

The Christian education of children who were not aristocrats or future clergymen or monks was irregular. Whereas in antiquity catechetical instruction was organized especially for the adult laity, after the 5th century more and more children and then infants received baptism, and, once baptized, a child was not required to receive any particular religious education. His parents and godparents assisted him in learning the minimum, if anything at all. Only by attending church services and listening to sermons did the child acquire his religious culture.

The Irish and English revivals. During the 5th and 6th centuries there was a renaissance of learning in the remote land of Ireland, introduced there initially by the patron saints of Ireland—Patrick, Bridget, and Columba—who established schools at Armagh, Kildare, and Iona. They were followed by a number of other native scholars, who also founded colleges—the most famous and greatest university being the one at Clonmacnois, on the Shannon River near Athlone. To these and lesser schools flocked Anglo-Saxons, Gauls, Scots, and Teutons from Britain and the Continent. From about AD 600 to 850, Ireland itself sent scholars to the Continent to teach, found monasteries, and establish schools.

Although the very earliest Irish scholars may have aimed primarily at propagating the Christian faith, their successors soon began studying and teaching the Greek and Roman classics (but only in Latin versions), along with Christian theology. Eventually there were additions of mathematics, nature study, rhetoric, poetry, grammar, and astronomy, all studied, it seems, very largely through the medium of the Irish language.

England was next to experience the reawakening, and, though there were notable schools at such places as Canterbury and Winchester, it was in Northumbria that the schools flourished most. At the monasteries of Jarrow and Wearmouth and at the Cathedral School of York, some of the greatest of early medieval writers and schoolmasters appeared, including the Venerable Bede and Alcuin. The latter went to France in 780 to become master of Charlemagne's palace school.

THE CAROLINGIAN RENAISSANCE AND ITS AFTERMATH

The cultural revival under Charlemagne and his successors. Charlemagne (742/743–814) has been represented as the sponsor or even creator of medieval education, and the Carolingian renaissance has been represented as the renewal of Western culture. This renaissance, however, built on earlier episcopal and monastic developments; and, although Charlemagne did help to ensure the survival of scholarly traditions in a relatively bleak and rude age, there was nothing like the general advance in education that occurred later with the cultural awakening of the 11th and 12th centuries.

Educational reforms of Charlemagne

Learning, nonetheless, had no more ardent friend than Charlemagne, who came to the Frankish throne in 768 distressed to find extremely poor standards of Latin prevailing. He thus ordered that the clergy be educated severely, whether by persuasion or under compulsion. He recalled that, in order to interpret the Holy Scriptures, one must have a command of correct language and a fluent knowledge of Latin; he later commanded, "in each bishopric and in each monastery let the psalms, the notes, the chant, calculation and grammar be taught and carefully corrected books be available" (capitulary of AD 789). His promotion of ecclesiastical and educational reform bore fruit in a generation of churchmen whose morals and whose education were of a higher standard than before.

The possibility then arose of providing, for the brighter young clerics and perhaps also for a few laymen, a more advanced religious and academic training. It was perhaps to meet this modest need that a school grew up within the precincts of the emperor's palace at Aachen. In order to develop and staff other centres of culture and learning, Charlemagne imported considerable foreign talent. During the 8th century England had been the scene of some intellectual activity; thus, Alcuin, who had been the master of the school at York, and other English scholars were brought over to transplant to the Continent the studies and disciplines of the Anglo-Saxon schools. From Moorish Spain came Christian refugees who also contributed to this intellectual revival; disputations with the Muslims had forced them to develop a dialectic skill in which they now instructed Charlemagne's subjects. From Italy came grammarians and chroniclers, men such as Paul the Deacon; the more formalistic classical traditions in which they had been bred supplied the framework to discipline the effervescent brilliance of the Anglo-Saxons. Irish scholars also arrived. Thanks to these foreigners, who represented the areas where classical and Christian culture had been maintained in the 6th and 8th centuries, the court became a kind of "academy," to use Alcuin's term. There the emperor, his heirs, and his friends discussed various subjects—the existence or nonexistence of the underworld and of nothingness, the eclipse of the sun, the relationship of Father, Son, and Holy Spirit, and so on. Recognizing the importance of manuscripts in the cultural revival, Charlemagne formed a library (the catalog of which is still extant), had texts and books copied and recopied, and bade every school to maintain a scriptorium. Alcuin developed a school of calligraphy at Tours, and its new

script spread rapidly throughout the empire; this Carolingian minuscule was more legible and less wasteful of space than the uncial scripts hitherto employed.

Outside the court at Aachen were to be found here and there a few seats of culture, but not many. The archbishop of Lyon reorganized the schools of readers and choir leaders; Alcuin in Saint-Martin-de-Tours and Angilbert in Saint-Riquier organized monastic schools with relatively well-stocked libraries. It was necessary to wait for the second generation or even the third to witness the greatest brilliance of the Carolingian renewal. Under Charlemagne's son Louis the Pious and especially under his grandsons, the monastic schools reached their apogee in France north of the Loire, in Germany, and in Italy. The most famous were at Saint-Gall, Reichenau, Fulda, Bobbio, Saint-Denis, Saint-Martin-de-Tours, and Ferrières. Unfortunately, the breakup of the Carolingian empire, following local rebellions and the Viking invasions, ended the progress of the Carolingian renaissance.

Educational accomplishments of Alfred the Great

Influences of the Carolingian renaissance abroad. In England, at least in the kingdom of Wessex, King Alfred the Great stands out as another royal patron of learning, one who wanted to imitate the creativity of Charlemagne. When he came to the throne in 871, cultural standards had fallen to a low level, partly because of the turmoil of the Danish invasions. He was grieved to find so few who could understand Latin church services or translate a letter from Latin into English. To accomplish an improvement, he called upon monks from the Continent, particularly those of Saint-Bertin. Moreover, he attracted to his court certain English clergy and young sons of nobles. Since the latter did not know Latin, he had translated into Wessex English some works of Pope Gregory the Great, Boethius, the theologian and historian Paulus Orosius, Venerable Bede, St. Augustine, and others. He himself translated Boethius' *Consolation of Philosophy,* Gregory the Great's *Pastoral Care,* and Bede's *Ecclesiastical History of the English People.* This promotion of learning was continued by Alfred's successors and spread elsewhere in England; and in the reformed monasteries at Canterbury, York, and Winchester, the young monks renewed the study of religious and secular sciences. Among the master scholars of the late 10th century was the Benedictine monk Aelfric, perhaps the greatest prose writer of Anglo-Saxon times. In order to facilitate the learning of Latin for young monks, Aelfric composed a grammar, glossary, and colloquy, containing a Latin grammar described in Anglo-Saxon, a glossary in which master and pupil could find a methodically classified Latin vocabulary (names of birds, fish, plants, and so forth), and a manual of conversation, inspired by the bilingual manuals of antiquity.

Among the other Saxons, those of the Continent who presided over the destinies of Germany, there were also significant gatherings of masters and students at selected monasteries, such as Corvey and Gandersheim. In any case, wherever teaching became important in the 10th century, it concentrated largely on grammar and the works of the classical authors. Thus when Gerbert of Aurillac, after a course of instruction in Catalonia, came to teach dialectic and the arts of the quadrivium (geometry, arithmetic, harmonics, and astronomy) at Reims, he aroused astonishment and admiration. His renown helped in his later election as Pope Sylvester II. The first half of the 11th century contained the first glimmerings of a rediscovered dialectic. A new stage in the history of teaching was beginning.

Religious and military emphases of general education

Education of the laity in the 9th and 10th centuries. The clergy who dominated society thought it necessary to give laymen some directives about life comparable to those offered in monastic rules and thus issued what were called *miroirs* ("mirrors"), setting forth the duties of a good sovereign and exalting the Christian struggle. Already the image of the courtly and Christian knight was beginning to take shape. It was not a question of governing a state well but, rather, of governing oneself. The layman must struggle against vice and practice virtue; he must emphasize his religious heritage. Alcuin became indignant when he heard it said that the reading of the Gospel was the duty of the clergy and not that of the layman. Huoda, wife of Bernard, duke of Septimania, addressed a manual to her 16-year-old son, stressing the reading and praying that a young man should do. In the libraries of the laity, the volumes of the Old and New Testaments took first place, along with prayer books, a kind of breviary designed for day-to-day use.

If a minority of aristocrats could receive a suitable moral and religious education, the masses remained illiterate and preferred a military apprenticeship to study. "He who has remained in school up to twelve years without mounting a horse is no longer good for anything but the priesthood," wrote a German poet. Writers of hagiographic texts were fond of contrasting the mother of the future saint, anxious to give education to her son, and the father, who wanted to harden his son at an early age to the chase or to war. The Carolingian tradition, however, was not totally forgotten by princes and others in high places. In Germany, Otto I and his successors, who wished to re-create the Carolingian empire, encouraged studies at the court: Wipo, the preceptor of Henry III, set out a program of education for the laity in his *Proverbia.* Rediscovering the ancient moralists, chiefly Cicero and Seneca, he praised moderation as opposed to warlike brutality or even the ascetic strength of the monks. The same tendency is found in other writings.

THE MEDIEVAL RENAISSANCE

The era that has been called the "renaissance of the 12th century" corresponds to a rediscovery of studies originating in the 11th century in a West in the process of transformation. The church cast off the tutelage of lay power, and there was general acceptance of the authority of the church in matters of belief, conduct, and education; the papacy took over the direction of Christianity and organized the Crusades to the East; the monarchies regrouped the political and economic forces of feudal society; the cities were reanimated and were organized into communes; the merchants traced out the great European trade routes and, before long, the Mediterranean ones. Soon contact with the East, by trade and in the Crusades, and with the highly cultivated Moors in Spain further stimulated intellectual life. Arabic renderings of some of the works of Aristotle, together with commentaries, were translated into Latin, exercising a profound influence on the trend of culture. It was inevitable that the world of education would take on a new appearance.

Decline of monastic studies

Changes in the schools and philosophies. *Monastic schools.* In the first place, the monastic reformers made the decision to close their schools to those who did not intend to enter upon a cloistered life. According to their idea of solitude and sanctity, recalling the words of St. Jerome, "the monk was not made to teach but to mortify himself." Divine works were to be the only object of study and meditation, and Pierre de Celle asserted that "divine science ought to mould rather than question, to nourish conscience rather than knowledge."

The scholarly monks completed their studies before being admitted to the monastery—the age of entrance in Benedictine houses, for instance, being fixed at 15 years at Cîteaux and 20 years at Cluny. If there were admitted a few oblates (who were laymen living in monasteries under modified rules), they were given an ascetic and moral education and were taught to read the Holy Writ and, what was still more desirable, to "relish" it. In the Carthusian monastery the four steps of required spiritual exercise were reading, meditation, prayer, and contemplation. Thus, there existed a monastic culture, but there were no truly monastic studies such as those that had existed in the 9th and 10th centuries. The rich libraries of the monasteries served only a few scholarly abbots, while the monks searched for God through prayer and asceticism.

Urban schools. In the cities, on the contrary, the schools offered to all the clergy who so desired the means of satisfying their intellectual appetite. More and more of them attended these schools, for the studies were a good means of social advancement or material profit. The development of royal and municipal administrations offered the clergy new occupations. Hence the success of the schools for notaries and the schools of law and rhetoric.

These schools were organized under the protection of the collegiate churches and the cathedrals. The schools for secular subjects were directed by an archdeacon, chancellor, cantor, or cleric who had received the title of *scholasticus, caput scholae,* or *magister scholarum* and who was assisted by one or more auxiliary masters. The success of the urban schools was such that it was necessary, in the middle of the 12th century, to define the teaching function. Only those could teach who were provided with the *licencia docendi* conferred by the bishop or, more often, by the *scholasticus.* Those who were licensed taught within the limits of the city or the diocese, whose clerical leaders supervised this monopoly and intervened if a cleric set himself up as master without having the right. The popes were sufficiently concerned about licensing that the Lateran Council of 1179 gave this institution universal application.

New curricula and philosophies. The pupils who attended these urban schools learned in them their future occupation as clerics; they learned Latin, learned to sing the various offices, and studied Holy Writ. The more gifted ones extended their studies further and applied for admission to the liberal arts (the trivium, made up of grammar, rhetoric, and logic; and the quadrivium, including geometry, arithmetic, harmonics, and astronomy) and, upon completion of the liberal arts, to philosophy. Philosophy had four branches: theoretical, practical, logical, and mechanical. The theoretical was divided into theology, physics, and mathematics; the practical consisted of morals or ethics (personal, economic, political). The logical, which concerned discourse, consisted of the three arts of the trivium. Finally, the mechanical included the work of processing wool, of navigation, of agriculture, of medicine, and so on. This was an ambitious humanistic program. In fact, the students became specialized in the study of one art or another according to their tastes or the presence of a renowned master, such as Guillaume de Champeaux at Paris and St. Victor for rhetoric and theology; Peter Abelard at Paris for dialectic and theology; Bernard de Chartres for grammar; William of Conches at Chartres for grammar, ethics, and medicine; and Thierry de Chartres for rhetoric. In particular, teachers of the "literary" arts, grammar and rhetoric, always had great success in a period of enthusiasm for the ancient authors. It may be noted that Bernard de Chartres organized his literary teaching in this fashion: grammatical explanations (*declinatio*), studies of authors, and each morning the correction of the exercises given the day before.

Study of the liberal arts and philosophy

The third art of the trivium, logic (or dialectics), was nevertheless a strong competitor of the other two, grammar and rhetoric. Since the 11th century, Aristotle's *Posterior Analytics,* which had been translated centuries earlier by Boethius, had developed the taste for reasoning, and, by the time that Abelard arrived in Paris around 1100, interest in dialectics was flourishing. The written words of the Scriptures and of the Fathers of the Church were to be subjected to the scrutiny of human reason; a healthy skepticism was to be the stepping-stone to knowledge, aided by an understanding of critical logic. While dialectic reigned in Paris, the masters at Chartres offered a study of the whole of the quadrivium. This interest in the sciences, which had been manifest at Chartres since the early 11th century, had been favoured by the stimulus of Greco-Arabic translations. The works of Euclid, Ptolemy, Hippocrates, Galen, and other Hellenic and Hellenistic scholars, as preserved in the Arabic manuscripts, were translated in southern Italy, Sicily, and Spain and were gradually transmitted northward. The scientific revival allowed the Chartrians to Christianize Greek cosmology, to explain Genesis according to physics, and to rediscover nature. Another revival was that of law. The conflicts in the second half of the 12th century between the church and the lay powers encouraged on both sides a new activity in the juridical field. The princes found in the Corpus Juris Civilis, the 6th-century Roman code of the emperor Justinian, the means of legitimizing their politics, and the papacy likewise used Roman sources to promote its claims.

Thomist philosophy. In the long view, the greatest educational and philosophical influence of the age was St. Thomas Aquinas, who in the 13th century made a monumental attempt to reconcile the two great streams of the Western tradition. In his teaching at the University of Paris and in his writings—particularly the *Summa theologiae* and the *Summa contra gentiles*—Aquinas tried to synthesize reason and faith, philosophy and theology, university and monastery, activity and contemplation. In his writings, however, faith and theology ultimately took precedence over reason and philosophy because the former were presumed to give access to truths that were not available through rational inquiry. Hence, Aquinas started with assumptions based on divine revelation and went on to a philosophical explication of man and nature. The model of the educated man that emerged from this process was the Scholastic, a man whose rational intelligence had been vigorously disciplined for the pursuit of moral excellence and whose highest happiness was found in contemplation of the Christian God.

The Scholastic model

The Scholastic model greatly affected the development of Western education, especially in fostering the notion of intellectual discipline. Aquinas' theological-philosophical doctrine was a powerful intellectual force throughout the West, being officially adopted by the Dominican order (of which Aquinas was a member) in the 13th century and by the Jesuits in the 17th century. Known as Thomism, this doctrine came to constitute the basis of official Roman Catholic theology from 1879. Although Aquinas made an important place in his hierarchy of values for the practical uses of reason, later Thomists were often more exclusively intellectual in their educational emphasis.

The development of the universities. The Middle Ages were thus beset by a multiplicity of ideas, both homegrown and imported from abroad. The multiplicity of students and masters, their rivalries, and the conflicts in which they opposed the religious and civil authorities obliged the world of education to reorganize. To understand the reorganization, one must review the various stages of development in the coming together of students and masters. The first stage, already alluded to, occurred when the bishop or some other authority began to accord to other masters permission to open schools other than the episcopal school in the neighbourhood of his church. A further stage was reached when a license to teach, the *jus ubique docendi*—granted only after a formal examination—empowered a master to carry on his vocation at any similar centre. A further development came when it began to be recognized that, without a license from pope, emperor, or king, no school could be formed possessing the right of conferring degrees, which originally meant nothing more than licenses to teach.

Students and teachers, as *clerici* ("clerks," or members of the clergy), enjoyed certain privileges and immunities, but, as the numbers traveling to renowned schools increased, they needed additional protection. In 1158 Emperor Frederick I Barbarossa of the Holy Roman Empire granted them privileges such as protection against unjust arrest, trial before their peers, and permission to "dwell in security." These privileges were subsequently extended and included protection against extortion in financial dealings and the *cessatio,* or the right to strike, discontinue lectures, and even to secede to protest against grievances or interference with established rights.

In the north of Europe licenses to teach were granted by the chancellor, *scholasticus,* or some other officer of a cathedral church; in the south it is probable that the guilds of masters (when these came to be formed) were at first free to grant their own licenses, without any ecclesiastical or other supervision. Gradually, however, toward the end of the 12th century, a few great schools, from the excellence of their teaching, came to assume more than local importance. In practice, a doctor of Paris or Bologna would be allowed to teach anywhere; and those great schools began to be known as studia generalia; that is, places resorted to by scholars from all parts. Eventually the term came to have a more definite and technical significance. The emperor Frederick II in 1225 set the example of attempting to confer upon his new school at Naples, by an authoritative bull, the prestige that the earlier *studia* had acquired by reputation and general consent. Pope Gregory IX did the

The studia generalia and the *universitas*

same for Toulouse in 1229, and he added to its original privileges in 1233 a bull by which anyone who had been admitted to the doctorate or mastership in that university should have the right to teach anywhere without further examination. Other studia generalia were subsequently founded by papal or imperial bulls, and in 1292 even the oldest universities, Paris and Bologna, found it desirable to obtain similar bulls from Pope Nicholas IV. From this time the notion began to prevail that the essence of the studium generale was the privilege of conferring a universally valid teaching license and that no new *studium* could acquire that position without a papal or imperial bull. There were, however, a few studia generalia (such as Oxford) the position of which was too well established to be questioned, even though they had never obtained such a bull; these were held to be studia generalia by repute. A few Spanish universities founded by royal charter were held to be studia generalia for the kingdom.

The word *universitas* originally applied only to the scholastic guild (or guilds)—that is, the corporation of students and masters—within the *studium,* and it was always modified, as *universitas magistrorum,* or *universitas scholarium,* or *universitas magistrorum et scholarium.* In the course of time, however, probably toward the latter part of the 14th century, the term began to be used by itself, with the exclusive meaning of a self-regulating community of teachers and scholars whose corporate existence had been recognized and sanctioned by civil or ecclesiastical authority.

The Italian universities. The earliest *studia* arose out of efforts to provide instruction beyond the range of the cathedral and monastic schools for the education of priests and monks. Salerno, the first great *studium,* became known as a school of medicine as early as the 9th century, and, under the teaching of Constantine the African (died 1087), its fame spread throughout Europe. In 1231 it was licensed by Frederick II as the only school of medicine in the kingdom of Naples. It remained a medical school only.

The Bologna prototype of universities

The great revival of legal studies that took place at Bologna about the year 1000 had been preceded by a corresponding activity at Pavia and Ravenna. In Bologna a certain Pepo was lecturing on parts of the Corpus Juris Civilis about the year 1076. The secular character of this new study and its close connection with the claims and prerogatives of the Western emperor aroused papal suspicion, and for a time Bologna and its students were regarded by the church with distrust. The students found their first real protector in the emperor Frederick I Barbarossa. The immunities and privileges he conferred eventually extended to all the other universities of Italy.

The first university of Bologna was not constituted until the close of the 11th century—the "universities" there being student guilds, formed to obtain by combination that protection and those rights that they could not claim as citizens. As the number of students increased, the number of *universitates,* or societies of scholars, increased, each representing the national origin of its members (France, England, Provence, Spain, Italy). These confederations were presided over by a common head, the *rector scholarium,* and the different nations were represented by their *consiliarii,* a deliberative assembly with which the rector habitually took counsel. The practice at Bologna was adopted as other studia generalia arose.

The students at Bologna were mostly of mature years. Because civil law and canon law were, at first, the only branches of study offered, the class they attracted was often composed of lawyers already filling office in some department of the church or state—archdeacons, heads of schools, canons of cathedrals, and like functionaries. About 1200 the two faculties of medicine and philosophy were formed. The former was developed by a succession of able teachers, among whom Thaddeus Alderottus was especially eminent. The faculty of arts, down to the 14th century, scarcely attained equal eminence.

At Bologna the term college long had a different meaning from the ordinary modern one. The masters formed themselves into collegia (that is, organizations), chiefly for the conferment of degrees. Places of residence for students existed at Bologna at a very early date, but it was not until the 14th century that they possessed any organization; the humble *domus,* as it was termed, was at first designed solely for necessitous students who were not natives of Bologna; a separate house, with a fund for the maintenance of a specified number of scholars, was all that was originally contemplated.

From the 13th to the 15th century a number of universities in Italy originated from migrations of students; others were established by papal or other charters. Almost all the schools taught civil or canon law or both. Of these institutions the most important were Padua, Piacenza, Pavia, Rome, Perugia, Pisa, Florence, Siena, and Turin.

The Paris prototype of universities

The French universities. The history of the University of Paris well illustrates the fact that the universities arose in response to new needs. The schools out of which the university arose were those attached to the Cathedral of Notre-Dame de Paris on the Île de la Cité and presided over by its chancellor. Although, in the second decade of the 13th century, some masters placed themselves under the jurisdiction of the abbot of the monastery of Sainte-Geneviève on the Left Bank of the Seine, it was around the bestowal of the license by the chancellor of Notre-Dame that the university grew. It is in this license that the whole significance of the master of arts degree was contained; for admission to that degree was the receiving of the chancellor's permission to "incept"; and by "inception" was implied the master's formal entrance upon the functions of a duly licensed teacher and his recognition as such by his brethren in the profession. The stage of bachelordom had been one of apprenticeship for the mastership; and his emancipation from this state was symbolized by the placing of the magisterial cap (biretta) upon his head. The new master gave a formal inaugural lecture, and he was then welcomed into the society of his professional brethren with set speeches and took his seat in his master's chair.

Some time between 1150 and 1170 the University of Paris came formally into being. Its first written statutes were not, however, compiled until about 1208, and it was not until long after that date that it possessed a "rector." Its earliest recognition as a legal corporation belongs to about the year 1211, when a brief of Innocent III empowered it to elect a proctor to be its representative at the papal court. With papal support Paris became the great transalpine centre of orthodox theological teaching. Successive pontiffs, down to the Great Schism of 1378, cultivated friendly relations with the university and systematically discouraged the formation of theological faculties at other centres. In 1231 Gregory IX, in the bull *Parens scientiarum* ("Mother of Learning"), gave full recognition to the right of the several faculties to regulate and modify the constitution of the university. The fully developed university was divided into four faculties: three superior, those of theology, canon law, and medicine; and one inferior, that of arts, which was divided into four student confederations, or nations (French, Picard, Norman, and English), which included both professors and scholars from the respective countries. The head of each faculty was the dean; of each nation, the proctor. The rector, in the first instance head of the faculty of arts, eventually became the head of the collective university.

After the close of the Middle Ages, Paris came to be virtually reduced to a federation of colleges, though at Paris the colleges were less independent of university authority than was often the case elsewhere. Other major French universities of the Middle Ages were Montpellier, Toulouse, Orléans, Angers, Avignon, Cahors, Grenoble, Orange, and Perpignan.

The English offshoots of Paris: Oxford and Cambridge

The English universities. The University of Paris became the model for French universities north of the Loire and for those of central Europe and England; Oxford would appear to have been the earliest. Certain schools, opened early in the 12th century within the precincts of the dissolved nunnery of St. Frideswide and of Oseney Abbey, are supposed to have been the nucleus around which it grew. But the beginning may have been a migration of English students from Paris about 1167 or 1168. Immediately after 1168, allusions to Oxford as a *studium* and a studium generale begin to multiply. In the 13th century, mention first occurs of university "chests," which

were benefactions designed for the assistance of poor students. Halls, or places of licensed residence for students, also began to be established. Against periodic vicissitudes such as student dispersions and plagues, the foundation of colleges proved the most effective remedy. The earliest colleges were University College, founded in 1249, Balliol College, founded about 1263, and Merton College, founded in 1264.

The University of Cambridge, although it came into existence somewhat later than Oxford, may reasonably be held to have had its origin in the same century. In 1112 the canons of St. Giles crossed the River Cam and took up their residence in the new priory in Barnwell, and their work of instruction acquired additional importance. In 1209 a body of students migrated there from Oxford. Then about 1224 the Franciscans established themselves in the town and, somewhat less than half a century later, were followed by the Dominicans. At both the English universities, as at Paris, the mendicants and other religious orders were admitted to degrees, a privilege that, until the year 1337, was extended to them at no other university. Their interest in and influence at these three centres were consequently proportionately great.

In 1231 and 1233 royal and papal letters afford satisfactory proof that the University of Cambridge was already an organized body, with a chancellor at its head.

Although both Oxford and Cambridge were modeled on Paris, their higher faculties never developed the same distinct organization; and, while the two proctors at Cambridge originally represented north and south, the nations are scarcely to be discerned. An important step was made, however, in 1276, when an ordinance was passed requiring that everyone who claimed to be recognized as a scholar should have a fixed master within 15 days after his entry into the university. The traditional constitution of the English universities was, in its origin, an imitation of the Parisian, modified by the absence of the cathedral chancellor. But the feature that most served to give permanence and cohesion to the entire community at Cambridge was, as at Oxford, the institution of colleges. The earliest of these was Peterhouse, in 1284. All the early colleges were expressly designed for the benefit of the secular clergy.

Universities elsewhere in Europe. From the 13th to the 15th centuries, studia generalia or universities proliferated in central and northern Europe and were usually modeled on the University of Paris. Although the earliest was Prague, which existed as a *studium* in the 13th century and was chartered by Pope Clement VI in 1348, perhaps no medieval university achieved a more rapid and permanent success than Heidelberg. The University of Heidelberg, the oldest in the German realm, received its charter in 1386 from Pope Urban VI as a studium generale and contained all the recognized faculties—theology, canon law, medicine, and the arts, as well as civil law. In the subsequent 100 years, universities were founded at Cologne, Erfurt, Leipzig, Rostock, Freiburg, Tübingen, Ofen (Budapest), Basel, Uppsala, and Copenhagen.

Higher education in Spain

Spain was also an important scene of developments in higher education. Valladolid received its charter in 1346 and attained great celebrity after it obtained the rank of studium generale and a *universitas theologiae* by a decree of Pope Martin V in 1418. Salamanca was founded in 1243 by Ferdinand III of Castile with faculties of arts, medicine, and jurisprudence, to which theology was added through the efforts of Martin V. The College of St. Bartholomew, the earliest founded at Salamanca, was noted for its ancient library and valuable collection of manuscripts. Other important early Spanish and Portuguese schools were Seville, Alcalá, and Lisbon.

General characteristics of medieval universities. Generally speaking, the medieval universities were conservative. Alexander Hegius and Rudolf Agricola carried on their work as reformers at places such as Deventer, in the Netherlands, remote from university influences. A considerable amount of mental activity went on in the universities; but it was mostly of the kind that, while giving rise to endless controversy, turned upon questions in connection with which the implied postulates and the terminology employed rendered all scientific investigation hopeless. At almost every university the realists and nominalists represented two great parties occupied with an internecine struggle (see EPISTEMOLOGY).

In Italian universities such controversies were considered endless and their effects pernicious. It was resolved, accordingly, to expel logic and allow its place to be filled by rhetoric, thereby effecting that important revolution in academic studies that constituted a new era in university learning and largely helped to pave the way for the Renaissance. The professorial body in the great Italian universities attained an almost unrivaled reputation throughout Europe. For each subject of importance there were always two, and sometimes three, rival chairs. While other universities became sectarian and local, those of Italy continued to be universal, and foreigners of all nations could be found among the professors.

The material life of the students was difficult. In order to aid the poorest, some colleges founded by clerical or lay benefactors offered board and lodging to a number of foundationers. Courses, too, could occasionally be difficult. The courses in theology were particularly long—eight years at the minimum (one could not be a teacher of theology in Paris before the age of 35). Many students preferred the more rapid and more lucrative paths of law and medicine. Others led the life of perpetual students, of vagabond clerics, disputatious goliards, the objects of repeated but ineffectual condemnation.

The methods of teaching are particularly well known in the case of Paris. The university year was divided into two terms: from St. Remi (October 1) to Lent and from Easter to St. Pierre (June 29). The courses consisted of lectures (*collatio*) but more often of explications of texts (*lectio*). There were also discussions and question periods. Examinations were given at the end of each term. The student could receive three degrees: the *determinatio,* or baccalaureate, gave him the right to teach under the supervision of a master; the *licencia docendi* was literally the "license to teach" and could be obtained at 21 years of age; then there was the doctorate, which marked his entrance into mastership and which involved a public examination.

Lay education and the lower schools. The founding of universities was naturally accompanied by a corresponding increase in schools of various kinds. In most parts of western Europe, there were soon grammar schools of some type available for boys. Not only were there grammar schools at cathedrals and collegiate churches, but many others were founded in connection with chantries and craft and merchant guilds and a few in connection with hospitals. It has been estimated, for example, that, toward the close of the Middle Ages, there were in England and Wales, for a population of about 2.5 million, approximately 400 grammar schools, although the number of their enrollments was generally quite small.

Early grammar schools

In fulfillment of its responsibility for education, the church from the 11th century onward made the establishment of an effective education system a central feature of ecclesiastical policy. During the papacy of Gregory VII (1073–85), all bishops had been asked to see that the art of grammar was taught in their churches, and a Lateran Council in 1215 decreed that grammar-school masters should be appointed not only in the cathedral church but also in others that could afford it. Solicitude at the centre for the advancement of education did not, however, result in centralized administration. It was the duty of bishops to carry out approved policy, but it was left to them to administer it, and they in turn allowed schools a large measure of autonomy. Such freedom as medieval schools enjoyed was, however, always subject to the absolute authority of the church, and the right to teach, as earlier noted, was restricted to those who held a bishop's license. This device was used to ensure that all teachers were loyal to the doctrines of the church.

Knowledge of the teaching provided in the grammar schools at this period is too slight to justify an attempt at a description. No doubt the curriculum varied, but religion was all-important, with Latin as a written and spoken language the other major element in the timetable. There might have been instruction in reading and writing in the vernacular, but, in addition to the grammar schools,

there were writing and song schools and other schools of an elementary type. Elementary teaching was given in many churches and priests' houses, and children who did not receive formal scholastic instruction were given oral teaching by parish priests in the doctrines and duties of the faith. The evidence of accounts, bills, inventories, and the like suggests that there was some careful teaching of writing and of an arithmetic that covered the practical calculations required in ordinary life. Literacy, however, was limited by the lack of printed materials; until the 15th century (when typesetting developed) books were laboriously cut page by page on blocks (hence they were known as block books) and consequently were rare and expensive. From the mid-15th century on, literacy increased as typeset books became more widely available.

Educational provision for girls in medieval society was much more restricted. Wealthy families made some provision in the home, but the emphasis was primarily on piety and secondarily on skills of household management, along with artistic "accomplishments." Neither girls nor boys of the lowest social ranks—peasants or unskilled urban dwellers—were likely to be literate. Nor were girls of the artisan classes until the 16th century, when female teaching congregations such as the Ursulines founded by Angela Merici began to appear. There were, however, provisions for boys of the artisan class to receive sufficient vernacular schooling to enable them to be apprenticed to various trades under the auspices of the guilds.

Training for feudalism

There was an entirely different training for boys of high rank, and this created a cultural cleavage. Instead of attending the grammar school and proceeding to a university, these boys served as pages and then as squires in the halls and castles of the nobility, there receiving prolonged instruction in chivalry. The training was designed to fit the noble youth to become a worthy knight, a just and prudent master, and a sensible manager of an estate. Much of this knowledge was gained from daily experience in the household, but, in addition, the page received direct instruction in reading and writing, courtly pastimes such as chess and playing the lute, singing and making verses, the rules and usages of courtesy, and the knightly conception of duty. As a squire he practiced more assiduously the knightly exercises of war and peace and acquired useful experience in leadership by managing large and small bodies of men. But this was a type of education that could flourish only in a feudal society; and, though some of its ideals survived, it was outmoded when feudalism was undermined by the growth of national feeling.

Education in Asian civilizations: c. 700 to the eve of Western influence

INDIA

During its medieval period, India was ruled by dynasties of Muslim culture and religion. Muslims from Arabia first appeared in the country in the 8th century, but the foundation of their rule was laid much later by Muḥammad Ghūri, who established his power at Delhi in 1192. The original Muslim rule was replaced successively by that of the Muslim Pashtuns and Mughals.

The foundations of Muslim education. Muslim educational institutions were of two types—a *maktab,* or elementary school, and a madrasah, or institution of higher learning. The content of education imparted in these schools was not the same throughout the country. It was, however, necessary for every Muslim boy at least to attend a *maktab* and to learn the necessary portions of the Qur'ān required for daily prayers. The curriculum in the madrasah comprised Ḥadīth (the study of Muslim traditions), jurisprudence, literature, logic and philosophy, and prosody. Later on, the scope of the curriculum was widened, and such subjects as history, economics, mathematics, astronomy, and even medicine and agriculture were added. Generally, all the subjects were not taught in every institution. Selected madrasahs imparted postgraduate instruction, and a number of towns—Āgra, Badaun, Bīdar, Gulbarga, Delhi, Jaunpur, and a few others—developed into university centres to which students flocked for study under renowned scholars. The sultans and amirs of Delhi and the Muslim rulers and nobles in the provinces also extended patronage to Persian scholars who came from other parts of Asia under the pressure of Mongol inroads. Delhi vied with Baghdad and Córdoba as an important centre of Islāmic culture. Indian languages also received some attention. The Muslim rulers of Bengal, for example, engaged scholars to translate the Hindu classics, the *Rāmāyaṇa* and the *Mahābhārata,* into Bengali.

Developments under the Pathans

Under the Pathan Lodis, a dynasty of Afghan foreigners (1451–1526), the education of the Hindus was not only neglected but was often adversely affected in newly conquered territories. The rulers generally tolerated Sanskrit and vernacular schools already in existence but did not help the existing ones with money or build new ones. At early stages, the *maktab*s and madrasahs were attended by Muslims only. Later, when Hindus were allowed into high administrative positions, Hindu children began to receive Persian education in Muslim schools.

The Mughal period. The credit for organizing education on a systematic basis goes to Akbar (lived 1542–1605), a contemporary of Queen Elizabeth I of England and undoubtedly the greatest of Mughal emperors. He treated all his subjects alike and opened a large number of schools and colleges for Muslims as well as for Hindus throughout his empire. He also introduced a few curricular changes, based on students' individual needs and the practical necessities of life. The scope of the curriculum was so widened as to enable every student to receive education according to his religion and views of life. The adoption of Persian as the court language gave further encouragement to the Hindus and the Muslims to study Persian.

Akbar's policy was continued by his successors Jahāngīr and Shāh Jahān. But his great-grandson Aurangzeb (1618–1707) changed his policy with regard to the education of the Hindus. In April 1669, for instance, he ordered the provincial governors to destroy Hindu schools and temples within their jurisdiction; and, at the same time, he supported Muslim education with a certain religious fanaticism. After his death, the glory of the Mughal empire began gradually to vanish, and the whole country was overrun by warlords.

During the Mughal period, girls received their education at home or in the house of some teacher living in close proximity. There were special arrangements for the education of the ladies of the royal household, and some of the princesses were distinguished scholars. Vocational education was imparted through a system of apprenticeship either in the house of *ustād*s (teachers) or in *kārkhānah*s (manufacturing centres).

Muslim rulers of India were also great patrons of literature and gave considerable impetus to its development. Akbar ordered various Hindu classics and histories translated into Persian. In addition, a number of Greek and Arabic works were translated into Persian. Literary activities did not entirely cease even in the troubled days of later rulers. Men of letters were patronized by such emperors as Bahādur Shāh and Muḥammad Shāh and by various regional officials and landlords.

Such is the history of Muslim education in India. It resembles ancient Indian education to a great extent: instruction was free; the relation between the teachers and the taught was cordial; there were great centres of learning; the monitorial system was used; and people were preoccupied with theology and the conduct of life. There were, however, several distinctive features of Muslim education.

Educational accomplishments of the Muslim period

First, education was democratized. As in mosques, so in a *maktab* or madrasah, all were equal, and the principle was established that the poor should also be educated. Second, Muslim rule influenced the system of elementary education of the Hindus, which had to accommodate itself to changed circumstances by adopting a new method of teaching and by using textbooks full of Persian terms and references to Muslim usages. Third, the Muslim period brought in many cultural influences from abroad. The courses of studies were both widened and brought under a humanistic influence. Finally, Muslim rule produced a cross-cultural influence in the country through the establishment of an educational system in which Hindus and

Muslims could study side by side and in which there would be compulsory education in Persian, cultivation of Sanskrit and Hindi, and translation of great classics of literature into different languages. Ultimately, it led to the development of a common medium of expression, Urdu.

Education in the Muslim era was not a concerted and planned activity but a voluntary and spontaneous growth. There was no separate administration of education, and state aid was sporadic and unsteady. Education was supported by charitable endowments and by lavish provision for the students in a madrasah or in a monastery.

The Muslim system, however, proved ultimately harmful. In the early stages genuine love of learning attracted students to the cultural centres, but later on "the bees that flocked there were preeminently drones." The whole system became stagnant and stereotyped as soon as cultural communication was cut off from the outside world because of political disturbances and internecine wars. The Indian teachers were reduced to dependence on their own resources, and a hardening tradition that became increasingly unreceptive to new ideas reduced the whole process to mere routine. (S.N.M.)

CHINA

The T'ang dynasty (AD 618–907). The T'ang was one of China's greatest dynasties, marked by military power, political stability, economic prosperity, and advance in art, literature, and education. It was an age in which Buddhist scholarship won recognition and respect for its originality and high intellectual quality and in which China superseded India as the land from which Buddhism was to spread to other countries in East Asia.

The T'ang was known for its literature and art and has been called the golden age of Chinese poetry. There were thousands of poets of note who left a cultural legacy unsurpassed in subsequent periods and even in other lands. Prose writers also flourished, as did artists whose paintings reflected the influences of Buddhism and Taoism.

One of the greatest gifts of China to the world was the invention of printing. Block printing was invented in the 8th century and movable type in the 11th century. The first book printed from blocks was a Buddhist sutra, or set of precepts, in 868. Printing met the demand created by the increase in the output of literature and by the regularized civil service examination system. It also met the popular demand for Buddhist and Taoist prayers and charms. One historian (Kenneth Scott Latourette) noted that "as late as the close of the eighteenth century the [Chinese] Empire possibly contained more printed books than all the rest of the world put together."

Education in the T'ang dynasty was under the dominant influence of Confucianism, notwithstanding the fact that Buddhism and Taoism both received imperial favours. A national academic examination system was firmly established, and officials were selected on the basis of civil service examinations. But Confucianism did not dominate to the extent of excluding other schools of thought and scholarship. Renowned scholars were known to spurn public office because they were not satisfied with a narrow interpretation of Confucianism. Artists and poets were, in general, rebellious against traditional Confucianism.

An emperor in the 5th century ordered the establishment of a "School of Occult Studies" along with the more commonly accepted schools of Confucian learning. It was devoted to the study of Buddhism and Taoism and occult subjects that transcended the practical affairs of government and society. Such schools were often carried on by the private effort of scholars who served as tutors for interested followers.

School structure in the T'ang era

The schools of T'ang were well organized and systematized. There were schools under the central government, others under local management, and private schools of different kinds. Public schools were maintained in each prefecture, district, town, and village. In the capital were "colleges" of mathematics, law, and calligraphy, as well as those for classical study. There was also a medical school.

Semiprivate schools formed by famous scholars gave lectures and tutelage to students numbering in the hundreds. Students from Korea and Japan came to study in China and took back the lunar calendar and the Buddhist sects, as well as the examination system and the Confucian theories of government and social life. Chinese culture also penetrated Indochina.

The examination system was at this time given the form that remained essentially unchanged until the 20th century. Examinations were held on different levels, and for each a corresponding academic degree was specified. Interestingly, there was provision for three degrees, not unlike the bachelor's, master's, and doctor's degrees of modern times. The first degree was the *hsiu ts'ai* ("cultivated talent"), the second the *ming ching* ("understanding the classics"), and the third the *chin-shih* ("advanced scholar"). The name of the second degree was in later periods changed to *chü jen* ("recommended man"). An academy of scholars later known as the Hanlin Academy was established for select scholars whom the emperor could call upon for advice and expert opinion on various subjects. Membership in this institution became the highest honour that could be conferred upon those who passed the *chin-shih* degree with distinction. To be appointed a Hanlin scholar was to be recognized as one of the top scholars of the land. Among the services that they rendered were the administration and supervision of examinations and the explanation of difficult texts in literature, classics, and philosophy.

Examinations were given for students of medicine and for military degrees. The study of medicine included acupuncture and massage, as well as the treatment of general diseases of the body and those of eye, ear, throat, and teeth.

The Sung (960–1279). The Sung was another dynasty of cultural brilliance. Landscape painting approached perfection, and cultural achievement was stimulated by the invention of movable type (first made of earthenware, then of wood and metal). This advance from the older method of block printing led to the multiplication of books; the printing of a complete set of the classics was a boon to literary studies in schools.

The rulers of Sung were receptive to new ideas and innovative policies. The outstanding innovator of the dynasty was Wang An-shih, prime minister from 1068 to 1076. He introduced a comprehensive program of reform that included important changes in education; more emphasis was subsequently placed on the study of current problems and political economy.

Educational controversy in the Sung era

Wang's reforms met with opposition from conservatives. The controversy was only a phase of a deeper and more far-reaching intellectual debate that made the philosophical contributions of the Sung scholars as significant as those of the Hundred Schools in the Chou dynasty over a millennium earlier. Confucianism and the dominant mode of Chinese thinking had been subject to the challenge of ideas from legalism, Taoism, and Buddhism, and, despite the resistance of conservatives, the traditional views had to be modified. Outstanding Confucian scholars of conservative bent argued vigorously with aggressive proponents of new concepts of man, of knowledge, and of the universe. The result was Neo-Confucianism, or what some prefer to call rational philosophy. The most eminent Neo-Confucianist was Chu Hsi, a Confucian scholar who had studied Taoism and Buddhism. His genius lay in his ability to synthesize ideas from a fresh point of view. Sung scholars distinguished themselves in other fields, too. Ssu-ma Kuang's *Tzu-chih t'ung-chien* ("Comprehensive Mirror for Aid in Government") was a history of China from the 5th century BC to the 10th century AD. The result of 20 years of painstaking research, it consisted of 1,000 chapters prepared under imperial direction. A volume on architecture was produced that is still used today as a basic reference work, and a treatise on botany contained the most ancient record of varieties of citrus fruits then known in China. No less worthy of mention is an encyclopaedia titled *T'ai-ping yü lan.*

The general pattern of the school system remained essentially the same, with provision for lower schools, higher schools, and technical schools, but there was a broadening of the curriculum. A noteworthy development was the rise of a semiprivate institution known as the *shu-yüan,* or academy. With financial support coming from both state grants and private contributions, these academies were

Academies

managed by noted scholars of the day and attracted many students and lecturers. Often located in mountain retreats or in the woods, they symbolized the influence of Taoism and Buddhism and a desire to pursue quiet study far away from possible government interference.

The Mongol period (1206–1368). The Mongols were ferocious fighters but inept administrators. Distrustful of the Chinese, they enlisted the services of many nationalities and employed non-Chinese aliens. To facilitate the employment of these aliens, the civil service examinations were suspended for a number of years. Later, when a modified form of examinations was in effect, there were special examinations for Mongol candidates to make sure of their admission into high offices.

The Mongols despised the Chinese and placed many limitations on them. Consequently, an aftermath of Mongol rule was a strong antiforeign reaction on the part of the Chinese, accompanied by an overanxious desire to preserve the Chinese heritage.

Despite the setback in Chinese culture under Mongol rule, the period was not devoid of positive cultural development. The increase in foreign contacts as a result of travel to and from China brought new ideas and new knowledge of other lands and other peoples. Mathematics and medicine were further influenced by new ideas from abroad. The classics were translated into the Mongol language, and the Mongol language was taught in schools.

Private schools and the academies of the Sung dynasty became more popular. As a result of a decrease in opportunities for government appointment, scholars withdrew into the provinces for study and tutoring. Relieved of the pressure of preparing for the examinations, they applied their talents to the less formal but more popular arts and literary forms, including the drama and the novel. Instead of the classical form, they used the vernacular, or the spoken, language. The significance of this development was not evident until the 20th century, when a "literary revolution" popularized the vernacular tongue.

The Ming period (1368–1644). The Ming dynasty restored Chinese rule. Ming was famous for its ceramics and architecture. There were excellent painters, too, but they were at best the disciples of the T'ang and Sung masters. The outstanding intellectual contribution of the period was the novel, whose development was spurred by increases in literacy and in the demand for reading materials. Ming novels are today recognized as masterpieces of popular vernacular literature. Also of note was the compilation of *Pen-ts'ao kang-mu* ("Great Pharmacopoeia"), a valuable volume on herbs and medicine that was the fruit of 26 years of labour.

The *Yung-lo* encyclopaedia

Of considerable scholarly and educational importance was the *Yung-lo ta-tien* encyclopaedia, which marked a high point in the Chinese encyclopaedic movement. It was a gigantic work resulting from the painstaking efforts of 2,000 scholars over a period of five years. It ran into more than 11,000 volumes, too costly to print, and only two extra copies were made.

The examination system remained basically the same. In the early period of the dynasty, the schools were systematized and regularized. In the latter part of the dynasty, however, the increasing importance of the examination system relegated the schools to a secondary position. The decline of the state-supported schools stimulated the further growth of private education.

The Manchu period (1644–1911/12). Except for two capable emperors, who ruled for a span of 135 years at the beginning, the Manchu dynasty was weak and undistinguished. Under Emperors K'ang-hsi and Ch'ien-lung, learning flourished, but there was little originality. The alien Manchu rulers concentrated on the preservation of what seemed best for stability and the maintenance of the status quo. They wanted new editions of classical and literary works, not creative contributions to scholarship.

Distrust of the Chinese by the Manchus and a feeling of insecurity caused the conquerors to erect barriers between themselves and the Chinese. The discriminatory policy was expressed in the administration of the examinations. To assure the appointment of Manchus to government posts, equal quotas were set aside for the Manchus and the Chinese, although the former constituted only about 3 percent of the population. The Chinese thus faced the keenest competition in the examinations, and those who passed tended to be brilliant intellects, whereas the Manchus could be assured of success without great effort.

Schools were encouraged and regulated during the early period of the dynasty. The public school system consisted of schools for nobles, national schools, and provincial schools. Separate schools were maintained for the Manchus, and, for their benefit, Chinese books were translated into the Manchu language. Village and charitable schools were supported by public funds, but they were neglected in later years; so that, by the end of the dynasty, private schools and tutoring had overshadowed them.

At the threshold of the modern era, China had sunk into political weakness and intellectual stagnation. The creativity and originality that had brightened previous periods of history were now absent. Examinations dominated the educational scene, and the content of the examinations was largely literary and classical. Taoism and Buddhism had lost their intellectual vigour, and Confucianism became the unchallenged model of scholarship.

Much could be said for the Chinese examination system at its best. It was instrumental in establishing an intellectual aristocracy whereby the nation could be sure of a cultural unity by entrusting government to scholars reared in a common tradition, nurtured in a common cultural heritage, and dedicated to common ideals of political and social life. It established a tradition of government by civilians and by scholars. It made the scholars the most highly esteemed people of the land. The examinations provided an open road to fame and position. Chinese society was not without classes, but there was a high degree of social mobility, and education provided the opportunity for raising one's position and status. There were no rigid prerequisites and no age limits for taking the examinations. Selection was rigorous, but the examinations were, on the whole, administered with fairness. The names of the candidates did not appear on the examination papers, and the candidates were not permitted to have any outside contacts while writing them.

Influence of the examination system

Nevertheless, the system had serious drawbacks. The content of the examinations became more and more limited in scope. The Confucianist classics constituted the core, and a narrow and rigid interpretation prevailed. In early times, Chinese education was broad and liberal, but, by the 19th century, art, music, and science had been dropped on the wayside; even arithmetic was not accorded the same importance as reading and writing. Modern science and technology were completely neglected.

After alien rule by the Mongols the Chinese were obsessed with restoring their heritage; they avoided deviating from established forms and views. This conservatism was accentuated under Manchu rule and resulted in sterility and stagnation. The creativity and original spirit of classical education was lost. The narrow curriculum was far removed from the pressing problems and changing needs of the 19th century. (T.H.C.)

JAPAN

The ancient period to the 12th century. The Japanese nation seems to have formed a unified ancient state in the 4th century AD. Society at that time was composed of shizoku, or clans, each of which served the *chōtei* ("the imperial court") with its specialized skill or vocation. People sustained themselves by engaging in agriculture, hunting, and fishing, and the chief problem of education was how to convey the knowledge of these activities and provide instruction in the skills useful for these occupations.

The influence of the civilizations of China and India had a profound effect on both the spiritual life and the education of the Japanese. Toward the 6th century the assimilation of Chinese civilization became more and more rapid, particularly as a result of the spread of Confucianism. Buddhism was also an important intellectual and spiritual influence. Originating in India and then spreading to China, Buddhism was transmitted to Japan through the Korean peninsula in the mid-6th century.

Influence of Chinese and Indian civilization

A monarchic state system with an emperor as its head

was established following a coup d'état in 645. The subsequent Taika (Great Reform) era saw the beginning of many new institutions, most of which were primarily imitations of institutions of the T'ang dynasty of China. In the field of education, a *daigakuryō,* or college house, was established in the capital, and *kokugaku,* or provincial schools, were built in the provinces. Their chief aim was to train government officials. The early curriculum was almost identical to that of the T'ang dynasty of China but by the 8th and 9th centuries had been modified considerably to meet internal conditions, particularly as regards the educational needs of the nobility.

Through the Nara and the Heian eras (8th to 12th century), the nobility (*kuge*) constituted the ruling class, and learning and culture were the concern primarily of the *kuge* and the Buddhist monks. The *kuge* lived an artistic life, so that the emphasis of education came to be placed on poetry, music, and calligraphy. Teaching in the *daigakuryō* gradually shifted in emphasis from Confucianism to literature, since the *kuge* set a higher value on artistic refinement than on more spiritual endeavours. Apart from the *daigakuryō,* other institutions were established in which families of influential clans lodged and developed their intellectual lives.

The feudal period (1192–1867). *Education of the warriors.* Toward the mid-12th century political power passed from the nobility to the *buke,* or warrior, class. The ensuing feudal period in Japan dates from the year 1192 (the establishment of the Kamakura shogunate) to 1867 (the decline of the Tokugawa shogunate).

The warrior's way of life was quite unlike that of the nobility, and the aims and content of education in the warrior's society inevitably differed. The warrior had constantly to practice military arts, hardening his body and training his will. Education was based on military training, and a culture characteristic of warriors began to flourish. Some emphasis, though, was placed on spiritual instruction. The warrior society, founded on firm master–servant relations and centring on the philosophy of Japanese family structure, set the highest value on family reputation and on genealogies. Furthermore, because the military arts proved insufficient to enable warriors to grasp political power and thereby maintain their ruling position, there arose a philosophy of *bumbu-kembi,* which asserted the desirability of being proficient in both literary and military arts. Thus, the children of warriors attended temples and rigorously trained their minds and wills. Reading and writing were the main subjects.

Temples were the centres of culture and learning and can be said to have been equivalent to universities, in that they provided a meeting place for scholars and students. Education in the temple, originally aimed at instructing novitiates, gradually changed its character, eventually providing education for children not destined to be monks. Thus, the temples functioned as institutions of primary education.

Education in the Tokugawa era. In 1603 a shogunate was established by a warrior, Tokugawa Ieyasu, in the city of Edo (present Tokyo). The period thence to the year 1867, the Tokugawa, or Edo, era, constitutes the later feudal period in Japan. This era, though also dominated by warriors, differed from former ones in that internal disturbances finally ended and long-enduring peace ensued. There emerged a merchant class that developed a flourishing commoner's culture. Schools for commoners thus were established.

Temple schools of the Tokugawa period

Representative of such schools were the *terakoya* (temple schools), deriving from the earlier education in the temple. As time passed, some *terakoya* used parts of private homes as classrooms. Designed to be one of the private schools, or *shijuku,* the *terakoya* developed rapidly in the latter half of the Tokugawa era, flourishing in most towns and villages. Toward the end of the era they assumed the characteristics of the modern primary school, with emphasis on reading, writing, and arithmetic. Other *shijuku,* emphasizing Chinese, Dutch, and national studies, as well as practical arts, contributed to the diversification of learning and permitted students with different class and geographic backgrounds to pursue learning under the guidance of the same teacher. Their curricula were free from official control.

The shogunate established schools to promote Confucianism, which provided the moral training for upper-class samurai that was essential for maintaining the ideology of the feudal regime. *Han,* or feudal domains, following the same policy, built *hankō,* or domain schools, in their castle towns for the education of their own retainers.

The officially run schools for the samurai were at the apex of the educational system in the Tokugawa era. The Confucian Academy, which was known as the Shōheikō and was administered directly by the shogunate, became a model for *hankō* throughout Japan. The *hankō* gradually spread after about 1750, so that by the end of the era they numbered over 200.

The curriculum in the *hankō* consisted chiefly of *kangaku* (the study of books written in Chinese) and, above all, of Confucianism. Classics of Confucianism, historical works, and anthologies of Chinese poems were used as textbooks. Brush writing, *kokugaku* (study of thought originating in Japan), and medicine were also included. Later, in the last days of the shogunate, *yōgaku,* or Western learning, including Western medicine, was added in several institutions.

Both *hankō* for samurai and *terakoya* for commoners were the typical schools after the middle of the Tokugawa era. Also to be found, however, were *gōgaku,* or provincial schools, for samurai as well as commoners. They were founded at places of strategic importance by the feudal domain.

Role played by private schools

The various *shijuku* became centres of interaction among students from different domains when such close contact among residents of different areas was prohibited. They served as centres of learning and dialogue for many of those who later constituted the political leadership responsible for the Meiji Restoration of 1868.

Effect of early Western contacts. The Europeans who first arrived in Japan were the Portuguese, in 1543. In 1549 the Jesuit Francis Xavier visited Japan, and, for the first time, the propagation of Christianity began. Many missionaries began to arrive, Christian schools were built, and European civilization was actively introduced.

In 1633 the shogunate, in apprehension of further Christian infiltration of Japan, banned foreign travel and prohibited the return of overseas Japanese. Further, in 1639, the shogunate banned visits by Europeans. This was the so-called *sakoku,* or period of national isolation. From that time on Christianity was strictly forbidden, and international trade was conducted with only the Chinese and the Dutch. Because contact with Europeans was restricted to the Dutch, Western studies developed as *rangaku,* or learning through the Dutch language.

It is noteworthy that the Tokugawa period laid the foundation of modern Japanese learning. As a result of the development of *hankō* and *terakoya,* Japanese culture and education had developed to such an extent that Japan was able to absorb Western influences and attain modernization at a remarkably rapid pace after the Meiji Restoration. (A.Na./N.S.)

European Renaissance and Reformation

THE CHANNELS OF DEVELOPMENT IN RENAISSANCE EDUCATION

The Muslim influence. Western civilization was profoundly influenced by the rapid rise and expansion of Islām from the 7th until the 15th century. By 732, 100 years after the death of Muḥammad, Islām had expanded from western Asia throughout all of northern Africa, across the straits of Gibraltar into Spain, and into France, reaching Tours, halfway from the Pyrenees to Paris. Muslim Spain rapidly became one of the most advanced civilizations of the period, where much of the learning of the past—Oriental, Greek, and Roman—was preserved and further developed. In particular, Greek and Latin scholarship was collected in great libraries in the splendid cities of Córdoba, Seville, Granada, and Toledo, which became major centres of advanced scholarship, especially in the practical arts of medicine and architecture.

Inevitably, scholarship in the adjacent Frankish, and subsequent French, kingdom was influenced, leading to a revitalization of western Christian scholarship, which had long been dormant as a result of the barbarian migrations. The doctrines of Aristotle, which had been assiduously cultivated by the Muslims, were especially influential for their emphasis on the role of reason in human affairs and on the importance of the study of humankind in the present, as distinct from the earlier Christian preoccupation with the cultivation of faith as essential for the future life. Thus, Muslim learning helped to usher in the new phase in education known as humanism, which first took definite form in the 12th century.

Humanism

The secular influence. The word humanism comes from *studia humanitatis* ("studies of humanity"). Toward the end of the Middle Ages there was a renewed interest in those studies that stressed the importance of man, his faculties, affairs, worldly aspirations, and well-being. The primacy of theology and otherworldliness was over; the *reductio artium ad theologiam* (freely, "reducing everything to theological argument") was rejected since it no longer expressed the reality of the new situation that was developing in Europe, particularly in Italy. Society had been profoundly transformed, commerce had expanded, and life in the cities had evolved. Economic and political power, previously in the hands of the ecclesiastical hierarchy and the feudal lords, was beginning to be taken over by the city burghers. Use of the vernacular languages was becoming widespread. The new society needed another kind of education and different educational structures; the burghers required new instruments with which to express themselves and found the old medieval universities inadequate.

The educational institutions of humanism had their origin in the schools set up in the free cities in the late 13th and the 14th centuries—schools designed to answer to the needs of the new urban population that was beginning to have greater economic importance in society. The pedagogical thought of the humanists took these transformations of society into account and worked out new theories that often went back to the classical Greek and Latin traditions; it was not, however, a servile imitation of the pedagogical thought and institutions of the classical world.

The Renaissance of the classical world and the educational movements it gave rise to were variously expressed in different parts of Europe and at various times from the 14th to the 17th century; there was a connecting thread, but there were also many differences. What the citizens of the Florentine republic needed was different from what was required by princes in the Renaissance courts of Italy or in other parts of Europe. Common to both, however, was the rejection of the medieval tradition that did not belong in the new society they were creating. Yet the search for a new methodology and a new relation with the ancient world was bitterly opposed by the traditionalists, who did not want renewal that would bring about a profound transformation of society; and, in fact, the educational revolution did not completely abolish existing traditions. The humanists, for example, were not concerned with extending education to the masses but turned their attention to the sons of princes and rich burghers.

The humanists had the important and original conception that education was neither completed at school nor limited to the years of one's youth but that it was a continuous process making use of varied instruments: companionship, games, and pleasure were part of education. Rather than suggesting new themes, they wanted to discover the method by which the ancient texts should be studied. For them knowledge of the classical languages meant the possibility of penetrating the thought of the past; grammar and rhetoric were being transformed into philological studies not for the sake of pedantic research but in order to acquire a new historical and critical consciousness. They reconstructed the past in order better to understand themselves and their own time.

THE HUMANISTIC TRADITION IN ITALY

Early influences. One of the most influential of early humanists was Manuel Chrysoloras, who came to Florence from Constantinople in 1396. He introduced the study of Greek and, among other things, translated Plato's *Republic* into Latin, which were important steps in the development of the humanistic movement.

Inspired by the ancient Athenian schools, the Platonic Academy established in Florence in the second half of the 15th century became a centre of learning and diffusion of Christian Platonism, a philosophy that conceived of all forms as the creative thoughts of God and that inspired considerable artistic innovation and creativity. Marsilio Ficino and Pico della Mirandola were two of the most original of the scholars who taught there. Florence was the first city to have such a centre, but Rome and Naples soon had similar academies, and Padua and Venice also became centres of culture.

A famous early humanist and professor of rhetoric at Padua was Pietro Paolo Vergerio (1370–1444). He wrote the first significant exclusively pedagogical treatise, *De ingenuis moribus et liberalibus studiis* ("On the Manners of a Gentleman and on Liberal Studies"), which, though not presenting any new techniques, did set out the fundamental principles by which education should be guided. He gave pedagogical expression to the ideal of harmony, or equilibrium, found in all aspects of humanism, and underlined the importance of the education of the body as well as of the spirit. The liberal arts were emphasized ("liberal" because of the liberation they reputedly brought); the program outlined by Vergerio focused upon eloquence, history, and philosophy but also included the sciences (mathematics, astronomy, and natural science) as well as medicine, law, metaphysics, and theology. The later subjects were not studied in depth; humanism was by its nature against encyclopaedism, but it brought out the relations between the disciplines and enabled students to know many subjects before they decided in which to specialize. Learning was not to be exclusively from books, and emphasis was placed on the advantages of preparing for social life by study and discussion in common. Vergerio felt that education should not be used as a means of entering the lucrative professions; medicine and law, especially, were looked on with suspicion if one's aim in studying them was merely that of gaining material advantages.

Emphasis on the liberal arts

Emergence of the new gymnasium. As a result of the renewed emphasis on Greek studies, early in the 15th century a definite sequence of institutions emerged, with the gymnasium as the principal school for young boys, preparatory to further liberal studies in the major nonuniversity institution of higher learning, the academy. Both terms, gymnasium and academy, were classical revivals, but their programs were markedly different from those of ancient Greece. The gymnasiums appeared in ducal courts; they were created for the liberal education of privileged boys and as the first stage of the *studia humanitatis.* Outstanding among these early gymnasiums were the school conducted by Gasparino da Barzizza in Padua from 1408 to 1421, considered a model for later institutions, and more particularly the gymnasium of Guarino Veronese (1374–1460) and that of his contemporary Vittorino da Feltre (1378–1446).

Guarino had first established a school in 1415 in Venice, where he was joined by Vittorino. He subsequently moved to Ferrara where, from 1429 to 1436, he assumed responsibility for the humanist education of the young son of Nicolò d'Este, the lord of Ferrara. Guarino wrote no treatises, but something may be learned about his work and methods from his large correspondence and from *De ordine docendi et studendi* (1485; "On the Order for Teaching and Studying"), written by his son Battista. Guarino organized his students' courses into three stages: the elementary level, at which reading and pronunciation were primarily taught, followed by the grammatical level, and finally the highest level, concentrating on rhetoric. The education given in his schools was perhaps the best example of the humanistic ideals, since it underlined the importance of literary studies together with a harmonious development of body and spirit, to the exclusion of any utilitarian purpose.

Humanist de-emphasis of "useful" education

Vittorino was a disciple of both Barzizza and Guarino. He conducted boarding schools at Padua and Venice and,

most importantly, from 1423 to 1446 one at Mantua, where he had been invited by the reigning lord, Gianfrancesco Gonzaga. This last school, known as La Giocosa (literally, "The Jocose, or Joyful"), soon became famous. At La Giocosa only those who had both talent and a modest disposition were accepted; wealth was neither necessary nor sufficient to gain admission; in fact, the school was one of the few efforts made during this period to extend education to a wider public. The program of study at La Giocosa was perhaps closer to the medieval tradition than that of the other boarding schools, but, in any case, the spirit was different. Studies were stimulating; mathematics was taught pleasantly—Vittorino going back to very ancient traditions of practicing mathematics with games. After having studied the seven arts of the trivium (grammar, rhetoric, and logic) and the quadrivium (geometry, arithmetic, harmonics, and astronomy), students completed the cycle by a study of philosophy and then, having mastered this discipline, could go on to higher studies leading to such professions as medicine, law, philosophy, and theology. Italian was completely ignored at Vittorino's school; all instruction was given in Latin, the study of which, together with Greek, reached a high level of excellence. Great importance was given to recreation and physical education; his concern for the health of his students did not come to an end with the scholastic year, for during the summers, when the cities became unhealthy, he would arrange for his students to go to Lake Garda or to the hills outside Verona.

Vittorino's educational philosophy was inspired by a profound religious faith and moral integrity, which contrasted with the general relaxation of standards within the church itself; but, if he was severe with himself, he was very open and tolerant with his pupils. The school continued only for a while after his death because, more than in the case of the other schools, La Giocosa was identified with the personality of the founder.

Nonscholastic traditions. Leon Battista Alberti, one of the most intelligent and original architects of the 15th century, also dedicated a treatise, *Della famiglia* (1435–44; "On the Family"), to methods of education. Alberti felt that the natural place for education was the home and not scholastic institutions. The language in which he wrote was Italian, education being in his view so important in social life that he felt that discussion of it should not be limited to scholars. He stressed the importance of the father in the educational process.

Baldassare Castiglione expressed the transition of humanism from the city to the Renaissance court. He himself was in the service of some of the most splendid princes, the Gonzagas at Mantua and the Montefeltros at Urbino. Just as in the 15th century the humanists had been concerned with the education of the city burgher, so in the 16th century they turned their attention to the education of the prince and of those who surrounded him. *Il cortegiano* ("The Courtier") was published in 1528, and within a few years it had been translated into Latin and all the major European languages. The courtier was to be the faithful collaborator of the prince. He had to be beautiful, strong, and agile; he had to know how to fight, play, dance, and make love. But this was not all, since great importance was also attached to the study of the classics and the practice of poetry and oratory; the courtier had to be able to write in rhyme and in prose and have perfect command of the vernacular, which was becoming important in political affairs; but above all he had to have skill at arms.

Education of the courtier

The courtier described by Castiglione, though in the service of necessarily devious princes, had to know how to keep his dignity and his virtue. Castiglione's moral standards, reflecting the spiritual climate at Urbino, completely disappeared, however, in Giovanni della Casa's work, *Galateo* (1551–54), in which considerations of etiquette were placed above all others; the values of humanism no longer existed, and all that was left was ceremonial.

THE HUMANISTIC TRADITION OF NORTHERN AND WESTERN EUROPE

The economic and social conditions behind the intellectual and cultural revolution of humanism in Italy were also present, though in different forms, in other parts of Europe. In some states, chiefly England, France, and Spain, humanism and educational reforms developed around the courts, where political power was being concentrated; in others, such as the Netherlands, they were brought about by the city burghers, whose power, both economic and political, was increasing. The educational reforms that the humanists brought about in northern and western Europe developed slowly, but on the whole they were lasting, since they affected a greater number of people than was the case in Italy, where they tended to be restricted to a narrow circle of families. There were close relations between Italian and other European educational humanists, as there were among English, Dutch, French, and German humanists, and, thus, national differences were not so significant.

Courtly and bourgeois forms of humanism

Dutch humanism. In the Netherlands the ground for educational reform had already been prepared in the 14th century by the Brethren of the Common Life, a group founded by Gerhard Groote to bring together laymen and religious men. Although their work was not originally in the field of education, education started when they set up hostels for students and exercised some moral direction over these students; this work was extended, and the Brethren eventually set up schools, first at Deventer, then in other cities. Some of the most important humanists of the Netherlands and Germany attended their schools—among others, Erasmus.

The school at Deventer came to have great prestige under Alexander Hegius, rector from 1465 to 1498 and author of a polemic treatise, *De utilitate Graeci* ("On the Usefulness of Greek"), underlining the importance of studying Greek, and of *De scientia* ("On Knowledge") and *De moribus* ("On Manners"). Hegius had great talent as an organizer and succeeded not only in attracting some of the best scholars of the time but also in giving the school an efficient structure that became a model for many schools in the north.

Desiderius Erasmus was a great scholar and educator, and his influence was felt all over Europe. His strong personality earned him the respect and sympathy of humanists who saw in him, as in few others, the symbol of their ideals and values. Unfortunately, his proposals for reform and greater tolerance were not always accepted in the tortured Europe of the 16th century.

Erasmus was a prolific writer, and part of his work was concerned with education: *De ratione studii* (1511; "On the Right Method of Study"), *De civilitate morum puerilium* (1526; "On the Politeness of Children's Manners"), *Ciceronianus* (1528), *De pueris statim ac liberaliter instituendis* (1529; "On the Liberal Education of Boys from the Beginning"). His educational program was original in many ways but in no sense democratic. The masses could not partake in higher education, since their aim was that of gaining skill in an occupation. He felt that religious instruction should be made available to all but that classical literary studies—the most important of all studies—were for a minority.

The classical and elitist tradition in humanism

Study of ancient languages and intelligent comprehension of texts formed the basis of Erasmus' system of education; he took a stand against the formalism and dogmatism that were already creeping into the humanist movement. Erasmus was in favour of acquiring a good general liberal arts education until the age of 18, being convinced that this would be a preparation for any form of further study. His great love for the classical languages, however, made him neglect the vernacular; he was not interested in local traditions; and he attributed very little importance to science, which he did not think necessary for a cultured man. He was against instruction being imposed without the participation of the student. His optimism about the nature of man and the possibilities of molding him made Erasmus feel that, if adequately educated, any man could learn any discipline. He further sought renewal of the schools and better training for teachers, which he felt should be a public obligation, certainly no less important than military defense. Many of Erasmus' themes were elaborated a century later by John Amos Comenius and form the basis of modern education, in particular the effort to understand the child psychologically and to consider education

as a process that starts before the school experience and continues beyond it.

Juan Luis Vives. Strongly influenced by Erasmus was Juan Luis Vives, who, though of Spanish origin, spent his life in various parts of Europe—Paris, Louvain, Oxford, London, Bruges. His most significant writings were *De institutione foeminae Christianae* (1523; "On the Education of a Christian Woman"), *De ratione studii puerilis* ("On the Right Method of Instruction for Children"), *De subventione pauperum* (1526; "On Aid for the Poor"), and *De tradendis disciplinis* (1531; "On the Subjects of Study").

The new social and utilitarian traditions

Not only was his vision of the organic unity of pedagogy new, but he was the first of the humanists to emphasize the importance of popular education. He felt that it was the responsibility of the city to provide instruction for the poor and that the craft and merchant guilds had an important contribution to make to education. Unlike other humanists, moreover, he did not despise the utilitarian aspects of education but on the contrary suggested that his pupils should visit shops and workshops and go out into the country to learn something of real life.

Just as he felt that education should not be limited to a single social class, so he felt that there should be no exclusion of women, though perhaps they required a different kind of education because of their different functions in life.

Vives worked out a plan to take account of both educational structures and teacher training. In emphasizing the social function of education, he was against schools being run for profit and believed that teachers should be prepared not only in their specific fields but also in psychology so as to understand the child. He also suggested that teachers should meet four times a year to examine together the intellectual capacities of each one of their pupils so that suitable programs of study could be arranged for them. Vives considered that, in teaching, games had psychological value. He favoured use of the vernacular for the first stage of education; but, as a humanist, he had a passion for Latin and felt that there was no substitute for Latin as a universal language. Classical studies were to be completed by investigation of the modern world, in particular its geography, the horizons having been greatly enlarged by recent discoveries. Vives' method was an inductive one, based not on metaphysical theories but on experiment and exercise.

The early English humanists. At the end of the 15th century there was a flowering in England of both humanistic studies and educational institutions, enabling a rapid transition from the medieval tradition to the Renaissance. The English humanists prepared excellent texts for studying the classical languages, and they started a new type of grammar school, long to be a model. Most important were John Colet and Thomas More. Thomas Linacre, author of *De emendata structura Latini sermonis libri sex* (1524; "Six Books on the Flawless Structure of the Latin Language"), should also be remembered, as well as William Lily, author of a Latin syntax, *Absolutissimus de octo orationis partium constructione libellus* (1515; "Comprehensive Study of the Construction of the Eight Parts of Speech"), and director of St. Paul's School in London from 1512 to 1522.

The English grammar schools

Colet has an important place in English education. As dean of St. Paul's Cathedral he founded St. Paul's School, thus favouring the introduction of humanism in England and the transformation of the old ecclesiastical medieval schools. He had traveled a great deal in France and Italy and wanted to bring to his country the humanistic culture that had so fascinated him. In 1510 he started a "grammar school," open to about 150 scholars who had an aptitude for study and had completed elementary school. Colet's personality and energy made his school a lively centre of English humanism.

More was both a distinguished humanist and a statesman. He was interested in pedagogy, to which he dedicated part of his work *Utopia* (1516). In his Utopia, More saw the connection between educational, social, and political problems and the influence that society therefore has on education. English humanists such as More were engaged in a bitter battle because medieval tradition was deeply rooted; they were fierce opponents of a group called the Trojans, who opposed the Greek language and all that the new instruction of that language represented.

EDUCATION IN THE REFORMATION AND COUNTER-REFORMATION

New political and social systems developed in those European countries that, for various reasons and at different times, broke away from the Roman Catholic church in the 16th century. The religious reforms brought about by Martin Luther, John Calvin, Huldrych Zwingli, and the ruling family of England were both cause and effect of these transformations. Characteristic of all these countries was the importance of the state in the organization of the educational system.

The Reformation and European humanism influenced one another. There were analogies between the flowering of the classical world in the European courts and the reawakening of religious interests; there were similarities in the critical position adopted toward Aristotelianism and in the interest shown toward the study of classical languages, such as Greek and Hebrew. The presuppositions behind the two movements—humanism and Reformation—were different, however, and sooner or later a clash was inevitable. The most spectacular of these clashes was between Erasmus and Luther, despite the fact that for a long time they had respected each other. It was important for Erasmus and for the humanists to encourage the development of a world of writers and artists who, free from material preoccupations, could devote their time to literary and artistic pursuits. For the Reformers the situation was different: they did not aim to educate a small minority; unlike Erasmus, Luther had to keep the masses in mind, for they had contributed to the success of the religious reforms.

Humanism and the Reformation

Luther and the German Reformation. Luther specifically wished his humble social origins to be considered a title of nobility. He wanted to create educational institutions that would be open to the sons of peasants and miners, though this did not mean giving them political representation. (The German princes were glad to promote the Reformation on condition that it would not diminish but would, on the contrary, increase their political power.) Luther realized that an educational system open to the masses would have to be public and financed by citizens' councils. His educational programs are set out in *An die Radsherrn aller Stedte deütsches Lands: Das sie christliche Schulen affrichten und hallten sollen* (1524; "Letter to the Mayors and Aldermen of All the Cities in Behalf of Christian Schools"), in *Dass man Kinder zur Schulen halten solle* (1530; "Discourse on the Duty of Sending Children to School"), and in various letters to German princes.

Although Luther advocated the study of classical languages, he believed that the primary purpose of such an education, in marked distinction to the aims of the humanists, was to promote piety through the reading of the Scriptures in their pure form. "Neglect of education," Luther wrote in a letter to Jacob Strauss in 1524, "will bring the greatest ruin to the Gospel." Accordingly, Luther argued that education must be extended to all children, girls as well as boys, and not simply to a leisured minority as in Renaissance Italy. Even those children who had to work for their parents in trade or in the fields should be enabled, if only for a few hours a day, to attend local, city-maintained schools in order to promote their reading skills and hence piety. Out of the Lutheran argument emerged a new educational concept, the *pietas litterata:* literacy to promote piety.

Lutheran emphasis on public schools for all

On the premise that a new class of cultivated men must be developed to substitute for the dispossessed monks and priests, new schools, whose upkeep was the responsibility of the princes and the cities, were soon organized along the lines suggested by Luther. In 1543 Maurice of Saxony founded three schools open to the public, supported by estates from the dissolved monasteries. It was more difficult to set up the city schools, for which there was no tradition. In towns and villages of northern Germany Johannes Bugenhagen (1485–1558) set up the earliest schools to teach religion and reading and writing in German, but it was

not until 1559 that the public ordinances of Württemberg made explicit reference to German schools in the villages. This example was shortly followed in Saxony.

Whereas Luther combined his interest in education with his work as a religious reformer and politician, another Reformer, Philipp Melanchthon (1497–1560), concentrated almost entirely on education, creating a new educational system and, in particular, setting up a secondary-school system. He taught for many years at the University of Wittenberg, which became one of the centres of theological studies in Reformation Germany; and his experience there enabled him to reorganize the old universities and set up new ones, such as Marburg, Königsberg, and Jena. His ideas about secondary education were put into practice in the schools he founded at Eisleben. Scholastic work was divided into three stages, access to each successive stage depending on the ability of the student to master the previous course work; this was a new concept (foretelling the later "grading system"), unknown in the traditional scholastic system. He was convinced that too many subjects should not be imposed on the student. He felt that Latin was important but not German, Greek, or Hebrew, as had been taught in the humanistic schools; such variety, he felt, was exhausting and possibly harmful. This opened the door to a new type of formalism, however, a danger that in other spheres the educational reformers had tried to fight.

Growing formalism in German schools

The work of Johannes Sturm (1507–89) illustrates this danger. He founded a grammar school in Strassburg (now Strasbourg, Fr.) that became a model for German schools. Sturm believed that methods of instruction in elementary schools and, to some degree, in secondary schools should be different from those in the institutes of higher education. Not much autonomy was to be allowed the child, who started learning Latin at the age of six by memorizing. Sturm's love of Latin was even greater than that of his friend Erasmus, who never wanted it to become a mechanical exercise. As a consequence, German was neglected, as was physical instruction, and too much importance was given to form and expression for its own sake.

The English Reformation. The separation of the Church of England from the church of Rome in the 16th century under Henry VIII did not have quite the repercussions in the scholastic field that were experienced by the continental Reformations. The secondary-school system in England had been strongly influenced by the Renaissance in the period preceding the reform, and about 300 grammar schools were already in existence. Nevertheless, the situation became precarious, for political reasons, under a succession of sovereigns.

Henry VIII included the schools in his policy of concentration and consolidation of power in the hands of the state. In 1548, under Henry's son Edward VI, the Chantries Act was passed, confiscating the estates of the church expressly for use in education; but the turmoil of the times, under the boy Edward and then his Roman Catholic sister Mary I, allowed the funds allocated to education to be diverted elsewhere. Many primary schools and grammar schools disappeared or retrenched their operations for lack of funds. Elizabeth I, however, succeeding to the throne in 1558, revived Henry VIII's educational policy; considerable sums were appropriated for education, even though it was not always possible to enforce the new provisions because of local opposition and some lack of concern on the part of the Anglican clergy.

The growth of a rich and prosperous mercantile class and the spread of Calvinist reforms through the Puritans in England and the Presbyterians in Scotland were also factors in the transformation of English education in the 16th and 17th centuries. Scholastic programs reflected changes in society: importance was given to English, to science, to modern languages (in particular French and Italian), and to sports, as is still the case in England today. The Puritan contribution was thus considerable, though often hindered by the traditional forces of the Anglican church and the old nobility.

The work of Sir Thomas Elyot and Roger Ascham

Sir Thomas Elyot, in *The Boke Named the Governour* (1531), wrote the first treatise in English that dealt specifically with education. He was interested in those who would have the future economic and political power in their hands. Though their education was to include the classics, it was to be supplemented by the needs of the new mercantile class—the national English language, manual arts, drawing, music, and all forms of sport. Elyot was obviously influenced by Erasmus.

Roger Ascham was close in thought to many of the English humanists. In *The Scholemaster* (1570) he underlined the importance of the English language (in spite of his being a professor of Greek) and proposed that it should be used in teaching the classical languages. He also believed that physical exercise and sport were important, not only for the nobility and the leisured classes but also for students and teachers. He was aware of the social changes in the country; and, observing with sadness the corruption of the new wealth, he was particularly chagrined to see students going to university not to gain culture but to prepare themselves for high offices of state.

Richard Mulcaster had 30 years of experience as an educator at St. Paul's School and at the Merchant Taylors School, a Latin secondary school maintained by the tailors' guild in London—and most famous of all the "guild schools." Mulcaster was in favour of efficient teacher training and of teachers being adequately paid. In agreement with some of the Lutheran educational reforms, he felt that schools should be open to all, including women, who should moreover have access to higher education. He is particularly remembered for his opposition to Italianate trends: "I love Rome, but London better. I favour Italy, but England more. I know the Latin, but worship the English."

Sir Francis Bacon was interested in education though it was not his main concern—his main concern being the championship of the scientific method and "sense" realism, or empiricism, in opposition to traditional Aristotelianism and Scholasticism. He was opposed to private tutors and felt that boys and youths were better off in schools and that their education should be geared to their social status and future activity. Schooling should aim at preparing statesmen and men of action as well as scholars and thus should include history, modern languages, and politics. Bacon himself had a passion for study not only for its utilitarian purposes but because of its being for him a true source of delight.

The French Reformation. Schools in 16th-century France were still largely under the control of the Roman Catholic church, as they had been in the Middle Ages. This traditional education faced opposition, however, both from Protestants and from reformers who had been influenced by the humanist principle of the primacy of the individual.

Reformers opposed to traditional education

François Rabelais was a great and original interpreter of humanistic ideals, and his views on education reflected this. He himself studied in various fields, from medicine to letters, and was passionately interested in all of them. His controversy with the Sorbonne, a remaining stronghold of medievalism and Scholasticism, was bitter; he satirized the school and the useless notions taught there in his novels *Pantagruel* (1532) and *Gargantua* (1534).

Rabelais's educational philosophy was entirely different from that of the medievalists—his being based on liberty of the pupil, in whom he had maximum faith. In *Gargantua* this cult of liberty was celebrated in the utopian Abbey of Thélème, where all could live according to their own pleasure but where the love of learning was so great that everyone was dedicated to it, getting much better results than those obtained at the medieval universities. And yet in the education of Gargantua and Pantagruel there were limits placed on liberty: Gargantua's day started at 4 in the morning; he studied all subjects, both literary and scientific; and this was alternated with play and pleasing diversions. The heavy program, however, was not a constriction because of Gargantua's delight in learning. The culture that Rabelais wanted for his two heroes was directly connected with the world in which they lived.

Gargantua and *Pantagruel* were perhaps among the first texts by a humanist in which not only the quadrivium but also scientific studies were enthusiastically proposed. There was nothing arid or abstract in Rabelais's approach

to nature, and in this context the classics also had a new flavour: ancient literature, no longer limited to Latin, Greek, and Hebrew but expanded to include Arabic and Chaldaic, could bring to light valuable knowledge that had been accumulated by the classical world.

Petrus Ramus, one of the most bitter critics of French medieval Aristotelianism, was an intelligent reformer of educational methods. His best-known treatises are *Aristotelicae animadversiones* (1543; "Animadversions on Aristotle") and *Dialecticae partitiones* (1543; "Divisions of Dialectic"), both condemned by royal decree; he also wrote two discourses on philosophy, *Oratio de studiis philosophiae et eloquentiae conjungendis* (1546; "Speech on Joining the Study of Philosophy with the Art of Speaking") and *Pro philosophica Parisiensis accademiae disciplina oratio* (1551; "Speech in Defense of the Philosophical Discipline of the Parisian Academy"), as well as *Ciceronianus,* published posthumously. In these works his criticism of traditional ways and of the degeneration of humanistic thought made him hated by all Roman Catholics, though not much better understood by Protestants; he died a Protestant victim of the massacre of St. Bartholomew. His program of study was fairly close to the traditional one, but his method was original, for he was concerned that the teacher should not suffocate the child with too many lessons and considered the child's autonomous activity important. He especially resented any pedagogy that relied on a blind appeal to authority; learning had to be utilitarian and issue from practice.

Michel de Montaigne (1533–92) was much influenced by his personal experience as a student. Though often critical of humanism, especially when it was misinterpreted and transformed into pedantic studies, he had great admiration for the classics and lacked the scientific interests of Rabelais or Ramus. Montaigne wrote specifically about education in two essays on the upbringing of children and on pedantry. Culture, he felt, had become imitation, often with no trace of originality left, whereas it should be a delight—not something a student is forced to assimilate but something to draw the student's participation. He was in favour of instruction by tutors capable of giving the student individual attention—the ideal tutor being one with a good mind rather than one filled with pedantic notions. He also believed in the importance of physical education and in a boy's being hardened to nature and to danger.

For Montaigne it was important not only to travel to foreign countries but also to stay there for a while, to learn languages and, even more, to learn about foreign customs and thus break out of the narrow limits of one's own province. There were many differences between Montaigne and Erasmus, but both were convinced that for the wise man there could be no geographic boundaries, for, through cultural diffusion, barriers would be broken down.

The Calvinist Reformation. The Protestant Reformer John Calvin was of French origin, but he settled in Geneva and made this Swiss city one of the most prominent centres of the Reformation. Unlike Luther, whose reforms were backed by princes hoping to gain greater political independence, Calvin was supported by the new mercantile class, which needed political and administrative changes for the purposes of its own expansion.

Calvin considered popular education important, but he was not an innovator. The theological academy he founded in Geneva in 1559 was modeled on Sturm's school in Strassburg, where Calvin had taught; it became distinguished under the directorship of Theodore Beza, an intelligent Reformer but unfortunately a very intolerant one, at least in theological matters. Calvin's influence on education was nevertheless felt in many of the European universities, even as far as England, where, in spite of Anglican opposition, the Puritans had gained a foothold.

Calvinist emphasis on universal literacy

Calvin was in favour of universal education under church control (the cost to be in large part borne by the community), but "universal" did not mean "democratic." Even if some form of instruction was to be given to everyone (so that everyone might in some measure read the Scriptures for himself, in good Calvinist tradition), very few individuals reached secondary or higher education, and of these only a minute percentage came from the working classes. Documents of the period show the steps taken to achieve the aim of universal education. In the Netherlands, the Calvinist Synod of The Hague in 1586 made provision for setting up schools in the cities, and the Synod of Dort in 1618 decreed that free public schools should be set up in all villages. In Scotland in 1560 John Knox, a disciple of Calvin and the leader of the Scottish Presbyterians, aimed at setting up schools in every community, but the nobility prevented this from actually being carried out. The major educational contributions of Calvinism were its diffusion to a larger number of people and the development of Protestant education at the university level. Not only was Geneva significant but also the universities of Leiden (1575), Amsterdam (1632), and Utrecht (1636) in the Netherlands and the University of Edinburgh (1582) in Scotland. The Puritan, or English Calvinist, movement was responsible for the founding of Emmanuel College at the University of Cambridge (1584).

The Roman Catholic Counter-Reformation. The religious upheaval, so important in northern Europe, also affected, though less violently, the Latin countries of southern Europe. If the new ferment in the Roman Catholic church was mainly directed at answering the Protestants, at times it also had something original to suggest. At the Council of Trent (1545–63) the Roman Catholic church tried to come to terms with the new political and economic realities in Europe.

Education was foremost in the minds of the leaders of the Counter-Reformation. The faithful were to be educated. For this, capable priests were needed, and, thus, seminaries multiplied to prepare the clergy for a more austere life in the service of the church. There was a flowering of utopian ideas, which should be remembered when trying to understand unofficial Catholic thought of the period. Writings such as *La città del sole* ("The City of the Sun"), by Tommaso Campanella, and *Repubblica immaginaria* ("The Imaginary Republic"), by Lodovico Agostini, are examples of this new vision of the church and of the duties of Christians. But if in the minds of the utopians this education was to be universal, it was in fact almost entirely directed at the ruling classes.

The growth of seminaries

The Society of Jesus, founded in 1534 by Ignatius Loyola, was not specifically a teaching order, but it was nevertheless very important in this field. The first Jesuit college was opened in Messina, Sicily, in 1548; by 1615 the Jesuits had 372 colleges, and by 1755, just 18 years before the suppression of the order, the number had risen to 728. (The society was not reestablished until 1814.) In *Ratio studiorum,* an elaborate plan of studies issued by the Jesuits in 1599, there is laid out an organization of these institutions down to the smallest details; an authoritarian uniformity was thus the rule in their colleges, and individual initiative was discouraged. The complete course of study took at least 13 years, divided into three periods: six or more years that included grammar and rhetoric, three years of philosophy, and four of theology. The teacher was thought of not only as an instructor but also as an educator and often a controller, for he was at the centre of a vast network of controls, in which those students considered promising also took part. Emulation was encouraged in the class, which was often divided into two groups to stimulate competition. These new techniques, as well as the Jesuits' efficient training of teachers, had good results, proof of this being the rapid increase in their colleges, which found greater favour than others started in the same period.

The legacy of the Reformation. The effects on education of a movement as complex and widespread as the Reformation were far-reaching. Perhaps its most original contribution was the extension of the idea of education at the elementary level. As a result, the vernacular language took on a new importance, and also the new pedagogy had to take account of the realities of the situation—namely, that the children brought into the new school network could not spend as much time on "useless" books, so that schoolwork had to be combined with learning a practical trade, which had not previously been considered a part of education. This, however, was to take several centuries to be implemented in practice. (E.Ge./J.Bo.)

European education in the 17th and 18th centuries

THE SOCIAL AND HISTORICAL SETTING

The Renaissance had been the beginning of a new era in history, which culminated in the 17th and 18th centuries in the development of the absolutist state everywhere but in England and Holland (and even in these states the issue was for some time in doubt). France, the Habsburg empire, England, and Russia became the leading powers in Europe. The absolutist state extended its control beyond the political and into the religious (with the creation of the established church) and into almost all other aspects of human life. Although the High and later Middle Ages had witnessed the growth of middle-class forces, the pattern of society still clearly bore the stamp of court life. The concentration of power determined this life, and the citizen and his possessions were more and more at the disposal of the aristocracy. The citizen was subject.

Influence of absolutism on education

Even in an absolutist state, however, education cannot be the sole privilege of the rich or the ruling classes, because an efficient absolutist state requires capable subjects, albeit bound to their social position. Elementary education for the middle classes thus developed in the 17th and 18th centuries, and more and more the state saw as its task the responsibility for establishing and maintaining schools. This tendency toward general education did not stem only from considerations of political expediency; it stemmed also from the desire to improve the world through education—making all areas of life orderly and subordinate to rational leadership. There was not only an inclination toward encyclopaedism and systemization of the sciences but also, in similar fashion, a tendency to set education aright by extensive school regulations.

In general, this distinction can be made between the 17th and the 18th centuries: in the 17th century the aim of education was conceived as a religious and rationalistic one, whereas in the 18th century the ideas of secularism and progress began to prevail. The 18th century is especially remembered for three leading reforms: teaching in the mother language grew in importance, rivaling Latin; the exact sciences were brought into the curriculum; and the correct methods of teaching became a pedagogic question.

The new scientism and rationalism. These social and pedagogic changes were bound up with new tendencies in philosophy. Sir Francis Bacon of England was one who criticized the teachers of his day, saying that they offered nothing but words and that their schools were narrow in thought. He believed that the use of inductive and empirical methods would bring the knowledge that would give man strength and make possible a reorganization of society. Therefore, he demanded that schools should be scientific workplaces in the service of life and that they should put the exact sciences before logic and rhetoric.

Another 17th-century critic of medievalism was René Descartes, but he did not proceed from empirical experience, as did Bacon; for him the only permanence and certainty lay in human reason or thinking (*cogito ergo sum,* "I think; therefore, I am"). The ability to think makes doubt and critical evaluation of the environment possible. A science based only on empiricism fails to achieve any vital, natural explanations but only mathematical, mechanistic ones of doubtful living use. Only what reason (*ratio*) recognizes can be called truth. Thus, education must be concerned with the development of critical rationality.

Knowledge conceived as thinking

Like Descartes, Benedict de Spinoza and Gottfried Wilhelm Leibniz also outlined rationalistic philosophic systems. Decisive for educational theory was their statement that knowledge and experience originate in thinking (not in sense impressions, which can provide only examples and individual facts) and that formal thinking categories should form the substance of education. They believed that the aim of education should be the mastery of thinking and judgment rather than the mere assimilation of facts.

The Protestant demand for universal elementary education. The schools that were actually developed fell short of these philosophically based demands. This is especially true of elementary education. In the Middle Ages, the grammar schools (especially for the education of the clergy) had developed, and the humanism of the Renaissance had strengthened this tendency; only those who knew Latin and Greek could be considered educated. For basic, popular education there were meagre arrangements. Although schools for basic writing and arithmetic had been established as early as the 13th and 14th centuries, they were almost exclusively in the towns; the rural population had to be content with religious instruction within the framework of the church. This changed as a result of Protestantism. John Wycliffe had demanded that everyone become a theologian, and Luther, by translating the Holy Scriptures, made the reading of original works possible. Everyone, he asserted, should have access to the source of belief, and all children should go to school. So it happened that church regulations of the 16th and 17th centuries began to contain items governing schools and the instruction of young people (mainly in reading and religion). At first, the Protestant schools were directed and supported almost entirely by the church. Not until the 18th century, following the general tendency toward secularization, did the state begin to assume responsibility for supporting the schools.

EDUCATION IN 17TH-CENTURY EUROPE

Central European theories and practices. It was while Europe was being shaken by religious wars and was disintegrating into countless small states that such writers as Campanella and Bacon dreamed their Utopias (*La Città del sole* and the *New Atlantis,* respectively), where peace and unity would be had through logical and realistic means. To even attempt realizing this dream, however, man needed suitable education. Both leading representatives of so-called pedagogic realism, Wolfgang Ratke and John Amos Comenius, were motivated by this ideal of world improvement through a comprehensive reform of the school system. Despite this common starting point, however, both were highly distinct personalities and, moreover, had divergent influences on the development of education and schools.

Realism in education

The pedagogy of Ratke. Ratke (1571–1635), a native of Holstein in Germany, journeyed to England, Holland, and through the whole of Germany and to Sweden expounding his ideas to the political authorities and finding considerable support. His plans for progressive reform failed for several reasons. First, political conditions during the Thirty Years' War were understandably not favourable for any kind of planning or reform of schools. Moreover, Ratke demonstrated little practical ability in executing his plans. Finally, Ratke's ideas were not free of exaggerations. He promised, for example, to be able to teach 10 languages in five years, each language in six months.

His ideas about the art of teaching are, nevertheless, of importance for the theory and practice of education. First, he believed that knowledge of things must precede words about things. This "sense realism" means that individual experience in contact with reality is the origin of knowledge; principles of knowledge follow, rather than precede, the study of specifics.

Second, everything must follow the order and course of what may be called human nature. In modern terms, one would say that a lesson should be designed with psychological conditions taken into consideration.

Third, he asserted that everything should be taught first in the mother language, the mother language being the natural and practical language for children and the one that allows them to concentrate wholly on the business at hand. Only when the mother language is fully commanded should a child attempt a foreign language; then special attention should be paid to speaking it and not merely reading it.

Fourth, Ratke emphasized what might now be called a kind of programmed learning. One piece of work should be fully completed before progress is made to the next piece, and there should be constant repetition and practice. The teacher's methods and the textbook program should agree and coincide.

Ratke's teacher-centred education

Fifth, there should be no compulsion. A teacher should not be a taskmaster. To strike a pupil was contrary to nature and did not help him learn. A pupil should be

brought to love his teacher, not hate him. On the other hand, all work was the teacher's responsibility. The pupil should listen and sit still. More generally, all children, without exception, should go to school, and no lessons should be canceled for any reason. There is, of course, a certain paradox in Ratke's views: there was to be no compulsion, and yet pupils were to remain disciplined and were not permitted to work independently.

As for curricula, Ratke suggested reading and writing in the native tongue, singing, basic mathematics, grammar, and, in the higher classes, Latin and Greek. The sciences had not yet appeared in his timetable. His demand that, above all, young people should be given instruction in the affairs of God is typical of the combination of rationalistic and religious education in the 17th century.

The pedagogy of Comenius. Comenius (1592–1670) was, even more than Ratke, a leading intellect of European educational theory in the 17th century. Born in Moravia, he was forced by the circumstances of the Thirty Years' War to wander constantly from place to place—Germany, Poland, England, Sweden, Hungary, Transylvania, and Holland—and was deprived of his wife, children, and property. He himself said, "My life was one long journey. I never had a homeland."

As a onetime bishop of the Bohemian Brethren, he sought to live according to their motto, "Away from the world towards Heaven." To prepare for the hereafter, Comenius taught, one should "live rightly"—that is, seek learned piety by living one's life according to correct principles of science and morality. Comenius' philosophy was both humanitarian and universalistic. In his *Pampaedia* ("Universal Education," discovered in 1935), he argued that "the whole of the human race may become educated, men of all ages, all conditions, both sexes and all nations." His aim was *pansophia* (universal wisdom), which meant that "all men should be educated to full humanity"—to rationality, morality, and happiness.

The curriculum of Comenius

Comenius realized that, to achieve *pansophia* by universal education, radical reforms in pedagogy and in the organization of schools were required, and he devised an all-embracing school system to meet this need. During infancy (up to six years of age), the child in the "mother school," or family grouping, would develop basic physical faculties. During the following period (seven to 12), the child would go to the "vernacular school," which was divided into six classes according to age and could be found in every town. The prime aim of these schools would be to develop the child's imagination and memory through such subjects as religion, ethics, diction, reading, writing, basic mathematics, music, domestic economy, civics, history, geography, and handicraft. This vernacular school formed the final stage of education for technical vocations. After this school would come the grammar school (or Latin school), which the pupils would attend during their youth (13–18) and which would exist in every town of every district. Through progressive courses in language and the exact sciences, the young people would be brought to a deeper understanding of things. Finally, the university (19–24) would be a continuation of this school. Every province ought to have one such university, whose central task would be the formation of willpower and powers of judgment and categorization. Over and above this four-tier school system Comenius also envisaged a "college of light," a kind of academy of the sciences for the centralized pooling of all learning. It is important to note, in this regard, that it was Comenius' stay in England (1641–42) that initiated discussions leading to the founding of the Royal Society (incorporated 1662). Furthermore, the German philosopher Leibniz, influenced by Comenius, founded the Berlin Academy, and similar societies sprouted elsewhere.

The Great Didactic (1657) sets forth Comenius' methodology—one for the arts, another for the sciences. Comenius believed that everything should be presented to the child's senses—and to as many senses as possible, using pictures, models, workshops, music, and other "objective" means. With proper presentation, the mind of the child could become a "psychological" counterpart of the world of nature. The mind can take in what is in nature if the method of teaching most akin to nature is used. For the upper age levels, he recommended that language study and other studies be integrated, and indeed he employed this scheme in his *Gate of Tongues Unlocked* (1631), a book of Latin and sciences arranged by subjects, which revolutionized Latin teaching and was translated into 16 languages. *The Visible World in Pictures* (1658), which remained popular in Europe for two centuries, attempted to dramatize Latin through pictures illustrating Latin sentences, accompanied by one or two vernacular translations.

The schools of Gotha. The zeal for reform on the part of such educators as Ratke and Comenius, on the one hand, and the interests of the ruling classes, on the other, led in the years after about 1650 to the publication of school regulations, free of church regulations. The circumstances in the central German principality of Gotha were typical. The duke, Ernst the Pious, commissioned the rector Andreas Reyher to compile a system of school regulations, which appeared in 1642 and is known historically as the *Gothaer Schulmethodus.* This was the first independent civil system of school regulations in Germany and was strongly influenced by Ratke. The most important points of these regulations were compulsory schooling from the age of five; division of the school into lower, middle, and higher classes; extension of the usual subjects (reading, writing, basic arithmetic, singing, and religion) to various other fields (natural history, local history, civics, and domestic economy); the introduction of textbooks (for reading and basic arithmetic), notably the first textbook of exact sciences for elementary schools, Reyher's own *Kurzer Unterricht von natürlichen Dingen* (1657; "Short Course on Natural Things"); and methodical instruction that, above all, emphasized the clarity of the lesson and the activity of the pupils.

Systematizing education

French theories and practices. In the second half of the 17th century Germany suffered from the aftereffects of the Thirty Years' War, whereas France under Louis XIV reached the zenith of political and military power. France's leadership was also demonstrated in the cultural field—including education. Some of the most important developments in France included the promotion of courtly education and the involvement of religious orders and congregations in the education of the poor.

Views of Montaigne

Courtly education. The rationalistic ideal of French courtly education can be seen foreshadowed in Montaigne's *Essays* (1580), in which the ideal man was described as having a natural, sensible way of life not deeply affected by the perplexities of the time but admitting of pleasure. He had a "correct" attitude toward the world and people, a certain spiritual freedom, and an independent judgment—all of which, in Montaigne's view, were more important than being steeped in knowledge. "As lamps are extinguished from too much oil, so is the mind from too much studying." Montaigne came from a merchant family that aspired to nobility, and thus there is a certain fashionable elitism in his views; he held, among other things, that courtly education succeeds best when the pupil studies under a private tutor.

This ideal, rather unlike the ideal of the learned and humanistic Renaissance man, became important in 17th-century France, especially after mid-century and the rise of the court of Louis XIV. The education of the would-be versatile and worldly-wise gentleman was furthered not only by the continuation of the institution of private tutoring but also by the establishment of schools and academies for chevaliers and nobles, in which the emphasis was on such subjects as deportment, modern languages, fencing, and riding. It was most emphatically an example of class education, designed for the nobility and higher military and not for any commoners.

The teaching congregations. In the countries, such as France, that remained Catholic, the Roman church retained control of education, and indeed, as monarchy became more absolute, so largely did the authority of the church in matters of education. In France, practically all schools and universities were controlled by so-called teaching congregations or societies, the most famous and powerful of which during the first half of the 17th century was the Society of Jesus. By mid-century the Jesuits

had 14,000 pupils under instruction in Paris alone; and their colleges (not including universities) all over the land numbered 612.

Jesuit education

It was their successful teaching and comparatively mild discipline that caused the Jesuit schools to attract thousands of pupils. "They are so good," said Bacon of the Jesuit teachers in his *Advancement of Learning,* "that I wish they were on our side." The curriculum was purely classical, but importance was attached to spacious, well-adapted buildings and amenities designed to make school life interesting. In general, however, the religious and international conflicts did great harm to education, which suffered much because those kings and religious factions that gained power in France (as elsewhere) used the schools to propagate their cause, discarding teachers not of the approved persuasion. Moreover, the schools continued largely to ignore the new directions of men's minds; in the universities staffed by Jesuit fathers, medieval Scholasticism, though purged of the formalistic excesses that had degraded it, was fully restored. Schools and universities declined for the most part to contemplate any enlargement of the frontiers of knowledge and were too often deeply involved in the religious conflicts of the time. The University of Paris in particular remained distracted throughout the 17th century by theological dissensions—in at least one instance as a result of the rivalry that ensued after the Jesuits had effected a footing at Clermont College.

Aside from the Jesuits, the most important teaching congregations in France were the Bérullian Oratory, or Oratorians, and the Jansenists of Port-Royal. The former, founded in 1611 and soon to open a number of schools and seminaries for young nobles, was composed of priests—but priests more liberal and rationalist than was common for the times. They offered instruction not only in the humanities but also in history, mathematics, the natural sciences, and such genteel accomplishments as dancing and music and, though continuing to use Latin in instruction, promoted also the use of the vernacular French in the initial years of their curriculum. They tended indeed to be drawn to the ideas of Descartes, to a faith based on reason. When in 1764 the Jesuits were banned from France, their teaching positions were largely assumed by Oratorians.

The Jansenists

More famous than the schools of the Oratorians, though enjoying a briefer career, were the Little Schools of Port-Royal. Their founder was Jean Duvergier de Haurame, better known as the abbot of Saint-Cyran, who was one of France's chief advocates of Jansenism, a movement opposed to Jesuitry and Scholasticism and favouring bold reforms of the church and a turn to a certain Pietism. About 1635 Saint-Cyran, with the help of some wealthy, influential Parisians, succeeded in gaining control of the convent of Port-Royal, near Versailles. There the Jansenist group began about 1637 to educate a few boys, and by 1646 it had established the Little Schools of Port-Royal in Paris itself. Their curriculum was similar to that of the Oratorians, though excluding dancing, and was celebrated for its excellence in French language and logic and in foreign languages. Influenced by Descartes's rationalistic philosophy, the Jansenists theorized that learning has a "natural" order and should begin with what is familiar to the child: thus, a phonetic system of teaching reading was used; all instruction was in French, not Latin; student compositions were directed toward topics drawing on one's own experiences or toward subjects in one's current reading. Involved in political struggles with the Jesuits, who were still influential at court, the Jansenists were fated to have all their schools closed down by 1660, but their theories and practices were widely adopted and became extremely influential.

Female education. During the century, the education of girls was not entirely neglected, and France was notable for its efforts. Mme de Maintenon, for instance, had been a pupil of the Ursuline nuns in Paris and then a governess at the court of Louis XIV before she was wedded to the king in 1684. From her royal vantage point, she took upon herself the founding of a school in 1686 at Saint-Cyr near Versailles—a higher school principally for orphan girls descended from noble families. Besides such basic subjects as reading and writing, the girls were prepared for their future lives as wives and mothers or as members of genteel professions. In 1692 this school was taken over by the Augustinian nuns. Another important worker in the field of female education was St. Jane Frances de Chantal, who, together with her father confessor, St. Francis de Sales, founded in 1610 the order of the Visitandines, a group dedicated to charitable work and the religious education of women.

Views of Fénelon

François de Salignac de La Mothe-Fénelon, archbishop of Cambrai and noted theologian and writer, is especially known for his views on the education of girls. In his *Traité de l'éducation des filles* (1687; "Treatise on the Education of Girls") he remarked on the importance of women in improving the morals of society and went on to express his thoughts about girls' education. Because girls, he believed, are meant to fulfill roles as housewives and mothers, they should pursue religious and moral education rather than scholarly learning. They should learn reading and writing, basic mathematics, history, music, needlework, Latin (because it is the church language), but no modern languages, since they tend to moral corruption. Education, he maintained, should make the lady of the house both Christian and accomplished, neither ignorant nor précieuse.

English theories and practices. The 17th century in England (up to the Glorious Revolution of 1688–89) was one of argument over religious and political settlements bequeathed by Queen Elizabeth I; the period was one characterized by the confrontation of two different world-views—on one side the royalist Cavaliers and on the other side the Puritans. The division was reflected in education.

The Puritan Reformers. In the Anglo-American world the Reformation came about in the form of Calvinism—"Puritan" being the derisory name for strict Calvinists. Their ideals were sober, practical behaviour, careful management, thrift, asceticism, and the rejection of hedonistic pleasures of life. Many of the educationists who sought this Puritan ideal were followers of the reform plans of Comenius. Samuel Hartlib, a Polish merchant residing in England who was friend, publisher, and patron of Comenius, tried to interest Parliament in the idea of popular education; his treatise *London's Charity Enlarged* (1650) proposed that a grant be made for the education of poor children, all in the interest of general social betterment. The Committee for Advancement of Learning, which he founded in 1653, was the impulse and model for later educational associations. In general, his ideas for reform included the introduction of agricultural schools and the state organization of the educational system, as well as the establishment of general elementary education.

The name of John Dury stands close to those of Comenius and Hartlib. In 1651 appeared his book *The Reformed School,* in which he proposed teaching societies in England much like the teaching congregations in France. Indeed, he was particularly insistent that control of education be in the hands not of a regimentizing state but of free educational organizations. He was also concerned about teaching youth the useful arts and sciences so that they might "become profitable instruments of the Commonwealth." From him, too, stemmed the draft of a nursery school; thus, he can be regarded as the first representative of infant teaching in England.

The humanism of John Milton

The most renowned of the Puritan intellectuals, John Milton, was more concerned with the education of "our nobler and our gentler youth" than with the education of common boys. *Of Education* (1644), written at the request of Hartlib, was one of the last in the long line of European expositions of Renaissance humanism. Milton's aim was the traditional aim, the molding of boys into enlightened, cultivated, responsible citizens and leaders. His proposed academy, which would take the place of both secondary school and college, was to concentrate on instruction in the ancient classics, with due subordination to the Bible and Christian teaching. Milton also emphasized the sciences, and physical and martial exercise had a place in his curriculum as well.

Royalist education. Frequently opposed to Puritanism on educational as well as political grounds were the royalists and supporters of the nobility. In education, their

views went back to Elyot and Ascham in the 16th century, who had written so persuasively about the education of gentlemen in the tradition of the so-called courtesy books. Influenced by these few English forerunners and also by Montaigne were James Cleland (*The Institution of a Young Nobleman,* 1607) and Henry Peacham (*The Compleat Gentlemen,* 1622). In the view of the latter, an extreme royalist, "Fashioning him [the pupil] absolute in the most necessary and commendable Qualities concerning Minde and Body to country's glory" was the overriding aim of education; the table of contents of *The Compleat Gentlemen* exhibits the variety of interests of an ideal gentleman or noble—cosmography, geometry, poetry, music, sculpture, drawing, painting, heraldry, and so on. John Gailhard (*The Compleat Gentleman,* 1678), another writer in the same tradition, can be said to have anticipated John Locke's empiricism (see below) when he wrote that "the nature of Youth is like Wax by fire, or a smooth table upon which anything can be written."

The academies. The beginning of academies for the promotion of philosophy, arts, or sciences can be traced to the early Renaissance, particularly in Italy and France. The Platonic Academy in Florence, cited earlier in this article, was one of the most noted of speculative societies. The first scientific academies belong to the 16th century: in 1560, for instance, the Academia Secretorum Naturae ("Secret Academy of Nature") was founded in Naples; in 1575 Philip II of Spain founded in Madrid the Academy of Mathematical Sciences. Then, in 1617, the first German academy, Fruchtbringende Gesellschaft ("Productive Society"), was founded at Weimar with the expressed purposes of the purification of the language and the cultivation of literature. A number of other academies were founded throughout Europe.

The Royal Society and the Academy of Sciences

It was in the 17th century that the two preeminent scientific academies were founded. Both the English Royal Society and the French Academy of Sciences began as informal gatherings of famous men. The "invisible college" of London and Oxford had its first meetings in 1645; it was incorporated as the Royal Society in 1662. In Paris, a group of men including the philosophers Descartes and Pascal started private meetings almost at the same time. In 1666 they were invited by the economic minister Jean-Baptiste Colbert to meet in the royal library. In 1699 the society was transferred to the Louvre under the name of the Academy of Sciences. The French Academy also started as a private society of men of letters some five years before its incorporation in 1635 under the patronage of Cardinal de Richelieu. In the 18th century, the fame and achievements of these English and French academies became internationally recognized, and many other European countries started to found their own national academies.

EDUCATION IN 18TH-CENTURY EUROPE

In the 18th century the theories and systems of education were influenced by various philosophical and social trends. Among these were realism, which had its origins in Ratke and Comenius, among others, and also Pietism, which derived principally from Philipp Jakob Spener and August Hermann Francke in the late 17th and early 18th centuries (see below). Another trend was the far-reaching rationalistic and humanitarian movement of the Enlightenment, best seen in the pedagogical views of Locke, in the upsurge of philanthropy, and in Denis Diderot's *Encyclopédie,* a comprehensive system of human knowledge in 28 volumes (1751–72). Also important was naturalism, of which Jean-Jacques Rousseau can be regarded as the main representative.

Locke's theory of knowledge

Education during the Enlightenment. *John Locke's empiricism and education as conduct.* The writings of the late 17th-century empiricist John Locke on philosophy, government, and education were especially influential during the Enlightenment. For education, Locke is significant both for his general theory of knowledge and for his ideas on the education of youth. Locke's empiricism, expressed in his notion that ideas originate in experience, was used to attack the doctrine that principles of reason are innate in the human mind. In *An Essay Concerning Human Understanding* (1690) Locke argued that ideas come from two "fountains" of experience: sensation, through which the senses convey perceptions into the mind, and reflection, whereby the mind works with the perceptions, forming ideas. Locke through of the mind as a "blank tablet" prior to experience, but he did not claim that all minds are equal. He insisted, in *Some Thoughts Concerning Education* (1693), that some minds have a greater intellectual potential than others.

For education, Locke's empiricism meant that learning comes about only through experience. Education, which Locke felt should address both character and intellect, is therefore best achieved by providing the pupil with examples of proper thought and behaviour, by training the child to witness and share in the habits of virtue that are part of the conventional wisdom of the rational and practical man. Virtue should be cultivated through proper upbringing, preparatory to "studies" in the strict sense. The child first learns to do through activity and, later, comes to understand what has been done. The intimacy between conduct and thinking is best illustrated in the title of Locke's *Of the Conduct of the Understanding,* written as an appendix to his *Essay.* There it is clear that understanding comes only with careful cultivation and practice; this means that understanding not only involves conduct but is itself a kind of conduct. If the child and the tutor share a kind of conduct, then the child will have learned the habits of character and mind that are necessary for education to continue.

Vico's emphasis on imagination

Giambattista Vico, critic of Cartesianism. Like Locke, the Italian philosopher Giambattista Vico believed that human beings are not innately rational; he argued, however, that understanding results not through sense perception but through imaginative reconstruction. Although Vico's ideas were not widely known in the 18th century, the importance of his work for the history of philosophy and education has been increasingly recognized since the late 1960s. Vico was professor of rhetoric at the University of Naples from 1699 to 1741. His best-known work is *New Science* (1725), in which he advanced the idea that human beings in their origins are not rational, like philosophers, but imaginative, like poets. The relation between imagination and reason in *New Science* is suggestive for educational theory: civilized human beings are rational, yet they came to be that way without knowing what they were doing; the first humans created institutions literally without reason, as poets do who follow their imagination rather than their reason. Only later, after they have become rational, can human beings understand what they are and what they have made. Vico's idea that early humans were nonrational and childlike prefigured Rousseau's primitivism and his conception of human development (see below); and the importance Vico accorded to imagination foreshadowed the place that feeling was to have in 19th-century Romantic thought.

De Nostri Temporis Studiorum Ratione (1709; "On the Study Methods of Our Time") defended the humanistic program of studies against what Vico took to be an encroachment by the rationalistic system of Descartes on the educational methods proper for youth. Vico asserted that the influential Cartesian treatise *The Port-Royal Logic,* by the Jansenists Antoine Arnauld and Pierre Nicole, inverted the natural course by which children learn by insisting on a training in logic at the beginning of the educational process. He argued, instead, that young people need to have their mental powers developed and nourished by promoting their memories through the study of languages and enhancing their imaginations through reading poets, historians, and orators. Young minds first need the kind of reasoning that common sense provides. Common sense, acquired through the experience of poets, orators, and people of prudence, teaches the young the importance of working with probabilities prior to an education in logic. To train youth first in logic in the absence of common sense is to teach them to make judgments before they have the knowledge necessary to do so. Vico's aim was to emphasize the importance of practical judgment in education, an echo of the ideals of Locke and a prefiguring of Rousseau and the 19th-century reformer Johann Heinrich

Pestalozzi. Outside of Italy, among those who were most influenced by *New Science* were Joseph de Maistre in the late 18th century and Victor Cousin and Jules Michelet in the 19th century.

The condition of the schools and universities. The school system became more and more in the 18th century an ordered concern of the state. Exponents of enlightened absolutism, as well as parliamentarians, recognized that the subject was of more use to the state if he had a school education. Ideally, there was to be compulsory schooling everywhere, but of course in practice the ideal was scarcely reached anywhere. The state also recognized that worthwhile school instruction depended on the standard of education of teachers: thus, the first teachers' colleges were established. But admittedly the standard of education of teachers was fairly poor. The teaching profession still did not provide a living wage, for which reason can be read from a regulation of 1736:

> If the teacher is a workman he can already support himself; if he is not, then he is hereby allowed to go to work for daily wages for 6 weeks at harvest-time (*Principia regulativa,* clause 10).

Ever since the 16th century the universities had suffered a decline, mainly as a result of religious wars. Progress in the exact sciences was accomplished under government support in the academies of science, not in the universities, which became more and more training institutions for higher civil servants. There was, however, a notable change for the better, at least in Germany.

Halle, the first modern university

The year 1694 saw the foundation of the University of Halle, which has been described as the first real modern university. It originated in a *Ritterschule,* or "knight's school," imitative of the schools for chevaliers in France, and in 1694 the Holy Roman emperor Leopold I granted it a charter. The primary object in founding a university in Halle was to create a centre for the Lutheran party; but its character, under the influence of its two most notable teachers, the philosophers Christian Thomasius and Francke, soon expanded beyond the limits of this conception. Thomasius was the first to set the example—soon after followed by all the universities of Germany—of lecturing in the vernacular instead of the customary Latin; this was a declaration of war against Scholasticism. Francke, as the founder of the Pietistic school, exercised great influence. Throughout the whole of the 18th century Halle was the leader of academic thought and advanced theology in Protestant Germany, although sharing that leadership, after the middle of the century, with the University of Göttingen (founded 1737). With Göttingen, another important contribution was made by the revival of classical studies and the creation of a faculty of philosophy distinct from that of theology. This was designed not only to advance scholarship but also to train teachers. Halle itself established the first chair of educational theory.

The background and influence of Pietism. The dispute over the correct religious dogma, fought for almost 200 years with the utmost strength, controversy, and academic subtlety and reaching its terrible culmination in the Thirty Years' War, led to a certain ill feeling against dogmatically sanctioned religious revelation. There was a widespread trend toward secularization. Everywhere, there was a clear tendency to free belief from dogmatic quarrels. The search for a new belief took generally two different paths. One

Rationalistic versus devotional experience

wanted to base belief in man's reason; the other wanted a godliness of the heart. For one line of thought, belief was a postulate of omnipotent human reason; for the other, man, corrupted by original sin, was to be saved only by simple belief in God's grace. The one path turned to the religious understanding of the Enlightenment; the other followed the subjective, mystical, zealous devoutness of Pietism. Such a movement away from the institutionalized church, away from the established church, and toward an intensified faith was evident in France within Roman Catholicism in the form of Jansenism and Quietism. In England it was clearly evident in certain forms of Puritanism and in Independent movements and Quakerism. In Germany it was evident in Pietism.

Pietism was a Protestant movement of renewed faith that became popular from about 1675 to 1740, though it remained residually influential even into the 19th century. Its spiritual centres were in Württemberg, among the Moravian Brethren, and above all in Halle. Pietism was principally opposed to dogmatic Protestant orthodoxy, which usually included impatience and polemics against other beliefs. Pietism, on the contrary, stood for the renewal of importance of the individual prayer and for humility. The experiences of belief were to be based less in the acceptance of fixed conditions of belief and more in a mystical, personal submersion in feelings. According to standard Protestant theory, salvation could be hoped for only by the suppression of the corrupted individuality and by waiting for the grace of God to show one the way. From this came the Pietists' inclination to turn away from the world with its temptations (*e.g.,* the theatre, dancing, games, and other enjoyments). The uneasiness that they felt toward church institutionalization led to their splitting into numerous separatist groups; their subjective certainty about their belief led to a certain arrogance; and finally their seclusion led often to a joyless and moralizing way of life.

Although the founder of German Pietism is considered to be Spener, who established several private devotional gatherings (*collegia pietatis*) for Bible study in Frankfurt am Main and elsewhere, he was important for education only in the sense that he fashioned a spirit or concept in which education could be conducted—a concept that would subordinate all education to a simple Christian faith. This concept was realized mainly by his follower Francke.

August Hermann Francke. Francke, after service as a grammar-school teacher and priest in Leipzig, Lübeck, Hamburg, and Erfurt, was, through Spener's recommendation, given a post at the University of Halle in 1691, at the same time assuming the post of parish priest nearby. Motivated by the sad conditions of neglect in his parish, he quickly devoted himself to practical pastoral duties. In 1695 he instituted a vernacular school for the poor, popularly called the "ragged school," whose purpose was

The schools of Halle

that the children should be led to a living knowledge of God and Christ and to a rightly accomplished Christianity. Through his activity and eloquence Francke won several charitable patrons for his school, and the institution quickly expanded. After the school for the poor came the establishment of an elementary school for children of fee-paying burghers, then an orphanage, and lastly a *Pädagogium,* or boarding school, for the sons of nobility. Because Francke felt a lack of suitable teachers for his schools, he subsequently established two teachers' seminaries, *seminarium praeceptorum* and *seminarium selectum* (for teachers in higher schools). In 1697 there followed a Latin grammar school and in 1698, even if short-lived, a *gynaeceum,* a school for the daughters of nobility. To the whole complex of Halle's institutions (known collectively as the Halle Foundation) there also belonged a bookshop with a publishing house and press, a very profitable chemistry laboratory, as well as four agricultural properties, a Bible institution, and an office for sending evangelical missions abroad. These institutions flourished, and about 1750 they were more and more brought under the control of the state.

Francke's main concern was ministerial work in the spirit of Pietism and not systematic educational theorizing. His educational aims were religious and at the same time practical. He himself paraphrased it as "true godliness and Christian wisdom"—true godliness meaning a pious, moral, devout life, and Christian wisdom referring to an

Strictness and realism in Pietistic schools

ability to work hard according to the Protestant ethic. Francke's style of education went along with this aim: the corrupted willfulness of man must be broken, not through severe punishment but through "loving reproaches," a close supervision of the pupils, and a schooled and regimented care of the spirit. Games and childlike exuberance have no place in the system; thus, education had a joyless and moralizing effect.

The harsh demands and regimentation are shown, for instance, in the daily timetable and the syllabus. The children arose at 5:00 AM; there was almost continuous instruction with frequent Bible reading and religious

lessons until 7:00 in the evening. The grammar school had lessons in reading, writing, basic mathematics, catechism, the Holy Scriptures, Latin, Greek, Hebrew, optionally another Oriental language, geography, history, mathematics (including astronomy and geometry), botany, zoology, mineralogy, anatomy, and theology, as well as lathework, glass polishing, field trips to observe trades, factory work, horticulture, and so on. These latter subjects were counted as "recreation." The pansophic idea of Comenius was being followed here, in the sense that there was to be an all-encompassing education. It is worth noting that Francke was actually trying to inject realism into education—promoting, as he did, scientific subjects, lessons in manual skills, planned field trips, and even the reading of newspapers in the classroom.

Johann Julius Hecker. Julius Hecker came to Halle shortly before Francke's death in 1727 and became a teacher in the *Pädagogium.* In 1739 he was summoned by Frederick I of Prussia to Berlin, where he established a six-year *Realschule,* or "realist school," designed to prepare youth for the Pietistic and Calvinistic ideal of hard work and, especially, for the new technical and industrial age that was already dawning in countries such as England and France. Godliness was to be combined with a realistic and practical way of life. As early as 1699 Francke had conceived the idea of a school for children who were not meant for scholarship but who could serve usefully in commercial pursuits or administration; and in 1739 one of his teachers, Christoph Semler, published a pamphlet proposing such a "mathematical and mechanical *Realschule.*" It was Hecker's fortune to put these plans into realization. His school included, among other things, classes for architecture, building, manufacturing, commerce, and trade. Both the exact sciences and manual skills were in the curriculum. A room for natural-history specimens, geographic maps, and realia was set aside for the illustration of lessons. Schools like Hecker's were gradually opened in other cities. In the 19th century courses were extended to nine years, and such an institution was renamed *Oberrealschule,* or "higher realist school"; henceforth it was one of the main types of German secondary education. Hecker also compiled the general school regulations (1763) that formed the main outlines of the Prussian school system.

Realschule, or "realist school"

The background and influence of naturalism. Pietists emphasized Christian devotion and diligence as paths to the good life; Enlightenment thinkers focused on reason and clear thinking as the sensible way to happiness. Rousseau and his followers were intrigued by a third and more elusive ideal: naturalism. Rousseau, in his *A Discourse on Inequality,* an account of the historical development of the human race, distinguished between "natural man" (man as formed by nature) and "social man" (man as shaped by society). He argued that good education should develop the nature of man. Yet Rousseau found that mankind has not one nature but several: man originally lived in a "pure state of nature" but was altered by changes beyond control and took on a different nature; this nature, in turn, was changed as man became social. The creation of the arts and sciences caused man to become "less pure," more artificial, and egoistic, and man's egoistic nature prevents him from regaining the simplicity of original human nature. Rousseau is pessimistic, almost fatalistic, about changing the nature of modern man.

Émile, his major work on education, describes an attempt to educate a simple and pure natural child for life in a world from which social man is estranged. Émile is removed from man's society to a little society inhabited only by the child and his tutor. Social elements enter the little society through the tutor's knowledge when the tutor thinks Émile can learn something from them. Rousseau's aim throughout is to show how a natural education, unlike the artificial and formal education of society, enables Émile to become social, moral, and rational while remaining true to his original nature. Because Émile is educated to be a man, not a priest, a soldier, or an attorney, he will be able to do what is needed in any situation.

Rousseau's educational ideas in *Émile*

The first book of *Émile* describes the period from birth to learning to speak. The most important thing for the healthy and natural development of the child at this age is that he learn to use his physical powers, especially the sense organs. The teacher must pay special attention to distinguishing between the real needs of the child and his whims and fancies. The second book covers the time from the child's learning to speak to the age of 12. Games and other forms of amusement should be allowed at this age, and the child should by no means be overtaxed by scholarly instruction at too early an age. The child Émile is to learn through experience, not through words; he is to bow not to the commands of man but to necessities. The third book is devoted to the ages from 12 to 15. This is the time of learning, not from books of course but from the "book of the world." Émile must gain knowledge in concrete situations provided by his tutor. He learns a trade, among other things. He studies science, not by receiving instruction in its facts but by making the instruments necessary to solve scientific problems of a practical sort. Not until the age of 15, described in the fourth book, does Émile study the history of man and social experience and thus encounter the world of morals and conscience. During this stage Émile is on the threshold of social maturity and the "age of reason." Finally, he marries and, his education over, tells his tutor that the only chains he knows are those of necessity and that he will thus be free anywhere on earth.

The final book describes the education of Sophie, the girl who marries Émile. In Rousseau's view, the education of girls was to be similar with regard to naturalness, but it differed because of sexual differences. A girl cannot be educated to be a man. According to Rousseau, a woman should be the centre of the family, a housewife, and a mother. She should strive to please her husband, concern herself more than he with having a good reputation, and be satisfied with a simple religion of the emotions. Because her intellectual education is not of the essence, "her studies must all be on the practical side."

At the close of *Émile,* Rousseau cannot assure the reader that Émile and Sophie will be happy when they live apart from the tutor; the outcome of his experiment is in doubt, even in his own mind. Even so, probably no other writer in modern times has inspired as many generations as did Rousseau. His dramatic portrayal of the estrangement of natural man from society jolted and influenced such contemporary thinkers as Immanuel Kant and continues to intrigue philosophers and social scientists. His idea that teachers must see things as children do inspired Pestalozzi and has endured as a much-imitated ideal. Finally, his emphasis on understanding the child's nature had a profound influence by creating interest in the study of child development, inspiring the work of such psychologists as G. Stanley Hall and Jean Piaget.

The Sensationists. A group of French writers contemporary with Rousseau and paralleling in some ways the thought of both Rousseau and Locke are known as the Sensationists, or, sometimes, the Sensationist psychologists. One of them was Étienne Bonnot de Condillac, who, along with Voltaire, may be said to have introduced Locke's philosophy to France and established it there.

In the *Treatise on Sensations* (1754) Condillac imagined a statue organized inwardly like a man but animated by a soul that had never received an idea or a sense impression. He then unlocked its senses one by one. The statue's power of attention came into existence through its consciousness of sensory experience; next, it developed memory, the lingering of sensory experience; with memory, it was able to compare experiences, and so judgment arose. Each development made the statue more human and dramatized Condillac's idea that man is nothing but what he acquires, beginning with sensory experience. Condillac rejected the notion of innate ideas, arguing instead that all faculties are acquired. The educational significance of this idea is found in Condillac's *An Essay on the Origin of Human Knowledge* (1746), where he writes of a "method of analysis," by which the mind observes "in a successive order the qualities of an object, so as to give them in the mind the simultaneous order in which they exist." The idea that there is a natural order which the mind can learn to follow demonstrates Condillac's naturalism along with

Views of Condillac

his sensationism. Condillac does not begin his work *Logic* (1780) with axioms or principles; rather, he writes, "we shall begin by observing the lessons which nature gives us." He explains that the method of analysis is akin to the way that children learn when they acquire knowledge without the help of adults. Nature will tell man how to know, if he will but listen as children "naturally" do. Thus the way in which ideas and faculties originate is the way of logic, and to communicate a truth is to follow the order in which ideas come from the senses.

Claude-Adrien Helvétius, a countryman of Condillac's who professed much the same philosophy, was perhaps even more insistent that all human beings lack any intellectual endowment at birth and that despite differing physical constitutions each person has the potential for identical passions and ideas. What makes people different in later life are differing experiences. Hypothetically, two men brought up with the same chance experiences and education would be exactly the same. From this it followed, in education, that the teacher must attempt to control the environment of the child and guide his instruction step by step. Helvétius was, perhaps, unique in joining such a strong belief in intellectual equalitarianism with the possibility of a controlling environmentalism.

The Rousseauists. Rousseau left behind no disciples in the sense of a definite academic community, but hardly a single theorist of the late 18th century or afterward could avoid the influence of his ideas. One of those influenced was the German Johann Bernhard Basedow, who agreed with Rousseau's enthusiasm for nature, with his emphasis on manual and practical skills, and with his demand for practical experience rather than empty verbalism. The teacher, in Basedow's view, should take pains over the clearness of the lesson and make use of the enjoyment of games: "It is possible to arrange nearly all playing of children in an instructive way." In another respect, however, the contrast between Rousseau and Basedow could not be sharper; Basedow tended to force premature learning and overload a child's capabilities. A foreign language, for instance, was to be learned in six months. He promoted, in general, a pedagogic hothouse atmosphere. Basedow was perhaps influenced by his seven-year-old daughter, who was put forward as a wonder child with extraordinary knowledge. He established an experimental school called a *Philanthropinum,* in Dessau, which lasted from 1774 to 1793.

Kant on pedagogy

Kant referred to Rousseau's influence on him. He dealt specifically with pedagogy only within a lecture he gave as holder of the chair of philosophy in Königsberg; the main features of the lecture were collected in a short work, *Über Pädagogik* (1803; "On Pedagogy"). In it he asserted, "A man can only become a man through education. He is nothing more than what education makes him." Education should discipline man and make him cultured and moral; its aim is ultimately the creation of a happier mankind. In general, Kant agreed with Rousseau's education according to nature; but, from his ethical posture, he insisted that restraints be put on the child's passionate impulses and that the child even be taught specific maxims of conduct. The child must learn to rule himself and come to terms with the twin necessities of liberty and constraint, the product of which is true freedom.

> Children should be educated, not with reference to the present conditions of things, but rather with regard to a possibly improved state of the human race—that is, according to the ideal of humanity and its entire destiny. (From *Über Pädagogik.*)

The influence of nationalism. The Enlightenment was cosmopolitan in its effort to spread the light of reason, but from the very beginning of the age there were nationalistic tendencies to be seen in varying shades. Although Rousseau himself was generally concerned with universal man in such works as *The Social Contract* and *Émile,* his *The Government of Poland* (1782) did lay out a proposal for an education with a national basis, and generally his ideas influenced the nationalistic generation of the French Revolution of 1789.

National views of the Philosophes

France. The real starting point generally of national pedagogic movements was in France. It perhaps began with the Philosophes, the rationalists and liberals such as Voltaire and Diderot, who emphasized the development of the individual through state education, not as a means, of course, of adjusting to the state and its current government but as a means of creating critical, detached, responsible citizens. The Marquis de Condorcet was closely connected with this line of thought. For him man was by nature good and capable of never-ending perfection, and the goal of education should be the "general, gradually increasing perfection of man." He drafted a democratic and liberal but at the same time somewhat socialist concept of school policy: there should be a uniform structure of public education and equal chances for all; ability and attainment should be the only standards for selection and careers; and private interests should be prevented from having influence in the educational system. An educational concept so rationalistic in its aims and with such a democratic and liberal structure cannot be narrowly nationalistic; it is cosmopolitan. But Condorcet was nationalistic insofar as he wanted "to show the world at last a nation in which freedom and equality for all was an actuality." He was, in fact, a strong supporter of the Revolution.

Many of the Rousseauists were nationalistic in a somewhat different way. They believed in a kind of "moral patriotism." They distrusted state-controlled nationalism and favoured instead a virtuous, patriotic citizen who experienced spontaneous feelings for his nation. Proper development in the family setting and in school would lead to the mastery of everyday situations and would naturally lay the foundations for this true nationalism.

Some of the French revolutionists, particularly Jacobins such as Robespierre and Saint-Just who were associated with the period of the Terror (1793–94), were concerned with an education for the revolutionary state, an education marked by an enmity toward the idea of scholarship for its own sake and by state control, collectivism, the stressing of absolute equality, and the complete integration of all. What is good is decided by the collective "people." Thus, it could be said that the Jacobins favoured a complete politicalization of educational practice and theory.

Benevolent despotism and education

National education under enlightened rulers. The absolutism of the 18th century has often been called "benevolent despotism," referring to the rule of such monarchs as Frederick II the Great of Prussia, Peter I the Great and Catherine II the Great of Russia, Maria Theresa and Joseph II of Austria, and lesser figures who were presumably sufficiently touched by the ideas of the Enlightenment to pursue social reforms. Their reforms were limited, however, and usually did not include anything likely to upset their sovereignty. Thus, they were often willing to improve education for middle-class persons useful in civil service and other areas of state administration, but they were often chary of educating the poor. That risked upsetting the social order.

Frederick the Great, however, issued general school regulations (1763) establishing compulsory schooling for boys and girls from five to 13 or 14 years of age. His minister Freiherr von Zedlitz founded a chair of pedagogy at Halle (1779) and generally planned for the improved education of teachers; he supported the founding of new schools and the centralization of school administration under an *Oberschulkollegium,* or national board of education (1787); and one of his colleagues, Friedrich Gedike, was instrumental in introducing the school-leaving examination for university entrance, the *Abitur,* which still exists.

The guarded though increasingly liberal attempt by benevolent despots to nationalize and expand education is well illustrated by the events in Russia. Until the 18th century, schools in Russia were founded by ecclesiastical organizations (monasteries), the clergy (priests, deacons, readers), and private persons (boyars, or lower-level aristocrats). Boys were taught reading, writing, arithmetic, singing, and religion. A system of state-owned schools was started by Peter the Great as a state organization for purposes of administration and for the development of mining and industry. Peter did not intend to promote the Orthodox faith or formal classical learning, whether Greek, Latin, or Slavonic, or universal education. He created mathematical, navigation, artillery, and engineering schools for utilitarian purposes. In 1725 an Academy of

Sciences with a university and a *gimnaziya* (secondary school) was founded at St. Petersburg. The utilitarian, secular, and scientific characteristics of Peter's schools became the dominant features of Russian education, but, as a result of the many changes of policy after Peter's death in 1725, a national system of education did not develop.

A second attempt at nationalizing education in Russia was made by Catherine II. After many abortive schemes, Catherine issued in 1786 a statute for schools, which can be considered the first Russian education act for the whole country. According to this act, a two-year course in minor schools was to be started in every district town and a five-year course in major schools in every provincial town. Catherinian schools were also to be utilitarian, scientific, and secular. At the end of the 18th century, 254 towns had the new schools, but 250 smaller towns and the rural districts had no schools whatever.

A third nationalizing attempt was made by Alexander I and was influenced by the disintegration of the serf system, by the development of industry and commerce, and by the ideas of the French Revolution. The new statutes (1803 and 1804) maintained the principles of utility and secular scientific instruction. The parochial schools (*prikhodskiye uchilishcha*) in the rural areas were to instruct the peasantry in reading, writing, arithmetic, and elements of agriculture; the district schools of urban areas (*uyezdnye uchilishcha*) and the provincial schools (*gimnazii*) were to give instruction in subjects necessary for civil servants—law, political economy, technology, and commerce. The system was state-controlled and free and formed a continuous ladder to the universities. Later conservative reactions, however, tended to blunt or reverse these reforms.

England. In England the development of a "national" education took a completely different course. It was influenced not by a political but by an industrial revolution. It is true that theorists such as Adam Smith, Thomas Paine, and Thomas Robert Malthus proposed state organization of elementary-schooling, but even they wanted to see limited state influence; the state could pay the musicians but not call the tune. Not until 1802 did Parliament intervene in the development of education, when the Health and Morals of Apprentices Act required employers to educate apprentices in basic mathematics, writing, and reading. For the most part this remained only a demand, since the employers were not interested in such education.

The reluctance on the part of the state induced several philanthropists to form educational societies, principally for the education of the poor. In 1796, for example, the Society for Bettering the Conditions of the Poor was founded. A further impulse for elementary education stemmed from the Sunday schools, the first of which was founded in 1780 in Gloucester; by 1785 their numbers had so increased that the Sunday School Society was founded. The lessons in such schools, however, were mainly those of Bible reading.

The monitorial, or Lancasterian, system

The educators Andrew Bell and Joseph Lancaster played a major role in progress toward an elementary-school system. They realized that the root of the problem lay in the lack of teachers and in the lack of money to hire assistants. Therefore, first Bell developed, then Lancaster modified, the so-called monitorial system (also called the Lancasterian system), whereby a teacher used his pupils to teach one another. The use of children to teach other children was not new, but Bell and especially Lancaster took the approach and developed it into a systematic plan of education. From 200 to 1,000 children were gathered in one room and seated in rows, usually of 10 pupils each. An adult teacher taught the monitors, and then each monitor taught his row of pupils the lesson in reading, writing, arithmetic, spelling, or higher subjects. Besides monitors who taught, there were, in Lancaster's system, monitors to take attendance, give examinations, issue supplies, and so on; school activity was to be directed with military precision; the emphasis was on drill and memorization. The system and the publicity connected with it expanded the efforts toward mass education, even though, pedagogically, the whole process was so routinized and formalized that opportunities for creative thinking or initiative scarcely existed. (H.-J.I./J.J.Ch.)

EUROPEAN OFFSHOOTS IN THE NEW WORLD

Spanish and Portuguese America. With the Spanish conquerors of the New World, the conquistadores, came friars and priests who immediately settled down to educate the Indians and convert them. Because there was little separation of church and state, the Roman Catholic church assumed complete control of elementary education, and the early Franciscan and Dominican friars were followed by Augustinians, Jesuits, and Mercedarians.

Church control of colonial education

The first elementary school in the New World was organized in Mexico by the Franciscan Pedro de Gante in 1523 in Texcoco, followed in 1525 by a similar school in San Francisco. Because such schools in Mexico were designed for Indian children, the monks learned the native languages and taught reading, writing, simple arithmetic, singing, and the catechism. The schools of the *hospicio* of the bishop Vasco de Quiroga in Michoacán added agriculture, trades, and crafts to their curriculum.

Mestizo children, the issue of Spanish and Indian parents, were often abandoned; thus, special institutions appeared to collect and educate them—for example, the Girls' School and the School of San Juan de Letrán, founded by Viceroy Mendoza in New Spain, and the Bethlehemite schools of Guatemala and Mexico.

In the beginning, children of Spaniards born in the colonies, called Creoles, had tutors. Eventually, schools promoted by cabildos (municipal authorities) emerged.

During the 18th century the Enlightenment came to Latin America, and with it a more secular and widespread education. Among famous projects were those of Viceroy Vertiz y Salcedo in Argentina and two model schools, free for children of the poor, by Archbishop Francos y Monroy in Guatemala. In New Spain the College of the Vizcainas (1767) became the first all-girl lay institution.

Because of the social structure, riches and administrative privilege were held by an elite, the Creoles, and secondary education was specially organized to serve them. Originally, secondary schools existed only in the monasteries, but when the Jesuits arrived in the late 1560s they founded important *colegios* (secondary institutions) to prepare students who wanted to enter the universities. There also existed a few special *colegios* for the Indian nobility, such as the outstanding Santa Cruz de Tlaltelolco (1536) in Mexico and San Andres in Quito, both founded by the Franciscans for liberal arts studies. The Jesuits also established schools for the Indians, including El Príncipe (1619) in Lima and San Borja in Cuzco. All these schools were eventually closed because of the jealousy of the Spanish bureaucracy.

Though the Dominicans and Franciscans had been pioneers in education, the Jesuits became the most important teachers. They offered an efficient education, molded to contemporary requirements, in boarding schools, where the elite of the Spaniards born in the Americas studied. When their order was expelled in 1767, education was dealt a severe blow. In Portuguese Brazil, where the expulsion edict had been issued eight years earlier and where they had been the only educators, the royal chancellor was forced to make feeble attempts toward organizing a secular education. The Spanish king Charles III also took advantage of the occasion and founded some new institutions—the Academy of San Carlos, the School of Mining in Mexico, the Royal College of San Carlos in Buenos Aires—and modernized others.

The Latin-American universities

Traditionally, Spanish universities had been organized on the model either of Paris or of Bologna. The former was a *universitas magistrorum,* governed by professors organized in faculties, whereas the latter, as a *universitas scholarium,* received its corporate authority from the student body organized into "nations" that elected leaders to whom even the professors were subject. In 1551 the Council of the Indies authorized the founding of the first American universities, one in Mexico and one in Lima; academic government was placed in the hands of a *claustro,* or faculty, composed of the rector, the teachers, and the professors. Dedicated to general studies, the universities required a papal as well as a royal authorization.

The Royal Pontifical University of Mexico was the first to open its doors, in 1553. In the Spanish colonies even-

tually 10 major and 15 minor universities came into existence. The latter were actually colleges—nine Jesuit, four Dominican, one Franciscan, and one Augustinian—which, because they were located far from the closest university (minimally 200 miles), were given special authorization to grant higher degrees. In Brazil no university existed, and Portuguese born in the colony had to go to Portugal for study.

Though in Spain itself law reigned supreme, in the Americas theology became the principal chair. Teaching was in scholastic mode: it began with the reading of a classical text; then the professor explained the thesis or proposition and offered arguments pro and contra so that a conclusion in accord with Roman Catholic dogma would result.

(J.Z.V.)

French Québec. Soon after the founding of the Québec colony in 1608, the first organized educational activity began with missionary work among the Indians, carried on mainly by members of the Récollet and Jesuit orders and, from 1639, by Ursuline nuns. The first mission "school" recorded was that of Pacifique du Plessis, established in 1616 in Trois-Rivières (Three Rivers).

Christian efforts among the Indians were only a dimension of the religious purposes that framed educational activity in Old World France. Roman Catholic social philosophy allowed no compromise in the spiritual direction of education, and both in informal socialization patterns and in what formal provisions existed the doctrine and aim of religion coincided with that of education. At the general level, education was intended to produce religious conformation in thought and behaviour; at the higher level, education was to produce a progeny of clerical leadership. The paternalistic authority of church and monarch was carried from the Old to the New World, where it perhaps became even more pervasive, due to the initial absence of alternative institutional developments. In education, the exclusive role of the state (though not insignificant) was confined to financial subsidization. Authority for the institution of education was vested in the bishop of Québec.

Most of the nonreligious functions now associated with formal education were, in the 17th and 18th centuries, carried in other institutional sectors: the family, the community, the vocation. Just as there was no sharp break between church and school in formal learning, there was an easy transition between the information and behaviour necessary for work and life as transmitted in the course of various socialization experiences. Thus, the self-sustaining and isolated life of the farmers, the wild and solitary ways of the coureurs de bois (fur traders), the miniature of European manners and customs established in the cities by the gentry—all contained within their own cycle the educative procedures for life in that society. Education as a separate institution was understandably associated with learning not related to the business of life.

The schools of New France

Institutional forms found in French colonial Québec included parish schools, girls' schools, secondary schools, and vocational schools; and literacy records indicate that the provision for education was in sum comparable to that in the Old World. Parish or common schools were irregularly provided to afford the rudiments of literacy and religion. Because of the relative sparseness of educational resources, social classes were frequently mixed in these schools. Girls' schools were established in Québec City by the Ursulines from 1642 and by the Sisters of the Congrégation de Notre Dame from 1659, with a rudimentary curriculum but including a characteristic "finishing" of social graces appropriate to the French-Canadian girl. Vocational training was probably of least concern in this early period, but specific attempts to institutionalize this educational area were begun as early as 1668 with the establishment of the School for Arts and Trades in Saint Joachim, for instruction in agriculture and certain trades.

Secondary education was offered by the Jesuits from 1636. The Jesuit college, offering early training for eventual entrance into the priesthood, was conducted along characteristically Jesuit lines: militaristic discipline in conduct, unequivocal authority in method, classical curriculum in content. The classical curriculum pattern, comprising basically Latin, Greek, mathematics, philosophy, and theology, was to be essentially preserved in the French-Canadian development of *collèges classiques* for secondary education.

In 1663 Bishop Laval established in the city of Québec the *grand séminaire* as the apex of the educational "system," as the first French-Canadian "university." Shortly thereafter, he also established the preparatory *petit séminaire.*

Following the cession of Québec to Britain in 1763, education fell prey to political and cultural disruption. Although the British military and colonial government attempted to preserve the structure of French civil and religious institutions, the cultural integrity of the system was inevitably broken. Financial grants from France for education discontinued and were not replaced by the British government; recruitment to religious orders was restricted; and educational development was obstructed by the continual association of educational plans with cultural-religious controversies. The end of the 18th century saw French-Canadian education fall backward into neglect.

(R.F.L.)

British America. *New England.* The year 1630, chronicled in New England annals as the beginning of the Great Migration, witnessed the founding there of Puritanism as the established religion. Rejecting democracy and toleration as unscriptural, the Puritans put their trust in a theocracy of the elect that brooked no divergence from Puritan orthodoxy. So close was the relation between state and church that an offense against the one was an offense against the other and, in either case, "treason to the Lord Jesus." The early Puritans also put their confidence in centralized church governance; however, geographic reality forced them to settle for a localized, congregational administration, for impossible roads made land travel over any distance onerous and even dangerous, and thus the focal point of social and political life had to be the village. Small and constricted, a place where the vital necessities, sacred and profane, were within walking range of all and where one's conduct was exposed to constant public watch, the New England village was the prime mover of communal life.

Puritan education in New England

In Puritan moral theology the young, like the old, were sinners doomed by almost insurmountable odds to perdition. To God, indeed, even infants were depraved, unregenerate, and damned. Hence, the sooner the young learned the ground rules of the good society, as revealed in the Bible, the better. The task of teaching them first befell the parents. Later, when they were old enough, the burden was conferred upon the school. The first secondary school was probably the Boston Latin School. Founded in 1635, it was modeled on the grammar schools of England, which is to say that it put an overwhelming emphasis on the ancient languages and "humane learning and good literature." By the 1640s the idea of town-supported schooling had lost its novelty.

If towns braved the first steps in education, then the Commonwealth of Massachusetts did not trail far behind. In 1642 it ordered parents and masters of apprentices to see to it that their charges were instructed in reading, religion, and the colony's principal laws. Five years later, the General Court reinforced this enactment with yet another. Aimed at the "old deluder Satan," it undertook to thwart him from keeping "men from a knowledge of the Scriptures," by requiring every township of 50 households to commission someone to teach reading and writing. The law also directed towns of 100 families to furnish instruction in Latin grammar so that youth might be "fitted for the university." Finally, the measure required teachers to be paid by "parents or masters . . . or by the inhabitants in general." The measure was given only a pallid obedience, but its assumption that the state may compel the schooling of its young and that in order to support education it may impose taxes is pertinent to subsequent times.

The founding of Harvard College

The first colonists had scarcely settled when in 1636 the General Court appropriated £400 "towards a school or college." When two years later John Harvard died and left the institution his library and some £800, the grateful founders honoured their school with his name. Designed to train youth for important Puritan places, particularly in the ministry, the college accepted only those who could

read, write, and speak Latin in prose and verse, besides knowing Greek nouns and verbs familiarly. Once admitted, the student was lodged at the college, pledged to a blameless behaviour, and put upon a prescribed four-year course of grammar, rhetoric, logic, arithmetic, geometry, astronomy, ethics, ancient history, Greek, and Hebrew. If he weathered these hazards, he was made a bachelor of arts (B.A.), and, if ambition still roweled him, he could enroll for another three years to become a master of arts (M.A.).

So things sat until the century's passing. Then, swayed by the intellectual breezes of Europe's Enlightenment, Harvard College ventured some earnest renovation. Its texts, cobwebbed with Aristotelianism, were replaced with newer ones by Locke and Sir Isaac Newton. In 1718 it added mathematics and sciences to its offerings, and 20 years later it enriched itself with a professorship of mathematics and natural philosophy. There were the usual grumblings from conservatives, and in 1701 a number of Congregational parsons, all Harvard sons, distressed by their alma mater's dalliance in newfangled ideas, inaugurated the collegiate school of Connecticut, now Yale University.

The new academies. Disdainful of the challenging intellectual values, the secondary schools continued in their classical tracks. By the 18th century, however, their tradition was playing out, especially among the rising nabobs of the marketplace. When the old schools failed to respond to their demands for an education calculated to prepare their sons for everyday living, they resorted to private schooling. From such endeavour emerged the academy. The first school of strictly native provenance, it made its advent in 1751 in Philadelphia (the Philadelphia Academy), the work in the main of Benjamin Franklin. What differentiated it from its classical antecedent was its promotion of "useful learning," to wit, the vernacular, modern languages, history, geography, chronology, navigation, mathematics, natural and applied science, and the like.

The first academies addressed themselves solely to boys, but time saw them vouchsafe instruction to girls in a "female department," which in turn gave way to the "female academy," whose curriculum reflected debates of the time about female education. Fine arts, domestic subjects, and training for occupations open to women were included, though some female educators stressed intellectual attainment rather than practical learning.

Private ventures always, academies generally were not loath to solicit outside assistance—some, indeed, as in New York, enjoyed a public subsidy. Whatever their special character, to their very end they maintained their original purpose of bringing education into closer consonance with "the great and the real business of living," as Phillips Academy of Andover, Massachusetts, phrased it when, in 1778, it held its first sessions.

Diversity of the middle colonies

The middle colonies. The religious uniformity that marked the Puritan theocracy was missing in the middle colonies. From New York through Delaware there flourished a host of sects whose scriptural interpretations were diverse—often, in fact, in collision. Nor was there even the tie of a common language, for the settlers came from many lands. Divergent in religion and language, the bedrock in those times of elementary schooling, the middle colonists could not accommodate themselves, as did the Puritans, to a single school teaching reading and religion to all the children of the neighbourhood. Instead, they depended on parish or parochial schools, each of them free to teach by its own denominational lights. True, for a time New Netherland, with its established Dutch Reformed church, maintained some town schools, but, after the English seized the colony (renaming it New York), such endeavours ceased. Pennsylvania, linguistically and denominationally the most heterogeneous of the colonies, began its educational history by ordering the erection of public schools and the instruction of children. But the ordinance fell prey to powerful sectarian antagonisms, and in 1701 the colony essayed to make peace by sanctioning the establishment of parochial schools.

Like the New Englanders, the middle colonists aspired to establish colleges, but, with no friendly lawmakers to sustain them, they found their task heavily hobbled, and the mid-1700s were upon them before their hopes materialized with the advent, in 1746, of the College of New Jersey (Princeton). There followed King's College (Columbia) in 1754; the College and Academy of Philadelphia (Pennsylvania) in 1755; and Queen's College (Rutgers) in 1766. Common to these schools was their stress on the ancient languages, metaphysics, and divine science. At the same time, however, one discerns signs of a new liberalism. Both Rutgers and Columbia announced their interdenominationalism. Pennsylvania offered courses in physics, and in 1765 it became the first colonial college to sponsor systematic instruction in medicine.

Effects of plantation life on Southern education

The Southern colonies. Unlike New Englanders, Southerners resided not in villages but on widely scattered plantations. For years, town life was impossible and so, per consequence, were town schools. But even had their establishment been feasible, the odds against them were staggering, since the ruling classes, like their analogues overseas in England, were averse to schooling the young under governmental direction. Instead, they regarded education as a personal concern, the affair of parent and church rather than of the state. Left thus to their own devices, Southerners schooled their young to suit their taste, the rich resorting to tutors and private schools and the rest scratching out an education as best they could. Time saw the appearance of a number of free schools serving those who were neither rich nor poor. For the offspring of the low-down and unregarded folk, Virginia enacted its law of 1642. An echo of England's Poor Law, it provided for the "relief of such parents whose poverty extends not to give them [the children] breeding." For this purpose it ordered the creation of a "workhouse school" at James City to which each county was to commit two children of an age of six or over. There, besides being reared as Anglicans, they were to be "instructed in honest and profitable trades and manufactures as also to avoid sloth and idleness." Amended several times, the statute became the model for similar legislation throughout the South.

The first Southern college was founded in Virginia in 1693. William and Mary College was chartered to propagate the "Liberal Arts and the Christian Faith," with particular stress on preparing young men for the Anglican pulpit. As the 18th century swept on, the secular interest that had invaded Harvard appeared in Virginia, and there ensued a waning of the earlier religious motivation. In 1779, led by Thomas Jefferson, the college trustees refurbished the school with chairs in medicine, mathematics, physics, moral philosophy, economics, law, and politics. The chair in divinity was discontinued as "incompatible with freedom in a republic." (A.E.M./R.F.L.)

Newfoundland and the Maritime Provinces. Newfoundland was, during most of this period, under British control, and, though there were settlers even before the 17th century, the island was not considered a settlement colony. Other than for naval training and fishing advantages, the British government had no concern for Newfoundland. Thus, policies were constructed with regard to the rights and advantages of British seamen, while, implicitly as well as in overt regulations, settlement was obstructed and restricted. Destruction from the running French-British military conflicts further discouraged development. These conditions of economic and political diminution of the settlement from outside were aggravated by the usurious conduct of merchants and the corruption of officials and by the national and religious divisions among the inhabitants themselves.

With such substantial problems of mere survival in Newfoundland, it is not surprising that the luxury of formal education was almost absent during this period. Some accounts verify that informal, unorganized efforts were made on an occasional basis to convey minimum schooling to settlers' children, but the only organized effort was that of the Society for the Propagation of the Gospel in Foreign Parts (SPGFP). The SPGFP founded or aided a school in Bonavista in 1722 and in St. John's in 1744 and sponsored schools in more than 20 settlements between 1766 and 1824. Religion was undoubtedly more important than education as such to the society, but its provision of reading materials as well as the mere act of establishing some kind of school filled a notable void in the Newfoundland

Society for the Propagation of the Gospel in Foreign Parts

settlement. Other charitable societies, such as the Society for Improving the Condition of the Poor in St. John's, the Benevolent Irish Society, the Newfoundland School Society (later the Colonial and Continental Church Society), the Wesleyan Society, the Sisters of the Presentation, the Sisters of Mercy, and the Irish Christian Brothers, carried the charity-school work into the 19th century and maintained a thread of education through the colonial "dark ages."

For a time after 1763 the Maritimes were all one colony—Nova Scotia—but Prince Edward Island was separated in 1769 and New Brunswick in 1784. This area comprised a heterogeneous population of French Acadians, English Protestants and others from Europe, Highland Scots, and loyalists from the United States. Each of these groups carried attitudes more or less favourable to education, and the regionalization of these attitudes, together with other conditions, influenced the differential development of education in the area. At the end of the 18th century, for example, New Brunswick, with a high loyalist population promoting political and educational development, probably ranked highest among the Maritime colonies in educational interest.

The first relatively organized attempt at common schooling in the Maritimes was made by the SPGFP, closely connected to the Church of England. The society opened both weekday and Sunday schools, and it might be said that it fostered teacher training in stipulating qualifications for its teachers. Other than SPGFP schools, education in the Maritime colonies was carried on by itinerant teachers and in scattered private-venture schools. Schools for separate ethnic or religious groups were discouraged by the Anglicans, but consistent pressure for such schools did succeed, at least temporarily; for example, in Lunenburg, Nova Scotia, and in Sydney, on Cape Breton Island. A school for blacks was established in Halifax in 1788.

Upper schools were established only toward the end of the 18th century in the Maritimes. As they were established singularly and recruited from a social class rather than from a lower school, there is no clear line of demarcation among the various types as there would be later in an integrated system. Basically, they were Anglican and classical, although the private schools, advertising to as wide a clientele as possible, often included some breadth, extending into practical studies. Probably the most influential of the early attempts were the two Latin grammar schools founded in 1788 and 1789 at Windsor and Halifax, Nova Scotia. The former became associated with King's College, established in Windsor at the same time. Thomas McCulloch's Academy at Pictou, Nova Scotia, and the College of New Brunswick at Fredericton, both founded around the turn of the century, were also early exemplars of higher education. (R.F.L.)

Western education in the 19th century

THE SOCIAL AND HISTORICAL SETTING

From the mid-17th century to the closing years of the 18th century, new social, economic, and intellectual forces steadily quickened—forces that in the late 18th and the 19th centuries would weaken and, in many cases, end the old aristocratic absolutism. The European expansion to new worlds overseas had stimulated commercial rivalry. The new trade had increased national wealth and encouraged a sharp rise in the numbers and influence of the middle classes. These social and economic transformations, joined with technological changes involving the steam engine and the factory system, together produced industrialism, urbanization, and the beginnings of mass labour. At the same time, intellectuals and philosophers were assaulting economic abuses, old unjust privileges, misgovernment, and intolerance. Their ideas, which carried a new emphasis on the worth of the individual—the citizen rather than the subject—helped not only to inspire political revolutions, sometimes successful, sometimes unsuccessful, but, more important, to make it impossible for any government, even the most reactionary, to disregard for long the welfare of the common man. Finally, there was a widespread psychological change: man's confidence in his power to use resources, master nature, and structure his own future was heightened beyond anything known before; and this confidence on a national scale—in the form of nationalism—moved all groups to struggle for the freedom to direct their own affairs.

Education as the responsibility of the state

All these trends influenced the progress of education. One of the most significant results was the gradual acceptance of the view that education ought to be the responsibility of the state. Some countries, such as France and Germany, were inspired by a mixture of national aspiration and ideology to begin the establishment of public educational systems early in the 19th century. Others, such as Great Britain and the United States, under the spell of laissez-faire, hesitated longer before allowing the government to intervene in educational affairs. The school reformers in these countries had to combat the prevailing notion that "free schools" were to be provided only for pauper children, if at all; and they had to convince society that general taxation upon the whole community was the only adequate way to provide education for all the children of all the people.

The new social and economic changes also called upon the schools, public and private, to broaden their aims and curricula. Schools were expected not only to promote literacy, mental discipline, and good moral character but also to help prepare children for citizenship, for jobs, and for individual development and success. Although teaching methods remained oriented toward textbook memorizing and strict discipline, a more sympathetic attitude toward children began to appear. As the numbers of pupils grew rapidly, individual methods of "hearing recitations" by children began to give way to group methods. The monitorial, or Lancasterian, system became popular because, in the effort to overcome the shortage of teachers during the quick expansion of education, it enabled one teacher to use older children to act as monitors in teaching specific lessons to younger children in groups. Similarly, the practice of dividing children into grades or classes according to their ages—a practice that began in 18th-century Germany—was to spread everywhere as schools grew larger.

THE EARLY REFORM MOVEMENT: THE NEW EDUCATIONAL PHILOSOPHERS

Influence of Rousseau

The late 18th and 19th centuries represent a period of great activity in reformulating educational principles, and there was a ferment of new ideas, some of which in time wrought a transformation in school and classroom. The influence of Rousseau was profound and inestimable. One of his most famous followers was Pestalozzi, who believed that children's nature, rather than the structure of the arts and sciences, should be the starting point of education. Rousseauist ideas are seen also in the work of Friedrich Froebel, who emphasized self-activity as the central feature of childhood education, and in that of Johann Friedrich Herbart, perhaps the most influential 19th-century thinker in the development of pedagogy as a science.

Pestalozzi. The theories of the Swiss reformer Johann Heinrich Pestalozzi laid much of the foundation of modern elementary education. Beginning as a champion of the underprivileged, he established near Zürich in 1774 an orphanage in which he attempted to teach neglected children the rudiments of agriculture and simple trades in order that they might lead productive, self-reliant lives. A few years later the enterprise failed, and Pestalozzi turned to writing, producing his chief work on method, *How Gertrude Teaches Her Children,* in 1801, and then began teaching again. Finally in 1805 he founded at Yverdon his famous boarding school, which flourished for 20 years, was attended by students from every country in Europe, and was visited by many important figures of the time, including the philosopher Johann Gottlieb Fichte, the educators Froebel and Herbart, and the geographer Carl Ritter.

The pedagogy of Pestalozzi. In spite of the quantity of his writings, it cannot be said that Pestalozzi ever wrote a complete and systematic account of his principles and methods; an outline of his theories must be deduced from his various writings and his work. The foundation of his doctrine was that education should be organic, meaning that intellectual, moral, and physical education (or, in his

Child-centred education

words, development of "head, heart, and body") should be integrated and that education should draw upon the faculties or "self-power" inherent in the human being. Education should be literally a drawing-out of this self-power, a development of abilities through activity—in the physical field by encouraging manual work and exercises, in the moral field by stimulating the habit of moral actions, and in the intellectual field by eliciting the correct use of the senses in observing concrete things accurately and making judgments upon them. Words, ideas, practices, and morals have meaning only when related to concrete things.

From these overarching principles there followed certain practical rules of educational method. First, experience must precede symbolism. There must be an emphasis on object lessons that acquaint the child with the realities of life; from these lessons abstract thought is developed. What one does is a means to what one knows. This means that the program should be child-centred, not subject-centred. The teacher is to offer help by participating with the child in his activities and should strive to know the nature of the child in order to determine the details of his education. This means that the stages of education must be related to the stages of child development. Finally, intellectual, moral, and physical activities should be as one.

Much of Pestalozzi's pedagogy was influenced by his work with children of the poor. Thus, there was a strong emphasis on education in the home. The development of skills was emphasized, not for their own sake, but in connection with intellectual and moral growth. Manual training was important for the head and heart, as well as for the hand. Whereas the reformers of the Enlightenment and the French Revolution stressed the "emancipation" of the lower classes, Pestalozzi aimed at helping poor people to help themselves. This was social reform, not social revolution.

The influence of Pestalozzi. "The art of education," Pestalozzi claimed, "must be significantly raised in all its facets to become a science that is to be built on and proceeds from the deepest knowledge of human nature." By his own efforts in this direction, he stimulated pedagogical theory and practice to an enormous degree in many parts of the Western world. By his philanthropic efforts on behalf of the poor, he inspired new movements toward the reform of philanthropic educational institutions and the pedagogy applied to such institutions; he created a new methodology for elementary education that was introduced not only into schools but also into programs of teacher education in Europe and America; and by his own example he gave teachers a high professional ethos. Pestalozzi, like few others at any time, recognized and sincerely tried to alter the misery existing in the world. If the Enlightenment saw its pedagogical mission as the spreading of the light of reason, then Pestalozzi showed that it was not reason alone but love above all that would show a way out of the "mire of the world."

Pestalozzi's influence abroad

It is hardly possible to name all of Pestalozzi's disciples—the Pestalozzians—for almost all the pedagogical figures of his time literally or figuratively went to his school. His influence was most profound in Germany, especially in Prussia and Saxony. Generally speaking, in the first half of the 19th century the English school system was completely under the influence of the disciplinarian monitorial systems of Bell and Lancaster. Pestalozzi for most Englishmen was "a distressing type of the German" and "an idealistic dreamer," as some critics put it. Nevertheless, he exercised some influence in England through James Pierrepont Greaves and the London Infant School Society and through Charles and Elizabeth Mayo and the Home and Colonial School Society. In the United States Pestalozzianism was introduced by a Philadelphia scientist and philanthropist, William Maclure, one of the sponsors of the utopian colony at New Harmony, Ind., and by Joseph Neef, who opened a school near Philadelphia.

In Switzerland itself, in Hofwil near Bern, Philipp Emanuel von Fellenberg founded an institution for the education of the poor. He tried to build up a kind of pedagogical province or miniature state, in which work was the means of self-help and in which the pedagogical program was the joint responsibility of teachers and pupils.

Froebel and the kindergarten movement. Next to Pestalozzi, perhaps the most gifted of early 19th-century educators was Froebel, the founder of the kindergarten movement and a theorist on the importance of constructive play and self-activity in early childhood. He was an intensely religious man who tended toward pantheism and has been called a nature mystic. Throughout his life he achieved very little literary fame, partly because of the style of his prose and philosophy, which is so academic and obscure that it is difficult to read and sometimes scarcely comprehensible.

In early life, Froebel tried various kinds of employment until in 1805 he met Anton Gruner, a disciple of Pestalozzi and director of the normal school at Frankfurt am Main, who persuaded him to become a teacher. After two years with Gruner, he visited Pestalozzi at Yverdon, studied at Göttingen and Berlin, and eventually determined upon establishing his own school, founded on what he considered to be psychological bases. The result in 1816 was the Universal German Educational Institute at Griesheim, transferred the following year to Keilhau, which constituted a kind of educational community for Froebel, his friends, and their wives and children. To this period belongs *The Education of Man* (1826), his most important treatise, though typical of his obscurantism. In 1831 he was again in Switzerland, where he opened a school, an orphanage, and a teacher-training course. Finally, in 1837, upon returning to Keilhau, he opened his first *Kindergarten,* or "garden of children," in nearby Bad Blankenburg. The experiment attracted wide interest, and other kindergartens were started and flourished, despite some political opposition.

The first kindergarten

The pedagogy of Froebel. Froebel's pedagogical ideas have a mystical and metaphysical context. He viewed man as a child of God, of nature, and of humanity who must learn to understand his own unity, diversity, and individuality, corresponding to this threefold aspect of his being. On the other hand, man must understand the unity of all things (the pantheistic element).

> Education consists of leading man, as a thinking, intelligent being, growing into self-consciousness, to a pure and unsullied, conscious and free representation of the inner law of Divine Unity, and in teaching him ways and means thereto.

Education had two aspects: the teacher was to remove hindrances to the self-development or "self-activity" of the child, but he was also to correct deviations from what man's experience has taught is right and best. Education is thus both "dictating and giving way." This means that ordinarily a teacher should not intervene and impose mandatory education, but when a child, particularly a child of kindergarten age, is restless, tearful, or willful, the teacher must seek the underlying reason and try to eradicate the uncovered hindrance to the child's creative development. Most important, the teacher's dictating and giving way should not flow from the mood and caprices of the teacher. Behaviour should be measured according to a "third force" between teacher and child, a Christian idea of goodness and truth.

School, for Froebel, was not an "establishment for the acquisition of a greater or lesser variety of external knowledge"; actually, he thought children were instructed in things they do not need. School instead should be the place to which the pupil comes to know the "inner relationship of things," "things" meaning God, man, nature, and their unity. The subjects followed from this: religion, language and art, natural history, and the knowledge of form. In all these subjects the lessons should appeal to the pupil's interests. It is clear that, in Froebel's view, the school is to concern itself not primarily with the transmission of knowledge but with the development of character and the provision of the right motivation to learn.

Froebel's emphasis on play

Froebel put great emphasis on play in child education. Just like work and lessons, games or play should serve to realize the child's inner destiny. Games are not idle time wasting; they are "the most important step in the development of a child," and they are to be watched by the teachers as clues to how the child is developing. Froebel was especially interested in the development of toys for children—what he called "gifts," devised to stim-

ulate learning through well-directed play, These gifts, or playthings, included balls, globes, dice, cylinders, collapsible dice, shapes of wood to be put together, paper to be folded, strips of paper, rods, beads, and buttons. The aim was to develop elemental judgment distinguishing form, colour, separation and association, grouping, matching, and so on. When, through the teacher's guidance, the gifts are properly experienced, they connect the natural inner unity of the child to the unity of all things: *e.g.*, the sphere gives the child a sense of unlimited continuity, the cylinder a sense both of continuity and of limitation. Even the practice of sitting in a circle symbolizes the way in which each individual, while a unity in itself, is a living part of a larger unity. The child is to feel that his nature is actually joined with the larger nature of things.

The kindergarten movement. The kindergarten was unique for its time. Whereas the first institutions for small children that earlier appeared in Holland, Germany, and England had been welfare nursery schools or day-care centres intended merely for looking after children while parents worked, Froebel stood for the socializing or educational idea of providing, as he put it in founding his kindergarten, "a school for the psychological training of little children by means of play and occupations." The school, that is, was to have a purpose for the children, not the adults. The curriculum consisted chiefly of three types of activities: (1) playing with the "gifts," or toys, and engaging in other occupations designed to familiarize children with inanimate things, (2) playing games and singing songs for the purpose not only of exercising the limbs and voice but also of instilling a spirit of humanity and nature, and (3) gardening and caring for animals in order to induce sympathy for plants and animals. All this was to be systematic activity.

The kindergarten plan to meet the educational needs of children between the ages of four and six or seven through the agency of play thereafter gained widespread acceptance. During the 25 years after Froebel's death in 1852, kindergartens were established in leading cities of Austria, Belgium, Canada, Germany, Great Britain, The Netherlands, Hungary, Japan, Switzerland, and the United States. In Great Britain the term infant school was retained for the kindergarten plan, and in some other countries the term crèche has been used.

Widespread acceptance of kindergartens

Herbart. Johann Friedrich Herbart was a contemporary of Froebel and other German Romanticists, but he can hardly be put into the ranks of such pedagogues. During his lifetime his sober, systematic "philosophical realism" found little approval; and only posthumously, during the latter half of the 19th century, did his work achieve great importance. He is regarded as one of the founders of theoretical pedagogy, injecting both metaphysics and psychology into the study of how people learn.

The psychology and pedagogy of Herbart. As a young man of 18, Herbart had studied at the University of Jena under the idealist philosopher Fichte. It was a long while before he broke from the spell of Fichte's teachings and turned to philosophical realism, which asserts that underlying the world of appearances there is a plurality of things or "reals." Change consists simply in the alteration in the relations between these reals, which resist the changed relationships as a matter of self-preservation.

Ideas, like things, always exist and always resist change and seek self-preservation. It is true that some ideas may be driven below the threshold of consciousness; but the excluded ideas continue to exist in an unconscious form and tend, on the removal of obstacles (as through education), to return spontaneously to consciousness. In the consciousness there are ideas attracting other ideas so as to form complex systems. These idea masses correspond to the many interests of the individual (such as his home and his hobbies) and to broader philosophical and religious concepts and values. In the course of mental development certain constellations of ideas acquire a permanent dominance that exercises a powerful selective facilitating influence upon the ideas struggling to enter or reenter the consciousness.

In his systematic account of the nature of education, Herbart conceived the process as beginning with the idea masses that the child has previously acquired from experience and from social intercourse. The teacher creates knowledge from the former and sympathy from the latter. The ultimate objective is the formation of character by the development of an enlightened will, capable of making judgments of right and wrong. Moral judgments (like reals) are absolute, springing from contemplation, incapable of proof and not requiring proof. Ethics, in other words, is the ultimate focus of pedagogy.

In the classroom, it is the aim of the lessons to introduce new conceptions, to bind them together, and to order them. Herbart speaks of "articulation," a systematic method of constructing correct, or moral, idea masses in the student's mind. First the student becomes involved in a particular problem; then he considers its context. Each of these two stages has a phase of rest and of progress, and thus there are four stages of articulation: (1) clarification, or the static contemplation of particular conceptions, (2) association, or the dynamic linking of new conceptions with old ones, (3) systematization, or the static ordering and modification of what in the conceptions are deemed of value, and (4) methodization, or the dynamic application and recognition of what has been learned. Herbart phrased this system of instruction only in very general terms, but his successors tended to turn this framework into a rigid schedule that had to be applied to every lesson. Herbart himself warned:

Articulation, or the systematization of lessons

> We must be familiar with them [the methods], try them out according to circumstances, alter, find new ones, and extemporize; only we must not be swallowed up in them nor seek the salvation of education there.

The Herbartians. Herbart's basing of educational methods on an understanding of mental processes or psychological considerations, his view that psychology and moral philosophy are linked, and his idea that instruction is the means to moral judgment had a large place in late 19th-century pedagogical thought. Among Herbart's followers were Tuiskon Ziller in Leipzig (who was the founder of the Association for Scientific Pedagogy) and Wilhelm Rein in Jena. From 1895 to 1901 a National Herbart Society for the Scientific Study of Education flourished in the United States; John Dewey was a major critic of Herbartianism in its proceedings.

Ziller's ideas are representative of the Herbartians. He insisted that all parts of the curriculum be closely integrated and unified—history and religion forming the core subjects on which everything else was hinged. The sequence of instruction was to be adjusted to the psychological development of the individual, which was seen as corresponding to the cultural evolution of mankind in stages from primitive savagery to civilization. His main aim in education, like the aim of most Herbartians, was promoting character building, not simply knowledge accumulation.

Other German theorists. In the history of pedagogy there is no period of such fruitfulness as the 19th century in Germany. In addition to Herbart, Froebel, Pestalozzi (in German Switzerland), and their followers, there were scores of the most important writers, philosophers, and theologians contributing their ideas on education—including Friedrich Schiller, Johann Wolfgang von Goethe, G.W.F. Hegel, Friedrich Ludwig Jahn, Johann Paul Friedrich Richter, Ernst Moritz Arndt, and Friedrich Nietzsche. To list the many ideas and contributions of these figures and others is impossible here, but it is worthwhile to suggest briefly the work of three men—Johann Gottlieb Fichte, Friedrich Schleiermacher, and Wilhelm von Humboldt—representing three divergent views.

When the great heterodox University of Berlin was founded in 1809, Fichte became one of its foremost professors and a year later its second rector, having already achieved fame throughout Germany as an idealist philosopher and fervent nationalist. At a time when Napoleon had humbled Prussia, Fichte in Berlin delivered the powerful *Addresses to the German Nation* (1807–08), full of practical views on national recovery and glory, including suggestions on the complete reorganization of the German schools along Pestalozzian lines. All children would be educated—and would be educated by the state. Boys and girls would be taught together, receiving virtually the same

Fichte's ordered education

education. There would be manual training in agriculture and the industrial arts, physical training, and mental training, the aim of which would be not simply the transmission of measures of knowledge but rather the instillation of intellectual curiosity and love and charity toward all men. Unlike Pestalozzi, however, Fichte was wary of the influence of parents and preferred educating children in a "separate and independent community," at least until a new generation of parents had arisen, educated in the new ideas and ideals. Here was an apparent revival of Plato's idea of a strictly ordered, authoritarian state.

Another of the founders of the University of Berlin (teaching there from 1810 to 1834) was the Protestant theologian Friedrich Schleiermacher, who sounded a very modern note by offering a social interpretation of education. Education, in his view, was an effort on the part of the older generation to "deliver" the younger generation into the four spheres of life—church, state, social life, and science. Education, however, not only assumes its organization in terms of these four areas of life but also serves to develop and influence these areas.

Perhaps more than any other individual, the philologist and diplomat Wilhelm von Humboldt was responsible for the founding of the University of Berlin. Supported by the king of Prussia, Frederick William III, he adopted for it principles that raised it to a foremost place among the universities of the world—the most important principle being that no teacher or student need adhere to any particular creed or school of thought. This academic freedom survived in Germany despite its temporary suspension and Humboldt's dismissal by a reactionary Prussian government in 1819. Philosophically and pedagogically, Humboldt was himself a humanist—a part of a wave of what were called new humanists—who reasserted the importance of studying the classical achievements of humanity in language, literature, philosophy, and history. The aim of education in these terms was not the service of society or the state but rather the cultivation of the individual.

Humboldt's humanism

French theorists. At this time there were two men in France who were making their names through the introduction of new methods—Jean-Joseph Jacotot and Édouard Séguin. Jacotot was a high-school teacher, politician, and pedagogue, whose main educational interests focused on the teaching of foreign languages. "You learn a foreign language," he said, "as you learn your mother-language." The pupil is confronted with a foreign language; he learns a text in the language almost by heart, compares it with a text in his own native language, and then tries gradually to free himself from the comparison of texts and to construct new combinations of words. The teacher controls this learning by asking questions. "My method is to learn one book and relate all the others to it." The learning of grammar came later.

Jacotot's method emphasized first the practical side and then the rule, constant repetition, and self-activity on the part of the pupils. Controversy arose, however, over his two basic theses: (1) that everyone has the same intelligence, differences in learning success being only a case of differences in industry and stamina, and (2) that everything is in everything: "Tout est dans tout," which suggests that any subject or book is analogous to any other.

The doctor and psychologist Édouard Séguin developed a pedagogy for pupils of below-average intelligence. Historically, scientific attempts to educate mentally retarded children had begun with the efforts of a French doctor, Jean-Marc-Gaspard Itard, during the latter part of the 18th century. In his classic book, *The Wild Boy of Aveyron* (1801), Itard related his five-year effort to train and educate a boy found, at about the age of 11, running naked and wild in the woods of Aveyron. Later, Séguin, a student of Itard, devised an educational method using physical and sensory activities to develop mental processes. Limbs and the senses were, in his view, a part of the whole personality, and their development was a part of the whole human education. His method was a specific adaptation of the idea that the development of intellectual and moral distinctions grows out of sensory experience.

Education of the mentally retarded

Spencer's scientism. The English sociologist Herbert Spencer was perhaps the most important popularizer of science and philosophy in the 19th century. Presenting a theory of evolution prior to Charles Darwin's *On the Origin of Species by Means of Natural Selection,* Spencer argued that all of life, including education, should take its essential lessons from the findings of the sciences. In *Education: Intellectual, Moral, and Physical* (1860) he insisted that the answer to the question "What knowledge is of most worth?" is the knowledge that the study of science provides. While the educational methodology Spencer advocated was a version of the sense realism espoused by reformers from Ratke and Comenius down to Pestalozzi, Spencer himself was a social conservative. For him, the value of science lies not in its possibilities for making a better world but in the ways science teaches man to adjust to an environment that is not susceptible to human engineering. Spencer's advocacy of the study of science was an inspiration to the American Edward Livingston Youmans and others who argued that a scientific education could provide a culture for modern times superior to that of classical education. (H.-J.I./J.J.Ch.)

DEVELOPMENT OF NATIONAL SYSTEMS OF EDUCATION

The great changes in Europe in the 19th century included, among other things, the further consolidation of national states, the spread of modern technology and industrialization, and increasing secularization. These changes had consequences for the design of school systems. National school systems had to be conceived and organized. Alongside the older schools, including elementary schools, Latin, or grammar, secondary schools, and universities, there developed so-called modern schools that stressed the exact sciences and modern languages, reflecting the new technological and commercial age. Vocational schools also appeared in greater numbers. The influence of the church was increasingly repressed, and the influence of the state on the school system correspondingly grew stronger. The ideal of universal education—education for all—became more and more a reality.

Germany. Luther's pronouncements on the educational responsibilities of the individual had no doubt helped create that healthy public opinion that rendered the principle of compulsory school attendance acceptable in Prussia at a much earlier date than elsewhere. State intervention in education was almost coincident with the rise of the Prussian state. In 1717 Frederick William I ordered all children to attend school if schools were available to them. This was followed in 1736 by edicts for the establishment of schools in certain provinces, in 1763 by Frederick II the Great's regulation asserting the principle of compulsory school attendance, and in 1794 by a codification of Prussian law recognizing the principle of state supremacy in education.

Humboldt's reforms. The schools, however, had established a traditional classical curriculum that ignored the changing needs of life and fields of knowledge. No effective reorganization of the educational system was carried out until after the disaster of the Battle of Jena (1806), during the Napoleonic Wars, which brought about the virtual collapse of Prussia. Fichte delivered his *Addresses to the German Nation* at this time, appealing to the spirit of patriotism over a selfish individualism. He advocated a nationalism to be cultivated and enhanced by controlling the education of the young. In the period of governmental reform which came about, one of the first acts of the prime minister Freiherr Karl vom Stein in 1807 was to abolish certain semi-ecclesiastical schools and to place education under the Ministry of the Interior, with Wilhelm von Humboldt at the head of a special section. Humboldt's policy in secondary education was a compromise between the narrow philological pedantry of the old Latin schools and the large demands of the new humanism that he espoused. The measure introduced by Humboldt in 1810 for the state examination and certification of teachers checked the then-common practice of permitting unqualified theological students to teach in the schools and raised the teaching profession to a high level of dignity and efficiency, placing Prussia in the forefront of educational progress. It was also a result of the initiative of Humboldt that the methods of Pestalozzi were

Reforms inspired by the Napoleonic disasters

introduced into the teachers' seminaries. To this period also belongs the revival, in 1812, of the *Abitur* (the school-leaving examination), which had fallen into abeyance.

Developments after 1815. The period that succeeded the peace of 1815 was one of political reaction, and not until the 1830s were there further significant reforms. In 1834, for example, an important step was taken in regard to secondary education by making it necessary for candidates for the learned professions, as well as for the civil service and for university studies, to pass the leaving examination of the *Gymnasien,* the classical secondary schools. Thus, through the leaving examination, the state held the key to the liberal careers and was thereby able to impose its own standards upon all secondary schools.

In connection with the so-called Kulturkampf, or struggle between the state and the Roman Catholic church, the school law of 1872 reasserted the absolute right of the state alone to the supervision of the schools. Nevertheless, the Prussian system remained both for Catholics and for Protestants essentially denominational. On the elementary level, in particular, the mixed school was established only when the creeds were so intermingled that a confessional school was impracticable. In all cases the teachers were appointed with reference to religious faith; religious instruction was given in school hours and was inspected by the clergy.

Types of German secondary schools

The official classification, or grading according to the type of curriculum, of secondary schools in Prussia (and throughout Germany) was very precise. The following were the officially recognized types: (1) the classical nine-year *Gymnasium,* with a curriculum that included Latin, Greek, and a modern language, (2) the semiclassical nine-year *Realgymnasium,* with a more modern curriculum that included, in addition to Latin and modern languages, the natural sciences and mathematics, and (3) the modern six-year *Realschule* or nine-year *Oberrealschule,* with a curriculum of sciences and mathematics.

The differentiation between the types was the result of a natural educational development corresponding to the economic changes that transformed Prussia from an agricultural to an industrial state. The classical schools long retained their social prestige and a definite educational advantage in that only their pupils were admissible to the universities. From the foundation of the German Empire in 1871 the history of secondary education was largely concerned with a struggle for a wider recognition of the work of the newer schools. The movement received a considerable impetus by the action of Emperor William II, who summoned a school conference in 1890 at which he set the keynote: "It is our duty to educate young men to become young Germans and not young Greeks or Romans." New schedules were framed in which the hours devoted to Latin were considerably reduced, and no pupil could obtain a leaving certificate without a satisfactory mark in the mother tongue. The reform lasted only a single school generation. In 1900 equality of privileges was granted to three types of schools, subject to certain reservations: the theological faculties continued to admit only students from classical schools, and the pupils of the *Oberrealschule* were excluded by their lack of Latin from the medical faculties; but insofar as Latin was required for other studies, such as law or history, it could be acquired at the university itself.

Girls' schools. In Prussia, as elsewhere, the higher education of girls lagged far behind that of boys and received little attention from the state or municipality, except insofar as the services of women teachers were needed in the elementary schools. Thus it came about that in Prussia secondary schools for girls were dealt with administratively as part of the elementary-school system. After the establishment of the German Empire in 1871, a conference of directors and teachers of these schools was held at Weimar and put forth a reasoned plea for better organization and improved status. The advocates of reform, however, were not at unity in their aims; some wished to lay stress on ethical, literary, and aesthetic training; others stressed intellectual development and claimed an equal share in all the culture of the age. Even the women teachers fought an unequal battle, for all the school heads and a large part of the staff were men, usually academically trained. The women continually demanded a larger share of the work, and this was secured by the establishment of a new higher examination for women teachers. University study, though not prescribed, was in fact essential, and yet women had not the right of access to the university in Germany. They were allowed to take the leaving examination, for which private institutions prepared them, but their admission to the university rested with the professor. Not until the 20th century were desired changes achieved.

The new German universities. Unquestionably one of the greatest worldwide influences exercised by German education in the 19th century was through its universities, to which students came from all over the world and from which every land drew ideas for the reformation of higher education. To understand this, one must be aware of the state of higher education in most countries in the 19th century. Although the century witnessed a steady expansion of scientific knowledge, the curriculum of the established universities went virtually untouched. Higher education followed a single dimension. This was the century of the scientists Michael Faraday, Hermann von Helmholtz, James Prescott Joule, Charles Darwin, Joseph Lister, Wilhelm Wundt, Louis Pasteur, and Robert Koch. Yet, until the end of the century, most of the significant research was done outside the walls of higher educational institutions. In Great Britain, for instance, it was the Royal Society and other such societies that fostered advanced studies and encouraged research. The basic curriculum of colleges and universities remained nontechnical and nonprofessional. The English cardinal John Henry Newman, lecturing in Dublin on *The Idea of a University* in 1852, stated that the task of the university was broadly to prepare young men "to fill any post with credit, and to master any subject with facility." The university ought not to attempt professional and technical education.

Condition of 18th- and 19th-century higher education

While Newman's words epitomized the views held in most of Europe and America, some of the new universities in Germany were moving toward the expansion of the educational enterprise. In 1807 Fichte had drawn up a plan for the new University of Berlin, which Humboldt two years later was able to realize in its founding. The school was dedicated to the scientific approach to knowledge, to the combination of research and teaching, and to the proliferation of academic pursuits; and its ideal was adopted in the founding or reconstitution of other universities—Breslau (1811), Bonn (1818), Munich (1826). By the third quarter of the 19th century the influence of German *Lernfreiheit* (freedom of the student to choose his own program) and *Lehrfreiheit* (freedom of the professor to develop the subject and to engage in research) was felt throughout the academic world. The unity of the universities, for better or worse, was more and more dissolved by the fragmentation of subjects into different branches. Some critics would eventually condemn what they considered to be the excesses of the free elective system and the extreme departmentalization of research and curricula. Much of the debate, however, would centre on the general education of undergraduates. In the meantime, the conviction, fathered in Germany, that research is a responsibility of universities was to inspire the founders of universities in the United States in the late 19th century.

Lernfreiheit and *Lehrfreiheit*

France. In France the Jesuit schools and the schools of other teaching orders created at the time of the Renaissance had reconciled the teaching of the new humanism with the established doctrines of the Roman Catholic church and flourished with special brilliance. But, despite the changes brought about by the Renaissance and the attention given to the sciences in the 17th and 18th centuries, it was not until the advent of the French Revolution that the universal right to education was proclaimed (1791).

That principle was compromised when Napoleon came to power, however. Although he maintained that the matter of education was an important issue and thought that a common culture with common ideals was essential to nation-building, he felt that, from a political standpoint, the bourgeoisie and upper classes were most important. His national education system therefore served children of those classes. This led to reorganization of the structure of

Napoleonic system of education

secondary and higher education in a unified state system, with secondary schools maintained by the communes, and with state lycées, universities, and special institutions of higher education. Within this structure the rector of a university headed a teaching body, recruited by the state and supervised by an inspectorate, ranging through various grades up to the university council. Grades of proficiency in studies, from simple certificates to the degrees of *baccalauréat, licence,* and doctorate were awarded on the result of examinations, and these tests were made a necessary condition of entry into such professions as medicine, law, and teaching. This structure, despite many modifications, has survived until modern times.

Development of state education. French educational history in the 19th century is essentially the story of the struggle for the freedom of education, of the introduction at the secondary level of the modern and scientific branches of learning, and, under the Third Republic, of the establishment of primary education, at once secular and compulsory, between the ages of six and 12. There were also a middle education between the ages of 13 and 16 and, finally, a professional and technical education.

Under the restoration of the monarchy in 1814, education fell inevitably under the control of the church; but, during the bourgeois monarchy of Louis Philippe, a law was passed in 1833 that laid the foundations of modern primary instruction, obliging the communes to maintain schools and pay the teachers. The higher primary schools that were founded were suppressed by Roman Catholic conservatives in 1850 (their restoration later constituted one of the great positive services rendered by the Third Republic to the cause of popular education). The 1850 law restored the "liberty of teaching" that, in effect, meant free scope for priestly schools, but it also made provision for separate communal schools for girls, for adult classes, and for the technical instruction of apprentices. In 1854 France

Centralization of French education

was divided for purposes of educational administration into 16 districts called *académies,* each administered by a rector and each with a university at the apex of the educational structure. The rector not only was made the chief administrator of the university but also was responsible for secondary and higher education within his *académie;* he nominated candidates for administrative positions in his area, appointed examination committees, supervised examination content and procedures, and presided over an academic council. Unlike the political division in some other countries, the *académies* were given little power or authority of their own; rather, they were administrative arms of the national ministry of education.

After the Franco-Prussian War, the Third Republic addressed itself to the organization of primary instruction as "compulsory, free, and secular." The law of 1878 imposed on communes the duty of providing school buildings and provided grants-in-aid. The national government also henceforth paid salaries throughout the public sector of education. In 1879 a law was passed compelling every department to maintain training colleges for male and female teachers. The law of 1881 abolished fees in all primary schools and training colleges; the law of 1882 established compulsory attendance; and, finally, the law of 1886 enacted that none but lay persons should teach in the public schools and abolished in those schools all distinctively religious teaching.

Secondary education. In European systems of education, secondary education was preeminently a preparation for the university, with aims and ideals of general culture that differentiated it radically and at the very outset from education of the elementary type. Down to the beginning of the 20th century, the French system could be regarded as a typical and extreme example of the European theory.

European dual plan

The characteristic European organization has been called the dual plan: elementary and secondary education were distinct types, and only a minority of the elementary-school pupils passed on to the secondary schools, generally only if they were bright and could win scholarships through a competitive examination. The secondary schools were of two kinds: lycées and communal colleges. The lycées, maintained by tuition fees and state scholarships, taught the ancient languages, rhetoric, logic, ethics, mathematics, and physical science. The communal colleges, established by municipalities or individuals and maintained by tuition fees, offered a partial lycée curriculum, featuring Latin, French, mathematics, history, and geography. Pupils who did not complete a secondary education program generally entered civil service or other white-collar occupations. With the development of commerce and industry in the 19th century, France instituted the *écoles primaires supérieures,* or "higher primary schools," for those who did not go on to universities but who needed a better education than the primary schools could give. The curricula of these schools were somewhat more advanced than those of the primary schools; pupils remained longer (up to the age of 16) and were prepared for employment in business as white-collar workers but generally at a lower level than pupils who came from the lycées. In effect, the different types of schools tended to maintain class cleavages since students of the secondary schools enjoyed higher social and occupational prestige than those of the upper primary schools.

The foundation of secondary schools for girls was in its way one of the most notable achievements of the Third Republic. It was inaugurated by the law of Dec. 22, 1880, called after its author the Loi Camille Sée. Until World War II, the curricula were different from those of the boys' schools, and the course of study was only five years. There were no ancient languages, and mathematics was not carried to so high a level as in the boys' lycées.

England. Influenced by doctrines of laissez-faire, England hesitated a long time before allowing the state to intervene in educational affairs. At the beginning of the 19th century, education was regarded as entirely the concern of voluntary or private enterprise, and there was much unsystematic philanthropy. Attempts were made to channel and concentrate it, and many hoped that the Church of England and the dissenting churches would join in a concerted effort to provide a national system of elementary education on a voluntary basis. But discordant views prevented such cooperation, and two voluntary societies were founded, one representative of the Church of England and the other of dissent. In 1829 the Roman Catholics were emancipated by law from disabilities they had long suffered, and so they also were able to provide voluntary schools. Other religious bodies joined in the effort to meet the growing need for elementary schools, but it was soon evident that voluntary finance would not be equal to this formidable task. In 1833 the government made a small building grant to these societies, and in this modest way state intervention began. Six years later a committee of the Privy Council was established to administer the state grants, now made annually, and to arrange for the inspection of voluntary schools aided from public funds. The work involved led to the establishment of a small central education department, which was the beginning of the ministry of education.

Laissez-faire and English voluntary education

Matthew Arnold was influential in pressing upon the English conscience the importance of public education for the state. While serving as inspector of elementary schools from 1851 to 1886, he studied European school systems and contrasted the meagre educational contributions of the English state with the more generous ones of Continental states.

Elementary Education Act. England prolonged its reliance on voluntary initiative for year after year as population increased, and, with the growing industrialization, people crowded into the new towns. At last in 1870 Parliament, after long, acrimonious debates, passed an Elementary Education Act, the foundation upon which the English educational system has been built. Religious teaching and worship were the crucial issues in the debates, and the essentials of the settlement agreed upon were (1) a dual system of voluntary and local-authority schools and (2) careful safeguards to ensure as far as possible that no child would receive religious teaching that was at variance with the wishes of his parents. It was left to the school boards—as these first local education authorities were called—to decide on an individual basis whether to make elementary education compulsory in their districts. In 1880, however, it was made compulsory throughout

England and Wales, and in 1891 fees were abolished in all but a few elementary schools.

Secondary and higher education. Secondary education, however, was still left to voluntary and private enterprise. Attention was focused on the "public" schools (independent secondary schools such as Eton and Harrow, usually for boarders from upper- and well-to-do middle-class homes), which under the leadership of outstanding headmasters such as Thomas Arnold were thoroughly reformed. As headmaster of Rugby School (1828–42), Arnold is credited with changing the face of public education in England by instilling a spirit of moral responsibility and intellectual integrity grounded in Christian ethics. Arnold's aims of school life—religious and moral principles, gentlemanly conduct, and intellectual ability—where to have an enduring influence on the English public-school system.

Several new universities were founded during the 19th century, and the latter half of it saw the founding of a number of girls' high schools and boarding schools offering an education that was comparable to that available in boys' public schools and grammar schools. Several training colleges for teachers were established by voluntary agencies, and universities and university colleges toward the end of the century undertook the training of postgraduates as teachers in departments of education created for this purpose.

Russia. Influenced by the disintegration of the serf system, the trend toward industrialization and modernization, and the democratic ideas of the French Revolution, Tsar Alexander I at the beginning of the 19th century tried to institute new educational reforms. The statutes of 1803 and 1804 followed the pattern set by Peter I the Great and Catherine II the Great in the 18th century for utilitarian, scientific, and secular education. The old Catherinian schools were remodeled and new schools founded. Schools were to be free and under state control. Rural peasants were to be taught reading, writing, arithmetic, and elements of agriculture at the parochial schools (*prikhodskiye uchilishcha*); pupils in the district schools of urban areas (*uyezdnye uchilishcha*) and the provincial schools (*gimnazii*) were to be prepared for careers as civil servants or for other white-collar occupations (law, political economy, technology, and commerce). The elementary and secondary schools were integrated with the universities.

Russian reform and reaction

Nicholas I, coming to the throne in 1825, considered this democratic trend harmful and decreed that:

> It is necessary that in every school the subjects of instruction and the very methods of teaching should be in accordance with the future destination of pupils, that nobody should aim to rise above that position in which it is his lot to remain.

A new statute of 1828 decreed that parochial schools were intended for the peasants, the district schools for merchants and other townspeople, and *gimnazii* for children of the gentry and civil servants. Instruction in the *gimnazii* in Latin and Greek was increased. Although the legislation of Nicholas I established a class system, the utilitarian character of the whole system remained.

The Russian radical intelligentsia was fiercely opposed to the privileged schools for the gentry and demanded the reestablishment of a democratic system with a more modern curriculum in secondary schools. This was coupled with the demand for the emancipation of the serfs and the equality of women in education. The new tsar in 1855, Alexander II, inaugurated a period of liberal reforms. The serfs were emancipated in 1861, and thus all social restrictions were removed. A new system of local government in rural areas (*zemstvo*) was enacted with a right to found schools for the peasantry, now free. Combined efforts of the government, *zemstva,* and peasant communities produced a growth of schools in the rural areas. The utilitarian trend was evident in the establishment of technical schools with vocational differentiation. The education of women was promoted, and the first higher courses for women were founded in main cities.

The reign of Alexander II, which was later marked by reactionary measures and political oppression, ended in his assassination in 1881 by the terrorist branch of the Narodniki revolutionary organization. A period of reaction followed under his successor, Alexander III. All reforms were suspended, and the growth of educational institutions was interrupted. The chief procurator of the Holy Synod attempted to build up a rival system of parochial schools under the control of the orthodox clergy; and the minister of public instruction tried to return to the class system of Nicholas I. These reactionary measures set back the growth of education. Four-fifths of all children were deprived of education. The result was that at the turn of the century nearly 70 percent of Russia's male population and 90 percent of its female population were illiterate (1897 census). The aboriginal dwellers of Russia's national outskirts (more than one-half of the country's population) were almost totally illiterate. (J.J.Ch.)

The United States. Administered locally everywhere, schooling of the United States's masses in the republic's younger days was immensely diverse. In New England, primary schooling enjoyed public support. In the South, apart from supplying a meagre learning to pauper children, the states abstained from educational responsibility. In the middle states elementary schools were sometimes public; more often they were parochial or philanthropic. Only beyond the Alleghenies was there any federal provision for education. There, under the Articles of Confederation, the Ordinance of 1787 reserved a plot of land in every prospective township for the support of education. The measure not only laid the groundwork for education in the states of the Ohio Valley and the Great Lakes, it also became a precedent for national educational aid. Thus, in 1862 the Morrill Act granted every state establishing a public agricultural college 30,000 acres (12,000 hectares) of public land for each of its lawmakers in Congress. Since then some 12 million acres (five million hectares) have been distributed, on which some 70 of the so-called land-grant colleges currently flourish.

American land-grant colleges

Several of the Founding Fathers expressed belief in the necessity of public education, but only Thomas Jefferson undertook to translate his conviction into actuality. Convinced that democracy can be effective only in the hands of an enlightened people, he offered Virginia's lawgivers a plan in 1779 to educate schoolchildren at public cost for three years and a few gifted boys beyond that. The proposal encountered resistance from both the ruling classes and the clergy; they regarded instruction as a private or an ecclesiastical prerogative. Jefferson's plan was rejected, as was another he submitted some 40 years later. Although his ideas enlightened educational thought throughout the country, only one of Jefferson's dreams reached actuality in his lifetime: the University of Virginia opened in 1825, the most up-to-date institution of its sort, the first frankly secular university in America and the closest to a modern-day conception of a state university.

The educational awakening. When Jefferson died in 1826 the nation stood on the threshold of a stupendous transformation. During the ensuing quarter century it expanded enormously in space and population. Old cities grew larger and new ones more numerous. The era saw the coming of the steamboat and the railroad. Commerce flourished and so did agriculture. The age witnessed the rise of the common man with the right to vote and hold office. It was a time of overflowing optimism, of dreams of perpetual progress, moral uplift, and social betterment.

The common school

Such was the climate that engendered the common school. Open freely to every child and upheld by public funds, it was to be a lay institution under the sovereignty of the state, the archetype of the present-day American public school. Bringing the common school into being was not easy. Against it bulked the doctrine that any education which excluded religious instruction—as all state-maintained schools were legally compelled to do—was godless. Nor had there been any great recession of the contention that education was not a proper governmental function and for a state to engage therein was an intrusion into parental privilege. Still more distasteful was the fact that public schooling would occasion a rise in taxes.

Yet the common school also mustered some formidable support, and finally, in 1837, liberal Massachusetts lawmakers successfully carried through a campaign for a

state board of education. It is especially to Horace Mann, the board's first secretary, that Massachusetts credits its educational regeneration. To gather data on educational conditions in Massachusetts, Mann roved the entire commonwealth. He lectured and wrote reports, depicting his dire findings with unsparing candour. There were outcries against him, but when Mann resigned, after 12 years, he could take pride in an extraordinary achievement. During his incumbency, school appropriations almost doubled. Teachers were awarded larger wages; in return they were to render better service. To help them Massachusetts established three state normal schools, the first in America. Supervision was made professional. The school year was extended. Public high schools were augmented. Finally, the common school, under the authority of the state, though still beset by difficulties, slowly became the rule.

What Mann accomplished in Massachusetts, Henry Barnard (1811–1900) achieved in Connecticut and Rhode Island. More reserved than Mann, Barnard has come down the ages as the "scholar of the educational awakening." He became the first president of the Association for the Advancement of Education and editor of its *American Journal of Education,* in whose 30 volumes he discussed virtually every important pedagogical idea of the 19th century.

Similar campaigns were under way in other areas. In Pennsylvania the assault centred on the pauper school; in New York it was against sectarianism. On the westward-moving frontier, old educational ideas and traditions had to compete in an environment antagonistic to privilege and permanence. There was controversy everywhere, however, over the state's right to assume educational authority and especially its power to levy school taxes. Future handling of this issue in the West was foretold in 1837, when Michigan realized a state-supported and state-administered system of education in which the state university, the University of Michigan under the leadership of Henry Tappan, played an integral part.

The rise of the American high school

Secondary education. Once the common school was solidly entrenched, the scant opportunity afforded the lower classes for more than a rudimentary education fell under increasing challenge. If it was right to order children to learn reading, writing, and arithmetic and to offer them free tax-supported schooling, some reasoned, then it was also right to accommodate those desiring advanced instruction. Before long, a few common schools, yielding to parental insistence, introduced courses beyond the elementary level. Such was the germ of the high school in the U.S.

The first high school in the United States opened in Boston in 1821 as the English Classical School, a designation that soon was changed to English High School. Designed for the sons of the "mercantile and mechanic classes," it provided three years of free instruction in English, mathematics, surveying, navigation, geography, history, logic, ethics, and civics. In 1825 New York City inaugurated the first high school outside New England. The next year Boston braved free secondary education for girls, judiciously diluted and restricted to 130. When the number of applicants vastly exceeded this figure, the city fathers abandoned the project.

The high-school movement was spurred less by these diffuse developments than by legislation by Massachusetts in 1827 that ordered towns of 500 families to furnish public instruction in American history, algebra, geometry, and bookkeeping, in addition to the common primary subjects. Furthermore, towns of 4,000 were to offer courses in history, logic, rhetoric, Latin, and Greek. The measure lacked public backing, but it set the guideposts for similar legislation elsewhere. The contention that government had no right to finance high schools remained an issue until the 1870s, when Michigan's supreme court, finding for the city of Kalamazoo in litigation brought by a taxpayer, declared the high school to be a necessary part of the state's system of public instruction.

Education for females. Though the common school vouchsafed instruction to girls, girls' chances to attend high school—not to say college—were slight. The "female academies," attended mainly by daughters of the middle class, were not numerous, and they varied in their emphases, often stressing social or domestic subjects. The truth is that as late as the 1840s, when the lowliest man could vote and hold office, women were haltered by taboos of every sort. But as America advanced industrially, and more and more women flocked to the mill and the office, their desire for greater educational opportunity grew. As in the struggle for the common school, the cause of women's education bred leaders, many of whom founded schools and communicated internationally. In 1833 Oberlin College in Ohio hazarded coeducation, and 20 years later Antioch College, also in Ohio, followed suit. Beyond the Mississippi every state university, except that of Missouri, was coeducational from its beginning. The East moved more warily; Cornell University was the first Eastern school to become coeducational, in 1872.

Co-education

Higher education. While women were crusading for greater educational opportunity, the college itself was undergoing alteration. It had begun as a cradle of divinity, but, as the 18th century waned, it was displaying a mounting secularity. In the course of the 19th century, not only did colleges surge in number, but some of the more enterprising of them undertook to reshape their purpose. Soon after its opening in 1885, Bryn Mawr College in Pennsylvania announced courses for the master's and doctor's degrees. Inspired by the scholarly accomplishments of German universities, Johns Hopkins University in Baltimore, founded in 1867, put its weight on research. Twenty years later Clark University in Massachusetts opened as a purely graduate school. Soon the graduate trend invaded older schools as well.

The early normal schools, or teacher-training schools, were primitive; often they were merely higher elementary schools, rehearsing their students for a year in basic reading and arithmetic, rectitude and piety, some history, mathematics, and physiology, and, if they survived, a rudimentary pedagogy. After the 1860s the ideas and experiments of Pestalozzi and Froebel combined with widespread social-democratic influences on education and advances in psychological thought to change schooling. This confluence, which was most noticeable in elementary education, resulted in the appearance of the kindergarten and in methods proceeding from the nature of the child and including content representing more of the present society. While much of the rationale was religious or mystical, the outcome was socially and psychologically more realistic. Since the early phases of schooling were initially the only concern of teacher training, it was natural that the idea of preparing teachers to use techniques derived from the new concepts, including the greater systematization introduced by Herbart, and the necessity for teachers to learn specifically about the child would substantially augment teacher-training programs and lay the groundwork for immense institutional expansion in the first half of the 20th century. (A.E.M./R.F.L.)

The British dominions. *Canada.* In the early period of the 19th century, until about 1840, schooling in Canada was much the same as it was in England; it was provided through the efforts of religious and philanthropic organizations and dominated by the Church of England. Although there was overlap among types of schools (identified historically), there are records of parish schools, charity schools, Sunday schools, and monitorial schools for the common people. The instructional fare was a rudimentary combination of religious instruction and literacy skills, perhaps supplemented by some practical work.

More advanced education was limited to the upper social classes and was given in Latin grammar schools or in private schools with various curricular extensions on the classical base. Academies, largely supported by the middle class of nonconformist groups, presented a broad curriculum of liberal arts that spanned the secondary and higher levels of education. In general, instruction relied on a simple chain concept of "transmission-absorption-mental storage," which was kept going by direct application of reward or punishment.

In the middle period, which lasted to about 1870, public systems of education emerged, accommodating religious interests in a state framework. Public support was won

for the common school, leading toward universal elementary education. Secondary and higher education began to assume a public character. The principle of local responsibility under central provincial authority was elaborated in the respective provinces.

Church and state relations in Canada

Of central importance in the development of Canadian education is the kind of agreement reached on church–state relations in education during this period. At one extreme is the arrangement made in Newfoundland from 1836 to accommodate all numerically represented denominations separately within a loose system (not until 1920 was a unified system of education developed, which still works through five denominational subsystems); at the other extreme are the arrangements made in British Columbia, which became decisive when it entered the Canadian Confederation, to establish and maintain a free, unified, centralized nonsectarian system. Other provinces eventually developed patterns that represented compromises. The Nova Scotia–New Brunswick pattern, for instance, provided a unified system that in principle was nonsectarian but that allowed the grouping of Roman Catholic children for education, thus legalizing sectarian schools within the system. Ontario placed separate Catholic schools within a unified school system. Québec supported a dual confessional system from the 1840s to the 1960s, with parallel structures for Roman Catholic and Protestant schooling at both the local and provincial levels. Manitoba adopted Québec's dual confessional system in 1871, then changed to a unified, centralized nonsectarian system amid much controversy in 1896.

The British North America Act of 1867, Canada's constitution, lodged authority for education in the provinces, at the same time guaranteeing denominational rights (in the "minority-school protective clause") if such rights existed by law at the time of entry into confederation. These two provisions established the pluralistic nature of Canadian education, and the union of the provinces and the entrance of western provinces gave Canada, by 1880, a national base on which to build the Canadian institution of education.

The final years of the 19th century were years of structural formalization of the educational foundations developed in the productive middle period. In this, Ontario's leadership was evident, especially as it affected the model of education evolving in the western territories. After Alberta and Saskatchewan were admitted as provinces in 1905, some divergence from Ontario took place: notably, both provinces required that Roman Catholic taxes go to separate Catholic schools (the decision in Ontario was based on free choice), and Alberta allowed separate school privileges through the secondary level. (Saskatchewan extended full funding of Roman Catholic separate schools to the end of high school in the early 1960s, Ontario in the late 1980s).

Toward the end of the 19th century, elementary schooling, by then established, was becoming compulsory. The cost of secondary education was diminishing, and the distinction in level and curriculum between the secondary and the elementary school was sharpened in the system of public schools. Communities were responsible for maintaining schools through a combination of local taxes and provincial grants, while provincial departments standardized the conduct of schooling through inspections, examinations, and prescription of course content and materials.

Changes in instructional theory, taking place during the latter part of the 19th century throughout the Western world, revolutionized the classroom. One major shift was from the imposition of knowledge on the mind of the learner to an emphasis on the learner's activity of perception and comprehension of knowledge. The impact of science on the higher-school curriculum was matched by its impact on educational theory and, consequently, on teacher training. Both scientific disciplines (such as educational psychology) and scientific methods of teaching became necessary to the training of teachers who were to operate in a new setting of teacher–pupil and subject-matter relations.

Australia. The development of Australian education through the 19th century was affected by a pervasive British influence, by a continuous economic struggle against harsh environmental conditions, and by the tendency for population to be concentrated in centres that accrued and extended political authority over the region. The particular historical thread around which educational developments took place was the question of denominational schools.

Church and state relations in Australia

From the first immigrant landing in 1788 through the early decades of the 19th century, education was provided on an occasional and rather haphazard basis, by the most expedient means available. In general, the assumption and the practice was that schooling would be provided by the church or by church organizations, such as the SPGFP, and colonial governments made small grants to aid such provision. It was also assumed that the Church of England would dominate the religious-educational scene, and a Church and School Corporation was set up in 1826 to administer endowments for Church of England efforts. Even at this early stage, however, the resistance of Nonconformists, especially Presbyterians and Roman Catholics, shortly defeated the attempt to "establish" Church of England institutions. The only early organized attempt at mass education was through monitorial systems.

In 1833 the governor of New South Wales asserted government responsibility for education by proposing the introduction of a nondenominational system that would reduce religion in schools to reading commonly approved scriptures and to providing release time for sectarian instruction by clergymen. The importance of the proposal lay in its spirit of religious compromise and its initiation of state responsibility for education, both of which were predictive of future development.

Because of sectarian resistance, mainly from Anglican and Catholic groups, so-called national schools were introduced alongside denominational schools in 1848 as a dual system, administered by two corresponding boards. Through the middle period of the century, similar sectarian compromises were found in other Australian colonies. The establishment of state systems were, however, seriously impeded by the extremity of the struggle for survival in hostile geographic conditions. In New South Wales a Public Schools Bill was passed in 1866, creating a single Council of Education. State aid to denominational schools was continued but under conditions stipulated by the state.

Victoria became a separate colony in 1850 and was initially fraught with particular problems occasioned by the arrival of a migrant gold-rush population. Little was accomplished in education, other than increased assistance to religious denominations, until 1856. After that the move for a state system gained impetus, and a Common Schools Bill was passed in 1862, establishing a system similar to that accepted in New South Wales. Soon after separation, Queensland's Primary Education Bill was passed in 1860, subordinating denominational schools and reinforcing the principle of common-school development in Australia. South Australia held to a continuous development of a general system based on common Christianity, but Western Australia's Elementary Education Bill of 1871 returned to dual support for both government and voluntary schools.

The support for state educational systems increased during the 1860s and 1870s as an alternative to interdenominational conflict was sought. In this development the Protestants, gradually and sometimes reluctantly, acquiesced. Catholic resistance was never overcome, and the consequent evolution of a separate Roman Catholic school system did not diminish Catholic dissatisfaction with the movement to state schools. The dilemma of Catholic citizens with regard to nonsectarian public education was universal: as citizens they were financially obligated for the public schools; as Roman Catholics they were committed to education in schools of their own faith.

The intention to educate all children and to raise the quality of instruction in common schools required governmental actions that could transform voluntary, exclusive, uneven provisions into uniform public standards. In Australia, particular motivating factors were the dramatic increases in population and economic growth and the recognized inadequacy of existing schools. The establishment

of secular public-school systems under government control was made unequivocal through the passage of legislation between 1872 and 1895. These bills did not abolish general Christian instruction, nor did they generally refuse release time for sectarian instruction. They did disallow sectarian claims for financial support and for a place in public education. The decision was for the operation of schools for all children, undertaken by the one agency that could act on behalf of the whole society, the government.

New Zealand. In New Zealand's early colonial period, between 1840 and 1852, certain provisions were made for endowments for religious and educational purposes, but education was considered, in accordance with prevailing views in England, a private or voluntary matter. Corresponding to general social distinctions, academic education was relegated to denominational, fee-charging schools, and common education was provided as a charitable service. Religious preference was avoided as much as possible, with the aim of minimizing sectarian conflict.

Church and state relations in New Zealand

Secular opposition to religious bias, even on a pluralistic basis, was, however, already evident. In 1852 New Zealand was granted self-government under the Constitution Act, and responsibility for education was placed in the councils of the six provinces. Although each province acted independently and somewhat according to the traditions of the dominant cultural group, the general sentiment moved in the next 20 years toward the establishment of public school systems. By 1876, when the provincial governments were abolished, the people of New Zealand, through varying regional decisions, had accepted governmental responsibility for education, had opted for nonsectarian schools, and had started on the path to free, compulsory common schooling.

The basic national legislation was passed in 1877. The Education Act provided for public elementary education that would be secular, free to age 15, and compulsory to age 13. Because of enforcement difficulties and legal exceptions, the compulsory clause was rather loose, but it instituted the rule. It was strengthened between 1885 and 1898, and high-school enrollments increased steadily after 1911. The act of 1877 also revised the administrative structure under a national ministerial Department of Education. Initially, the central department was little more than a funding source, while critical control was vested in regional boards elected by local school committees. In the competitive struggle between the department and the regional boards that waxed and waned well into the 20th century, neither gained the exclusive dominance sometimes sought. The primary position of the central authority in educational administration was confirmed in the reform period between 1899 and 1914, however, when control of inspectors, effective control of primary teacher appointment and promotion, and stipulative control in fund granting went to the Department of Education. These developments, together with curriculum and examination reforms, marked a new beginning in New Zealand education. (R.F.L.)

THE SPREAD OF WESTERN EDUCATIONAL PRACTICES TO ASIAN COUNTRIES

India. Originally the British went to India as tradesmen, but gradually they became the rulers of the country. On Dec. 31, 1600, the East India Company was established, and, like all commercial bodies, its main objective was trade. Gradually during the 18th century the pendulum swung from commerce to administration; the deterioration of Mughal power in India, the final expulsion of French rivals in the Seven Years' War, and the virtual appropriation of Bengal and Bihār in a treaty of 1765 had all made the company a ruling power. In spite of this, the company did not recognize the promotion of education among the natives of India as a part of its duty or obligation. For a long time the British at home were greatly opposed to any system of public instruction for the Indians, as they were for their own people.

Education under the East India Company

The feelings of the public authorities in England were first tested in the year 1793, when William Wilberforce, the famous British philanthropist, proposed to add two clauses to the company's charter act of that year for sending out schoolmasters to India. This encountered the greatest opposition in the council of directors, and it was found necessary to withdraw the clauses. For 20 years thereafter, the ruling authorities in England refused to accept responsibility for the education of Indian people. It was only in 1813, when the company's charter was renewed, that a clause was inserted requiring the governor-general to devote not less than 100,000 rupees annually to the education of Indians.

Some organization was required in order to disburse the educational grant. A General Committee of Public Instruction, constituted in Calcutta in 1823, started its work with an Orientalist policy, rather than a Western-oriented one, since the majority of the members were Orientalists. The money available was spent mainly on the teaching of Sanskrit and Arabic and on the translation of English works into these languages. Some encouragement was also given to the production of books in English.

Meanwhile, a new impetus was given to education from two sources of different character. One was from the Christian missionaries and the other from a "semirationalist" movement. The Christian missionaries had started their educational activities as early as 1542, upon the arrival of St. Francis Xavier. Afterward the movement spread throughout the land and exercised a lasting influence on Indian education. It gave a new direction to elementary education through the introduction of instruction at regular and fixed hours, a broad curriculum, and a clear-cut class system. By printing books in different vernaculars, the missionaries stimulated the development of Indian languages. But hand in hand with the study of the vernaculars went the teaching of Western subjects through the medium of English, called in India "English education."

Besides the missionaries, there were men in Bengal who, though admitting the value of Oriental learning for the advancement of civilization, thought that better things could be achieved through the so-called English education. In 1817 these semirationalists, led by Rām Mohan Roy, the celebrated Indian reformer, founded the Hindu College in Calcutta, the alumni of which established a large number of English schools all over Bengal. The demand for English education in Bengal thus preceded by 20 years any government action in that direction.

In the meantime the influence of the Orientalists was waning in the General Committee, as younger members with more radical views joined it. They challenged the policy of patronizing Oriental learning and advocated the need for spreading Western knowledge through the medium of English. Thus arose the controversy as to whether educational grants should be used to promote Oriental learning or Western knowledge. The controversy between the Orientalists and the Anglicists was decided in favour of the latter by the famous Minute on Education of 1835 submitted by Thomas Babington Macaulay, the legal member of the governor-general's executive council. His recommendations were accepted by Lord William Bentinck, the governor-general. The decision was announced on March 7, 1835, in a brief resolution that determined the character of higher education in India for the ensuing century. Although the schools for Oriental learning were maintained for some years, the translation of English books into Sanskrit and Arabic was immediately discontinued. Thus the system of "English education" was adopted by the government. It should be noted, however, that primary education did not attract any attention at all.

Orientalists versus Anglicists

Bentinck's resolution was followed by other enactments accelerating the growth of English education in India. The first was the Freedom of Press Act (1835), which encouraged the printing and publication of books and made English books available at low cost. Two years later, Persian was abolished as the language of record and the courts (to the dismay of the Muslims) and was replaced by English and Indian languages in higher and lower courts, respectively. Finally, Lord Hardinge, as governor-general, issued a resolution on Oct. 10, 1844, declaring that for all government appointments preference would be given to the knowledge of English. These measures strengthened the position of English in India, and the lingering prejudices against learning English vanished forever.

Although English education held its ground in Bengal, the Bengal government did not neglect vernacular education altogether. Moreover, in Bombay, Madras, and the North-Western Provinces there was as yet little effective demand for English, and the tendency was to lay the main stress on Indian languages. Bombay adopted the policy of encouraging primary education and spreading Western science and knowledge through the mother tongue. This was done under the able guidance of Mountstuart Elphinstone, then the governor, even though the government also conducted an English school in almost every district in the province. Between 1845 and 1848 a bitter controversy arose regarding the language of instruction, but the issue was between the mother tongue and English, and not between a classical language and English as it was in Bengal. The controversy gathered strength every day; and, in those days of centralization, the matter had to be referred to the Bengal government, which advised the Bombay government to concentrate its attention on English education alone, thus throttling the growth of education through the mother tongue in Bombay. Meanwhile, the Madras government was biding its time, leaving the field of positive effort open to Christian missionaries; as a result of this missionary initiative, English education in the Madras presidency was more extensively imparted than in Bombay.

A laudable experiment in the field of vernacular education was carried out by Lieutenant Governor James Thomason in the North-Western Provinces. Thomason's *ḥalqabandī* system attempted to bring primary education within easy reach of the common people. In each *ḥalqah* (circuit) of villages, a school was established in the most central village so that all the villagers within a radius of two miles might avail themselves of it. For the maintenance of these schools the village landholders agreed to contribute at the rate of 1 percent of their land income. The experiment proved successful, and in 10 years Thomason opened 897 schools and provided elementary education for 23,688 children.

Ḥalqabandī system

The next step in the history of Indian education is marked by Sir Charles Wood's epoch-making Dispatch of 1854, which led to (1) the creation of a separate department for the administration of education in each province, (2) the founding of the universities of Calcutta, Bombay, and Madras in 1857, and (3) the introduction of a system of grants-in-aid. Even when the administration of India passed from the East India Company into the hands of the British crown in 1858, Britain's secretary of state for India confirmed the educational policy of Wood's Dispatch.

The newly established universities did not initially undertake any teaching responsibilities but were merely examining bodies. Their expenses were confined to administration and could be met from the fees paid by the candidates for their degrees and certificates. Although the establishment of the universities did result in a rapid expansion of college education and although the products of the new learning displayed keen scholarship, the value of learning nevertheless soon decayed. In such circumstances it was ironic for the Indian Education Commission of 1882 to declare, "The university degree has become an accepted object of ambition, a passport to distinction in public services and in the learned professions." Another undesirable practice was the domination of the universities over secondary education through their entrance examinations. University policies regarding curricula, examination systems, language of instruction, and other vital problems began to be chalked out by university teachers who had little experience in schoolteaching and who kept the administrative needs and requirements of colleges in the forefront. Thus, secondary schools increasingly prepared their students for a college education and not for life in general.

Excessive emphasis on higher education

The new system also became top-heavy. It must be stated that the commission of 1882 made a very valuable recommendation that the "elementary education of the masses, its provision, extension and improvement requires strenuous efforts of the state in a still larger measure than heretofore." It also desired to check the wild race for academic distinction and "to divert some part of the rapidly swelling stream of students into channels of a more practical character." Despite this warning, however, alternative courses in commerce, agriculture, and technical subjects that were offered in a limited number of selected schools did not prove popular. The educated classes could not be diverted from their conventional path.

In a general view of education during the last two decades of the 19th century, drift was more apparent than government resolve. Elementary education was starved and undernourished, and secondary education was suffering from want of proper supervision. There was an unplanned growth of high schools and colleges since the Education Commission had given a free charter to private enterprise. Many of these private institutions were "coaching institutions rather than places of learning." The universities had no control over them, and state control was negligible because the government had adopted a laissez-faire policy.

The second half of the 19th century is, nonetheless, of great significance to the country because modern India may indeed be said to be a creation of this period. It brought about a renaissance by breaking down geographic barriers and bringing different regions and long-separated Indian communities into close contact with one another. The blind admiration for Western culture was gradually passing away, and a new vision and reorientation in thought were coming about. A feeling of dissatisfaction also developed toward the existing governmental and missionary institutions. It was felt by some of the Indian patriots that the character of Indian youths could be built by Indians themselves. This led to the establishment of a few notable institutions aiming at imparting sound education to Indian youth on national lines—institutions such as the Anglo-Mohammedan Oriental College in Alīgarh (1875), the D.A.V. College in Lahore (1886), and the Central Hindu College in Vārānasi (1898). The politically minded classes of the country had also come to regard education as a national need. They were critical of the government's educational policy and resented any innovation that might restrain the pace of educational advance or diminish liberty. (S.N.M.)

Japan. *The Meiji Restoration and the assimilation of Western civilization.* In 1867 the Tokugawa (Edo) shogunate, a dynasty of military rulers established in 1603, was overthrown and the imperial authority of the Meiji dynasty was restored, leading to drastic reforms of the social system. This process has been called the Meiji Restoration, and it ushered in the establishment of a politically unified and modernized state.

In the following generation Japan quickly adopted useful aspects of Western industry and culture to enhance rapid modernization. But Japan's audacious modernization would have been impossible without the enduring peace and cultural achievements of the Tokugawa era. It had boasted a high level of Oriental civilization, especially centring on Confucianism, Shintōism, and Buddhism. The ruling samurai had studied literature and Confucianism at their *hankō* (domain schools); the commoners had learned reading, writing, and arithmetic at numerous *terakoya* (temple schools). Both samurai and commoners also pursued medicine, military science, and practical arts at *shijuku* (private schools). Some of these schools had developed a fairly high level of instruction in Western science and technology by the time of the Meiji Restoration. This cultural heritage helped equip Japan with a formidable potential for rapid Westernization. Indeed, some elements of Western civilization had been gradually introduced into Japan even during the Tokugawa era. The shogunate, notwithstanding its isolationist policy, permitted trade with the Dutch, who conveyed modern Western sciences and arts to Japan. After 1853, moreover, Japan opened its door equally to other Western countries, a result of pressures exerted by the United States Navy under Admiral Matthew C. Perry. Thenceforth, even before the Meiji Restoration, Japanese interest in foreign languages became intense and diverse.

The Tokugawa heritage

Western studies, especially English-language studies, became increasingly popular after the Restoration, and Western culture flooded into Japan. The Meiji government dispatched study commissions and students to Europe and to the United States, and the so-called Westernizers

defeated the conservatives who tried in vain to maintain allegiance to traditional learning.

Establishment of a national system of education. In 1871 Japan's first Ministry of Education was established to develop a national system of education. Ōki Takatō, the secretary of education, foresaw the necessity of establishing schools throughout the nation to develop national wealth, strength, and order, and he outlined a strategy for acquiring the best features of Western education. He assigned commissioners, many of whom were students of Western learning, to design the school system, and in 1872 the Gakusei, or Education System Order, was promulgated. It was the first comprehensive national plan to offer schooling nationwide, according to which the nation was divided into eight university districts, which were further divided into 32 middle-school districts, each accommodating 210 primary-school districts. Unlike the class-based schooling offered during the Tokugawa period, the Gakusei envisioned a unified, egalitarian system of modern national education, designed on a ladder plan. Although the district system was said to have been borrowed from France, the new Japanese education was based on the study of Western education in general and incorporated elements of educational practice in all advanced countries. Curricula and methods of education, for instance, were drawn primarily from the United States.

Gakusei, or Education System Order

This ambitious modern plan for a national education system fell short of full realization, however, because of the lack of sufficient financial support, facilities and equipment, proper teaching materials, and able teachers. Nevertheless, the plan represented an unprecedented historic stage in Japanese educational development. Under the Gakusei system, the Ministry of Education, together with local officials, managed with difficulty to set up elementary schools for children aged six to 14. In 1875 the 24,000 elementary schools had 45,000 teachers and 1,928,000 pupils. This was achieved by gradually reorganizing *terakoya* in many areas into modern schools. The enrollment rate reached only 35 percent of all eligible children, however, and no university was erected at all.

In 1873 David Murray, a professor from the United States, was invited to Japan as an adviser to the Ministry of Education; another, Marion M. Scott, assumed direction of teacher training and introduced American methods and curricula at the first normal school in Tokyo, established under the direct control of the ministry. Graduates of the normal school played an important role in disseminating teacher training to other parts of the country. By 1874 the government had set up six normal schools, including one for women. The normal school designed curricula for the primary schools, modeled after those of the United States, and introduced textbooks and methods that spread gradually into the elementary schools of many regions.

The work of educators and teachers from abroad

The conservative reaction. Following the repression of the Satsuma Rebellion, a samurai uprising in 1877, Japan again forged ahead toward political unity, but there was an increasing trend of antigovernment protest from below, which was epitomized by the Movement for People's Rights. Because of the Satsuma Rebellion, the government was in heavy financial difficulties. Also, with the people's inclination toward Western ideas fading away, a conservative reaction began to emerge, calling for a revival of the Confucian and Shintō legacies and a return to local control of education as practiced in the pre-Restoration era.

Discontent had been mounting among the rural people against the Education System Order of 1872, mainly because it had imposed upon them the financial burdens of establishing schools and yet had not lived up to expectations. Another cause of dissatisfaction was a sense of irrelevance that Japanese attributed to schooling largely based on Western models. The curriculum developed according to the 1872 order was perceived to have little relation to the social and cultural needs of that day, and ordinary Japanese continued to favour the traditional schooling of the *terakoya.* Tanaka Fujimaro, then deputy secretary of education, just returning from an inspection tour in the United States, insisted that the government transfer its authority over education to the local governments, as in the United States, to reflect local needs in schooling. Thus, in 1879 the government nullified the Gakusei and put into force the Kyōikurei, or Education Order, which made for rather less centralization. Not only did the new law abolish the district system that had divided the country into districts, it also reduced central control over school administration, including the power to establish schools and regulate attendance. The Kyōikurei was intended to encourage local initiatives. Such a drastic reform to decentralize education, however, led to an immediate deterioration of schooling and a decline in attendance in some localities; criticism arose among those prefectural governors who had been striving to enforce the Gakusei in their regions.

As a countermeasure, the government introduced a new education order in 1880 calling for a centralization of authority by increasing the powers of the secretary of education and the prefectural governor. Thereafter, the prefecture would provide regulations within the limits of criteria set by the Ministry of Education; some measure of educational unity was thus reached on the prefectural level, and the school system received some needed adjustment. Yet, because of economic stagnation, school attendance remained low.

Conservatism in education gained crucial support when the Kyōgaku Seishi, or the Imperial Will on the Great Principles of Education, was drafted by Motoda Nagazane, a lecturer attached to the Imperial House in 1870. It stressed the strengthening of traditional morality and virtue to provide a firm base for the emperor. Thereafter, the government began to base its educational policy on the Kyōgaku Seishi with emphasis on Confucian and Shintōist values. In the elementary schools, *shūshin* (national moral education) was made the all-important core of the curricula, and the ministry compiled a textbook with overtones of Confucian morality.

Reemphasis on Confucian and Shintōist values

Establishment of nationalistic education systems. With the installation of the cabinet system in 1885, the government made further efforts to pave the way for a modern state. The promulgation of the Meiji constitution, the constitution of the empire of Japan, in 1889 established a balance of imperial power and parliamentary forms. The new minister of education, Mori Arinori, acted as a central figure in enforcing a nationalistic educational policy and worked out a vast revision of the school system. This set a foundation for the nationalistic educational system that developed during the following period in Japan. Japanese education thereafter, in the Prussian manner, tended to be autocratic.

Based on policies advocated by Mori, a series of new acts and orders were promulgated one after another. The first was the Imperial University Order of 1886, which rendered the university a servant of the state for the training of high officials and elites in various fields. Later that year orders concerning the elementary school, the middle school, and the normal school were issued, forming the structural core of the pre-World War II education system. The ministry carried out sweeping revisions of the normal-school system, establishing it as a completely independent track, quite distinct from other educational training. It was marked by a rigid, regimented curriculum designed to foster "a good and obedient, faithful, and respectful character." As a result of these reforms the rate of attendance at the four-year compulsory education level reached 81 percent by 1900.

Together with these reforms, the Imperial Rescript on Education (Kyōiku Chokugo) of 1890 played a major role in providing a structure for national morality. By reemphasizing the traditional Confucian and Shintō values and redefining the courses in *shūshin,* it was to place morality and education on a foundation of imperial authority. It would provide the guiding principle for Japan's education until the end of World War II.

Promotion of industrial education. Ever since the Meiji Restoration in 1868, the national target had been *fukoku-kyōhei* ("wealth accumulation and military strength") and industrialization. From the outset the Meiji government had been busy introducing science and technology from Europe and America but nevertheless had difficulties in realizing such goals.

Inoue Kowashi, who became minister of education in 1893, was convinced that modern industries would be the most vital element in the future development of Japan and thus gave priority to industrial and vocational education. In 1894 the Subsidy Act for Technical Education was published, followed by the Technical Teachers' Training Regulations and the Apprentice School Regulations. The system of industrial education was in general consolidated and integrated. These measures contributed to the training of many of the human resources required for the subsequent development of modern industry in Japan.

Education in the 20th century

SOCIAL AND HISTORICAL BACKGROUND

International wars, together with an intensification of internal stresses and conflicts among social, racial, and ideological groups, have characterized the 20th century and have had profound effects on education. Rapidly spreading prosperity but widening gaps between rich and poor, immense increases in world population but a declining birth rate in Western countries, the growth of large-scale industry and its dependence on science and technological advancement, the increasing power of both organized labour and international business, and the enormous influence of both technical and sociopsychological advances in communication, especially as utilized in mass media, are changes that have had far-reaching effects. Challenges to accepted values, including those supported by religion; changes in social relations, especially toward versions of group and individual equality; and an explosion of knowledge affecting paradigms as well as particular information mark a century of social and political swings, always toward a more dynamic and less categorical resolution. The institutional means of handling this uncertain world have been to accept more diversity while maintaining basic forms and to rely on management efficiency to ensure practical outcomes.

The two world wars weakened the military and political might of the larger European powers. Their replacement by "superpowers" whose influence did not depend directly on territorial acquisition and whose ideologies were essentially equalitarian helped to liquidate colonialism. As new independent nations emerged in Africa and Asia and the needs and powers of a "third world" caused a shift in international thinking, education was seen to be both an instrument of national development and a means of crossing national and cultural barriers. One consequence of this has been a great increase in the quantity of education provided. Attempts have been made to eradicate illiteracy, and colleges and schools have been built everywhere.

The growing affluence of masses of the population in high-income areas in North America and Europe has brought about, particularly since World War II, a tremendous demand for secondary and higher education. Most children stay at school until 16, 17, or even 18 years of age, and a substantial fraction spend at least two years at college. The number of universities in many countries doubled or trebled between 1950 and 1970, and the elaboration of the tertiary level continues.

Demands of industry for technical and continuing education

This growth is sustained partly by the industrial requirements of modern scientific technology. New methods, processes, and machines are continually introduced. Old skills become irrelevant; new industries spring up. In addition, the amount of scientific, as distinct from merely technical, knowledge grows continually. More and more researchers, skilled workers, and high-level professionals are called for. The processing of information has undergone revolutionary change. The educational response has mainly been to develop technical colleges, to promote adult education at all levels, to turn attention to part-time and evening courses, and to provide more training and education within the industrial enterprises themselves.

The adoption of modern methods of food production has diminished the need for agricultural workers, who have headed for the cities. Urbanization, however, brings problems: city centres decay, and there is a trend toward violence. The poorest remain in these centres, and it becomes difficult to provide adequate education. The radical change to large numbers of disrupted families, where the norm is a single working parent, affects the urban poor extensively but in all cases raises an expectation of additional school services. Differences in family background, together with the cultural mix partly occasioned by change of immigration patterns, requires teaching behaviour and content appropriate to a more heterogeneous school population.

MAJOR INTELLECTUAL MOVEMENTS

Influence of psychology and other fields on education. The attempt to apply scientific method to the study of education dates back to the German philosopher Johann Friedrich Herbart, who called for the application of psychology to the art of teaching. But not until the end of the 19th century, when the German psychologist Wilhelm Max Wundt established the first psychological laboratory at the University of Leipzig in 1879, were serious efforts made to separate psychology from philosophy. Wundt's monumental *Principles of Physiological Psychology* (1874) had significant effects on education in the 20th century.

Influence of William James

William James, often considered the father of American psychology of education, began about 1874 to lay the groundwork for his psychophysiological laboratory, which was founded officially at Harvard in 1891. In 1878 he established the first course in psychology in the United States and in 1890 published his famous *The Principles of Psychology,* in which he argued that the purpose of education is to organize the child's powers of conduct so as to fit him to his social and physical environment. Interests must be awakened and broadened as the natural starting points of instruction. James's *Principles* and *Talks to Teachers on Psychology* cast aside the older notions of psychology in favour of an essentially behaviourist outlook; they asked the teacher to help educate heroic individuals who would project daring visions of the future and work courageously to realize them.

James's student Edward L. Thorndike is credited with the introduction of modern educational psychology, with the publication of *Educational Psychology* in 1903. Thorndike attempted to apply the methods of exact science to the practice of psychology. James and Thorndike, together with the American philosopher John Dewey, helped to clear away many of the fantastic notions once held about the successive steps involved in the development of mental functions from birth to maturity.

Interest in the work of Sigmund Freud and the psychoanalytic image of the child in the 1920s, as well as attempts to apply psychology to national training and education tasks in the 1940s and '50s, stimulated the development of educational psychology, and the field has become recognized as a major source for educational theory. Eminent researchers in the field have advanced knowledge of behaviour modification, child development, and motivation. They have studied learning theories ranging from classical and instrumental conditioning and technical models to social theories and open humanistic varieties. Besides the specific applications of measurement, counseling, and clinical psychology, psychology has contributed to education through studies of cognition, information processing, the technology of instruction, and learning styles. After much controversy about nature versus nurture and about qualitative versus quantitative methods, Jungian, phenomenological, and ethnographic methods have taken their place alongside psychobiological explanations to help educationists understand the place of heredity, general environment, and school in development and learning.

The relationship between educational theory and other fields of study has become increasingly close. Social science may be used to study interactions and speech to discover what is actually happening in a classroom. Philosophy of science has led educational theorists to attempt to understand paradigmatic shifts in knowledge. The critical literature of the 1960s and '70s attacked all institutions as conveyors of the motives and economic interests of the dominant class. Both social philosophy and critical sociology have continued to elaborate the themes of social control and oppression as embedded in educational institutions. In a world of social as well as intellectual

change, there are necessarily new ethical questions, such as those dealing with abortion, biological experimentation, and child rights, which place new demands on education and require new methods of teaching.

Traditional movements. Against the various "progressive" lines of 20th-century education, there have been strong voices advocating older traditions. These voices were particularly strong in the 1930s, in the 1950s, and again in the 1980s. Essentialists stress those human experiences that they believe are indispensable to people living today or at any time. They favour the "mental disciplines" and, in the matter of method and content, put effort above interest, subjects above activities, collective experience above that of the individual, logical organization above the psychological, and the teacher's initiative above that of the learner.

Essentialist, liberal, and religious education

Closely related to essentialism is what used to be called humanistic, or liberal, education in its traditional form. Although many intellectuals have argued the case, Robert M. Hutchins, president and then chancellor of the University of Chicago from 1929 to 1951, and Mortimer J. Adler, professor of the philosophy of law at the same institution, are its most recognized proponents. Adler argued for the restoration of an Aristotelian viewpoint in education. Maintaining that there are unchanging verities, he sought a return to education fixed in content and aim. Hutchins denounced American higher education for its vocationalism and "anti-intellectualism," as well as for its delight in minute and isolated specialization. He and his colleagues urged a return to the cultivation of the intellect.

Opposed to the fundamental tenets of pragmatism is the philosophy that underlies all Roman Catholic education. Theocentric in its viewpoint, Catholic scholasticism has God as its unchanging basis of action. It insists that without such a basis there can be no real aim to any type of living, and hence there can be no real purpose in any system of education. The church's

> whole educational aim is to restore the sons of Adam to their high position as children of God. [It insists that] education must prepare man for what he should do here below in order to attain the sublime end for which he was created. (From Pius XI, encyclical on the "Christian Education of Youth," Dec. 31, 1929.)

Everything in education—content, method, discipline—must lead in the direction of man's supernatural destiny.

New foundations. The three concerns that guided the development of 20th-century education were: the child, science, and society. The foundations for this trilogy were laid by so-called progressive education movements supporting child-centred education, scientific-realist education, and social reconstruction.

Progressive education. The progressive education movement was part and parcel of a broader social and political reform called the Progressive movement, which dates to the last decades of the 19th century and the early decades of the 20th. Elementary education had spread throughout the Western world, largely doing away with illiteracy and raising the level of social understanding. Yet, despite this progress, the schools had failed to keep pace with the tremendous social changes that had been going on.

Dissatisfaction with existing schools led several educational reformers who wished to put their ideas into practice to establish experimental schools during the last decade of the 19th century and in the early 20th century. The principal experimental schools in America until 1914 were the University of Chicago Laboratory School, founded in 1896 and directed by John Dewey; the Francis W. Parker School, founded in 1901 in Chicago; the School of Organic Education at Fairhope, Ala., founded by Marietta Johnson in 1907; and the experimental elementary school at the University of Missouri (Columbia), founded in 1904 by Junius L. Meriam. The common goal of all was to eliminate the school's traditional stiffness and to break down hard and fast subject-matter lines. Each school adopted an activity program. Each operated on the assumption that education was something that should not be imposed from without but should draw forth the latent possibilities from within the child. And each believed in the democratic concept of individual worth.

Some early experimental schools

Dewey, whose writings and lectures influenced educators throughout the world, laid the foundations of a new philosophy that continues to affect the whole structure of education, particularly at the elementary level. His theories were expounded in *School and Society* (1899), *The Child and the Curriculum* (1902), and *Democracy and Education* (1916). For Dewey, philosophy and education render service to each other. Education becomes the laboratory of philosophy. Society should be interpreted to the child through daily living in the classroom, which acts as a miniature society. Education leads to no final end; it is something continuous, "a reconstruction of accumulated experience," which must be directed toward social efficiency. Education is life, not merely a preparation for life.

The views of John Dewey

The influence of progressive education advanced slowly during the first decades of the 20th century. Nevertheless, a number of progressive schools were established, including the Play School and the Walden School in New York City, the Shady Hill School in Cambridge, Mass., the Elementary School of the University of Iowa, and the Oak Lane Day School in Philadelphia. Helen Parkhurst's Dalton Plan, introduced in 1920 at Dalton, Mass., pioneered individually paced learning of broad topics. Carleton Washburne's Winnetka Plan, instituted in 1919 at Winnetka, Ill., viewed learning as a continuous process guided by the child's own goals and capabilities. The Gary Plan, developed in 1908 at Gary, Ind., by William Wirt, established a "complete school," embracing work, study, and play for all grades on a full-year basis.

The spread of progressive education became more rapid from the 1920s on and was not confined to any particular country. In the United States the Progressive Education Association (PEA) was formed in 1919. The PEA did much to further the cause of progressive education until it ended, as an organization, in 1955. In 1921 Europe's leading progressives formed the New Education Fellowship, later renamed the World Education Fellowship.

The notions expressed by progressive education have influenced public-school systems everywhere. Some of the movement's lasting effects can be seen in the activity programs, imaginative writing and reading classes, projects linked to the community, flexible classroom space, dramatics and informal activities, discovery methods of learning, self-assessment systems, and programs for the development of citizenship and responsibility found in school systems all over the world.

Child-centred education. Proponents of the child-centred approach to education have typically argued that the school should be fitted to the needs of the child and not the child to the school. These ideas, first explored in Europe, notably in Rousseau's *Émile* (1762) and in Pestalozzi's *How Gertrude Teaches Her Children* (1801), were implemented in American systems by pioneering educators such as Francis W. Parker. Parker became superintendent of schools in Quincy, Mass., in 1875. He assailed the mechanical, assembly-line methods of traditional schools and stressed "quality teaching," by which he meant such things as activity, creative self-expression, excursions, understanding the individual, and the development of personality.

A different approach to child-centred education arose as a result of the study and care of the physically and mentally handicapped. Teachers had to invent their own methods to meet the needs of such children, because the ordinary schools did not supply them. When these methods proved successful with handicapped children, the question arose whether they might not yield even better results with ordinary children. During the first decade of the 20th century, the educationists Maria Montessori of Rome and Ovide Decroly of Brussels both successfully applied their educational inventions in schools for ordinary boys and girls.

The Montessori method's underlying assumption is the child's need to escape from the domination of parent and teacher. According to Montessori, children, who are the unhappy victims of adult suppression, have been compelled to adopt defensive measures foreign to their real nature in the struggle to hold their own. The first move toward the reform of education, therefore, should be directed toward educators: to enlighten their consciences, to

The Montessori method

remove their perceptions of superiority, and to make them humble and passive in their attitudes toward the young. The next move should be to provide a new environment in which the child has a chance to live a life of his own. In the Montessori method, the senses are separately trained by means of apparatuses calculated to enlist spontaneous interest at the successive stages of mental growth. By similar self-educative devices, the child is led to individual mastery of the basic skills of everyday life and then to schoolwork in arithmetic and grammar.

The Decroly method can be characterized as a program of work based on centres of interest and educative games. Its basic feature is the workshop-classroom, in which children can go freely about their own occupations. Behind the complex of individual activities there is a carefully organized scheme of work based on an analysis of the fundamental needs of the child. The principle of giving priority to wholes rather than to parts is emphasized in teaching children to read, write, and count, and care is taken to reach a comprehensive view of the experiences of life.

The Montessori and the Decroly methods have spread throughout the world and have widely influenced attitudes and practices of educating young children.

Pestalozzian principles have also encouraged the introduction of music education into early childhood programs. Research has shown that music has an undeniable effect on the development of the young child, especially in such areas as movement, temper, and speech and listening patterns. The four most common methods of early childhood music education are those developed by Émile Jaques-Dalcroze, Carl Orff, and Zoltán Kodály and the Comprehensive Musicianship approach. The Dalcroze method emphasizes movement; Orff, dramatization; Kodály, singing games; and Comprehensive Musicianship, exploration and discovery. Another popular method, developed by the Japanese violinist Shinichi Suzuki, is based on the theory that young children learn music in the same way that they learn their first language.

Scientific-realist education. The scientific-realist education movement began in 1900 when Édouard Claparède, then a doctor at the Psychological Laboratory of the University of Geneva, responded to an appeal from the women in charge of special schools for backward and abnormal children in Geneva. The experience brought him to realize some of the defects of ordinary schools. Not as much thought is given, he argued, to the minds of children as is to their feet. Their shoes are of different sizes and shapes, made to fit their feet. When shall we have schools to measure? The psychological principles needed to adapt education to individual children were expounded in his *Psychologie de l'enfant et pédagogie experimentale* (1909). Later Claparède took a leading part in the creation of the J.-J. Rousseau Institute in Geneva, a school of educational sciences to which came students from all over the world.

Jean Piaget's studies of child development

Theorists such as Claparède hoped to provide a scientific basis for education, an aim that was furthered by the Swiss psychologist Jean Piaget, who studied in a philosophical and psychological manner the intellectual development of children. Piaget argued, on the basis of his observations, that development of intelligence exhibits four chief stages and that the sequence is everywhere the same, although the ages in the stages of development may vary from culture to culture.

The first stage takes place during infancy, when children, even before they learn to speak, put objects together (addition), then separate them (subtraction), perceiving them as collections, rings, networks, groups. By the age of two or three, a basis has been laid. The children have developed kinetic muscular intelligence to some degree—they can think with their fingers, their hands, their bodies. Aided by language, the capacity for symbolic thinking slowly develops. This constitutes the second stage. Up to the age of seven or eight, some of the fundamental categories of adult thinking are still absent: there is seldom any notion, for instance, of cause and effect relationships.

The third stage is that of concrete operation. The child has begun to know how to deal with mental symbols and acquires abstract notions such as "responsibility." But the child operates only when in the presence of concrete objects that can be manipulated. Pure abstract thinking is still too difficult. Teaching at this stage must be exceedingly concrete and active; purely verbal teaching is out of place. Only after about 12 years of age, with the onset of adolescence, do children develop the power to deal with formal mental operations not immediately attached to objects. Only then do theories begin to acquire real significance, and only then can purely verbal teaching be used.

The child's total development, particularly emotional and social growth, also concerned educational reformers. They pointed out the error in assuming that incentives to mental effort are the same for adults and children. The English philosopher Alfred North Whitehead, in his doctrine of the "Cycle of Interests," put forward a theory in line with the ideas of the reformers. Romance, precision, and generalization, said Whitehead, are the stages through which, rhythmically, mental growth proceeds.

> Education should consist in a continual repetition of such cycles. Each lesson in a minor way should form an eddy cycle issuing in its own subordinate process.

Whitehead believed that any scheme of education must be judged by the extent to which it stimulates a child to think. From the beginning of education, children should experience the joy of discovery.

Social-reconstructionist education. Social-reconstructionist education is based on the theory that society can be reconstructed through the complete control of education. The objective is to change society to conform to the basic ideals of the political party or government in power or to create a utopian society through education.

Communist education is probably the most pervasive version of operational social-reconstructionism in the world today. Originally based on the philosophy of Karl Marx and institutionalized in the Soviet Union, it now reaches a large proportion of the world's youth. From the 1950s onward, much attention has been paid to the ideal of "polytechnization." Man, so the argument runs, is not simply *Homo sapiens* but rather *Homo faber,* the constructor and builder. He attains full mental, moral, and spiritual development through entering into social relations with others, particularly in cooperative efforts to produce material, artistic, and spiritual goods and achievements. The school should prepare pupils for such productive activities—for instance, by studying and, if possible, sharing in the work done in field, farm, or factory.

Reconstructionist education in Israel

A different social-reconstructionist movement is that of the kibbutzim (collective farms) of Israel. The most striking feature of kibbutz education is that the parents forgo rearing and educating their offspring themselves and instead hand the children over to professional educators, sometimes immediately after birth. The kibbutzim type of education developed for both practical and economic reasons, but gradually educational considerations gained prominence. These were: (1) that the kibbutz way of life makes for complete equality of the sexes, (2) that the education of children in special children's houses is the best way of perpetuating the kibbutz way of life, (3) that collective education is more "scientific" than education within the family, inasmuch as children are reared and trained by experts (*i.e.,* qualified nurses, kindergarten teachers, and other educators), in an atmosphere free of the tensions engendered by family relationships, and (4) that collective education is more democratic than traditional education and more in keeping with the spirit of cooperative living.

MAJOR TRENDS AND PROBLEMS

The idea of social-reconstructionist education rests on a 19th-century belief in the power of education to change society. In the last quarter of the 20th century there has been considerable pessimism, but the idea that schooling can influence either society or the individual is widely held, affecting the growth of tertiary-level alternatives, management strategies, and education of disadvantaged people, both in industrialized and in developing countries.

Integrative trends

The international concern with assistance to people in the non-Western world has been paralleled by the inclusiveness that has characterized education in the 20th century. Education has been seen as a primary instrument in recognizing and providing equality for those suffering

disadvantage because of sex, race, ethnic origin, age, or physical disability. This has required revisions of textbooks, new consciousness about language, and change in criteria for admission to higher levels. It has led to more demanding definitions of equality involving, for example, equality of outcome rather than of opportunity.

The inclusion of all children and youth is part of a general integrative trend that has accelerated since World War II. It relates to some newer developments as well. Concern for the earth's endangered environment has become central, emphasizing in both intellectual and social life the need for cooperation rather than competition, the importance of understanding interrelationships of the ecosystem, and the idea that ecology can be used as an organizing concept. In a different vein, the rapid development of microelectronics, particularly the use of computers for multiple functions in education, goes far beyond possibilities of earlier technological advances. Although technology is thought of by some as antagonistic to humanistic concerns, others argue that it makes communication and comprehension available to a wider population and encourages "system thinking," both ultimately integrative effects.

The polarization of opinion on technology's effects and most other important issues is a problem in educational policy determination. In addition to the difficulties of governing increasingly large and diverse education systems, as well as those of meeting the never-ending demands of expanding education, the chronic lack of consensus makes the system unable to respond satisfactorily to public criticism and unable to plan for substantive long-range development. The political and administrative responses so far have been (1) to attend to short-run efficiency by improving management techniques and (2) to adopt polar responses to accommodate polar criticisms. Thus, community and community schools have been emphasized along with central control and standardization, and institutional alternatives have been opened, while the structure of main institutions has become more articulated. For example, the focus of attention has been placed on the transition stages, which earlier were virtually ignored: from home to school, from primary to secondary to upper secondary, from school to work. Tertiary institutions have been reconceived as part of a unified level; testing has become more sophisticated and credentials have become more differentiated either by certificate or by transcript. Alternative teaching strategies have been encouraged in theory, but basic curriculum uniformity has effectively restricted the practice of new methods. General education is still mainly abstract, and subject matter, though internally more dynamic, still rests on language, mathematics, and science. There has been an increasing reliance on the construction of subject matter to guide the method of teaching. Teachers are entrusted with a greater variety of tasks, but they are less trusted with knowledge, leading political authorities to call for upgrading of teacher training, teacher in-service training, and regular assessment of teacher performance.

Recent reform efforts have been focused on integrating general and vocational education and on encouraging lifelong or recurrent education to meet changing individual and social needs. Thus, not only has the number of students and institutions increased, as a result of inclusion policies, but the scope of education has also expanded. This tremendous growth, however, has raised new questions about the proper functions of the school and the effectiveness for life, work, or intellectual advancement of present programs and means of instruction.

WESTERN PATTERNS OF EDUCATION

The United Kingdom. *Early 19th to early 20th century.* English education has been less consciously nationalist than that of continental European countries, but it has been deeply influenced by social class structure. Traditionally, the English have held that the activity of the government should be restricted to essential matters such as the defense of property and should not interfere in education, which was the concern of family and church. The growth of a national education system throughout the 19th century continued without a clear plan or a national decision. The cornerstone of the modern system was laid by the Elementary Education Act of 1870, which accepted the principle that the establishment of a system of elementary schools should be the responsibility of the state. It did not, however, eliminate the traditional prominence of voluntary agencies in the sphere of English education. Nor did it provide for secondary education, which was conducted largely by voluntary fee-charging grammar schools and "public" schools. These public schools were usually boarding schools charging rather high fees. Their tradition was aristocratic, exclusive, formal, and classical. Their main goal was to develop "leaders" for service in public life. In 1900 one child in 70 could expect to enter a secondary school of some kind. The grammar schools copied the curriculum of the public schools, so that only the intellectual and social elite were able to attend.

The Elementary Education Act of 1870

In 1899 an advance was made toward the development of a national system encompassing both elementary and secondary education by creating a Board of Education as the central authority for education. The Balfour Act of 1902 established a comprehensive system of local government for both secondary and elementary education. It created new local education authorities and empowered them to provide secondary schools and develop technical education. The Education Act of 1918 (The Fisher Act) aimed at the establishment of a "national system of public education available for all persons capable of profiting thereby." Local authorities were called upon to prepare plans for the orderly and progressive development of education. The school-leaving age was raised to 14, and power was given to local authorities to extend it to 15.

Education Act of 1944. The Education Act of 1944 involved a thorough recasting of the educational system. The Board of Education was replaced by a minister who was to direct and control the local education authorities, thereby assuring a more even standard of educational opportunity throughout England and Wales. Every local education authority was required to submit for the minister's approval a development plan for primary and secondary education and a plan for further education in its area. Two central advisory councils were constituted, one for England, another for Wales. These had the power, in addition to dealing with problems set by the minister, to tender advice on their own initiative. The total number of education authorities in England and Wales was reduced from 315 to 146.

The educational systems of Scotland and Northern Ireland are separate and distinct from that of England and Wales, although there are close links between them. The essential features of the Education Act of 1944 of England and Wales were reproduced in the Education Act of 1945 in Scotland and in the Education Act of 1947 in Northern Ireland. There were such adaptations in each country as were required by local traditions and environment.

The complexity of the education system in the United Kingdom arises in part from the pioneer work done in the past by voluntary bodies and a desire to retain the voluntary element in the state system. The act of 1944 continued the religious compromise expressed in the acts of 1870 and 1902 but elaborated and modified it after much consultation with the parties concerned. The act required that, in every state-aided primary and secondary school, the day should begin with collective worship on the part of all pupils and that religious instruction should be given in every such school. As in earlier legislation there was, however, a conscience clause and another to ensure that no teacher should suffer because of religious convictions. Religious instruction continues to be given in both fully maintained and state-aided voluntary schools, and opportunities exist for religious training beyond the daily worship and minimum required instruction. In many schools the religious offering has become nondenominational, and in areas of high non-Christian immigrant population consideration may be given to alternative religious provision.

Structural changes under the 1944 act

Two fundamental reforms in the act of 1944 were the requirement of secondary education for all, a requirement that meant that no school fees could be charged in any school maintained by public authority; and replacement of the former distinction between elementary and higher ed-

ucation by a new classification of "three progressive stages to be known as primary education, secondary education, and further education." To provide an adequate secondary education in accordance with "age, ability, and aptitude," as interpreted by the Ministry of Education, three separate schools were necessary: the grammar school, modeled on elite public schools, the less intellectually rigorous secondary modern school, and the technical school. If, in exceptional circumstances, such provisions were made in a single school, then the school would have to be large enough to comprise the three separate curricula under one roof. Children were directed to the appropriate school at the age of 11 by means of selection tests.

The tripartite system of grammar, secondary modern, and technical schools did not, in fact, flourish. The ministry had never been specific about the proportion of "technically minded" children in the population, but, in terms of school places provided in practice, it was about 5 percent. Since, on the average, grammar-school places were available to 20 percent, this left 75 percent of the child population to be directed to the secondary modern schools for which the ministry advocated courses not designed to lead to any form of qualification.

The comprehensive movement. Selection procedures at the age of 11 proved to be the Achilles' heel of the grammar school–secondary modern system. Various developments contributed to the downfall of selection at 11: first, the examination successes of the secondary modern schoolchildren; second, the failure of a significant proportion of the children so carefully selected for grammar schools; third, the report of a committee appointed by the British Psychological Society supported arguments that education itself promotes intellectual development and that "intelligence" tests do not in fact measure genetic endowment but rather educational achievement.

The main issue in the 1950s and '60s was whether or not the grammar schools should be retained with selection at 11 plus. One of the main arguments used was that the right of "parental choice" must be upheld. Another was that it was in the "English tradition" to retain a selective system. But gradually the number of comprehensive (nonselective) schools increased.

Policies of Labour and Conservative governments

The Labour Party during the election of 1964 promised to promote the establishment of the comprehensive school and to abolish selection at 11 plus. On taking office, however, the Labour government, instead of legislating, issued a circular in the belief that this would enlist local support and encourage local initiative. The result was conflict between national policy and local policy in some areas. The Conservative government elected in 1970 declared its intention of leaving decisions about reorganization to the local authorities. The comprehensive principle has since become dominant, and the number of comprehensive schools has grown under both Labour and Conservative governments so that most state-maintained secondary schools are now comprehensive. The administrative compromise of leaving organizational options open to local authorities has permitted variations to continue, however. Five to 6 percent of the school population attend completely independent private schools. Enrollment at the exclusively academic, often prestigious, and costly independent secondary schools may be preceded by attendance at private preparatory schools.

The primary school begins at age five and is usually divided into an infant stage (ages five to seven) and a junior stage (ages eight to 11). In those few localities using a middle-school organization, children attend the middle school from age eight or nine to age 13 or 14. Preschool provision is uneven, but a great deal of innovation has taken place in ideas and practices of early-childhood learning. In the infant school children work together with their teacher. Children may be placed together vertically in the same class, like a family group. Play is considered an activity of central significance in the infant school. It is a vehicle for the child's motivation and learning, carefully structured to promote cognitive development. The teacher's job is to set the environment through organization of space, time, and materials; to encourage, guide, and stimulate; and to see that all children learn and develop independence and responsibility. Studies are interrelated, and the curriculum is flexible.

British educational administration

The compromise regarding school organization is representative of the British educational administration's attempt to balance local and national interests delicately. Local education authorities are responsible for basic school operations, and much of the professional responsibility is passed on to the school. This representation of community and professional interest is underscored in policy documents, such as the 1980 Education Act's stipulation that governing boards include at least two parent and two teacher representatives. Local education authorities maintain a professional administrative staff and administer school finances, which are funded primarily by government grants and local property taxes.

Ultimate authority for education is at the national level, with the Department of Education and Science (formerly the Ministry of Education) headed by the secretary of state for education and science. The department is the agent of governmental policy. It reaches schools through circulars and directives as well as through Her Majesty's Inspectors of Schools. The inspectors increasingly advise and report on the general condition of schooling.

Under the Conservative government of Margaret Thatcher emphasis has been placed on management efficiency. While decentralization has applied to operational decisions, the government has increasingly pushed for standardization of curriculum and streamlining of assessment procedures. Traditionally, curriculum had been decentralized to the extreme in the United Kingdom, being a matter of teacher's professional judgment, unified only informally (though effectively) through the influence of teacher training, publicized curriculum projects, textbook choices, and public examination syllabi. This resulted in a great deal of curriculum agreement in the common schooling period, narrowing to a secondary core to age 16, including a wide range of options in the comprehensive school, and different basic curricula in selective systems. Independent schools showed some variations, particularly in the requirement of Latin, and the upper secondary stage was characterized by specialization. Through the 1970s and '80s, however, there was central pressure on curriculum improvement in science, practical elements, technical and vocational education, and the relationship of education to economic life. Influential publications have proposed standardization of the curriculum nationally.

Probably the issue that has received the most attention has been the relationship of education to the economy, to industry, to work. Much of the impact of this attention has been on the post-compulsory sector. Schemes developed outside of the educational establishment are providing training for young school-leavers. The Technical and Vocational Education Initiative calls for local education authority cooperation with the Manpower Services Commission in the introduction of technical courses which span school and post-school training. Recent reforms to the examination and certification system exemplify the government's thrust toward improvement of the education–economy link, toward rationalization of the system, and toward coordinated, standardized assessment procedures.

Further education. Further education is officially described as the "post-secondary stage of education, comprising all vocational and nonvocational provision made for young people who have left school, or for adults." Further education thus embraces the vast range of university, technical, commercial, and art education and the wide field of adult education. It is this sector of education, which is concerned with education beyond the normal school-leaving ages of 16 or 18, that has experienced the most astonishing growth in the number of students.

In the 19th century the dominance of Oxford and Cambridge was challenged by the rise of the civic universities, such as London, Manchester, and Birmingham. Following the lead of the 18th-century German universities and responding to a public demand for increased opportunity for higher education, Britain's new civic universities quickly acquired recognition—not only in technological fields but also in the fine and liberal arts.

Many new post-school technical colleges were founded

in the early 20th century. The Fisher Act of 1918 empowered the local authorities to levy a rate (tax) to finance such colleges. The universities, on the other hand, received funds from the central government through the University Grants Committee, established in 1911 and reorganized in 1920, after World War I.

A new type of technical college was established in the 1960s—the polytechnic, which provides mainly technological courses of university level as well as courses of a general kind in the arts and sciences. Polytechnics are chartered to award degrees validated by a Council for National Academic Awards.

Thus, the tertiary level in the United Kingdom is made up of colleges of further education, technical colleges, polytechnics, and universities. The colleges offer full-time and part-time courses beyond compulsory-school level. Polytechnics and universities are mainly responsible for degrees and research. The innovative Open University, with its flexible admission policy and study arrangements, opened in 1971. It uses various media to provide highly accessible and flexible higher education for working adults and other part-time students. It serves as an organizational model and provides course materials for similar institutions in other countries.

The Open University

Changes in British education in the second half of the 20th century have, without changing the basic values in the system, extended education by population, level, and content. New areas for expansion include immigrant cultural groups and multicultural content, the accommodation of special needs, and the development of tools and content in the expanding fields of microelectronics.

Germany. *Imperial Germany.* The formation of the German Empire in 1871 saw the beginning of centralized political control in the country and a corresponding emphasis on state purposes for education. Although liberal and socialist ideas were discussed, and even practiced in experimental schools, the main features of the era were the continued systematization of education, which had progressed in Prussia from 1763, and the class-based division of schools. Education for the great bulk of the population stressed not only literacy but also piety and morality, vocational and economic efficiency, and above all obedience and discipline. The minority of citizens in the upper social and economic strata were educated in separate schools according to a classical humanist rationale of intelligence and fitness that equipped them to fill the higher positions in the Reich. Reform proposals in the last decade of the 19th century led to an overhaul of the education system, but the changes did not remove class privileges.

The *Volksschule* was universal, free, and compulsory. The fundamental subjects were taught along with gymnastics and religion, which held important places in the curriculum. Girls and boys were taught in separate schools except when it was uneconomical to do so. Boys usually received training in manual work, and girls in domestic science. Graduates of the *Volksschule* found it almost impossible to enter the secondary school, which was attended almost exclusively by graduates of private preparatory schools charging fees. The *Volksschule* led its students directly to work and was thus separate and parallel to the secondary-school program rather than sequential.

The *Volksschule*

Boys who, at the age of nine, were about to enter secondary school had to decide on one of the three types of schools, each offering a different curriculum. The traditional classical *Gymnasium* stressed Latin and Greek. The *Realgymnasium* offered a curriculum that was a compromise between the humanities and modern subjects. The *Oberrealschule* stressed modern languages and sciences. Although Kaiser William II threw his influence on the side of the modernists in 1890, the *Gymnasium* continued to overshadow the other two schools until after World War II.

Secondary schools for girls were recognized by Prussia in 1872 and were extended and improved in 1894 and again in 1908. These schools were fee-paying and were thus available chiefly to the upper social and economic strata. The course of instruction lasted 10 years, from six to 16. This 10-year school was called the *Lyzeum,* the first three years being preparatory. Beyond it was the *Oberlyzeum,* which was divided into two courses: the *Frauenschule,* which offered a two-year general course, and the *Lehrerinnenseminar,* which offered a four-year course for prospective elementary-school teachers. Girls who wanted a secondary-school education similar to that of the boys transferred at the age of 13 to the *Studienanstalt.*

Continuation schools for the working class augmented apprenticeship training with part-time education. They were the forerunners of the part-time vocational *Berufsschulen,* which continue today. Greatly influenced by the ideas of Georg Kerschensteiner, these schools increased in importance in the early 20th century. Between 1919 and 1938 they filled out the secondary sector to ensure attendance at some kind of school for all youth to the age of 18.

Weimar Republic. In no sphere of public activity did the establishment of the Weimar Republic after 1919 cause more creative discussion and more far-reaching changes than in that of education. A four-year *Grundschule* was established, free and compulsory for all children. It was the basic building block for all subsequent social liberalization in education. Besides the elementary subjects and religion, the child was instructed in drawing, singing, physical training, and manual work. The *Oberstufe,* the four upper classes of the elementary school, combined with the *Grundschule,* formed a complete whole. Most elementary schools thus provided an eight-year course of study. Intermediate schools (*Mittelschulen*) were established for children who wished a longer and more advanced elementary-school course and were able to pay modest fees.

The Weimar constitution preserved the religious tradition, which had been an essential part of the school curriculum in Germany since the Reformation. No pupil, however, could be compelled to study religion, and no teacher could be forced to teach it. Communities were accorded the right to establish schools in accordance with the particular religious beliefs of the pupils.

As regards secondary education, the Weimar Republic kept the prewar division of *Gymnasium, Realgymnasium,* and *Oberrealschule.* (There were three comparable schools for girls.) In addition, there was established the *Aufbauschule,* which was a six-year school following completion of the seventh year of the elementary school, and the *Deutsche Oberschule,* a nine-year school that required two modern foreign languages and stressed German culture.

Secondary schools in the Weimar period

Nazi Germany. After Adolf Hitler's accession to power in 1933, the Nazis set out to reconstruct Germany society. To do that, the totalitarian government attempted to exert complete control over the populace. Every institution was infused with National Socialist ideology and infiltrated by Nazi personnel in chief positions. Schools were no exception. Even before coming to power, Hitler in *Mein Kampf* had hinted at his plans for broad educational exploitation. The Ministry of Public Enlightenment and Propaganda exercised control over virtually every form of expression—radio, theatre, cinema, the fine arts, the press, churches, and schools. The control of the schools began in March 1933 with the issuing of the first educational decree, which held that "German culture must be treated thoroughly."

The Nazi government attempted to control the minds of the young and thus, among other means, intruded Nazi beliefs into the school curriculum. A major part of biology became "race science," and health education and physical training did not escape the racial stress. Geography became geopolitics, the study of the fatherland being fundamental. Physical training was made compulsory for all, as was youth labour service. Much of the fundamental curriculum was not disturbed, however.

Changes after World War II. Immediately after World War II the occupying powers (Britain, France, and the United States in the western zones and the Soviet Union in the east) instituted education programs designed to clean out Nazi influence and to reflect their respective educational values. These efforts were soon absorbed into independent German educational reconstruction. The Basic Law of the Federal Republic of Germany (West Germany) of May 1949 granted autonomy in educational matters to the *Länd* (state) governments. Although efforts to strengthen the federal government's presence have waxed and waned, *Länd* governments remain independent and divided along political lines on educational reforms.

The two main political issues dividing the states have always been confessional schooling and the tripartite division of secondary schooling, with conservative states like Bavaria and Baden-Württemberg on the one side and socially progressive states like Hessen and West Berlin on the other. After a 20-year period of reform discussion on these issues, marked by influential state or national proposals, the balance shifted in the mid-1970s to the conservatives, albeit with a great deal of internal liberalization. That is, confessional schools and confessional instruction in schools remained, but the latter was increasingly in ecumenical or ethical versions. This change, like others, has been supported by the presence of a large number of non-German children representing various cultural beliefs and behaviours. On the issue of dividing secondary schools, in spite of continued strong intellectual and political support from some quarters, the movement toward comprehensive schools has at least for the time being died out. Even where comprehensive schools (*Gesamtschulen*) exist, they usually incorporate separate secondary paths. Nevertheless, the effective extension of common schooling through an "orientation stage" between elementary and secondary schooling, the attempt to develop each level so that it better serves more youth, even if differentially, and the functional integration of school branches through curriculum reform and transfer possibilities all point to a comprehensiveness within the system.

The German school structure

Education is compulsory from age six to 18. In general, pupils spend four years in the elementary school (*Grundschule*), six years in one of the lower secondary branches, and two years in one of the upper secondary branches. The first two years of the lower secondary school constitute the "orientation stage." Long governed by entrance examination, the choice of secondary school is now made by the parents, although performance at the orientation stage, especially in the subjects of German, mathematics, and foreign language (English), influences decisions.

About 25 percent of secondary-school-age children enter the *Gymnasium,* which, with different academic emphases, remains the successor to its classical ancestor. Roughly 40 percent attend the nonselective *Hauptschule* ("main school"), which offers basic subjects to grade nine or 10 and is followed by apprenticeship with part-time vocational school or by full-time vocational school. Approximately 25 percent attend the *Realschule* (formerly *Mittelschule*), which offers academic and prevocational options. It leads to vocational school or technical school, which in turn lead to commercial, technical, or administrative occupations. The vocational-technical sector has always been given careful government and industry attention, and the network now includes a wide range of methods and content alternatives, with levels up to a university equivalent. All of these institutions encompass general education, theory of the trade or industrial field, and work practice. The schools can be reentered from work and can provide an alternative path to the university.

One of the means of coordinating differences among *Länd* systems has been through the Conference of the Cultural Ministers of the states, and one of the important resolutions of this body, in 1973, was for reform of the upper secondary stage. Attention has been given to equalizing opportunities at this stage. This has affected the *Gymnasium* by shifting much of the traditional load to the upper level. Although the first stage is still academically demanding, the foreign-language requirement is much more flexible, and many students now leave for work at the end of the 10th school year. The upper level is required to reach the *Abitur,* qualifying the student for university entrance. Although the range of subjects has been extended, courses have been diversified, and final achievement is now indicated by a cumulative point system. The upper level of the *Gymnasium* is characterized by breadth of knowledge at a high intellectual standard, including cultural essentials as well as an academic concentration, and thus still captures the German educational ideal.

Whether due to periodic change, German tradition, or inadequate understanding of the reform process, the educational system has irresistibly returned to basic principles. The incorporation of new alternatives and individual opportunities yields an open rather than a fundamentally changed system. This may be the best way for education to meet the major political themes of modern Germany: individual rights as the criterion of policy determination and the European community as the broader context of national development.

France. *The Third Republic.* The establishment of the Third Republic (1870) brought about the complete renovation of the French schools, in the process of which education became a national enterprise. In 1882 primary education was made compulsory for all children between the ages of six and 13. In 1886, members of the clergy were forbidden to teach in the public schools, and in 1904 the teaching congregations were suppressed. France had thus established a national free, compulsory, and secularized system of elementary schooling. (Although secularization was a necessary government strategy, it was also necessary to permit private Catholic schools, and these have continued to enroll a significant number of French children.)

In spite of the attempt to unify education through national purpose and centralized means, two parallel systems existed, that of the public elementary schools and higher primary schools and that of the selective, overwhelmingly intellectual secondary lycées and their preparatory schools. The lycées emphasized classical studies through the study of Greek and Latin. It was not until 1902 that this exclusive emphasis was challenged by a reform promoting the study of modern languages and science and not until the period between World Wars I and II that education was seen to have a vocational function, other than grossly in a social-class sense, and thus to require democratization.

Centralized administration in French education

The administration of education in France has remained highly centralized and has continued to be concerned with every aspect of national education, including curricula, syllabi, textbooks, and teacher performance. At the head of the system is the minister of national education, who is advised and assisted by a hierarchy of officials. The country is divided into 27 educational administrative areas, each known as an "academy." The chief education officer is the rector, the minister's most important representative, who administers the laws and regulations. The inspectorate, represented by regional inspectors under an *inspecteur d'académie* and by national inspectors, has extensive bureaucratic and supervisory powers.

Changes after World War II. Since 1946 education has been included in the plans developed by the central planning commission in France. In general, government has been friendly to educational development and reform. Student protests in the late 1960s caused an antagonistic reaction, however, and teacher resistance appears to work against many government reform initiatives. Government reform trends in recent years have been toward increasing administrative efficiency and accountability, meeting national economic needs through improved technological education, improving the articulation of system parts, opening the school to the community, and correcting inequalities, through both curricular and organizational provisions. Attention has been given not only to "socializing" the system but also to correcting inequalities suffered by French ethnic minorities and immigrant children, to amending social-geographic inequalities, and to increasing options for the handicapped, in both special schools and, after the mid-1970s, regular schools.

The French school structure

In 1947 a commission established to examine the educational system recommended a thorough overhauling of the entire school system. Education was to be compulsory from the age of six to 18. Schooling was to be divided into three successive stages: (1) six to 11, aimed at mastery of the basic skills and knowledge, (2) 11 to 15, a period of guidance to discover aptitudes, and (3) 15 to 18, a stage during which education was to be diversified and specialized. The system has since consistently developed from one featuring a common elementary school to one incorporating a progression into separate paths. Reforms have aimed to provide equality of educational experience at each stage and to create curricular conditions that further career advancement without abridging general education or forcing students to choose a profession prematurely.

Preschool education is given in the *école maternelle,* in

which attendance is voluntary from the age of two to six years. Education is compulsory between six and 16 years of age and is free. The five-year elementary school is followed by a four-year lower secondary school, the *collège unique,* which has been the object of much attention. The first two years at the *collège unique* constitute the observation cycle, during which teachers observe student performance; during the remaining two years, the orientation cycle, teachers offer guidance and assist pupils in identifying their abilities and determining a career direction.

At the upper secondary level, from age 15 to 18, students enter either the general and technological high school (*lycée d'enseignement général et technologique*), successor to the traditional academic high school, or the vocational senior high school (*lycée d'enseignement professionel*), encompassing a range of vocational-technical studies and qualifications. Students entering the former choose one of three basic streams the first year, then concentrate the next two years on one of five sections of study: literary-philosophical studies, economics and social science, mathematics and physical science, earth science and biological science, or scientific and industrial technology. The number of sections and particularly the number of technological options is scheduled to be expanded. There is a common core of subjects plus options in grades 10 and 11, but all subjects are oriented to the pupil's major area of study. In grade 12 the subjects are optional. The *baccalauréat* examination taken at the end of these studies qualifies students for university entrance. It consists of written and oral examinations. More than half of the 70 percent who pass are females. The proportion of the age group reaching this peak of school success has risen continuously, with corresponding effects on entrance to higher education.

Vocational-technical secondary education includes a number of options. Each of the courses leading to one of the 30 or so technical *baccalauréats* requires three years of study and gives access to corresponding studies in higher education. Students may also choose to obtain, in descending order of qualification requirements and course demands, the technician diploma (*brevet de technicien*), the diploma of vocational studies (*brevet d'études professionelles*), or the certificate of vocational aptitude (*certificat d'aptitude professionelle*). A one-year course conferring no particular qualification is also available, or youths may opt for apprenticeship training in the workplace.

French university education

Higher education is offered in universities, in institutes attached to a university, and in the *grandes écoles.* Students attend for two to five years and sit either for a diploma or, in certain establishments, for university degrees or for a competitive examination such as the agrégation. Undergraduate courses last for three or four years, depending on the type of degree sought.

The universities went through a period of violent student dissatisfaction in the late 1960s. Reforms ensued encouraging decentralization, diversification of courses, and moderation of the importance of examinations. Nevertheless, the failure or dropout rate in the first two years is still high, and there are marked differences in status among institutions and faculties.

Teachers are graded according to the results of a competitive academic examination, and their training and qualifications vary by grade. The five grades range from the elementary teacher to the highly qualified graduate agrégé, who enjoys the lightest teaching load and the highest prestige and who teaches at the secondary level or higher. The differences have long been a matter of concern, as has the entrenchment of the higher levels of the teaching establishment, which has resisted reforms calling for more uniformity in teacher status as well as changes in method and content orientation, encouraging teacher cooperation, interdisciplinarity, and technological familiarity. Reforms to extend the level of common education, to increase options at the upper secondary level, to strengthen the technological component, and to introduce steps to improve the link between school and work have nonetheless been achieved. Internal reform proposals include the more flexible organization of time and content and the addition of extracurricular activities appropriate to the real life of youth and society. Government forays into decentralization have promoted community links at the school level and school program initiatives. The outcomes will at best affect the system gradually, however.

Other European countries. Most eastern European systems of education follow the Soviet model (see below). In western Europe many countries have been influenced by the British, German, and French systems, but there are numerous variations, some of which are discussed here.

Italy. Education in Italy up to 1923 was governed by the Casati Law, passed in 1859, when the country was being unified. The Casati Law organized the school system on the French plan of centralized control. In 1923 the entire national school system was reformed. The principle of state supremacy was reinforced by introducing at the end of each main course of studies a state examination to be taken by pupils from both public and private schools.

Eight years of schooling has been compulsory since 1948, although this plan was not realized until 1962. The five-year elementary school, for pupils aged six to 11, is followed by the undifferentiated middle or lower secondary school (*scuola media*) for pupils from 11 to 14. There continues to be a strong private (mainly Roman Catholic) interest in preschools and in teacher training for elementary and preschool levels.

Although reform proposals call for an extension of the unitary principle through the five-year upper secondary level, this level is highly diversified, with classical and scientific *licei* (schools) and a vast array of programs in vocational and industrial technical institutes. Shorter courses are given in institutes for elementary teachers and in art schools.

Italian university education

Entrance to Italian universities is gained by successful completion of any of the upper secondary alternatives. Universities are basically the only form of postsecondary education. They require the passing of a variable number of examinations, at the end of which the students sit for a degree (*laurea*), which gives them the title of *dottore.* To be able to exercise any profession, such as that of lawyer, doctor, or business consultant, the student must take a state examination. Students who do not complete their studies in the normal period of time, from four to six years, may remain at the university for several years as *fuori corso* ("out of sequence").

The unification of the lower levels and the expansion of academic and particularly vocational-technical alternatives at the upper level are notable advances, but the Italian education system still suffers from fragmentation and lack of articulation. Indications of low achievement and regional inequalities, in spite of relatively heavy public investment, suggest problems with system effectiveness. The force of conservative political, religious, and educational resistance to change is likely to maintain divisions of policy and outcome.

The Netherlands. The first modern school law in the Netherlands was passed in 1801, when the government laid down the principle that each parish had the right to open and maintain schools. A debate between the proponents of denominational and nondenominational schools went on during the 19th century. The controversy was closed by a law of 1920, which declared that denominational schools were fully equal with state schools, both types being eligible for public funds. The resultant decentralization is unique. Roughly two-thirds of the Dutch school-age children attend private schools. In return for public funds, the private school, which may be Protestant, Roman Catholic, or secular, must provide a curriculum equivalent to that offered by the public schools.

Religious-philosophical diversity is a characteristic feature of Dutch schools. Secondary education comprises four main types, which may be further differentiated: preuniversity, general, vocational, and miscellaneous, which may be part-time. Selection decisions are strongly influenced by examinations. Preprimary and primary schools were recently combined into single eight-year schools for children aged four to 12. Other recent changes include the growth of vocational education at the postsecondary level and the increase in opportunity for females, as indicated by increasing enrollment at higher levels and by the estab-

lishment of special programs, such as that giving women whose schooling was interrupted the chance to return and finish their education.

Switzerland. The Swiss constitution of 1874 provided that each canton or half canton must organize and maintain free and compulsory elementary schools. The federal government exercises no educational function below the university level, except to help finance the municipal and cantonal schools. The Swiss school system thus consists of 26 cantonal systems, each having its own department of education, which sets up its own school regulations. The Swiss Conference of Cantonal Directors of Education has increased its efforts to achieve some educational unity, but great diversity remains.

In general, schooling is compulsory for eight or nine years, beginning at the age of six or seven. The elementary and lower secondary curriculum continues to stress mathematics and language. Cantonal differences in the training of elementary-school teachers remain a matter of concern, but provisions for additional training of in-service teachers are good. Each cantonal system begins to diversify at the lower secondary level and is even further differentiated at the post-compulsory upper secondary level. The pupil's future professional life is a decisive factor in the selection of post-compulsory schooling. Most pupils enter one of the many vocational courses, in which apprenticeship has long played a serious role. Among preuniversity schools, three types have been added to the two traditional ones emphasizing classical languages; the new schools stress mathematics and science (1925), modern languages (1972), and economics (1972). New proposals favour the consolidation of the preuniversity schools.

Swedish educational reforms

Sweden. After World War II the Swedish government began to extend and unify the school system, which had historically been the domain of the Lutheran church. In 1950 the National Board of Education introduced a nine-year compulsory comprehensive school, with differentiation of pupils postponed until late in the program. This *grundskola* replaced all other forms in the compulsory period by 1972–73. Following the unification of the elementary and lower secondary levels was the systematic integration of the upper secondary level, covering ages 16 to 19. This *gymnasieskola* uses organizational and extracurricular means of integration, but students are separated into 25 "lines," of which many are general-academic but most are vocational. Reforms have been implemented to make higher education available to more people, and adult education is encouraged.

The Swedish reform has attracted much attention in Europe for several reasons. It achieved the earliest unequivocal unification of the compulsory-school sector. While moving toward increased levels of integration in the system, the reciprocity of differentiation and integration was used as a principle of school development. As a result, the vocational sector was incorporated into the general upper secondary school. Theory and practice were recognized as components of all programs. The reform process, which specified a long period of experimentation and voluntary action (1950 to 1962) and a correspondingly long period of implementation (1962 to 1972), was singularly well conceived to build planning into participation and practice. The resultant organization is stable but open to change on the same principles. Thus, the new equality thrust goes beyond establishing equal opportunity to providing compensatory measures, even though they sometimes limit free choice, as, for example, in the use of sex quotas to bring women or men into occupations where they had been underrepresented.

Attention has also been focused on the Swedish approach to recurrent education, which introduces the idea of interchanging school and work as early as the secondary level. The coordination of school and work life, which is a worldwide goal, is not only built into institutional programs in Sweden but is also pursued there at a grassroots level through local councils.

(J.A.L./R.L.Sw./R.F.L.)

The United States. As the United States entered the 20th century, the principles that underlie its present educational enterprise were already set. Educational sovereignty rested in the states. Education was free, compulsory, universal, and articulated from kindergarten to university, though the amount of free schooling varied from state to state, as did the age of required school attendance. Although a state could order parents to put their children to their books, it could not compel them to send them to a public school. Parents with sectarian persuasions could send their offspring to religious schools. In principle there was to be equal educational opportunity.

American principle of equal educational opportunity

Expansion of American education. Though such principles remained the basis of America's educational endeavour, that endeavour, like America, has undergone a vast evolution. The once-controversial parochial schools have not only continued to exist but have also increasingly drawn public financial support for programs or students. The currency of privatization, carrying the idea of free choice in a private-sector educational market, strengthens the bargaining position of religious as well as other private schools. The issue of equality has succeeded the issue of religion as the dominant topic of American educational debate. Conditions vary markedly among regions of the country. Definitions of equal opportunity have become more sophisticated, referring increasingly to wealth, region, physical disability, race, sex, or ethnic origin, rather than simply to access. Means for dealing with inequality have become more complex. Since the 1950s, measures to open schools, levels, and programs to minority students have changed from the passive "opportunity" conception to "affirmative action." Measured by high-school completion and college attendance figures, both generally high and continually rising in the United States, and by standardized assessment scores, gains for blacks and other minority students have been noteworthy from the 1970s. Although state departments of education use equalization formulas and interdistrict incentives to reach the poorest areas under their jurisdiction, conditions remain disadvantageous and difficult to address in some areas, particularly the inner cities, where students are mostly minorities. City schools often represent extremes in the array of problems facing youth generally: drug and alcohol abuse, crime, suicide, unwanted pregnancy, and illness; and the complex situation seems intractable. Meeting the needs of a racially and ethnically mixed population has, however, turned from the problem of the cities and from an assimilationist solution toward educational means of knowing and understanding the disadvantaged groups. States have mandated multicultural courses in schools and for teachers. Districts have introduced bilingual instruction and have provided instruction in English as a second language. Books have been revised to better represent the real variety in the population. The status of women has been given attention, particularly through women's studies, through improved access to higher education (women are now a majority of U.S. college students) and to fields previously exclusive to men, and through attempts to revise sexist language in books, instruction, and research.

Programs of special education

The idea persists that in the American democracy everyone, regardless of condition, is expected to have a fair chance. Such is the tenet that underlay the establishment of the free, tax-supported common school and high school. As science pointed the way, the effort to bridge the gulf between the haves and have-nots presently extended to those with physical and mental handicaps. Most states and many cities have long since undertaken programs to teach the handicapped, though financially the going has been difficult. In 1958 Congress appropriated $1 million to help prepare teachers of mentally retarded children. Thenceforward, federal aid for the handicapped steadily increased. With the Education for All Handicapped Children Act of 1975—and with corresponding legislation in states and communities—facilities, program development, teacher preparation, and employment training for the handicapped have advanced more rapidly and comprehensively than in any other period. Current reforms aim to place handicapped children in the least restrictive environment and, where possible, to "mainstream" them in regular schools and classes.

As the century began, American youths attended an eight-year elementary school, whereupon those who continued

went to a four-year high school. This "eight–four system" wholly prevailed until about 1910, when the "six–three–three system" made a modest beginning. Under the rearrangement, the pupil studied six years in the elementary and three in the junior and senior high schools, respectively. Both systems are in use, there being almost the same number of four-year high schools and three–three junior–senior high school arrangements. There has been a change at the elementary–junior high connection to include a system in which children attend an elementary school for four or five years and then a middle school for three or four years. The rapid growth of preschool provisions, with the establishment of an immense body of early-childhood teachers, day-care workers, new "nannies," producers of learning materials, and entrepreneurs, has secured the place of the kindergarten as an educational step for five-year-olds and has made available a wide, but mainly non-public, network of education for younger children.

In 1900 only a handful of the lower school's alumni—some 500,000—advanced into the high school. Of those who took their high-school diploma during this early period, some three out of every four entered college. The ratio reversed, as high-school enrollments swelled 10-fold over the first 50 years of the century, with only one of every four high-school graduates going on to higher learning. As even more students finished high school (more than 75 percent by 1980), demands for access to the post-secondary level increased until nearly half of all high-school graduates, or nearly one-third of the age group, were entering college.

From such experimental programs as the Dalton Plan, the Winnetka Plan, and the Gary Plan, and from the pioneering work of Francis W. Parker and notably John Dewey, which ushered in the "progressive education" of the 1920s and '30s, American schools, curricula, and teacher training have opened up in favour of flexible and cooperative methods pursued within a school seen as a learning community. The attempt to place the nature and experience of the child and the present life of the society at the centre of school activity was to last long after progressive education as a defined movement ended.

Some retrenchment occurred in the 1950s as a result of scientific challenges from the Soviet Union in a period of international political tension. Resulting criticisms of scientific education in the United States were, however, parried by educationists. America's secondary school attuned itself more and more to preparing the young for everyday living. Consequently, though it still served prospective collegians the time-honoured academic fare, it went to great lengths to accommodate the generality of young America with courses in automobile driving, cookery, carpentry, writing, and the like. In addition to changes in the form of earlier practical subjects, the curriculum has responded to social issues by including such subjects as consumer education (or other applications of the economics of a free-enterprise society), ethnic or multicultural education, environmental education, sex and family-life education, and substance-abuse education. Recent interest in vocational-technical education has been directed toward establishing specialized vocational schools, improving career information resources, integrating school and work experience, utilizing community resources, and meeting the needs of the labour market.

Expansion of American high-school curriculum

National prosperity and, even more, the cash value that a secondary diploma was supposed to bestow upon its owner enhanced the high school's growth. So did the fact that more and more states required their young to attend school until their 16th, and sometimes even their 17th, birthday. Recently, however, economic strains, the ineffectiveness of many schools, and troubled school situations in which the safety of children and teachers has been threatened have led to questions about the extension of "compulsory youth" in high schools.

Criticisms have also been leveled at the effects and after-effects on education of 1960s idealism and its conflict with harsh realities. The publicized emphases on alternatives in life-style and on deinstitutionalization were ultimately, in their extreme form, destructive to public education. They were superseded by conservative attitudes favouring a return to the planning and management of a clearly defined curriculum. The dramatic fall in scores on the Scholastic Aptitude Test (a standardized test taken by a large number of high-school graduates) between 1963 and 1982 occasioned a wave of public concern. A series of national, state, and private-agency reviews followed. The report of the National Commission on Excellence in Education, *A Nation at Risk* (1983), set the tone. The emphasis was now on quality of school performance and the relation of schooling to career. The main topics of concern were the curriculum, standardization of achievement, credentialing, and teacher preparation and performance. In order to clarify what is expected of teachers and students, states have increasingly detailed curricula, have set competency standards, have mandated testing, and have augmented the high-school diploma by adding another credential or by using transcripts to show superior achievement. Curriculum reforms have accentuated the academic basics, particularly mathematics, science, and language, as well as the "new basics," including computers. Computers have become increasingly important in education not only as a field of study but also as reference and teaching aids. Teachers are using computers to organize and prepare course materials; children are being taught to use computers at earlier ages; and more and more institutions are using computer-assisted instruction systems, which offer interactive instruction on a one-on-one basis and can be automatically modified to suit the user's level of ability. Other technological developments, such as in broadcasting and video production, are being employed to increase the availability of quality education.

The reports on the state of education also expressed concern for gifted children, who have tended to be neglected in American education. Until psychologists and sociologists started to apply their science to the superior child, gifted children were not suspected of entertaining any particular problems, apart from occasionally being viewed as somewhat freakish. Eventually, however, augmented with federal, state, and sometimes foundation money, one city after another embarked on educational programs for the bright child. From the 1970s, gifted children were directly recruited into special academic high schools and other local programs. American education is still aimed at broadening or raising the level of general provision, however, so neither programs for the gifted nor those for vocational education have been treated as specifically as in some other countries.

Federal involvement in local education

Although the U.S. Constitution has delegated educational authority to the states, which have in turn passed on the responsibility for the daily administration of schools to local districts, there has been no lack of federal counsel and assistance. Actually, national educational aid is older than the Constitution, having been initiated in 1787 in the form of land grants. Seventy-five years later the Morrill Act disbursed many thousands of acres to enable the states to promote a "liberal and practical education." Soon thereafter, the government created the federal Department of Education under the Department of the Interior and, in 1953, established the Office of Education in the Department of Health, Education, and Welfare. As the independent Department of Education from 1980, this agency has taken a vigorous role in stating national positions and in researching questions of overall interest. Its findings have proved influential in both state and local reforms.

Financing of education is shared among local districts, states, and the federal government. Beginning with the Smith–Lever Act of 1914, Congress has legislated measure upon measure to develop vocational education in schools below the college plane. A new trail was opened in 1944, when the lawgivers financed the first "GI Bill of Rights" to enable veterans to continue their education in school or college.

During the 1960s, school difficulties experienced by children from disadvantaged families were traced to lack of opportunities for normal cognitive growth in the early years. The federal government attempted to correct the problem and by the mid-1960s was giving unprecedented funding toward compensatory education programs for disadvantaged preschool children. Compensatory interven-

tion techniques include providing intensive instruction and attempting to restructure home and living conditions. The Economic Opportunity Act of 1964 provided for the establishment of the Head Start program, a total program that was designed to prepare the child for success in public schools and that includes medical, dental, social service, nutritional, and psychological care. Head Start has grown steadily since its inception and has spawned similar programs, including one based in the home and one for elementary-school-age children. In the 1970s child development centres began pilot programs for children aged four and younger. Other general trends of the late 1970s include: extending public schools downward to include kindergarten, nursery school, child development centres, and infant programs; organizing to accommodate culturally different or exceptional children; including educational purposes in day care; extending the hours and curriculum of kindergartens; emphasizing the early-childhood teacher's role in guiding child development; "mainstreaming" handicapped children; and giving parents a voice in policy decisions. Early-childhood philosophy has infiltrated the regular grades of the elementary school. Articulation or interface programs allow preschool children to work together with first graders, sharing instruction. Extended to higher grades, the early-childhood learning methods promote self-pacing, flexibility, and cooperation.

Changes in higher education. The pedagogical experimentalism that marked America's elementary learning during the century's first quarter was less robust in the high school and feebler still in the college. The first venture of any consequence into collegiate progressivism was undertaken in 1921 at Antioch College, in Ohio. Antioch required its students to divide their time between the study of the traditional subjects and the extramural world, for which, every five weeks or so, they forsook the classroom to work at a full-time job. In 1932 Bennington College for women, in Vermont, strode boldly toward progressive ends. Putting a high value on student freedom, self-expression, and creative work, it staffed its faculty largely with successful artists, writers, musicians, and other creative persons, rather than Ph.D.'s. It also granted students a large say in making the rules under which they lived.

Experiments at Antioch, Bennington, Chicago, and Harvard

Such developments in America's higher learning incited gusty blasts from Robert M. Hutchins, president and then chancellor of the University of Chicago from 1929 to 1951. He recommended a mandatory study of grammar, rhetoric, logic, mathematics, and Aristotelian metaphysics. One consummation of the Hutchins prescription is the study of some 100 "great books," wherein reside the unalterable first principles that Hutchins insisted are the same for all men always and everywhere.

The vocationalism that Hutchins deplored was taken to task by several others, but with quite different results—notably by Harvard in its report on *General Education in a Free Society* (1945). Declaring against the high school's heavy vocational leaning, it urged the adoption of a general curriculum in English, science, mathematics, and social science.

In the great expansion of higher education between about 1955 and 1975, when expansionist ideas about curriculum and governance prevailed, colleges became at times almost ungovernable. New colleges and new programs made the higher-education landscape so blurred that prospective students and admissions officers in other countries needed large, coded volumes to characterize individual institutions. The college curriculum, like that of the high school, was altered in response to vocal demands made by groups and had expanded in areas representing realities of contemporary social life. Internal reviews, undergraduate curriculum reforms, and the high standards set by some universities demonstrated to some observers that quality education was being maintained in the university. Other critics, however, felt that grade inflation, the multiplication of graduate programs, and increasing economic strains had led to a decline in quality. Financial problems and conservative reactions to the more extreme reforms led some universities to place a strong emphasis on management.

The junior college

Probably the most significant change in higher education has been the establishment and expansion of the junior college, which was conceived early in the century by William Rainey Harper, president of the University of Chicago. He proposed to separate the four-year college into an upper and a lower half, the one designated as the "university college" and the other as the "academic college." The junior college is sometimes private but commonly public. It began as a two-year school, offering early college work or extensions to secondary education. It has since expanded to include upper vocational schools (including a wide range of technical and clerical occupations), community colleges (offering vocational, school completion, and leisure or interest courses), and pre- or early-college institutions. Junior colleges recruit from a wide population range and tend to be vigorous innovators. Many maintain close relationships with their communities. Colleges limited to the undergraduate level, especially in articulated state systems, may not differ much from well-developed junior colleges.

Professional organizations. American educators began to organize as early as 1743, when the American Philosophical Society was founded, and they have been at it increasingly ever since. Not a few of their organizations, such as the American Historical Association, the Modern Language Association of America, and the American Home Economics Association, are for the advancement of some specialty. Others are more concerned with the interests of the general educational practitioner. Of these the National Education Association (NEA) is the oldest. Founded in 1857, it undertook "to elevate the character and advance the interest of the teaching profession." Despite its high mission, it threw off no sparks, and it was not until after 1870 that it began to grow and prosper. With headquarters in Washington, D.C., the NEA conducts its enormous enterprise through a brigade of commissions and councils. A youngster by comparison, the American Federation of Teachers, an affiliate of the AFL-CIO, was formed in 1916. Through collective bargaining and teachers' strikes, it has successfully obtained for teachers better wages, pensions, sick leaves, academic freedom, and other benefits. The distinction between a union and a professional organization is neither as clear nor as important an issue as it was in earlier days.

Such bodies as the American Association of Colleges for Teacher Education, the American Association of University Professors, the American Educational Research Association, the National Commission on Teacher Education and Professional Standards, and the National Council for Accreditation of Teacher Education have laboured industriously and even with a fair success to bring order and dignity to the teaching profession. Nevertheless, teaching has become an increasingly arduous profession in the United States. Even the security formerly assocated with the profession is in question as waves of teacher shortages and surpluses generate frantic responses by educational authorities. Recent educational reviews have addressed teaching inadequacies by encouraging prospective teachers to earn degrees in other subjects before beginning studies in the field of education. They have recommended establishing proficiency tests, regular staff-development activities, certification stages, and workable teacher-evaluation and dismissal procedures. They insist on the necessity for the reform and evaluation of training programs, and some have questioned the institutional context of teacher training.

(A.E.M./R.F.L.)

Elder members of the British Commonwealth. *Canada.* Although a Canadian nation had been formed by the end of the 19th century, separate political, economic, and geographic influences continued through the 20th century to restrain unified educational development. The historical principle of maintaining minority rights resulted in a truly pluralistic cultural concept, recognized to some extent in religious and linguistic concessions in schools. Each provincial system developed unilaterally, thus producing separately centralized educational units; and, even within a province, the evolving principle of local responsibility and the sparseness of settlement in many areas of Canada challenged the effectiveness of simple control principles. Different production emphases and differential advantages of territorial acquisition after confederation in 1867 cre-

ated basic inequalities among the provinces, with a corresponding effect on schools. Finally, European principles of education were slow to be reconciled with those evolving out of the North American environment. Canadian educational development has consequently been marked by eclectic, pragmatic actions rather than by philosophically or politically unified decisions.

It is nevertheless possible, because of a common national experience and because of the communication stimulated by national development, to describe education in national terms. Educational movements afoot in the early 20th century and associated with "progressive education" (such as child study, kindergarten development, and curriculum integration) had a relatively mild impact on traditional practices and forms. Instruction in the Canadian school remained essentially teacher-centred, with a strong emphasis on obedience and conformity.

Traditional versus progressive education

The major change in school structure occurred at the secondary level. The standard eight-year elementary program was first extended by continuation classes or schools alongside exclusive secondary schools, producing an uneven, overlapping postelementary structure. In the 1930s an expanded school population, reaching into the secondary grades, led to decisive action on compulsory attendance and to standardization of high-school provisions. Junior high schools were introduced in some provinces as a transitional level between elementary and secondary schooling, while some provinces simply developed junior and senior stages of a total secondary program. The two extremes in secondary development were probably represented by Québec and the west. In the French-speaking schools of Québec, the secondary system consisted of private classical colleges leading to a *baccalauréat* on the one side and terminal courses in special schools or institutes on the other. Only after 1956 were public high schools with a variety of courses established. The administration of the system was unified under a ministry of education in 1964, although with continuing provision for local school boards of a distinctly Roman Catholic or Protestant nature. In the western provinces, large regional schools and composite high schools were developed extensively, Alberta having proceeded apace in this direction. British Columbia, following the Chant Commission Report in 1960, reorganized its secondary program to include five core streams, only one of which was academic-technical.

Canadian educational reforms

In general, the secondary curriculum has been modified by expanding the catalog of optional subjects and by reorganizing to include new courses of study. Secondary schools in Canada are now mainly comprehensive and enroll about 85 percent of the age group. After extensive provincial reviews in the 1980s, emphasis has been returned to academic standards and newly placed on the relation of education to work, in response to the economic needs both of society and of the individual. This new emphasis may include teaching specific job skills and industrial information, coordinating vocational and academic studies in school programs, and cooperating with industry through work-study programs. Alternatives to the basic choice between university preparation and a general terminal course have appeared.

In response to the requirements of an expanded school population in the first half of the century and to the later demand for increased access, particularly for women, native Canadians, immigrants, and low-income groups, changes to structure, curriculum, and methods have occurred regularly since the 1960s. Many revisions originated with developments in the United States but took a particularly Canadian form. The first wave of reforms emphasized openness (open-area schools and classrooms, curriculum choice), comprehensiveness (composite high schools, consolidated rural schools, group work, and peer cooperation), and continuity up the school ladder (although with an abundance of alternatives). From the late 1970s, reforms shifted toward renewed emphasis on basic learning, selection of students, moral and social values, increased administrative control, and assessment procedures for school, system, and aggregate student performance.

The educational scene shows characteristics of both periods of reform. Some of the notable innovations include: the provision of preschool classes in most elementary schools or systems; the use in early elementary grades of new educational methods developed at the preschool level; a concentrated attempt to decrease newly discovered functional illiteracy at all levels, including the adult level; the rapid introduction of electronic learning programs and instructional assistance; and direct concern with values instruction, usually secular and oriented to both personal and social issues. Both the attempt to reconcile individual educational requirements with the demands of mass systems and the current emphasis on essential subject matter have led to a search for new techniques of selecting and transmitting knowledge in schools.

The most demanding issues of the second half of the century have reached beyond the traditional time and scope of public schooling: early-childhood education, adult education, private schooling, postsecondary education, and bilingual multicultural provisions. Whether as a reflection of concern over the direction of public schools, of an increasingly pluralistic society, or of affluence among parents, private-school attendance has risen steadily. It is still a small proportion of the school-age group in Canada (less than 5 percent), but the increase in interest as well as in attendance has put pressure on provincial governments for funding. Most provinces now offer limited grants to authorized private schools, though at a level far below public-school financing.

Consistent with Canada's claim to multicultural social development and bolstered by the Canadian Charter of Rights and Freedoms, multicultural and bilingual emphases have made perhaps the strongest single impact on schooling. French-language instruction, both as a mother tongue and as a second language, has expanded in traditionally English-speaking areas. Restrictions have been placed on English-language schooling in Québec as the French-language population struggles for cultural survival in North America. Court challenges against required Christian religious exercises and religious instruction in elementary schools have been successful. Demands have been made to give attention to other languages as languages of instruction and to revise the exclusively Western bias of curriculum content.

Regional patterns of Canadian universities

A new dimension in higher education was added with the establishment of provincial universities in the west (1901–08). This completed a set of regional patterns for university development that has continued to this day. Canadian universities have, within these patterns, drawn their criteria from French, British, or American models. From the 1950s, a boom in Canadian higher education has led to increasingly independent considerations on the role of universities in Canadian development. While the 1950s and '60s saw a great expansion of universities, the 1970s and '80s saw rapid growth in postsecondary, nonuniversity education in provincially funded colleges. These colleges all offer some range of vocational programs. Their relationships with universities vary: some offer university transfer programs (Alberta); some offer university prerequisites (Québec); some have no formal relationship (Ontario). With an increasing student population in a wider range of postsecondary alternatives, the rationalization, planning, and funding of this sector is a primary issue for provincial governments.

The administration of public education is the exclusive responsibility of the provinces, which have worked out schemes of local authority under provincial oversight. Although the specific structure of the departments of education varies among the provinces, they conform to a basic structure. Each is headed by a politically appointed minister of education, who may be advised by a council. The main functions of educational supervision are usually carried out through specific directorates for such areas as curriculum, examinations, vocational education, teacher training and certification, and adult education. Three developments, however, strengthened local autonomy in educational administration. Throughout the second quarter of the 20th century, consolidation of rural schools and administrative units took place in the west, thus resulting in stronger educational units more competent to act independently. Moves toward regional decentralization, especially

in Ontario, Québec, and New Brunswick, produced rather independent subprovincial units. Finally, urban development led to relatively autonomous city school operations. Provincial authority has been reemphasized, however, with the demands for better system articulation and for standardization of requirements, programs, and testing.

Federal influences in Canadian education

Canada's federal government has no constitutional authority in education and therefore maintains no general office dealing directly with educational matters. Federal activities in education are nevertheless carried out under other areas of responsibility, and certain functions of an office of education are subsumed under the secretary of state. The Council of Ministers of Education, Canada, brings together the chief educational officers of the provinces and ensures national communication at governmental level. Under its responsibility for native peoples and its jurisdiction over extra-provincial territories, the federal government, through the Department of Indian Affairs and Northern Development, finances and supervises the education of Indians and Eskimo. In the Yukon, schools are administered by the territorial government, though largely financed from Ottawa.

Through agricultural and technical assistance acts in 1913 and 1919, the federal government began to promote vocational education, and this principle was extended through emergency programs in the depression years of the 1930s and during World War II. More recently, vocational programs of wide scope have been introduced on a principle of federal support and provincial operation. The Technical and Vocational Assistance Act of 1960 was followed by a great surge in vocational education, including the construction of new schools and school additions, special institutes, and the preparation of vocational teachers. Program definitions in this area have become ever broader.

The federal government has maintained and supported the education of armed-forces personnel. Research and development in higher education are promoted directly through grants from national research councils for social sciences and humanities, for the natural sciences and engineering, for medicine, and for the arts. Statistics Canada disseminates organized statistical information on schools and on social factors affecting education. Perhaps less direct but of great importance are national agencies operating in the area of mass communications media, such as the National Film Board. Together, the activities of the federal government not only support but also strongly influence certain areas of education and complete a picture of local-provincial-federal involvement in Canadian education.

Australia. The 20th-century development of Australian education continued to be influenced by British models and to be characterized by the exercise of strong central authority in the states. Yet, because Australian national development has taken place entirely in this century, increasing attention has been given to the role of education in nation building.

Educational systems were built through the establishment of primary schools by the end of the 19th century, the extension of these through continuation programs, and the development of state secondary schools in the early part of the 20th century. The independent secondary schools that offered the bulk of secondary education before 1900 continued to be influential, either as components of the separate Roman Catholic system or as "elite" private schools of denominational or nondenominational character, but the growth of state systems carried the state high schools into numerical prominence.

The early development of educational systems before and around the turn of the century was a crude beginning, the minimal provisions being accentuated by poor teacher preparation, administrative thrift schemes, and excess in the exercise of administrative authority. Improvement of these conditions and systematic positive development can be dated from the Fink Report of 1898 in Victoria and similar reform appeals in other states between 1902 and 1909. The steady pace of progress from that time was broken by a surge of growth and innovation in Australian institutions after World War II.

Education in small, isolated communities throughout the vast Australian area has required special attention. As a means of reaching isolated children and adults, correspondence education was begun in 1914 in Victoria, and other states followed after 1922. The procedures have been gradually refined and the levels extended. More formal early efforts included the introduction of provisional schools, itinerant teachers, and central schools in the outback. The small one-teacher bush schools became typical after federation in 1901. Much attention was given to methods of teaching in the one-room school, earning Australia international recognition for expertise in this area. Progress toward rural school consolidation began in Tasmania in 1936. The Tasmanian model combined special features of school independence, pupil freedom, involvement in agricultural projects, and parental cooperation with the "area school" movement. Recently, there has been a rapid decline in one-teacher all-age schools in Australia in favour of consolidated schools in central locations.

State and federal powers in Australia

Education is a state, rather than a federal, responsibility in Australia. Authority is concentrated in a state department of education. The political head is the minister of education, and the permanent official in charge is the director or director general of education. The main divisions of the department are those for primary, secondary, and technical education, each directed by a senior official; additional divisions, such as for special education or in-service training, are particular to the states. Department policy has been executed through a hierarchy of educational experts. Through the 1980s major changes in administrative organization took place in all state systems toward devolution of authority to local regions and schools. A corporate style of management has become current, using criteria of rationalization, effectiveness, and economic efficiency to guide organizational decisions. Although parties agree on many overall goals, disagreements among state authorities, powerful teachers' unions, and public groups promise the continuation of a politically volatile and changing administrative scene.

Since World War II, with the financial assets of exclusive income-taxing power, the commonwealth (federal) government has played an increasing role in educational development, particularly at the tertiary level. Through the States Grants Act in 1951, the Murray Report in 1957, the Martin Report in 1964, the Karmel Report in 1973, and a series of position papers leading to the 1988 Policy Statement on higher education, the federal government moved into the planning as well as the funding of post-secondary education concurrently with the states. After four decades of rapid expansion in higher education (from less than 50,000 students in 1948 to more than 400,000 in 1988), the government has set a course toward a unified national system at the tertiary level. The government has negotiated directly with higher education institutions, without the traditional buffer of consultative councils, and has moved directly to amalgamate institutions and otherwise to rationalize the system. The organizational rationale is based on the contribution of higher education to the national economic interest, and strategies link higher education to the training needs of the economy. System integrity, efficiency and output measures, and indications of privatization (a private university, tertiary fees, sale of educational services) characterize the political thrust. The Commonwealth Office of Education was established in 1945 to advise on financial assistance to the states and on educational matters generally, to act as a liaison agent among the states and between Australia and other countries, and to provide educational information and statistics. After several title changes, it became, in 1987, the Department of Employment, Education, and Training, bringing together education and training policy with employment strategy at the national level.

About three-quarters of Australian schools are public. The remainder are made up of Roman Catholic schools (which constitute about 80 percent of the nonpublic schools) and other private schools, many of which have considerable influence in the leadership of Australian society. The curriculum and syllabus for each program or course in the state schools is prescribed by the Department of Education, and nonpublic schools generally follow this standard. Since 1965 significant government funding has

been provided to private schools. There has been a resurgence of interest in and a consequent increase of influence from this sector again in recent years.

The Australian school structure

Primary schools are normally of six years' duration, to about age 12, though some schools retain the seventh year of the old pattern. Within primary schools, pupils are organized in grades and advance by annual promotion. Secondary education is offered for five or six years, generally in comprehensive schools. The minimum school-leaving age is 15 (16 in Tasmania). From the 1950s to the mid-1970s, rapid growth occurred throughout the systems, but especially at higher levels. The technical and further education (TAFE) sector has had a singular influence, operating at upper secondary and tertiary levels and providing widespread nonformal activities. TAFE colleges enroll about 700,000 students of school-leaving age annually and serve the great majority of Australian tertiary students. Recent moves have improved cross-crediting between TAFE and other tertiary institutions.

Since the 1970s, three educational goals have emerged: the first emphasizes equality, diversity, devolution, and participation; the second, national and social unity; the third, effective means of managing what had become, because of rapid growth, a huge and nearly ungovernable education sector. As a result, there have been internal reforms in teaching practice, curriculum, school organization, teacher education, and methods of assessment.

The attempts to increase the number of students continuing education and to improve or expand programs to serve the whole population have raised interest in system unification, including such issues as establishing common curricula and stronger Australian content, improving the transition from school to work, and providing equal opportunity for Aborigines, the disabled, and other groups designated as disadvantaged. The government has recently highlighted recognition of the contribution of Aboriginal cultures as well as of Australian studies.

The emphasis on management techniques may conflict with socially broader objectives. The enormous amount of debate current in Australian education has heightened national interest but has hardened ideological lines. The immediacy of political decisions for education and the momentum of present activity will continue to produce system change.

New Zealand. The religious and regional issues that have fettered educational development in other countries of the British Commonwealth were basically settled in New Zealand when the decisions were made in the last quarter of the 19th century to provide wholly secular primary schools and administrative centralization. The major issue in the 20th century has been the achievement of equal educational opportunity. Although New Zealand has accepted the responsibility to educate each child—without racial, social, or narrowly intellectual restriction—to the limits of the child's ability, the unification of the total system to this end has proved quite difficult.

New Zealand's goal of equal educational opportunity

The Education Act of 1914 consolidated the changes that had taken place since 1877. In subsequent reform periods during the '30s and after World War II, barriers to pupil progress through the system were removed or modified. In 1934 the school-leaving certificate examination was established on a broader basis than the university entrance examination, and, in 1936, the proficiency examination governing secondary entrance was abolished. In 1944–45 the school-leaving age was raised to 15; a common core of early secondary studies, including English, social studies, general science, mathematics, physical education, and a craft or fine-arts subject, was established; and universities agreed to accept accredited-school courses without further examination for university entrance. These actions illustrate a gradual but steady facilitation of access through an increasingly coordinated system. The recommendations of the Currie Commission (1962) and the provisions of the Education Act of 1964 continued this direction.

Since 1877 education has been supervised and funded by a central Department of Education, which is headed politically by a minister and permanently by a director general. Administrative duties are generally handled locally, however. Secondary schools are administered by their own boards of governors and primary schools by elected regional boards of education. Universities receive grants negotiated by the University Grants Committee, and grants for other tertiary institutions are administered by the Department of Education. Three regional offices and teams of primary and secondary inspectors link the central Department of Education and the network of local authorities. Education is free until the age of 19 for qualified pupils. University tuition is also paid for successful students.

New Zealand children generally start school at the age of five years and spend eight years in primary school. The secondary system developed through the growth of three separate kinds of school: (1) the district high school, which represented more or less a secondary "top" on a primary school, (2) the independent, academic, one-sex secondary school proper, and (3) the technical school, which took shape between 1900 and 1908. The isolated position of the fee-charging secondary schools of the 19th century was compromised by free-place legislation in 1903, and, by 1914, they were brought into the state system, though retaining a good deal of their independent status. The district high schools remained in the primary system, but their incorporation in the secondary inspection scheme and in secondary teacher classification placed them clearly within that sector of school operation. The technical high school evolved into a general high school with technical bias. Through common departmental inspection, curriculum, and examination standards, and through the effect of the movement for more general postprimary provisions after 1945, the secondary schools increasingly approximated a single pattern.

At the end of the 11th year of schooling, students take the School Certificate examination, a general test that partially determines admittance to the upper secondary level (12th and 13th years). About half the students leave school at this time. Youths qualifying for university entrance find that admission to professional schools is limited. Although the technical institutes and community colleges have been expanded since 1970, demand continues to increase for these programs. Enrollment in teachers' colleges has been limited due to a declining school population.

Private and rural schools

An extensive Roman Catholic private school system grew up after the secularization of state education. From 1970 these schools were subsidized, and after 1975 most became integrated into the state system and funded by the state.

Rural and native education have been given increasing attention in New Zealand. Consolidated schools, served by an extensive transportation system, have long been a feature of rural education. The expansion of community colleges and the establishment of rural education activity programs have extended regional opportunities. Children and adults in isolated districts are served by several correspondence schools. Maori education became a responsibility of the Department of Education in 1879. Since 1962 the government has attempted to balance the need for remediation of deficiencies in general schooling with Maori cultural rights. As in other countries, equity and the relationship between school and work are the two main issues facing the New Zealand school system. Together they represent growing social and economic demands which may not be compatible with the traditional order of schooling.

(R.F.L.)

REVOLUTIONARY PATTERNS OF EDUCATION

Russia: from tsarism to communism. *Before 1917.* At the turn of the 20th century the Russian Empire was in some respects educationally backward. According to the census of 1897, only 24 percent of the population above the age of nine were literate; by 1914 the rate had risen to roughly 40 percent. The large quota of illiteracy reflected the fact that, by this time, only about half the children between eight and 12 attended school. The elementary schools were maintained by the *zemstvo* (local government agencies), the Orthodox church, or the state, the secondary schools mainly by the Ministry of Education.

After the Revolution of 1905 the Duma (parliament) made considerable efforts to introduce compulsory elementary schooling. At the upper stages of the educational

system, progress was significant, too; nevertheless, the secondary schools (*gimnazii, realnyye uchilishcha*) were only to a small degree attended by students of the lower classes, and the higher institutions even less. Preschool education as well as adult education was left to the private initiative of the educationally minded intelligentsia, who were opposed to the authoritarian character of state education in the schools. In 1915–16 the minister of education, Count P.N. Ignatev, started serious reforms to modernize the secondary schools and to establish a system of vocational and technical education, which he regarded as most important for the industrialization of Russia. During the Provisional government (February to October 1917, old style), the universities were granted autonomy, and the non-Russian nationalities received the right of instruction in their native languages. The education system envisaged by the liberal-democratic and moderate Socialist parties was a state common school for all children based on local control and the direct participation of society.

1917–30. After the October Revolution of 1917, the Bolshevik Party proclaimed a radical transformation of education. Guided by the principles of Karl Marx and influenced by the contemporary movement of progressive education in the West as well as in Russia itself, the party and its educational leaders, Nadezhda K. Krupskaya and Anatoly V. Lunacharsky, tried to realize the following revolutionary measures as laid down in the party's program of 1919: (1) the introduction of free and compulsory general and polytechnical education up to the age of 17 within the Unified Labour School, (2) the establishment of a system of preschool education to assist in the emancipation of women, (3) the opening of the universities and other higher institutions to the working people, (4) the expansion of vocational training for persons from the age of 17, and (5) the creation of a system of mass adult education combined with the propaganda of communist ideas. In 1918 the Soviet government had ordered by decree the abolition of religious instruction in favour of atheistic indoctrination, the coeducation of both sexes in all schools, the self-government of students, the abolition of marks and examinations, and the introduction of productive labour. In 1919, special workers' faculties (rabfaks) were created at higher institutions and universities for the development of a new intelligentsia of proletarian descent.

Revolutionary experimentalism

During the period of the New Economic Policy (1921–27), when there was a partial return to capitalistic methods, the revolutionary spirit somewhat diminished, and the educational policy of party and state concentrated on the practical problems of elementary schooling, the struggle against juvenile delinquency, and the schooling of adult illiterates. When the policy of five-year plans began in 1928 under the slogan of "offensive on the cultural front" and with the help of the Komsomol (the communist youth league), the campaign against illiteracy and for compulsory elementary schooling reached its climax.

The Stalinist years, 1931–53. In connection with the policy of rapid industrialization and collectivization of farmers and with the concentration of political power in the hands of Joseph Stalin, the Soviet educational policy in the 1930s experienced remarkable changes. Starting with the decree of 1931, the structure and the contents of school education underwent the following process of "stabilization" in the next few years: (1) four years was laid down as the compulsory minimum of schooling for the rural districts, and seven years for the cities; (2) the new system of general education embraced the grades one to four (*nachalnaya shkola*), the grades five to seven, which continued the elementary stage on the lower secondary level (*nepolnaya srednyaya shkola*), and the grades eight to 10, which provided a full secondary education (*polnaya srednyaya shkola*); (3) the new curriculum was to provide the students with a firm knowledge of the basic academic subjects and was to be controlled by a system of marks and examinations; (4) the decisive role of the teacher within the educational process was reestablished, while the Pioneers and Komsomol organizations (for youth aged 10 to 15 years and 14 to 26 years, respectively) were above all to instill a sense of discipline and an eagerness for learning; (5) manual work disappeared from the school curriculum as well as from the teacher-training institutions. In addition, the ideas of progressive education were rejected, and older Russian traditions began to be cultivated. During World War II the idea of Soviet patriotism emerged fully, penetrating the theory and practice of education. The principles of the outstanding educator Anton S. Makarenko, with their emphasis on collectivism, gained ground upon the former influence of Western educational thought.

The institutions of higher learning were reshaped in the 1930s, too. The number of students in institutions providing secondary specialized education, usually called *tekhnikumy,* rapidly grew from one million in 1927–28 to 3.8 million in 1940–41. The number of students in institutions of higher education (*vyssheye uchebnoye zavedeniye*) grew from 168,554 to 811,700 in the same period. The main characteristics of higher education that developed in this period remained unchanged for the next decades: the paramount task of higher learning was to provide specialized vocational training within the framework of manpower policy and economic plans; strict control of the student's program was to be imposed by the central authorities; and the system of evening and correspondence instruction on the level of higher and secondary specialized education (*vecherneye i zaochnoye obrazovaniye*) was to parallel full-time studies.

During the 1940s, "labour reserve" trade schools and factory schools for skilled and semiskilled labour were filled by drafting youths between the ages of 14 and 17. In the period 1940 to 1958, an average of 570,000 persons were annually subjected to such recruitment. The draft first affected those students who were unsuccessful academically in regular secondary schools and could not achieve even the seventh grade. For youngsters of this kind and for people who could not continue general secondary education, schools for the working youth (*shkoly rabochey molodyozhi*) and schools for rural youth (*shkoly selskoy molodyozhi*) were established in 1943–44 as part-time institutions. The main features of education policy, developed in the late 1930s, remained in force after the war: the orientation of all kinds of schooling and training to the paramount necessities of the economic system; the inculcation of communist discipline and Soviet patriotic attitudes; and finally a rigid control of the whole educational system by party and state administration.

Labour training

The Khrushchev reforms. After the death of Stalin in 1953, changes in official policy affected both education and science. The 20th Party Congress in 1956 paved the way for a period of reforms inaugurated by Nikita S. Khrushchev. The central idea was formulated as "strengthening ties between school and life" at all levels of the educational system. The Soviet reform influenced to a high degree similar reforms in the eastern European countries.

The old idea of polytechnical education was revived, but mainly in the sense of preparing secondary-school students for specialized vocational work in industry or agriculture. Since the early 1950s there had been a growing imbalance between the output of secondary-school graduates desiring higher education and the economic demands of skilled manpower at different levels. The educational reforms of 1958 pursued the aim of combining general and polytechnical education with vocational training in a way that directed the bulk of young people after the age of 15 straight into "production."

The new structure of the school system after 1958 developed as follows: (1) the basic school with compulsory education became the eight-year general and polytechnical labour school, for ages seven to 15 (*vosmiletnyaya shkola*); and (2) secondary education, embracing grades nine to 11, was provided alternatively by secondary general and polytechnical labour schools with production training (*srednyaya obshcheobrazovatelnaya trudovaya politekhnicheskaya shkola s proizvodstvennym obucheniem*) or by evening or alternating-shift secondary general education schools (*vechernyaya smennaya srednyaya obshcheobrazovatelnaya shkola*).

The connection of study and productive work was to be continued during the course of higher education. Great emphasis was laid upon the further expansion of evening and correspondence education both at the level of sec-

ondary specialized education and at the level of the universities and other higher institutes. In the academic year 1967–68, 56.3 percent of all Soviet students in higher education (of the total number of 4,311,000) carried out their studies in this way.

The reform of 1958 also brought a transformation of the former labour-reserve schools into urban vocational-technical schools or rural schools of the same type (*gorodskiye i selskye professionalno-tekhnicheskiye uchilishcha*). As a rule these schools require the completion of the eight-year school, but in fact there are many pupils with lower achievements; the length of training is from one to three years, depending upon the type of career.

Collective education

Besides introducing polytechnical education and productive labour, the Khrushchev reforms emphasized the idea of collective education from early childhood. Preschool education for the age group up to seven years was to be rapidly developed within the newly organized unified crèches and nursery schools (*yasli i detskiye sady*); and, as a new type of education, boarding schools (*shkoly-internaty*) that embraced grades one to eight or one to 11 had been created in 1956. Some party circles wanted this kind of boarding education for the majority of all young people, but development lagged behind planning, and the idea of full boarding education was later abandoned.

The polytechnization of the Soviet school system as it took shape during the Khrushchev period turned out, in the course of its realization, to be a failure. A revision of the school reform was carried out between August 1964 and November 1966 that brought about several important results: (1) the grade 11 of the secondary school (except for the evening school) was abolished; general education returned to the 10-year program; (2) vocational training in the upper grades was retained only in a small number of well-equipped secondary schools; and (3) a new curriculum and new syllabi for all subjects were elaborated. After 1958 hundreds of secondary schools for gifted pupils in mathematics, science, or foreign languages were developed, besides the well-known special schools for music, the arts, and sports. They recruit students mainly from the urban intelligentsia and have therefore sometimes been criticized by adherents of egalitarian principles in education.

From Brezhnev to Gorbachev. Leonid I. Brezhnev assumed leadership after Khrushchev retired in 1964. On Nov. 10, 1966, a decree was issued outlining the new policy in the field of general secondary education. A union–republic Ministry of Public Education was established to augment the already existing central agencies for higher and secondary specialized education and for vocational-technical training. The main aim of educational policy in the 1970s was to achieve universal 10-year education. In 1977 it was claimed that about 97 percent of the pupils who graduated from the basic eight-year school continued their education at the secondary level. An important step toward the realization of universal secondary education was the creation of secondary vocational-technical schools (*srednye professionalno-tekhnicheskiye uchilishcha*) in 1969. These schools offered a full academic program as well as vocational training. Preschool education for children under seven years of age was extended: enrollments in nursery schools, kindergartens, and combined nursery–kindergarten facilities increased from 9.3 million in 1970 to 15.5 million in 1983. The number of institutions for higher education also grew steadily (from 805 in 1970 to 890 in 1983), meeting regional demands. Day, evening, and correspondence courses were provided.

The expansion of secondary education

The quantitative gains achieved during this period were not matched by corresponding improvements in the quality of education. Government authorities, as well as teachers and parents, expressed growing dissatisfaction with student achievement and with student attitude and behaviour. The youngsters themselves often felt alienated from the official value system in education. Furthermore, there was a growing imbalance between the careers preferred by general-school graduates and the national economic requirements for skilled manpower—an unforeseen result of the policy of universal secondary education. Therefore, from 1977 the scope of labour training in the upper grades of the general school was enhanced in order to provide youngsters with a basic practical training and to direct them into so-called mass occupations after leaving school.

In 1984, two years after Brezhnev's death, new reforms of general and vocational education were instituted. Teachers' salaries, which had been lower than other professional incomes, were raised. The age at which children enter primary school was lowered from seven to six years, thus extending the complete course of general-secondary schooling from 10 to 11 years. Vocational training in the upper grades of the general school was reinforced. To meet the requirements of computer literacy, appropriate courses were introduced into the curricula of the general school, even though most schools lacked sufficient equipment. The main emphasis, however, was placed on the development of a new integrated secondary vocational-technical school that would overcome the traditional barriers between general and vocational education.

Perestroika and education. The 1984 reform of Soviet education was surpassed by the course of economic and structural reforms (*perestroika*) instituted since 1986 under the leadership of Mikhail S. Gorbachev. In February 1988 some earlier reforms were revoked, including the compulsory vocational training in the general school and the plans to create the integrated secondary school. Universal youth education was limited to a nine-year program of "basic education," with subsequent secondary education divided into various academic and vocational tracks. The newly established State Committee of Public Education incorporated the three formerly independent administration systems for general schooling, vocational training, and higher education. Even more important was the rise of an educational reform movement led by educationists who favoured an "education of cooperation" (*pedagogika sotrudnichestva*) over the authoritarian and dogmatic principles of collective education that originated in the Stalin period. These theorists advocated individualizing the learning process, emphasizing creativity, making teaching programs and curricula more flexible, encouraging teacher and student participation, and introducing varying degrees of self-government in schools and universities as a part of the proclaimed "democratization" of Soviet society. Some of the proposals were approved by the State Committee; for example, the universities and other institutions of higher learning were granted some autonomy. Other proposals were being tested by teachers in experimental groups.

Education in the non-Russian republics

In the non-Russian republics the language of instruction is a key issue. After the October Revolution of 1917, education in native languages was promoted. In the 1970s, however, the number of Russian-language and bilingual schools grew steadily at the expense of schools offering instruction in the native languages, even in territories with a majority of non-Russian ethnic groups. This Russianization provoked increasing opposition, and in 1987 the Baltic republics (Estonia, Latvia, Lithuania) began to demand the national-cultural autonomy that is formally guaranteed by the Soviet constitution. Political and educational concessions made to the Union republics seemed to herald further decentralization of the so-far uniform and centralized system of education. (O.A.)

China: from Confucianism to communism. *The modernization movement.* The political and cultural decline of the Manchu dynasty was already evident before the 19th century, when mounting popular discontent crystallized into open revolts, the best known of which was the Taiping Rebellion (1850–64). The dynasty's weakness was further exposed by its inability to cope with the aggressive Western powers during the 19th century. After the military defeats administered by the Western powers, even Chinese leaders who were not in favour of overthrowing the Manchus became convinced that change and reform were necessary.

Most of the proposals for reform provided for changes in the educational system. New schools began to appear. Missionary schools led the way in the introduction of the "new learning," teaching foreign languages and knowledge about foreign countries. New schools established by the government fell under two categories: foreign-language schools to produce interpreters and translators and schools

for military defense. Notable among the latter were the Foochow Navy Yard School to teach shipbuilding and navigation and a number of academies to teach naval and military sciences and tactics.

China's defeat by Japan in 1894–95 gave impetus to the reform movement. A young progressive-minded emperor, Kuang-Hsü, who was accessible to liberal reformers, decided upon a fairly comprehensive program of reform, including reorganizing the army and navy, broadening the civil service examinations, establishing an Imperial University in the national capital and modern schools in the provinces, and so on. The imperial edicts in the summer of 1898 spelled out a program that has been called the Hundred Days of Reform. Unfortunately for China and for the Manchu dynasty, conservative opposition was supported by the empress dowager Tz'u-hsi, who took prompt and peremptory action to stop the reform movement. The edicts of the summer were reversed and the reforms nullified. Frustration and disappointment in the country led in 1900 to the emotional outburst of the Boxer Rebellion.

Hundred Days of Reform and the aftermath

After the Boxer settlement even the empress dowager had to accept the necessity of change. Belatedly, she now ordered that modern schools, teaching modern subjects such as Western history, politics, science, and technology, along with Chinese classics, be established on all levels. The civil service examinations were to be broadened to include Western subjects. A plan was ordered to send students abroad for study and recruit them for government service upon return from abroad. But these measures were not enough to meet the pressing demands now being presented with increasing forcefulness. Finally, an edict in 1905 abolished the examination system that had dominated Chinese education for centuries. The way was now cleared for the establishment of a modern school system.

The first modern school system was adopted in 1903. The system followed the pattern of the Japanese schools, which in turn had borrowed from Germany. Later, however, after establishment of the republic, Chinese leaders felt that the Prussian-style Japanese education could no longer satisfy the aspirations of the republican era, and they turned to American schools for a model. A new system adopted in 1911 was similar to what was then in vogue in the United States. It provided for an eight-year elementary school, a four-year secondary school, and a four-year college. Another revision was made in 1922, which again reflected American influence. Elementary education was reduced to six years, and secondary education was divided into two three-year levels.

Education in the republic. The first decade of the republic, up to the 1920s, was marked by high hopes and lofty aspirations that remained unfulfilled in the inclement climate of political weakness, uncertainty, and turmoil. The change from a monarchy to a republic was too radical and too sudden for a nation lacking any experience in political participation. The young republic was torn by political intrigue and by internecine warfare among warlords. There was no stable government.

A school system was in existence, but it received scant attention or support from those responsible for government. School buildings were in disrepair, libraries and laboratory equipment were neglected, and teachers' salaries were pitifully low and usually in arrears.

New intellectual movements during the republic

It was, nevertheless, a period of intellectual ferment. The intellectual energies were channeled into a few movements of great significance. The first was the New Culture Movement, or what some Western writers have called the Chinese Renaissance. It was at once a cordial reception to new ideas from abroad and a bold attempt to reappraise China's cultural heritage in the light of modern knowledge and scholarship. China's intellectuals opened their minds and hearts to ideas and systems of thought from all parts of the world. They eagerly read translated works of Western educators, philosophers, and literary writers. There was a mushroom growth of journals, school publications, literary magazines, and periodicals expounding new ideas. It was at this time that Marxism was introduced into China.

Another movement of great significance was the Literary Revolution. Its most important aspect was a rebellion against the classical style of writing and the advocacy of a vernacular written language. The classics, textbooks, and other respectable writings had been in the classical written language, which, though using the same written characters, was so different from the spoken language that a pupil could learn to read without understanding the meaning of the words. Now, progressive scholars rejected the heretofore respected classical writing and declared their determination to write as they spoke. The new vernacular writing, known as *pai-hua* ("plain speech"), won immediate popularity. Breaking away from the limitations of stilted language and belaboured forms, the *pai-hua* movement was a boon to the freedom and creativity released by the New Thought Movement and produced a new literature attuned to the realities of contemporary life.

A third movement growing out of the intellectual freedom of this period was the Chinese Student Movement, or what is known as the May Fourth Movement. The name of the movement rose from nationwide student demonstrations on May 4, 1919, in protest against the decision of the Paris Peace Conference to accede to the Japanese demand for territorial and economic advantages in China. So forceful were the student protests and such overwhelming support did they get from the public that the weak and inept government was emboldened to take a stand at the conference and refused to sign the Versailles Treaty. The students thus had a direct hand in changing the course of history at a crucial time, and from now on Chinese students constituted an active force on the political and social scene.

Education under the Nationalist government. Nationalist China rose in the mid-1920s amid a resurgence of nationalism and national consciousness stimulated by post-World War I developments. It was led by the Kuomintang, the political party organized by Sun Yat-sen, the founder of the republic. Cognizant of the popular appeal of nationalism, the Kuomintang set up a Nationalist government pledged to achieve national unity at home and national independence from foreign control as prerequisites to a program of modernization and national reconstruction. In education, it set out to systematize and stabilize a shaky and ill-supported school system and use it as a means of national regeneration. Schools were assured of financial support, however inadequate, and placed under strict supervision and firm control by public authorities.

State control and centralization of education

State control of education by means of centralized administration was instituted. Measures were adopted to correct the abuses and chaos that had resulted from the laissez-faire educational policy of the warlords. Decrees and regulations issued by the Nationalist Ministry of Education were strictly enforced, with the aid of a centrally administered system of inspection and accreditation. Detailed regulations covered the curricula of schools on all levels, minimum standards of achievement, teaching procedures, teachers' qualifications, and specifications for school buildings, libraries, laboratories, and the like. Private schools were permitted but were as subject to government control as public schools and were required to follow the same regulations with regard to curriculum and all other details.

A uniform system of schools was in effect throughout the country. Elementary education was provided in the four-year primary school, followed by the two-year higher elementary. In areas where there were not enough funds to support longer courses, there were abbreviated schools having only one or two grades. Theoretically, the government was committed to the goal of four-year compulsory education, but financial problems prevented an early realization of this goal. Adult education was given much attention in adult schools, in mass education projects, and in different forms of "social education." The latter term encompassed a variety of educational agencies outside the schools, such as libraries, museums, public reading rooms, recreational centres, music, sports, radio broadcasting, and films. Reduction of illiteracy was a major objective.

There were three parallel types of secondary education: the academic middle school, the normal school, and the vocational school. To counteract the traditional preference for the academic type of education, the government restricted the growth of the academic middle school. At the same time, vocational schools were encouraged.

Nationalist promotion of "practical studies"

A major objective of government policy was to promote "practical studies." In secondary education, "practical studies" meant the development of vocational and technical schools and more attention to science and laboratory experience in middle schools. In higher education, measures were taken to steer students away from liberal arts, law, education, and commerce to the "practical courses" of science, engineering, technology, agriculture, and medicine. Government grants for private as well as public colleges were usually designated for the science program. As a result of this policy, the years prior to World War II saw a steady increase of enrollment in the "practical courses" of study and a corresponding decline of enrollment in the arts–law–education–commerce courses. The increase of interest in science was also evident in the secondary schools.

It may be said that the thrust of educational policy in Nationalist China was to rectify the imbalance of the past, especially the nonvocational literary tradition of premodern days. In the attempt to counteract past tendencies, however, it was possible that the pendulum might swing to the other extreme. Some educators expressed the fear that the promotion of "practical studies" might lead to a narrow, utilitarian concept of education and a neglect of the humanities and social sciences. Others were uneasy over the danger of regimentation through centralized administration. Nevertheless, education under the Nationalist government did succeed in establishing an effective national system of education, promoting science and technical studies and correcting the abuses and irregularities of the earlier period. Thanks to dependable financial support, state schools and universities gained in prestige and academic performance until they were recognized as among the outstanding educational institutions of the country.

Other accomplishments of this period include the growth of postgraduate education and research, the general acceptance of coeducation in elementary and higher education, and the use of the Kuo yü (National Tongue) as an effective means of unifying the spoken language and thus overcoming the difficulties of local dialects.

Education under communism. The communist revolution aimed at being total revolution, demanding no less than the establishing of a new society radically different from what the orthodox communists called the feudal society of traditional China. This new society called for people with new loyalties, new motivations, and new concepts of individual and group life. Education was recognized as playing a strategic role in achieving this revolution and development. Specifically, education was called upon to produce, on the one hand, zealous revolutionaries ready to rebel against the old society and fight to establish a new order and, at the same time, to bring up a new generation of skilled workers and technical personnel to take up the multitudinous tasks of development and modernization.

The People's Republic of China generally makes no distinction between education and propaganda or indoctrination. All three share the common task of changing man. The agencies of education, indoctrination, and propaganda are legion—newspapers, posters, and propaganda leaflets, neighbourhood gatherings for the study of current events, as well as political rallies, parades, and many forms of "mass campaigns" under careful direction. It is evident that the schools constitute only a small part of the educational program.

When the Communists came to power in 1949, they took up three educational tasks of major importance: (1) teaching many illiterate people to read and write, (2) training the personnel needed to carry on the work of political organization, agricultural and industrial production, and economic reform, and (3) remolding the behaviour, emotions, attitudes, and outlook of the people. Millions of cadres were given intensive training to carry out specific programs; there were cadres for the enforcement of the agrarian law, the marriage law, the electoral law; some were trained for industry or agriculture, others for the schools, and so on. This method of short-term ad hoc training is characteristic of communist education in general.

Because the new Communist leaders had no experience in government administration, they turned to their ideological ally, the Soviet Union, for aid and guidance. Soviet advisers responded quickly, and Chinese education and culture, which had been Westernized under the Nationalists, became Sovietized. An extensive propaganda campaign flooded the country with hyperbolic eulogies of Soviet achievements in culture and education. The emphasis on Soviet cultural supremacy was accompanied by the repudiation of all Western influence.

Soviet influence on Chinese education

A major agency designed to popularize the Soviet model was the Sino-Soviet Friendship Association (SSFA), inaugurated in October 1949 immediately after the new regime was proclaimed. Headed by no less a personage than Liu Shaoqi, the second highest Chinese Communist leader, the association extended its activities to all parts of the country, with branch organizations in schools, factories, business enterprises, and government offices. In schools, students were urged to enlist as members of the association and to participate in its activities. In many schools more than 90 percent of the students became SSFA members. Throughout the nation, the SSFA sponsored exhibits, motion pictures, mass meetings, parades, and lectures to engender interest in the Soviet Union and in the study of Russian language, education, and culture.

Soviet advisers drew up a plan for the merging and geographic redistribution of colleges and universities and for the reorganization of collegiate departments and areas of specialization in line with Soviet concepts. Colleges and departments of long standing were eliminated without regard to established traditions or to the interests and scholarly contributions of their faculties. Russian replaced English as the most important foreign language.

From curriculum content to teaching methods, from the grading system to academic degrees, communist China followed the Soviet model under the tutelage of Soviet advisers, whose wisdom few dared question. Even the new youth organizations (which displaced the Boy Scouts and Girls Scouts) were comparable to the Pioneers and Komsomols of the U.S.S.R. According to one report, at the peak of the Sovietization frenzy, the first lesson in a Chinese-language textbook used in primary schools was a translation from a Russian textbook.

Never before in the history of education in China had such an extensive effort been made to imitate the education of a foreign country on such a large scale within such a short period of time. Nevertheless, there were many reasons why the campaign did not produce many lasting changes in Chinese education. Russian education and culture had not been well known in China, and the nation was not psychologically prepared for such a sudden and intensive dose of indoctrination to "learn from the Soviet Union." Students, teachers, and intellectuals in general, who would have reacted favourably to a reform to make education more Chinese, were skeptical of the wisdom of switching from Western influence to Soviet influence.

Ideology and education

Chinese leaders justified the indiscriminate imitation of the Soviet model on ideological grounds. The Soviet Union was the leader of the socialist countries; Lenin and Stalin were the shining lights that led the people of the world in their struggle for freedom and equality; the supremacy of the Soviet Union had proved the superiority of socialism over capitalism.

The paramount importance of ideology in education may also be seen in other ways. Ideological and political indoctrination was indispensable to all levels of schools and to adult education and all forms of "spare-time education." It consisted of learning basic tenets of Marxism–Leninism and studying documents describing the structure and objectives of the new government as well as major speeches and utterances of the party and government leaders. Its aim was to engender enthusiasm for the proletarian-socialist revolution and fervent support for the new regime. Class and class struggle were related concepts that occupied a central place in the ideology, and a specific aim of education was to develop class consciousness so that all citizens, young and old, would become valiant fighters in the class struggle. School regulations stipulated that 10 percent of the curriculum should be set aside for ideological and political study, but, in practice, ideology and politics were taught and studied in many other sub-

jects, such as language, arithmetic, and history. Ideology and politics permeated the entire curriculum and school life, completely dominating extracurricular activities.

Among the most important educational changes of this period was the establishment of "spare-time" schools and other special schools for peasants, workers, and their families. Adults attended the spare-time school after their day's work or during the lax agricultural season. Workers and peasants were admitted to these schools by virtue of their class origin. Political fervour and ideological orthodoxy replaced academic qualifications as prerequisites for further study. As a result of the Cultural Revolution of 1966–76, higher education was greatly curtailed and production and labour were emphasized. Mao Zedong, the Communist Party chairman, issued a directive sending millions of students and intellectuals into the rural areas for long-term settlement and "reeducation." He asserted that the intelligentsia could overcome the harmful effects of bourgeois-dominated education only by identifying with the labouring masses through engaging in agricultural and industrial production. Proletarian leadership was also emphasized, as "Mao Zedong thought propaganda teams," made up of workers, peasants, and soldiers who were well-versed in quotations from Chairman Mao but otherwise often barely literate, took over the management of almost all educational institutions.

Post-Mao education. After Mao's death on Sept. 9, 1976, the new leaders lost no time in announcing a turnabout of ideological-political emphasis from revolution to development. They decreed that all effort should be directed toward "the four modernizations" (industry, agriculture, national defense, and science and technology). The primary task of education was to train the personnel needed to speed up the modernization program.

The post-Mao schools are very different from those of the revolutionary education. The conventional school system has been reinstated. Full-time schools have again become the mainstay of a system of coordinated schools, with orderly advance from level to level regulated by examinations. School discipline has been restored, and due respect for teachers is expected of students. Serious study is not to be overshadowed by extracurricular activities; the line of demarcation between formal and informal education is clearly drawn. The main task of students, said the Communist leader Deng Xiaoping, is "to study, to learn book knowledge," and the task of the school is to make "strict demands on students in their study . . . making such studies their main pursuit."

Acquisition of knowledge is again a legitimate aim of education. Academic learning and the development of the intellect have returned after a decade of banishment. Efforts are being made to raise academic standards not only in the universities but in the lower schools as well.

Key schools

The "key schools," outstanding schools that elevate the standards of teaching and learning and serve as models for others, have been revived. They are provided with funds for well-equipped libraries and laboratories and are staffed with highly qualified teachers. Condemned during the Cultural Revolution as "little treasure pagodas" that catered to bourgeois children to the exclusion of workers, peasants, and soldiers, these centres of academic scholarship are now hailed as the standard-bearers of quality education.

Examinations have returned with a vengeance. Every year the government sets a date and time for the unified competitive college examination. High-school graduates take the examination locally, indicating, in order of preference, the colleges they would like to attend if they pass.

Although in theory every college has a president, a vice president, deans, and the like, the real educational policymaker is the Communist Party organization in each school. School presidents or other administrators must often be party members, but even they cannot make decisions without the full cooperation of party representatives. Recently there have been demands for reforms giving more power to school administrators and faculty members.

Despite the renewed emphasis on academics, the national budget allotment for education is insufficient. Administrators and faculty members are underpaid. The government thus permits teachers to have secondary occupations.

Communism and the intellectuals. Throughout China's long history, the intellectuals considered themselves the preservers and transmitters of the precious culture of their country. Their road to success was not always smooth, but the intellectuals were strengthened by the belief that once they won recognition as first-rank scholars they would be rewarded with position, honour, and lasting fame.

The attitude of the Chinese communists toward intellectuals is in large measure influenced by their ideology. While workers and peasants were raised to the top position, the intellectuals were downgraded because they were considered products of bourgeois and feudal education and perpetuators of bourgeois ideology. The communist policy was to "absorb and reform" the intellectuals.

The intellectuals were made to undergo thorough thought remodeling to be "cleansed" of bourgeois ideas and attitudes. The remodeling began with relatively mild measures, such as "political study" and "reeducation." The policy became increasingly oppressive in the 1950s when intellectuals were pressured to take part in the class struggle of the land reform and in orchestrated attacks on university professors, writers, artists, and intellectuals in different walks of life. The intellectuals, especially those who had studied in Western schools or had been employed by Western firms, were forced to write autobiographies giving details of their reactionary family and educational background, pinpointing their ideological shortcomings, and confessing their failings.

Following Khrushchev's 1956 speech criticizing Stalin, violence broke out in Poland and Hungary. This worried Mao, who agreed to try Premier Zhou Enlai's proposal to relax the Communist Party's pressure on intellectuals. This resulted in the slogan "Let a hundred flowers bloom, a hundred schools of thought contend." Mao indicated that intellectuals would be allowed to speak freely.

The Hundred Flowers Campaign

The result, however, was unexpected and shocking. Once they began to speak freely, the intellectuals unleashed a torrent of angry words, fierce criticisms, and open attacks upon the repressive measures under which they had suffered. Some recanted the confessions they had made under duress; others went so far as to denounce the Communist Party and its government. To avoid a more serious outburst of explosive ideas and emotions, the government decided to put a stop to the "blooming–contending." Outspoken critics were labeled rightists, and an anti-rightist campaign not only silenced the intellectuals but also placed them under more restrictive controls than before. The "flowers" wilted and the "schools" were muffled.

During the Cultural Revolution, Mao's criticism of the intellectuals instigated young radicals all over the country to join the struggle against the intellectuals. Students were urged to slap and to spit at their teachers; insult, humiliation, and torture were common. Some teachers chose suicide. Others were sent to May 7th cadre schools or to the countryside to be reformed by labour.

After Mao's death and the repudiation of the radical extremists, the intellectuals began to grow stronger. A movement called "Peking Spring" was launched in November 1978. Huge wall-posters condemning the communist regime appeared on Peking's so-called Democracy Wall. The movement's leaders expanded the modernization program by adding a fifth modernization which clearly emphasized democracy, freedom, and human rights. The "Peking Spring" movement was short-lived, but Chinese intellectuals in the United States and Hong Kong, as well as in China, continued to organize themselves and to advocate democracy and freedom. In China Fang Lizhi, an astrophysicist, toured university campuses speaking against the repression that he believed had killed the initiative and creativity of Chinese scholars. In the spring of 1989 a grand prodemocracy demonstration took place in Peking. The university students took the lead, demanding a higher allotment of funds for education and protesting corruption, but people from all walks of life joined the demonstration. The movement drew attention and support both at home and abroad; but it was soon suppressed by the government, and the country, including educational affairs, continues to be controlled by the Communist Party. (T.H.C.)

PATTERNS OF EDUCATION IN NON-WESTERN OR DEVELOPING NATIONS

Japan. *Education at the beginning of the century.* Between 1894 and 1905 Japan experienced two conflicts, the Sino-Japanese and Russo-Japanese wars, which increased nationalistic feelings; it also experienced accelerated modernization and industrialization. In accord with the government's new nationalism and efforts to modernize the country, educational reform was sought. The Japanese education system took as its model the western European educational systems, especially that of Germany. But the basic ideology of education remained the traditional one outlined in 1890 in the Imperial Rescript on Education (Kyōiku Chokugo).

Effect of Japan's nationalism and economic growth

In 1900 the period of ordinary elementary schooling was set at four years, and schooling was made compulsory for all children. At the same time, the cost of compulsory education was subsidized from the national treasury. In 1907 the period of compulsory education was extended from four to six years. As the educational system gradually improved and as modernization progressed and the standard of living increased, school enrollments soared. The percentage of elementary-age children in school rose from 49 in 1890 to 98 in 1910.

In those days, boys and girls in primary school studied under the same roof, though in separate classrooms. In secondary education, however, there were entirely separate schools for boys and girls—the *chūgakkō,* or middle school, for boys and the *jogakkō,* or girls' high school, both aiming at providing a general education. Other than these, there was the *jitsugyōgakkō,* or vocational school, which was designed to afford vocational or industrial education for both boys and girls. All three secondary schools were for students who had completed the six- or four-year course of primary education.

As for the elementary and secondary curriculum, the Imperial Rescript on Education made it clear that traditional Confucian and Shintō values were to serve as the basis of moral education. This emphasis was implemented by courses on "national moral education" (*shūshin*), which served as the core of the curriculum. In 1903 a system of national textbooks was enacted, giving the Ministry of Education the authority to alter texts in accordance with political currents.

To meet the demand for an expansion of education, a new system for training primary-school teachers was established under the Normal School Order of 1886 and subsequently developed under the strong control of the government. All the normal schools were run by the prefectures, and none was private. At first only the graduates of the higher primary schools were qualified for the normal school, but in 1907 a new course was introduced for graduates of the middle schools and the girls' high schools. For training secondary-school teachers, there was after 1886 the *kōtō Shihangakkō,* or higher normal school for women. Additionally, temporary teachers' training institutes were established after 1902. These were all state-run. There were also state-run institutes for training vocational-school teachers.

Japan's imperial universities

For higher education, there were academies for the study of Confucianism, but a university of the European variety did not appear in Japan until 1877. In that year the University of Tokyo was founded, with four faculties—law, physical sciences, literature, and medicine. In the early years, research and education were dominated by foreigners: most programs were taught in the English language by English and American teachers or, in the medical faculty, in the German language by German instructors. In 1886 the University of Tokyo was renamed the Imperial University by imperial order and, as a state institution, was assigned to engage exclusively in research and instruction of such sciences and technology as were considered useful to the state. Modern Western sciences formed the core of this research and instruction, though some traditional Japanese learning was revived. Engineering and agricultural science were added to the four established faculties. Tokyo Imperial University borrowed much of the style and mode of the German universities and served as the model for the imperial universities established thereafter. Meanwhile, the higher middle schools established in 1886 were remodeled into the *kōtō-gakkō,* or higher schools, in 1894; and in the 20th century these higher schools developed as preparatory schools for the universities.

Higher education was advanced in another area by the College Order of 1903, which enabled certain upper-level private schools to be approved as *semmongakkō,* or colleges, and to receive the same treatment as state-run universities. Until then the private colleges had not been given a clear legal status and had been treated as rather inferior.

Education to 1940. The events of World War I and its aftermath tremendously influenced Japanese society. In the postwar days, Japan experienced the panic and social confusion that was sweeping many nations of the world. Moreover, the intensified leftist movement and the terrible Kantō earthquake of 1923 caused uncertainty and confusion among the Japanese. Nevertheless, the period was one that earned the name of the "Taishō democracy" era, which featured the dissemination of democratic and liberal ideas. It was also a period that marked Japan's real advancement on the world scene and the expansion of its capitalistic economy, all conducive to the flourishing of nationalism. It was quite natural that these social and economic changes should greatly influence education.

Efforts at reform

The Special Council for Education, established in 1917, was charged with making recommendations for school reforms that would adapt the nationalistic education system to the rapid economic growth. Their recommendations involved modifying the existing educational organizations rather than creating new ones. The reform emphasized higher education, though secondary education also grew remarkably. As for elementary education, the target of the reform was to improve the content and methods of education and to establish the financial foundation of compulsory education.

After World War I, the new educational movements generally called progressive in the West were introduced into Japan and came to thrive there. Many private schools advocating this "new education" were established, and the curricula of many state and public schools were also refashioned. The method of new education was gradually introduced into the state textbooks. Preschool education was also encouraged; a state-run kindergarten attached to Tokyo Girls' Normal School had been first established in 1876, and later many public and private kindergartens emerged, particularly after issuance of the Kindergarten Order in 1926.

Government aid for compulsory education was gradually put forward, and by 1940 this developed into a system whereby the government financed half the teachers' salaries and the prefectural governments the other half. Elementary education thus further expanded. Between 1910 and 1940 the number of elementary teachers and pupils almost doubled. In the latter year there were 287,000 teachers and 12,335,000 pupils.

Secondary education continued to be provided by the middle schools for boys, the girls' high schools, and the vocational schools. These schools increased remarkably both in numbers of institutions and in enrollments after World War I, reflecting the social demand. As a result, the secondary schools assumed more of a popular and less of an elitist character than they had evidenced in the Meiji era. In 1931 two courses were provided for the middle-school system; one was for those who advanced on to higher schools, and the other course was for those who went directly on to a vocation. Enrollments of all kinds leaped: whereas in 1910 the enrollments in middle schools, girls' high schools, and vocational schools had been 122,000 pupils, 56,200 pupils, and 64,700 pupils, respectively, the respective figures in 1940 were 432,000 pupils, 555,000 pupils, and 625,000 pupils.

Increases in enrollments, 1910–40

A drastic reform of higher education was instituted in 1918, when the University Order and the Higher School Order were issued on the recommendation of the Special Council for Education. Before that, there had been only the imperial universities, which were state-run. The order approved the founding of private universities and colleges. As a consequence, the old influential private col-

leges, or *semmongakkō,* rich in tradition, were approved as formal universities or colleges, resulting eventually in such famous universities as Keiō and Waseda. National colleges of commerce, manufacturing, medicine, and so on were also opened. In general, universities and colleges multiplied, numbering in 1930 as many as 46 (17 state, five public, and 24 private). College-preparatory education concurrently enlarged through the establishment of public and private higher schools under the Higher School Order. The higher schools were remodeled after the German *Gymnasium* and the French lycée and offered a seven-year course.

The schools could not keep pace with the mounting demand for education. The ratio of applicants to the total number of seats being offered at higher schools, for example, rose from 4.3 in 1910 to 6.9 in 1920 and 10.5 in 1926. Because pupils could not proceed from elementary to secondary schools, and from there to colleges or universities, unless they passed a competitive entrance examination at each stage, the importance and severity of the examinations grew with the number of applicants. Despite efforts by the Ministry of Education to revise and deemphasize the examination system, which was established in the Meiji era, its importance continues to the present day.

After World War I, social education, or education offered outside the formal school system, gained greater recognition in Japan. During the Meiji era, social education, then called "popular education," had been promoted by the Ministry of Education to encourage school enrollment, but by 1890 it had taken the form of adult education, attempting to enlighten middle- and working-class adults with public lectures and library resources. By 1929 social education had again become important as a result of the Ministry of Education's emphasis on youth organizations, supplementary vocational education, youth training, and adult education. The *jitsugyō hoshūgakkō,* or supplementary vocational schools, which had been built after 1893 as part-time educational institutions for working students, reached enrollments exceeding 1,277,000 by 1930. In 1935 *seinengakkō,* or youth schools, were newly established, uniting these supplementary vocational schools with the *seinen kunrenjo,* or youth-training centres, that had earlier been set up to provide military training for youth.

Education changes during World War II. The Manchurian Incident in 1931 escalated into the Sino-Japanese War of 1937, and national life became more and more militaristic. Education acquired an intensely nationalistic character. With the outbreak of war in the Pacific in 1941, the education system underwent emergency "reforms." Elementary schools were renamed *kokumingakkō,* or national schools, under the National School Order issued in 1941. The order proclaimed the idea of a national polity or spirit peculiar to Japan; the content and the methods of education were revised to reflect this nationalism. Moreover, the period of compulsory education was officially extended to eight years, though it actually remained six years because of the worsening war situation.

Militarism and nationalism

Secondary education was similarly made "national." In 1943 the Secondary School Order was issued in an attempt to unify all the secondary schools, but it also, because of the war, shortened secondary education to four years. In the same year the normal school was upgraded to the level of the professional schools. As the war worsened, students above the secondary schools were mobilized as temporary workers in military industries and agricultural communities in order to increase production, and a great number of students were sent to the battlefields. As a result, classes were virtually closed at schools higher than secondary toward the end of World War II.

Education after World War II. On Aug. 14, 1945, Japan accepted the Potsdam Declaration and surrendered unconditionally to the Allied powers. The overriding concern at the general headquarters (GHQ) of the Allied powers was the immediate abolition of militaristic education and ultranationalistic ideology. This was the theme of a directive issued by GHQ to the Japanese government in October 1945. In early 1946 GHQ invited the United States Education Mission to Japan, and it played a decisive role in creating a new educational system. The mission's report recommended thorough and drastic reforms of education in Japan. The report was subsequently adopted in its entirety as the basic framework for a new democratic educational system. The Education Reform Committee, which was directly responsible to the prime minister, was established to make recommendations for the implementation of the new education. Based on these recommendations the Japanese Diet passed a series of legislative acts that forged the foundation of postwar education.

The Fundamental Law of Education and the School Education Law, both enacted in 1947, and the Boards of Education Law of 1948 set the outlines of the new education. The prewar system was replaced by a democratic single-track system, in which school programs were integrated and simplified and the period of attendance was settled in six, three, three, and four years, respectively, for *shōgakkō,* or elementary schools, *chūgakkō,* or lower secondary schools, *kōtōgakkō,* or upper secondary schools, and *daigaku,* or universities. The period of compulsory attendance was extended to nine years; coeducation was introduced; and provisions were made for education for the physically handicapped and other special education.

The new Japanese school system

The reform of the content of education proceeded to reduce the strong state control of former days and to encourage teachers' initiative. State textbooks were abolished in favour of commercial ones, and schools were controlled locally by elective boards of education. *Shūshin* disappeared from the curricula and was replaced by new subjects, such as *shakaika,* or social studies, designed to prepare children for life in a democratic society. The educational reform also altered the character of the universities, which offered access to all citizens. The former institutions—universities, colleges, and normal schools—were reorganized into four-year universities and colleges. Teacher education was placed within the university system, and anyone who completed professional training was eligible for teacher certification. This reorganization had an immense impact upon the development of higher education.

The peace treaty of 1952 not only liberated Japan from the restraints of occupation but also allowed education there to be adjusted to intrinsic cultural and political orientations. Centralization of control increased with respect to administration, curriculum, textbooks, and teacher performance through a series of legislative and administrative measures in the 1950s. In addition, the political indoctrination of the leftist Japan Teachers' Union was hindered, and moral education was reintroduced as a requirement at the elementary and lower secondary levels. On the whole, however, the postwar educational reforms were retained and advanced, and their subsequent elaboration helped match Japan's rapid economic growth.

Changes after the end of Allied occupation

The postwar educational administration was organized into a three-tiered structure, with national, prefectural, and municipal components—all under the general supervision of the Ministry of Education, which also wields a considerable measure of authority over curricular standards, textbooks, and school finance, among other functions. Through its central, advisory role, the Ministry of Education has guided the development of egalitarian and efficient schooling in the postwar era.

The progressive curriculum, which emphasized child interest and was introduced from the United States immediately after the war, produced deteriorating student performance. Thus, during 1961–63 the Ministry of Education replaced that curriculum with a discipline-centred curriculum at the elementary and lower secondary levels in order to improve academic achievement, moral education, science and technical education, and vocational education. This curricular revision set the tone for later changes in the national curriculum. Each major curricular revision represented an educational response to a variety of social needs, above all economic.

The 1960s was a period of high growth for both the economy and education. The unprecedented economic growth was stimulated by an ambitious national plan to boost individual income, industry, and trade. Responding to the changing economic and industrial environment, enrollments in high schools and in colleges or universities increased, respectively, from 57.7 and 10.3 percent of

the eligible students in 1960 to 91.9 and 37.8 percent in 1975. Ninety percent of this increase in university and college enrollments was absorbed into poorly financed private institutions, which contributed to the deterioration of higher education. Problems also arose at the upper secondary level, where education remained rigidly uniform, even though students were increasingly diverse in ability, aptitudes, and interests. The inability of the postwar educational system to meet either student requirements or the insatiable demands for secondary and postsecondary education became of critical concern, and in 1971 the Central Council for Education recommended reforming Japan's education to eradicate these problems.

The Central Council initiated a sustained school reform debate that set the stage for the establishment, in 1984, of an advisory council on educational reform, which is directly responsible to the prime minister. The advisory council called for elimination of the uniformity and rigidity of education at all levels and for the enhancement of "individuality" through education. Its recommendations in 1987 included diversifying upper secondary education, improving moral education, encouraging greater local freedom and responsibility in developing curriculum, improving teacher training, and fostering diversity in higher education. Thus, Japan's educational policy is being directed toward meeting the diversified needs of the future. (A.Na./N.S.)

South Asia. *Preindependence period.* Amid the rising nationalism of the latter part of the 19th century, Indians became more and more critical of the domination of Western learning as imposed by the British rulers and demanded instead more attention to Indian languages and culture. The Indian National Congress, several Muslim associations, and other groups raised their voices against the British system of education. Nor were British authorities altogether blind to the needs of the country. When Baron Curzon of Kedleston arrived as viceroy in 1898, his determination to improve education was immediately translated into an order for a close survey of the entire field of education. It revealed: "Four out of five villages are without a school. Three boys out of four grow up without any education and only one girl out of forty attends any kind of school." Education had advanced, but it had not penetrated the country as the British had earlier expected.

Political conflicts involved in education in India

Curzon applied himself to the task of putting matters in order. He disapproved of the doctrine of state withdrawal and instead considered it necessary for the government to maintain a few institutions of every type as models for private enterprise to imitate. He also abandoned the existing policy of educational laissez-faire and introduced a stricter control over private schools through a vigilant policy of inspection and control. Such a policy aroused bitter feelings among some educated Indians, since it was believed that Curzon was bent on bringing the entire system of education under government control.

The main battle, however, was fought over the universities. With Eton and Balliol in mind, Baron Curzon set up the Indian Universities Commission of 1902 to bring about a better order in higher education. The commission made a number of important recommendations—namely, to limit the size of the university senates; to entrust teaching in addition to examining powers to universities; to insist on a high educational standard from affiliated colleges; to grant additional state aids to universities; to improve courses of studies; to abolish second-grade colleges; and to fix a minimum rate of fees in the affiliated colleges. The report was severely criticized, and the last two recommendations had to be dropped. Legislation in regard to the other proposals was passed despite bitter opposition in the legislature and the press.

The conflict resulted less from educational differences than from political opinions on centralization. In one part of the country, violent agitation had already started on the question of the partition of Bengal. In another, the patriot Bal Gangadhar Tilak declared: "Swaraj [self-rule] is our birthright." Thus, Baron Curzon's educational reforms were considered sinister in their intentions, and his alleged bureaucratic attitude was resented.

The administrative policy of Baron Curzon also gave rise to the first organized movement for national education. This effort was part of the swadeshi movement, which called for national independence and the boycotting of foreign goods. A body known as the National Council of Education, in Calcutta, established a national college and a technical institution (the present Jadavpur University) in Calcutta and 51 national schools in Bengal. These schools sought to teach a trade in addition to ordinary subjects of the matriculation syllabus. The movement received a great impetus, because the Calcutta Congress (1906) resolved that the time had arrived for organizing a national system of education. With the slackening of the swadeshi movement, however, most of the national schools were eventually closed. The effect of the movement was nevertheless noticeable elsewhere: Rabindranath Tagore started his famous school in West Bengal near Bolpur in 1901; the Arya Pratinidhi Sabha established *gurukulas* at Vrindāban and Hardwār; the Indian National Congress and the All-India Muslim League at their sessions in Allahābād and Nāgpur, respectively, passed resolutions in favour of free and compulsory primary education.

Swadeshi movement

In 1905 Baron Curzon left India. In order to pacify the general public, his successors modified his policy to some extent, but the main program was resolutely enforced. Although Indian public opinion continued its opposition, the reforms of Baron Curzon brought order into education. Universities were reconstituted and organized, and they undertook teaching instead of merely conducting examinations for degrees. Colleges were no longer left to their own devices but were regularly visited by inspectors appointed by the universities. The government also became vigilant and introduced a better system for inspecting and granting recognition to private schools; the slipshod system of elementary education was also improved. The number of colleges and secondary schools continued to increase as the demand for higher education developed.

In 1917 the government appointed the Sadler Commission to inquire into the "conditions and prospects of the University of Calcutta," an inquiry that was in reality nationwide in scope. Covering a wide field, the commission recommended the formation of a board with full powers to control secondary and intermediate education, the institution of intermediate colleges with two-year courses, the provision of a three-year degree course after the intermediate stage, the institution of teaching and unitary universities, the organization of postgraduate studies and honours courses, and a greater emphasis on the study of sciences, on tutorial systems, and on research work. The government of India issued a resolution in January 1920, summarizing the report of the commission. Since then, all legislation of any importance on higher education in any part of India has embodied some of the recommendations of the commission.

Meanwhile, World War I had ended, and the new Indian constitution in 1921 made education a "transferred" subject (that is, transferred from British to Indian control), entrusting it almost entirely to the care of the provinces. In each province, educational policy and administration passed into the hands of a minister of education, responsible to the provincial legislature and ultimately to the people. Although European-style education was still maintained as a "reserved" subject and was not placed under the control of the Indian minister of education, this anomaly was corrected by the Government of India Act of 1935, which removed the distinction between transferred and reserved subjects and introduced a complete provincial autonomy over education.

Generally, the new constitution of 1921 was considered inadequate by the Indian National Congress. In protest, Mahatma Gandhi launched the Non-cooperation Movement, the campaign to boycott English institutions and products. National schools were established throughout the country, and *vidyapeeths* ("national universities") were set up at selected centres. The courses of study in these institutions did not differ much from those in recognized schools, but Hindi was studied as an all-India language in place of English, and the mother tongue was used as the medium of instruction. These institutions functioned for a short time only and disappeared with the suppression of

Non-cooperation Movement

the Non-cooperation Movement. The Congress' struggle for self-rule, however, became more vigorous, and with it spread the national movement toward education to suit national needs. The Government of India Act of 1935 further strengthened the position of the provincial ministers of education, since the Congress was in power in major provinces. The developmental program of provincial governments included the spread of primary education, the introduction of adult education, a stress on vocational education, and an emphasis on the education of girls and underprivileged people. The importance of English was reduced, and Indian languages, both as subjects of study and as media of instruction, began to receive greater attention.

General educational trends, 1921–47

On this general background, educational developments from the inauguration of reforms in 1921 until independence in 1947 can be viewed. In the field of elementary education, the most important event was the passing of compulsory-education acts by provincial governments—acts empowering local authorities to make primary education free and compulsory in the areas under their jurisdiction. Another noteworthy feature was the introduction of Gandhi's "basic education," which was designed to rescue education from its bookish and almost purely verbal content by emphasizing the teaching of all school subjects in correlation with some manual productive craft. A general demand for secondary education developed with the political awakening among the masses. Schools in rural, semi-urban, and less advanced communities were established, as well as schools for girls. Some provision was made for alternative or vocational courses when the provincial governments started technical, commercial, and agricultural high schools and gave larger grants to private schools providing nonliterary courses. But the expected results were not achieved because of a lack of funds and of trained teachers. Secondary schools still concentrated on preparing students for admission to colleges of arts and sciences.

The period is also marked by a diminishing of the prejudices against the education of girls. The impetus came from the national movement launched by Gandhi, which led thousands of women to come out of the purdah for the cause of national emancipation. It was also realized that the education of the girl was the education of the mother and through her of her children. Between 1921–22 and 1946–47, the number of educational institutions for girls was nearly doubled.

In the field of university education, outstanding developments included (1) the establishment of 14 new universities, unitary as well as affiliating, (2) the democratization of the administrative bodies of older universities by a substantial increase in the number of elected members, (3) the expansion of academic activities through the opening of several new faculties, courses of studies, and research, (4) a substantial increase in the number of colleges and student enrollments, (5) the provision of military training and greater attention to physical education and recreational activities of students, and (6) the constitution of the Inter-University Board and the development of intercollegiate and interuniversity activities. With these improvements, however, the educational system of the country had become top-heavy.

The postindependence period in India. India and Pakistan were partitioned and given independence in 1947. Since then, there has been remarkable improvement in scientific and technological education and research, but illiteracy remains high (less than 40 percent of Indians aged four and older are literate). The new constitution adopted by India did not change the overall administrative policy of the country. Education continues to be the prime responsibility of the state governments, and the union (central) government continues to assume responsibility for the coordination of educational facilities and the maintenance of appropriate standards in higher education and research and in scientific and technical education.

In 1950 the government of India appointed the Planning Commission to prepare a blueprint for the development of different aspects of life, education being one of them. Since then, successive plans (usually on a five-year basis) have been drawn and implemented. The main goals of these plans have been to achieve universal elementary education; to eradicate illiteracy; to establish vocational and skill training programs; to upgrade standards and modernize all stages of education, with special emphasis on technical education, science, and environmental education, on morality, and on the relationship between school and work; and to provide facilities for high-quality education in every district of the country.

The education commissions and their recommendations

Since 1947 the government of India has also appointed three important commissions for suggesting educational reforms. The University Education Commission of 1949 made valuable recommendations regarding the reorganization of courses, techniques of evaluation, media of instruction, student services, and the recruitment of teachers. The Secondary Education Commission of 1952–53 focused mainly on secondary and teacher education. The Education Commission of 1964–66 made a comprehensive review of the entire field of education. It developed a national pattern for all stages of education. The commission's report led to a resolution on a national policy for education, formally issued by the government of India in July 1968. This policy was revised in 1986. The new policy emphasizes educational technology, ethics, and national integration. A core curriculum was introduced to provide a common scheme of studies throughout the country.

The national department of education is a part of the Ministry of Human Resource Development, headed by a cabinet minister. A Central Advisory Board of Education counsels the national and state governments. There are several autonomous organizations attached to the Department of Education. The most important bodies are the All-India Council of Technical Education (1945), the University Grants Commission (1953), and the National Council of Educational Research and Training (1961). The first body advises the government on technical education and maintains standards for the development of technical education. The second body promotes and coordinates university education and determines and maintains standards of teaching, examination, and research in the universities. It has the authority to enquire into the financial methods of the universities and to allocate grants. The third body works to upgrade the quality of school education and assists and advises the Ministry of Human Resource Development in the implementation of its policies and major programs in the field of education.

The central government runs and maintains about 1,000 central schools for children of central government employees. It has also developed schools offering quality education to qualified high achievers, irrespective of ability to pay or socioeconomic background. The seventh five-year plan (1985–90) specified that one such *vidyalaya* would be set up in each district. The state governments are responsible for all other elementary and secondary education. Conditions, in general, are not satisfactory, although they vary from state to state. Higher education is provided in universities and colleges.

From the 1950s to the '80s the number of educational institutions in India tripled. The primary schools, especially, experienced rapid growth because the states have given highest priority to the universalization of elementary education in order to fulfill the constitutional directive of providing universal, free, and compulsory education for all children up to the age of 14. Most but not all children have a primary school within one kilometre of their homes. A large percentage of these schools, however, are understaffed and do not have adequate facilities. The government, when it revised the national policy for education in 1986, resolved that all children who attained the age of 19 years by 1990 would have five years of formal schooling or its equivalent. Plans have also been made to improve or expand adult and nonformal systems of education. Dissension among political parties, industrialists, businessmen, teacher politicians, student politicians, and other groups and the consequent politicization of education have hampered progress at every stage, however.

The postindependence period in Pakistan. On Aug. 14, 1947, Pakistan emerged as a national sovereign state. For the new state the initial years proved to be a period essentially of consolidation and exploration. The constitution adopted in 1956 recognized the obligation of the state to

provide education as one of the basic necessities of life. The new constitution implemented by the National Assembly in 1973 made practically no changes to the original educational policy. The federal Ministry of Education, headed by the federal education secretary, oversees education in the federal capital territory and in national institutions and determines policies and standards. Provincial governments handle all other administrative duties.

Aims of Pakistani educational policy

Beginning in 1955, Pakistan adopted a series of five-year plans to improve economic and educational development. The most important educational objectives of the sixth plan (1983–88) were: (1) to strengthen training programs for all categories of manpower, (2) to establish technical trade schools and vocational institutes, (3) to provide adequate machinery, materials, and books for workshops, laboratories, and other facilities, and (4) to strengthen and develop centres for advanced engineering studies. Because less than 30 percent of the adult population is able to read and write, literacy is also a major area of concern. The National Education Policy of 1979 emphasized the need for improving vocational and technical education and for disseminating a common culture based on Islāmic ideology. It also announced plans for gradually replacing the four-tier school structure (primary, secondary, college, and university) with a three-tier system consisting of primary (grades one through eight), secondary (grades nine through 12), and higher education.

The government has accepted responsibility for providing free primary education for a length of time fixed provisionally at five years. Only a little more than 50 percent of primary-age children are enrolled in schools, however, with attendance concentrated in urban areas. Religious classes providing Islāmic moral and sociocultural education have been taught in the schools since about 1980. An alternative course for non-Muslim students is also being introduced.

The postindependence period in Bangladesh. Comprising what was formerly the eastern wing of Pakistan, Bangladesh emerged as an independent sovereign state in December 1971. Thus, it shares its educational history with India until 1947 and with Pakistan from 1947 to 1971. After independence Bangladesh continued to follow the primary education scheme originally established by Pakistan. One of the country's most valued educational assets is its rich national language, Bengali.

Article 17 of the constitution of the People's Republic of Bangladesh declares that it is the duty of the state to provide education to all its children to such stage as may be determined by law. In 1973 and 1974 the government nationalized most of the primary schools, but it was found that about 33 percent of primary-school-age children in Bangladesh never went to school and that about 70 percent of those who did left school before attaining the minimum educational standard. The majority of children thus enter adulthood illiterate. It has now been recognized that universalization of primary education for an overpopulated developing country like Bangladesh is a difficult task. Major reforms are under way to orient the educational system to a new social order inspired by the ideals of "nationalism, democracy, socialism, and secularism" on which the new nation is founded.

The postindependence period in Sri Lanka. Sri Lanka (formerly Ceylon) gained independence in 1947. Successive governments have since continued the policy of democratizing education that began under British rule. The political and social changes ushered in during the preindependence period paved the way for a gradual process of constitutional reforms. Schools and schooling are seen as great instruments of socioeconomic development.

Education is free from the kindergarten to the university level in all state and state-aided institutions. Although there are a few fee-levying private institutions, management of education is primarily a state responsibility. General education within the formal system is divisible into primary, junior secondary, and senior secondary education. There are few dropouts or grade repeaters at the primary level. Thus, the percentage of literacy rose from 57.8 (70.1 for males and 43.8 for females) in 1948 to 86.5 (90.5 males, 82.4 females) in 1981. At the junior secondary stage, instruction is provided according to a common curriculum that consists of religion and other subjects. Students at the senior secondary stage are streamed into science, commerce, or liberal arts courses.

The University Act of 1978 established the University Grants Commission and the University Services Appeals Board to provide for the establishment, maintenance, and administration of universities and other higher educational institutions together with their campuses and faculties. The National Institute of Education was established in 1987 to coordinate curriculum development, textbook development, teacher education, and eventually certification and entrance examinations. (S.N.M.)

Africa. Before the arrival of the European colonial powers, education in Africa was designed to prepare children for responsibility in the home, the village, and the tribe. It provided religious and vocational education as well as full initiation into the society. In sub-Saharan Africa it varied from the simple instruction given by fathers to children among the San of the Kalahari to the complex educational system of the sophisticated and highly organized Poro society of western Africa (extending over Liberia, Sierra Leone, and Guinea). The majority of ethnic groups in Africa fell somewhere between the San and the Poro with respect to the educational arrangements they provided for their youth. Most societies offered rituals to mark the end of puberty and relied heavily upon custom and example as the principal educational agents. The rites of passage marked the culmination of an epoch in a boy's life. As a child, he had been introduced by his elders to the legends surrounding previous exploits of his tribe, to the mysteries of his religion, to the practical aspects of hunting, fishing, farming, or cattle-raising, and to his community responsibility. Now he occupied a new position in the society. In some cases he had been prepared for the rites; in others secrecy surrounded the event, for reaction to the ceremony was itself an important part of the ritual. A variety of formal observances, in addition to the experiences of daily living, impressed upon the youth his place in the society, a society in which religion, politics, economics, and social relationships were inextricably interwoven. Girls underwent a similar, though usually shorter, initiation period.

Traditional African education

An exception to this pattern could be found in those areas where Islām had spread. Islām reached eastern Africa in the 9th and 10th centuries and western Africa in the 11th. It introduced the Arabic script, and, because knowledge of the Qur'ān became an important religious requirement, Qur'ānic schools developed. These schools concentrated on the teaching and memorization of the Qur'ān; some were little more than gathering places beneath a tree where teachers held classes. Qur'ānic schools placed young Africans in contact with Arab civilizations, and boys selected as potential leaders could attend higher educational institutions in the Arab world. Nevertheless, Islām touched but a small fraction of the total African population of sub-Saharan Africa.

Western-style schooling was introduced in most of Africa after the establishment of the European colonial powers. As African nations gained independence in the late 20th century, they abolished the racial segregation that had existed and instituted other reforms but, in general, kept the structure of the existing school systems, at least initially. Thus, 20th-century education in these countries can be discussed according to former colonial status. Education in Ethiopia, Liberia, and South Africa, however, must be treated separately—Ethiopia and Liberia because they have long histories as independent nations and South Africa because it remains under the control of a white minority government.

Ethiopia. Christianity was recognized in Ethiopia in the 4th century. For nearly 1,500 years all education was church-related and hence church-controlled, except in the eastern part of the country where the Islāmic population maintained Qur'ānic schools. In 1908 Emperor Menelik II created the embryonic government school system, modeling it on European systems. The real development of education, however, came after World War II under the direction of Emperor Haile Selassie. Despite his efforts, by 1969 less than 10 percent of the children between the

Post-World War II expansion of Ethiopian education

ages of seven and 12 were in school. Education at the secondary level benefited from the infusion of more than 400 Peace Corps teachers in the 1960s and early 1970s. In the 1950s the first Ethiopian colleges were founded. By 1970, 2,800 Ethiopian students were enrolled in higher education either in their own country or overseas.

In 1974 a military revolution overthrew the emperor. Ethiopia declared itself a socialist state and proclaimed that socialism would permeate all aspects of the society. The government's stated aims of education were (1) education for production, (2) education for scientific consciousness, and (3) education for social consciousness. Political alliance with the Soviet Union influenced educational reform. Polytechnical education, which emphasizes familiarizing children with the important branches of production and acquainting them with first-hand practical experience, was widely introduced by Soviet educational advisers. A number of Ethiopian students have been sent to the Soviet Union or Eastern-bloc countries for higher education or to Cuba for schooling at the secondary level.

The structure of the Ethiopian school system remained unchanged from that established in the late 1950s. Children begin the 12-year program at age seven. Grades one through six make up the primary cycle, seven through eight the junior secondary cycle, and nine through 12 the senior secondary cycle. Students who pass the Ethiopian School Leaving Certificate Examination at the end of grade 12 are eligible for higher education, but space in the country's colleges and universities is limited.

Liberia. Education in Liberia, the oldest republic in Africa (1847), is distinctly different from that in any other African country. Liberia was founded by freed slaves from the United States, and its educational system was modeled after the American system. Public primary and secondary schools were established in the 19th century for the children of the settlers, but there was little money to extend schooling into the interior of the country for the indigenous people. Church schools were also established. The Western-style schools trained Liberians in the new settlements for work in offices. A few students were prepared for the legal or theological profession.

American influence on Liberian education

In 1912 a centralized educational system was established under a Cabinet-level official, but, except for the establishment of a few secondary schools and colleges, nothing of importance happened until the end of World War II. In the prewar period three-fourths of the schools were either private or mission-run. Economic growth and the interest of President William V.S. Tubman in the 1950s resulted in a greater extension of education for indigenous Liberians. The educational system was organized to provide preprimary education for children aged four and five years, six years of elementary education for children aged six to 12, and three years each of junior and senior high school. Postsecondary education can be pursued at three leading institutions: the University of Liberia, sponsored by the government; Cuttington University College, administered and financially supported by the Episcopal church with some financial aid from the government; and the William V.S. Tubman College of Technology. The educational expansion started by President Tubman in the 1950s has, however, due to the lack of finances, reached only a small fraction of the people. (Da.G.S.)

South Africa. From the time of the first white settlements in South Africa, the Protestant emphasis on home Bible reading ensured that basic literacy would be achieved in the family. Throughout the development from itinerant teachers to schools and school systems, the family foundation of Christian education remained, though it was gradually extended to embrace an ethnic-linguistic "family."

Early efforts to establish education in South Africa

Despite some major 19th-century legislation on the administration of education (1874 in the Transvaal and the Orange Free State, 1865 in Cape of Good Hope, 1873–77 in Natal) and some early efforts to establish free schools, political and linguistic problems impeded the development of public education before 1900. Natal had gone furthest in affirming government responsibility for education and setting up the necessary administrative machinery, but, by and large, provision for schooling remained voluntary and piecemeal until the beginning of the 20th century.

The Boer, or South African, War (1899–1902) suspended educational development entirely and confirmed the resolve of each white South African group to protect its own cultural prerogatives. When the Union of South Africa was created in 1910, it was a bilingual state, and, in education, English-speaking and Afrikaans-speaking schools were established for white Europeans. Furthermore, a political tightness and separateness increased among the Afrikaners after the war and strengthened their tendency to exclude nonwhites from the cultural and political life of the dominant society. The trend toward separate schools for linguistic and racial groups became a rigid practice in most of South Africa after union.

Church mission schools attempted to replace the preliterate tribal education of native Africans in the South African colonies. Established from 1789, they were dedicated to converting the natives to Christianity and generally inculcating an attitude of service and subservience to whites. These schools spread from 1823 to 1842, and colonial governments made occasional grants to them from 1854. Some mission schools included a mixture of races, but, by and large, segregation was established by custom. Although some exemplary schools followed rather liberal social and curricular policies, most schools held to narrowly religious content. The mission schools were virtually brought into the state system through government subsidies and through provincial supervision, inspection, and control of teaching, curriculum, and examination standards.

The union and school systems

By the time the union was formed, the new provinces had each established school systems, structured mainly for European children but including provisions for other groups. Specific arrangements varied, but basically the systems were headed by a department of education under a director and controlled through an inspectorate. Three of the provinces had school boards that localized the department administration. Compulsory-attendance regulations were being effected for European children, while separate school developments were under way for other groups. The language of instruction had been established provincially, with both Afrikaans and English in use.

The South Africa Act of 1909 left the control of primary and secondary education with the provinces, while reserving higher education to the union government. The Union Department of Education, Arts, and Science became the central educational authority and expanded its responsibilities by accepting control of special sectors such as vocational, technical, and artistic education. In 1935 an Interprovincial Consultative Committee was established to coordinate educational matters among the provinces and between the provinces and the central government. In 1967 the union government passed the National Education Policy Act, which, with the Amendment Act of 1982 and the Constitution Act of 1983, forms the basis for South African education. The provinces have incorporated this policy into their own legislation and administrative provision.

Administration of education is divided between national departments and provincial authorities. Because education is differentiated by race, four separate systems must be distinguished, although recent legislation has stated the principle of equal education opportunity and structures have become similar for white, Coloured (of mixed ancestry), and Indian (Asian) population groups. Education for whites is under control of the Minister of National Education, and provincial federal coordination is accomplished through a National Education Council and a Committee of Heads of Education. Education for Coloureds and Indians is administered through the legislative bodies representing these groups, the House of Representatives and the House of Delegates, respectively. Education for blacks is the responsibility of the four independent (although not internationally recognized) republics (Transkei, Bophuthatswana, Venda, Ciskei) and the six nonindependent "states" (Gazankulu, KaNgwane, KwaNdebele, KwaZulu, Lebowa, and Qwaqwa) established by the government. For blacks not in these areas, the Department of Education and Training administers education.

All four systems are now supposed to be following the same basic organizational and curricular patterns. Legis-

lation in 1973 and 1983–84 has made it possible to refer to the education of Coloured and Indian children when describing structural features of schooling developed for white children. The system is organized into four three-year cycles: junior primary, senior primary, junior secondary, and senior secondary. Because the first year of the junior secondary cycle is taken in the primary school, the primary and secondary units are seven and five years respectively (replacing the earlier eight–four organization). Schooling is compulsory from age seven to 16. Core syllabi are established by the National Education Council and elaborated by the provinces or other departments. The general high schools are predominantly academic but offer a range of streams. Specialized high schools, at the senior secondary level, offer technical, agricultural, commercial, art and domestic science courses. Apprenticeship may be begun after the first year of the senior secondary phase (grade 10). Attempts are now being made to form regional comprehensive schools. Private schools, both independent and aided, are found mainly in Transvaal and Cape Province, but over 90 percent of South African white children are in state schools.

English and Afrikaans and the division of education

The language of instruction does not greatly affect the curriculum or organization of schools, but it does present a basic educational division in South Africa. Both English and Afrikaans are official languages of the republic. About 60 percent of the white population speak Afrikaans and about 40 percent English, and the two languages are used almost proportionately in schools. By law, instruction is given in the mother tongue, the other language being introduced as a second language. Coloured and Asiatic pupils are taught in the official language common to their area of residence, normally Afrikaans and English respectively. African pupils are taught in their mother tongue at least until they begin the senior primary cycle (grade 4), and then one of the official languages is used. They must study both English and Afrikaans, although they may offer one African and one official language for the examination at the end of the secondary course. Language is intimately related to politics and to African aspirations. It was the imposition of Afrikaans as the compulsory language of instruction that triggered the Soweto riots in 1976 and the subsequent wave of unrest. Black parents and students want recognition of their own language and culture (Africanization) as well as the access to the metropolitan culture of their own and other countries that English gives.

In 1922, when the Phelps–Stokes Commission on education in Africa offered its report, South Africa's example in the development of liberal and adaptable educational provisions for Africans, particularly in Natal and Cape Province, was held up for emulation. The passing of the tribal system was noted and efforts toward interracial cooperation complimented. It was obvious, however, that little of value to Africans was being done in the European-model schools and that noteworthy educational efforts were associated with special institutions, such as Lovedale School and University College of Fort Hare in the Cape.

Concern over Bantu education in the 1940s led to the creation of the Eiselen Commission, whose report in 1951 accorded with the separatist views of the nationalist government coming to power in 1948 and presented a basis for apartheid legislation in education. The Bantu Education Act of 1953 resulted.

Apartheid and Bantu education

The policy of apartheid, or "separate development," has been controversial, both within South Africa and throughout the world. Fundamentally, the government position rests on three assumptions: (1) that each cultural group should be encouraged to retain its identity and develop from its present stage according to its unique characteristics, (2) that, with a population of diverse racial-social groups, the way to ensure peaceful coexistence and general progress is through legal and institutional separation, and (3) that the only agency capable of exercising overall responsibility for this development is the central government. Implementation of apartheid policy has led to a virtually total separation of educational facilities for white, black, Coloured, and Indian populations, with resulting divergence of opportunity between the extremes of black and white education.

The Education and Training Act of 1979 established principles following the pattern of white education for the education of blacks. Slightly different school organization, designation of state-aided community schools with school committees, provision for African language instruction, and separate administration are formal characteristics distinguishing the system for blacks. More important are the effects of inequality on the system's operation. Although the government has introduced a limited experiment in compulsory education, the dropout rate among blacks is high from the earliest years, and markedly so after the fourth year. Because of work conditions, pupils may be educated in factory, mine, or farm schools that are less adequate than general schools. Teacher qualifications are lower for blacks than for the other groups. Illiteracy is high. Rural schools are crowded and short of materials. Although black pupils constitute about 70 percent of the primary school enrollment, few attend secondary schools.

There have been some attempts made to close the gap between black and white education at both lower and higher levels. The government has proclaimed the principle of equal educational opportunity and has increased financing, private and community efforts have augmented schooling and introduced experimental integrated schools, and private schools and white universities have opened to black students. Black schools remain severely inadequate, however; and the government's position that the immensity of the problem defies immediate solution conflicts with the demands of black activist student organizations, which have multiplied since 1976 (partly through division) and intensified their resistance through strikes and boycotts. Thus, violence and fear have increasingly intruded on township schools and on black universities.

South African university education

The tertiary sector of South African education includes universities, technikons—successors to the colleges of advanced technical education, offering programs of one to six years in engineering and other technologies, management, and art—technical colleges and institutes, and colleges of education. Technical centres, industrial training centres, and adult education centres extend training to early school-leavers. The previously discriminatory qualifications required for primary and secondary teachers as well as for teachers from the different racial groups have been standardized. All teachers must complete the full secondary course plus a three-year training course. Teachers' professional organizations comprise a bewildering array of English, Afrikaaner, African. Coloured, and Indian organizations on the national and local levels. Recently, there has been agitation for a single teacher-registering body. Joint bodies already exist.

By the Extension of University Education Act in 1959, nonwhites were barred from entrance to white universities and separate university colleges were set up on an ethnic-linguistic basis. This well-organized system of differentiating groups has begun to break down, however, as first English, then Afrikaans universities stated their policies of admission by merit, as university decisions and legislation have opened nonwhite universities to other groups, and protests against government quotas on university admissions have become increasingly effective. The universities have become centres of agitation against apartheid.

A major government commission, conducted through the Human Sciences Research Council, in 1981 recommended the establishment of a single system of education under a single ministry. Although principles of the report were accepted, the government has held to a cultural policy from which institutional separation is derived. The change from an ideological basis to a pragmatic basis for this separation, combined with the elimination of formal barriers to racial crossovers and black mobility in education, has produced a policy that is competing with revolutionary strategies for social change. (R.F.L.)

Early mission and lay schools

General influences and policies of the colonial powers. During the colonial period, the first direct "educational" influences from outside came from religious missionaries, first Portuguese (from the 15th century) and then French, Dutch, English, and German (from the 15th to the 19th century). Starting from coastal bases, they undertook to penetrate into the interior and begin campaigns to convert

the black populations. The missions were the first to open schools and to develop the disciplined study of African languages, in order to translate sacred texts or to conduct religious instruction in the native tongues.

The partition of Africa by the colonial powers in the 19th and early 20th centuries led first to the establishment of mission schools and then to the establishment of "lay" or "public" or "official" schools. The importance of either the lay or the religious system depended on the political doctrines of the mother country, its institutions (a firmly secular state or one with a state religion), and the status of the colony and its history. But, whatever the system, the fundamental purpose of colonial instruction was the training of indigenous subaltern cadres—clerks, interpreters, teachers, nurses, medical assistants, workers, and so forth—all indispensable to colonial administration, businesses, and other undertakings. Though inspired by the system in the mother country, no colonial system was equivalent to its prototype. The intention was not to "educate" the subject peoples but to extend the language and policies of the colonizer.

Such a generalization, though, is subject to a slight qualification with reference to the religious missions. Both the missions and the political administrations wished to model the African man in accordance with their own needs and objectives. The religious missions, however, became involved in the cultures of the Africans through continual contact with them in the daily ministrations; they used African languages in instruction wherever the colonial administration permitted it. Moreover, for a long while, religious establishments were alone in offering vocational education, some secondary education, and even some higher education to Africans—frequently in the face of the fears or opposition of the colonial authorities.

Education in Portuguese colonies and former colonies. Angola and Mozambique shared a common historical legacy of hundreds of years of Portuguese colonization, and the general overall educational philosophy for both countries was the same until independence. For Portugal, education was an important part of its civilizing mission. In 1921, Decree 77 forbade the use of African languages in the schools. The government believed that since the purpose of education was integration of Africans into Portuguese culture the use of African languages was unnecessary. In 1940 the Missionary Accord signed with the Vatican made Roman Catholic missions the official representatives of the state in educating Africans. By the 1960s an educational pattern similar to that in Portugal had emerged. It began with a preprimary year in which the Portuguese language was stressed, followed by four years of primary school. Secondary education consisted of a two-year cycle followed by a three-year cycle. After 1963 two universities were opened, one in Angola and the other in Mozambique. In addition, postprimary education was offered in agricultural schools, in nursing schools, and in technical service courses provided by government agencies. Despite remarkable progress in the 1960s, primary education was available to few Africans outside urban areas, and even there, the proportion of African children in secondary schools was low.

Educational reforms after independence

Marxist governments triumphed in both Angola and Mozambique when independence came in 1975. Dissident groups, however, have maintained bloody civil wars in both countries that have had disastrous effects on the educational systems. The Popular Liberation Movement of Angola (Movimento Popular de Libertação de Angola; MPLA), which gained control of Angola when Portugal withdrew, had educational reform as one of its main objectives even during the fight for independence. A report of the first congress of the MPLA published in 1977 provided a blueprint that has been followed with few deviations. Marxism-Leninism is stressed as the base for the educational system. The training of all people to contribute to economic development is a major objective. Eight years of primary education is to be universal. Secondary education, offered on a limited basis, includes vocational as well as college preparatory courses. At the University of Angola special emphasis has been placed on scientific and engineering courses.

The governing Mozambique Liberation Front (Frente de Libertação de Moçambique; Frelimo) introduced its educational system in the areas it controlled even before independence. After independence, at the Third Congress of Frelimo in February 1977, policies for the transition to socialism were formalized. While Marxism would provide a foundation, the particular needs of Mozambique would be addressed. All schools were nationalized, but because most of the teachers, who were Portuguese, had left the country, the government was faced with a tremendous teacher shortage. Crash programs in teacher training were introduced. Textbooks, although very limited, were produced that reflected the culture of Mozambique. Most are in Portuguese, which remained the official language of the country, in part because none of the multitude of different cultural groups dominates.

German educational policy in Africa. Well before Chancellor Otto von Bismarck had granted a charter to the German Colonial Society in 1885, German missionaries, both Protestant and Catholic, were operating in various regions of western, central, and eastern Africa—from 1840 in Mombasa (now in Kenya), from 1845 in Cameroon, from 1847 in Togo, and from 1876 in Buganda (now Uganda) and in Mpwapwa and Tanga (now in Tanzania). Instruction was everywhere conducted in the local languages, which were objects of study by numerous missionaries and by eminent scholars.

Missionary schools in German areas

On the eve of World War I, more than 95 percent of the schools in German Africa were operated by religious groups. In the southwestern part of the continent the government did not establish any schools at all, relying completely on missionary activity. (In eastern Africa, however, where the large Muslim population was unwilling to send its children to schools managed by Christian religious groups, the government did assume a more active educational role.) To assist the missions, the government granted aid to those schools that met requirements based on specific government needs that changed with time. An example of this sort of aid was the fund founded in 1908 for the dissemination of the German language. The missions had not previously been required to include German in the curriculum but were now forced to do so in order to receive money from the new fund. The language problem was a persistent one and was handled differently in different colonies. In eastern Africa, Swahili was recognized as a language and emphasized in the lower schools, thus providing a lingua franca for the entire area. The government attempted a similar policy with Ewe in Togo and Douala in the Cameroons, but, in southwestern Africa, German was the language of instruction.

Throughout the literature on German educational policy in the African colonies, there is a continued emphasis on the necessity for vocational education and practical work. The missions, however, were more interested in establishing schools providing general education, and lay German educators took a dualistic approach to African education, emphasizing both practical and academic studies.

The absorption of German colonies by England and France after World War II eradicated most of the German influence in education. However, the German insistence on Swahili in German East Africa left that area far more unified linguistically than any other colonial area.

Education in British colonies and former colonies. In the British colonies, as elsewhere, religious missions were instrumental in introducing European-type education. The Society for the Propagation of the Gospel in Foreign Parts, the Moravian Mission, the Mission of Bremen, the Methodists, and Roman Catholic missionaries all established themselves on the Gold Coast (Ghana) between 1820 and 1881, opening elementary schools for boys and girls, a seminary, and eventually a secondary school (in 1909). In Nigeria, Protestant missions were opened at Badagry, Abeokuta, Lagos, and Bonny from 1860 to 1899, and the Roman Catholic missions entered afterward and opened the first catechism, primary, secondary, and normal schools. In Uganda and Kenya the Church Missionary Society, the Universities Mission to Central Africa, the White Fathers, and the London Missionary Society opened the first mission schools between 1840 and 1900.

The first official lay schools came later and for a long time constituted a weak minority. In 1899 in Nigeria, for instance, only 33 of the 8,154 primary schools were government-run and only nine of the 136 secondary schools and 13 of the 97 normal schools. Similarly in the Gold Coast in 1914 the government was responsible for only 8 percent of the schools. In Kenya and Uganda, all schools were conducted by missions. Not until 1922 did the British government assume some responsibility for education in Uganda by opening the first government technical school at Makerere (the future Makerere University College). Only in territories seized from the Germans in World War I did the British take over the administration of existing government schools. Generally the British preferred to leave education to missions, which were given variable financial aid, usually from local and inadequate sources.

British efforts at reform in the 1920s and '30s

Following the publication of critical reports in 1922 and 1925, when there was growing uneasiness among the Africans, the missions, the governors, and the administrators, the necessity of a precise policy on education was imposed on the British authorities. In 1925 an Advisory Committee on Education in the Colonies, created in 1924 and presided over by William Ormsby-Gore, published an important report. The ideas, principles, and methods formulated in this document covered the matters involved in defining a policy; namely, the encouragement and control of private educational institutions, the cooperation by the governmental authorities with these institutions, and the adaptation of education to the traditions of the African peoples. Special importance was attached to religious and moral instruction, to the organization and status of education services, to subsidies to private schools, to instruction in the African languages, to the training of native teachers, to the inspection of schools and the upgrading of teachers, to professional training and technique, and to the education of young girls and women. The structure of an educational system, at the most advanced stage, was to consist of an elementary education (generally six years), diversified middle and secondary education (four to six years), technical and professional schools, specialized schools of higher education, and adult education.

In practice, subsequent British policy in black Africa was far from the recommendations of the Ormsby-Gore committee. The subsidies to mission schools were subject to regulations that varied from one colony to another and paid insufficient attention to the character of the education. The development of instruction, especially secondary, was generally curbed, and various local associations and numerous organizations therefore arose to promote the expansion of education. The colonial governments exerted real effort only on behalf of schools that trained subaltern cadres for administration and commerce (mostly schools for the children of chiefs and prominent persons and the colleges at Makerere and Achimota). Government-sponsored secondary education began only after 1930 in the Gold Coast, only in a conditional manner in 1933 at Makerere College in East Africa, and only after 1935 in Nigeria. In Uganda no complete secondary school existed until 1945.

The Advisory Committee reports published in 1935 and 1944 raised the same questions and the same fundamental themes, indicating that the government still was playing an insufficient role in education. Development was primarily a result of the efforts of missions, of various private local or foreign institutions, and of local indigenous authorities. After World War II the different sectors of education were developed with the growing participation of Africans, who were gaining more autonomy. Secondary education expanded. Institutions of higher learning were improved and increased in number: university colleges were established at Accra and Ibadan in 1948, at Makerere in 1949, and at Khartoum in 1951; a College of Technology (later, University of Science and Technology) was founded in Kumasi in 1951; and the Royal Technical College of East Africa (later, University College) was founded in Nairobi in 1954. Beginning in 1950, development plans for the various colonies—Ghana (the Gold Coast), Nigeria, Sierra Leone, Kenya, Uganda, and Tanganyika—contributed to educational progress.

Upon achieving home rule and then independence, the new African states born of the old British colonies were inheritors of an educational system that, though better than that of the other African states, was still a cause for concern. In most states (Ghana, Kenya, and Malawi being the only exceptions) less than 40 percent of the population had a primary education. Secondary education was even less widespread, Ghana being the only country in which it exceeded 10 percent. Higher education existed in urban centres but still in an embryonic state. Other serious obstacles to the ultimate development of education for all the people included the diversity of organizations and institutions responsible for education, the necessity for students to pay fees, and the complexity of the legislation in force.

Educational improvements after independence

Every one of the various countries set out to improve education. They offered subsidies to private schools, extended supervision over them, and regulated their tuition. They increased the number of primary and secondary schools offering free or partly free instruction and created numerous institutions of higher learning, such as the universities of Cape Coast in Ghana, of Lagos, of Ifẹ̀, and of Ahmadu Bello in Nigeria, and the universities of Dar es Salaam in Tanzania, Nairobi in Kenya, and Makerere in Uganda. The educational systems inherited from colonial rule were racially integrated and subjected to "Africanization." The rate of educational growth is not spectacular, however. Moreover, the place made for African languages in primary education seems everywhere to have been eclipsed by English, the official language—in spite of the widespread use of African languages in the mass media.

Education in French colonies and former colonies. As elsewhere in Africa, mission schools were the first to be established in French colonies. Although public or official schools appeared in Senegal between 1847 and 1895, the first such schools in Upper Senegal, Niger, Guinea, the Ivory Coast, and Dahomey were begun only from 1896 on.

Only after 1900, with the organization of the federated colonies of French West Africa and French Equatorial Africa, was there a French colonial policy on education. By decree in 1903, education in French West Africa was organized into a system of primary schools, upper primary schools, professional schools, and a normal school. Two further reorganizations followed decrees in 1912 and 1918, and important schools were established—the St. Louis Normal School in 1907 (transferred to Gorée in 1913), the School for Student Marine Mechanics of Dakar in 1912, and the School of Medicine of Dakar in 1916. The educational organization that remained in force in French West Africa from 1924 until 1947 included a system consisting of primary instruction for six years (regional urban schools), of intermediate–higher primary education given in upper primary schools and in professional schools (generally one for each colony), and at the top the federal schools—two normal schools, a school of medicine and pharmacy, a veterinary school, a school for marine mechanics, and a technical school. The two schools for secondary education, both in Senegal (the Faidherbe State Secondary School of St. Louis and Van Vollenhoven State Secondary School, at Dakar), were reserved for Europeans and those rare Africans having French status.

Total enrollment in French West African schools rose from 15,500 in 1914 to 94,400 in 1945. The number of students in the higher primary schools grew in the same period only from 400 to 800 or 900. (The area's total population in 1945 was almost 16 million.)

French educational policy in Africa

Educational policy was stated frankly in the official statements of governors general:

> Above all else, education proposes to expand the influence of the French language, in order to establish the [French] nationality or culture in Africa (*Bulletin de l'Enseignement en AOF*, No. 45, 1921); Colonial duty and political necessity impose a double task on our education work: on the one hand it is a matter of training an indigenous staff destined to become our assistants throughout the domains, and to assure the ascension of a carefully chosen elite, and on the other hand it is a matter of educating the masses, to bring them nearer to us and to change their way of life. (From *Bulletin de l'Enseignment en AOF*, No. 74, 1931.)

After World War II, all inhabitants of the newly established "French Union" became citizens in common who

were represented in the French Parliament. This political policy carried over into education, which became even more assimilationist: the old higher primary schools, for instance, became classical and modern secondary schools on the French model. An Investment Fund for Economic and Social Development provided financial and developmental aid to education—to the extent that primary enrollments rose to 156,000 in 1950 and to 356,800 in 1957, and higher primary enrollments rose to 5,800 in 1950 and to 14,100 in 1957. Technical and professional education also expanded, from 2,200 students in 1951 to 6,900 in 1957. Scholarships, awarded by the central government, the colonies, and local groups, enabled an increasing number of African youths to pursue higher education in France. In Senegal in 1950 the first French West African university was established, the Institute for Higher Studies, later called the University of Dakar, followed by those of Abidjan and Brazzaville.

In 1957 and 1958, when the colonies achieved autonomy and then a kind of commonwealth status within the new French Community established by the Gaullist constitution, education began a more intensive development, at least quantitatively. More primary and secondary schools were opened; teacher training was accentuated; and more scholarship students went to France. Within three years, after the French African countries had achieved full independence, this upgrading of education accelerated. Curricular reforms, however, have been slow. Although such countries as Guinea, Mali, and the Congo (Brazzaville) introduced such reforms as the Africanization of history and geography, generally the traditional French system persists, and courses are taught in French. The so-called ruralization of primary education—that is, the spread of education out beyond the towns—proceeds under the aegis of the governments and French educational officials.

The rise in the number of primary students was spectacular at first: between 1955 and 1965, for instance, the percentage of primary-age children enrolled in school increased in Guinea from 5 to 31, in Senegal from 14 to 40, in Niger from 2 to 12, and in Chad from 5 to 30. Such progress, however, depended on recourse to unqualified teaching personnel. Since then, some countries have successfully continued programs of rapid educational expansion (the percentage of primary-age children enrolled in school rose to 28 in Niger and to 55 in Senegal in 1985). Progress has been slower in other countries (in 1984 the percentage had risen only to 38 in Chad), and in some areas enrollment has even declined (the percentage dropped to 30 in Guinea in 1985). Also, in the former French areas, the number of students attaining a higher education has remained among the lowest in Africa.

Education in Belgian colonies and former colonies. As elsewhere and perhaps more than elsewhere, the Catholic and Protestant missions played the prime role in the development of education in the Belgian Congo (today Zaire) and in Ruanda-Urundi (the present states of Rwanda and Burundi). In the period before 1908, when the Belgian king Leopold II treated the Congo as virtually his private preserve, the missions had assumed an unofficial responsibility for education. After 1908, when the Belgian parliament assumed control of the Congo, the Roman Catholic mission schools were given a privileged official status, with government subsidies, while the Protestant schools, though financially unassisted, were also officially authorized to operate. Throughout the colonial period the overwhelming majority of schools were missionary, and until 1948 the systems were limited to two-year primary schools, three-year middle schools, and a sprinkling of technical schools for training indigenous cadres. In 1948 the Belgian government issued a new plan entitled "Organization of Free Subsidized Instruction for the Indigenous with the Assistance of Christian Missionary Societies," which promised more diversification in primary education (both vocational and secondary-preparatory) and, more radically, recommended the establishment of secondary schools that would prepare the Congolese for higher education.

Missionary schools in Belgian areas

In 1962 the government of the newly independent Congo proceeded with a reform of the old educational system: the first primary degree was standardized and its length extended from two or four years to six years; and pupils were to take a common primary course prior to their orientation toward general, normal, or technical secondary education or toward professional education. Numerous specialized schools of higher education were created: the National Institute of Public Works and Construction, the School of Civil Engineers, the National Institute of Mines, the Higher Pedagogical Institute, the Higher Institute of Architecture, and the National School of Administration. To the already existing Lovanium University of Kinshasa (founded in 1954) and the Official University of the Congo (founded in 1955 in Lubumbashi) there was added the Free University of the Congo (founded in 1963 in Kinshasa). Although less pronounced, an analogous evolution characterized Burundi and Rwanda.

By 1970 the Congo was among the African countries enjoying the best school and university infrastructure. Then, from 1974 to 1977, the Congo, renamed Zaire in 1971, went through a period of intense nationalism. Zairians with Christian names were ordered to change them to African names. Foreign-owned businesses were sold to Zairian citizens. All schools were nationalized, and mission schools were made state schools. A program of accelerated teacher training was instituted. The old universities were combined with the National University of Zaire. The economic chaos that resulted from these moves caused the government to quickly rescind its plans, however. Businesses were returned to foreign owners in 1977. The church schools were reinstated in 1976, and the universities once again separated in 1981. The result of this upheaval was disastrous for the educational system.

Problems and tasks of education in contemporary Africa. The independent African states face numerous problems in implementing an educational policy that will encourage economic and social development. Pedagogical problems and economic and political problems all intermix. The difficulties confronting most governments, however, are basically political.

African educational crisis

Numerical increases in school enrollments, though occasionally spectacular, fail to correspond to the legitimate aspirations of the people or even, more modestly, to the initial objectives fixed by the governments themselves. The Conference of Nairobi in July 1968 viewed as rather alarming the lack of progress in education and literacy in the context of growing populations. Increasing emphasis has been placed on improving and expanding vocational-technical, adult, and nonformal programs of education. There has also been concern about the financial difficulties of the different states, the unsuitability of current educational systems to local needs, the waste and duplications in primary and secondary education, and the insufficient liaison between educational policy makers and the planners of economic and social development. In short, an educational crisis has developed and ripened in black Africa.

(A.M./Da.G.S.)

The Middle East. Modern education was introduced into the Middle East in the early 19th century through several channels. Rulers in both Egypt and the Ottoman Empire (1300–1922) established new military and civilian schools to teach people the skills required to build modern states. In Iran, too, rulers opened new schools, though on a much smaller scale. Many missionary and foreign schools were also established, especially in the Levant. These modern institutions affected only a small percentage of the people, however; the mass continued to receive a traditional education in the Islāmic schools.

Colonialism and its consequences. Following World War I and the destruction of the Ottoman Empire, new states emerged, which—with the exception of Turkey and Iran—fell under French or British control. Although the new nations inherited educational institutions of various size, each needed to build a new educational system, either from scratch or by expanding a small existing system. Each country sought to use education to provide the skilled manpower required for national development and to socialize its diverse population into feeling loyal to the new state. Educational expansion was pursued everywhere, but the particular pattern of change was profoundly affected by the nature of the political regime, particularly by colonial

status. In Lebanon, Syria, Tunisia, Morocco, and Algeria educational policy reflected French interests. In Egypt, Jordan, Palestine, and Iraq, British policy prevailed. Both colonial powers shared similar goals: to preserve the status quo, train a limited number of mid-level bureaucrats, limit the growth of nationalism, and, especially in the case of France, impose its culture and language. Accordingly, they limited educational expansion, particularly at the higher levels, even though the demand continued to grow.

Aims of colonial educational policy

Private, foreign, and missionary schools were favoured everywhere as alternatives, for the upper classes, to the inadequate public schools. The public systems were centrally administered. Their curricula were usually copied from the British or the French and thus were of limited relevance to local needs; the numbers and quality of teachers were seldom adequate; and dropout rates were high. Few modern schools were to be found in the Arabian Peninsula. Only in Lebanon and in the Jewish community in Palestine (which developed its own educational system) were significant numbers of students enrolled in modern schools. Elsewhere, only a small percentage of the populace (including a few women) received a modern education.

Upon achieving independence, the Middle Eastern nations nationalized the private schools, which were regarded as promoting alien religions and cultures, and greatly expanded educational opportunities, especially at the upper levels. Egypt, for example, in 1925 nationalized a small, poor private institution (founded in Cairo in 1908) and made it into a national university and subsequently opened state universities in Alexandria (1942) and 'Ain Shams (1950). The newly independent countries also sought to equalize educational opportunities. Iraq provided free tuition and scholarships to lower-class students. Syria, in 1946, made primary education free and compulsory. Jordan enacted a series of laws calling for free and compulsory education and placed strict controls on foreign schools, especially the missionary ones.

Despite their importance, these reforms did not transform education. The schools in Egypt, Iraq, Syria, and Jordan, for example, continued to be characterized by rigidity, formalism, high dropout rates, and limited relevance to national needs. Moreover, rapid population increases often offset the educational gains, especially in Egypt. Egypt also could not overcome the existing fragmentation of its educational system. Its modern system was divided into schools for the masses and schools that provided access to the higher levels for the elite. Both types coexisted uneasily with the traditional Islāmic schools, which ran the gamut from rudimentary primary schools to the venerable al-Azhar University.

Educational reforms under Atatürk

Countries with strong nationalist leaders were more successful in modernizing education. Mustafa Kemal Atatürk of Turkey, who was determined to create a modern state, initiated a dramatic program of social and cultural change in which education played an important role. He closed the religious schools, promoted coeducation, prepared new curricula, emphasized vocational and technical education, launched a compulsory adult education project, established the innovative Village Institutes program to train rural teachers, and, in 1933, reorganized Istanbul University into a modern institution staffed mainly by refugees from Nazi Germany. Later, Istanbul Technical University also reorganized and Ankara University was established.

Reza Shah Pahlavi followed similar policies in Iran, albeit to a lesser degree, for he was a reformer rather than a modernizer and ruled a country that had been largely isolated from modern influences. He integrated and centralized the educational system, expanded the schools, especially the higher levels, founded the University of Tehrān (1934), sent students abroad for training, moved against the Islāmic schools, promoted the education of women, and inaugurated an adult education program. Nevertheless, the Iranian educational system remained small and elitist.

After World War II new leaders came to power, including Gamal Abdel Nasser in Egypt in 1952, Habib Bourguiba in Tunisia when it became independent in 1956, and the revolutionary government that deposed the monarchy in Iraq in 1958. They began to make major administrative and social reforms and adopted educational policies similar to those of Atatürk. Bourguiba's reform plans called for universal primary education, an emphasis upon vocational training, expansion of the higher levels, incorporation of the Qur'ānic schools into the modern system, and the promotion of women's education.

Problems of Arabicization in French areas

Tunisia, like the other French possessions in North Africa, had to face yet another educational challenge—nationalizing a system that was designed to socialize students into French culture. Arabicization, the substitution of Arabic for French as the language of instruction and of texts and syllabi representing Arab concerns for ones developed to meet French needs, presented many difficulties. Most teachers were qualified to teach only in French, and appropriate texts were not available. When Algeria and Morocco gained independence from France they adopted similar policies and encountered the same problems, which have been expensive and difficult to overcome. By the 1980s the Arabicization process remained incomplete; in all three countries, some instruction was still being given in French.

Egypt's President Nasser also sought to transform society and culture. He integrated and unified the Egyptian educational system by bringing the religious schools under secular control and by transforming al-Azhar University, long a centre of Islāmic learning, into a modern institution. The old elementary system, which provided access to further education only for urban students, was abolished, and major curricular and other reforms were implemented. All public education was made free, and strong efforts were made to universalize primary education, to upgrade technical and vocational education, and to improve the quality of education generally.

These important reforms did not always produce the anticipated results. Nasser failed to devise a coherent educational strategy that paid adequate attention to the systemic implications and the fit between educational expansion and developments in other sectors. Tunisia, too, despite large investments, was unable to coordinate educational expansion with the needs of the economy.

The contemporary scene. Every modern Middle Eastern state is striving to create an educational system that promotes economic growth and provides equal educational opportunities. In addition, the Arab states wish to promote cultural unity. In 1957 Egypt, Syria, and Jordan replaced the educational structures that had been established by the colonial powers with a common one consisting of six years of primary school, three years of middle school, and three years of secondary school. Most of the Arab states have since followed this pattern, although the length of the school year varies from country to country. The Arab systems also differ in the emphasis they place on certain subjects, especially religious instruction and Arabic, which occupy an especially prominent place in Saudi Arabian schools.

Turkey, Iran, and all the Arab states except Lebanon have another feature in common. Education to the secondary level in these countries is planned and administered by a central ministry. These ministries are generally characterized by administrative weaknesses that severely handicap the provision of education. University education may also be the responsibility of the ministry or, as in Turkey, Iraq, and Egypt, may be supervised by a separate body.

Educational planners have usually attained, or surpassed, their quantitative targets for academic schooling. School enrollments and literacy rates have risen substantially throughout the Middle East. These gains, however, have been at least partly offset by rapidly growing populations. In Egypt the absolute number of illiterates has increased, and Turkey's goal of universalizing primary education was not achieved until the 1980s. Some governments, notably those of Iraq, Algeria, Kuwait, Egypt, Iran, and Turkey, have initiated adult literacy programs, with varying degrees of success.

Inequalities in education

Planners have been less successful in achieving their other goals. Despite great efforts, primary and secondary education everywhere retain certain traditional features. Inequalities remain in such areas as rural and urban access to education and women's education. Although female school enrollment ratios have risen throughout the Mid-

dle East, they remain considerably lower than male ratios in every country except Lebanon and Israel, which have achieved almost universal elementary literacy. Moreover, at the higher levels of education, the percentage of women students becomes progressively lower. Many countries, especially Egypt and Tunisia, have made strenuous efforts to overcome the economic and cultural factors that limit women's education, but their experience demonstrates how difficult it is to do so.

Qualitative goals have also been difficult to achieve. Financial, human, and physical resources have not been able to keep pace with growing enrollments. As a result, the quality of primary and secondary education has suffered. Split shifts, crowded classrooms, serious shortages of qualified teachers, and inadequate textbooks and curricula are common problems. The strict examination system used by most countries to determine which students may advance to the next level of education also hurts educational quality. Most experts agree that the examination system does not provide a valid or reliable indication of student ability. Furthermore, they feel that it reinforces traditional tendencies toward memorization and a rigid classroom culture.

Various innovations have been introduced in an attempt to remedy these shortcomings. One of the most important is the nine-year basic education program, which seeks to provide all children between the ages of six and 15 years with an integrated study program that is practical, does not involve examinations, and prepares students to function in a changing environment. It has been widely implemented in Egypt and has been introduced in Tunisia and Syria as well.

University education in the Middle East

The Middle Eastern nations have also been confronted by serious problems at the university level. Because a degree was widely regarded as a passport to elite status, the demand for higher education grew dramatically. Every government sought to limit the flood of entrants through examinations but managed only to slow, not stop, the growth, which far outpaced projections and resources. To help accommodate the surplus, Egypt and Turkey established programs of "external students" and open universities, which allow students to take courses at home at their convenience through correspondence, radio and television broadcasts, recordings, and other techniques. Every year more and more students of lower-class backgrounds receive a university education, but the entrance examinations tend to limit admissions to the most desirable faculties (medicine and engineering) to students of elite backgrounds. The rising number of graduates with unneeded skills has in turn aggravated problems caused by lack of coordination between education and employment needs. Except in the Gulf states, which have manpower shortages, governments face the difficult task of absorbing poorly prepared graduates into the work force while they try to find qualified managers, technicians and skilled workers.

The development of higher education has been adversely affected by political considerations. Most Middle Eastern countries have never accepted the principle of academic freedom. Turkey, Lebanon, and Israel are prominent exceptions, but even Lebanese and Turkish universities have been subject to political control. The Lebanese civil war has created a difficult environment for education at all levels. In Turkey the universities became so politicized in the 1970s that ideology influenced many aspects of university life. After the military coup of 1980, the government proceeded to limit university autonomy and to eliminate political activism. Iran and most Arab countries have always been ruled by more or less authoritarian regimes that regard universities as potential sources of opposition. The governments in these countries try to use schools and colleges to disseminate the prevailing ideology. Hence scholars often emigrate and those who remain at home are compelled to teach and research in ways that will not create difficulties.

Vocational education

Efforts to increase vocational and technical training have not been very successful because of the continuing appeal of white-collar careers. In Egypt the government's determined attempt to channel students into technical and vocational schools yielded mixed results. Enrollments did increase, but the quality and relevance of such education was questioned as authorities considered the costs involved in purchasing necessary expensive equipment and in training and retaining qualified teachers, whose skills enable them to obtain more remunerative positions in industry. The same difficulties prevail in the other Middle Eastern countries, though Turkey is now initiating, with World Bank support, a promising experiment involving the establishment of a network of modern vocational schools.

Technical training in the agricultural sector is also deficient. There is a shortage of qualified extension agents and other specialists everywhere. Moreover, the bias toward academics means that rural education tends to be neglected, even though the need for agricultural modernization in national development requires that peasants acquire a wide range of skills. Israel is one country where rural education receives the attention that it deserves.

The Islāmic revival. The rapid expansion of modern education and knowledge has produced results that have not been welcomed everywhere. Islām remains, in all societies, a powerful force, one nurtured by traditional factors and by religious education, which continues to be widely offered in one form or another. Believing that traditional Islāmic values have been eroded by Western knowledge based on erroneous assumptions, numerous Islāmic scholars have called for the creation and diffusion of knowledge within an Islāmic framework. The Iranian revolution and the rise of Islāmic fundamentalist movements demonstrate the power of this appeal. Religiously based polities like Saudi Arabia and Iran emphasize Islāmic teachings and values in all schools and colleges, but many other states are providing more religious education than previously.

Migration and the brain drain. Educational systems have also been affected by the widespread international migration of professionals and skilled workers that characterizes the Middle East. Formerly, the West siphoned off a significant percentage of the skilled manpower from Lebanon, Syria, Turkey, Egypt, and Jordan. Now, large numbers of educated persons have migrated from Turkey, Lebanon, Syria, and especially Egypt and Jordan to the oil-rich states, especially to Bahrain, Kuwait, Libya, Saudi Arabia, Qatar, Oman, Algeria, and the United Arab Emirates, all of which face severe manpower shortages. This flow aggravates shortages of skilled workers in many of the exporting countries, especially Jordan, Syria, and Lebanon.

Effects of migration on education and employment

These migration patterns are influenced by and influence educational developments in several ways. They are the result of systems that do not meet a country's labour requirements. The outflows further reduce existing standards, because migrants include the most qualified teachers, especially those with vocational and technical skills. Moreover, the attraction of working abroad is so strong that many persons choose schools and subjects in order to enhance their potential for migration, regardless of the domestic demand. Thus, domestic educational systems have become geared to meet the needs of other societies while domestic employment needs are neglected.

Despite the many problems, it should be emphasized that all the Middle Eastern states have built modern educational systems in the face of considerable difficulties. The importance of education is acknowledged everywhere, and every state is striving to make education more relevant to personal and societal needs, to achieve greater equity, to lower the high wastage rates, and to improve quality.

(J.S.Sz.)

Latin America. The term Latin America is a facile concept hiding complex cultural diversity. This abstraction covers a conglomerate of areas, distinguished by differences not only in the Indian and Negro population base but also in the superimposed nonindigenous patterns—Spanish, Portuguese, French, Dutch, and Anglo-Saxon. In this brief survey, generalizations will be limited to the major Spanish and Portuguese patterns, which account for 95.7 percent of the population and 98.3 percent of the area.

The heritage of independence. At the beginning of the 19th century, the Spanish colonies enjoyed a prosperity that led to optimism, thoughts of independence, and republican rule. In the prolonged struggle for independence,

they were all but ruined, and the change from absolute monarchy to popular democracy was far from easy. The revolutionaries tried to follow the U.S. model, but novel institutions clashed with those of the past; governmental practice did not follow political theory; and the legal equality of the citizens hardly corresponded to economic and educational realities.

Roman Catholicism and education in Latin America

The new governments all considered education essential to the development of good citizens and to the process of modernization. Accordingly, they tried to expand schools and literacy, but they faced two obstacles. Their first was a disagreement over what should form the content of education. Since the time of the Enlightenment, political tyranny and the Roman Catholic church had been blamed for backwardness. Thus, once independence had been achieved, the liberals tried to get rid of the church's privileges and to secularize education. The conservatives, however, wanted to follow traditional educational patterns and considered Catholicism a part of the national character. After decades of confrontation the liberals in many countries managed to make education both secular in character and a state monopoly. In other countries, such as Colombia, by way of a concordat with the Holy See, religious education became the official one.

The second obstacle to educational expansion was a financial one. The new governments lacked the means with which to establish new schools. Thus, they began to import the Lancaster method of "mutual" instruction (so named from its developer, the English educator Joseph Lancaster), which in monitorial fashion employed brighter or more proficient children to teach other children under the direction of an adult master or teacher. Its obvious advantage was that it could accomplish an expansion of education rather quickly and cheaply. Beginning in 1818, it was introduced in Argentina and then in Chile, Colombia, Peru, Mexico, and Brazil. Until well into the second half of the 19th century, it was to be the most widely used system.

Almost all the heroes of independence tried to establish schools and other educational institutions. José de San Martín founded the National Library and the Normal Lancasteriana, a teacher-training school, in Lima; Simón Bolívar established elementary schools in convents and monasteries and founded the Ginecco (1825), known afterward as the Normal Lancasterian School for Women. Bernardino Rivadavia, the first president of Argentina, also stimulated educational development, including the establishment of the University of Buenos Aires. In mid-century, Benito Juárez in Mexico also championed education as the only bulwark against chaos and tyranny.

By the 1870s the liberals had won the day almost everywhere throughout Latin America. Education was declared to be compulsory and free, the lack of teachers and teacher colleges notwithstanding. A program to remedy this situation was launched. Chile paid for the educator Domingo Faustino Sarmiento's travels to the United States and Europe and enabled him to found, on his return in 1842, the Normal School for Teachers. This was the first non-Lancasterian teachers' college and was to be followed in 1850 by the Central Normal School in Lima and in 1853 by the Normal School for Women in Santiago. Countries with more acute educational problems, such as Ecuador, simply imported the Brothers and Sisters of the Sacred Heart and put them in charge of organizing their educational system. During the 1870s and '80s, foreign teachers began to be imported and students were sent abroad. Sarmiento had already called in North American teachers to open his normal schools in the 1860s, and Chile invited Germans for its Pedagogical Institute (1889). Germans and Swiss came to Mexico and Colombia; a number of distinguished Mexican educators were trained by Germans in the Model School in Orizaba. With the foreign professors came new pedagogical ideas—especially those of Friedrich Froebel and Johann Friedrich Herbart—and also new ideologies, foremost among them positivism, which flourished in Argentina, Brazil, Chile, and Mexico.

Administration. With independence, the task of overseeing public instruction fell to the state and local authorities. Fiscal poverty and a lack of trained personnel soon proved them unequal to the task. Furthermore, since most existing schools were confessional and private, the need for intervention by the central authorities to enforce unity became obvious. In 1827 the Venezuelan government established a Subdirectory of Public Instruction, which in 1838 became a directory. Mexico established a General Directory of Primary Instruction in 1833. Soon, some countries decided to assume responsibility for centralization through a ministry for public instruction—Chile and Peru in 1837, Guatemala in 1876, Venezuela in 1881, and Brazil in 1891. Other governments abstained from accepting total responsibility. In Mexico, no ministry was created until 1905 and then only with jurisdiction over the Federal District and territories; even that became a victim of the revolution of 1910. In 1922 a Mexican ministry was reestablished, now in charge of the whole republic and taking up the functions that the states could not fulfill. In Argentina the Lainez Law, decreed in 1905, authorized the National Council of Education to maintain, if need be, schools in the provinces.

Efforts to centralize educational administration

Today, in all countries the control over education is in the hands of a ministry of public education or a similar government unit. Its functions include planning, building, and administering schools, authorizing curricula and textbooks for public elementary and secondary schools, and supervising private ones. In some countries, the states sustain their own educational systems, which the federal government then supplements, but, because of the disparity between city and countryside, these federal governments often have had to shoulder almost the total burden of rural elementary education.

Primary education and literacy. At the time of independence, elementary education consisted of teaching reading and writing, the religious and civil catechisms, and rudiments of arithmetic and geometry. By the second half of the century, it became differentiated between "elementary primary" and "superior primary" education, and the curriculum was enlarged to include the teaching of national language, history, geography, rudimentary natural sciences, hygiene, civics, drawing, physical education, and crafts for boys and needlework for girls. The elementary primary school was increased to five or six years, and the superior primary was to become the secondary school of the 20th century. These educational levels absorbed the greatest part of the governmental efforts and became a means to do away with illiteracy and also to create a concept of citizenship.

Primary instruction was improved by special programs and teacher training, and both benefited from educational influences coming from abroad but also from improvements resulting from the study of national problems. Today, primary-school teachers are trained in teachers' colleges having the status of secondary schools.

Problems of rural and native education

Thanks to solid foundations laid during the 19th century, public education in Argentina and Chile reached a high level of competence. In other countries, because of such factors as a more heterogeneous population, a higher level of demographic growth, and greater geographical barriers, the results of great efforts have been less than impressive. Although all countries have declared primary instruction to be free and compulsory, the situation in reality is rather complex. Whereas, in towns, many children have gone from kindergarten to secondary schools since the beginning of the century, in the rural areas, even today, many schools have only one teacher to handle students of all levels. Furthermore, because many Indian citizens do not understand Spanish, special instruction is required. In the 20th century, governments have established special institutions for Indians. The first such cultural mission was created by the Mexican secretary of education, José Vasconcelos, in 1923. The idea was to send an elementary-school teacher, an expert in trades and crafts, a nurse, and a physical-education teacher to underdeveloped communities, in which, during a limited period, the population would be provided with some general education. The United Nations Educational, Scientific and Cultural Organization (UNESCO) has helped in the training of teachers for these special areas through two regional centres of fundamental education for Latin America (CREFAL), one in

Mexico and the other in Venezuela. Many countries have tried to master the dropout problem by offering at least one free meal a day to those who continue their schooling.

Uruguay, Argentina, and Chile have been able to multiply their schools and thus to provide facilities for their entire population of school age. In other countries, the efforts may be gauged by comparing statistics. In Peru, only 29,900 children went to school in 1845; but there were 59,000 in 1890 and 2,054,000 in 1965. In Brazil, there were 115,000 pupils in 1869; 300,000 in 1889; and 9,923,000 in 1965. In Mexico, there were 349,000 in 1874; 800,000 in 1895; and 7,813,000 in 1969. Unfortunately, the high population-growth rate (2.9 percent) makes it difficult to keep up with the ever-increasing needs.

Fight against illiteracy

Illiteracy has been fought by various means in accordance with the political and socioeconomic situation. Until the middle of the 19th century, illiteracy in Latin America was in excess of 90 percent. Of Brazil's population, only 1.5 percent were literate in 1823. Around the beginning of the 20th century, illiteracy had decreased to 39 percent in Argentina (1908), 50.4 percent in Uruguay (1908), and 68.2 percent in Chile (1895); in other countries it fluctuated between 80 and 98 percent. By 1985 illiteracy was down to 6.0 percent in Argentina, 5.7 percent in Uruguay, 10 percent in Chile, 26 percent in Mexico, 28 percent in Peru, 25 percent in Bolivia, and 26 percent in Brazil. Nations with the greatest illiteracy were Guatemala, with 50 percent, and Haiti, with 77 percent.

Secondary education. During the 19th century, many countries established new secondary schools on the basis of colonial institutions. Thus, in 1821 Argentina converted its College of San Carlos into its College of Moral Sciences. Mexico attempted a total reform in 1833 but would not complete it until 1867 with the founding of the National Preparatory School, which involved reforming the whole system on the basis of positivist philosophy. In Brazil the Royal Military Academy was established in 1810 and the Pedro II College in 1830, but secondary instruction did not prosper until the return of the Jesuits in 1845 and was to be supplemented later by *gimnasios*—that is, *Gymnasien* on the German model. Peru and Venezuela established national colleges, and Chile and Argentina created *liceos* (modeled on the French *lycées*) and, later, national colleges. (The term college in all cases here is used in the continental European sense to refer to secondary institutions, not institutions of higher education.)

Secondary emphasis on university preparation

In all countries (except perhaps Chile), secondary instruction has been considered a preparation for the university. All attempts to make it more formative and practical have failed, in spite of the fact that the government has taken charge. The secondary-preparatory course lasts from five to six years, with a degree of bachelor (*bachillerato*) usually given upon its completion. Its teachers come from the humanities departments of the universities and the superior normal schools (which have existed since 1869 in Argentina, since 1889 in Chile, and in the 20th century in the other countries).

Polytechnical education—industrial, commercial, and agricultural—had been a concern of liberal governments since the end of the 19th century but has developed only recently. Traditional prejudices against practical instruction were overcome only after industrialization began. It has been emphasized only in Argentina, Venezuela, Chile, and Mexico.

Higher education. Imbued with a revolutionary spirit in which education was a vital element, Latin Americans founded 10 universities between 1821 and 1833, among them the University of Buenos Aires (1821). Bolívar himself established two in Peru—Trujillo (1824) and Arequipa (1828). With independence, practically all theological faculties had disappeared, and their position of preeminence was taken over by faculties of law.

Four universities were founded in the 1840s, Chile's among them, and 10 more in the second half of the 19th century. In Mexico the new institutions called themselves institutes of arts and sciences, because the University of Mexico (founded in 1551) was associated with colonialism and had become a favourite target of the liberals. The University of Mexico was suppressed in 1865, not to be reopened until 1910, the year of the revolution. Argentine liberals solved their problem by passing the Avellaneda Law (1885), which allowed only national universities, prohibiting private universities (until the reform of 1955).

In Brazil the plans to open a university in 1823 failed. Several professional schools were established, but the first university opened its doors in 1912 in Paraná. In 1920 the Federal University of Rio de Janeiro was founded.

Almost all higher education in Latin America came to be secular and state-operated. The fact that Latin-American governments, themselves unstable, generally took charge of higher education, however, explains in part its uncertain existence.

Emphasis on state universities

Some colonial religious institutions nevertheless survived. During part of the 19th century, for instance, the University of the Republic in Montevideo maintained its ties with the church. In 1855 the University of San Carlos in Guatemala, through a concordat with Rome, reverted to pontifical status. But, with the exception of the Catholic University in Chile (1888), the Pontifical Catholic University of Peru (1917), and the Javeriana University in Colombia (1931), all religious universities are recent creations. Indeed, today the majority of private institutions are religious or confessional, with the significant exception of some recently established technological institutes (in Monterrey, Mex., and in Buenos Aires). The need for technical education was also recognized by the Mexican government when it founded, in 1936, the National Polytechnical Institute as its second national institution of higher learning, with several branches in the country (regional technological institutes) to serve the particular needs of each region.

Until the 20th century, universities were mainly professional schools. Often, they also supervised primary and secondary education (Uruguay, 1833–37; Chile, 1842–47; Mexico, 1917–21). Today, they also conduct research and try to encourage regional developments. Unofficially, they have sometimes played a role in political life. Since the reform movement for student representation at the University of Córdoba in Argentina in 1918, they have become involved in political controversies. The Mexican government tried to extricate the National University from political strife by giving it autonomy in 1929. Student demonstrations by the late 1960s, however, proved this measure to lack effectiveness.

Higher education has proved to be the best means of furthering social mobility. In spite of this, institutions of higher learning in Latin America have suffered from several handicaps. Foremost is the lack of sufficient funds, which usually results in poor research facilities. Second, both students and professors are generally engaged only half-time. This increases the dropout rate and decreases performance. Thus, most highly qualified professionals are trained abroad. At the same time, both the political situation and economic pressures have induced an exodus of the most highly educated Latin Americans to the United States.

In 1985 there were more than 1,500 institutions of higher learning in Latin America. Brazil, Mexico, Argentina, and Colombia had the highest numbers of university students, but, on the basis of the number of students per population, Argentina was first, distantly followed by Uruguay, Cuba, Chile, Colombia, Mexico, and Brazil.

Reform trends. Although most of the Latin-American countries achieved nominal independence in the 19th century, they remained politically, economically, and culturally dependent on U.S. and European powers throughout the first half of the 20th century. By 1960, many viewed this dependency as the reason for Latin America's state of "underdevelopment" and felt that the situation could best be remedied through educational reform. The most general reform movement (*desarrollista*) simply accepted the idea of achieving change through "modernization," in order to make the system more efficient. The Brazilian educationist Paulo Freire, however, advocated mental liberation through self-consciousness, a view that was influential in the 1960s and '70s throughout Latin America. Because political dictatorship prevailed through the 1960s and part of the 1970s in many countries, authoritarian

pedagogy became the practice, especially in Chile. In the 1980s the deep economic crisis in Latin America proved to be the greatest influence on education, obstructing all renovation or modernization of public education.

(J.Z.V.)

Historical background of modern Southeast Asian education

Southeast Asia. Indigenous culture, colonialism, and the post-World War II era of political independence influenced the forms of education in the nations of Southeast Asia—Myanmar (Burma), Kampuchea (Cambodia), Indonesia, Laos, Malaysia, the Philippines, Singapore, Thailand, and Vietnam.

Before AD 1500, education throughout the region consisted chiefly of the transmission of cultural values through family and community living, supplemented by some formal teaching of each locality's dominant religion—animism, Hinduism, Buddhism, Taoism, Confucianism, or Islām. Religious schools typically were attended by boys living in humble quarters at the residence of a pundit who guided their study of the scriptures for an indeterminate period of time.

With the advent of Western colonization after 1500, and particularly from the early 19th to mid-20th century, Western schooling with its dominantly secular curriculum, sequence of grades, examinations, set calendar, and diplomas began to make strong inroads on the region's traditional educational practices. For the indigenous peoples, Western schooling had the appeal of leading to employment in the colonial government and in business and trading firms.

After World War II, as all sectors of Southeast Asia gained political independence, each newly formed nation attempted to achieve planned development—to furnish primary schooling for everyone, extend the amount and quality of postprimary education, and shift the emphasis in secondary and tertiary education from liberal, general studies to scientific and technical education. Although indigenous culture was still learned through family living and traditional religion continued to be important in people's lives, most formal schooling throughout Southeast Asia had become predominantly of a Western, secular variety.

Schooling in all of these countries was organized in three main levels, primary, secondary, and higher. In addition, nursery schools and kindergartens, operated chiefly by private groups, were gradually gaining popularity. The typical length of primary schooling was six years. Secondary education was usually divided into two three-year levels. A wide variety of postsecondary institutions offered academic and vocational specializations. Beginning in the 1950s, nonformal education to extend literacy and vocational skills among the adult population expanded dramatically throughout the region. Most of the nations were committed to compulsory basic education, typically for six years but up to nine years in Vietnam. However, by the close of the 1980s, the inability of governments to furnish enough schools for their growing populations prevented most from fully realizing the goal of universal basic schooling.

In each nation a central ministry of education set schooling structures and curriculum requirements, with some responsibilities for school supervision, curriculum, and finance often delegated to provincial and local educational authorities. Government-sponsored educational research and development bureaus had been established since the 1950s in an effort to make the countries more self-reliant in fashioning education to their needs. Regional cooperation in attacking educational problems was furthered by membership in such alliances as the Southeast Asian Ministers of Education Organization (SEAMEO) and the Association of Southeast Asian Nations (ASEAN).

Problems which most Southeast Asian education systems continued to face were those of reducing school dropout and grade-repeater rates, providing enough school buildings and teachers to serve rapidly expanding numbers of children, furnishing educational opportunities to rural areas, and organizing curricula and the access to education in ways that suited the cultural and geographical conditions of multiethnic populations.

Myanmar (formerly Burma). The indigenous system of education in Myanmar consisted mainly of Buddhist monastic schools of both primary and higher levels. They were based on (1) the moral code of Buddhism, (2) the divine authority of the kings, (3) the institution of *myothugyi* (township headmen), and (4) widespread male literacy. The Western system was established after the British occupation in 1886. The new system recognized women's right to formal education in public schools, and women began to play an increasingly important role as teachers. The Government College at Rangoon and the Judson College established in the 19th century were incorporated as the University of Rangoon under the University Act of 1920.

Buddhist and Socialist influence in Myanmar

Following independence in 1948, the country experienced more than a decade of political instability until a coup d'état in 1962 brought a strongly centralized socialist government to power. Subsequently, marked improvements in education occurred. Science was emphasized along with general academic subjects, civic education, and practical arts. Primary-school attendance for children ages five through nine became free where available. From 1965 to 1985 enrollments increased in primary schools from two to five million, in secondary schools from 503,000 to 1.25 million, and in higher education from 21,000 to 189,000.

Malaysia and Singapore. The Malay States, Singapore, and sectors of North Borneo were British colonies until reorganized as the nation of Malaysia in 1963. Singapore left the coalition in 1965 to become an independent city-nation. As a result, while Malaysia and Singapore share common educational roots, their systems have diverged since 1965.

The language issue in Malaysia and Singapore

Under British rule, the most significant feature of education on the Malay peninsula was the structuring of primary schools in four language streams—Malay, Chinese, English, and Tamil. Students in the English stream enjoyed favoured access to secondary and higher education as well as to employment in government and commerce. After 1963 Malaysian leaders sought to indigenize and unify their society by adopting the Malay language as the medium of instruction in schools beyond the primary level and by teaching English only as a second language. In contrast, the government of Singapore urged everyone to learn English, plus one other local tongue—Chinese, Malay, or Tamil. Thus, in both nations the learning of languages became a critical issue in people's efforts to gain access to socioeconomic opportunity and in political leaders' attempts to unify their multiethnic populations.

Efforts to popularize schooling in Malaysia and Singapore were notably successful. By the early 1980s, 93 percent of all Malaysian children ages six to 11 attended primary school, with nearly 90 percent of primary-school graduates entering lower-secondary school. By 1968, all primary-age children in Singapore were in school. In both countries, secondary- and higher-education enrollments continued to increase rapidly. Both nations were well supplied with school buildings, textbooks, and trained teachers.

Indonesia. From AD 100 to 1500 the Indonesian aristocracy adopted Hindu and Buddhist teachings, while education for the common people was provided mainly informally, through daily family living. Islām, introduced into the archipelago around 1300, spread rapidly in the form of Qur'ān schools, which have continued through the 20th century, though in diminishing numbers. The first few schools on Western lines were established by Portuguese and Spanish priests in the 16th century. As the Dutch colonialists gained increasing control over the islands, they set up schools patterned after those in Holland, primarily for European and Eurasian pupils. In 1848 the Dutch East Indies government officially committed itself to providing education for the native population. However, even though the amount of education for indigenous islanders increased over the following century, Western schooling under the Dutch never reached the majority of the population.

After Indonesians gained independence from the Dutch in 1949, they sought to provide universal elementary schooling and a large measure of secondary and higher education. Progress toward this goal after 1950 was rapid, despite the challenge of an annual population growth rate of around 2.3 percent. Enrollments over the 1950–1985 period increased from five million to 30 million at the

elementary level, from 230,000 to 7.5 million at the secondary level, and from 6,000 to one million at the tertiary level. Although the Indonesian population was 90 percent Muslim, three-fourths of the nation's schools were of a Western secular variety. The remaining one-fourth were Islāmic schools required to offer at least 70 percent secular studies and no more than 30 percent religious subjects. This ratio reflected the government's efforts to use the schools for preparing manpower for socioeconomic modernization, as guided by a sequence of five-year national development plans.

Philippines. The pre-Spanish Philippines possessed a system of writing similar to Arabic, and it was not uncommon for adults to know how to read and write. Inculcation of reverence for the god Bathala, obedience to authority, loyalty to the family or clan, and respect for truth and righteousness were the chief aims of education. After the Spanish conquest, apart from parochial schools run by missionaries, the first educational institutions to be established on Western lines were in higher education. The Santo Tomás College, established in 1611 and raised to the status of a university in 1644–45, served for centuries as a centre of intellectual strength to the Filipino people. Educational growth, however, was slow, mainly because of lack of government support.

Spanish and American influences in the Philippines

With the advent of American rule, the stress laid on universal primary education in the policy announced by U.S. President William McKinley on April 7, 1900, led to a rapid growth in primary education. A number of institutions of higher education were also established between 1907 and 1941, including the University of the Philippines (1908). Private institutions of higher education, however, far outnumbered the state institutions, thus indicating a trend that remains a characteristic feature of the system of higher education in the Philippines.

The new Republic of the Philippines emerging after World War II launched a series of national development plans that included components aimed at the renovation and expansion of education to promote socioeconomic modernization. Over the period 1948 to 1986, enrollments rose in primary schools from four million to nine million and in secondary schools from 424,000 to 3.3 million. By the late 1980s, 1.5 million students were in the nation's more than 1,000 higher-education institutions. More than 95 percent of primary pupils and 41 percent of secondary students attended public schools, while the remainder attended private institutions.

Thailand. The traditional system of education in Thailand was inspired by the Thai philosophy of life based on (1) dedication to Theravāda Buddhism, with its emphasis on moral excellence, generosity, and moderation, (2) veneration for the king, and (3) loyalty to the family. The beginning of the present system of education can be traced to 1887, when King Chulalongkorn set up a department of education with foreign advisers, mostly English educationists. Gradually, temple schools were established. The process of westernization of education was strengthened with the establishment of a medical school in 1888, a law school in 1897, and a royal pages' school in 1902 for the general education of "the sons of the nobility." It was converted into the Civil Service College in 1910.

The Thai philosophy

The abolition of the absolute monarchy after the 1932 revolution stimulated the government to increase educational provisions at all levels, particularly for training specialists in higher-learning institutions. Beginning in 1962, the nation's series of five-year development plans assigned educational institutions a crucial role in manpower preparation. The government supervises all educational institutions, public and private. Financing education is primarily a government responsibility, supplemented by the private sector. Thai is the language of instruction at all levels, with English taught as a second language above grade four.

By the mid-1980s there were more than 7.3 million pupils (over 90 percent of the age group) enrolled in the compulsory six-year elementary schools, 2.2 million in the six years of secondary schooling, and 715,000 in the nation's 31 registered universities and colleges.

Kampuchea (formerly Cambodia). For nearly four centuries before the advent of the French in 1863, the educational system in Cambodia grew up around Theravāda Buddhism, which became the established religion toward the end of 1430 under Thai influence. In 1887 Cambodia became a part of the French Indochina Union and did not achieve complete independence until 1954. Pagoda schools, imparting education at the primary level, were remodeled and integrated into the primary school system administered by the Ministry of Education.

Indo-Chinese education under colonialism and war

Civil war throughout the 1970s disrupted education until Vietnamese forces overthrew the Khmer Rouge government in 1979. By the mid-1980s schools had reopened with a total enrollment of nearly two million throughout the four-year primary, three-year junior-secondary, and three-year senior-secondary structure. Secondary schools and the country's few higher-education colleges were in a state of rebuilding. Much of the teacher-training was in the form of short courses, and nonformal adult literacy classes multiplied at a rapid pace.

Laos. The pagoda school was the main unit of the traditional educational system in Laos. Efforts toward modernization came in the wake of the country's becoming a French protectorate in 1893 and finally after its inclusion in 1904 within the French Indochina Union. The medium of education was changed to French when the French Education Service was created.

In 1975, after 30 years of uninterrupted revolution, a socialist government was established and schooling was accorded high priority. By the mid-1980s 79 percent of all children seven to 11 years old were in the five-year primary school, 48 percent of children 12 to 14 years old were in the three-year junior-secondary school, and 23 percent of the 15- to 17-year-olds were in the three-year senior-secondary school.

Vietnam. Long Chinese domination over the emperors of Vietnam resulted in strong Confucian and Taoist influences on the Vietnamese educational system, though it centred on Buddhism. The establishment of French rule, commencing with the occupation of Saigon (now Ho Chi Minh City) in 1859, led to the gradual growth of a pattern of education similar to that of the rest of the former Indochina Union. Vietnamese attempts to develop education were thwarted by the continued fighting from World War II onward and, after the partition of the country in 1954, by fighting between the South and the North. After the war's end in 1975, the Communist government attempted to "reeducate" the conquered South and sought to establish urgently needed technical and vocational education in secondary and higher levels. By the mid-1980s there were eight million pupils in elementary schools, four million in secondary schools, and more than 115,000 in higher-education institutions. (M.S.H./R.M.T.)

BIBLIOGRAPHY

General works: General histories of education are mainly concerned with the educational history of the West. In some works early chapters survey non-Western educational developments in the context of ancient civilizations, and medieval Muslim education is frequently treated because of its impact upon Western education. Given these limitations, among the best general histories are ELLWOOD P. CUBBERLEY, *The History of Education* (1920, reissued 1948); JAMES BOWEN, *A History of Western Education,* 3 vol. (1972–81); WILLIAM BOYD and EDMUND J. KING, *The History of Western Education,* 11th ed. (1975, reprinted 1980); R. FREEMAN BUTTS, *The Education of the West* (1973); ROBERT ULICH, *The Education of Nations,* rev. ed. (1967), and *History of Educational Thought,* rev. ed. (1968); HARRY G. GOOD and JAMES D. TELLER, *A History of Western Education,* 3rd ed. (1969); JAMES MULHERN, *A History of Education: A Social Interpretation,* 2nd ed. (1959); MEHDI NAKOSTEEN, *The History and Philosophy of Education* (1965); and MARGARET SCOTFORD ARCHER, *Social Origins of Educational Systems* (1979).

Despite its age, The five-volume *A Cyclopedia of Education,* ed. by the American educator PAUL MONROE (1911–13, reprinted 1968), remains a comprehensive source of historical information. Its influence was recognized in FOSTER WATSON (ed.), *The Encyclopaedia and Dictionary of Education,* 4 vol. (1921–22), a British work whose foreign contributors included John Dewey and Benedetto Croce. LEE C. DEIGHTON (ed.), *The Encyclopedia of Education,* 10 vol. (1971), also has numerous historical references. There are many national encyclopaedias of historical interest in education.

Among historical surveys of individual countries, the fol-

lowing are useful: W.H.G. ARMYTAGE, *Four Hundred Years of English Education,* 2nd ed. (1970); S.J. CURTIS, *History of Education in Great Britain,* 7th ed. (1967); CHRISTOPHER BROOKE and ROGER HIGHFIELD, *Oxford and Cambridge* (1988); CHARLES FOURRIER, *L'Enseignement français de l'Antiquité à la Révolution* (1964), and *L'Enseignement français de 1789 à 1945* (1965), on France; WILLIAM H.E. JOHNSON, *Russia's Educational Heritage* (1950, reissued 1969); TOKIOMI KAIGO, *Japanese Education: Its Past and Present,* 2nd ed. (1968); PING-WEN KUO, *The Chinese System of Public Education* (1915, reprinted 1972); T.N. SIQUEIRA, *The Education of India: History and Problems,* 4th rev. ed. (1952); AHMAD SHALABY, *History of Muslim Education* (1954, reissued 1979); ALLAN BARCAN, *A History of Australian Education* (1980); ROGER OPENSHAW and DAVID MCKENZIE (eds.), *Reinterpreting the Educational Past: Essays in the History of New Zealand Education* (1987); LAWRENCE A. CREMIN, *American Education, the Colonial Experience, 1607–1783* (1970), *American Education, the National Experience, 1783–1876* (1980), and *American Education, the Metropolitan Experience, 1875–1980* (1988); DAVID B. TYACK, *The One Best System: A History of American Urban Education* (1974); and J. DONALD WILSON, ROBERT M. STAMP, and LOUIS-PHILIPPE AUDET (eds.), *Canadian Education* (1970).

Education in primitive and early civilized cultures: There are few monographs dealing solely with education in primitive civilizations; information is to be found chiefly in works treating larger subjects, such as MARGARET MEAD, *Continuities in Cultural Evolution* (1964); GEORGE DEARBORN SPINDLER (ed.), *Education and Cultural Process: Anthropological Approaches,* 2nd ed. (1987); THOMAS WOODY, *Life and Education in Early Societies* (1949, reprinted 1970); CHRISTOPHER J. LUCAS, *Our Western Educational Heritage* (1971); HENRI MASPERO, *China in Antiquity* (1978; originally published in French, 1927); J. ERIC S. THOMPSON, *The Rise and Fall of Maya Civilization,* 2nd enlarged ed. (1966, reprinted 1977); RUDOLPH VAN ZANTWIJK, *The Aztec Arrangement: The Social History of Pre-Spanish Mexico* (1985; originally published in Dutch, 1977); and GEORGE A. COLLIER, RENATO I. ROSALDO, and JOHN D. WIRTH (eds.), *The Inca and Aztec States, 1400–1800* (1982).

Education in classical cultures: In addition to the treatments offered in the general histories cited above, see HOWARD S. GALT, *A History of Chinese Educational Institutions: To the End of the Five Dynasties, A.D. 960* (1951); FREDERICK A.G. BECK, *Greek Education, 450–350 B.C.* (1964), and *Album of Greek Education: The Greeks at School and at Play* (1975); STANLEY F. BONNER, *Education in Ancient Rome: From the Elder Cato to the Younger Pliny* (1977); M.L. CLARKE, *Higher Education in the Ancient World* (1971); JOHN P. LYNCH, *Aristotle's School: A Study of a Greek Educational Institution* (1972); O.W. REINMUTH, *The Ephebic Inscriptions of the Fourth Century B.C.* (1971); W.H. STAHL, R. JOHNSON, and E.L. BURGE, *Martianus Capella and the Seven Liberal Arts* (1971); RADHAKUMUD MOOKERJI, *Ancient Indian Education: Brahmanical and Buddhist,* 4th ed. (1969); and NATHAN DRAZIN, *History of Jewish Education from 515 B.C.E. to 220 C.E.* (1940, reprinted 1979).

Education in Persian, Byzantine, early Russian, and Islāmic civilizations: Ancient Persian culture and civilization are studied in MANECKJI NUSSERVANJI DHALLA, *Zoroastrian Civilization* (1922, reprinted 1977). For surveys of Byzantine education, see appropriate chapters in STEVEN RUNCIMAN, *Byzantine Civilization* (1933, reissued 1975); and NORMAN H. BAYNES and HENRY ST. L.B. MOSS (eds.), *Byzantium: An Introduction to East Roman Civilization* (1948, reprinted 1969). Special works include PAUL LEMERLE, *Byzantine Humanism, the First Phase: Notes and Remarks on Education and Culture in Byzantium from Its Origins to the 10th Century* (1986; originally published in French, 1971); and N.G. WILSON, *Scholars of Byzantium* (1983). On early Russian education, see NICHOLAS HANS, *The Russian Tradition in Education* (1963, reprinted 1973); WILLIAM K. MEDLIN and CHRISTOS G. PATRINELIS, *Renaissance Influences and Religious Reforms in Russia: Western and Post-Byzantine Impacts on Culture and Education, 16th–17th Centuries* (1971); and HUGH F. GRAHAM, "Did Institutionalized Education Exist in Pre-Petrine Russia?" in DON KARL ROWNEY and G. EDWARD ORCHARD (eds.), *Russian and Slavic History* (1977), pp. 260–273. Medieval Muslim education and its impact upon Western education is studied in GEORGE MAKDISI, *The Rise of the Colleges: Institutions of Learning in Islam and the West* (1981), an authoritative work; and MEHDI NAKOSTEEN, *History of Islamic Origins of Western Education, A.D. 800–1350* (1964).

The European Middle Ages: Some of the best surveys of medieval European education are contained in the general histories of education listed at the beginning of this bibliography. On elementary and grammar schooling of the period, the first major work was A.F. LEACH, *The Schools of Medieval England* (1915, reprinted 1969). Also important are JOAN SIMON, *Education and Society in Tudor England* (1966, reprinted 1979), which also covers the Renaissance and the Reformation; JOHN WILLIAM ADAMSON, *The Illiterate Anglo-Saxon: And Other Essays on Education, Medieval and Modern* (1946, reprinted 1977); and NICHOLAS ORME, *English Schools in the Middle Ages* (1973). For higher learning, see R.R. BOLGAR, *The Classical Heritage and Its Beneficiaries* (1954, reprinted 1977); CHARLES HOMER HASKINS, *The Rise of Universities* (1923, reprinted 1976); HASTINGS RASHDALL, *The Universities of Europe in the Middle Ages,* new ed., ed. by F.M. POWICKE and A.B. EMDEN, 3 vol. (1936, reprinted 1987), a standard work; HELENE WIERUSZOWSKI, *The Medieval University: Masters, Students, Learning* (1966); and ALAN B. COBBAN, *The Medieval Universities: Their Development and Organization* (1975). Relevant monographs are WILLIAM J. COURTENAY, *Schools & Scholars in Fourteenth-Century England* (1987); DAVID KNOWLES, *The Evolution of Medieval Thought,* 2nd ed. (1988); and NANCY G. SIRAISI, *Arts and Sciences at Padua: The Studium of Padua Before 1350* (1973).

Education in Asian civilizations, c. 700 to the eve of Western influence: S.M. JAFFAR, *Education in Muslim India* (1936, reprinted 1973), is a vivid documentary account. NARENDRA NATH LAW, *Promotion of Learning in India During Muhammadan Rule, by Muhammadans* (1916, reprinted 1984 with a new introduction), is informative. For China and Japan, see EDWARD A. KRACKE, *Civil Service in Early Sung China, 960–1067* (1953, reprinted 1968); R.P. DORE, *Education in Tokugawa Japan* (1965, reprinted 1984); and RICHARD RUBINGER, *Private Academies of Tokugawa Japan* (1982).

European Renaissance and Reformation: Introductions to Renaissance education include WILLIAM HARRISON WOODWARD, *Studies in Education During the Age of the Renaissance, 1400–1600* (1906, reprinted 1967), *Vittorino da Feltre and other Humanist Educators* (1897, reprinted 1970), and *Desiderius Erasmus Concerning the Aim and Method of Education* (1904, reprinted 1971). See also DAVID CRESSY, *Literacy and the Social Order: Reading and Writing in Tudor and Stuart England* (1980). Important works on the Reformation and Counter-Reformation are JOHN LAWSON, *Mediaeval Education and the Reformation* (1967); FREDERICK EBY, *Early Protestant Educators: The Educational Writings of Martin Luther, John Calvin, and Other Leaders of Protestant Thought* (1931, reprinted 1971); GERALD STRAUSS, *Luther's House of Learning* (1978); and ALLAN P. FARRELL, *The Jesuit Code of Liberal Education* (1938).

European education in the 17th and 18th centuries: The general histories cited at the beginning of this bibliography offer good accounts of educational developments of the 17th and 18th centuries. For the 17th century, a useful work is JOHN WILLIAM ADAMSON, *Pioneers of Modern Education 1600–1700* (1905, reissued 1972). Major theorists are treated in JEAN PIAGET, "Introduction," in JOHN AMOS COMENIUS, *Selections* (1957), published by UNESCO; JOHN W. YOLTON, *John Locke & Education* (1971); MICHAEL MOONEY, *Vico in the Tradition of Rhetoric* (1985); H.C. BARNARD, *The French Tradition in Education: Ramus to Mme. Necker de Saussure* (1922, reprinted 1970); WILLIAM BOYD, *The Educational Theory of Jean Jacques Rousseau* (1911, reissued 1963); ALLAN BLOOM, "Introduction," in his edition of JEAN JACQUES ROUSSEAU, *Emile: Or, On Education* (1979); and J.J. CHAMBLISS, *Educational Theory as Theory of Conduct: From Aristotle to Dewey* (1987). Introductions to the 18th century include NICHOLAS HANS, *New Trends in Education in the Eighteenth Century* (1951, reprinted 1966); F. DE LA FONTAINERIE (ed.), *French Liberalism and Education in the Eighteenth Century: The Writings of La Chalotais, Turgot, Diderot, and Condorcet on National Education* (1932, reprinted 1971); and L.W.B. BROCKLISS, *French Higher Education in the Seventeenth and Eighteenth Centuries* (1987). For European influence on colonial developments, see LUÍS MARTÍN and JO ANN GEURIN PETTUS (eds.), *Scholars and Schools in Colonial Peru* (1973); and JOSEPH MAIER and RICHARD W. WEATHERHEAD, *The Latin American University* (1979).

Western education in the 19th century: This period is treated in the general histories cited above. *The American Journal of Education* (1856–82), ed. by HENRY BARNARD, remains a valuable source for European and U.S. educational developments. For analysis of theories, see KATE SILBER, *Pestalozzi: The Man and His Work,* 3rd ed. (1973); and JOHN ANGUS MACVANNEL, *The Educational Theories of Herbart and Froebel* (1905, reissued 1972). Works on individual countries include FRIEDRICH PAULSEN, *German Education Past and Present* (1908, reprinted 1976; originally published in German, 1906), a classic analysis; JOHN WILLIAM ADAMSON, *English Education, 1789–1902* (1930, reprinted 1964); PATRICK L. ALSTON, *Education and the State in Tsarist Russia* (1969); BEN EKLOF, *Russian Peasant Schools* (1986); BRUCE CURTIS, *Building the Educational State: Canada West, 1836–1871* (1988); A.G. AUSTIN, *Australian Education, 1788–1900,* 2nd ed. (1965); and A.G. BUTCHERS, *Young New Zealand: A History of the Early Contact of the Maori Race with the European, and of the Establishment of a National System of Education for Both Races* (1929). The spread of Western influences to Asia is studied in MAKOTO ASO and IKUO AMANO,

Education and Japan's Modernization (1972, reissued 1983); SYED NURULLAH and J.P. NAIK, *A History of Education in India During the British Period,* 2nd rev. ed. (1951, reissued 1968); S.N. MUKERJI, *History of Education in India: Modern Period,* 6th ed. (1974); and BHAGWAN DAYAL SRIVASTAVA, *The Development of Modern Indian Education,* rev. ed. (1963).

Education in the 20th century: Surveys of 20th-century practices and theories are found in the general histories listed at the beginning of this bibliography. See also ROBIN BARROW and GEOFFREY MILBURN, *A Critical Dictionary of Educational Concepts* (1986); T. NEVILLE POSTLETHWAITE (ed.), *The Encyclopedia of Comparative Education and National Systems of Education* (1988); J. CAMERON *et al.* (eds.), *International Handbook of Educational Systems,* 3 vol. (1983–84); HAROLD E. MITZEL (ed.), *Encyclopedia of Educational Research,* 5th ed., 4 vol. (1982); TORSTEN HUSÉN and T. NEVILLE POSTLETHWAITE (eds.), *The International Encyclopedia of Education: Research and Studies,* 10 vol. (1985), with supplementary volumes, the first of which appeared in 1989; and GEORGE THOMAS KURIAN (ed.), *World Education Encyclopedia,* 3 vol. (1988).

Major trends and practical problems of education across the world are discussed in THOMAS F. GREEN, *The Activities of Teaching* (1971); GILBERT R. AUSTIN, *Early Childhood Education: An International Perspective* (1976); ISABELLE DEBLÉ, *The School Education of Girls: An International Comparative Study on School Wastage Among Girls and Boys at the First and Second Levels of Education* (1980); DIETMAR ROTHERMUND and JOHN SIMON (eds.), *Education and the Integration of Ethnic Minorities* (1986); JAMES A. BANKS and JAMES LYNCH (eds.), *Multicultural Education in Western Societies* (1986); EDMUND J. KING, *Other Schools and Ours,* 5th ed. (1979); J.R. HOUGH (ed.), *Educational Policy: An International Survey* (1984); ROBERT F. LAWSON (ed.), *Changing Patterns of Secondary Education: An International Comparison* (1987); DANIEL C. LEVY (ed.), *Private Education: Studies in Choice and Public Policy* (1986); ALEXANDER N. CHARTERS *et al., Comparing Adult Education Worldwide* (1981); NELL P. EURICH, *Systems of Higher Education in Twelve Countries* (1981); BURTON R. CLARK, *The Higher Education System: Academic Organization in Cross-National Perspective* (1983); and PHILIP H. COOMBS, *The World Crisis in Education: The View from the Eighties* (1985).

Studies of various contemporary educational philosophies and trends include JOHN DEWEY, *Democracy and Education: An Introduction to the Philosophy of Education* (1916, reprinted 1966); HARRY S. BROUDY, *Building a Philosophy of Education,* 2nd ed. (1961, reprinted 1977), and *The Uses of Schooling* (1988); PAUL H. HIRST, *Knowledge and the Curriculum: A Collection of Philosophical Papers* (1974); MERLE CURTI, *The Social Ideas of American Educators* (1935, reprinted 1978); MADAN SARUP, *Marxism and Education* (1978); JONAS F. SOLTIS (ed.), *Philosophy and Education* (1981); and ERNEST STABLER, *Founders: Innovators in Education, 1830–1980* (1986).

Works on individual countries are legion, and only a sample can be cited here. For Europe, see KEITH EVANS, *The Development and Structure of the English School System* (1985); and BRIAN SIMON and WILLIAM TAYLOR, *Education in the Eighties: The Central Issues* (1981), focusing on Great Britain; CHRISTOPH FÜHR, *Education and Teaching in the Federal Republic of Germany* (1979; originally published in German, 1979); W.D. HALLS, *Education, Culture, and Politics in Modern France* (1976); and LEON BOUCHER, *Tradition and Change in Swedish Education* (1982).

Studies specifically on U.S. education include LAWRENCE A. CREMIN, *The Transformation of the School: Progressivism in American Education, 1876–1957* (1961); SAMUEL BOWLES and HERBERT GINTIS, *Schooling in Capitalist America* (1976); ERNEST L. BOYER, *High School: A Report on Secondary Education in America* (1983); CHRISTOPHER JENCKS *et al., Inequality: A Reassessment of the Effect of Family and Schooling in America* (1972); CLARENCE J. KARIER, PAUL C. VIOLAS, and JOEL SPRING, *Roots of Crisis: American Education in the Twentieth Century* (1972); MICHAEL B. KATZ, *Class, Bureaucracy, and Schools: The Illusion of Educational Change in America,* expanded ed. (1975); JUDY JOLLEY MOHRAZ, *The Separate Problem: Case Studies of Black Education in the North, 1900–1930* (1979); DIANE RAVITCH, *The Troubled Crusade: American Education, 1945–1980* (1983); and FRED F. HARCLEROAD and ALLAN W. OSTAR, *Colleges and Universities for Change: America's Comprehensive Public State Colleges and Universities* (1987). ALLAN BLOOM, *The Closing of the American Mind* (1987), provides an example of intellectual criticism of the educational system.

For Canada, see CAROLYN COSSAGE, *A Question of Privilege: Canada's Independent Schools* (1977); ROBIN S. HARRIS, *A History of Higher Education in Canada, 1663–1960* (1976); ORGANISATION FOR ECONOMIC CO-OPERATION AND DEVELOPMENT, *Reviews of National Policies for Education: Canada* (1976); HUGH A. STEVENSON and J. DONALD WILSON, *Quality in Canadian Public Education: A Critical Assessment* (1988); T.H.B. SYMONS, *To Know Ourselves: The Report of the Commission on Canadian Studies,* 3 vol. in 2 (1975–84); and GEORGE S. TOMKINS, *A Common Countenance: Stability and Change in the Canadian Curriculum* (1986). For Australia, see PETER DWYER, BRUCE WILSON, and ROGER WOOK, *Confronting School and Work: Youth and Class Cultures in Australia* (1984); L.E. FOSTER, *Australian Education: A Sociological Perspective* (1981); PETER KARMEL (ed.), *Education, Change, and Society* (1981), papers of a conference of the Australian Council for Educational Research; and R.J.R. KING and R.E. YOUNG, *A Systematic Sociology of Australian Education* (1986). For New Zealand, see IAN CUMMING and ALAN CUMMING, *History of State Education in New Zealand, 1840–1975* (1978); and ORGANISATION FOR ECONOMIC CO-OPERATION AND DEVELOPMENT, *Reviews of National Policies for Education: New Zealand* (1983).

There are many works discussing the systems of education in those countries that have experienced major social upheavals. For the Soviet Union, see JOSEPH I. ZAJDA, *Education in the USSR* (1980); SHEILA FITZPATRICK, *Education and Social Mobility in the Soviet Union, 1921–1934* (1979); LUDWIG LIEGLE, *The Family's Role in Soviet Education* (1975; originally published in German, 1970); MERVYN MATTHEWS, *Education in the Soviet Union: Policies and Institutions Since Stalin* (1982); JOHN DUNSTAN, *Paths to Excellence and the Soviet School* (1978); and J.J. TOMIAK (ed.), *Soviet Education in the 1980s* (1983). For China, see THEODORE E. HSIAO, *The History of Modern Education in China* (1932); RONALD F. PRICE, *Education in Modern China,* 2nd ed. (1979); THEODORE HSI-EN CHEN, *Chinese Education Since 1949* (1981), *The Maoist Educational Revolution* (1974), and "Educational Development in the People's Republic of China, 1949–1981," in HUNGDAH CHIU and SHAO-CHUAN LENG (eds.), *China Seventy Years After the 1911 Hsin-Hai Revolution* (1984), pp. 364–389; WOLFGANG FRANKE, *The Reform and Abolition of the Traditional Chinese Examination System* (1960, reprinted 1972); KNIGHT BIGGERSTAFF, *The Earliest Modern Government School in China* (1961, reprinted 1972); and RUTH HAYHOE, *China's Universities and the Open Door* (1988). RONALD F. PRICE, *Marx and Education in Russia and China* (1977), is a comparative philosophical study.

Afro-Asian patterns of education are studied in ROBERT LEESTMA *et al., Japanese Education Today: A Report from the U.S. Study of Education in Japan* (1987); JAPAN PROVISIONAL COUNCIL ON EDUCATIONAL REFORM, *First Report on Educational Reform* (1985); RICHARD LYNN, *Educational Achievement in Japan: Lessons for the West* (1988); R. MURRAY THOMAS and T. NEVILLE POSTLETHWAITE (eds.), *Schooling in East Asia: Forces of Change: Formal and Nonformal Education in Japan, the Republic of China, the People's Republic of China, South Korea, North Korea, Hong Kong, and Macau* (1983), *Schooling in the ASEAN Region: Primary and Secondary Education in Indonesia, Malaysia, the Philippines, Singapore, and Thailand* (1980), and *Schooling in the Pacific Islands: Colonies in Transition* (1984); PAKISTAN. MINISTRY OF EDUCATION, *National Education Policy and Implementation Programme* (1979); ASIAN PROGRAMME OF EDUCATIONAL INNOVATION FOR DEVELOPMENT, *Towards Universalisation of Primary Education in Asia and the Pacific: Country Studies,* 12 vol. (1984), a UNESCO publication covering Bangladesh, China, India, Indonesia, Nepal, Pakistan, Papua New Guinea, the Philippines, South Korea, Vietnam, Sri Lanka, and Thailand; A. BISWAS and S.P. AGRAWAL (comps.), *Development of Education in India: A Historical Survey of Educational Documents Before and After Independence* (1986); S.N. MUKERJI, *Education in India Today and Tomorrow,* 7th ed. (1976); R.M. RUPERTI, *The Education System in Southern Africa* (1976; originally published in Afrikaans, 1974); PAM CHRISTIE, *The Right to Learn: The Struggle for Education in South Africa* (1985); and A.L. BEHR, *New Perspectives in South African Education* (1984).

Education in developing countries is the subject of A.R. THOMPSON, *Education and Development in Africa* (1981); A. BABS FAFUNWA and J.U. AISIKU (eds.), *Education in Africa: A Comparative Survey* (1982); DAVID G. SCANLON (ed.), *Church, State, and Education in Africa* (1966); ALI A. MAZRUI, *Political Values and the Educated Class in Africa* (1978); R.H. DAVE, A. OUANE, and A.M. RANAWEERA (eds.), *Learning Strategies for Post-Literacy and Continuing Education in Algeria, Egypt, and Kuwait* (1987); JUDITH COCHRAN, *Education in Egypt* (1986); JAMES ALLMAN, *Social Mobility, Education, and Development in Tunisia* (1979); JOSEPH S. SZYLIOWICZ, *Education and Modernization in the Middle East* (1973); BYRON G. MASSIALAS and SAMIR AHMED JARRAR, *Education in the Arab World* (1983); JOSEFINA VÁZQUEZ, *Nacionalismo y educación en México,* 2nd ed. (1975); GEORGE R. WAGGONER and BARBARA ASHTON WAGGONER, *Education in Central America* (1971); FAY HAUSSMAN and JERRY HAAR, *Education in Brazil* (1978); and DANIEL C. LEVY, *Higher Education and the State in Latin America* (1986).

Egypt

Egypt (Arabic Miṣr), or the Arab Republic of Egypt (Jumhūrīyah Miṣr al-ʿArabīyah), as it has been known since 1971, has a total area of about 385,230 square miles (997,740 square kilometres). Its land frontiers border Libya in the west, The Sudan in the south, and Israel in the northeast. (Israeli forces occupied the Sinai Peninsula and the Gaza Strip in eastern Egypt after the Arab–Israeli War of 1967. In 1982 the Sinai was returned to Egypt.) In the north its Mediterranean coastline is about 620 miles (1,000 kilometres) and in the east its coastline on the Red Sea and the Gulf of Aqaba is about 1,200 miles. The capital is Cairo.

Egypt was the home of one of the principal civilizations of the ancient Near East and, like Mesopotamia, of one of the very earliest urban and literate societies. Its culture had an important influence on both ancient Israel and ancient Greece, which in turn helped to form the civilization of the modern West. Egypt also provided Africa with its earliest civilization and may well have had considerable influence on the development of other African cultures.

The special character evident in the civilization of ancient Egypt over a period of 3,000 years developed very rapidly at the time when the country first achieved unity. This great event happened in about 3100 BC, and while some of the seeds of Egyptian culture had sprouted before this time, it is proper to regard the start of the 1st dynasty as the virtual beginning of Egypt as the country and its civilization are now generally envisaged.

Perhaps the first and most important quality that typified this civilization was continuity. In every aspect of Egyptian life, in every manifestation of its culture, a deep conservatism can be observed. This clinging to the traditions and ways of earlier generations was the particular strength of the Egyptians. It can also be regarded as a weakness; but for a relatively primitive culture there was more to be gained than lost in attachment to the past. Regularity was a built-in characteristic of Egypt; life in the Nile Valley was determined to a great extent by the behaviour of the river itself. The pattern of inundation and falling water, of high Nile and low Nile, established the Egyptian year and controlled the lives of the Egyptian farmers—and most Egyptians were tied to a life on the land—from birth to death, from century to century. On the regular behaviour of the Nile rested the prosperity, the very continuity, of the land. The three seasons of the Egyptian year were even named after the land conditions produced by the river; *akhet,* the "inundation"; *peret,* the season when the land emerged from the flood; and *shomu,* the time when water was short. When the Nile behaved as expected, which most commonly was the case, life went on as normal; when the flood failed or was excessive, disaster followed.

Egypt has always been a hub for routes—westward along the coast of North Africa, northwest to Europe, northeast to the Levant, south along the Nile to Africa, and southeast to the Indian Ocean and the Far East. This natural advantage was enhanced in 1869 by the opening of the Suez Canal. The concern of the European powers to safeguard this link for strategic and commercial reasons is probably the most important single factor influencing the history of Egypt since the 19th century. The increasing presence of the United States and the Soviet Union in the Mediterranean since World War II has kept Egypt in the spotlight of world concern. It is not, however, simply in the context of the balance of power in the Mediterranean but also in Africa and in the Indian Ocean that Egypt's significance must be assessed. In addition, Egypt occupies a central position in the Arabic-speaking world. The country's geopolitical importance has increased during the 20th century as Arab nationalism has become a powerful and emotional political force in the Middle East and North Africa.

This article is divided into the following sections:

Physical and human geography

THE LAND

Relief. The topography of Egypt is dominated by the Nile. For about 750 miles of its northward course through the country, the river cuts its way through bare desert, its narrow valley a sharply delineated strip of green, abundantly fecund in contrast to the desolation that surrounds it. From Lake Nasser, the river's entrance into southern Egypt, to Cairo in the north, the Nile is hemmed into its trenchlike valley by bordering cliffs, but at Cairo these disappear, and the river begins to fan out into its delta. As many as seven branches of the river once flowed through the Delta, but its waters are now concentrated in two, the Damietta Branch to the east and the Rosetta Branch to the west. Though totally flat apart from an occasional mound projecting through the alluvium, the Delta is far from featureless; it is crisscrossed by a maze of canals and drainage channels.

The Nile divides the desert plateau through which it flows into two unequal sections—the Western Desert (Arabic aṣ-Ṣaḥrāʾ al-Gharbīyah), between the river and the Libyan frontier; and the Eastern Desert (Arabic aṣ-Ṣaḥrāʾ ash-Sharqīyah), extending to the Suez Canal, the Gulf of Suez, and the Red Sea. Each of them has its own character, as does the third and smallest of the Egyptian deserts, the Sinai. The Western (Libyan) Desert is arid and without wadis (dry beds of seasonal rivers), while the Eastern Desert is extensively dissected by wadis and fringed by rugged mountains in the east. The desert of central Sinai is open country, broken by isolated hills and scored by wadis.

The mountains

Egypt is not, as is often believed, an unrelievedly flat country. Mountainous areas occur in the extreme southwest of the Western Desert, along the Red Sea coast, and in southern Sinai. The high ground in the southwest is associated with the ʿUwaynāt mountain mass, which lies just outside Egyptian territory. A number of peaks in the Red Sea Hills (Itbāy) rise to more than 6,000 feet (1,800 metres), and the highest, Mount Shāiyb al-Banāt, reaches 7,175 feet (2,187 metres). The sharply serrated crests of the mountains of southern Sinai reach elevations of more than 8,000 feet; among them is Mount Catherine (Jabal Kātrīnā), Egypt's highest mountain, which has an elevation of 8,668 feet (2,642 metres).

The coastal regions of Egypt, with the exception of the Delta, are everywhere hemmed in either by desert or by mountain; they are arid or of very limited fertility. The coastal plain, in both the north and east, tends to be narrow; it seldom exceeds a width of 30 miles. With the exception of the cities of Alexandria, Port Said, and Suez and a few small ports and resorts, the coastal regions are sparsely populated and underdeveloped.

Drainage and soils. Apart from the Nile, the only natural perennial surface drainage consists of a few small streams in the mountains of southern Sinai. Most of the valleys of the Eastern Desert drain westward to the Nile. They are eroded by water but normally dry; only after heavy rainstorms in the Red Sea Hills do they carry torrents. The shorter valleys on the eastern flank of the Red Sea Hills drain toward the Red Sea; they, too, are normally dry. Drainage in the Sinai mountains is toward the gulfs of Suez and Aqaba; as in the Red Sea Hills, torrent action has produced valleys that are deeply eroded and normally dry.

The central plateau of Sinai drains northward toward Wadi al-ʿArīsh, a depression in the desert that occasionally carries surface water. One of the features of the Western Desert is its aridity, as shown by the absence of drainage lines. There is, however, an extensive water table beneath the Western Desert. Where the water table comes near the surface it has been tapped by wells in some oases.

Outside the areas of Nile silt deposits, the nature of such cultivable soil as exists depends upon the availability of the water supply and the type of rock in the area. Almost one-third of the total land surface of Egypt consists of Nubian sandstone, which extends over the southern sections of both the Eastern and Western deserts. Limestone deposits of the Eocene Epoch (from 38,000,000 to 54,000,000 years old) cover a further one-fifth of the land surface, including central Sinai and the central portions of both the Eastern and Western deserts. The northern part of the Western Desert consists of Miocene limestone (from 7,000,000 to 26,000,000 years old). About one-eighth of the total area, notably the mountains of Sinai, the Red Sea, and the southwest part of the Western Desert, consists of ancient igneous and metamorphic rocks.

The Nile silt

The silt, which constitutes the present-day cultivated land in the Delta and the Nile Valley, has been carried down from the Ethiopian Highlands by the Nile's upper tributary system, consisting of the Blue Nile and the ʿAṭbarah rivers. The depth of the deposits ranges from more than 30 feet in the northern Delta to about 22 feet at Aswān. The White Nile, which is joined by the Blue Nile at Khartoum, in The Sudan, supplies important chemical constituents. The composition of the soil varies and is generally more sandy toward the edges of the cultivated area. A high clay content makes it difficult to work, and a concentration of sodium carbonate sometimes produces infertile black-alkali soils. In the north of the Delta, salinization has produced the sterile soils of the so-called *barārī* ("barren") regions.

Climate. Egypt lies within the North African desert belt; its general climatic characteristics, therefore, are low annual rainfall and a considerable seasonal and diurnal (daily) temperature range, with sunshine occurring throughout the year. In the desert, cyclones stir up sand or dust storms, called khamsins, which occur most frequently from March to June; these are caused by tropical air from the south that moves northward as a result of the extension northeastward of the low-pressure system of The Sudan. A khamsin is accompanied by a sharp increase in temperature of from 14° to 20° F (8° to 11° C), a drop in relative humidity (often to 10 percent), and thick dust; it can reach gale force.

The climate is basically biseasonal, with winter lasting from November to March and summer from May to September, with short transitional periods intervening. The winters are cool and mild, and the summers are hot. Mean January minimum and maximum temperatures show a variation of between 48° and 65° F (9° and 18° C) in Alexandria and 48° and 74° F (9° and 23° C) at Aswān. The summer months are hot throughout the country, with mean midday June maximum temperatures ranging from 91° F (33° C) at Cairo to 106° F (41° C) at Aswān. Egypt enjoys a very sunny climate, with some 12 hours of sunshine per day in the summer months and between eight and 10 hours per day in winter. Extremes of temperature can occur, and prolonged winter cold spells or summer heat waves are not uncommon.

Humidity diminishes noticeably from north to south and on the desert fringes. Along the Mediterranean coast the humidity is high throughout the year, but it is highest in summer. When high humidity levels coincide with high temperatures, oppressive conditions result.

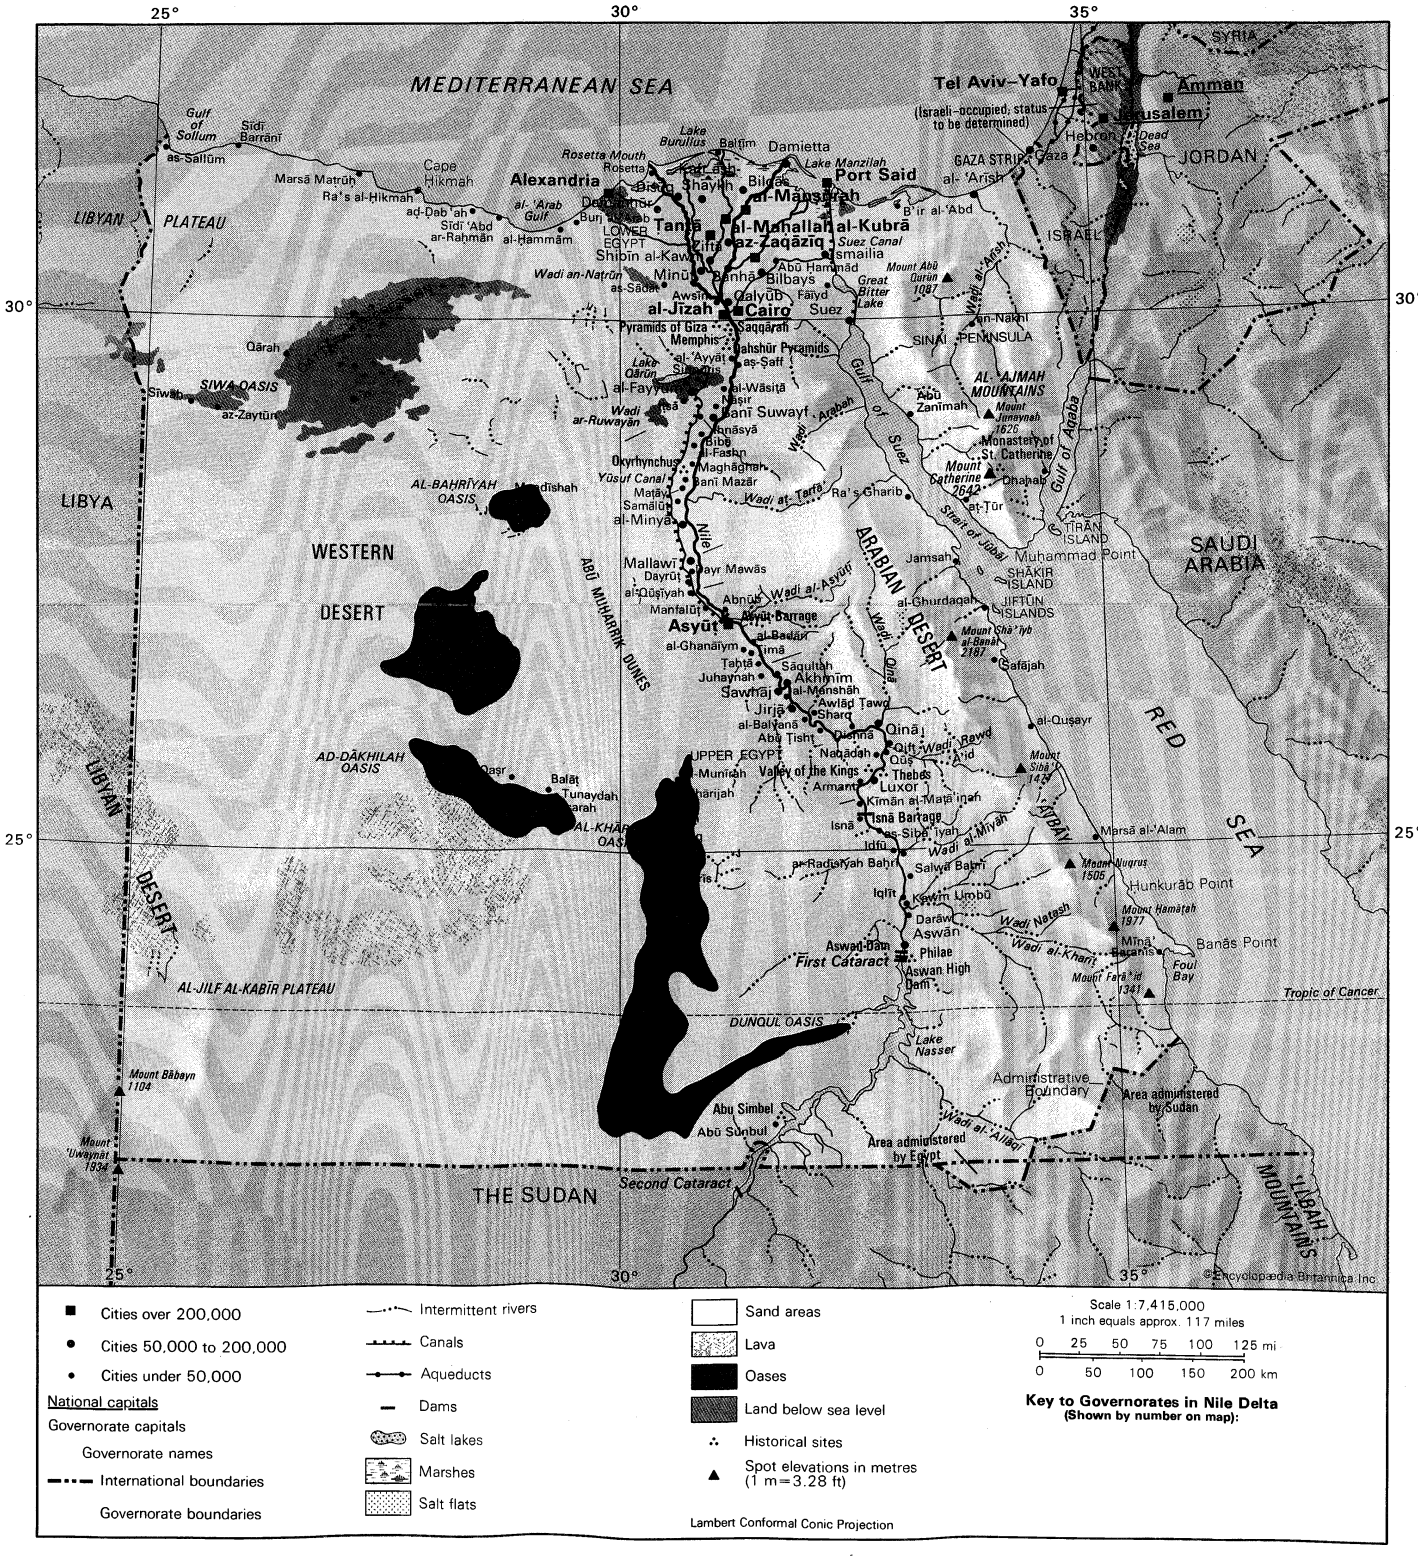
The rainfall in Egypt occurs largely in the winter months; it is meagre on average but highly variable. The amount diminishes sharply southward; the annual average at Alexandria is about seven inches (178 millimetres), Cairo

has about one inch, and Aswān receives only about one-tenth of an inch. The Red Sea coastal plain and the Western Desert are almost rainless. The Sinai Peninsula receives somewhat more rainfall: the northern sector has an annual average of about five inches.

Plant and animal life. In spite of the lack of rainfall, the natural vegetation of Egypt is varied. Much of the Western Desert is totally devoid of plant life of any kind, but where some form of water exists the usual desert growth of perennials and grasses is found; the coastal strip has a rich plant life in spring. The Eastern Desert receives sparse rainfall; it supports a varied vegetation that includes tamarisk, acacia, and *markh* (a leafless, thornless tree with bare branches and slender twigs), as well as a great variety of thorny shrubs, small succulents, and aromatic herbs. This growth is even more striking in the wadis of the Red Sea Hills and of Sinai and in the Elba Mountains in the southeast.

Water plants

The Nile and irrigation canals and ditches support many varieties of water plants; the lotus of antiquity is to be found in drainage channels in the Delta. There are more than 100 kinds of grasses, among them bamboo and *ḥalfā'* (a coarse, long grass growing near water). Robust perennial reeds such as the Spanish reed and the common reed are widely distributed in Lower Egypt, but the papyrus, cultivated in antiquity, is now found only in botanical gardens.



MAP INDEX

The date palm, both cultivated and subspontaneous, is found throughout the Delta, in the Nile Valley, and in the oases. The doum palm (an African fan palm) is identified particularly with Upper Egypt and the oases, although there are scattered examples elsewhere.

There are very few native trees. The Phoenician juniper is the only native conifer, although there are several cultivated conifer species. The acacia is widely distributed, as are eucalyptus and sycamore. The casuarina, one of the most important timber trees in the country, was introduced in the 19th century. Other foreign importations, such as jacaranda, poinciana (a tree with orange or scarlet flowers), and lebbek (a leguminous tree), have become a characteristic feature of the Egyptian landscape.

Domestic animals include buffalo, camels, donkeys, sheep, and goats, the last of which are particularly noticeable in the Egyptian countryside. The animals that figure so prominently on the ancient Egyptian friezes—hippopotamuses, giraffes, and ostriches—no longer exist in Egypt; crocodiles are found only south of the Aswān High Dam. The largest wild animal is the mountain sheep, which survives in the southern fastnesses of the Western Desert. Other desert animals are the dorcas gazelle, the miniature desert fox, the mountain goat, the Egyptian hare, and two kinds of jerboa (a mouselike rodent with long hindlegs for jumping). The Egyptian jackal still exists, and the cony (a small rodent) is found in the Sinai mountains. There are two carnivorous mammals: a species of wildcat and the striped Egyptian mongoose. Several varieties of lizard are found, including the large monitor. Poisonous snakes include more than one species of viper; the speckled snake is found throughout the Nile Valley and the Egyptian cobra in agricultural areas. Scorpions are common in desert regions. There are numerous species of rodents, among which can be found the powerfully built Pharaoh's rat. Many varieties of insects are to be found, including the Egyptian locust.

Bird life

Egypt is rich in bird life. Many birds pass through in large numbers on their spring and autumn migrations; in all, there are more than 200 migrating types to be seen, as well as more than 150 resident birds. The hooded crow is a familiar resident, and the black kite is a characteristic resident along the Nile Valley and in al-Fayyūm. Among the birds of prey are the lanner falcon and the kestrel. Lammergeier and golden eagles are residents of the Eastern Desert and Sinai. The sacred ibis (a long-billed wading bird) is no longer found, but the great egret and buff-backed heron are residents of the Nile Valley and al-Fayyūm, as is the hoopoe (a bird with an erectile, fanlike crest). Resident desert birds are a distinct category, numbering about 24 kinds.

The Nile contains about 190 varieties of fish, the most common being *bulṭī* (a coarse-scaled, spiny-finned fish) and the Nile perch. The lakes on the Delta coast contain mainly *būrī* (gray mullet). Lake Qārūn in al-Fayyūm *muḥāfaẓah* (governorate) has been stocked with *būrī,* and Lake Nasser with *bulṭī,* which grow very large in its waters.

Settlement patterns. Physiographically, Egypt is usually divided into four major regions—the Nile Valley and Delta, the Eastern Desert, the Western Desert, and Sinai. When both physical and cultural characteristics are considered together, however, the country may be divided into six subregions—the Nile Delta; the Nile Valley from Cairo to south of Aswān; the Nubian Valley (since the early 1970s filled by Lake Nasser); the Eastern Desert and the Red Sea coast; Sinai; and the Western Desert and its oases.

The Delta. The Nile Delta, or Lower Egypt, covers an area of 9,650 square miles. It is 100 miles long from Cairo to the Mediterranean, with a coastline stretching 150 miles from Alexandria to Port Said. Much of the Delta coast is taken up by the brackish lagoons of Lakes Maryūṭ, Idkū, Burullus, and Manzilah. The conversion of the Delta to perennial irrigation has made possible the raising of two or three crops a year, instead of one, over more than half of its total area.

The Delta population

About half of the population of the Delta are peasants (fellahin)—either small landowners or labourers—living on the produce of the land. The remainder live in towns or cities, the largest of which is Cairo. As a whole, they have had greater contact with the outside world, particularly with the rest of the Middle East and Europe, than the inhabitants of the more remote southern valley and are generally less traditional and conservative.

The Valley. The cultivated portion of the Nile Valley between Cairo and Aswān varies from five to 10 miles in width, although there are places where it narrows to a few hundred yards and others where it broadens to 14 miles. Since the completion of the Aswān High Dam in 1970, the 2,500,000-acre valley has been under perennial irrigation. The inhabitants of the Valley from Cairo up to Aswān *muḥāfaẓah* are referred to as Ṣaʿīdī (Upper Egyptians) and are more conservative than the Delta people. In some areas women still do not appear in public without a veil; family honour is very important, and vendetta laws apply. Until the building of the High Dam, the Aswān *muḥāfaẓah* was one of the poorest in the Valley and the most remote from outside influences.

The Nubian Valley, or Lake Nasser. Until it was flooded by the waters impounded behind the High Dam to form Lake Nasser, the Nubian Valley of the Nile extended for 160 miles between the town of Aswān and the Sudanese border—a narrow and picturesque gorge with a limited cultivable area. The 100,000 inhabitants were resettled, mainly in the government-built villages of New Nubia, at Kawm Umbū (Kom Ombo), north of Aswān. Lake Nasser was developed during the 1970s for its fishing and as a tourist area, and settlements have grown up around it.

The Eastern Desert. The Eastern Desert comprises almost one-fourth of the land surface of Egypt and covers an area of about 85,690 square miles. The northern tier is a limestone plateau, consisting of rolling hills, stretching from the Mediterranean coastal plain to a point roughly opposite Qinā on the Nile. Near Qinā, the plateau breaks up into cliffs about 1,600 feet high and is deeply scored by wadis, which make the terrain very difficult to traverse. The outlets of some of the main wadis form deep bays, which contain small settlements of seminomads. The second tier includes the sandstone plateau from Qinā southward. The plateau is also deeply indented by ravines, but they are relatively free from obstacles, and some are usable as routes. The third tier consists of the Red Sea Hills and the Red Sea coastal plain. The hills run from near Suez to the Sudanese border; they are not a continuous range but consist of a series of interlocking systems more or less in alignment. They are geologically complex, with ancient igneous and metamorphic rocks. These include granite that, in the neighbourhood of Aswān, extends across the Nile Valley to form the First Cataract—that is, the first set of rapids on the river. At the foot of the Red Sea Hills the narrow coastal plain widens southward, and parallel to the shore there are almost continuous coral reefs. In popular conception and usage, the Red Sea Littoral can be regarded as a subregion in itself.

The majority of the sedentary population of the Eastern Desert live in the few towns and settlements along the coast, the largest being Ra's Gharib. No accurate figures are available for the nomadic population, but they are believed to constitute about 12 percent of the region's total population. They belong to various tribal groups, the most important being—from north to south—the Ḥuwayṭāt, Maʿāzah, ʿAbābdah, and Bishārīn. There are more true nomads in the Eastern than the Western Desert because of the greater availability of pasture and water. They live either by herding goats, sheep, and camels or by trading—mainly with mining and petroleum camps or with the fishing communities on the coast.

Nomads of the Eastern Desert

The Western Desert. The Western Desert comprises two-thirds of the land surface of Egypt and covers an area of about 262,800 square miles. From its highest altitude—more than 3,300 feet—on the plateau of al-Jilf al-Kabīr in the southeast, the rocky plateau slopes gradually northeastward to the first of the depressions that are a characteristic feature of the Western Desert—that containing the oases of al-Khārijah and ad-Dākhilah. Farther north are the hollows containing the oases of al-Farāfirah and al-Baḥrīyah. Northwestward from the latter the plateau continues to fall toward the Qattara Depression (Munkhafaḍ al-Qaṭṭārah), which is uninhabited. West of the Qattara Depression and near the Libyan border is the largest and most populous oasis, that of Siwa. It has been inhabited for thousands of years and is less influenced by modern development. South of the Qattara Depression, and extending west to the Libyan border, the Western Desert is composed of great ridges of blown sand, interspersed with stony tracts. Beyond the Qattara Depression northward, the edge of the plateau follows the Mediterranean, leaving a narrow coastal plain.

Outside the oases, the habitable areas of the Western Desert, mainly near the coast, are occupied by the Awlād ʿAlī tribe. Apart from small groups of camel herders in the south, the population is no longer totally nomadic. Somewhat less than half are seminomadic herdsmen; the remainder are settled and, in addition to maintaining herds of sheep and goats, pursue such activities as fruit growing, fishing, trading, and handicrafts.

The Western Desert supports a much larger population than the Eastern Desert. Maṭrūḥ, an important summer resort on the Mediterranean, is the only urban centre. Other scattered communities are found mainly near railway stations and along the northern cultivated strip.

The oases, though geographically a part of the Western Desert, are ethnically and culturally distinct. The southern oases of al-Khārijah and ad-Dākhilah have been developed to some extent as part of a reclamation project centred on exploiting underground water resources. Other oases are al-Farāfirah, al-Baḥrīyah, and Siwa.

Sinai. Sinai comprises a wedge-shaped block of territory with its base along the Mediterranean coast and its apex bounded by the Gulfs of Suez and Aqaba; it covers an area of approximately 23,000 square miles. Its southern portion consists of rugged, sharply serrated mountains. The central area of Sinai consists of two plateaus, at-Tīh and al-ʿAjmah, both deeply indented and dipping northward toward Wadi al-ʿArīsh. Toward the Mediterranean, the northward plateau slope is broken by dome-shaped hills; between them and the coast are long, parallel lines of dunes, some of which are more than 300 feet high. The most striking feature of the coast itself is the 60-mile-long salt lagoon, Lake Bardawīl.

The majority of the population are Arabs, many of whom have settled around al-ʿArīsh and in the northern coastal area, although substantial numbers in the central plateau and the Sinai mountains continue to be nomadic or seminomadic. Another concentration of sedentary population is found at al-Qanṭarah, on the east side of the Suez Canal.

Rural settlement. The settled Egyptian countryside, throughout the Delta and the Nile Valley to the High Dam, exhibits great homogeneity, although minor variations occur from north to south.

Villages of the Delta and the Nile Valley

The typical rural settlement is a compact village surrounded by intensively cultivated fields. The villages range in population from 500 to more than 10,000. They are basically similar in physical appearance and design, except for minor local variations in building materials, design, and decoration. The date palm, sycamore, eucalyptus, and casuarina are common features of the landscape. Until comparatively recently, the only source of drinking water was the Nile; in consequence, many of the villages are built along the banks of its canals. Some of the oldest villages are situated on mounds—a relic of the days of basin irrigation and annual flooding.

In the Delta the houses, one or two stories high, are built of mud bricks plastered with mud and straw; in the southern parts of the Valley more stone is used. The houses are joined to one another in a continuous row. In a typical house the windows consist of a few small round or square openings, barely permitting enough air or light to enter. The roofs are flat, built of layers of dried date leaves, with date-palm rafters; they are used to store corn (maize) and cotton stalks, as well as dung cakes used for fuel. Roofs are also a favourite sleeping place on hot summer nights. For grain storage small cone-shaped silos of plastered mud are built on the roof and are then sealed to prevent the ravages of insects and rodents.

The houses of the poorer peasants usually consist of a narrow passageway, a bedroom, and a courtyard; part of the courtyard may be used as an enclosure for farm animals. Furniture is sparse. Ovens are made of plastered mud and are built into the wall of the courtyard or inside the house. In the larger and more prosperous villages, houses are built of burnt bricks reinforced with concrete, are more spacious, and often house members of an extended family. Furniture, running water, bathroom installations, and electricity are additional signs of prosperity.

Typical features of the smaller Egyptian village, in both the Delta and the Valley, are the mosque or the church, the primary school, the decorated pigeon cote, service buildings belonging to the government, and a few shops. Most of the people in the smaller villages are engaged in agriculture. In the larger villages, there may be some professional and semiprofessional inhabitants as well as more artisans, skilled workers, and shopkeepers. Outside the larger settlements, "combined service units"—consisting of modern buildings enclosing the social service unit, village cooperative, health unit, and school—are sometimes found, standing in striking contrast to the mud houses of the village itself.

The rural life-style

The population density of the inhabited area is such that the presence of people is obvious everywhere, even in the open countryside. In the early morning and the late afternoon, the peasants can be seen in large numbers on the roads, going to or coming from the fields with their farm animals. During the entire day the men, with their long tunics (*gallābīyahs*) tucked up around the waist, can be seen working the land with age-old implements such as the *fās* (hoe) and *minjal* (sickle); occasionally a modern tractor is seen. In the Delta older women in long, black robes, younger ones in more colourful cottons, and children over six years of age help with the less laborious tasks. In some parts of the Valley, however, women over age 16 do not work in the field, and their activities are confined to the household. They seldom appear in public except with a black muslin headdress covering their heads and faces. Young children can be seen everywhere—an omnipresent reminder of the high birthrate.

Unless situated on a highway, villages are reached by unpaved dirt roads. Inside the villages the roads consist mainly of narrow, winding footpaths. All villages, however, have at least one motorable road.

The Western Desert oases are not compact villages but small, dispersed agglomerations surrounded by green patches of cultivation; they are often separated from each other by areas of sand. Al-Khārijah, for example, is the largest of five scattered villages. Traditionally, the houses in the oases were up to six stories high, made of packed mud, and clustered close together for defense. Modern houses are usually two stories high and farther apart.

Urban settlement. Although for census purposes Egyptian towns are considered to be urban centres, some of them are overgrown villages, containing large numbers of peasants and persons engaged in work relating to agriculture and rural enterprises. Some of the towns that have acquired urban status in the second half of the 20th century continue to be largely rural, although they have government officials, people engaged in trade and commerce, industrial workers, technicians, and professional people among their residents. One characteristic of towns and, indeed, of the larger cities is their rural fringe. Towns and cities have grown at the expense of agricultural land, with urban dwellings and apartment buildings mushrooming haphazardly among the fields. There is little evidence of town or city planning or of adherence to building regulations; often mud village houses are embraced within the confines of a city.

Urban characteristics

Al-Qaṣr, in the oasis of ad-Dākhilah in the Western Desert.
© Georg Gerster—Photo Researchers, Inc.

Buildings in towns and smaller cities are usually two-storied houses or apartment blocks four to six stories high. The better ones are lime washed, with flat roofs and numerous balconies; other houses and buildings are often of unpainted red brick and concrete.

Whereas most of the cities of Egypt do not have many distinctive features, some such as Cairo, Alexandria, and Aswān have special characteristics of their own. Cairo is a complex and crowded metropolis, with architecture representing more than 1,000 years of history. Greater Cairo (including al-Jīzah and other suburban settlements) and Alexandria, together with the most important towns along the Suez Canal—Port Said, Ismailia, and Suez—are modern and Western in appearance. Extensive rebuilding of the towns in the canal zone, severely damaged in the fighting between 1967 and 1973, followed the peace treaty with Israel in 1979.

THE PEOPLE

The use of Arabic

Linguistic composition. For almost 13 centuries Arabic has been the written and spoken language of Egypt. Before the Arab invasion in AD 639, Coptic, the language descended from ancient Egyptian, was the language of both religious and everyday life for the mass of the population; by the 12th century, however, it had been totally replaced by Arabic, continuing only as a liturgical language for the Coptic Orthodox Church. Arabic has become the language of both the Egyptian Christian and Muslim.

The written form of the Arabic language, in grammar and syntax, has remained substantially unchanged since the 7th century. In other ways, however, the written language has changed—the modern forms of style, word sequence, and phraseology are simpler and more flexible than in classical Arabic and are often directly derivative of English or French.

This modern literary Arabic, which is developing out of classical or medieval Arabic, is the lingua franca shared by educated persons throughout the Arab world. Alongside it there exist the various regional dialects of Arabic, which differ widely from it as well as from one another. Within the amorphous grouping referred to as Egyptian colloquial, a number of separate dialects can be discerned—each fairly homogeneous but with further strata of variation within the group. One of these is the dialect of the Bedouin of the Eastern Desert and of Sinai; the Bedouin of the Western Desert constitute a separate dialect group. Upper Egypt has its own vernacular, markedly different from that of Cairo. The Cairo dialect is used, with variations, throughout the towns of the Delta; the rural people have their own vernacular. Direct contact with foreigners over a long period has led to the incorporation of many loanwords into Cairene colloquial Arabic. The long contact with foreigners and the existence of foreign-language schools also explains the polyglot character of Egyptian society. Most educated Egyptians are fluent in English or French or both, in addition to Arabic.

Non-Arabic languages

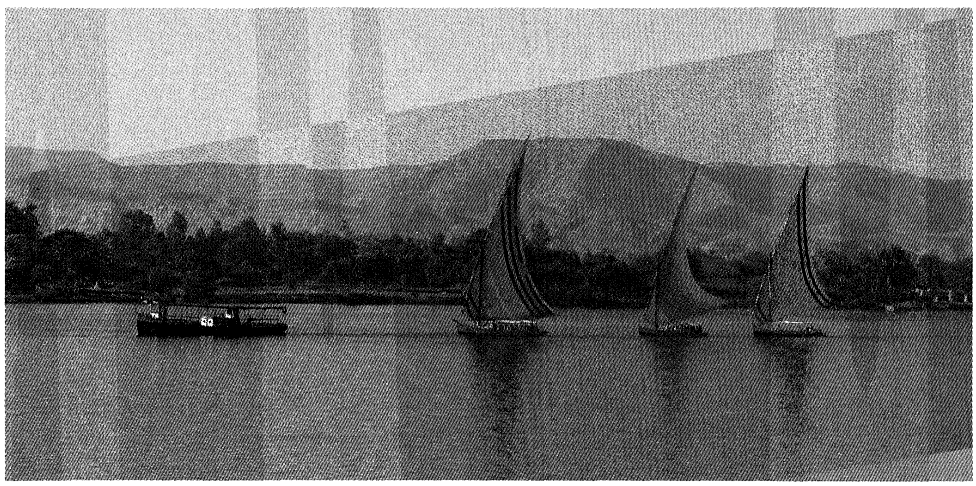
There are other minor linguistic groups. The Hamitic Beja (Bujah) of the southern section of the Eastern Desert use To Badawī. At Siwa Oasis in the Western Desert there are groups whose language is related to Berber. The Nubian speak a language containing both Sudanic and Hamitic features. There are other minority linguistic groups, notably Greek, Italian, and Armenian, although they are much smaller than they once were.

Ethnic composition. The population of the Nile Valley and the Delta (comprising about 99 percent of Egypt) forms a fairly homogeneous group whose dominant physical characteristics are the result of the admixture of the indigenous pre-Islāmic Hamitic–Armenoid population with Arab stock. The peasant, or fellah, is less racially mixed than the town dweller. In the towns—the northern Delta towns especially—the foreign invader, Persian, Roman, Greek, crusader, and Turk, has left behind a more heterogeneous mixture. The inhabitants of the middle Nile Valley up to Aswān, the Ṣaʿīdī (Upper Egyptians), are of the same racial stock as the inhabitants of the Delta but have darker skin and are slightly taller and have a sturdier build. Settled communities in Aswān *muḥāfaẓah* tend to be a mixture of Ṣaʿīdī, long-settled nomads such as the Jaʿāfirah and ʿAbābdah, and Nubian.

The Nubian, though having Arab blood, have preserved racial characteristics that are non-Arab. They are tall and thin, with Caucasoid features, and are of a much darker colouring than the average Egyptian. They also differ in that their kinship structure goes beyond the lineage; they are divided into clans and broader segments, whereas among other Egyptians of the Valley and Lower Egypt known members of the lineage are the only ones recognized as kin.

The deserts of Egypt contain nomadic, seminomadic, or sedentary but formerly nomadic groups, with distinct ethnic characteristics. Apart from a few tribal groups of non-Arab stock and the mixed urban population, the inhabitants of Sinai and the northern section of the Eastern Desert are all fairly recent immigrants from Arabia. Like the Arabian Bedouin, they are usually slightly built and brown skinned and have prominent, hooked noses. Their social organization is tribal, each group conceiving of itself as being united by a bond of blood and as having descended from a common ancestor. Originally tent dwellers and nomadic herders, many have become seminomads or even totally sedentary, as in northern Sinai.

The southern section of the Eastern Desert is inhabited by the Hamitic Beja. Though claiming Arab descent, they are of different racial stock, with oval faces, straight noses, and large eyes; they bear a distinct resemblance to the sur-



Feluccas on the Nile River, near Luxor in Upper Egypt.

viving depictions of predynastic Egyptians. The Egyptian Beja are divided into two tribes—the ʿAbābdah and the Bishārīn. The ʿAbābdah occupy the Eastern Desert south of a line between Qinā and al-Ghurdaqah; there are also several groups settled along the Nile between Aswān and Qinā. The Bishārīn live mainly in The Sudan, although some dwell in the Elba Mountain region, their traditional place of origin. Both the ʿAbābdah and Bishārīn people are nomadic pastoralists who tend herds of camels, goats, and sheep.

The Saʿādī and the Mūrābiṭīn

The inhabitants of the Western Desert, outside the oases, claim Arab descent but are a mixture of Arab and Berber stock. They are divided into two groups, the Saʿādī and the Mūrābiṭīn. The Saʿādī regard themselves as descended from Banū Hilāl and Banū Sulaymān, the great Arab tribes that immigrated into North Africa in the 11th century. The most important and numerous of the Saʿādī group are the Awlād ʿAlī. The Mūrābiṭīn clans occupy a client status in relation to the Saʿādī and may be descendants of the original Berber inhabitants of the region. Originally herders and tent dwellers, the Bedouin of the Western Desert have become either seminomadic or totally sedentary. They are not localized by clan, and members of a single group may be widely dispersed.

The original inhabitants of the oases of the Western Desert were of Berber stock. There has, however, been a considerable admixture of blood—Egyptian from the Nile Valley, Arab, Sudanese, Turkish, and, particularly in the case of al-Khārijah, black African—for this was the point of entry into Egypt of the caravan route from Darfur, the Darb al-Arbaʿīn.

In addition to the indigenous groups, there are in Egypt a number of small foreign ethnic groups. In the 19th century there was rapid growth of communities of unassimilated foreigners, mainly European, living in Egypt; these acquired a dominating influence over finance, industry, and government. In the 1920s, which was a peak period, the number of foreigners in Egypt was in excess of 200,000, the largest community being the Greeks, followed by the Italians, British, and French. Since Egypt's independence the size of the foreign communities has been greatly reduced.

Religions. Islām is the official religion of Egypt, and a large majority of the population embrace the Sunnī, or orthodox, branch of Islām. A strong sense of piety is a characteristic of the Egyptian Muslim. Prayer is observed punctiliously, particularly public prayer in the mosques, and fasting during the month of Ramaḍān (the ninth month of the Islāmic calendar) is strictly observed. Almsgiving and pilgrimage to Mecca are, if possible, also enjoined.

The Copts

The majority of the Christian population of Egypt are Copts. In language, dress, and way of life they are indistinguishable from Muslim Egyptians; their church ritual and traditions, however, date from before the Arab conquest in the 7th century. Ever since it broke with the Eastern Church in the 5th century, the Coptic Orthodox Church has maintained its autonomy, and its beliefs and ritual have remained basically unchanged. The Copts have traditionally been associated with certain handicrafts and trades and, above all, with accountancy, banking, commerce, and the civil service; there are, however, rural communities that are wholly Coptic, as well as mixed Coptic–Muslim villages. As a result of marrying almost exclusively within their community, many Copts preserve in their facial and body features the characteristics of the people of Pharaonic Egypt.

The Copts are most numerous in the middle Nile Valley *muḥāfaẓāt* of Asyūṭ, al-Minyā, and Qinā. About one-fourth of the total Coptic population lives in Cairo.

Among other religious groups are the Coptic Catholic, Greek Orthodox, Greek Catholic, Armenian Orthodox and Catholic, Maronite, Syrian Catholic, Anglican, and Protestant. There is also a small Jewish community.

Demographic trends. Most of Egypt's people live along the banks of the Nile River, where the population density, estimated to be more than 2,700 persons per square mile (1,100 persons per square kilometre), is one of the highest in the world. The rapidly growing population is young, with two-fifths of the total under 15 years of age. Despite improvements in health care, infant mortality is very high and about half of all deaths occur among children less than five years of age. Life expectancy, however, increased from only about 33 years in 1927 to almost 60 years by the mid-1980s. Almost half of the population lives in urban areas. (L.S.El H./Ma.J./D.H./C.G.S.)

THE ECONOMY

The economy of Egypt, according to the constitution of 1971, is one based on socialism, with the people controlling all means of production. The progress of socialism after 1952 was initially hesitant, despite land-reform measures, but it gathered momentum after 1961, when major nationalization steps were taken in an attempt to curb the private sector and destroy the political power of Egyptian capitalists. Until the early 1970s almost all important sectors of the economy either were public or were strictly controlled by the government. This included large-scale industry, communications, banking and finance, the cotton trade, foreign trade as a whole, and many other sectors. Private enterprise came gradually to find its scope restricted, but some room for maneuver was still left in real estate and in agriculture and, later, in the export trade. Personal income, as well as land ownership, was strictly limited by the government. Some of these restrictions have been relaxed, permitting greater private sector participation in various economic areas.

The public sector and the role of government. As the role of the private sector lessened in the 1950s and '60s, that of the government continuously expanded. The government, when not actually in possession, regulates all important aspects of production and distribution. It im-

poses controls on agricultural prices, controls rent, runs the internal trade, regulates foreign travel and the use of foreign exchange, and appoints and supervises the boards of directors of corporations. The government initiates projects and allocates investment. Although the everyday running of corporations is left to the boards of directors, these receive instructions from public boards, and the chairmen of boards receive their instructions from the appropriate minister. The government formulates five-year development plans to guide economic development.

Direct taxation

Taxation. With the majority of the population earning very low incomes, direct taxation falls on the few rich; income-tax rates are made sharply progressive in an attempt to achieve a degree of equality in income distribution. Direct taxes on income, mostly levied on businesses, account for about two-thirds of governmental revenue.

Trade unions and employer associations. Trade unions are closely controlled by the government. Workers obtain a share of the profits earned by corporations and elect their representatives to boards of directors; they are also heavily represented in the National Assembly. In all these activities, however, official selection works side by side with free elections. Trade unions are often vocally active in national policies but are seldom the instrument for negotiating higher wages or better work conditions. There are a few employers' associations, but they have little industrial power.

Contemporary economic policies. In the early 1970s the Egyptian government campaigned for increased foreign investment and began receiving financial aid from the oil-rich Arab states. Although Arab aid was suspended after the signing of the 1979 peace treaty with Israel, the subsequent return of several Western and Japanese corporations, associated with the normalization of Egyptian relations with Israel, increased the potential for further foreign investment in the country. Much of the effort exerted by the government in the early 1980s was devoted to adjusting the economy to the situation resulting from the 1979 Egyptian-Israeli peace treaty. With decreased expenditure on defense, increased allocations were made available for development. Egypt's economy began to be more resilient, primarily because of discoveries of oil and increased Western aid.

Increases in population have put pressure on resources, however, and underemployment has become endemic.

Living standards

Wages and cost of living. The general standard of living in Egypt is rather low; in relation to the size of its population, its economic resources are limited. Land remains its main source of natural wealth, but the amount of land is insufficient to support the population adequately. The realization of the need to curb the rate of population increase led, in 1964, to a national family planning program, which has had only limited success.

The rural population, especially the landless agricultural labourers, has the lowest standard of living in the country. Industrial and urban workers enjoy, on the whole, a higher standard. The highest wages are earned in such industries as the petroleum and manufacturing industries; many workers in industry receive additional benefits by way of social insurance and extra health and housing facilities. The salaries of professional groups are also low. Low wage levels have to some extent been offset by the low cost of living, but by the late 1970s this advantage was eliminated by high inflation rates.

Resources. About 96 percent of Egypt's total area is desert. Lack of forests, permanent meadows, or pastures places a heavy burden on the available arable land, which constitutes only about 3 percent of the total area. This limited area, which sustains on the average almost seven persons per acre, is, however, highly fertile and is cropped more than once a year. Although a large percentage of the population derives its livelihood from agriculture, a growing proportion of the labour force is engaged in manufacturing, and the contribution of the manufacturing and mining sectors to the domestic product has grown to twice that of agriculture—with service activities contributing most of the remainder. Because of the shortage of land, underemployment of labour began to be manifest in agriculture early in the 20th century, and the development of nonagricultural production since then has failed to provide full employment to the increasing labour force.

Mineral resources. Compared with the physical size of the country and the level of its population, the mineral resources of Egypt are scanty. The search for petroleum began earlier in Egypt than elsewhere in the Middle East, and production on a small scale began as early as 1908, but it was not until the mid-1970s that significant results were achieved. By the early 1980s Egypt had become an important oil producer, although total production was relatively small by Middle Eastern standards. Several of Egypt's major known phosphate deposits are mined at Isnā, Ḥamrāwayn, and Safājah. Coal deposits are located in the partially developed Maghara mines in the Sinai Peninsula. Manganese deposits located in the Eastern Desert have been the primary source for manganese production since 1967, and there are also reserves of manganese on the Sinai Peninsula. Egypt mines iron ore from deposits at Aswān, and development work has continued at al-Wāḥāt al-Baḥrīyah Oasis. Chromium, uranium, and gold deposits are also found in the country.

Biological resources. Egypt's biological resources, centred around the Nile, have long been one of its principal assets. There are no forests or any permanent vegetation of economic significance, apart from the land under cultivation. Water buffalo, cattle, asses, goats, sheep, and camels are the most important livestock. Animal husbandry and poultry production have continued to increase.

Hydroelectric and other power resources. The Nile constitutes an incomparable source of energy; further sources are represented by coal, oil, and gas deposits. Almost half of Egypt's electrical energy comes from thermal stations; hydroelectric plants, including those at the Aswān High Dam, supply the remainder.

Agriculture and fishing. Agriculture is an important sector of the Egyptian economy. It contributes substantially to the gross national product, employs a large part of the labour force, and provides the country—through agricultural exports—with an important part of its foreign exchange. Increased pressure of population has led to an intensification of cultivation almost without parallel elsewhere. Heavy capital is invested in the form of canals, drains, dams, water pumps, and barrages; the investment of skilled labour, commercial fertilizers, and pesticides is also great. Thus, despite multiple cropping, the yields of the land are exceptionally high. Strict crop rotation—in addition to government controls on the allocation of area to crops, on varieties planted, on the distribution of fertilizers and pesticides, and on marketing—contributes to the high productivity of agriculture.

Investments in agriculture

Unlike the situation in comparable developing countries, Egyptian agriculture has an overwhelmingly commercial rather than subsistence basis. Field crops contribute some three-fourths of the total value of Egypt's agricultural production, while the rest comes from livestock products, fruits and vegetables, and other specialty crops. Egypt has two seasons of cultivation, one for winter and another for summer crops. The main summer field crop is cotton, which occupies more than one-fifth of the season's arable land, absorbs much of the available labour, and represents a sizable portion of the value of exports. Egypt is the world's principal producer of long-staple cotton ($1\frac{1}{8}$ inches [2.85 centimetres] and longer), normally producing about one-third of the world crop, although total Egyptian production is only about 3 percent of all cotton produced in the world.

Among other principal field crops are corn (maize), rice, wheat, millet, and broad beans. Despite a considerable output, the cereal production in Egypt falls short of the country's total consumption; a substantial proportion of foreign exchange is spent annually on the import of cereals and milling products. Other important crops include sugarcane, alfalfa (lucerne), potatoes, and onions—the latter being normally an export item. Many varieties of fruit are grown, and some, such as citrus, are also exported.

Reclaimed land

In 1960–61 and 1968–69 about 896,100 acres were reclaimed. The total land reclaimed as a result of the Aswān High Dam project reached more than 1,000,000 acres by 1975, in addition to 700,000 acres converted from basin

(one crop a year) irrigation to perennial irrigation. During the same period, however, an area almost as large was lost to agriculture as industry and towns grew.

Egypt has been the scene of one of the most successful attempts at land reform. In 1952 a limit of 200 acres was imposed on individual ownership of land, and this was lowered to 100 acres in 1961 and to 50 acres in 1969. By 1975 less than one-eighth of the total cultivated area was held by owners with 50 acres or more. The success of Egyptian land reform is indicated by the substantial rise of land yields after 1952. This was partly the result of several complementary measures of agrarian reform, such as regulation of land tenure and rent control, that accompanied the redistribution of the land.

Following the construction of the Aswān High Dam, the Egyptian government encouraged the development of a thriving fishing industry. Construction of such projects as a fish farm and fishery complex at Lake Nasser have led to a considerable increase in the number of freshwater fish and in the size of the yearly total catch. At the same time, catches of sea fish in the waters off the Nile Delta have declined. This is thought to be a consequence of the change in the flow and character of Nile water after the construction of the Aswān High Dam.

Industry. The development of the manufacturing industry was handicapped by the policy of free trade imposed on Egypt from the middle of the 19th century until about 1930. Nationalism and World War II gave great impetus to the foundation of industrial projects that are largely agriculturally based and oriented toward import substitution. During the 1950s the country's manufacturing sector began to grow, and manufacturing and mining now account for a substantial portion of the gross domestic product.

Emphasis was placed on the development of heavy industry after a long-term agreement was signed with the Soviet Union in 1964. Another agreement with the Soviet Union, signed in 1970, provided aid for the expansion of the iron and steel complex at Ḥulwān; the establishment of a number of power-based industries, including an aluminum complex to utilize the power generated by the High Dam; and the electrification of the countryside. An ammonium nitrate fertilizer plant was opened in 1971, based on the gases generated in the coking unit of the steel mill at Ḥulwān. There is also a nitrate fertilizer plant at Aswān.

Egypt has made great achievements in increasing industrial production in such traditional industries as spinning and weaving, as well as in modern industries like engineering and iron and steel production. Food processing and the manufacture of chemical products also are important to the Egyptian economy.

Energy

Before the completion of the Aswān High Dam power station in 1970, the bulk of Egypt's electricity was generated in thermal stations using coal or diesel fuel, but some hydroelectric power was also generated by the old Aswān Dam. The 12 turbines of the High Dam power station have a capacity of about 2,000,000 kilowatts and are capable of producing 10,000,000,000 kilowatt-hours a year; the capacity of the thermal stations is about 45 percent of that of the High Dam. Transmission lines carry the current from Aswān to Cairo and to points farther north for use in urban centres and in manufacturing. The production of electric power from the High Dam has been limited, however, by the need to reconcile demands for power with the demands for irrigation water.

The bulk of Egypt's petroleum comes from the rich Morgan, Ramadan, and July fields (both onshore and offshore) in the Gulf of Suez, which are operated by the Gulf of Suez Petroleum Company, and from the Abū Rudays area of the Sinai on the Gulf of Suez. In cooperation with Phillips Petroleum Company, Egypt also extracts oil from fields at al-'Alamayn and Razzāq in the Western Desert. Active drilling for oil, involving several international interests, including those of the United States and several European nations, has continued in both the Eastern and the Western deserts.

Natural gas

In the process of searching for oil some significant natural gas deposits have been located. Phillips has located wells in the Abū Qīr area, northeast of Alexandria. A joint Egyptian-Italian gas discovery was made in the north Delta near Abū Māḍī in 1970; this was developed partly to supply a fertilizer plant and partly to fuel the industrial centres in the north and northwest Delta. In 1974 Abū Mādī became the first Egyptian gas field to begin production. Other natural gas fields are located in the Western Desert and the Gulf of Suez.

Egypt has several oil refineries, two of which are located at Suez. The first of Egypt's twin crude pipelines, linking the Gulf of Suez to the Mediterranean near Alexandria, was opened in 1977. This Suez–Mediterranean pipeline, known as Sumed, has an annual capacity for transmitting 80,000,000 tons of oil. The Sumed pipeline was financed by a consortium of Arab countries, primarily Saudi Arabia, Kuwait, and Egypt. In 1981 a crude oil pipeline was opened to link Ras Shuqir, on the Red Sea coast, with the refinery at Musturud, north of Cairo. An additional oil pipeline links Musturud with Alexandria.

Finance. The banking system of Egypt is centred on the Central Bank of Egypt, created in 1960 from the issue department of the National Bank of Egypt. In 1961 all banks operating in Egypt were nationalized, and their operations were concentrated in five commercial banks, in addition to the Central Bank, the government-sponsored Public Organization for Agricultural Credits and Co-operatives, the Development Industrial Bank, and three mortgage banks.

The government again reorganized the banking system in the early 1970s, merging some of the major banks and assigning special functions to each of the rest. Two new banks were created, and foreign banks were again permitted in the country as part of a program aimed at liberalizing the economy. Of particular interest were joint banking ventures between Egyptian and foreign banks. The stock exchanges at Cairo and Alexandria, which had been closed since the early 1960s, were reopened. The cotton exchanges in Cairo and Alexandria, which had also been closed, were replaced by a supervisory council responsible for regulating the cotton industry. In 1980 Egypt's first international bank was opened and a national investment bank was established.

The supply of money has, in general, followed the development of the economy; the authorities have aimed at tolerable increases in the price level, although since the 1973 war some prices have soared and inflation rates have risen sharply.

Egypt is a member of the International Monetary Fund. Since World War II the international liquidity of the Egyptian economy, including the Special Drawing Rights, added in 1970, has been depressed. In the late 1970s internal and external debts rose, mainly due to large government subsidies to the private sector. In the 1980s the government gradually introduced price increases on goods and services, with the goal of eventually reducing subsidies.

Imports and exports

Trade. Imports into Egypt average about one-third and exports about one-tenth of the gross domestic product. Since World War II exports have tended to fall short of imports. The trade deficit reached a peak in 1966 and was particularly sizable from 1960 to 1965 as expenditure on development rose. After the 1973 war there was a decided effort to restrict imports and stimulate exports, but this met with little success. The trade deficit continued to rise to record highs in the early and mid-1980s, largely because of the decline in revenue from petroleum exports and the increase in food imports.

Almost two-thirds of imports consist of raw materials, mineral and chemical products, and capital goods (machinery, electrical apparatus, and transport equipment), more than one-fourth are foodstuffs, and the remainder are other consumer goods. More than one-half of the exports by value consist of petroleum and petroleum products, followed by raw cotton, cotton yarn, and fabrics. Raw materials, mineral and chemical products, and capital goods are also exported. Among agricultural exports are rice, onions, garlic, and citrus fruit.

Italy, France, and the Soviet Union are among Egypt's largest markets. The United States, however, is the major source of Egypt's imports, followed by West Germany, Italy, and France.

The economic boycott by other Arab states, which resulted from the 1979 peace treaty between Israel and Egypt, did not have a serious effect on Egypt's economy. In the early and mid-1980s Egypt's revenue fluctuated, however, in response to changes in oil sales and tourist revenue, and the country continued to have deficits in its foreign-trade balance. The deficit has been financed by international borrowing (primarily from the International Monetary Fund), transfers from Arab oil-producing countries, revenue from expatriate remittances, Suez Canal revenue, and changes in foreign assets and liabilities.

(E.I.U./D.H./C.G.S.)

Transportation. Almost the entire communication system is state owned. It is adequate in terms of coverage, but stresses arise from excessive usage. The main patterns of transport flow reflect the topographical configuration of the country—that is to say, they follow the north–south course of the Nile, run along the narrow coastal plain of the Mediterranean Sea, and expand into a more complex system in the Delta.

Road network. About half of Egypt's total road network is paved. Rural roads are of dried mud, usually following the lines of the irrigation canals; many of the desert roads are little more than tracks. The Cairo–Alexandria highway runs via Banhā, Ṭanṭā, and Damanhūr. The alternate desert road to Cairo from Alexandria has been extensively improved, and a good road links Alexandria with Libya by way of Maṭrūḥ on the Mediterranean coast. There are paved roads between Cairo and al-Fayyūm, and good roads connect the various Delta and Suez Canal towns. A paved road parallels the Nile from Cairo south to Aswān, and another paved road runs from Asyūṭ to al-Khārijah and ad-Dākhilah in the Western Desert. The coastal Red Sea route to Marsā al-'Alām is poorly paved, as are the connecting sections inland.

Railways. Railways connect Cairo with Alexandria and with the Delta and canal towns and also run southward to Aswān and the High Dam. Branch lines connect Cairo with al-Fayyūm and Alexandria with Maṭrūḥ. A network of light railways connects the Fayyūm area and the Delta villages with the main lines. Diesel-driven trains operate along the main lines; electric lines connect Cairo with the suburbs of Ḥulwān and Heliopolis.

Navigable waterways. The Suez Canal, closed in 1967, was reopened in 1975; it serves as a major link between the Mediterranean and Red seas. The Nile and its associated navigable canals provide an important means of transportation, primarily for heavy goods. There are approximately 2,000 miles of navigable waterways—about one-half of this total on the Nile itself, which is navigable throughout its length. The inland-waterway freight fleet consists of tugs, motorized barges, towed barges, and flat-bottomed feluccas (two- or three-masted lateen-rigged sailing ships).

Rivers and canals

Ports and shipping. In spite of its long coastline, Egypt has only three ports of any significance—Alexandria, Port Said, and Suez. Alexandria, with a fine natural harbour, handles most of the country's imports and exports, as well as the bulk of passenger traffic. Port Said, at the northern entrance to the Suez Canal, lacks the berthing and loading facilities of Alexandria. Suez's main function is that of an entry port for petroleum and minerals from the Egyptian Red Sea coast and for goods from the Far East.

Air transport. Cairo is an important communication centre for world air routes. The enlarged airport at Heliopolis, with its modern terminal building, is used by major international airlines, as is Nuzhah airport at Alexandria.

The national airline, Egypt Air, runs external services throughout the Middle East, as well as to Europe, North America, Africa, and the Far East; it also operates a domestic air service.

GOVERNMENT AND SOCIAL CONDITIONS

Government. Before the 1952 revolution, Egypt was a constitutional monarchy; the 1923 constitution, which followed the declaration of the end of the British protectorate, stated that Egypt was an independent sovereign Islāmic state with Arabic as its language and provided for a representative parliament. This constitution was abolished in 1952, political parties were dissolved in 1953, and a new constitution was introduced in 1956. The Republic of Egypt was declared. Between 1958 and 1961 Egypt and Syria were merged into one state, called the United Arab Republic; the name was retained by Egypt upon Syria's secession in 1961. The National Union, organized in 1957 in place of the political parties abolished in 1953, became the Arab Socialist Union (ASU) in 1962.

In 1971 Egypt, Libya, and Syria agreed to the establishment of the Confederation of Arab Republics. A draft constitution was agreed to by the heads of state of each country and was approved by referenda in each of the three member states. The capital of the confederation was Cairo. In 1979, however, deteriorating relations between Egypt and other Arab nations led to the end of the confederation; following the signing of the Egyptian-Israeli peace treaty, most Arab economic ties with Egypt also were suspended.

On Sept. 11, 1971, a new constitution for Egypt was approved by referendum. It proclaimed the Arab Republic of Egypt to be "a democratic, socialist state" with Islām as its state religion and Arabic as its national language. It recognized three types of ownership—public, cooperative, and private. It guaranteed the equality of all Egyptians before the law and their protection against arbitrary intervention in the processes of law. It also affirmed the rights to peaceful assembly, education, and health and social security, and the right to organize into associations or unions and to vote.

According to the constitution and its subsequent amendments, the president of the republic is the head of state, and, together with the Cabinet, constitutes the executive authority. The president must be Egyptian, born of Egyptian parents, and not less than 40 years old. The presidential term is six years and may be extended to additional terms. The president has the power to appoint and dismiss one or more vice presidents, the prime minister, ministers, and deputy ministers. The legislative body is composed of the People's Assembly, which nominates the presidential candidate by a two-thirds majority. The candidate is then confirmed by national plebiscite.

The president is the supreme commander of the armed forces and has the right to grant amnesty and reduce sentence, the power to appoint civil and military officials and to dismiss them in a manner prescribed by the law, and the authority to call a referendum of the people on matters of supreme importance. The president can, in exceptional cases and by investiture of the assembly, issue decrees having the force of law—but only for a defined period of time.

Legislative power resides in the People's Assembly, which is composed of 448 elected members, some of whom must be women, and 10 additional members appointed by the president. The assembly is elected, under a complex system of proportional representation, for a five-year term. All males 18 years of age and older are required to vote, as well as all women on the register of voters. The president convenes and closes the sessions of the People's Assembly.

The People's Assembly

The People's Assembly's main function is to approve policy. Its members must ratify all laws and examine and approve the national budget. It also approves the program of each newly appointed Cabinet. Should it withdraw its confidence from the Cabinet or any of its members, that person is required to resign. The president cannot dissolve the assembly except under special circumstances and after a vote of approval by a people's referendum. Elections for a new assembly must be held within 60 days of dissolution.

The constitution also provides for a judiciary, independent of other authorities, whose functions and authority are governed by special legislation. A Council of National Defence, presided over by the president of the republic, is responsible for matters relating to security and defense.

Local government and administration. Until 1960, government administration was highly centralized; in that year, however, the local-government administrative system was established to promote decentralization and greater citizen participation in local government.

The 1960 Local Administration Law provides for three levels of local administration—the *muḥāfaẓāt* (gover-

Governorates, districts, and villages

norates), the *markaz* (districts or counties), and the *qarīyah* (villages). The structure combines features of both local administration and local self-government. There are two councils at each administrative level: a mostly elected people's council and an appointed executive council. Although these councils exercise broad legislative powers, they are controlled by the central government.

The country is divided into 26 *muḥāfaẓāt*. Five cities—Cairo, Alexandria, Ismailia, Port Said, and Suez—have *muḥāfaẓah* status. The governor is appointed and can be dismissed by the president of the republic. He is the highest executive authority in the *muḥāfaẓah,* has administrative authority over all government personnel except judges in his *muḥāfaẓah,* and is responsible for implementing policy.

The *muḥāfaẓah* council is composed of a majority of elected members. Although it has not been possible in practice, according to law at least one-half of the members of the *muḥāfaẓah* council are to be farmers and workers. The town or district councils and the village councils are established on the same principles as those underlying the *muḥāfaẓah* councils.

The local councils perform a wide variety of functions in education, health, public utilities, housing, agriculture, and communications; they are also responsible for promoting the cooperative movement and for implementing parts of the national plan. Local councils obtain their funds from national revenue, a tax on buildings and lands within the *muḥāfaẓah,* miscellaneous local taxes or fees, profits from public utilities and commercial enterprises, and national subsidies, grants, and loans.

The political process. After 1962 all popular participation and representation in the political process was through the Arab Socialist Union. In 1976, however, the ASU lost its status as the sole legal political organization, and other political parties soon formed; their right to exist was recognized by a law adopted in June 1977. The ASU was abolished by constitutional amendment in 1980.

The Arab Socialist Union

The National Democratic Party (NDP), formed by Pres. Anwar el-Sādāt in 1978, serves as the official government party and holds a majority of seats in the People's Assembly. The left-wing opposition is the National Progressive Unionist Party and the Socialist Labour Party. The prerevolutionary Wafd Party has been re-formed, and one religious party, the Umma, has been licensed. Officially unrepresented are the Communists, extreme religious groups, and avowed Nasserists.

Justice. The Egyptian constitution emphasizes the independent nature of the judiciary. There is to be no external interference with the due processes of justice. Judges are subject to no authority other than the law; they cannot be dismissed and are disciplined in the manner prescribed by law. Judges are appointed by the state, with the prior approval of the Supreme Judicial Council under the chairmanship of the president. The council is also responsible for the affairs of all judicial bodies; its composition and special functions are specified by law.

The courts

The court structure can be regarded as falling into four categories, each of which has a civil and criminal division. These courts of general jurisdiction include district tribunals, tribunals of the first instance, courts of appeal, and the Court of Cassation. Court sessions are public, except where consideration of matters of public order or decency decides otherwise. Sentence is passed in open session.

In addition, there are special courts, such as military courts and courts of public security—the latter dealing with crimes against the well-being or security of the state. The Council of State is a separate judicial body, dealing especially with administrative disputes and disciplinary actions. The Supreme Constitutional Court in Cairo is the highest court in Egypt. Its functions include judicial review of the constitutionality of laws and regulations and the resolution of judicial conflicts among the courts.

Law enforcement. The Ministry of the Interior has direct control and supervision over all police and security functions at the *muḥāfaẓah,* district, and village levels. At the central level, the deputy minister for public security is responsible for general security, emigration, passports, port security, criminal investigation, ministerial guards, and emergency services. The deputy minister for special police is responsible for civil defense, traffic, prison administration, tourist police, and police transport and communications.

Education. At the end of the 19th century there were only three secondary and nine "higher" schools in Egypt; the educational structure continued to be based on the *kuttābs*, or Qur'ān schools. In 1916 the latter were turned into elementary schools, and in 1923 a law was passed providing free compulsory education between the ages of seven and 12. A sharp increase in the annual budgetary allocation devoted to education occurred after World War II. Following the revolution of 1952, educational progress already achieved was accelerated and was accompanied by both the Egyptianization and Arabicization of the educational system. One of the most significant features of this progress has been the spread of women's education. By the late 1970s almost one-third of the students attending university were women. Women are no longer confined to the home; many fields of employment, including the professions and even politics, are now open to them. A further result of the expansion of education has been the emergence of an intellectual elite and the growth of a middle class, consisting of members of the professions, government officials, and businessmen. In spite of the rapid advance in the provision of education services, however, illiteracy has remained relatively high.

There are three stages of state general education—primary (six years), preparatory (three years), and secondary (three years). Primary education between the ages of six and 12 is compulsory. Pupils who are successful in examinations have the opportunity to continue their education first at the preparatory and then at the secondary level. There are two types of secondary school, general and technical; most technical schools are either commercial, agricultural, or industrial.

Alongside the Ministry of Education's system of general education, there is that provided by the institutes associated with al-Azhar University, centred on al-Azhar Mosque in the medieval quarter of Cairo. Al-Azhar has been a teaching centre for the entire Muslim world for nearly a millennium. Instruction is given at levels equivalent to those of the state schools, but in order to allow for greater emphasis on traditional Islāmic subjects, the duration of training is lengthened by one year at the preparatory stage and two at the secondary. A large-scale modernization of the college-level curriculum, making it comparable to those of other state universities, has been carried out since 1961.

In the 1950s there were almost 300 foreign schools in Egypt, the majority of them French; many of these have since become, to varying degrees, Egyptianized. Pupils who attend these schools, at all levels, sit for the same state certificate examinations as those in the normal state system.

The universities

The major state universities are Cairo, Alexandria, 'Ayn Shams, and Asyūṭ. In addition to the state university system, there is one private university, the American University in Cairo.

There are many institutes of higher learning, excluding institutes attached to universities or affiliated to the Ministry of Culture—such as the Institute of Dramatic Arts, the Cinema Institute, and the Institute of Ballet. These institutes specialize in commerce, industry, agriculture, the arts, physical culture, social service, domestic economy, and languages. Courses of study lead to a degree.

Health and welfare. The budget of the Ministry of Health has reflected a steadily increasing expenditure on public-health programs, and the numbers of government health centres, beds in public hospitals, doctors, and dentists have increased dramatically.

An important aspect of this development has been the expansion of health facilities in the rural areas of the country. In 1953 the government introduced what are termed combined service units; these differ from health centres in that they combine the functions of health centre, school, social-welfare unit, and agricultural extension services. In addition, rural health units further extend the health services available in rural communities. Each unit

is operated by a team of seven or eight people, including one physician.

Well-trained physicians and specialists are available in large numbers in the cities and larger towns. The medical profession has prestige, and only the better qualified high school graduates are accepted into medical schools.

Public health campaigns

Significant efforts have been made to promote preventive medicine. Compulsory vaccination against smallpox, diphtheria, tuberculosis, and poliomyelitis is enforced for all infants during their first two years. Schistosomiasis, a parasitic disease that is widespread among the rural population, presents a serious health problem. All health centres offer treatment against it, but reinfection can easily occur. Epidemics of malaria have been eliminated, but the disease still exists in endemic form, mainly in southern Egypt. Treatment for malaria is provided at all health centres, and the spraying of houses in mosquito-breeding areas is carried out regularly. Attention has also been given to the problem of tuberculosis; centres have been established in every *muḥāfaẓah,* and mass X-ray and immunization campaigns have been carried out.

The government has attempted to socialize medicine through such measures as the nationalization and control of pharmaceutical industries, the nationalization of hospitals run by private organizations and associations, and expanded health insurance. A health insurance law was passed in 1964; it provides for compulsory health insurance for workers in firms employing more than 100 persons, as well as for all governmental and public employees.

Housing. Egypt has faced a serious urban housing shortage since World War II. The situation subsequently became aggravated by increased immigration from rural to urban areas, resulting in extreme urban overcrowding.

Housing construction

Although there is considerable concern over the housing problem, the combined efforts of both public and private sectors have been unable to meet the growing demand. Between 1970 and 1980, for example, approximately 300,000 housing units were built; this represented an increase of more than one-fourth of the total number of housing units. The increase in the urban population, however, was estimated at more than 40 percent during the same period; *i.e.,* for every new housing unit built, 13 persons were added to the urban population.

In the rural areas villagers build their own houses at little cost with the materials available. The government has experimented in aiding self-help projects with state loans. Ambitious rural housing projects have been carried out on newly reclaimed land: entire villages with all the necessary utilities have been built.

CULTURAL LIFE

In spite of the many ancient civilizations with which it has come into contact, Egypt unquestionably belongs to a sociocultural tradition that is Arabic and Islāmic. This tradition remains a constant factor in determining Egyptian views both of itself and of the world.

The story of the cultural development of modern Egypt is, in essence, that of the response of this traditional system to the intrusion into it, at first by conquest and later by the penetration of ideas, of the alien and materially superior civilization of the West. The response covered a broad spectrum—from the rejection of new ideas and reversion to traditionalism through self-examination and reform to an uncritical acceptance of new concepts and the values that went with them. The result has been the emergence of a cultural identity devoid of self-consciousness, which has assimilated much that is new, while remaining distinctively Egyptian. The process is to be seen at work in all branches of contemporary culture.

The state of the arts. The impact of the West is one of the recurring themes in the modern Egyptian novel, as in Tawfīq al-Ḥakīm's *'Usfūr min ash-Sharq* ("The Bird from the East") and Yaḥyā Ḥaqqī's novella *Qindīl Umm Hāshim* ("The Lamp of Umm Hāshim"). A further theme is that of the Egyptian countryside—romantically handled at first, as in Muḥammad Ḥusayn Haykal's *Zaynab,* and later realistically, as in 'Abd al-Raḥmān ash-Sharqāwī's *al-Arḍ* (*The Land*) and *al-Fallāḥ* ("The Peasant") and in Yūsuf Idrīs' *al-Ḥarām* ("The Forbidden"). A Dickensian capacity to catch the colour of life among the urban poor is a characteristic quality of the early and middle work of Egypt's greatest modern novelist, Najīb Maḥfūẓ, notably in *Zuqāq al-Midaqq* (*Midaq Alley*).

The modern theatre in Egypt is a European importation—the first Arabic-speaking plays were performed in 1870. Two dramatists, both born at the turn of the century, have dominated its development—Maḥmūd Taymūr and Tawfīq al-Ḥakīm. The latter, a versatile and cerebral playwright, has reflected in his themes not only the development of the modern theatre but also, in embryo, the cultural and social history of modern Egypt. The changes in Egyptian society are reflected in the themes adopted by younger dramatists.

Film-making in Egypt

There is a relatively long tradition of filmmaking in Egypt going back to World War I, but it was the founding of Miṣr Studios in 1934 that stimulated the growth of the Arabic-speaking cinema. Modern Egyptian films are shown to audiences throughout the Arab world and are also distributed in Asian and African countries. The industry is both privately and state owned—there are many private film-production companies, as well as the Ministry of Culture's Egyptian General Cinema Corporation.

Contemporary Egyptian music embraces indigenous folk music, traditional Arabic music, and Western-style music. The revival of traditional Arabic music, both vocal and instrumental, owes much to state sponsorship. Popular Arabic music consists of a blend of classical Arabic music, folk songs, and Western music. Muḥammad 'Abd al-Wahhāb has been one of the leading figures in the development of this genre, as both composer and singer. Umm Kulthūm was the leading vocalist not only of Egypt but also of the whole Arab world for almost 50 years. Western-style music has been a familiar component in Egyptian musical culture since the 19th century. Pioneers such as Yūsuf Greiss and Abū Bakr Khayrat succeeded in incorporating Arabic elements to give a national colouring to their Western-style compositions.

A return to folklore as a source of inspiration for the arts is a generalized phenomenon in modern Egyptian culture. It has resulted in a revived interest in traditional crafts, in the collection of folk music, and the maintaining, with government sponsorship, of two folk-dance ensembles—the Riḍā Troupe and the National Folk Dance Ensemble. In the plastic arts the highly original use of local themes is particularly striking. An active school of Egyptian painting and sculpture has emerged.

Cultural institutions. The oldest learned academy in Egypt, the Institut d'Égypte, was founded in 1859, but its antecedents go back to the institute established by Napoleon in 1798. The Academy of the Arabic Language, founded in 1932 and presided over by the veteran educator Ṭaha Ḥusayn, became, in terms of prestige and influence, one of the most important cultural institutions in Egypt. Linked to the Ministry of Culture, it enjoys a large measure of autonomy, guaranteed by its own charter. Also attached to the Ministry of Culture is the Higher Council for Arts, Letters, and the Social Sciences. Intended as a consultative body on cultural matters, the Higher Council is also a means of channeling state patronage.

The learned societies

Learned societies in Egypt support a wide variety of interests—including the physical and natural sciences, medicine, agriculture, the humanities, and the social sciences. Increased government concern with research, especially in science and technology, was reflected in the founding of the National Research Centre, where laboratory work in both pure and applied science began in 1956, and of the Atomic Energy Establishment, in 1957. In addition, there are many specialized research institutes in the country.

Most of the learned societies and research institutes have library collections of their own. In addition to large collections at the universities, the municipalities of Alexandria, al-Manṣūrah, and Ṭanṭā maintain libraries. There is also a central public library in each *muḥāfaẓah,* with branches in small towns and service points in the villages. The Ministry of Culture is responsible for the Egyptian National Library (Dār al-Kutub) and the National Archives, both in Cairo, and the Public Libraries Administration. The

Egyptian National Library, which has a large collection of printed materials, is also a centre for the collection and preservation of manuscripts.

The Ministry of Culture is also responsible, through its department of antiquities, for the Egyptian Museum, the Coptic Museum, and the Museum of Islāmic Art, all in Cairo; the Greco-Roman Museum in Alexandria; and for other institutions, including fine-arts museums such as the Mukhtār Museum, the Nājī Museum, and the Museum of Modern Art, all in Cairo, and the Museum of Fine Arts in Alexandria.

All newspapers and magazines in Egypt are subject to supervision through the government's Supreme Press Council. Daily newspapers include the long-established *al-Ahram,* published in Cairo, and other Arabic-language papers, together with daily English-language and French-language newspapers. The government owns and operates the Egyptian Radio and Television Corporation, which provides programs in a variety of languages. Cairo is considered to be the largest centre of publishing in the Middle East.

For statistical data on the land and people of Egypt, see the *Britannica World Data* section in the BRITANNICA WORLD DATA ANNUAL. (L.S.El H./Ma.J./D.H./C.G.S.)

History

INTRODUCTION TO ANCIENT EGYPTIAN CIVILIZATION

Life in ancient Egypt. Ancient Egypt can be thought of as an oasis in the desert of northeast Africa, dependent on the annual inundation of the Nile to support its agricultural population. The country's chief wealth came from the fertile floodplain of the Nile Valley, where the river flows between bands of limestone hills, and the Nile Delta, in which it fans into several branches north of modern Cairo. Between the floodplain and the hills is a variable band of low desert, which supported a certain amount of game. The Nile was Egypt's sole transportation artery.

The Nile floodplain

The First Cataract at Aswān, where the riverbed is turned into rapids by a belt of granite, was the country's only well-defined boundary within a populated area. To the south lay the far less hospitable area of Nubia, in which the river flowed through low sandstone hills that left a very narrow strip of cultivable land. Nubia was significant for Egypt's periodic southward expansion and for access to products from farther south. West of the Nile was the arid Sahara, broken by a chain of oases some 125–185 miles (about 200–300 kilometres) from the river and lacking in all other resources except for a few minerals. The eastern desert, between the Nile and the Red Sea, was more important, for it supported a small nomadic population and desert game, contained numerous mineral deposits including gold, and was the route to the Red Sea.

To the northeast was the Isthmus of Suez. It offered the principal route for contact with Sinai, from which came turquoise and possibly copper, and with western Asia, Egypt's most important area of cultural interaction, from which were received stimuli for technical development and cultivars for crops. Immigrants and ultimately invaders crossed the Isthmus into Egypt, attracted by the country's stability and prosperity. From the late 2nd millennium BC on, numerous attacks were made by land and sea along the eastern Mediterranean coast.

At first, relatively little cultural contact came by way of the Mediterranean Sea, but from an early date Egypt maintained trading relations with the Lebanese port of Byblos (modern Jubayl). Egypt needed few imports to maintain basic standards of living, but good timber was essential and not available within the country, so it usually was obtained from Lebanon. Minerals such as obsidian and lapis lazuli were imported from as far afield as Anatolia and Afghanistan.

Agriculture

Agriculture centred on the cultivation of cereal crops, chiefly emmer wheat (*triticum dicoccum*) and barley (*hordeum vulgare*). The fertility of the land and general predictability of the inundation ensured very high productivity from a single annual crop. This productivity made it possible to store large surpluses against crop failures and also formed the chief basis of Egyptian wealth, which was, until the creation of the large empires of the 1st millennium BC, the greatest of any state in the ancient Near East.

Irrigation was achieved by simple means and multiple cropping was not feasible until much later times, except perhaps in the lakeside area of Fayyūm. As the river deposited alluvial silt, raising the level of the floodplain, and land was reclaimed from marsh, the area available for cultivation in the Nile Valley and Delta increased, while pastoralism declined slowly. In addition to grain crops, fruit and vegetables were important, the latter being irrigated year-round in small plots; and fish was vital to the diet. Papyrus, which grew abundantly in marshes, was gathered wild and in later times was cultivated. It may have been used as a food crop; and it certainly was used to make rope, matting, and sandals. Above all it provided the characteristic Egyptian writing material, which, with cereals, was the country's chief export in Late Period Egyptian and then Greco-Roman times.

After the introduction of cultivated cereal crops, meat was eaten mainly by the wealthy. Domesticated animals lost much of their significance for nutrition, but they retained great cultural importance and practical value. Cattle may have been domesticated in northeastern Africa. The Egyptians kept many as draft animals and for their various products, showing some of the interest in breeds and individuals that is found to this day in the Sudan and eastern Africa. The donkey, which was the principal transport animal (the camel did not become common until Roman times), was probably domesticated in the region. The native Egyptian breed of sheep became extinct in the 2nd millennium BC and was replaced by an Asiatic breed. Wool was rarely used, so that sheep were primarily a source of meat. Goats were more numerous than sheep and were commonly depicted browsing on tree foliage. Pigs, although subject to some sort of taboo, were raised and eaten. Ducks and geese were kept for food, and many of the vast numbers of wild and migratory birds found in Egypt were hunted and trapped. Desert game, principally various species of antelope and ibex, were hunted by the elite; it was a royal privilege to hunt lions and wild cattle. Pets included dogs, which were also used for hunting; cats (domesticated in Egypt); and monkeys. In addition, the Egyptians had a great interest in, and knowledge of, most species of mammals, birds, reptiles, and fish in their environment.

Most Egyptians were probably descended from settlers who came to the Nile Valley in prehistoric times, with increase coming through natural fertility. In various periods there were immigrants from Nubia, Libya, and especially the Near East. They were historically significant and may have contributed to population increase, but their numbers are unknown. Most people lived in villages and towns in the Nile Valley and Delta. Dwellings were normally built of mud brick and have long since disappeared beneath the rising water table, thereby obliterating evidence for settlement patterns. In antiquity, as now, the most favoured location of settlements was on slightly raised ground near the riverbank, where transport and water were easily available and flooding was unlikely. Until the 1st millennium BC Egypt was not urbanized to the same extent as Mesopotamia. Instead, a few centres, notably Memphis and Thebes, attracted population and particularly the elite, while the rest of the people were relatively evenly spread over the land. The size of the population has been estimated as rising from between 1,000,000 and 1,500,000 in the 3rd millennium BC to perhaps twice as many in the late 2nd millennium and 1st millennium BC. (Much higher levels of population were reached in Greco-Roman times.)

Ownership of land

Nearly all of the people were engaged in agriculture and were probably tied to the land. All the land belonged in theory to the king, although in practice those living on it could not easily be removed and some categories of land could be bought and sold. Land was assigned to high officials to provide them with an income, and most categories of land paid substantial dues to the state, which had a strong interest in keeping it in agricultural use. Abandoned land was taken back into state ownership and reassigned for cultivation. The people who lived on and worked the

land were not free to leave and were obliged to work it, but they were not slaves; most paid a proportion of their produce to major officials. Free citizens who worked the land on their own behalf did emerge; terms used for them tended originally to refer to poor people, although they were probably not in fact poor. Slavery was never very common, being restricted to captives and foreigners or to people who were forced by poverty or debt to sell themselves into service. Slaves sometimes were even married by members of their owners' families, so that in the long term those belonging to households tended to be assimilated into free society. In the New Kingdom (from about 1539 to 1075 BC), large numbers of captive slaves were acquired by major state institutions or incorporated into the army. Punitive treatment of foreign slaves or of native fugitives from their obligations included forced labour, exile (in, for example, the oases of the western desert), or compulsory enlistment in dangerous mining expeditions. Even nonpunitive employment such as quarrying in the desert was hazardous. The official record of one expedition shows a mortality rate of more than 10 percent.

Just as the Egyptians optimized agricultural production with simple means, their crafts and techniques, many of which originally came from Asia, were raised to extraordinary levels of perfection. The Egyptians' most striking technical achievement, massive stone building, also exploited the potential of a centralized state to mobilize a huge labour force, which was made available by efficient agricultural practices. Some of the technical and organizational skills involved were remarkable. The construction of the great pyramids of the 4th dynasty (*c.* 2575–*c.* 2465 BC) has yet to be fully explained and would be a major challenge to this day. This expenditure of skill contrasts with sparse evidence for an essentially neolithic way of living for the rural population of the time, while the use of flint tools persisted even in urban environments at least until the late 2nd millennium BC. Metal was correspondingly scarce, much of it being used for prestige rather than everyday purposes.

Family, marriage, and the role of women

In urban and elite contexts the Egyptian ideal was the nuclear family, but on the land and outside the central ruling group there is evidence for extended families. Egyptians were monogamous, and the choice of partners in marriage, for which no formal ceremony or legal sanction is known, did not follow a set pattern. Consanguineous marriage was not practiced during the Dynastic Period, except for the occasional marriage of a brother and sister within the royal family, and the practice may have been open only to kings or heirs to the throne. Divorce was in theory easy, but it was very costly. Women had a legal status only marginally inferior to that of men. They could own and dispose of property in their own right, and they could initiate divorce and other legal proceedings. They hardly ever held administrative office but increasingly were involved in religious cults as priestesses or "chantresses." Elite married women held the title "Mistress of the House," the precise significance of which is unknown. Lower down the social scale they probably worked on the land as well as in the house.

The uneven distribution of wealth, labour, and technology was related to the only partly urban character of society, especially in the 3rd millennium BC. The country's resources were not fed into numerous provincial towns but instead were concentrated to great effect around the capital—itself a dispersed string of settlements rather than a city—and focused on the central figure in society, the king. In the 3rd and early 2nd millennia the elite ideal, expressed in the decoration of private tombs, was manorial and rural. Not until much later did Egyptians have pronouncedly urban values.

The king and ideology: administration, art, and writing. In official terms, Egyptian society consisted of a descending hierarchy of the gods, the king, the dead, and humanity (by which was understood chiefly the Egyptians). Of these groups, only the king was single, and hence he was individually more prominent than any of the others. A text that summarizes the king's role states that he "is on earth for ever and ever, judging mankind and propitiating the gods, and setting order [*ma'at,* a central concept] in place of disorder. He gives offerings to the gods and mortuary offerings to the spirits [the blessed dead]." The king was a god, but not in any simple or unqualified sense. His divinity accrued to him from his office and was reaffirmed through rituals, but it was vastly inferior to that of major gods; he was god rather than man by virtue of his potential, which was immeasurably greater than that of any human being. To humanity, he manifested the gods on earth, a conception that was elaborated in a complex web of metaphor and doctrine; less directly, he represented humanity to the gods. The text quoted above also gives great prominence to the dead, for whom the living performed a cult and who could intervene in human affairs; in many periods the chief visible expenditure and focus of display of nonroyal individuals, as of the king, was on provision for the tomb and the next world. Egyptian kings are commonly called pharaohs, following the usage of the Old Testament. The term pharaoh, however, is derived from the Egyptian *per 'aa* ("great estate") and goes back to the designation of the royal palace as an institution. This term for palace was used increasingly from about 1400 BC as a way of referring to the living king; in earlier times it was rare.

The king's relation to the gods

Rules of succession to the kingship are poorly understood. The common conception that the heir to the throne had to marry his predecessor's oldest daughter has been disproved; kingship did not pass through the female line. The choice of queen seems to have been free: often the queen was a close relative of the king, but she also might be unrelated to him. In the New Kingdom, for which evidence is abundant, each king had a queen with distinctive titles, as well as a number of minor wives.

Sons of the queen seem to have been the preferred successors to the throne, but other sons could also become king. In many cases the successor was the eldest (surviving) son, and such a pattern of inheritance agrees with more general Egyptian values, but often he was some other relative, or was completely unrelated. New Kingdom texts depict, after the event, how kings were appointed heirs either by their predecessors or by divine oracles, and such may have been the pattern when there was no clear successor. From the middle of the 5th dynasty (*c.* 2450 BC) to the 19th (1292–1190 BC) there is no certain attestation of a prince in the reign of his brother; rival claimants, therefore, must have been eliminated or silenced after one of them had succeeded. Dissent and conflict are suppressed from public sources. From the Late Period (664–332 BC), when sources are more diverse and patterns less rigid, numerous usurpations and interruptions to the succession are known; they probably had many forerunners.

The king's position changed gradually from that of an absolute monarch at the centre of a small ruling group who were mostly his kin to that of the head of a bureaucratic state—in which his rule was still absolute—based on officeholding and, in theory, on free competition and merit. By the 5th dynasty, fixed institutions were added to the force of tradition and the regulation of personal contact as brakes on autocracy, but the charismatic and superhuman power of the king remained vital.

The bureaucratic elite

The elite of administrative officeholders received their positions and commissions from the king, whose general role as judge over humanity they put into effect. They commemorated their own justice and concern for others, especially their inferiors, and recorded their own exploits and ideal conduct of life in inscriptions for others to see. Thus the position of the elite was affirmed by reference to the king, to their prestige among their peers, and to their conduct toward their subordinates, justifying to some extent the fact that they—and still more the king—appropriated much of the country's surplus production for their own benefit.

These attitudes and their potential dissemination through society counterbalanced inequality, but how far they were accepted cannot be known. The core group of wealthy officeholders numbered at most a few hundred, and the administrative class of minor officials and scribes, most of whom could not afford to leave memorials or inscriptions, perhaps 5,000. With their dependents, these two groups formed perhaps 5 percent of the early population. Monu-

ments and inscriptions commemorated no more than one in a thousand people.

According to royal ideology, the king appointed the elite on the basis of merit, and in ancient conditions of high mortality the elite had to be open to recruits from outside. In addition, royal caprice resulted in many falls from favour, especially in the 18th dynasty (1539–1292 BC). There was, however, also an ideal that a son should succeed his father. In periods of weak central control this principle predominated, and in the Late Period the whole society became more rigid and stratified.

Writing was a major instrument in the centralization of the Egyptian state and its self-presentation. The two basic forms of writing, hieroglyphs, which were used for monuments and display, and the cursive form known as hieratic, were invented at much the same time in late predynastic Egypt (*c.* 3000 BC). Writing was chiefly used for administration and until about 2650 BC no continuous texts were recorded; the only literary texts written down before the early Middle Kingdom (*c.* 1950 BC) seem to have been lists of important traditional information and possibly medical treatises. The use and potential of writing were restricted both by the rate of literacy, which was probably well below 1 percent, and expectations of what writing might do. Hieroglyphic writing was publicly identified with Egypt. Perhaps because of this association with a single powerful state, its language, and its culture, Egyptian writing was seldom adapted to write other languages; in this it contrasts with the cuneiform script of the relatively uncentralized, multilingual Mesopotamia. Nonetheless, Egyptian hieroglyphs probably served in the middle of the 2nd millennium BC as the model from which the alphabet, ultimately the most widespread of all writing systems, evolved.

Use of hieroglyphs

The dominant visible legacy of ancient Egypt is in works of architecture and representational art. Until the Middle Kingdom, most of these were mortuary: royal tomb complexes, including pyramids and mortuary temples, and private tombs. There were also temples dedicated to the cult of the gods throughout the country, but most of these were modest structures. From the beginning of the New Kingdom (*c.* 1539 BC), temples of the gods became the principal monuments; royal palaces and private houses, which are very little known, were less important. Temples and tombs were ideally executed in stone with relief decoration on their walls and were filled with stone and wooden statuary, inscribed and decorated stelae (freestanding small stone monuments), and, in their inner areas, composite works of art in precious materials. The design of the monuments and their decoration goes back in essence to the beginning of the historical period and presents an ideal, sanctified cosmos. Little in it is related to the everyday world and, except in palaces, works of art may have been rare outside temples and tombs. Decoration may record real historical events, rituals, or the official titles and careers of individuals, but its prime aim is the more general assertion of values, and the information presented must be evaluated for its plausibility and compared with other evidence. Some of the events depicted in relief on royal monuments were certainly fictitious.

Temples and tombs and their decoration

The highly distinctive Egyptian method of rendering nature and artistic style were also creations of early times and can be seen in most works of Egyptian art. In content, these are hierarchically ordered so that the most important figures, the gods and the king, are shown together, while before the New Kingdom gods seldom occur in the same context as humanity. The decoration of a nonroyal tomb characteristically shows the tomb's owner with his subordinates, who administer his land and present him with its produce. The tomb owner is also typically depicted hunting in the marshes, a favourite pastime of the elite that may additionally symbolize passage into the next world. The king and the gods are absent in nonroyal tombs, and overtly religious matter is restricted to rare scenes of mortuary rituals and journeys and to textual formulas. Temple reliefs, in which king and gods occur freely, show the king defeating his enemies, hunting, and especially offering to the gods, who in turn confer benefits upon him. Human beings are present at most as minor figures supporting the king. On both royal and nonroyal monuments an ideal world is represented in which all are beautiful and everything goes well; only minor figures may have physical imperfections.

This artistic presentation of values originated at the same time as writing, but before the latter could record continuous texts or complex statements. Some of the earliest continuous texts of the 4th and 5th dynasties show an awareness of an ideal past that the present could only aspire to emulate. A few "biographies" of officials allude to strife, but more nuanced discussion occurs first in literary texts of the Middle Kingdom. The texts consist of stories, dialogues, lamentations, and especially instructions on how to live a good life, and they supply a rich commentary on the more one-dimensional rhetoric of public inscriptions. Literary works were written in all the main later phases of the Egyptian language—Middle Egyptian; the "classical" form of the Middle and New kingdoms, continuing in copies and inscriptions into Roman times; Late Egyptian, from the 19th dynasty to about 700 BC; and demotic (texts from the 4th century BC to the 3rd century AD)—but many of the finest and most complex are among the earliest.

Literary works also included treatises on mathematics, astronomy, medicine, and magic, as well as various religious texts and canonical lists that classified the categories of creation (probably the earliest genre, going back to the beginning of the Old Kingdom, *c.* 2575 BC, or even a little earlier). Among these texts, little is truly systematic, a notable exception being a medical treatise on wounds. The absence of systematic enquiry contrasts with Egyptian practical expertise in such fields as surveying, which was used both for orienting and planning buildings to remarkably fine tolerances and for the regular division of fields after the inundation; the Egyptians also surveyed and established the dimensions of their entire country by the beginning of the Middle Kingdom. These precise tasks required both knowledge of astronomy and highly ingenious techniques, but they apparently were achieved with little theoretical analysis.

Whereas in the earliest periods Egypt seems to have been administered almost as the personal estate of the king, by the central Old Kingdom it was divided into about 35 nomes, or provinces, each with its own officials. Administration was concentrated at the capital, where most of the central elite lived and died. In the nonmonetary Egyptian economy, its essential functions were the collection, storage, and redistribution of produce; the drafting and organization of manpower for specialized labour, probably including irrigation and flood protection works, and major state projects; and the supervision of legal matters. Administration and law were not fully distinct and both depended ultimately on the king. The settlement of disputes was in part an administrative task, for which the chief guiding criterion was precedent, while contractual relations were regulated by the use of standard formulas. State and temple both partook in redistribution and held massive reserves of grain; temples were economic as well as religious institutions. In periods of decentralization similar functions were exercised by local grandees. Markets had only a minor role, and craftsmen were employees who normally traded only what they produced in their free time. The wealthiest officials escaped this pattern to some extent by receiving their income in the form of land and maintaining large establishments that included their own specialized workers.

Administration and law

The essential medium of administration was writing, reinforced by personal authority over the nonliterate 99 percent of the population; texts exhorting the young to be scribes emphasize that the scribe commanded while the rest did the work. Most officials (almost all of whom were men) held several offices and accumulated more as they progressed up a complex ranked hierarchy, at the top of which was the vizier, the chief administrator and judge. The vizier reported to the king, who in theory retained certain powers, such as authority to invoke the death penalty, absolutely.

Before the Middle Kingdom, the civil and the military were not sharply distinguished. Military forces consisted

of local militias under their own officials and included foreigners, and nonmilitary expeditions to extract minerals from the desert or to transport heavy loads through the country were organized in similar fashion. Until the New Kingdom there was no separate priesthood. Holders of civil office also had priestly titles, and priests had civil titles. Often priesthoods were sinecures: their chief significance was the income they brought. The same was true of the minor civil titles accumulated by high officials. At a lower level, minor priesthoods were held on a rotating basis by "laymen" who served every fourth month in temples. State and temple were so closely interconnected that there was no real tension between them before the late New Kingdom.

Sources, calendars, and chronology. For all but the last century of Egyptian prehistory, whose neolithic and later phases are normally termed "predynastic," evidence is exclusively archaeological; later native sources have only mythical allusions to such remote times. The dynastic period of native Egyptian rulers is generally divided into 30 dynasties, following the *Aegyptiaca* of the Greco-Egyptian writer Manetho of Sebennytos (early 3rd century BC), excerpts of which are preserved in later writers. Manetho apparently organized his dynasties by the capital cities from which they ruled, but several of his divisions also reflect political or dynastic changes, that is, changes of the party holding power. He gave the lengths of reign of kings or of entire dynasties and even longer periods. Because of textual corruption and a tendency to inflation, his figures cannot be used to reconstruct chronology and reign lengths without supporting evidence and analysis.

Basis for outline of dynasties

Manetho's prime sources were earlier Egyptian king lists, the organization of which he imitated. The most significant preserved example of a king list is the Turin Canon, a fragmentary papyrus in the Egyptian Museum in Turin, Italy, which originally listed all kings of the 1st through the 17th dynasty, preceded by a mythical dynasty of gods and one of the "spirits, followers of Horus." The document gave reign lengths for individual kings, as well as totals for some dynasties and longer periods.

In early periods the kings' years of reign were not given numbers but were named for salient events, and lists were made of the names. More extensive details were added to the lists for the 4th and 5th dynasties, when dates were assigned according to biennial cattle censuses numbered through each king's reign. Fragments of such lists are preserved on the Palermo Stone, an inscribed piece of basalt (at the Regional Museum of Archaeology in Palermo, Italy), and related pieces in the Cairo Museum and University College London; these are probably all parts of a late copy of an original document.

Calculating dates for Egyptian prehistory

The Egyptians did not date by eras longer than the reign of a single king, so a historical framework must be created from totals of reign lengths, which are then related to astronomical data that may allow whole periods to be fixed precisely. This is done through references to astronomical events and correlations with the three calendars in use in Egyptian antiquity. All dating was by a civil calendar, derived from the lunar calendar, which was introduced in the first half of the 3rd millennium BC. The civil year had 365 days and started in principle when Sirius, or the Dog Star—also known as Sothis (Ancient Egyptian: Il Sopdet)—became visible above the horizon after a period of absence, which at that time occurred some weeks before the Nile began to rise for the inundation. Every four years the civil year advanced one day in relation to the Julian year (with 365¼ days), and after a cycle of about 1,460 years it would again agree with the lunisolar calendar. Religious ceremonies were organized according to two lunar calendars that had months of 29 or 30 days, with extra, intercalary months every three years or so.

Four mentions of the rising of Sirius (generally known as Sothic dates) are preserved in texts from the 3rd to the 1st millennia, but by themselves these references cannot yield an absolute chronology. Such a chronology can be computed from larger numbers of lunar dates and cross-checked from solutions for the observations of Sirius. Various chronologies are in use, however, differing by up to 40 years for the 2nd millennium BC and by more than a century for the beginning of the 1st dynasty. The chronologies offered in most publications up to 1985 have been disproved for the Middle and New kingdoms by a restudy of the evidence for the Sothic and especially the lunar dates. For the 1st millennium, dates in the Third Intermediate Period are approximate; a supposed fixed year of 945 BC, based on links with the Old Testament, turns out to be variable by a number of years. Late Period dates (664–332 BC) are almost completely fixed. Before the 12th dynasty, plausible dates for the 11th can be computed backward, but for earlier times dates are approximate. A total of 955 years for the 1st through the 8th dynasty in the Turin Canon has been used to assign a date of about 3100 BC for the beginning of the 1st dynasty, but this requires excessive average reign lengths, and an estimate of 2925 BC is preferable. Radiocarbon and other scientific dating of samples from Egyptian sites have not improved on, or convincingly contested, computed dates. Recent work on radiocarbon dates from Egypt does, however, yield results encouragingly close to dates computed in the manner described above.

King lists and astronomy give only a chronological framework. A vast range of archaeological and inscriptional sources for Egyptian history survives, but none of it was produced with the interpretation of history in mind. No consistent political history of ancient Egypt can be written. The evidence is very unevenly distributed, there are gaps of many decades, and in the 3rd millennium BC no continuous royal text recording historical events was inscribed. Private biographical inscriptions of all periods from the 5th dynasty (*c.* 2465–*c.* 2325 BC) to the Roman conquest (30 BC) record individual involvement in events but are seldom concerned with their general significance. Royal inscriptions from the 12th dynasty (1938–1756 BC) to Ptolemaic times aim to present a king's actions according to an overall conception of "history," in which he is the re-creator of the order of the world and the guarantor of its continued stability or its expansion. The goal of his action is not to serve humanity but the gods, while nonroyal individuals may relate their own successes to the king in the first instance and sometimes to the gods. Only in the decentralized intermediate periods did the nonroyal recount internal strife. Kings did not mention dissent in their texts unless it came at the beginning of a reign or a phase of action and was quickly and triumphantly overcome in a reaffirmation of order. Such a schema often dominates the factual content of texts, and it creates a strong bias toward recording foreign affairs, because in official ideology there is no internal dissent after the initial turmoil is over. "History" is as much a ritual as a process of events; as a ritual, its protagonists are royal and divine. Only in the Late Period did these conventions weaken significantly. Even then, they were retained in full for temple reliefs, where they kept their vitality into Roman times.

Despite this idealization, the Egyptians were well aware of history, as is clear from their king lists. They divided the past into periods comparable with those used by Egyptologists, and they evaluated the personalities of rulers as the founders of epochs, for salient exploits, or, especially in folklore, for their bad qualities. The Demotic Chronicle, a text of the Ptolemaic period, purports to foretell the bad end that would befall numerous Late Period kings as divine retribution for their wicked actions.

The recovery and study of ancient Egypt. European interest in ancient Egypt was strong in Roman times and revived in the Renaissance, when the small amount of information provided by visitors to the country was compensated for by the wealth of Egyptian remains in the city of Rome. Views of Egypt were dominated by the classical tradition that it was the land of ancient wisdom; this wisdom was thought to inhere in the hieroglyphic script, which was believed to impart profound symbolic ideas, not—as it in fact does—the sounds and words of texts. Between the 15th and 18th centuries, Egypt had a minor but significant position in general views of antiquity, and its monuments gradually became better known through the work of scholars in Europe and travelers in the country itself; the finest publications of the latter were by Richard Pococke, Frederik Ludwig Norden, and Carsten Niebuhr,

all of whose works in the 18th century helped to stimulate an Egyptian revival in European art and architecture. Coptic, the Christian successor of the ancient Egyptian language, was studied from the 17th century, notably by Athanasius Kircher, for its potential to provide the key to Egyptian.

Napoleon's expedition to and short-lived conquest of Egypt in 1798 was the culmination of 18th-century interest in the East. The expedition was accompanied by a team of scholars who recorded the ancient and contemporary country, issuing in 1809–28 the *Description de l'Égypte,* the most comprehensive study to be made before the decipherment of the hieroglyphic script. The Rosetta Stone, which bears a decree of Ptolemy V Epiphanes in hieroglyphs, demotic, and Greek, was discovered during the expedition and was ceded to the British after the French capitulation; it became the property of the British Museum in London. This document greatly assisted the decipherment, accomplished by Jean-François Champollion in 1822.

Discovery of the Rosetta Stone

The Egyptian language revealed by the decipherment and more than 150 years of study is a member of the Afro-Asiatic, or Hamito-Semitic, language family. The Egyptian is closest to the family's Semitic branch but is distinctive in many respects. During several millennia it changed greatly. The script does not write vowels. Because Greek forms for royal names were known from Manetho long before the Egyptian forms became available, those used to this day are a mixture of Greek and Egyptian.

In the first half of the 19th century vast numbers of antiquities were exported from Egypt, forming the nucleus of collections in many major museums. These were removed rather than excavated, inflicting, together with the economic development of the country, colossal damage on ancient sites. At the same time, many travelers and scholars visited the country and recorded the monuments. The most important, and remarkably accurate, record was produced by the Prussian expedition led by Karl Richard Lepsius, in 1842–45, which explored sites as far south as the central Sudan.

Egyptology as a scholarly pursuit

In the mid-19th century Egyptology developed as a subject in France and in Prussia. The Antiquities Service and a museum of Egyptian antiquities were established in Egypt by the French Egyptologist Auguste Mariette, a great excavator who attempted to preserve sites from destruction, and the Prussian Heinrich Brugsch made great progress in the interpretation of texts of many periods and published the first major Egyptian dictionary. In 1880 Flinders (later Sir Flinders) Petrie began more than 40 years of methodical excavation, which created an archaeological framework for all the chief periods of Egyptian culture except for remote prehistory. Petrie was the initiator of much in archaeological method, but he was later surpassed by George Andrew Reisner, who excavated for American institutions from 1899 to 1937. The greatest late 19th-century Egyptologist was Adolf Erman of Berlin, who put the understanding of the Egyptian language on a sound basis and wrote general works that for the first time organized what was known about the earlier periods.

From the 1890s on, complete facsimile copies of Egyptian monuments have been published, providing a separate record that becomes more vital as the originals decay. The pioneer of this epigraphy was Norman de Garis Davies, who was joined in the 1920s by the Oriental Institute of the University of Chicago and other enterprises. Many scholars are now engaged in epigraphy.

In the first half of the 20th century some outstanding archaeological discoveries were made: Howard Carter uncovered the tomb of Tutankhamen in 1922; Pierre Montet found the tombs of 21st–22nd-dynasty kings at Tanis in 1939–44; and W.B. Emery and L.P. Kirwan found tombs of the Ballānah culture (the 4th through the 6th century AD) in Nubia in 1931–34. The last of these was part of the second survey of Lower Nubia in 1929–34, which preceded the second raising of the Aswān Dam. This was followed in the late 1950s and '60s by an international campaign to excavate and record sites in Egyptian and Sudanese Nubia before the completion of the Aswān High Dam in 1970. Lower Nubia is now one of the most thoroughly explored archaeological regions of the world. Most of its many temples have been moved, either to higher ground nearby, as happened to Abu Simbel and Philae, or to quite different places, including various foreign museums. The campaign also had the welcome consequence of introducing a wide range of archaeological expertise to Egypt, so that standards of excavation and recording in the country have risen greatly.

Excavation and survey of great importance continues in many places. For example, at Ṣaqqārah, part of the necropolis of the ancient city of Memphis, new areas of the Sarapeum have been uncovered with rich finds, and a major New Kingdom necropolis is being thoroughly explored. The site of ancient Memphis itself has been systematically surveyed, its position in relation to the ancient course of the Nile has been established, and urban occupation areas have been studied in detail for the first time.

Egyptology is, however, a primarily interpretive subject. There have been outstanding contributions, for example in art, for which Heinrich Schäfer established the principles of the rendering of nature, and in language. New light has been cast on texts, the majority of which are written in a simple metre that can serve as the basis of sophisticated literary works. The physical environment, social structure, kingship, and religion are other fields in which great advances have been made, while the reconstruction of the outline of history is constantly being improved in detail.

THE PREDYNASTIC AND EARLY DYNASTIC PERIODS

Predynastic Egypt. The peoples of predynastic Egypt were the successors of the Paleolithic inhabitants of northeastern Africa, who had spread over much of its area; during wet phases they had left remains in regions as inhospitable as the Great Sand Sea. The final desiccation of the Sahara was not complete until the end of the 3rd millennium BC; over thousands of years people must have migrated from there to the Nile Valley, the environment of which improved as it dried out. In this process, the decisive change from the nomadic hunter-gatherer way of life of Paleolithic times to settled agriculture has not so far been identified. Some time after 5000 BC the raising of crops was introduced, probably on a horticultural scale, in small, local cultures that seem to have penetrated southward through Egypt into the oases and the Sudan. Several of the basic food plants that were grown are native to the Near East, so the new techniques probably spread from there. No large-scale migration need have been involved, and the cultures were at first largely self-contained. The preserved evidence for them is unrepresentative, because it comes from the low desert, where relatively few people lived; as later, most people probably settled in the Valley and Delta.

The earliest known Neolithic cultures in Egypt have been found at Marimda Banī Salāma, on the southwest edge of the Delta, and farther to the southwest, in the Fayyūm. The site at Marimda Banī Salāma, which dates to the 6th–5th millennia BC, gives evidence of settlement and shows that cereals were grown. In the Fayyūm, where evidence dates to the 5th millennium BC, the settlements were near the shore of Lake Qārūn, and the settlers engaged in fishing. Marimda is a very large site that was occupied for many centuries. The inhabitants lived in lightly-built huts; they may have buried their dead within their houses, but areas where burials have been found may not have been occupied by dwellings at the same time. Pottery was used in both cultures. In addition to these Egyptian Neolithic cultures, others have been identified in the Western Desert, in the Second Cataract area, and north of Khartoum. Some of these are as early as the Egyptian ones, while others overlapped with the succeeding Egyptian predynastic cultures.

Tasian and Badarian cultures

In Upper Egypt, between Asyūṭ and Luxor, have been found the Tasian culture (named after Dayr Tasa) and the Badarian culture (named after al-Badārī); these date from the late 5th millennium BC. Most of the evidence for them comes from cemeteries, where the burials included fine black-topped red pottery, ornaments, some copper objects, and glazed steatite beads. The most characteristic predynastic luxury objects, slate palettes for grinding cos-

metics, occur for the first time in this period. The burials show little differentiation of wealth and status and seem to belong to a peasant culture without central political organization.

Probably contemporary with both predynastic and dynastic times are thousands of rock drawings of a wide range of motifs, including boats, found throughout the Eastern Desert, in Lower Nubia, and as far west as Mount ʿUwaynāt, which stands near modern Egypt's borders with Libya and The Sudan in the southwest. The drawings show that nomads were common throughout the desert, probably down to the late 3rd millennium BC, but they cannot be dated precisely; they may all have been produced by nomads, or inhabitants of the Nile Valley may often have penetrated the desert and made drawings.

Naqādah I

Naqādah I, named after the major site of Naqādah but also called Amratian after al-ʿAmīrah, is a distinct phase that succeeded Badarian and has been found as far south as Kawm al-Aḥmar (Hierakonpolis; ancient Egyptian Nekhen), near the sandstone barrier of Jabal al-Silsila, which was the cultural boundary of Egypt in predynastic times. Naqādah I differs from Badarian in its density of settlement and in the typology of its material culture, but hardly at all in the social organization implied by finds. Burials were in shallow pits in which the bodies faced to the west, like those of later Egyptians. Notable types of material found in graves are fine pottery decorated with representational designs in white on red, figurines of men and women, and hard stone mace-heads that are the precursors of important late predynastic objects.

Naqādah II

Naqādah II, also known as Gerzean after al-Girza, is the most important predynastic culture. The heartland of its development was the same as that of Naqādah I, but it spread gradually throughout the country. South of Jabal al-Silsila, sites of the culturally similar Nubian A Group are found as far as the Second Cataract and beyond; these have a long span, continuing as late as the Egyptian Early Dynastic Period. During Naqādah II, large sites developed at Kawm al-Aḥmar, Naqādah, and Abydos, showing by their size the concentration of settlement, as well as exhibiting increasing differentiation in wealth and status. Few sites have been identified between Asyūṭ and the Fayyūm, and this region may have been sparsely settled, perhaps supporting a pastoral rather than agricultural population. Near modern Cairo, at al-ʿUmārī, Maʿādi, and Wādī Digla, and stretching as far south as the latitude of the Fayyūm, are sites of a separate, contemporary culture. Maʿādi was an extensive settlement that traded with the Near East and probably acted as an intermediary for transmitting goods to the south. In this period, imports of lapis lazuli provide evidence that trade networks extended as far afield as Afghanistan.

The material culture of Naqādah II included increasing numbers of prestige objects. The characteristic mortuary pottery is made of buff desert clay, principally from around Qena, and is decorated in red with pictures of uncertain meaning showing boats, animals, and scenes with human figures. Stone vases, many made of hard stones that come from remote areas of the Eastern Desert, are common and of remarkable quality, and cosmetic palettes display elaborate designs, with outlines in the form of animals, birds, or fish. Flint was worked with extraordinary skill to produce large ceremonial knives of a type that continued in use during dynastic times.

Sites of late Naqādah II (sometimes termed Naqādah III) are found throughout Egypt, including the Memphite area and the Delta, and appear to have replaced the local Lower Egyptian cultures. Links with the Near East intensified and some distinctively Mesopotamian motifs and objects were briefly in fashion in Egypt. The cultural unification of the country probably accompanied a political unification, but this must have proceeded in stages and cannot be reconstructed in detail. In an intermediate stage, local states may have formed at Kawm al-Aḥmar, Naqādah, and Abydos, and in the Delta at such sites as Buto (modern Tall al-Farāʿīn) and Sais. Ultimately, Abydos became preeminent; its late predynastic cemetery of Umm al-Qaʿāb was extended to form the burial place of the kings of the 1st dynasty. In the latest predynastic period, objects bearing written symbols of royalty were deposited throughout the country, and primitive writing also appeared in marks on pottery. Because the basic symbol for the king, a falcon on a decorated palace facade, hardly varies, these objects are thought to have belonged to a single line of kings or a single state, and not to a set of small states. This symbol became the royal Horus name, the first element in a king's titulary, which presented the reigning king as the manifestation of an aspect of the god Horus, the leading god of the country. Over the next few centuries several further definitions of the king's presence were added to this one.

Thus at this time Egypt seems to have been a state unified under kings who introduced writing and the first bureaucratic administration. These kings, who could have ruled for more than a century, may correspond with a set of names preserved on the Palermo Stone, but no direct identification can be made between them. The latest was probably Narmer, whose name has been found near Memphis, at Abydos, on a ceremonial palette and mace-head from Kawm al-Aḥmar, and at the Palestinian sites of Tall Gat and ʿArad. The relief scenes on the palette show him wearing the two chief crowns of Egypt and defeating northern enemies, but these probably are stereotyped symbols of the king's power and role and not records of specific events of his reign. They demonstrate that the position of the king in society and its presentation in mixed pictorial and written form had been elaborated by this date.

During this time Egyptian artistic style and conventions were formulated, together with writing. The process led to a complete and remarkably rapid transformation of material culture, so that many dynastic Egyptian prestige objects hardly resemble their forerunners.

The Early Dynastic Period (c. 2925–c. 2575 BC). *The 1st dynasty (c. 2925–c. 2775 BC).* The beginning of the historical period is characterized by the introduction of written records in the form of regnal year names—the records that later were collected in documents such as the Palermo Stone. The first king of Egyptian history, Menes, is therefore a creation of the later record, not the actual unifier of the country; he is known from Egyptian king lists and from classical sources and is credited with irrigation works and with founding the capital, Memphis. On small objects from this time, one of them dated to the important king Narmer but certainly mentioning a different person, there are two possible mentions of a "Men" who may be the king Menes. If these do name Menes, he was probably the same person as Aha, Narmer's probable successor, who was then the founder of the 1st dynasty. Changes in the naming patterns of kings reinforce the assumption that a new dynasty began with his reign. Aha's tomb at Abydos is altogether more grandiose than previously built tombs, while the first of a series of massive tombs at Ṣaqqārah, next to Memphis, supports the tradition that the city was founded then as a new capital. This shift from Abydos is the culmination of intensified settlement in the crucial area between the Valley and the Delta, but Memphis did not yet overcome the traditional pull of its predecessor: the large tombs at Ṣaqqārah appear to belong to high officials, while the kings were buried at Abydos in tombs without formal superstructures. Their mortuary cult may have been conducted in flimsy buildings in designated areas nearer the cultivation, around which a number of burials of important individuals were grouped.

Introduction of written records

In the late predynastic period and the first half of the 1st dynasty, Egypt extended its influence into southern Palestine and probably Sinai and conducted a campaign as far as the Second Cataract. The First Cataract area, with its centre on Elephantine, an island in the Nile opposite the modern town of Aswān, was permanently incorporated into Egypt, but Lower Nubia was not.

Between late predynastic times and the 4th dynasty—and probably early in the period—the Nubian A Group came to an end. There is some evidence that political centralization was in progress around Qustul, but this did not lead to any further development and may indeed have prompted a preemptive strike by Egypt. For Nubia, the malign proximity of the largest state of the time stifled

advancement. During the 1st dynasty, writing spread gradually, but because it was used chiefly for administration, the records, which were kept within the floodplain, have not survived. The artificial writing medium of papyrus was invented by the middle of the 1st dynasty. There was a surge in prosperity, and thousands of tombs of all levels of wealth have been found throughout the country. The richest contained magnificent goods in metal, ivory, and other materials, the most widespread luxury products being extraordinarily fine stone vases. The high point of 1st-dynasty development was the long reign of Den (flourished *c.* 2850 BC).

Elements of the kings' names

During the 1st dynasty three titles were added to the royal Horus name: "Two Ladies," an epithet presenting the king as making manifest an aspect of the protective goddesses of the south (Upper Egypt) and the north (Lower Egypt); "Golden Horus," the precise meaning of which is unknown; and "Dual King," a ranked pairing of the two basic words for king, later associated with Upper and Lower Egypt. These titles were followed by the king's own birth name, which in later centuries was written in a cartouche.

The 2nd dynasty (c. 2775–c. 2650 BC). From the end of the 1st dynasty there is evidence of rival claimants to the throne. One line may have become the 2nd dynasty, whose first king's Horus name, Hetepsekhemwy, means "peaceful in respect of the two powers" and may allude to the conclusion of strife between two factions or parts of the country, to the antagonistic gods Horus and Seth, or to both. Hetepsekhemwy and his successor, Reneb, moved their burial places to Ṣaqqārah; the tomb of the third king, Nynetjer, has not been found. The second half of the dynasty was a time of conflict and rival lines of kings, some of whose names are preserved on stone vases from the 3rd-dynasty Step Pyramid at Ṣaqqārah or in king lists. Among these contenders, Peribsen took the title of Seth instead of Horus and was probably opposed by Horus Khasekhem, whose name is known only from Kawm al-Aḥmar and who used the programmatic epithet "effective sandal against evil." The last ruler of the dynasty combined the Horus and Seth titles to form the Horus-and-Seth Khasekhemwy, "arising in respect of the two powers," to which was added "the two lords are at peace in him." Khasekhemwy was probably the same person as Khasekhem after the successful defeat of his rivals, principally Peribsen. Both Peribsen and Khasekhemwy had tombs at Abydos, and the latter also built a monumental brick funerary enclosure near the main temple (there were two further such enclosures).

The 3rd dynasty (c. 2650–c. 2575 BC). There were links of kinship between Khasekhemwy and the 3rd dynasty, but the change between them is marked by a definitive shift of the royal burial place to Memphis. Its first king, Sanakhte, is attested in reliefs from Maghāra in Sinai. His successor, Djoser (Horus name Netjerykhet), was one of the outstanding kings of Egypt. His Step Pyramid at Ṣaqqārah is both the culmination of an epoch and—as the first large all-stone building, many times larger than anything attempted before—the precursor of later achievements. The pyramid is set in a much larger enclosure than that of Khasekhemwy at Abydos and contains reproductions in stone of ritual structures that had previously been built of perishable materials. Architectural details of columns, cornices, and moldings provided many models for later development. The masonry techniques look to brickwork for models and show little concern for the structural potential of stone. The pyramid itself evolved through numerous stages from a flat mastaba (an oblong tomb with a burial chamber dug beneath it, common at earlier nonroyal sites) into a six-stepped, almost square pyramid. There was a second, symbolic tomb with a flat superstructure on the south side of the enclosure; this probably substituted for the traditional royal burial place of Abydos. The king and some of his family were buried deep under the pyramid, where tens of thousands of stone vases were deposited, a number bearing inscriptions of the first two dynasties. Thus, in perpetuating earlier forms in stone and burying this material, Djoser invoked the past in support of his innovations.

Djoser's Step Pyramid at Ṣaqqārah

Djoser's name was famous in later times and his monument was studied in the Late Period. Imhotep, whose title as a master sculptor is preserved from the Step Pyramid complex, may have been its architect; he lived on into the next reign. His fame also endured, and in the Late Period he was deified and became a god of healing. In Manetho's history he is associated with reforms of writing and this may reflect a genuine tradition, for hieroglyphs were simplified and standardized at this time.

Djoser's successor, Sekhemkhet, planned a still more grandiose step pyramid complex, and a later king, Khaba, began one at Zawyat al-'Aryan, a few miles south of Giza. The burial place of the last king of the dynasty, Huni, is unknown. It has often been suggested that he built the pyramid of Maydūm, but this probably was the work of his successor, Snefru. Inscribed material naming 3rd-dynasty kings is known from Maghāra to Elephantine but not from the Near East or Nubia.

The organizational achievements of the 3rd dynasty are reflected in its principal monument, whose message of centralization and concentration of power is reinforced in a negative sense by the archaeological record. Outside the vicinity of Memphis, the Abydos area continued to be important, and four enormous tombs, probably of high officials, were built at the nearby site of Bayt Khallaf; there were small, nonmortuary step pyramids throughout the country, some of which may date to the 4th dynasty. Otherwise, little evidence comes from the provinces, from which wealth must have flowed to the centre, leaving no rich local elite. By the 3rd dynasty the rigid structure of the later nomes, or provinces, which formed the basis of Old Kingdom administration, had been created, and the imposition of its uniform pattern may have impoverished local centres. Tombs of the elite at Ṣaqqārah, notably those of Hezyre and Khabausokar, contained artistic masterpieces that look forward to the Old Kingdom.

THE OLD KINGDOM (c. 2575–c. 2130 BC) AND THE FIRST INTERMEDIATE PERIOD (c. 2130–1938 BC)

The Old Kingdom. *The 4th dynasty (c. 2575–c. 2465 BC).* The first king of the 4th dynasty, Snefru, probably built the step pyramid of Maydūm and then modified it to form the first true pyramid. Due west of Maydūm was the small step pyramid of Saylah, in the Fayyūm, at which Snefru also worked. He built two pyramids at Dahshūr; the southern of the two is known as the Bent Pyramid because its upper part has a shallower angle of inclination than its lower part. This difference may be due to structural problems or may have been planned from the start, in which case the resulting profile may reproduce a solar symbol of creation. The northern Dahshūr pyramid, the later of the two, has the same angle of inclination as the upper part of the Bent Pyramid and a base area exceeded only by that of the Great Pyramid. Both pyramids had mortuary complexes attached to them. Snefru's building achievements were thus at least as great as those of any later king and introduced a century of unparalleled construction.

Snefru's monuments

In a long perspective, the 4th dynasty was an isolated phenomenon, a period when the potential of centralization was realized to its utmost and a disproportionate amount of the state's resources was used on the kings' mortuary provisions, almost certainly at the expense of general living standards. No significant 4th-dynasty sites have been found away from the Memphite area. Tomb inscriptions show that high officials were granted estates scattered over many nomes, especially in the Delta. This pattern of landholding may have avoided the formation of local centres of influence while encouraging intensive exploitation of the land. People who worked on these estates were not free to move, and they paid a high proportion of their earnings in dues and taxes. The building enterprises must have relied on drafting vast numbers of men, probably after the harvest had been gathered in the early summer and during part of the inundation.

Snefru's was the first king's name that was regularly written inside the cartouche, an elongated oval that is one of the most characteristic Egyptian symbols. The cartouche itself is older and was shown as a gift bestowed by gods on

the king, signifying long duration on the throne. It soon acquired associations with the sun, so that its first use by the builder of the first true pyramid, which is probably also a solar symbol, is not coincidental.

The Great Pyramid at Giza

Snefru's successor, Khufu (Cheops), built the Great Pyramid at Giza, to which were added the slightly smaller second pyramid of one of Khufu's sons, Khafre (more correctly Rekhaef, the Chephren of Greek sources), and that of Menkaure (Mycerinus). Khufu's successor, his son Redjedef, began a pyramid at Abū Ruwaysh, and a king of uncertain name began one at Zawyat al-'Aryan. The last known king of the dynasty (there was probably one further), Shepseskaf, built a monumental mastaba at south Ṣaqqārah and was the only Old Kingdom ruler not to begin a pyramid. These works, especially the Great Pyramid, show a great mastery of monumental stoneworking: individual blocks were large or colossal and were very accurately fitted to one another. Surveying and planning also were carried out with remarkable precision.

Apart from the colossal conception of the pyramids themselves, the temple complexes attached to them show great mastery of architectural forms. Khufu's temple or approach causeway was decorated with impressive reliefs, fragments of which were incorporated in the 12th-dynasty pyramid of Amenemhet I at al-Lisht. The best known of all Egyptian sculpture, Khafre's Great Sphinx at Giza and his extraordinary seated statue of Nubian gneiss, date from the middle 4th dynasty.

The Giza pyramids form a group of more or less completed monuments surrounded by many tombs of the royal family and the elite, hierarchically organized and laid out in neat patterns. This arrangement contrasts with that of the reign of Snefru, when important tombs were built at Maydūm and Ṣaqqārah, while the King was probably buried at Dahshūr. Of the Giza tombs, only those of the highest-ranking officials were decorated: except among the immediate entourage of the kings, the freedom of expression of officials was greatly restricted. Most of the highest officials were members of the very large royal family, so that power was concentrated by kinship as well as other means. This did not prevent factional strife: the complex of Redjedef was deliberately and thoroughly destroyed, probably at the instigation of his successor, Khafre.

Egyptian expansion into Nubia

The Palermo Stone records a campaign to Lower Nubia in the reign of Snefru that may be associated with graffiti in the area itself. The Egyptians founded a settlement at Buhen, at the north end of the Second Cataract, which endured for 200 years; others may have been founded between there and Elephantine. The purposes of this penetration were probably to establish trade farther south and to create a buffer zone. No archaeological traces of a settled population in Lower Nubia have been found for the Old Kingdom period: the oppressive presence of Egypt seems to have robbed the inhabitants of their resources, rather as the Egyptian provinces were exploited in favour of the king and the elite.

Snefru and the builders of the Giza pyramids represented a classic age to later times. Snefru was the prototype of a good king, whereas Khufu and Khafre had tyrannical reputations, perhaps only because of the size of their monuments. Little direct evidence for political or other attitudes survives from the dynasty, in part because writing was only just beginning to be used for recording continuous texts. Many great works of art were, however, produced for kings and members of the elite, and these set a pattern for later work. Kings of the 4th dynasty identified themselves, at least from the time of Redjedef, as Son of Re (the sun god); worship of the sun god reached a peak in the 5th dynasty.

The 5th dynasty (c. 2465–c. 2325 BC). The first two kings of the 5th dynasty, Userkaf and Sahure, were sons of a lady, Khentkaues, who was a member of the 4th-dynasty royal family. The third king, Neferirkare, may also have been her son. A story from the Middle Kingdom that makes them all sons of a priest of Re may derive from a tradition that they were true worshipers of the sun god and implies, probably falsely, that the 4th-dynasty kings were not. Six kings of the 5th dynasty displayed their devotion to the sun god by building personal temples to his cult. These temples, of which the two so far identified are sited similarly to pyramids, probably had a mortuary significance for the king as well as honouring the god. The kings' pyramids should therefore be seen in conjunction with the temples, some of which received lavish endowments and were served by many high-ranking officials.

Pyramids have been identified for seven of the nine kings of the dynasty, at Ṣaqqārah (Userkaf and Unas, the last king), Abū Ṣīr (Sahure, Neferirkare, Reneferef, and Nuserre), and south Ṣaqqārah (Djedkare Izezi, the eighth king). The pyramids are smaller and less solidly constructed than those of the 4th dynasty, but the reliefs from their mortuary temples are better preserved and of very fine quality; that of Sahure gives a fair impression of their decorative program. The interiors contained religious scenes relating to provision for Sahure in the next life, while the exteriors presented his "historical" role and relations with the gods. Sea expeditions to Lebanon to acquire timber are depicted, as are aggression against and capture of Libyans. Despite their apparent precision, in which captives are named and total figures given, these scenes may not refer to specific events, for the same motifs with the same details were frequently shown over the next 250 years; Sahure's use of them might not have been the earliest.

Relations with foreign lands

Foreign connections were far-flung. Goldwork of the period has been found in Anatolia, while stone vases named for Khafre and Pepi I (6th dynasty) have been found at Tall Mardīkh in Syria, the capital of the important state of Ebla, which was destroyed around 2250 BC. The absence of 5th-dynasty evidence from the site is probably a matter of chance. Expeditions to the turquoise mines of Sinai continued as before. In Nubia, graffiti and inscribed seals from Buhen document Egyptian presence until late in the dynasty, when control was probably abandoned in the face of immigration from the south and the deserts; later generations of the immigrants are known as the Nubian C Group. From the reign of Sahure on, there are records of trade with Punt, a partly legendary land probably in the region of Eritrea, from which the Egyptians obtained incense and myrrh, as well as exotic African products that had been traded from still farther afield. Thus the reduced level of royal display in Egypt does not imply a less prominent general role for the country.

Organization of the country's administration

High officials of the 5th dynasty were no longer members of the royal family, although a few married princesses. Their offices still depended on the king, and in their biographical inscriptions they presented their exploits as relating to him, but they justified other aspects of their social role in terms of a more general morality. They progressed through their careers by acquiring titles in complex ranked sequences that were manipulated by kings throughout the 5th and 6th dynasties. This institutionalization of officialdom has an archaeological parallel in the distribution of elite tombs, which no longer clustered so closely around pyramids. Many are at Giza, but the largest and finest are at Ṣaqqārah and Abū Ṣīr. The repertory of decorated scenes in them continually expanded, but there was no fundamental change in their subject matter. Toward the end of the 5th dynasty some officials with strong local ties began to build their tombs in the Nile Valley and the Delta, in a development that symbolized the elite's slowly growing independence from royal control.

Something of the working of the central administration is visible in papyri from the mortuary temples of Neferirkare and Reneferef at Abū Ṣīr. These show well-developed methods of accounting and meticulous recordkeeping and document the complicated redistribution of goods and materials between the royal residence, the temples, and officials who held priesthoods. Despite this evidence for detailed organization, the consumption of papyrus was modest and cannot be compared, for example, with that of Greco-Roman times.

The last three kings of the dynasty, Menkauhor, Djedkare Izezi, and Unas, did not have personal names compounded with "-Re," the name of the sun god (Djedkare is a name assumed on accession); and Izezi and Unas did not build solar temples. Thus there was a slight shift away from the solar cult. The shift could be linked with the rise

of Osiris, the god of the dead, who is first attested from the reign of Neuserre. His origin was, however, probably some centuries earlier. The pyramid of Unas, whose approach causeway was richly decorated with historical and religious scenes, is inscribed inside with spells intended to aid the deceased in the hereafter; varying selections of the spells occur in all later Old Kingdom pyramids. (As a collection they are known as the Pyramid Texts.) Many of the spells were old when they were inscribed; their presence documents the increasing use of writing rather than a change in beliefs. The Pyramid Texts show the importance of Osiris, at least for the king's passage into the next world: it was an undertaking that aroused anxiety and had to be assisted by elaborate rituals and spells.

The 6th dynasty (c. 2325–c. 2150 BC). No marked change can be discerned between the reigns of Unas and Teti, the first king of the 6th dynasty. Around Teti's pyramid in the northern portion of Ṣaqqārah was built a cemetery of large tombs, including those of several viziers. Together with tombs near the pyramid of Unas, this is the latest group of private monuments of the Old Kingdom in the Memphite area.

Information on 6th-dynasty political and external affairs is more abundant because inscriptions of high officials were longer. Whether the circumstances they describe were also typical of less loquacious ages is unknown, but the very existence of such inscriptions is evidence of a tendency to greater independence among officials. One, Weni, who lived from the reign of Teti through those of Pepi I and Merenre, was a special judge in the trial of a conspiracy in the royal household, mounted several campaigns against a region east of Egypt or in southern Palestine, and organized two quarrying expeditions. In the absence of a standing army, the Egyptian force was levied from the provinces by officials from local administrative centres and other settlements; there were also contingents from several southern countries and a tribe of the Eastern Desert.

Trading expeditions in the 6th dynasty

Three biographies of officials from Elephantine record trading expeditions to the south in the reigns of Pepi I and Pepi II. The location of the regions named in them is debated and may have been as far afield as the Butāna, south of the Fifth Cataract. Some of the trade routes ran through the Western Desert, where the Egyptians established an administrative post at Balāṭ in ad-Dākhilah Oasis, some distance west of al-Khārijah Oasis. Egypt no longer controlled Lower Nubia, which was settled by the C Group and formed into political units of gradually increasing size, possibly as far as Karmah, south of the Third Cataract; relations with this state deteriorated into armed conflict in the reign of Pepi II. Karmah was the southern cultural successor of the Nubian A Group and became an urban centre in the late 3rd millennium BC, remaining Egypt's chief southern neighbour for seven centuries. To the north, the Karmah state stretched as far as the Second Cataract and at times farther still. Its southern extent has not been determined, but sites of similar material culture are scattered over vast areas of the central Sudan.

Increase in provincialization

The provincializing tendencies of the late 5th dynasty continued in the 6th, especially during the extremely long reign (up to 94 years) of Pepi II. Increasing numbers of officials resided in the provinces, amassed local offices, and emphasized local concerns, including religious leadership, in their inscriptions. At the capital the size and splendour of the cemeteries decreased, and some tombs of the end of the dynasty were decorated only in their subterranean parts, as if security could not be guaranteed aboveground. The pyramid complex of Pepi II at southern Ṣaqqārah, which was probably completed in the first 30 years of his reign, stands out against this background as the last major monument of the Old Kingdom, comparable with its predecessors in artistic achievement. Three of his queens were buried in small pyramids around his own; these are the only known queens' monuments inscribed with Pyramid Texts.

The 7th and 8th dynasties (c. 2150–30 BC). Pepi II was followed by several ephemeral rulers, who were in turn succeeded by the short-lived 7th dynasty of Manetho's history (from which no king's name is known) and the 8th, one of whose kings, Ibi, built a small pyramid at southern Ṣaqqārah. Several 8th-dynasty kings are known from inscriptions found in the temple of Min at Qift in the south; this suggests that their rule was recognized throughout the country. The instability of the throne is, however, a sign of political decay, and the fiction of centralized rule may have been accepted only because there was no alternative style of government to kingship.

Collapse of the Old Kingdom state

With the end of the 8th dynasty the Old Kingdom state collapsed. About this time there was widespread famine and violence; the consequent rise in the death rate can be seen in sharply increased numbers of burials in cemeteries. The country emerged impoverished and decentralized from this episode, the prime cause of which may have been political failure, environmental disaster, or, more probably, a combination of the two. In this period the desiccation of northeastern Africa reached a peak, producing conditions similar to those of modern times, and a related succession of low inundations may have coincided with the decay of central political authority. These environmental changes are, however, only approximately dated and their relationship with the collapse cannot be proved.

The First Intermediate Period. *The 9th dynasty (c. 2130–2080 BC).* After the end of the 8th dynasty the throne passed to kings from Heracleopolis, who made their native city the capital, although Memphis continued to be important. They were acknowledged throughout the country, but inscriptions of nomarchs (chief officials of nomes) in the south show that the kings' rule was nominal. At Dara, north of Asyūṭ, for example, a local ruler called Khety styled himself king and built a pyramid with a surrounding "courtly" cemetery. At al-Mi'alla, south of Luxor, Ankhtify, the nomarch of the al-Jabalayn region, recorded his annexation of the Idfū nome and extensive raiding in the Theban area. Ankhtify acknowledged an unidentifiable king Neferkare but campaigned with his own troops. Major themes of inscriptions of the period are the nomarch's provision of food supplies for his people in times of famine and his success in promoting irrigation works. Artificial irrigation had probably long been practiced, but exceptional poverty and crop failure made concern with it worth recording. Inscriptions of Nubian mercenaries employed by local rulers in the south indicate how entrenched military action was.

The 10th (c. 2080–c. 1970 BC) and 11th (2081–1938 BC) dynasties. A period of generalized conflict focused on twin dynasties at Thebes and Heracleopolis. The latter, the 10th, probably continued the line of the 9th. The founder of the 9th or 10th dynasty was named Khety and the dynasty as a whole was termed the House of Khety. Several Heracleopolitan kings were named Khety; another important name is Merikare. Whereas the Theban dynasty was stable, kings succeeded one another rapidly at Heracleopolis. There was continual conflict, and the boundary between the two realms shifted around the region of Abydos. As yet, the course of events in this period cannot be reconstructed.

Several major literary texts purport to describe the upheavals of the First Intermediate Period, the "Instruction for Merikare," for example, being ascribed to one of the kings of the 9th or 10th dynasty. These texts led earlier Egyptologists to posit a Heracleopolitan literary flowering, but there is now a tendency to date them to the Middle Kingdom, so that they would have been written with enough hindsight to allow a more effective critique of the sacred order. The "Heracleopolitan Age" may therefore be a fiction.

Until the 11th dynasty made Thebes its capital, Hermonthis (modern Armant), on the west bank of the Nile, had been the centre of the Theban nome. The dynasty honoured as its ancestor the God's Father Mentuhotep, probably the father of its first king, Inyotef I (2081–65 BC), whose successors were Inyotef II and Inyotef III (2065–16 and 2016–08 BC, respectively). The fourth king, Mentuhotep I (sometimes numbered II; 2008–1957 BC, whose throne name was Nebhepetre), gradually reunited Egypt and ousted the Heracleopolitans, changing his titulary in stages to record his conquests. Around his 20th regnal year he assumed the Horus name Divine of the White Crown,

implicitly claiming all of Upper Egypt. By his regnal year 42 this was changed to Uniter of the Two Lands, a traditional royal epithet that he revived with a literal meaning and presented in a new, emphatic iconography. In later times Mentuhotep was celebrated as the founder of the epoch now known as the Middle Kingdom. His remarkable mortuary complex at Dayr al-Baḥrī, which seems to have had no pyramid, was the architectural inspiration for Hatshepsut's later structure built alongside.

In the First Intermediate Period, monuments were set up by a slightly larger section of the population and, in the absence of central control, internal dissent and conflicts of authority became visible in public records. Nonroyal individuals took over some of the privileges of royalty, notably identification with Osiris in the hereafter and the use of the Pyramid Texts; these were incorporated into a more extensive corpus inscribed on coffins (and hence termed the Coffin Texts) and continued to be inscribed during the Middle Kingdom. The unified state of the Middle Kingdom did not reject these acquisitions and so had a broader cultural basis than the Old Kingdom.

THE MIDDLE KINGDOM (1938–c. 1600 BC) AND THE SECOND INTERMEDIATE PERIOD (c. 1630–1540 BC)

The Middle Kingdom. Mentuhotep I campaigned in Lower Nubia, where he may have been preceded by the Inyotefs. In Thebes he built a novel and impressive mortuary complex at Dayr al-Baḥrī, which served as inspiration for Hatshepsut's adjacent temple 500 years later. The complex contained some of the earliest known depictions of Amon-Re, the dynastic god of the Middle Kingdom and the New Kingdom. Mentuhotep I was himself deified and worshiped, notably in the Aswān area. In administration, he attempted to break the power of the nomarchs, but his policy was unsuccessful in the longer term.

Mentuhotep I's mortuary complex at Dayr al-Baḥrī

Mentuhotep I's successors, Mentuhotep II (1957–45 BC) and Mentuhotep III (1945–38 BC) also ruled from Thebes. The reign of Mentuhotep III corresponds to seven years marked "missing" in the Turin Canon, and he may later have been deemed illegitimate. Records of a quarrying expedition to the Wadi Ḥammāmāt (Wādī Rawḍ ʿĀyd) from his second regnal year were inscribed on the order of his vizier Amenemhet, who almost certainly usurped the throne and founded the 12th dynasty. Not all the country welcomed the 11th dynasty, the monuments and self-presentation of which remained local and Theban.

The 12th dynasty (1938–c. 1756 BC). In a text probably circulated as propaganda during the reign of Amenemhet I (1938–08 BC), the time preceding his reign is depicted as a period of chaos and despair, from which a saviour called Ameny from the extreme south was to emerge. This presentation may well be stereotyped, but there could have been armed struggle before he seized the throne. Nonetheless, his mortuary complex at al-Lisht contained monuments on which his name was associated with that of his predecessor. In style, his pyramid and mortuary temple looked back to Pepi II of the end of the Old Kingdom, but the pyramid was built of mud brick with a stone casing and consequently is badly ruined.

Amenemhet I moved the capital back to the Memphite area, founding a residence named Itj-towy "[Amenemhet is] he who takes possession of the Two Lands," which was for later times the archetypal royal residence. Itj-towy was probably situated between Memphis and the pyramids of Amenemhet I and Sesostris I (at modern al-Lisht), while Memphis remained the centre of population. From later in the dynasty there is the earliest evidence for a royal palace (not a capital) in the eastern Delta. The return to the Memphite area was accompanied by a revival of Old Kingdom artistic styles, in a resumption of central traditions that contrasted with the local ones of the 11th dynasty. In his policy toward the nomarchs, Amenemhet retreated from the absolutism of the Mentuhoteps, and major tombs of the first half of the dynasty, which display considerable local independence, are preserved at several sites, notably Beni Hasan, Mayr, and Qau. After the second reign of the dynasty, no more important private tombs were constructed at Thebes, but several kings made benefactions to Theban temples.

In his 20th regnal year, Amenemhet I took his son Sesostris I (or Senwosret, 1918–1875 BC) as his co-regent, presumably in order to avoid the instability of the First Intermediate Period and its aftermath. This practice was followed in the next two reigns and recurred sporadically in later times. During the following 10 years of joint rule Sesostris undertook campaigns in Lower Nubia that led to its conquest as far as the central area of the Second Cataract. A series of fortresses was begun in the region and there was a full occupation, but the local C Group population was not integrated culturally with the conquerors.

Sesostris I's campaigns to the south

Amenemhet I apparently was murdered during Sesostris' absence on a campaign to Libya, but Sesostris was able to maintain his hold on the throne without major disorder. He consolidated his father's achievements, but, in one of the earliest preserved inscriptions recounting royal exploits, he spoke of internal unrest. An inscription of the next reign alludes to campaigns to Syria-Palestine in the time of Sesostris; whether these were raiding expeditions and parades of strength, in what was then a seminomadic region, or whether a conquest was intended or achieved, is not known. It is clear, however, that the traditional view that the Middle Kingdom hardly intervened in the Near East is incorrect.

In the early 12th dynasty the written language was regularized in its classical form of Middle Egyptian, a rather artificial idiom that was probably always somewhat removed from the vernacular. The first datable corpus of literary texts was composed in Middle Egyptian. Two of these relate directly to political affairs and offer fictional justifications for the rule of Amenemhet I and Sesostris I, respectively. Several that are ascribed to Old Kingdom authors or that describe events of the First Intermediate Period, but are composed in Middle Egyptian, probably also date from around this time. The most significant of these is the "Instruction for Merikare," a discourse on kingship and moral responsibility. It is often used as a source for the history of the First Intermediate Period but may preserve no more than a memory of its events. Most of these texts continued to be copied in the New Kingdom.

Little is known of the reigns of Amenemhet II (1876–42 BC) and Sesostris II (1844–37 BC). These kings built their pyramids in the Fayyūm, while also beginning an intensive exploitation of its agricultural potential that reached a peak in the reign of Amenemhet III (1818–1770 BC). The king of the 12th dynasty with the most enduring reputation was Sesostris III (1836–18 BC), who extended Egyptian conquests to Semna, at the south end of the Second Cataract, while also mounting at least one campaign to Palestine. Sesostris III completed an extensive chain of fortresses in the Second Cataract; at Semna he was worshiped as a god in the New Kingdom.

Frequent campaigns and military occupation, which lasted another 150 years, required a standing army. A force of this type may have been created early in the 12th dynasty but becomes better attested near the end. It was based on "soldiers," whose title means literally "citizens," levied by district, and officers of several grades and types. It was separate from New Kingdom military organization and seems not to have enjoyed very high status.

Egypt's standing army

The purpose of the occupation of Lower Nubia is disputed, because the size of the fortresses and the level of manpower needed to occupy them might seem disproportionate to local threats. An inscription of Sesostris III set up in the fortresses emphasizes the weakness of the Nubian enemy, while a boundary marker and fragmentary papyri show that the system channeled trade with the south through the central fortress of Mirgissa. The greatest period of the Karmah state to the south was still to come, but for centuries it had probably controlled a vast stretch of territory. The best explanation of the Egyptian presence is that Lower Nubia was annexed by Egypt whenever possible, while Karmah was a rival worth respecting and preempting; in addition, the physical scale of the fortresses may have become something of an end in itself. It is not known whether Egypt wished similarly to conquer Palestine, but an inscription of Sesostris' reign records a campaign in Palestine, and numerous administrative seals of the period have been found there.

Sesostris III's administrative reorganization

Sesostris III finally broke the power of the nomarchs and reorganized Egypt into four regions corresponding to the northern and southern halves of the Nile Valley and the eastern and western Delta. Rich evidence for middle-ranking officials from the religious centre of Abydos, and for administrative practice in documents from al-Lahūn, conveys an impression of a pervasive, centralized bureaucracy, which later came to run the country under its own momentum. The prosperity created by peace, conquests, and agricultural development is visible in royal monuments and monuments belonging to the minor elite, but there was no small, powerful, and wealthy group of the sort seen in the Old and New Kingdoms. Sesostris III and his successor, Amenemhet III (1818–*c.* 1770 BC), left a striking artistic legacy in the form of statuary depicting them as aging, careworn rulers, probably alluding to a conception of the suffering king known from literature of the dynasty. This departure from the bland ideal, which may have sought to bridge the gap between king and subjects in the aftermath of the attack on elite power, was not taken up in later times.

The reigns of Amenemhet III and Amenemhet IV (*c.* 1770–1760 BC) and Sebeknefru (*c.* 1760–1756 BC), the first certainly attested female monarch, were apparently peaceful, but the accession of a woman marked the end of the dynastic line.

The 13th dynasty (c. 1756–c. 1630 BC). Despite a continuity of outward forms and of the rhetoric of inscriptions between the 12th and 13th dynasties, there was a complete change in kingship. In little more than a century about 70 kings occupied the throne. Many can have reigned only for months, and there were probably rival claimants to the throne, but in principle the royal residence remained at Itj-towy and the kings ruled the whole country. Egypt's hold on Lower Nubia was maintained, as was its position as the leading state in the Near East. Large numbers of private monuments document the prosperity of the official classes, and a proliferation of titles is evidence of their continued expansion. In government the vizier assumed prime importance, and a single family held the office for much of a century.

Waves of immigration

Asiatic immigration is known in the late 12th dynasty and became widespread in the 13th. From the late 18th century BC the northeastern Delta was settled by successive waves of Palestinians, who retained their own material culture. Starting with the "Instruction for Merikare," Egyptian texts warn against the dangers of infiltration of this sort, and its occurrence shows a weakening of government. There may also have been a rival dynasty, called the 14th, at Xois in the north central Delta, but this is known only from Manetho's history and could have had no more than local significance. Several late 13th-dynasty kings are attested only at Thebes and may have formed a rival line or moved their residence there from the north. Toward the end of this period Egypt lost control of Lower Nubia, where the garrisons, which had been regularly replaced with fresh troops, settled and were partly assimilated. The Karmah state overran and incorporated the region. Some Egyptian officials resident in the Second Cataract area served the new rulers. The site of Karmah has yielded many Egyptian artifacts, including old pieces pillaged from their original contexts. Most were items of trade between the two countries, some probably destined for exchange against goods imported from sub-Saharan Africa. Around the end of the Middle Kingdom and during the Second Intermediate Period, Medjay tribesmen from the Eastern Desert settled in the Nile Valley from around Memphis to the Third Cataract. Their presence is marked by distinctive shallow graves with black-topped pottery, and they have traditionally been termed the "Pan-grave" culture by archaeologists. They were assimilated culturally in the New Kingdom, but the word Medjay came to mean police or militia; they probably came as mercenaries.

The Second Intermediate Period. The increasing competition for power in Egypt and Nubia crystallized in the formation of two new dynasties: the 15th, called the Hyksos (*c.* 1630–*c.* 1523 BC), with its capital at Avaris (Tall ad-Dab'a) in the Delta, and the 17th (*c.* 1630–1540 BC), ruling from Thebes. The word Hyksos goes back to an Egyptian phrase meaning "ruler of foreign lands" and occurs in Manetho's narrative cited in the works of the Jewish historian Josephus (1st century AD), which depicts the new rulers as sacrilegious invaders who despoiled the land. They may have invaded, but they presented themselves—with the exception of the title Hyksos—as Egyptian kings and appear to have been accepted as such. The main line of Hyksos was acknowledged throughout Egypt and may have been recognized as overlords in Palestine, but they tolerated other lines of kings, both those of the 17th dynasty and the various minor Hyksos who are termed the 16th dynasty. The 17th dynasty therefore had to accept that it was a junior line, and in this distinction of status lay an occasion, if not a cause, of later conflict. The 15th dynasty consisted of six kings, the best known being the fifth, Apopis, who reigned for up to 40 years. There were many 17th-dynasty kings, probably belonging to several different families. The northern frontier of the Theban domain was at al-Qusiyya, but there was trade across the border and the Thebans pastured their herds in the Delta.

Rule of the Hyksos

Asiatic rule brought many technical innovations to Egypt, as well as cultural innovations such as new musical instruments and musical styles. The changes affected techniques from bronze working and pottery to looms; and new breeds of animals and new crops were introduced. In warfare, composite bows, new types of daggers and scimitars, and above all the horse and chariot transformed previous practice, although the chariot may ultimately have been as important as a prestige vehicle as for tactical advantages it conferred. The effect of these changes was to bring Egypt, which had been technologically backward, onto the level of western Asia. Because of these advances and the perspectives it opened up, Hyksos rule was decisive for Egypt's later empire in the Near East.

Whereas the 13th dynasty was fairly prosperous, the Second Intermediate Period may have been impoverished. The regional centre of the cult of Osiris at Abydos, which has produced the largest quantity of Middle Kingdom monuments, lost importance, but sites such as Thebes, Idfū, and Kawm al-Aḥmar have yielded significant, if sometimes crudely worked, remains. Virtually no information has come from the north, where the Hyksos ruled, and it is impossible to assess their impact on the economy or on high culture. The Second Intermediate Period was the consequence of political fragmentation and immigration and was not associated with the severe economic collapse of the early First Intermediate Period.

Kamose's challenge of the Hyksos

Toward the end of the 17th dynasty (*c.* 1545 BC), the Theban king Seqenenre challenged Apopis, probably dying in battle against him. Seqenenre's successor, Kamose, renewed the challenge, stating in an inscription that it was intolerable to share his land with an Asiatic and a Nubian (the Karmah ruler). By the end of his third regnal year he had made raids as far south as the Second Cataract (and possibly much farther) and in the north to the neighbourhood of Avaris, also intercepting in the Western Desert a letter sent from Apopis to a new Karmah ruler on his accession. By campaigning to the north and to the south Kamose acted out his implicit claim to the territory ruled by Egypt in the Middle Kingdom. His exploits formed a vital stage in the long struggle to expel the Hyksos.

(J.R.Ba.)

THE NEW KINGDOM

The 18th dynasty. *Ahmose.* Although Ahmose (ruled *c.* 1539–14 BC) had been preceded by Kamose, who was either his father or brother, Egyptian tradition regarded Ahmose as the founder of a new dynasty because he was the native ruler who reunified Egypt. Continuing a recently inaugurated practice, he married his full sister Ahmose-Nofretari. The queen was given the title of God's Wife of Amon. Like her predecessors of the 17th dynasty, Queen Ahmose-Nofretari was influential and highly honoured. A measure of her importance was her posthumous veneration at Thebes, where later pharaohs were depicted offering to her as a goddess among the gods.

Ahmose was very young at his accession, and his campaigns to expel the Hyksos from the Delta and regain former Egyptian territory to the south probably started around

his 10th regnal year. Destroying the Hyksos stronghold at Avaris, in the eastern Delta, he finally drove them beyond the eastern frontier and then besieged Sharuhen (Tall al-Farʿah) in southern Palestine; the full extent of his conquests may have been much greater. His penetration of the Near East came at a time when there was no major established power in the region. This political gap facilitated the creation of an Egyptian "empire."

Ahmose's officers and soldiers were rewarded with spoil and captives, who became personal slaves. This marked the creation of an influential military class. Like Kamose, Ahmose campaigned as far south as Buhen. For the administration of the regained territory he created a new office, overseer of southern foreign lands, which ranked second only to the vizier. Its incumbent was accorded the honorific title of king's son, indicating that he was directly responsible to the king as deputy.

Administration

The early New Kingdom bureaucracy was modeled after that of the Middle Kingdom. The vizier was the chief administrator and the highest judge of the realm. By the middle of the 15th century BC the office had been divided into two, one vizier for Upper and one for Lower Egypt. During the 18th dynasty some young bureaucrats were educated in temple schools, reinforcing the integration of civil and priestly sectors. Early in the dynasty many administrative posts were inherited, but royal appointment of capable officials, often selected from military officers who had served the king on his campaigns, later became the rule. The trend was thus away from bureaucratic families and the inheritance of office.

Amenhotep I. Ahmose's son and successor, Amenhotep I (ruled *c.* 1514–1493 BC), pushed the Egyptian frontier southward to the Third Cataract, near the capital of the Karmah state, while also gathering tribute from his Asiatic possessions and perhaps campaigning in Syria. The emerging kingdom of Mitanni in northern Syria, which is first mentioned on a stela of one of Amenhotep's soldiers and was also known by the name of Nahrin, may have threatened Egypt's conquests to the north.

The New Kingdom saw increased devotion to the state god Amon-Re, whose cult gave the king, as his representative, the mission of expanding Egypt's frontiers. Amon-Re benefited as Egypt was enriched by the spoils of war. Riches were turned over to the god's treasuries, and the king had sacred monuments constructed at Thebes. Under Amenhotep I the pyramidal form of royal tomb was abandoned in favour of a rock-cut tomb, and, except for Akhenaton, all subsequent New Kingdom rulers were buried in concealed tombs in the famous Valley of the Kings in western Thebes. Separated from the tombs, royal mortuary temples were erected at the edge of the desert. Perhaps because of this innovation, Amenhotep I later became the patron deity of the workmen who excavated and decorated the royal tombs. The location of his own tomb is unknown.

Thutmose I and Thutmose II. Lacking a surviving heir, Amenhotep I was succeeded by one of his generals, Thutmose I (ruled 1493–*c.* 1482 BC), who married his own full sister Ahmose. In the south Thutmose destroyed the Karmah state. He inscribed a rock as a boundary marker, later confirmed by Thutmose III, near Kanisa-Kurgus, north of the Fifth Cataract. He then executed a brilliant campaign into Syria and across the Euphrates, where he erected a victory stela near Carchemish.

Thus in the reign of Thutmose I, Egyptian conquests in the Near East and Africa reached their greatest extent, but they may not yet have been firmly held. His little-known successor, Thutmose II (*c.* 1482–79 BC), continued his policies.

Hatshepsut and Thutmose III. At Thutmose II's death his queen and sister, Hatshepsut, had only a young daughter; but a minor wife had borne him a boy, who served as a priest in the Temple of Amon. This son, Thutmose III (ruled 1479–26 BC), later reconquered Egypt's Asiatic empire and became an outstanding ruler. During his first few regnal years Thutmose III theoretically controlled the land, but Hatshepsut governed as regent. Sometime between Thutmose III's second and seventh regnal years she assumed the kingship herself. According to one version of the event, the oracle of Amon proclaimed her king at Karnak, where she was crowned. A more propagandistic account, preserved in texts and reliefs of her splendid mortuary temple at Dayr al-Baḥrī, ignores the reign of Thutmose II and asserts that her father, Thutmose I, proclaimed her as his successor. Upon becoming king, Hatshepsut became the dominant partner in a joint rule that lasted until her death in about 1458 BC; there are monuments dedicated by Hatshepsut that depict both kings. She had the support of various powerful personalities, who did not, however, form a homogeneous faction; the most notable among them was Senenmut, the steward and tutor of her daughter Neferure. In styling herself king, Hatshepsut adopted the royal titulary but avoided the epithet "mighty bull," regularly employed by other kings. Although in her reliefs she was depicted as a male, pronominal references in the texts generally reflect her womanhood. Similarly, much of her statuary shows her in male form, but there are rarer examples that render her as a woman. In less formal documents she was referred to as "King's Great Wife," that is, "Queen," while Thutmose III was "King." There is thus a certain ambiguity in the treatment of Hatshepsut as king.

Hatshepsut's assumption of the kingship

Her temple reliefs depict pacific enterprises, such as the transporting of obelisks for Amon's temple and a commercial expedition to Punt; her art style looked back to Middle Kingdom ideals. Some warlike scenes are depicted, however, and she may have waged a campaign in Nubia. In one inscription she blamed the Hyksos for the supposedly poor state of the land before her rule, even though they had been expelled from the region more than a generation earlier.

During Hatshepsut's ascendancy Egypt's position in Asia deteriorated because of the expansion of Mitannian power in Syria. Shortly after her death, the Prince of Kadesh, a Syrian city, stood with troops of 330 princes of a Syro-Palestinian coalition at Megiddo; such a force was more than merely defensive and the intention may have been to advance against Egypt. The 330 must have represented all the places of any size in the region that were not subject to Egyptian rule and may be a schematic figure derived from a list of place-names. It is noteworthy that Mitanni itself was not directly involved.

Thutmose III proceeded to Gaza with his army and then to Yehem, subjugating rebellious Palestinian towns along the way. His annals relate how, at a consultation concerning the best route over the Mount Carmel ridge, the King overruled his officers and selected a shorter but more dangerous route through the ʿArūnah Pass and then led the troops himself. The march went smoothly, and when the Egyptians attacked at dawn they prevailed over the enemy troops and besieged Megiddo.

Thutmose III meanwhile coordinated the landing of other army divisions on the Syro-Palestinian littoral, whence they proceeded inland, so that the strategy resembled a pincer technique. The siege ended in a treaty by which Syrian princes swore an oath of submission to the King. As was normal in ancient diplomacy and in Egyptian practice, the oath was binding only upon those who swore it, not upon future generations.

By the end of the first campaign Egyptian domination extended northward to a line linking Byblos and Damascus. Although the Prince of Kadesh remained to be vanquished, Assyria sent lapis lazuli as tribute; Asiatic princes surrendered their weapons, including a large number of horses and chariots. Thutmose III took only a limited number of captives. He appointed Asiatic princes to govern the towns and took their brothers and sons to Egypt, where they were educated at the court. Most eventually returned home to serve as loyal vassals, though some remained in Egypt at court. In order to ensure the loyalty of Asiatic city-states, Egypt maintained garrisons that could quell insurrection and supervise the delivery of tribute. There never was an elaborate Egyptian imperial administration in Asia.

Thutmose III conducted numerous subsequent campaigns in Asia. The submission of Kadesh was finally achieved, but Thutmose III's ultimate aim was the defeat of Mitanni. He used the navy to transport troops to

Asiatic coastal towns, avoiding arduous overland marches from Egypt. His great eighth campaign led him across the Euphrates; although the countryside around Carchemish was ravaged, the city was not taken, and the Mitannian prince was able to flee. The psychological gain of this campaign was perhaps greater than its military success, for Babylonia, Assyria, and the Hittites all sent tribute in recognition of Egyptian dominance. Although Thutmose III never subjugated Mitanni, he placed Egypt's conquests on a firm footing by constant campaigning that contrasts with the forays of his predecessors. His annals inscribed in the temple of Karnak are remarkably succinct and accurate, but his other texts, notably one set up in his newly founded Nubian capital of Napata, are more conventional in their rhetoric.

Thutmose III initiated a truly imperial Egyptian rule in Nubia. Much of the land became estates of institutions in Egypt, while local cultural traits disappear from the archaeological record. Sons of chiefs were educated at the Egyptian court; a few returned to Nubia to serve as administrators—and some were buried there in Egyptian fashion. Nubian fortresses lost their strategic value and became administrative centres. Open towns developed around them, and in several temples outside their walls the cult of the divine king was established. Lower Nubia supplied gold from the desert and hard and semiprecious stones. From farther south came African woods, perfumes, oil, ivory, panther skins, and ostrich plumes. There is scarcely any trace of local population from the later New Kingdom, when many more temples were built in Nubia; by the end of the 20th dynasty the region had almost no prosperous settled population.

Under Thutmose III the wealth of empire became apparent in Egypt. Many temples were built and vast sums were donated to the estate of Amon-Re. There are many tombs of his high officials at Thebes. The capital had been moved to Memphis, but Thebes remained the religious centre.

The campaigns of kings like Thutmose III required a large military establishment, including a hierarchy of officers and a very expensive chariotry. The king grew up with military companions whose close connection with him enabled them to participate increasingly in government. Military officers were appointed to high civil and religious positions, and by the Ramesside period the influence of such people came to outweigh that of the traditional bureaucracy.

Amenhotep II. About two years before his death Thutmose III appointed his 18-year-old son, Amenhotep II (ruled *c.* 1426–1400 BC), as co-regent. Just prior to his father's death, Amenhotep II set out on a campaign to an area near Kadesh, in Syria, whose city-states were now caught up in the power struggle between Egypt and Mitanni; Amenhotep II killed seven princes and shipped their bodies back to Egypt to be suspended from the ramparts of Thebes and Napata. In his seventh and ninth years Amenhotep II made further campaigns into Asia, where the Mitannian king pursued a more vigorous policy. The revolt of the important coastal city of Ugarit was a serious matter, because Egyptian control over Syria required bases along the littoral for inland operations and the provisioning of the army. Ugarit was pacified, and the fealty of Syrian cities, including Kadesh, was reconfirmed.

Amenhotep II's campaigns into Asia

Thutmose IV. Amenhotep II's son Thutmose IV (ruled 1400–1390 BC) sought to establish peaceful relations with the Mitannian king Artatama, who had been successful against the Hittites. Artatama gave his daughter in marriage, the prerequisite for which was probably the Egyptian cession of some Syrian city-states to the Mitannian sphere of influence. This was the first such diplomatic marriage, paving the way for the age of Amenhotep III, when the emphasis shifted from war to diplomacy and the enjoyment of the luxury of empire.

Foreign influences during the early 18th dynasty. During the empire period Egypt maintained commercial ties with Phoenicia, Crete, and the Aegean islands. The Egyptians portrayed goods obtained through trade as foreign tribute. In the Theban tombs there are representations of Syrians bearing Aegean products and of Aegeans carrying Syrian bowls and amphorae—indicative of close commercial interconnections among Mediterranean lands. Egyptian ships trading with Phoenicia and Syria journeyed beyond to Crete and the Aegean, a route that explains the occasional confusion of products and ethnic types in Egyptian representations. The most prized raw material from the Aegean world was silver, which was lacking in Egypt, where gold was relatively abundant.

One result of empire was a new appreciation of foreign culture. Not only were foreign objets d'art imported into Egypt but Egyptian artisans imitated Aegean wares as well. Imported textiles inspired the ceiling patterns of Theban tomb chapels, and Aegean art with its spiral motifs and rendition of movement influenced Egyptian artists. Under Amenhotep II, Asiatic gods are found in Egypt: Astarte and Resheph became revered for their reputed potency in warfare, and Astarte was honoured also in connection with medicine, love, and fertility. Some Asiatic gods were eventually identified with similar Egyptian deities; thus, Astarte was associated with Sekhmet, the goddess of pestilence, and Resheph with Mont, the war god. Just as Asiatics resident in Egypt were incorporated into Egyptian society and could rise to important positions, so their gods, though represented as foreign, were worshiped according to Egyptian cult practices. The breakdown of Egyptian isolationism and increased cosmopolitanism in religion are also reflected in hymns that praise Amon-Re's concern for the welfare of Asiatics.

Amenhotep III. Thutmose IV's son Amenhotep III (ruled 1390–53 BC) acceded to the throne at about the age of 12. He soon wed Tiy, who became his queen. Earlier in the dynasty military men had served as royal tutors; but Tiy's father was a commander of the chariotry, and through this link the royal line became even more directly influenced by the military. In his fifth year Amenhotep III claimed a victory over Cushite rebels, but the Viceroy of Cush, the southern portion of Nubia, probably actually led the troops. The campaign may have led into the Butana, west of the ʿAṭbarah River, farther south than any previous Egyptian military expedition had gone. Several temples erected under Amenhotep III in Upper Nubia between the Second and Third cataracts attest to the importance of the region.

Peaceful relations prevailed with Asia, where control of Egypt's vassals was successfully maintained. A commemorative scarab from the king's 10th year announced the arrival in Egypt of the Mitannian princess Gilukhepa, along with 317 women; thus, another diplomatic marriage helped maintain friendly relations between Egypt and its former foe. Another Mitannian princess was later received into Amenhotep III's harem, and during his final illness the Hurrian goddess Ishtar of Nineveh was sent to his aid. At the expense of older bureaucratic families and the principle of inheritance of office, military men acquired high posts in the civil administration. Most influential was the aged scribe and commander of the elite troops, Amenhotep, son of Hapu, whose reputation as a sage survived into the Ptolemaic period.

Amenhotep III sponsored building on a colossal scale, especially in the Theban area. At Karnak he erected the huge third pylon, and at Luxor he dedicated a magnificent new temple to Amon. The King's own mortuary temple in western Thebes was unrivaled in its size; little remains of it today, but its famous Colossi of Memnon testify to its proportions. He also built a huge harbour and palace complex nearby. Some colossal statues served as objects of public veneration, before which men could appeal to the king's *ka,* which represented the transcendent aspect of kingship. In Karnak, statues of Amenhotep, son of Hapu, were placed to act as intermediaries between supplicants and the gods.

Among the highest-ranking officials at Thebes were men of Lower Egyptian background, who constructed large tombs with highly refined decoration. An eclectic quality is visible in the tombs, certain scenes of which were inspired by Old Kingdom reliefs. The revolutionary art of the succeeding Amarna period perhaps reflects a reaction against the studied perfection of Theban art. The earliest preserved important New Kingdom monuments from Memphis also date from this reign. Antiquarianism is ev-

idenced in Amenhotep III's celebration of his *sed* festivals (rituals of renewal celebrated after 30 years of rule), which were performed at his Theban palace in accordance, it was claimed, with ancient writings. Tiy, whose role was much more prominent than that of earlier queens, participated in these ceremonies.

Amenhotep III's last years were spent in ill health. To judge from his mummy and less formal representations of him from Amarna, he was obese when, in his 38th regnal year, he died and was succeeded by his son Amenhotep IV (ruled 1353–36 BC), the most controversial of all the kings of Egypt.

Amenhotep IV (Akhenaton). The earliest monuments of Amenhotep IV, who in his fifth regnal year changed his name to Akhenaton ("one useful to Aton"), are conventional in their iconography and style, but from the first he gave the sun god a didactic title naming Aton, the solar disk. This title was later written inside a pair of cartouches, as a king's name would be. The king declared his religious allegiance by the unprecedented use of "high priest of the sun god" as one of his own titles. The term Aton had long been in use, but under Thutmose IV the Aton had been referred to as a god, and under Amenhotep III those references became more frequent. Thus, Akhenaton did not create a new god but rather singled out this aspect of the sun god from among others. He also carried further radical tendencies that had recently developed in solar religion, in which the sun god was freed from his traditional mythological context and presented as the sole beneficent provider for the entire world. The King's own divinity was emphasized: the Aton was said to be his father, of whom he alone had knowledge, and they shared the status of king and celebrated jubilees together.

In his first five regnal years, Akhenaton built many temples to the Aton, of which the most important were in the precinct of the temple of Amon-Re at Karnak. In these open-air structures was developed a new, highly stylized form of relief and sculpture in the round. The Aton was depicted not in anthropomorphic form but as a solar disk from which radiating arms extend the hieroglyph for "life" to the noses of the king and his family. During the construction of these temples the cult of Amon and other gods was suspended, and the worship of the Aton in an open-air sanctuary superseded that of Amon, who had dwelt in a dark shrine of the Karnak temple. The King's wife Nefertiti, whom he had married before his accession, was prominent in the reliefs and had a complete shrine dedicated to her that included no images of the King. Her prestige continued to grow for much of the reign.

The transfer of the capital to Amarna

At about the time that he altered his name to conform with the new religion, the King transferred the capital to a virgin site at Amarna (now Tell el-Amarna) in Middle Egypt. There, he constructed a well-planned city—Akhetaton ("The Horizon of Aton")—comprising temples to the Aton, palaces, official buildings, villas for the high ranking, and extensive residential quarters. In the eastern desert cliffs surrounding the city, tombs were excavated for the courtiers; and deep within a secluded wadi the royal sepulchre was prepared. Reliefs in these tombs have been invaluable for reconstructing life at Amarna. The tomb reliefs and stelae portray the life of the royal family with an unprecedented degree of intimacy. They also show that the city was laid out as a great stage, on which the king's daily journeys from palace to city and back made manifest the passage of the sun across the sky.

In Akhenaton's ninth year a more monotheistic didactic name was given to the Aton, and an intense persecution of the older gods, especially Amon, was undertaken. Amon's name was excised from many older monuments throughout the land, and occasionally the word "gods" was expunged. This evidence suggests that the King's monotheistic fervour intensified.

Akhenaton's religious and cultural revolution was highly personal. The peculiar depiction of his physiognomy became the norm for representing not only members of the royal family but commoners as well. In religion the accent was upon the sun's life-sustaining power, and naturalistic scenes adorned the walls and even the floors of Amarna buildings. The king's role in determining the composition of the court is expressed in epithets given to officials he selected from the lesser ranks of society, including the military. Few officials had any connection with the old ruling elite, and some courtiers who had been accepted at the beginning of the reign were purged. Even at Amarna the new religion was not widely accepted below the level of the elite; numerous small objects relating to traditional beliefs have been found at the site.

Akhenaton's revolutionary intent is visible in all of his actions. In representational art, many existing conventions that had no special religious meaning were reversed to emphasize the break with the past. Such a procedure is comprehensible because traditional values were consistently incorporated in cultural expression as a whole; in order to change one part it was necessary to change the whole.

A vital innovation was the introduction of current vernacular forms into the written language. This led in later decades to the creation of new styles for monumental inscriptions and for everyday use. The latter variant, which is now known as Late Egyptian, was not fully developed until the later 19th dynasty.

Akhenaton's violent changes could not have been accomplished without the military, who are ubiquitous in the reliefs, especially from the Karnak temples. Akhenaton's foreign policy and use of force abroad are less well understood. He mounted one minor campaign in Nubia. In the Near East, Egypt's hold on its possessions was not as secure as earlier, but the cuneiform tablets found at Amarna recording his diplomacy are difficult to interpret because the vassals who requested aid from him exaggerated their plight. One reason for unrest in the region was the decline of Mitanni and the resurgence of the Hittites. Between the reign of Akhenaton and the end of the 18th dynasty, Egypt lost control of much territory in Syria.

The aftermath of Amarna. Akhenaton had six daughters by Nefertiti and one or two sons, perhaps by a secondary wife Kiya or by his own daughter Maketaton, who may have died in childbirth and whose infant son is shown in the royal tomb at Amarna. His immediate, ephemeral successor was a woman, possibly his eldest daughter Meritaton. Either she or the widow of Tutankhamen called on the Hittite king Suppiluliumas to supply a consort because she could find none in Egypt; a prince Zannanza was sent, but he was murdered as he reached Egypt. Thus Egypt never had a diplomatic marriage in which a foreign man was received into the country.

Succession of Tutankhaten (Tutankhamen)

After the brief rule of Smenkhkare (1335–32 BC), possibly a son of Akhenaton, Tutankhaten, a nine-year-old child, succeeded and was married to the much older Ankhesenpaaten, Akhenaton's third daughter. Around his third regnal year, the King moved his capital to Memphis, abandoned the Aton cult, and changed his and the Queen's names to Tutankhamen and Ankhesenamen. In an inscription recording Tutankhamen's actions for the gods, the Amarna period is described as one of misery and of the withdrawal of the gods from Egypt. This change, made in the name of the young king, was probably the work of high officials. The most influential were Ay, known by the title God's Father, who served as vizier and regent (his title indicates a close relationship to the royal family), and the general Horemheb, who functioned as royal deputy and whose tomb at Ṣaqqārah contains remarkable scenes of Asiatic captives being presented to the King.

Just as Akhenaton had adapted and transformed the religious thinking that was current in his time, the reaction to the religion of Amarna was influenced by the rejected doctrine. In the new doctrine, all gods were in essence three: Amon, Re, and Ptah (to whom Seth was later added), and in some ultimate sense they too were one. The earliest evidence of this triad is on a trumpet of Tutankhamen and is related to the naming of the three chief army divisions after these gods; religious and secular life were not separate. This concentration on a small number of essential deities may possibly be related to the piety of the succeeding Ramesside period, because both viewed the cosmos as being thoroughly permeated with the divine.

Under Tutankhamen a considerable amount of building was accomplished in Thebes. His Luxor colonnade bears detailed reliefs of the traditional beautiful festival of Opet;

at Karnak he decorated a structure with warlike scenes. He affirmed his legitimacy by referring back to Amenhotep III, whom he called his father. Tutankhamen's modern fame comes from the discovery of his rich burial in the Valley of the Kings. His tomb equipment was superior in quality to the fragments known from other royal burials, and the opulent display—of varying aesthetic value—represents Egyptian wealth at the peak of the country's power.

Ay and Horemheb. Tutankhamen's funeral in about 1323 BC was conducted by his successor, the aged Ay (ruled 1323–19 BC), who in turn was succeeded by Horemheb. The latter probably ruled from 1319 to *c.* 1292 BC, but the length of his poorly attested reign is not certain. Horemheb dismantled many monuments erected by Akhenaton and his successors and used the blocks as fill for huge pylons at Karnak. In this process Nefertiti's image seems to have been defaced more than others. At Karnak and Luxor he appropriated Tutankhamen's reliefs by surcharging the latter's cartouches with his own. Horemheb appointed new officials and priests not from established families but from the army. His policies concentrated on domestic problems. He issued police regulations dealing with the misbehaviour of palace officials and personnel, and he reformed the judicial system, reorganizing the courts and selecting new judges.

The Ramesside period (19th and 20th dynasties). Horemheb was the first post-Amarna king to be considered legitimate in the 19th dynasty, which looked to him as the founder of an epoch. Having no son, he selected his general and vizier, Ramses, to succeed him.

Ramses I and Seti I. Ramses I (ruled 1292–90 BC) hailed from the eastern Delta, and with the 19th dynasty there was a political shift into the Delta. Ramses I was succeeded by his son and co-regent, Seti I, who buried his father and provided him with mortuary buildings at Thebes and Abydos.

Seti I (ruled 1290–79 BC) was a successful military leader who reasserted authority over Egypt's weakened empire in the Near East. The Mitanni state had been dismembered and the Hittites had become the dominant Asiatic power. Before tackling them, Seti laid the groundwork for military operations in Syria by fighting farther south against nomads and Palestinian city-states; then, following the strategy of Thutmose III, he secured the coastal cities and gained Kadesh. Although his engagement with the Hittites was successful, Egypt acquired only temporary control of part of the north Syrian plain. A treaty was concluded with the Hittites who, however, subsequently pushed farther southward and regained Kadesh by the time of Ramses II. Seti I ended a new threat to Egyptain security when he defeated Libyans attempting to enter the Delta. He also mounted a southern campaign, probably to the Fifth Cataract region.

Seti I's reign looked for its model to the mid-18th dynasty and was a time of considerable prosperity. Seti I restored countless monuments that had been defaced in the Amarna period, and the refined decoration of his monuments, particularly his temple at Abydos, shows a classicizing tendency. He also commissioned striking and novel reliefs showing stages of his campaigns, which are preserved notably on the north wall of the great hypostyle hall at Karnak. This diversity of artistic approach is characteristic of the Ramesside period, which was culturally and ethnically pluralistic.

Ramses II. Well before his death, Seti I appointed his son Ramses II, sometimes called Ramses the Great, as crown prince. During the long reign of Ramses II (1279–13 BC) there was a prodigious amount of building, ranging from religious edifices throughout Egypt and Nubia to a new cosmopolitan capital, Pi Ramesse (Tall ad-Dab'a), in the eastern Delta; his cartouches were carved ubiquitously, often on earlier monuments. Ramses II's penchant for decorating vast temple walls with battle scenes gives the impression of a mighty warrior king. His campaigns were, however, relatively few, and after the first decade his reign was peaceful. The most famous scenes record the battle of Kadesh, fought in his fifth regnal year. These and extensive accompanying texts present the battle as an Egyptian victory, but in fact the opposing Hittite coalition fared at least as well as the Egyptians. After this inconclusive struggle, his officers advised him to make peace, saying, "There is no reproach in reconciliation when you make it." In succeeding years Ramses II campaigned in Syria; after a decade of stalemate, a treaty in his 21st year was concluded with Hattusilis III, the Hittite king.

Treaty with the Hittites

The rise of Assyria and unrest in western Anatolia encouraged the Hittites to accept this treaty, while Ramses II may have feared a new Libyan threat to the western Delta. Egyptian and Hittite versions of the treaty survive. It contained a renunciation of further hostilities, a mutual alliance against outside attack and internal rebellion, and the extradition of fugitives. The gods of both lands were invoked as witnesses. The treaty was further cemented 13 years later by Ramses II's marriage to a Hittite princess.

The King had an immense family by his numerous wives, among whom he especially honoured Nefertari. He dedicated a temple to her at Abu Simbel, in Nubia, and built a magnificent tomb for her in the Valley of the Queens.

For the first time in more than a millennium, princes were prominently represented on the monuments. Ramses II's fourth surviving son, Khaemwese, was famous as high priest of Ptah at Memphis. He restored many monuments in the Memphite area, including pyramids and pyramid temples of the Old Kingdom, and had buildings constructed near the Sarapeum at Ṣaqqārah. He was celebrated into Roman times as a sage and magician and became the hero of a cycle of stories.

Merneptah. Ramses II's 13th son, Merneptah (ruled 1213–04 BC), was his successor. Several of Merneptah's inscriptions, of unusual literary style, treat an invasion of the western Delta in his fifth year by Libyans, supported by groups of Sea Peoples who had traveled from Anatolia to Libya in search of new homes. The Egyptians defeated this confederation and settled captives in military camps to serve as Egyptian mercenaries.

One of the inscriptions concludes with a poem of victory (written about another battle), famous for its words, "Israel is desolated and has no seed." This is the earliest documented mention of Israel; it is generally assumed that the exodus of the Jews from Egypt took place under Ramses II.

Merneptah was able to hold most of Egypt's possessions, although early in his reign he had to reassert Egyptian suzerainty in Palestine, destroying Gezer in the process. Peaceful relations with the Hittites and respect for the treaty of Ramses II are indicated by Merneptah's dispatch of grain to them during a famine and by Egyptian military aid in the protection of Hittite possessions in Syria.

Last years of the 19th dynasty. Upon the death of Merneptah, competing factions within the royal family contended for the succession. Merneptah's son Seti II (ruled 1204–1198 BC) had to face a usurper, Amenmeses, who rebelled in Nubia and was accepted in Upper Egypt. His successor, Siptah, was installed on the throne by a Syrian royal butler, Bay, who had become chancellor of Egypt. Siptah was succeeded by Seti II's widow Tausert, who ruled as king from 1193 to 1190 BC, counting her regnal years from the death of Seti II, whose name she restored over that of Siptah. A description in a later papyrus of the end of the dynasty alludes to a Syrian usurper, probably Bay, who subjected the land to harsh taxation and treated the gods as mortals with no offerings in their temples.

The early 20th dynasty: Setnakht and Ramses III. Order was restored by a man of obscure origin, Setnakht (ruled 1190–87 BC), the founder of the 20th dynasty, who appropriated Tausert's tomb in the Valley of the Kings. An inscription of Setnakht recounts his struggle to pacify the land, which ended in the second of his three regnal years.

Setnakht's son Ramses III (ruled 1187–56 BC) was the last great king of the New Kingdom. There are problems in evaluating his achievements because he emulated Ramses II and copied numerous scenes and texts of Ramses II in his mortuary temple at Madīnat Habu, one of the best preserved temples of the empire period. Thus, the historicity of certain Nubian and Syrian wars depicted as his accomplishments is subject to doubt. He did, however, fight battles that were more decisive than any fought by

Ramses II. In his fifth year Ramses III defeated a large-scale Libyan invasion of the Delta in a battle in which thousands of the enemy perished.

A greater menace lay to the north, where a confederation of Sea Peoples was progressing by land and sea toward Egypt. This alliance of obscure tribes came south in the aftermath of the destruction of the Hittite empire. In his eighth regnal year Ramses III engaged them successfully on two frontiers—a land battle in Palestine and a naval engagement in one of the mouths of the Delta. Because of these two victories, Egypt did not undergo the political turmoil or experience the rapid technical advance of the early Iron Age in the Near East. Forced away from the borders of Egypt, the Sea Peoples sailed farther westward, and some of their groups may have given their names to the Sicilians, Sardinians, and Etruscans. The Philistine and Tjekker peoples, who had come by land, were established by the Egyptians in military camps in the southern Palestinian coastal district in an area where the overland trade route to Syria was threatened by attacks by nomads. Initially settled to protect Egyptian interests, these groups later became independent of Egypt. Ramses III used some of these peoples as mercenaries, even in battle against their own kinfolk. In his 11th year he successfully repulsed another great Libyan invasion by the Meshwesh tribes. Meshwesh prisoners of war, branded with the king's name, were settled in military camps in Egypt, and in later centuries their descendants became politically important because of their ethnic cohesiveness and their military role.

These great defensive wars drained the Egyptian economy. Under Ramses III the estate of Amon received only one-fifth as much gold as in Thutmose III's time. Although there are artistic masterpieces at Madīnat Habu, much of the relief inside the temple and the quality of the masonry betray a decline. Toward the end of his reign, administrative inefficiency and the deteriorating economic situation resulted in the government's failure to deliver grain rations on time to necropolis workers, whose dissatisfaction was expressed in demonstrations and in the first recorded strikes in history. Such demonstrations continued sporadically throughout the dynasty. A different sort of internal trouble originated in the royal harem, where a minor queen plotted unsuccessfully to murder Ramses III so that her son might become king. Involved in the plot were palace and harem personnel, government officials, and army officers. A special court of 12 judges was formed to try the accused, who received the death sentence.

Harem conspiracy against Ramses III

Many literary works date to the Ramesside period. Earlier works in Middle Egyptian were copied in schools and in good papyrus copies, and new texts were composed in Late Egyptian. Notable among the latter are stories, several with mythological or allegorical content, that look to folk models rather than to the elaborate written literary types of the Middle Kingdom.

Ramses IV. Ramses III was succeeded by his son Ramses IV (ruled 1156–50 BC). In an act of piety that also reinforced his legitimacy, Ramses IV saw to the compilation of a long papyrus in which the deceased Ramses III confirmed the temple holdings throughout Egypt; Ramses III had provided the largest benefactions to the Theban temples, in terms of donations of both land and personnel. Most of these probably endorsed earlier donations, to which each king added his own gifts. Of the annual income to temples, 86 percent of the silver and 62 percent of the grain was awarded to Amon. The document demonstrates the economic power of the Theban temples, for the tremendous landholdings of Amon's estate throughout Egypt involved the labour of a considerable portion of the population; but the ratio of temple to state income is not known, and the two were not administratively separate. In addition, the temple of Amon, which figures prominently in the papyrus, included within its estates the King's own mortuary temple, for Ramses III was himself deified as a form of Amon-Re, known as Imbued with Eternity.

The later Ramesside kings. The Ramesside period saw a tendency toward the formation of high-priestly families, which kings sometimes tried to counter by appointing outside men to the high priesthood. One such family had developed at Thebes in the second half of the 19th dynasty, and Ramses IV tried to control it by installing Ramessesnakht, the son of a royal steward, as Theban high priest. Ramessesnakht participated in administrative as well as priestly affairs; he personally led an expedition to the Wadi Ḥammāmāt (modern Wādī Rawḍ ʿĀ'id) quarries in the Eastern Desert, and at Thebes he supervised the distribution of rations to the workmen decorating the royal tomb. Under Ramses V (ruled 1150–45 BC), Ramessesnakht's son not only served as steward of Amon but also held the post of administrator of royal lands and chief taxing master. Thus, this family acquired extensive authority over the wealth of Amon and over state finances; but to what extent this threatened royal authority is uncertain. Part of the problem in evaluating the evidence is that Ramesside history is viewed from a Theban bias, because Thebes is the major source of information. Evidence from Lower Egypt, where the king normally resided, is meagre because of unfavourable conditions there for the preservation of monuments or papyri.

Rise in power of high-priestly families

A long papyrus from the reign of Ramses V contains valuable information on the ownership of land and taxation. In Ramesside Egypt most of the land belonged to the state and the temples, while most peasants served as tenant farmers. Some scholars interpret this document as indicating that the state retained its right to tax temple property, at an estimated one-tenth of the crop.

Ramses VI (ruled 1145–37 BC), probably a son of Ramses III, usurped much of his two predecessors' work, including the tomb of Ramses V; a papyrus refers to a possible civil war at Thebes. Following the death of Ramses III the Asiatic empire had rapidly withered away, and Ramses VI is the last king whose name appears at the Sinai turquoise mines. The next two Ramses (ruled 1137–26 BC) were obscure rulers, whose sequence has been questioned. During the reigns of Ramses IX (ruled 1126–08 BC) and Ramses X (1108–04 BC) there are frequent references in the papyri to the disruptions of marauding Libyans near the Theban necropolis.

By the time of Ramses IX the Theban high priest had attained great local influence, though he was still outranked by the king. Early in the reign of Ramses XI (ruled 1104–*c.* 1075 BC), during a civil war at Thebes, the high priest Amenhotep, the son of Ramessesnakht, was suppressed from his office for nine months; the King called upon Panehsy, the viceroy of Cush, to restore order and the fighting spread as far north as Middle Egypt. By Ramses XI's 19th regnal year the Viceroy was driven back and the new high priest of Amon, Herihor—who seems to have had a military background and also claimed the vizierate and the office of Viceroy of Cush—controlled the Theban area. In reliefs at the temple of Khons at Karnak, Herihor was represented as high priest of Amon in scenes adjoining those of Ramses XI. This in itself was unusual, but subsequently he took an even bolder step in having himself depicted as king to the exclusion of the still-reigning Ramses XI. Herihor's kingship was restricted to Thebes, where these years were referred to as a "repeating of [royal] manifestations," which lasted a decade.

With the shrinkage of the empire, the supply of silver and copper was cut off, and the amount of gold entering the economy was reduced considerably. During the reign of Ramses IX the economically distressed inhabitants of western Thebes were found to have pillaged the tombs of kings and nobles (already a common practice in the latter case); the despoiling continued into the reign of Ramses XI, and even the royal mortuary temples were stripped of their valuable furnishings. Nubian troops, called in to restore order at Thebes, themselves contributed to the depredation of monuments. This pillaging brought fresh gold and silver into the economy, and the price of copper rose. The price of grain, which had been inflating, dropped.

Despoiling of tombs

While Ramses XI was still king, Herihor died and was succeeded as high priest by Piankh, a man of similar military background. A series of letters from Thebes tell of Piankh's military venture in Nubia against the former Viceroy of Cush, while Egypt was on the verge of losing control of the south. With the death of Ramses XI, the governor of Tanis, Smendes, became king, founding the 21st dynasty (known as the Tanite).

The Ramesside growth of priestly power was matched by increasingly overt religiosity. Private tombs, the decoration of which had been mostly secular, came to include only religious scenes; oracles were invoked in many kinds of decisions; and private letters contain frequent references to prayer and to regular visits to small temples to perform rituals or consult oracles. The common expression used in letters, "I am all right today; tomorrow is in the hands of god," reflects the ethos of the age. This fatalism, which emphasizes that the god may be capricious and that his wishes cannot be known, is also typical of late New Kingdom Instruction Texts, which show a marked change from their Middle Kingdom forerunners by moving toward a passivity and quietism that suits a less expensive age.

Some of the religious material of the Ramesside period exhibits changes in conventions of display, and some categories have no parallel in the less abundant earlier record, but the shift is real as well as apparent. In its later periods, Egyptian society, the values of which had previously tended to be centralized, secular, and political, became more locally based and more thoroughly pervaded by religion, looking to the temple as the chief institution.

EGYPT FROM 1075 BC TO THE MACEDONIAN INVASION

The Third Intermediate Period (1075–656 BC). *The 21st dynasty.* At the end of the New Kingdom, then, Egypt was divided. The north was inherited by the Tanite 21st dynasty (1075–*c.* 950 BC), and much of the Nile Valley came under the control of the Theban priests (the northern frontier of their domain was the fortress town of al-Hība). Some Theban priests locally assumed the title of king, but there is no indication of conflict between the priests and the Tanite pharaohs. Indeed, the dating of documents, even at Thebes, was in terms of the Tanite reigns, and apparently there were close family ties between the pharaohs and the Thebans. Piankh's son, Pinudjem I, who relinquished the office of high priest and assumed the kingship at Thebes, was probably the father of the Tanite pharaoh Psusennes I. Some members of both the Theban priestly and the Tanite royal lines had Libyan names. With the coming of the new dynasty, and possibly a little earlier, the Meshwesh Libyan military elite, which had been settled mainly in the north by Ramses III, penetrated the ruling group, although it did not become dominant until the 22nd dynasty.

Beginning with Herihor and continuing through the 21st dynasty, the high priests' activities included the pious rewrapping and reburial of New Kingdom royal mummies. The ransacking of the royal tombs during the 20th dynasty necessitated the transfer of the royal remains in stages to two caches—the tomb of Amenhotep II and a cliff tomb at Dayr al-Baḥrī—where they remained undisturbed until modern times. Dockets pertaining to the reburial of these mummies contain important chronological data from the 21st dynasty.

The burials of King Psusennes I (ruled *c.* 1045–*c.* 997 BC) and his successor, Amenemope (ruled *c.* 998–*c.* 989 BC), were discovered at Tanis, but little is known of their reigns. This was a period of the usurpation of statuary and the reuse of material of earlier periods. At Karnak, Pinudjem I, who decorated the facade of the Khons temple, usurped a colossal statue of Ramses II, and Psusennes I's splendid sarcophagus from Tanis had originally been carved for Merneptah. Much of the remains from Tanis comprises material transported from other sites, notably from Pi Ramesse.

After the demise of Egypt's Asiatic empire, the kingdom of Israel eventually developed under the kings David and Solomon. During David's reign, Philistia served as a buffer between Egypt and Israel; but upon David's death the next to the last king of the 21st dynasty, Siamon, invaded Philistia and captured Gezer. If Egypt had any intention of attacking Israel, Solomon's power forestalled Siamon, who presented Gezer to Israel as a dowry in the diplomatic marriage of his daughter to Solomon. This is indicative of the reversal of Egypt's status in foreign affairs since the time of Amenhotep III, who had written the Babylonian king, "From of old, a daughter of the king of Egypt has not been given to anyone."

Siamon's presentation of Gezer to Israel

Libyan rule: the 22nd and 23rd dynasties. The fifth king of the 21st dynasty, Osorkon I (ruled *c.* 979–*c.* 973 BC), was of Libyan descent and probably was an ancestor of the 22nd dynasty, which followed a generation later. From his time to the 26th dynasty, leading Libyans in Egypt kept their Libyan names and ethnic identity, but in a spirit of ethnicity rather than cultural separatism. Although political institutions were different from those of the New Kingdom, the Libyans were culturally Egyptian, retaining only their group identity, names, and perhaps a military ethos. Toward the end of the 21st dynasty the Libyan leader of Bubastis, the great Meshwesh chief Sheshonk I (the biblical Shishak), secured special privileges from King Psusennes II (ruled *c.* 964–*c.* 950 BC) and the oracle of Amon for the mortuary cult of his father at Abydos. The oracle proffered good wishes not only for Sheshonk and his family but, significantly, also for his army. With a strong military backing, Sheshonk eventually took the throne. His reign (*c.* 950–929 BC) marks the founding of the 22nd dynasty (*c.* 950–*c.* 730 BC). Military controls were established, with garrisons under Libyan commandants serving to quell local insurrections, so that the structure of the state became more feudalistic. The dynasty tried to cement relations with Thebes through political marriages with priestly families. King Sheshonk's son Osorkon married Psusennes II's daughter, and their son eventually became high priest at Karnak. By installing their sons as high priests and promoting such marriages, kings strove to overcome the administrative division of the country. But frequent conflicts arose over the direct appointment of the Theban high priest from among the sons of Libyan kings and over the inheritance of the post by men of mixed Theban and Libyan descent. This tension took place against a background of Theban resentment of the northern dynasty. During the reign of Takelot II, strife concerning the high priestship led to civil war at Thebes. The King's son Osorkon was appointed high priest, and he achieved some semblance of order during his visits to Thebes, but he was driven from the post several times.

Renewed influence in Palestine

The initially successful 22nd dynasty revived Egyptian influence in Palestine. After Solomon's death (*c.* 936), Sheshonk I entered Palestine and plundered Jerusalem. Prestige from this exploit may have lasted through the reign of Osorkon II (formerly numbered I; ruled *c.* 929–*c.* 914 BC). In the reign of Osorkon III (ruled *c.* 888–*c.* 860 BC), Peywed Libyans posed a threat to the western Delta, perhaps necessitating a withdrawal from Palestine.

The latter part of the dynasty was marked by fragmentation of the land: Libyan great chiefs ruled numerous local areas, and there were as many as six kings in the land at a time. Increased urbanization accompanied this fragmentation, which was most intense in the Delta. Meanwhile, in Thebes, a separate 23rd dynasty was recognized.

From the 9th century BC a local Cushite state, which looked to Egyptian traditions from the colonial period of the New Kingdom, arose in the Sudan and developed around the old regional capital of Napata. The earliest ruler of the state known by name was Alara, whose piety toward Amon is mentioned in several inscriptions. His successor, Kashta, proceeded into Upper Egypt, forcing Osorkon IV (ruled *c.* 777–*c.* 750 BC) to retire to the Delta. Kashta assumed the title of king and compelled Osorkon IV's daughter Shepenwepe I, the God's Wife of Amon at Thebes, to adopt his own daughter Amonirdis I as her successor. The Cushites stressed the role of the God's Wife of Amon, who was a virgin and the consecrated partner of Amon, and sought to bypass the high priests.

The 24th and 25th dynasties. Meanwhile, the eastern Delta capital, Tanis, lost its importance to Sais in the western Delta. A Libyan prince of Sais, Tefnakhte, attempting to gain control over all Egypt, proceeded southward to Heracleopolis after acquiring Memphis. This advance was met by the Cushite ruler Piye (now the accepted reading of "Piankhi," ruled *c.* 750–*c.* 719 BC), who executed a raid as far north as Memphis and received the submission of the northern rulers (in about 730 BC). In his victory stela, Piye is portrayed as conforming strictly to Egyptian norms and reasserting traditional values against contemporary decay.

Upon Piye's return to Cush, Tefnakhte reasserted his

authority in the north, where he was eventually succeeded by his son Bocchoris, according to Manetho the sole king of the 24th dynasty (*c.* 722–*c.* 715 BC). Piye's brother Shabaka meanwhile founded the rival 25th dynasty and brought all Egypt under his rule (*c.* 719–703 BC). He had Bocchoris burned alive and removed all other claimants to the kingship.

Growth of the Assyrian Empire

In this period Egypt's internal politics were affected by the growth of the Assyrian Empire. In Palestine and Syria frequent revolts against Assyria were aided by Egyptian forces. Against the power of Assyria, the Egyptian and Nubian forces met with little success, partly because of their own fragmented politics and divided loyalties.

Although the earlier years of King Taharqa (ruled 690–664 BC), who as second son of Shabaka had succeeded his brother Shebitku (ruled 703–690 BC), were prosperous, the confrontation with Assyria became acute. In 671 BC the Assyrian king Esarhaddon entered Egypt and drove Taharqa into Upper Egypt. Two years later Taharqa regained a battered Memphis, but in 667 BC Esarhaddon's successor, Ashurbanipal, forced Taharqa to Thebes, where the Cushites held ground. Taharqa's successor, Tanutamon, defeated at Memphis a coalition of Delta princes who supported Assyria, but Ashurbanipal's reaction to this was to humiliate Thebes, which the Assyrians plundered. By 656 the Cushites had withdrawn from the Egyptian political scene, although Cushite culture survived in the Sudanese Napatan and Meroitic kingdom for another millennium.

The Late Period (664–332 BC). *The 26th dynasty (664–525 BC).* Assyria, unable to maintain a large force in Egypt, supported several Delta vassal princes, including the powerful Psamtik I of Sais. But the Assyrians faced serious problems closer to home, and Psamtik (or Psammetichus I, ruled 664–610 BC) was able to assert his independence and extend his authority as king over all Egypt without extensive use of arms, inaugurating the Saite 26th dynasty. In 656 Psamtik I compelled Thebes to submit. He allowed its most powerful man, who was Montemhat, the mayor and the fourth prophet of Amon, to retain his post and, in order to accommodate pro-Cushite sentiments, he allowed the God's Wife of Amon and the Votaress of Amon (the sister and daughter of the late king Taharqa) to remain. Psamtik I's own daughter Nitocris was adopted by the Votaress of Amon and thus became heiress to the position of God's Wife. Essential to the settling of internal conflicts was the Saite dynasty's superior army, composed of Libyan soldiers, whom the Greeks called Machimoi (warriors), and Greek and Carian mercenaries, who formed part of the great emigration from the Aegean in the 7th and 6th centuries BC. Greek pirates raiding the Delta coast were induced by Psamtik I to serve in his army and were settled like the Machimoi in colonies at the Delta's strategically important northeastern border. Trade developed between Egypt and Greece, and more Greeks settled in Egypt.

Foreign policy under the Saites

The Saite dynasty generally pursued a foreign policy that avoided territorial expansion and tried to preserve the status quo. Assyria's power was waning. In 655 BC Psamtik I marched into Philistia in pursuit of the Assyrians, and in 620 BC he apparently repulsed Scythians from the Egyptian frontier. During the reign of his son Necho II (610–595 BC), Egypt supported Assyria as a buffer against the potential threat of the Medes and the Babylonians. Necho was successful in Palestine and Syria until 605 BC, when the Babylonian Nebuchadrezzar inflicted a severe defeat on Egyptian forces at Carchemish. After withdrawing his troops from Asia, Necho concentrated on developing Egyptian commerce; the grain that was delivered to Greece was paid for in silver. He also built up the navy and began a canal linking the Nile with the Red Sea. Under Psamtik II (ruled 595–589 BC) there was a campaign through the Napatan kingdom involving the use of Greek and Carian mercenaries who left their inscriptions at Abu Simbel; at the same time the names of the long-dead Cushite rulers were erased from their monuments in Egypt. Psamtik II also made an expedition to Phoenicia accompanied by priests; whether it was a military or a goodwill mission is unknown.

The next king, Apries (ruled 589–570 BC), tried unsuccessfully to end Babylonian domination of Palestine and Syria. With the withdrawal of Egyptian forces, Nebuchadrezzar destroyed the temple in Jerusalem in 586 BC. In the aftermath of his conquest, many Jews fled to Egypt, where some were enlisted as soldiers in the Persian army of occupation. Apries' army was then defeated in Libya when it attacked the Greek colony at Cyrene, some 620 miles west of the Delta; this led to an army mutiny and to civil war in the Delta. A new Saite king, Amasis (or Ahmose II; ruled 570–526 BC), usurped the throne and drove Apries into exile. Two years later Apries invaded Egypt with Babylonian support, but he was defeated and killed by Amasis, who nonetheless buried him with full honours. Amasis returned to a more conservative foreign policy in a long, prosperous reign. To reduce friction between Greeks and Egyptians, especially in the army, Amasis withdrew the Greeks from the military colonies and transferred them to Memphis, where they formed a sort of royal bodyguard. He limited Greek trade in Egypt to Sais, Memphis, and Naukratis, the latter becoming the only port to which Greek wares could be brought, so that taxes on imports and on business could be enforced. Naukratis prospered and Amasis was seen by the Greeks as a benefactor. In foreign policy he supported a waning Babylonia, now threatened by Persia; but six months after his death in 526 BC the Persian Cambyses II (ruled as pharaoh 525–522 BC) penetrated Egypt, reaching Nubia in 525.

Nationalism and cultural revival

As was common in the Near East in this period, the Saite kings used foreigners as mercenaries to prevent foreign invasions. An element within Egyptian culture, however, resisted any influence of the resident foreigners and gave rise to a nationalism that provided psychological security in days of political uncertainty. A cultural revival was initiated in the 25th dynasty and continued throughout the 26th. Temples and the priesthood were overtly dominant. In their inscriptions the elite displayed their priestly titles but did not mention the administrative roles that they probably also performed. Throughout the country, people of substance dedicated land to temple endowments that supplemented royal donations. The god Seth, who had been an antithetic element in Egyptian religion, came gradually to be proscribed as the god of foreign lands.

The revival of this period was both economic and cultural, but there is less archaeological evidence preserved than for earlier times because the economic centre of the country was now the Delta, where conditions for the preservation of ancient sites were unfavourable. Prosperity increased throughout the 26th dynasty, reaching a high point in the reign of Amasis. Temples throughout the land were added to, often in hard stones carved with great skill. The chief memorials of private individuals were often temple statues, of which many fine examples were dedicated, again mostly in hard stones. In temple and tomb decoration and in statuary, the Late Period rejected its immediate predecessors and looked to the great periods of the past for models. There was, however, also significant innovation. In writing, the demotic script, the new cursive form, was introduced from the north and spread gradually through the country. Demotic wrote a contemporary form of the language, and administrative Late Egyptian disappeared. Hieratic was, however, retained for literary and religious texts, among which very ancient material, such as the Pyramid Texts, was revived and inscribed in tombs and on coffins and sarcophagi.

The Late Period saw the greatest development of animal worship in Egypt. This feature of religion, which was the subject of much interest and scorn among classical writers, had always existed but had been of minor importance. In the Late and Ptolemaic periods, it became one of the principal forms of popular religion in an intensely religious society. Many species of animal were mummified and buried, and towns sprang up in the necropolises to cater for the needs of dead animals and their worshipers. At Ṣaqqārah the Apis bull, which had been worshiped as a manifestation of the god Ptah since the 1st dynasty, was buried in a huge granite sarcophagus in ceremonies in which royalty might take part. At least 10 species, from ibises, buried by the million, to dogs, were buried by the

heterogeneous population of Memphis, Egypt's largest city.

Egypt under Achaemenid rule. *The 27th dynasty.* According to the Greek historian Herodotus, who visited Egypt around 450 BC, Cambyses II's conquest of Egypt was ruthless and sacrilegious. Contemporary Egyptian sources, however, treat him in a more favourable light. He assumed the full titulary of an Egyptian king and paid honour to the goddess Neith of Sais. His unfavourable later reputation probably resulted from adverse propaganda by Egyptian priests, who resented his reduction of temple income. Darius I, who succeeded Cambyses in 522 BC and ruled as pharaoh until 486 BC, was held in higher esteem because he was concerned with improving the temples and restored part of their income, and because he codified laws as they had been in the time of Amasis. These stances, which aimed to win over priests and learned Egyptians, were elements of his strategy to retain Egypt as a lasting part of the Persian Empire. Egypt, together with the Libyan oases and Cyrenaica, formed the sixth Persian satrapy (province), whose satrap resided at Memphis, while Persian governors under him held posts in cities throughout the land. Under Darius I the tax burden upon Egyptians was relatively light, and Persians aided Egypt's economy through irrigation projects and improved commerce, enhanced by the completion of the canal to the Red Sea.

The Persian defeat by the Athenians at Marathon in 490 BC had significant repercussions in Egypt. On Darius I's death in 486 BC a revolt broke out in the Delta, perhaps instigated by Libyans of the west Delta. The result was that the Persian king Xerxes reduced Egypt to the status of a conquered province. Egyptians dubbed him the "criminal Xerxes." He never visited Egypt and appears not to have utilized Egyptians in high positions in the administration. Xerxes' murder in 465 BC was the signal for another revolt in the western Delta. It was led by a dynast, Inaros, who acquired control over the Delta and was supported by Athenian forces against the Persians. Inaros was crucified by the Persians in 454 BC, when they regained control of most of the Delta. In the later 5th century BC, under the rule of Artaxerxes I (ruled as pharaoh 465–424 BC) and Darius II (ruled as pharaoh 424–404 BC), conditions in Egypt were very unsettled, and scarcely any monuments of the period have been identified.

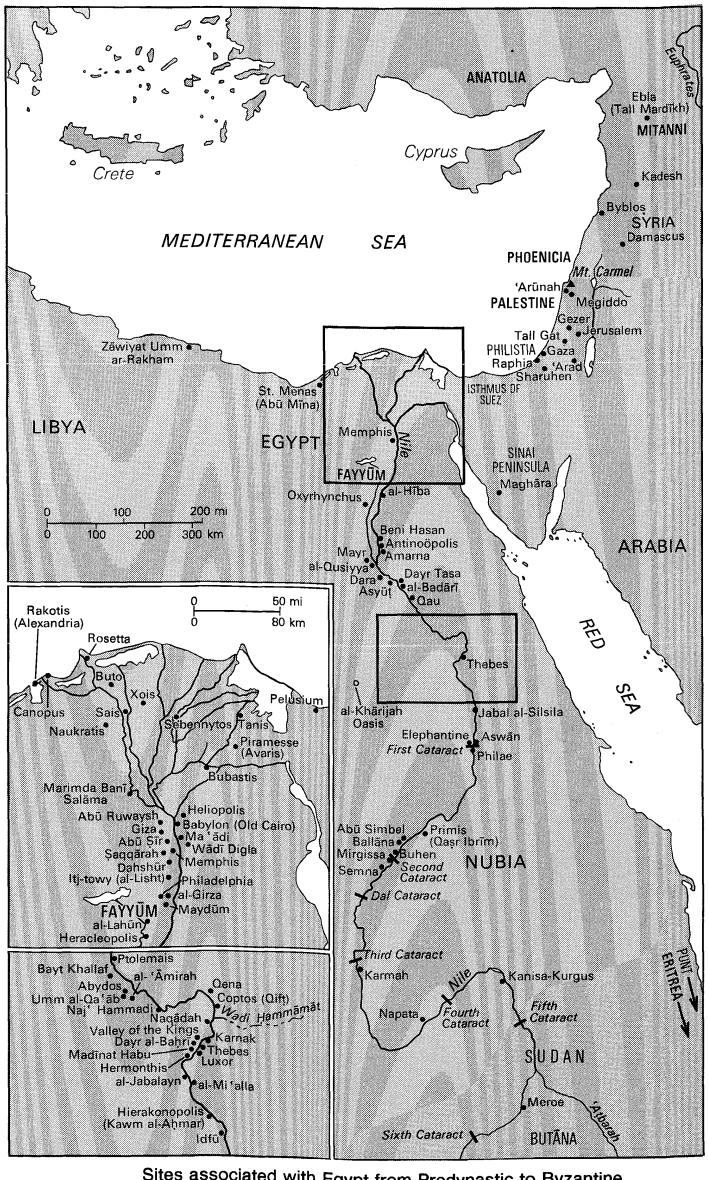
The 28th, 29th, and 30th dynasties. The death of Darius II in 404 BC prompted a successful rebellion in the Delta, and the Egyptian Amyrtaeus formed a Saite 28th dynasty, of which he was the sole king (404–399 BC). His rule was recognized in Upper Egypt by 401 BC, at a time when Persia's troubles elsewhere forestalled an attempt to regain Egypt.

Despite growing prosperity and success in retaining independence, 4th-century Egypt was characterized by continual internal struggle for the throne. After a long period of fighting in the Delta, a 29th dynasty (399–380 BC) emerged from Mendes. Achoris (ruled 393–380 BC), its third and final ruler, was especially vigorous, and the prosperity of his reign is indicated by many monuments in Upper and Lower Egypt. Once again Egypt was active in international politics, forming alliances with the opponents of Persia and building up its army and navy. The Egyptian army included Greeks both as mercenaries and as commanders; the mercenaries were not permanent residents of military camps in Egypt but native Greeks seeking payment for their services in gold. Payment was normally made in non-Egyptian coins, because as yet Egypt had no coinage in general circulation; the foreign coins may have been acquired in exchange for exports of grain, papyrus, and linen. Some Egyptian coins were minted in the 4th century, but they do not seem to have gained widespread acceptance.

Aided by the Greek commander Chabrias of Athens and his elite troops, Achoris prevented a Persian invasion; but after Achoris' death in 380 BC his son Nepherites II lasted only four months before a general, Nectanebo I (Nekhtnebef; ruled 380–362 BC) of Sebennytos, usurped the throne, founding the 30th dynasty (380–343 BC). In 373 BC the Persians attacked Egypt, and, although Egyptian losses were heavy, disagreement between the Persian satrap Pharnabazus and his Greek commander over strategy, combined with a timely inundation of the Delta, saved the day for Egypt. With the latent dissolution of the Persian Empire under the weak Artaxerxes II, Egypt was relatively safe from further invasion; it remained prosperous throughout the dynasty.

Egypt had a more aggressive foreign policy under Nectanebo's son Tachos (ruled *c.* 365–360 BC). Possessing a strong army and navy composed of Egyptian Machimoi and Greek mercenaries and supported by Chabrias and the Spartan king Agesilaus, Tachos (in Egyptian called Djeho) invaded Palestine. But friction between Tachos and Agesilaus and the cost of financing the venture proved to be Tachos' undoing. In an attempt to raise funds quickly, he had imposed taxes and seized temple property. Egyptians, especially the priests, resented this burden and supported Tachos' nephew Nectanebo II (Nekhtharehbe; ruled 360–343 BC) in his usurpation of the throne. The cost of retaining the allegiance of mercenaries proved too high for a nonmonetary economy.

Agesilaus supported Nectanebo in his defensive foreign policy, and the priests sanctioned the new king's building activities. Meanwhile, Persia enjoyed a resurgence under Artaxerxes III (Ochus); but a Persian attack upon Egypt in 350 BC was repulsed. In 343 BC the Persians once again marched against Egypt. The first battle was fought at Pelusium and proved the superiority of Persia's strategy.



Sites associated with Egypt from Predynastic to Byzantine times.

Eventually the whole Delta, then the rest of Egypt, fell to Artaxerxes III, and Nectanebo fled to Nubia.

The 4th century BC was the last flourishing period of an independent Egypt and saw notable artistic and literary achievements. The 26th dynasty artistic revival evolved further toward more complex forms that culminated briefly in a Greco-Egyptian stylistic fusion, as seen in the tomb of Petosiris at Tūnah al-Jabal from the turn of the 3rd century BC. In literature works continued to be transmitted, and possibly composed, in hieratic, but that tradition was to develop no further. Demotic literary works began to appear, including stories set in the distant past, mythological tales, and an acrostic text apparently designed to teach an order of sounds in the Egyptian language.

Return of Persian rule

The second Persian period. Artaxerxes dealt harshly with Egypt, razing city walls, rifling temple treasuries, and removing sacred books. Persia acquired rich booty in its determination to prevent Egypt from further rebelling. After the murder of Artaxerxes III, in 338 BC, there was a brief obscure period during which a Nubian prince, Khabbash, seems to have gained control over Egypt, but Persian domination was reestablished in 335 BC under Darius III Codommanus. It was to last only three years.

(E.F.W./J.R.Ba.)

MACEDONIAN AND PTOLEMAIC EGYPT (332–30 BC)

The Macedonian conquest. In the autumn of 332 BC Alexander the Great invaded Egypt with his mixed army of Macedonians and Greeks and found the Egyptians ready to throw off the oppressive control of the hated Persians.

Alexander's welcome in Egypt

Alexander was welcomed by the Egyptians as a liberator and took the country without a battle. He journeyed to Siwa Oasis in the Western Desert to visit the Oracle of Amon, renowned in the Greek world; it disclosed the information that Alexander was the son of Amon. There may also have been a coronation at the Egyptian capital, Memphis, which, if it occurred, would have placed him firmly in the tradition of the pharaohs; the same purpose may be seen in the later dissemination of the romantic myth that gave him an Egyptian parentage by linking his mother, Olympias, with the last pharaoh, Nectanebo II.

Alexander left Egypt in the spring of 331 BC, dividing the military command between Balacrus, son of Amyntas, and Peucestas, son of Makartatos. The earliest known Greek documentary papyrus, found at Ṣaqqārah in 1973, reveals the sensitivity of the latter to Egyptian religious institutions in a notice that reads: "Order of Peucestas. No-one is to pass. The chamber is that of a priest." The civil administration was headed by an official with the Persian title of satrap, one Cleomenes of Naukratis. When Alexander died in 323 BC and his generals divided his empire, the position of satrap was claimed by Ptolemy, son of a Macedonian nobleman named Lagus. The senior general Perdiccas, the holder of Alexander's royal seal and prospective regent for Alexander's posthumous son, might well have regretted his failure to take Egypt. He gathered an army and marched from Asia Minor to wrest Egypt from Ptolemy in 321 BC; but Ptolemy had Alexander's corpse, Perdiccas' army was not wholehearted in support, and the Nile crocodiles made a good meal from the flesh of the invaders.

The Ptolemaic dynasty. Until the day when he openly assumed an independent kingship as Ptolemy I Soter, on Nov. 7, 305 BC, Ptolemy used only the title satrap of Egypt, but the great hieroglyphic Satrap stela, which he had inscribed in 311 BC, indicates a degree of self-confidence that transcends his viceregal role. It reads, "I, Ptolemy the satrap, I restore to Horus, the avenger of his father, the lord of Pe and to Buto, the lady of Pe and Dep, the territory of Patanut, from this day forth for ever, with all its villages, all its towns, all its inhabitants, all its fields." The inscription emphasizes Ptolemy's own role in wresting the land from the Persians (though the epithet of Soter, meaning "Saviour," resulted not from his actions in Egypt but from the gratitude of the people of Rhodes for his having relieved them from a siege in 315 BC) and links him with Khabbash, who had laid claim to the kingship during the last Persian occupation in about 338 BC.

Egypt was ruled by Ptolemy's descendants until the death of Cleopatra VII on Aug. 12, 30 BC. The kingdom was one of several that emerged in the aftermath of Alexander's death and struggles of his successors. It was the wealthiest, however, and, for much of the next 300 years, the most powerful politically and culturally, and it was the last to fall directly under Roman dominion. In many respects, the character of the Ptolemaic monarchy in Egypt set a style for other Hellenistic kingdoms; this style emerged from the Greeks' and Macedonians' awareness of the need to dominate Egypt, its resources, and its people and at the same time to turn the power of Egypt firmly toward the context of a Mediterranean world that was becoming steadily more Hellenized.

The Ptolemies (305–145 BC). The first 160 years of the Ptolemaic dynasty are conventionally seen as its most prosperous era. Little is known of the foundations laid in the reign of Ptolemy I Soter (304–282 BC), but the increasing amount of documentary, inscriptional, and archaeological evidence from the reign of his son and successor, Ptolemy II Philadelphus (285–246 BC), shows that the kingdom's administration and economy underwent a thorough reorganization. A remarkable demotic text of the year 258 BC refers to orders for a complete census of the kingdom that was to record the sources of water; the position, quality, and irrigation potential of the land; the state of cultivation; the crops grown; and the extent of priestly and royal landholdings. There were important agricultural innovations in this period. New crops were introduced, and massive irrigation works brought under cultivation a great deal of new land, especially in the Fayyūm, where many of the immigrant Greeks were settled.

Macedonian-Greek character of the monarchy

The Macedonian-Greek character of the monarchy was vigorously preserved. There is no more emphatic sign of this than the growth and importance of the city of Alexandria. It had been founded, on a date traditionally given as April 7, 331 BC, by Alexander the Great on the site of the insignificant Egyptian village of Rakotis in the northwestern Delta, and it ranked as the most important city in the eastern Mediterranean until the foundation of Constantinople in the 4th century AD. The importance of the new Greek city was soon emphasized by contrast to its Egyptian surroundings when the royal capital was transferred, within a few years of Alexander's death, from Memphis to Alexandria. The Ptolemaic court cultivated extravagant luxury in the Greek style in its magnificent and steadily expanding palace complex, which occupied as much as a third of the city by the early Roman period. Its grandeur was emphasized in the reign of Ptolemy II Philadelphus by the foundation of a quadrennial festival, the Ptolemaieia, which was intended to enjoy a status equal to that of the Olympic Games. The festival was marked by a procession of amazingly elaborate and ingeniously constructed floats, with scenarios illustrating Greek religious cults.

Ptolemy II gave the dynasty another distinctive feature when he married his full sister, Arsinoe II, one of the most powerful and remarkable women of the Hellenistic age. They became, in effect, co-rulers, and both took the epithet Philadelphus ("Brother-Loving" and "Sister-Loving"). The practice of consanguineous marriage was followed by most of their successors and imitated by ordinary Egyptians too, even though it had not been a standard practice in the pharaonic royal houses and had been unknown in the rest of the native Egyptian population. Arsinoe played a prominent role in the formation of royal policy. She was displayed on the coinage and was eventually worshiped, perhaps even before her death, in the distinctively Greek style of ruler cult that developed in this reign.

Ptolemaic empire

From the first phase of the wars of Alexander's successors the Ptolemies had harboured imperial ambitions. Ptolemy I won control of Cyprus and Cyrene and quarreled with his neighbour over control of Palestine. In the course of the 3rd century a powerful Ptolemaic empire developed, which, for much of the period, laid claim to sovereignty in the Levant, in many of the cities of the western and southern coast of Asia Minor, in some of the Aegean islands, and in a handful of towns in Thrace, as well as in Cyprus and Cyrene. Family connections and dynastic alliances, especially between the Ptolemies and the neigh-

bouring Seleucids, played a very important role in these imperialistic ambitions. Such links were far from able to preserve harmony between the royal houses (between 274 and 200 BC five wars were fought with the Seleucids over possession of territory in Syria and the Levant), but they did keep the ruling houses relatively compact, interconnected, and more true to their Macedonian-Greek origins.

When Ptolemy II Philadelphus died in 246 BC, he left a prosperous kingdom to his successor, Ptolemy III Euergetes (246–222 BC). His reign saw a very successful campaign against the Seleucids in Syria, occasioned by the murder of Euergetes' sister, Berenice, who had been married to the Seleucid Antiochus II. To avenge Berenice, Euergetes marched into Syria, where he won a great victory. He gained popularity at home by recapturing statues of Egyptian gods originally taken by the Persians. The decree promulgated at Canopus in the Delta on March 4, 238 BC, attests both this event and the many great benefactions conferred on Egyptian temples throughout the land. It was during Euergetes' reign, for instance, that the rebuilding of the great Temple of Horus at Idfū (Apollinopolis Magna) was begun.

Euergetes was succeeded by his son Ptolemy IV Philopator (222–205 BC), whom the Greek historians portray as a weak and corrupt ruler, dominated by a powerful circle of Alexandrian Greek courtiers. The reign was notable for another serious conflict with the Seleucids, which ended in 217 BC in a great Ptolemaic victory at Raphia in southern Palestine. The battle is notable for the fact that large numbers of native Egyptian soldiers fought alongside the Macedonian and Greek contingents. Events surrounding the death of Philopator and the succession of the youthful Ptolemy V Epiphanes (205–180 BC) are obscured by court intrigue. Before Epiphanes had completed his first decade of rule, serious difficulties arose. Native revolts in the south, which had been sporadic in the second half of the 3rd century, became serious and weakened the hold of the monarch on a vital part of the kingdom. These revolts, which produced native claimants to the kingship, are generally attributed to the native Egyptians' realization, after their contribution to the victory at Raphia, of their potential power. Trouble continued to break out for several more decades. By about 196 a great portion of the Ptolemaic overseas empire had been permanently lost (though there may have been a brief revival in the Aegean islands in about 165–145 BC). To shore up and advertise the strength of the ruling house at home and abroad, the administration adopted a series of grandiloquent honorific titles for its officers. To conciliate Egyptian feelings, a religious synod that met in 196 to crown Epiphanes at Memphis (the first occasion on which a Ptolemy is certainly known to have been crowned at the traditional capital) decreed extensive privileges for the Egyptian temples, as recorded on the Rosetta Stone.

Loss of the overseas empire

The reign of Ptolemy VI Philometor (180–145 BC), a man of pious and magnanimous character, was marked by renewed conflict with the Seleucids after the death of his mother, Cleopatra I, in 176 BC. In 170 BC Antiochus IV of Syria invaded Egypt and established a protectorate; in 168 BC he returned, accepted coronation at Memphis, and installed a Seleucid governor. But he had failed to reckon with more powerful interests: those of Rome. In the summer of 168 BC a Roman ambassador, Popillius Laenas, arrived at Antiochus' headquarters near Pelusium in the Delta and staged an awesome display of Roman power. He ordered Antiochus to withdraw from Egypt. Antiochus asked for time to consult his advisers. Laenas drew a circle around the King with his stick and told him to answer before he stepped out of the circle. Only one answer was possible, and by the end of July Antiochus had left Egypt. Philometor's reign was further troubled by rivalry with his brother, later Ptolemy VIII Euergetes II Physcon. The solution, devised under Roman advice, was to remove Physcon to Cyrene, where he remained until Philometor died in 145 BC; but it is noteworthy that in 155 BC Physcon took the step of bequeathing the kingdom of Cyrene to the Romans in the event of his untimely death.

Dynastic strife and decline (145–30 BC). Physcon was able to rule in Egypt until 116 BC with his sister Cleopatra II (except for a period in 131–130 BC when she was in revolt) and her daughter Cleopatra III. His reign was marked by generous benefactions to the Egyptian temples, but he was detested as a tyrant by the Greeks, and the historical accounts of the reign emphasize his stormy relations with the Alexandrian populace.

During the last century of Ptolemaic rule, Egypt's independence was exercised under Rome's protection and at Rome's discretion. For much of the period Rome was content to support a dynasty that had no overseas possession except Cyprus after 96 BC (the year in which Cyrene was bequeathed to Rome by Ptolemy Apion) and no ambitions threatening Roman interests or security. After a series of brief and unstable reigns, Ptolemy XII Auletes acceded to the throne in 80 BC. He maintained his hold for 30 years, despite the attractions that Egypt's legendary wealth held for avaricious Roman politicians. In fact, Auletes had to flee Egypt in 58 BC and was restored by Pompey's friend Gabinius in 55 BC, no doubt after spending so much in bribes that he had to bring back Rabirius Postumus, one of his Roman creditors, to Egypt with him to manage his financial affairs.

In 52 BC, the year before his death, Auletes associated with himself on the throne his daughter Cleopatra VII and his elder son Ptolemy XIII (who died in 47 BC). The reign of Cleopatra was that of a vigorous and exceptionally able queen who was ambitious, among other things, to revive the prestige of the dynasty by cultivating influence with powerful Roman commanders and using their capacity to aggrandize Roman clients and allies. Julius Caesar pursued Pompey to Egypt in 48 BC. After learning of Pompey's murder at the hands of Egyptian courtiers, Caesar stayed long enough to enjoy a sightseeing tour up the Nile in the Queen's company in the summer of 47 BC. When he left for Rome, Cleopatra was pregnant with a child she claimed was Caesar's. The child, a son, was named Caesarion ("Little Caesar"). Cleopatra and Caesarion later followed Caesar back to Rome but, after his assassination in 44 BC, they returned hurriedly to Egypt and she tried for a while to play a neutral role in the struggles between the Roman generals and their factions.

Reign of Cleopatra VII

Her long liaison with Mark Antony began when she visited him at Tarsus in 41 BC and he returned to Egypt with her. Between 36 and 30 BC the famous romance between the Roman general and the eastern queen was exploited to great effect by Antony's political rival Octavian. By 34 BC Caesarion was officially co-ruler with Cleopatra, but his rule clearly was an attempt to exploit the popularity of Caesar's memory. In the autumn Cleopatra and Antony staged an extravagant display in which they made grandiose dispositions of territory in the east to their children, Alexander Helios, Ptolemy, and Cleopatra Selene. Cleopatra and Antony were portrayed to the Roman public as posing for artists in the guise of Dionysus and Isis or whiling away their evenings in rowdy and decadent banquets that kept the citizens of Alexandria awake all night. But this propaganda war was merely the prelude to armed conflict, and the issue was decided in September 31 BC in a naval battle at Actium in western Greece. When the battle was at its height Cleopatra and her squadron withdrew, and Antony eventually followed suit. They fled to Alexandria but could do little more than await the arrival of the victorious Octavian 10 months later. Alexandria was captured and Antony and Cleopatra committed suicide—he by falling on his sword, she probably by the bite of an asp—in August of 30 BC. It is reported that when Octavian reached the city he visited and touched the preserved corpse of Alexander the Great, causing a piece of the nose to fall off. He refused to gaze upon the remains of the Ptolemies, saying "I wished to see a king, not corpses."

Government and conditions under the Ptolemies. The changes brought to Egypt by the Ptolemies were momentous; the land's resources were harnessed with unparalleled efficiency and the result was that it became the wealthiest of the Hellenistic kingdoms. Land under cultivation was increased, new crops were introduced (especially important was the introduction of naked tetraploid wheat, *triticum durum,* to replace the traditional husked emmer,

Improvements to agriculture

triticum dicoccum). The population, estimated at perhaps 3,000,000–4,000,000 in the Late Dynastic Period, may have more than doubled by the early Roman period to a figure of 7,500,000 or 8,000,000, a level not reached again until the late 19th century. Some of the increase was due to immigration; particularly during the 2nd and 3rd centuries many settlers were attracted from the cities of Asia Minor and the Greek islands, as well as large numbers of Jews from Palestine. The flow may have decreased later in the Ptolemaic period, and it is often suggested, on slender evidence, that there was a serious decline in prosperity in the 1st century BC. If so, there may have been some reversal of this trend under Cleopatra VII.

Administration. The foundation of the prosperity was the governmental system devised to exploit the country's economic resources. Directly below the monarch were a handful of powerful officials whose competence extended over the entire land: a chief finance minister, a chief accountant, and a chancery of ministers in charge of records, letters, and decrees. A level below them lay the broadening base of a pyramid of subordinate officials with competence in limited areas, which extended down to the chief administrator of each individual village (*kōmarchēs*). Between the chief ministers and the village officials stood those such as the nome-steward (*oikonomos*) and *stratēgoi,* whose competence extended over one of the more than 30 nomes of Egypt, the long-established geographic divisions. In theory this bureaucracy could regulate and control the economic activities of every subject in the land, its smooth operation guaranteed by the multiplicity of officials capable of checking each upon the other. In practice, it is difficult to see a rigid civil-service mentality at work, involving clear demarcation of departments; specific functions might well have been performed by different officials according to local need and the availability of a person competent to take appropriate action.

By the same token, rigid lines of separation between military and civil, legal and administrative matters are difficult to perceive. The same official might perform duties in one or all of these areas, and the law in particular regulated every activity to an extent that the use of the terms legal and judicial tends to hide. The military was inevitably integrated into civilian life because its soldiers were also farmers who enjoyed royal grants of land, either as Greek cleruchs (holders of allotments) with higher status and generous grants, or as native Egypt *machimoi* with small plots. Interlocking judiciary institutions, in the form of Greek and Egyptian courts (*chrēmatistai* and *laokritai*), provided the means for Greeks and Egyptians to regulate their legal relationships according to the language in which they conducted their business. The bureaucratic power was heavily weighted in favour of the Greek speakers, the dominant elite. Egyptians were nevertheless able to obtain official posts in the bureaucracy, gradually infiltrating to the highest levels, but in order to do so they had to Hellenize.

Economy. The basis of Egypt's legendary wealth was the highly productive land, which technically remained in royal ownership. A considerable portion was kept under the control of temples, and the remainder was leased out on a theoretically revocable basis to tenant-farmers. A portion also was available to be granted as gifts to leading courtiers; one of these was Apollonius, the finance minister of Ptolemy II Philadelphus, who had an estate of 10,000 arourae (about 6,500 acres) at Philadelphia in the Fayyūm. Tenants and beneficiaries were able to behave very much as if these leases and grants were private property. The revenues in cash and kind were enormous, and royal control extended to the manufacture and marketing of almost all important products, including papyrus, oil, linen, and beer. An extraordinarily detailed set of revenue laws, promulgated under Ptolemy II Philadelphus, laid down rules for the way in which officials were to monitor the production of such commodities. In fact, the Ptolemaic economy was very much a mixture of direct royal ownership and exploitation by private enterprise under regulated conditions.

Control of land

One fundamental and far-reaching Ptolemaic innovation was the systematic monetarization of the economy. This too the monarchy controlled from top to bottom by operating a closed monetary system, which permitted only the royal coinage to circulate within Egypt. A sophisticated banking system underpinned this practice, operating again with a mixture of direct royal control and private enterprise and handling both private financial transactions and those that directed money into and out of the royal coffers. One important concomitant of this change was an enormous increase in the volume of trade, both within Egypt and abroad, which eventually reached its climax under the peaceful conditions of Roman rule. Here the position and role of Alexandria as the major port and trading entrepôt was crucial: the city handled a great volume of Egypt's domestic produce, as well as the import and export of luxury goods to and from the East and the cities of the eastern Mediterranean. It developed its own importance as an artistic centre, the products of which found ready markets throughout the Mediterranean. Alexandrian glassware and jewelry were particularly fine; Greek-style sculpture of the late Ptolemaic period shows especial excellence; and it is likely that the city was also the major production centre for high-quality mosaic work.

Alexandria's importance to trade

Religion. The Ptolemies were powerful supporters of the native Egyptian religious foundations, the economic and political power of which was, however, carefully controlled. A great deal of the building and restoration work in many of the most important Egyptian temples is Ptolemaic, particularly from the period of about 150–50 BC, and the monarchs appear on temple reliefs in the traditional forms of the Egyptian kings. The native traditions persisted in village temples and local cults, many having particular associations with species of sacred animals or birds. At the same time, the Greeks created their own identifications of Egyptian deities, identifying Amon with Zeus, Horus with Apollo, Ptah with Hephaestus, and so on. They also gave some deities, such as Isis, a more universal significance that ultimately resulted in the spread of her mystery cult throughout the Mediterranean world. The impact of the Greeks is most obvious in two phenomena. One is the formalized royal cult of Alexander and the Ptolemies, which evidently served both a political and a religious purpose. The other is the creation of the cult of Sarapis, which at first was confined to Alexandria but soon became universal. The god was represented as a Hellenized deity and the form of cult is Greek; but its essence is the old Egyptian notion that the sacred Apis bull merged its divinity in some way with the god Osiris when it died.

Greek identifications of Egyptian deities

Culture. The continuing vitality of the native Egyptian artistic tradition is clearly and abundantly expressed in the temple architecture and the sculpture of the Ptolemaic period. The Egyptian language continued in use in its hieroglyphic and demotic forms until late in the Roman period, and it survived through the Byzantine period and beyond in the form of Coptic. The Egyptian literary tradition flourished vigorously in the Ptolemaic period and produced a large number of works in demotic. The genre most commonly represented is the romantic tale, exemplified by several story cycles, which are typically set in the native, Pharaonic milieu and involve the gods, royal figures, magic, romance, and the trials and combats of heroes. Another important category is the Instruction Text, the best known of the period being that of Ankhsheshonq, which consists of a list of moralizing maxims, composed, as the story goes, when Ankhsheshonq was imprisoned for having failed to inform the pharaoh of an assassination plot. Another example, known as Papyrus Insinger, is a more narrowly moralizing text. But the arrival of a Greek-speaking elite had an enormous impact on cultural patterns. The Egyptian story cycles were probably affected by Greek influence; literary and technical works were translated into Greek; and under royal patronage an Egyptian priest named Manetho of Sebennytos wrote an account of the kings of Egypt, in Greek. Most striking is the diffusion of the works of the poets and playwrights of classical Greece among the literate Greeks in the towns and villages of the Nile Valley.

Influence of Greek on the literature

Thus there are clear signs of the existence of two interacting but distinct cultural traditions in Ptolemaic Egypt.

This was certainly reflected in a broader social context. The written sources offer little direct evidence of racial discrimination by Greeks against Egyptians, but Greek and Egyptian consciousness of the Greeks' social and economic superiority comes through strongly from time to time; intermarriage was one means, though not the only one, by which Egyptians could better their status and Hellenize. Many native Egyptians learned to speak Greek, some to write it as well; some even went so far as to adopt Greek names in an attempt to assimilate themselves to the elite group.

Hellenization of the Egyptians

Alexandria occupied a unique place in the history of literature, ideas, scholarship, and science for almost a millennium after the death of its founder. Under the royal patronage of the Ptolemies, and in an environment almost oblivious to its Egyptian surroundings, Greek culture was preserved and developed. Early in the Ptolemaic period, probably in the reign of Ptolemy I Soter, the Museum ("Shrine of the Muses") was established within the palace complex. Strabo, who saw it early in the Roman period, described it as having a covered walk, an arcade with recesses and seats, and a large house containing the dining hall of the members of the Museum, who lived a communal existence. The Great Library of Alexandria (together with its offshoot in the Sarapeum) was indispensable to the functioning of the scholarly community in the Museum. Books were collected voraciously under the Ptolemies, and at its height the library's collection probably numbered close to 500,000 papyrus rolls, most of them containing more than one work.

Poets and scholars at Alexandria

The major poets of the Hellenistic period, Theocritus, Callimachus, and Apollonius of Rhodes, all took up residence and wrote there. Scholarship flourished, preserving and ordering the manuscript traditions of much of the classical literature from Homer onward. Librarian-scholars such as Aristophanes of Byzantium and his pupil Aristarchus made critical editions and wrote commentaries and works on grammar. Also notable was the cultural influence of Alexandria's Jewish community, which is inferred from the fact that the Pentateuch was first translated into Greek at Alexandria during the Ptolemaic period. One by-product of this kind of activity was that Alexandria became the centre of the book trade, and the works of the classical authors were copied there and diffused among a literate Greek readership scattered in the towns and villages of the Nile Valley.

The Alexandrian achievement in scientific fields was also enormous. Great advances were made in pure mathematics, mechanics, physics, geography, and medicine. Euclid worked in Alexandria in about 300 BC and achieved the systematization of the whole existing corpus of mathematical knowledge and the development of the method of proof by deduction from axioms. Archimedes was there in the 3rd century BC and is said to have invented the Archimedean screw when he was in Egypt; Eratosthenes calculated the Earth's circumference and was the first to attempt a map of the world based on a system of lines of latitude and longitude; and the school of medicine founded in the Ptolemaic period retained its leading reputation into the Byzantine era. Late in the Ptolemaic period Alexandria began to develop as a great centre of Greek philosophical studies as well. In fact, there was no field of literary, intellectual, or scientific activity to which Ptolemaic Alexandria failed to make an important contribution. (A.E.S./A.K.B.)

ROMAN AND BYZANTINE EGYPT (30 BC–AD 642)

Egypt as a province of Rome. "I added Egypt to the Empire of the Roman people." With these words the emperor Augustus (as Octavian was known from 27 BC) summarized the subjection of Cleopatra's kingdom in the great inscription that records his achievements. The province was to be governed by a viceroy, a prefect with the status of a Roman knight (eques) who was directly responsible to the emperor. The first viceroy was the Roman poet and soldier Cornelius Gallus, who boasted too vaingloriously of his military achievements in the province and paid for it first with his position and then with his life. Roman senators were not allowed to enter Egypt without the emperor's permission, because this wealthiest of provinces could be held militarily by a very small force; and the threat implicit in an embargo on the export of grain supplies, vital to the provisioning of the city of Rome and its populace, was obvious. Internal security was guaranteed by the presence of three Roman legions (later reduced to two), each about 6,000 strong, and several cohorts of auxiliaries. In the first decade of Roman rule the spirit of Augustan imperialism looked farther afield, attempting expansion to the east and to the south. An expedition to Arabia by the prefect Aelius Gallus in about 26–25 BC was undermined by the treachery of the Nabataean Syllaeus, who led the Roman fleet astray in uncharted waters. Arabia was to remain an independent though friendly client of Rome until AD 106, when the emperor Trajan (ruled AD 98–117) annexed it, making it possible to reopen Ptolemy II's canal from the Nile to the head of the Gulf of Suez. To the south the Meroitic people beyond the First Cataract had taken advantage of Gallus' preoccupation with Arabia and mounted an attack on the Thebaid. The next Roman prefect, Petronius, led two expeditions into the Meroitic kingdom (*c.* 24–22 BC), captured several towns, forced the submission of the formidable queen, who was characterized by Roman writers as "the one-eyed Queen Candace," and left a Roman garrison at Primis (Qaṣr Ibrīm). But thoughts of maintaining a permanent presence in Lower Nubia were soon abandoned, and within a year or two the limits of Roman occupation had been set at Hiera Sykaminos, some 50 miles south of the First Cataract. The mixed character of the region is indicated, however, by the continuing popularity of the goddess Isis among the people of Meroe and by the Roman emperor Augustus' foundation of a temple at Kalabsha dedicated to the local god Mandulis.

Attempts to expand Rome's territory

Egypt achieved its greatest prosperity under the shadow of the Roman peace which, in effect, depoliticized it. Roman emperors or members of their families visited Egypt—Tiberius' nephew and adopted son, Germanicus; Vespasian and his elder son, Titus; Hadrian; Septimius Severus; Diocletian—to see the famous sights, receive the acclamations of the Alexandrian populace, attempt to ensure the loyalty of the volatile subjects, or initiate administrative reform. Occasionally its potential as a power base was realized. Vespasian, the most successful of the imperial aspirants in the "Year of the Four Emperors," was first proclaimed at Alexandria on July 1, AD 69, in a maneuver contrived by the prefect of Egypt, Tiberius Julius Alexander. Others were less successful. Avidius Cassius, the son of a former prefect of Egypt, revolted against Marcus Aurelius in AD 175, stimulated by false rumours of Marcus' death, but his attempted usurpation lasted only three months. For several months in AD 297/298 Egypt was under the dominion of a mysterious usurper named Lucius Domitius Domitianus. The emperor Diocletian was present at the final capitulation of Alexandria after an eight-month siege and swore to take revenge by slaughtering the populace until the river of blood reached his horse's knees; the threat was mitigated when his mount stumbled as he rode into the city. In gratitude, the citizens of Alexandria erected a statue of the horse.

The only extended period during the turbulent 3rd century AD in which Egypt was lost to the central imperial authority was 270–272, when it fell into the hands of the ruling dynasty of the Syrian city of Palmyra. Fortunately for Rome, the military strength of Palmyra proved to be the major obstacle to the overrunning of the Eastern Empire by the powerful Sāsānian monarchy of Persia.

Internal threats to security were not uncommon but normally were dissipated without major damage to imperial control. These included rioting between Jews and Greeks in Alexandria in the reign of Caligula (Gaius Caesar Germanicus; ruled AD 37–41); a serious Jewish revolt under Trajan (ruled AD 98–117); a revolt in the Delta in AD 172 that was quelled by Avidius Cassius; and a revolt centred on the town of Coptos (Qift) in AD 293/294 that was put down by Galerius, Diocletian's imperial colleague.

Revolts against Rome

Administration and economy under Rome. The Romans introduced important changes in the administrative system, aimed at achieving a high level of efficiency and

maximizing revenue. The duties of the prefect of Egypt combined responsibility for military security through command of the legions and cohorts, for the organization of finance and taxation, and for the administration of justice. This involved a vast mass of detailed paperwork: one document of AD 211 notes that in a period of three days 1,804 petitions were handed into the prefect's office. But the prefect was assisted by a hierarchy of subordinate equestrian officials with expertise in particular areas. There were three or four *epistratēgoi* in charge of regional subdivisions; special officers were in charge of the emperors' private account, the administration of justice, religious institutions, and so on. Subordinate to them were the local officials in the nomes (*stratēgoi* and royal scribes) and finally the authorities in the towns and villages.

It was in these growing towns that the Romans made the most far-reaching changes in administration. They introduced colleges of magistrates and officials who were to be responsible for running the internal affairs of their own communities on a theoretically autonomous basis and, at the same time, were to guarantee the collection and payment of tax quotas to the central government. This was backed up by the development of a range of "liturgies," compulsory public services that were imposed on individuals according to rank and property to ensure the financing and upkeep of local facilities. These institutions were the Egyptian counterpart of the councils and magistrates that oversaw the Greek cities in the eastern Roman provinces. They had been ubiquitous in other Hellenistic kingdoms, but in Ptolemaic Egypt they had existed only in the so-called Greek cities (Alexandria, Ptolemais in Upper Egypt, Naukratis, and later Antinoöpolis, founded by Hadrian in AD 130). Alexandria lost the right to have a council, probably in the Ptolemaic period. When it recovered its right in AD 200 the privilege was diluted by being extended to the nome capitals (*mētropoleis*) as well. This extension of privilege represented an attempt to shift more of the burden and expense of administration onto the local propertied classes, but it was eventually to prove too heavy. The consequences were the impoverishment of many of the councillors and their families and serious problems in administration that led to an increasing degree of central government interference and, eventually, more direct control.

Taxation under Roman rule

The economic resources that this administration existed to exploit had not changed since the Ptolemaic period, but the development of a much more complex and sophisticated taxation system was a hallmark of Roman rule. Taxes in both cash and kind were assessed on land, and a bewildering variety of small taxes in cash, as well as customs dues and the like, was collected by appointed officials. A massive amount of Egypt's grain was shipped downriver both to feed the population of Alexandria and for export to Rome. Despite frequent complaints of oppression and extortion from the taxpayers, it is not obvious that official tax rates were very high. In fact the Roman government had actively encouraged the privatization of land and the increase of private enterprise in manufacture, commerce, and trade, and low tax rates favoured private owners and entrepreneurs. The poorer people gained their livelihood as tenants of state-owned land or of property belonging to the emperor or to wealthy private landlords, and they were relatively much more heavily burdened by rentals, which tended to remain at a fairly high level.

Overall, the degree of monetarization and complexity in the economy, even at the village level, was intense. Goods were moved around and exchanged through the medium of coin on a large scale and, in the towns and the larger villages, a high level of industrial and commercial activity developed in close conjunction with the exploitation of the predominant agricultural base. The volume of trade, both internal and external, reached its peak in the 1st and 2nd centuries AD. But by the end of the 3rd century AD, major problems were evident. A series of debasements of the imperial currency had undermined confidence in the coinage, and even the government itself was contributing to this by demanding more and more irregular tax payments in kind, which it channeled directly to the main consumers, the army personnel. Local administration by the councils was careless, recalcitrant, and inefficient; the evident need for firm and purposeful reform had to be squarely faced in the reigns of Diocletian and Constantine.

Society, religion, and culture. One of the more noticeable effects of Roman rule was the clearer tendency to classification and social control of the populace. Thus, despite many years of intermarriage between Greeks and Egyptians, lists drawn up in AD 4/5 established the right of certain families to class themselves as Greek by descent and to claim privileges attaching to their status as members of an urban aristocracy, known as the gymnasial class. Members of this group were entitled to lower rates of poll tax, subsidized or free distributions of food, and maintenance at the public expense when they grew old. If they or their descendants were upwardly mobile, they might gain Alexandrian citizenship, Roman citizenship, or even equestrian status, with correspondingly greater prestige and privileges. The preservation of such distinctions was implicit in the spread of Roman law and was reinforced by elaborate codes of social and fiscal regulations such as the "Rule-Book of the Emperors' Special Account." The "Rule-Book" prescribed conditions under which people of different status might marry, for instance, or bequeath property and fixed fines, confiscations, and other penalties for transgression. When an edict of the emperor Caracalla conferred Roman citizenship on practically all of the subjects of the empire in AD 212, the distinction between citizens and noncitizens became meaningless; but it was gradually replaced by an equally important distinction between *honestiores* and *humiliores* (meaning, roughly, upper and lower classes), groups that, among other distinctions, were subjected to different penalities in law.

Social and fiscal codes

Naturally, it was the Greek-speaking elite that continued to dictate the visibly dominant cultural pattern, though Egyptian culture was not moribund or insignificant; one proof of its continued survival can be seen in its reemergent importance in the context of Coptic Christianity in the Byzantine period. An important reminder of the mixing of the traditions comes from a family of Panopolis in the 4th century, whose members included both teachers of Greek oratory and priests in Egyptian cult. The towns and villages of the Nile Valley have preserved thousands of papyri that show what the literate Greeks were reading: the poems of Homer and the lyric poets, works of the classical Greek tragedians, and comedies of Menander, for example. The pervasiveness of the Greek literary tradition is strikingly demonstrated by evidence left by an obscure and anonymous clerk at the Fayyūm village of Karanis in the 2nd century AD. In copying out a long list of taxpayers, the clerk translated an Egyptian name in the list by an extremely rare Greek word that he could only have known from having read the Alexandrian Hellenistic poet Callimachus; he must have understood the etymology of the Egyptian name as well.

Alexandria continued to develop as a spectacularly beautiful city and to foster Greek culture and intellectual pursuits, though the great days of Ptolemaic court patronage of literary figures had passed. But the flourishing interest in philosophy, particularly Platonic, had important effects. The great Jewish philosopher and theologian of the 1st century, Philo of Alexandria, brought a training in Greek philosophy to bear on his commentaries on the Old Testament. This anticipates by a hundred years the period after the virtual annihilation of the great Jewish community of Alexandria in the revolt of AD 115–117, when the city was the intellectual crucible in which Christianity developed a theology that took it away from the influence of the Jewish exegetical tradition and toward that of Greek philosophical ideas. There the foundations were laid for the teaching of the heads of the Christian catechetical school, such as Clement of Alexandria. And in the 3rd century there was the vital textual and theological work of Origen, the greatest of the Christian Neoplatonists, without which there would hardly have been a coherent New Testament tradition at all.

Outside the Greek ambience of Alexandria, traditional Egyptian religious institutions continued to flourish in the towns and villages; but the temples were reduced to financial dependence on a state subvention (*syntaxis*) and they

became subject to stringent control by secular bureaucrats. Nevertheless, like the Ptolemies before them, Roman emperors appear in the traditional form as Egyptian kings on temple reliefs until the middle of the 3rd century; and five professional hieroglyph cutters were still employed at the town of Oxyrhynchus in the 2nd century. The animal cults continued to flourish, despite Augustus' famous sneer that he was accustomed to worship gods, not cattle. As late as the reign of Diocletian (AD 285–305) religious stelae preserved the fiction that in the cults of sacred bulls (best known at Memphis and at Hermonthis), the successor of a dead bull was "installed" by the monarch. Differences between cults of the Greek type and the native Egyptian cults were still very marked, in the temple architecture as in the status of the priests. Priests of Egyptian cult formed, in effect, a caste distinguished by their special clothing, whereas priestly offices in Greek cult were much more like magistracies and tended to be held by local magnates. Cult of Roman emperors, living and dead, became universal after 30 BC, but its impact is most clearly to be seen in the foundations of Caesarea (Temples of Caesar) and in religious institutions of Greek type, where divine emperors were associated with the resident deities.

Egyptian and Roman cults

One development that did have an important effect on this pagan religious amalgam, though it was not decisive until the 4th century, was the arrival of Christianity. The tradition of the foundation of the church of Alexandria by St. Mark cannot be substantiated, but a fragment of a text of the Gospel According to John provides concrete evidence of Christianity in the Nile Valley in the second quarter of the 2nd century AD. Inasmuch as Christianity remained illegal and subject to persecution until the early 4th century, Christians were reluctant to advertise themselves as such, and it is therefore difficult to know how numerous they were, especially because later pro-Christian sources may often be suspected of exaggerating the zeal and the numbers of the early Christian martyrs. But several papyri survive of the *libelli* submitted in the first official state-sponsored persecution of Christians, under the emperor Decius (ruled 249–251): these were certificates in which people swore that they had performed sacrifices to pagan gods in order to prove that they were not Christians. By the 290s, a decade or so before the great persecution of Diocletian, a list of buildings in the sizeable town of Oxyrhynchus, some 125 miles south of the apex of the delta, included two Christian churches, probably of the house-chapel type.

Arrival of Christianity

Egypt's role in the Byzantine Empire. Diocletian was the last reigning Roman emperor to visit Egypt, in AD 302. Within about 10 years of his visit, the persecution of Christians ceased. The end of persecution had such far-reaching effects that from this point on it is necessary to think of the history of Egypt in a very different framework. No single point can be identified as the watershed between the Roman and Byzantine periods, as the divide between the peace, culture, and prosperity of the Principate and the darker age of the Dominate, supposedly characterized by a more oppressive state machinery in the throes of decline and fall. The crucial changes occurred in the last decade of the 3rd century and the first three decades of the 4th. With the end of persecution of Christians came the restoration of the property of the church. In 313 a new system of calculating and collecting taxes was introduced, with 15-year tax cycles, called indictions, inaugurated retrospectively from the year 312. Many other important administrative changes had already taken place. In 296 the separation of the Egyptian coinage from that of the rest of the empire had come to an end when the Alexandrian mint stopped producing its tetradrachmas, which had been the basis of the closed currency system.

One other event that had an enormous effect on the political history of Egypt was the founding of Constantinople on May 11, 330. First, Constantinople was established as an imperial capital and an eastern counterpart to Rome itself, thus undermining Alexandria's traditional position as the first city of the Greek-speaking East. Second, it diverted the resources of Egypt away from Rome and the West. Henceforth, part of the surplus of the Egyptian grain supply, which was put at 8,000,000 *artabs* (about 300,000,000 litres) of wheat in an edict of the emperor Justinian of about 537 or 538, went to feed the growing population of Constantinople, and this created an important political and economic link. The cumulative effect of these changes was to knit Egypt more uniformly into the structure of the empire and to give it, once again, a central role in the political history of the Mediterranean world.

Founding of Constantinople and its effect on Egypt

The key to understanding the importance of Egypt in this period lies in seeing how the Christian Church came rapidly to dominate secular as well as religious institutions and to acquire a powerful interest and role in every political issue. The corollary of this was that the head of the Egyptian Church, the patriarch of Alexandria, became the most influential figure within Egypt, as well as the person who could give the Egyptian clergy a powerful voice in the councils of the Eastern Church. During the course of the 4th century, Egypt was divided for administrative purposes into a number of smaller units but the patriarchy was not, and its power thus far outweighed that of any local administrative official. Only the governors of groups of provinces (*vicarii* of dioceses) were equivalent, the praetorian prefects and emperors superior; and when a patriarch of Alexandria was given civil authority as well, as happened in the case of Cyrus, the last patriarch under Byzantine rule, the combination was very powerful indeed.

The turbulent history of Egypt in the Byzantine period can largely be understood in terms of the struggles of the successive (or, after AD 570, coexisting) patriarchs of Alexandria to maintain their position both within their patriarchy and outside it in relation to Constantinople. What linked Egypt and the rest of the Eastern Empire was the way in which the imperial authorities, when strong (as, for instance, in the reign of Justinian), tried to control the Egyptian Church from Constantinople, while at the same time assuring the capital's food supply and, as often as not, waging wars to keep their empire intact. Conversely, when weak they failed to control the church. For the patriarchs of Alexandria, it proved impossible to secure the approval of the imperial authorities in Constantinople and at the same time maintain the support of their power base in Egypt. The two made quite different demands, and the ultimate result was a social, political, and cultural gulf between Alexandria and the rest of Egypt, and between Hellenism and native Egyptian culture, which found a powerful new means of expression in Coptic Christianity. The gulf was made more emphatic after the Council of Chalcedon in 451 established the official doctrine that Christ was to be seen as existing in two natures, inseparably united. The council's decision in effect sent the Egyptian Coptic (now Coptic Orthodox) Church off on its own path of Monophysitism, which centred around a firm insistence on the singularity of the nature of Christ.

Power of the patriarchs of Alexandria

Despite the debilitating effect of internal quarrels between rival churchmen, and despite the threats posed by the hostile tribes of Blemmyes and Nubade in the south (until their conversion to Christianity in the mid-6th century), emperors of Byzantium still could be threatened by the strength of Egypt if it were properly harnessed. The last striking example is the case of the emperor Phocas, a tyrant who was brought down in 609 or 610. Nicetas, the general of the future emperor Heraclius, made for Alexandria from Cyrene, intending to use Egypt as his power base and cut off Constantinople's grain supply. By the spring of 610 Nicetas' struggle with Bonosus, the general of Phocas, was won, and the fall of the tyrant duly followed.

The difficulty of defending Egypt from a power base in Constantinople was forcefully illustrated during the last three decades of Byzantine rule. First, the old enemy, the Persians, advanced to the Nile Delta and captured Alexandria. Their occupation was completed early in 619 and continued until 628, when Persia and Byzantium agreed to a peace treaty and the Persians withdrew. This had been a decade of violent hostility to the Egyptian Coptic Christians; among other oppressive measures, the Persians are said to have refused to allow the normal ordination of bishops and to have massacred hundreds of monks in their cave monasteries. The Persian withdrawal hardly heralded the return of peace to Egypt.

In Arabia events were taking place that would soon

bring momentous changes for Egypt. These were triggered by the flight of the Prophet Muḥammad from Mecca to Medina and by his declaration in AD 632 of a holy Islāmic war against Byzantium. Ten years later, by Sept. 29, 642, the Arab general ʿAmr ibn al-ʿĀṣ was able to march into Alexandria, and the Arab conquest of Egypt, which had begun with an invasion three years earlier, ended in peaceful capitulation. The invasion itself had been preceded by several years of vicious persecution of Coptic Christians by the Chalcedonian patriarch of Alexandria, Cyrus, and it was he who is said to have betrayed Egypt to the forces of Islām.

Islāmic conquest of Egypt

The Islāmic conquest was not bloodless. There was desultory fighting at first in the eastern Delta, then the Fayyūm was lost in battle in 640, and a great battle took place at Heliopolis (now a suburb of Cairo) in July 640 in which 15,000 Arabs engaged 20,000 Egyptian defenders. The storming and capture of Trajan's old fortess at Babylon (on the site of the present-day quarter called Old Cairo) on April 6, 641, was crucial. By September 14 Cyrus, who had been recalled from Egypt 10 months earlier by the emperor Heraclius, was back with authority to conclude a peace. Byzantium signed Egypt away on Nov. 8, 641, with provision for an 11-month armistice to allow ratification of the treaty of surrender by the emperor and the caliph. In December 641 heavily laden ships were dispatched to carry Egypt's wealth to its new masters. Nine months later the last remnants of Byzantine forces had left Egypt in ships bound for Cyprus, Rhodes, and Constantinople, and ʿAmr ibn al-ʿĀṣ had taken Alexandria in the name of the caliph. The new domination by the theocratic Islāmic caliphate was more strikingly different than anything that had happened in Egypt since the arrival of Alexander the Great almost a thousand years earlier.

Byzantine government of Egypt. The reforms of the early 4th century had established the basis for another 250 years of comparative prosperity in Egypt, at a cost of perhaps greater rigidity and more oppressive state control. Egypt was subdivided for administrative purposes into a number of smaller provinces, and separate civil and military officials were established (the *praeses* and the *dux*). By the middle of the 6th century the emperor Justinian was eventually forced to recognize the failure of this policy and to combine civil and military power in the hands of the *dux* with a civil deputy (the *praeses*) as a counterweight to the power of the church authorities. All pretense of local autonomy had by then vanished. The presence of the soldiery was more noticeable, its power and influence more pervasive in the routine of town and village life. Taxes were perhaps not heavier than they had been earlier, but they were collected ruthlessly, and strong measures were sanctioned against those who tried to escape from their fiscal or legal obligations. The wealthier landowners probably enjoyed increased prosperity, especially as a result of the opportunity to buy state-owned land that had been sold into private ownership in the early 4th century. The great landlords were powerful enough to offer their peasant tenants a significant degree of collective fiscal protection against the agents of the state, the rapacious tax collector, the officious bureaucrat, or the brutal soldier. But, if the life of the average peasant did not change much, nevertheless the rich probably became richer, and the poor became poorer and more numerous as the moderate landholders were increasingly squeezed out of the picture.

The advance of Christianity. The advance of Christianity had just as profound an effect on the social and cultural fabric of Byzantine Egypt as on the political power structure. It brought to the surface the identity of the native Egyptians in the Coptic Church, which found a medium of expression in the development of the Coptic language—basically Egyptian written in Greek letters with the addition of a few characters. Coptic Christianity developed its own distinctive art too, much of it pervaded by the long-familiar motifs of Greek mythology. These motifs coexisted with representations of the Virgin and Child and with Christian parables and were expressed in decorative styles that owed a great deal to both Greek and Egyptian precedents. Although Christianity had made great inroads into the populace by AD 391, the year in which the practice of pagan religion was officially made illegal, it is hardly possible to quantify it or to trace a neat and uniform progression. It engulfed its pagan precedents slowly and untidily. In the first half of the 5th century a pagan literary revival occurred, centred on the town of Panopolis, and there is evidence that fanatical monks in the area attacked pagan temples and stole statues and magical texts. Outside the rarefied circles in which doctrinal disputes were discussed in philosophical terms, there was a great heterogeneous mass of commitment and belief. Both the Gnostics, who believed in redemption through knowledge, and the Manichaeans, followers of the Persian prophet Mani, for example, clearly thought of themselves as Christians. In the 4th century a Christian community, the library of which was discovered at Najʿ Ḥammādī in 1945, was reading both canonical and apocryphal gospels as well as mystical revelatory tracts. At the lower levels of society pagan magical practices remained ubiquitous and were simply converted into a Christian context.

The Egyptian Coptic Church

By the middle of the 5th century Egypt's landscape was dominated by the great churches, such as the magnificent Church of St. Menas (Abū Mīna), south of Alexandria, and by the monasteries. The latter were Egypt's distinctive contribution to the development of Christianity and were particularly important as strongholds of native loyalty to the Monophysite Church. The origins of Antonian communities, named for the founding father of monasticism, St. Anthony of Egypt (*c.* 251–356), lay in the desire of individuals to congregate about the person of a celebrated ascetic in a desert location, building their own cells, adding a church and a refectory, and raising towers and walls to enclose the unit. Other monasteries, called Pachomian after Pachomius, the founder of cenobitic monasticism, were planned from the start as walled complexes with communal facilities. The provision of water cisterns, kitchens, bakeries, oil presses, workshops, stables, and cemeteries and the ownership and cultivation of land in the vicinity made these communities self-sufficient to a high degree, offering their residents peace and protection against the oppression of the tax collector and the brutality of the soldier. But it does not follow that they were divorced from contact with nearby towns and villages. Indeed, many monastics were important local figures and many monastery churches were probably open to the local public for worship.

Monasticism in Egypt

The economic and social power of the Christian Church in the Nile Valley and Delta is the outstanding development of the 5th and 6th centuries. By the time of the Arab invasion, in the mid-7th century, the uncomplicated propaganda of Islām might have seemed attractive and drawn attention to the political and religious rifts that successive and rival patriarchs of the Christian Church had so violently created and exploited. But the advent of Arab rule did not suppress Christianity in Egypt. Some areas remained heavily Christian for several centuries more.

(A.K.B.)

FROM THE ISLĀMIC CONQUEST TO 1250

Medieval Egyptian history opens and closes with foreign conquests of Egypt: the Arab invasion led by ʿAmr ibn al-ʿĀṣ in 639 and the Napoleonic expedition of 1798 mark the beginning and end of an era. Within the context of Egyptian internal history alone, this era was one in which Egypt cast off the heritage of the past to embrace a new language and a new religion—in other words, a new culture. While it is true that the past was by no means immediately and completely abandoned and that many aspects of Egyptian life, especially rural life, continued virtually unchanged, it is nevertheless clear that the civilization of Islāmic Egypt diverged sharply from that of the Greco-Roman period and was transformed under the impact of Western occupation. The history of medieval Egypt is therefore largely a study of the processes by which Egyptian Islāmic civilization evolved, particularly the processes of Arabization and Islāmization. But to confine Egyptian history to internal developments is to distort it, for during the entire medieval period Egypt was a part of a great world empire; and within this broader context, Egypt's history is a record of its long struggle to dominate

an empire—a struggle that is not without its parallels, of course, in both ancient and modern times.

Period of Arab and Turkish governors (639–868). The sending of a military expedition to Egypt from the caliphal capital in Medina came in a second phase of the first Arab conquests. Theretofore the conquests had been directed against lands on the northern borders of Arabia and were in the nature of raids for plunder; they had grown in scale and momentum as the Byzantines and Persians put up organized resistance. By 635 the Arabs had realized that in order to meet this resistance effectively they must begin the systematic occupation of enemy territory, especially Syria, where the Byzantine army was determined to halt the Arab forays.

The Arab expedition to Egypt

The Arab conquest. The Arabs defeated the Byzantines and occupied the key cities of Syria and Palestine, and they vanquished the Persian army on the eastern front in Mesopotamia and Iraq. The next obvious step was to secure Syria against a possible attack launched from the Byzantine province of Egypt. Beyond this strategic consideration, Arab historians call attention to the fact that ʿAmr ibn al-ʿĀṣ, the Arab general who later conquered Egypt, had visited Alexandria as a youth and had himself witnessed Egypt's enormous wealth. In spite of the obvious economic gain to be had from conquering Egypt, the caliph ʿUmar, according to some sources, showed reluctance to detach ʿAmr's expedition from the Syrian army and even tried to recall the mission once it had embarked; but ʿAmr, with or without the Caliph's permission, undertook the invasion in 639 with a small army of some 4,000 men (later reinforced). With what seems astonishing speed the Byzantine forces were routed and had withdrawn from Egypt by 642. An attempt by a Byzantine fleet and army to reconquer Alexandria in 645 was quickly defeated by the Arabs.

Various explanations have been given for the speed with which the conquest was achieved, most of which stress the weakness of Byzantine resistance rather than Arab strength. Certainly the division of the Byzantine government and army into autonomous provincial units militated against the possibility of a concerted and coordinated response. Although there is only dubious evidence for the claim that the Copts welcomed the Arab invasion in the belief that Muslim religious tolerance would be preferable to Byzantine enforced orthodoxy and repression, Coptic support for their Byzantine oppressors was probably unenthusiastic at best.

Early Arab rule. In Egypt—as in Syria, Iraq, and Iran—the Arab conquerors did little in the beginning to disturb the status quo; as a small religious and ethnic minority, they thus hoped to make the occupation permanent.

Arab policies

Treaties concluded between ʿAmr and the *muqawqis* (presumably a title referring to Cyrus, archbishop of Alexandria) granted protection to the native population in exchange for the payment of tribute. There was no attempt to force, or even to persuade, the Egyptians to convert to Islām; the Arabs even pledged to preserve the Christian churches. The Byzantine system of taxation, combining a tax on land with a poll tax, was maintained, though it was streamlined and centralized for the sake of efficiency. The tax was administered by Copts, who staffed the tax bureau at all but the highest levels.

To the mass of inhabitants, the conquest must have made little practical difference, because the Muslim rulers left them alone, in the beginning at least, as long as they paid their taxes; if anything, their lot may have been slightly easier, because Byzantine religious persecution had ended. Moreover, the Arabs deliberately isolated themselves from the native population, according to ʿUmar's decree that no Arab could own land outside the Arabian Peninsula; this policy aimed at preventing the Arab tribal armies from dispersing and at ensuring a steady revenue from agriculture, on the assumption that the former landowners would make better farmers than would the Arab nomads.

As was their policy elsewhere, the conquerors refrained from using an established city such as Alexandria as their capital; instead, they founded a new garrison town laid out in tribal quarters. As the site for this town they chose the strategic apex of the triangle formed by the Nile Delta—at that time occupied by the Byzantine fortified township of Babylon. They named the town Fusṭāṭ, which is probably an Arabized form of the Greek term for "encampment" and gives a good indication of the nature of the earliest settlement. Like garrison towns founded by the Arabs in Iraq—Basra and Kūfah—Fusṭāṭ became the main agency of Arabization in Egypt inasmuch as it was the only town with an Arab majority and therefore required an extensive knowledge of Arabic from the native inhabitants.

The process of Arabization, however, was slow and gradual. Arabic did not displace Greek as the official language of state until 706, and there is evidence that Coptic continued to be used as a spoken language in Fusṭāṭ. Given the lack of pressure from the conquerors, the spread of their religion must have been even slower than that of their language. A mosque was built in Fusṭāṭ bearing the name of ʿAmr ibn al-ʿĀṣ, and each quarter of the town had its own smaller mosque. ʿAmr's mosque served not only as the religious centre of the town but also as the seat of certain administrative and judicial activities as well.

Although Alexandria was maintained as a port city, Fusṭāṭ, being built on the Nile bank, was itself an important port and remained so until the 14th century. ʿAmr enhanced the port's commercial significance by clearing and reopening Trajan's Canal, so that shipments of grain destined for Arabia could be sent from Fusṭāṭ to the Red Sea by ship rather than by caravan.

Egypt under the caliphate. For more than 200 years—that is, throughout the Umayyad caliphate and well into the ʿAbbāsid—Egypt was ruled by governors appointed by the caliphs. As a province in an empire, Egypt's status was much the same as it had been for centuries under foreign rulers whose main interest was to supply the central government with Egyptian taxes and grain. In spite of evidence that the Arab governors tried in general to collect the taxes equitably, taking into account the capacities of individual landowners to pay and the annual variations in agricultural yield, resistance to paying the taxes increased in the 8th century and sometimes erupted into rebellion in times of economic distress. Periodically, religious unrest was manifested in the form of political insurrections, especially in those exceptional times when a governor openly discriminated against the Copts by forcing them to wear distinctive clothing or, worse, by destroying their icons. Still, the official policy, especially in Umayyad times, was tolerance, partly for fiscal reasons. In order to maintain the higher tax revenues collected from non-Muslims, the Arab governors discouraged conversion to Islām and even required those who did convert to continue paying the non-Muslim tax. New Christian churches were sometimes built, and the government took an interest in the selection of patriarchs.

Resistance to taxation

More than just a source of grain and taxes, Egypt also became a base for Arab-Muslim expansion, by both land and sea. The former Byzantine shipyards in Alexandria provided the nucleus of the Egyptian navy, which between 649 and 669 joined in expeditions with the Syrian navy against Rhodes, Cyprus, and Sicily and defeated the Byzantine navy in a major battle at Phoenix in 655. By land, the Arab armies advanced both to the south and to the west. As early as 651–652 the governor of Egypt invaded Nubia and imposed a treaty that required the Nubians to pay an annual tribute and to permit the unmolested practice of Islām in the province. Raids against North Africa by Arab armies based in Egypt began in 647; by 670 the Arabs had succeeded in establishing a garrison city in Ifrīqīyah (now Tunisia), called al-Qayrawān (Kairouan), which thenceforth displaced Egypt as the base for further expansion.

While some Arabs were passing through Egypt on their way to campaign in North Africa, others were being sent to the Nile Valley on a permanent basis. In addition to tribal contingents that at times escorted newly appointed governors to Egypt (some of which settled in towns), tribesmen were sometimes imported and settled in an effort to increase the Arab-Muslim concentration in the vicinity of Fusṭāṭ. The settlement of large numbers of anarchic tribesmen in Egypt, with tribal ties and allegiances elsewhere in the empire, meant that Egypt became embroiled in po-

Civil strife

litical difficulties with the central government. Civil strife centring around the assassination of the caliph ʿUthmān (656) began in Egypt, where the tribesmen resented the favouritism shown by the caliph to members of his own family. Uprisings led by the dissident Khārijite sect (the Seceders) were frequent in the mid-8th century. In the 9th century the caliph Maʾmun himself led an army from Iraq to put down a rebellion raised both by tribesmen and by Copts; repression of the Copts accompanying their defeat in 829–830 is usually cited as an important factor in accelerating conversion to Islām.

The difficulty inherent in ruling Egypt from Baghdad, which was itself undergoing stress and turbulence, is evident from the rapid turnover in governors assigned to Egypt; the ʿAbbāsid caliph Hārūn ar-Rashīd (ruled 786–809), for example, appointed 24 governors in a reign of 23 years. Possibly as a means of both removing the governorship from the level of tribal strife and paying the central government's Turkish troops, the caliphs began assigning Egypt to Turks rather than to Arabs. But this policy resulted in no tangible improvement in the administration of Egyptian affairs until 868, when the reign of Aḥmad ibn Ṭūlūn inaugurated a new phase of medieval Egyptian history.

The Ṭūlūnid dynasty (868–905). Though short-lived, the Ṭūlūnid dynasty succeeded in restoring a measure of Egypt's ancient glory. For the first time since the pharaohs, Egypt became virtually autonomous and the bulk of its revenues remained within its borders. What is more, Egypt became the centre of a small empire when Ibn Ṭūlūn conquered Syria in 878–879. These developments were paralleled in other provinces of the ʿAbbāsid Empire and were the direct result of the decline of the caliph's power. In order to strengthen their armies, the ʿAbbāsid caliphs had begun early in the 9th century to form contingents of Turkish slaves. To finance these new military formations and, in particular, to pay the Turkish commanders who headed them, the caliphs began to give them administrative grants (*iqṭāʿ* in Arabic, usually translated "fief") consisting of tax revenues from certain territories. In 868 Egypt was granted as a fief to the Turkish general Babak, who chose to remain in Iraq but appointed his stepson, Aḥmad ibn Ṭūlūn, as his agent in Egypt. Ibn Ṭūlūn's great achievement was that he quickly established his own authority in Egypt and backed it up with an army of his own creation, powerful enough to defy the central government of Baghdad and to embark upon foreign expansion.

Ibn Ṭūlūn's first step was to eliminate possible rivals in Egypt. From an early date the administration of Egypt had been divided between the *amīr* (military governor), appointed by the caliph, and the *ʿāmil* (fiscal officer), who was sometimes appointed by the caliph, sometimes by the governor. When Ibn Ṭūlūn entered Egypt in 868 he found the office of *ʿāmil* filled by one Ibn al-Mudabbir, who over a period of years had gained control of Egyptian finances, enriching himself in the process, and was therefore reluctant to acknowledge Ibn Ṭūlūn's authority. A struggle for power soon broke out between the two, which ended four years later with the transfer of Ibn al-Mudabbir to Syria and the assumption of his duties and powers by Ibn Ṭūlūn. An even more important step was the acquisition of an army that would be independent of the caliphate and loyal to Ibn Ṭūlūn. To build such an army, Ibn Ṭūlūn resorted to the same method the caliphs themselves used—the purchase of slaves who could be trained as military units loyal to their owner.

In 877, when Ibn Ṭūlūn failed to pay Egypt's full contribution to the ʿAbbāsid campaign against a black slave uprising in Iraq, the caliphal government, dominated by the caliph's brother al-Muwaffaq, realized that Egypt was slipping from imperial control. An expedition dispatched by al-Muwaffaq to remove Ibn Ṭūlūn from the governorship failed. Taking advantage of the caliphate's preoccupation with the revolt, Ibn Ṭūlūn in 878 invaded Syria, where he occupied the principal cities and garrisoned them with his troops. Thereafter he signified his autonomy by imprinting his name on the coinage along with the name of the caliph. Although the regent al-Muwaffaq lacked the resources to engage Ibn Ṭūlūn in battle, he did have him publicly cursed in the mosques of the empire as a means of retaliation.

Autonomy under Ibn Ṭūlūn

Internally, Ibn Ṭūlūn took active measures to raise Egyptian agricultural productivity and thereby to increase tax revenues; the huge surplus he left in the state treasury at his death in 884 is a measure of his success. Another tangible indication of his achievement for Egypt is an enormous mosque (still standing) that he erected in a suburb of Fusṭāṭ; in contrast, no building comparable in grandeur had even been contemplated by the governors who preceded him.

The great benefits Ibn Ṭūlūn had gained for Egypt by using its resources within the country were squandered by his son and successor, Khumārawayh. He expended huge sums on luxurious appointments for his residence and paid a fortune as a dowry for a daughter he married to the caliph al-Muʿtaḍid in 895. Nevertheless, Khumārawayh was able to maintain the Egyptian armies in the field, and he led them to victory both in Syria and in Mesopotamia. He resolved his father's conflict with the caliphate by a combination of arms and diplomacy, so that Khumārawayh's authority over Egypt, Syria, and Mesopotamia was given official caliphal recognition. This apparent strength evaporated when Khumārawayh was murdered in 896, leaving no funds with which his heir, a 14-year-old youth, could pay the troops. Both Egypt and Syria fell into anarchy, which lasted until 905 when a caliphal army invaded Egypt and momentarily restored it to the status of a province ruled by governors sent from Baghdad.

The Ikhshīdid dynasty (935–969). For 30 years the governors were unable to restore stability in Egypt. During this time, Egypt was subjected to attacks from the Fāṭimid state based in North Africa and to the rampages of an unruly domestic army. The appointment of Muḥammad ibn Ṭughj, from Sogdiana in Central Asia, as governor in 935 led to a repetition of Ibn Ṭūlūn's achievement; by bold measures Muḥammad established his authority over the treasury and the army, reasserted Egyptian influence in Syria, and won the governorship of the Holy Cities of Arabia (Mecca and Medina). In addition, he founded a dynasty; his sons inherited his Sogdian princely title of *ikhshīd,* but their authority was usurped by their Abyssinian slave tutor, Kāfūr, who ruled Egypt with the caliph's sanction. When Kāfūr died in 968 the Ikhshīdids were unable to maintain order in the army and the bureaucracy. In the following year the Fāṭimids took advantage of the disorder in Egypt to launch yet another attack, this one so successful that it led to the occupation of the country by a Berber army led by the Fāṭimid general Jawhar.

The Fāṭimid dynasty (969–1171). The establishment of the Fāṭimid caliphate in 973 in the newly built palace city of Cairo had dramatic consequences for the evolution of Islāmic Egypt. Politically, the Fāṭimids went a step further than the Ṭūlūnids by setting up Egypt as an independent rival to the ʿAbbāsid caliphate. In fact, an avowed aim of the early Fāṭimid propagandists was to achieve world dominion, eradicating the ʿAbbāsid caliphate in the process. For a variety of reasons they achieved neither of these goals; nevertheless, at the height of Fāṭimid power at the beginning of the 11th century, the Fāṭimid caliph could claim sovereignty over the whole North African coastal region, Sicily, the Hejaz and Yemen in Arabia, and southern Syria. Although actual political-military control was never firm except in Egypt, allegiance paid to the Fāṭimids by their provinces was just as meaningful as that paid to the ʿAbbāsids and for a time was certainly more widespread. Even when the Fāṭimid state fell into decline later in the 11th century and abandoned its imperial vision, Egypt continued to play an independent role in the Islāmic world under the leadership of Armenian generals who had gained control of the Fāṭimid armies.

Egypt set up as a rival to the ʿAbbāsid caliphate

Islāmization. It is difficult to estimate the religious change effected by the new dynasty except on the level of the governmental elite, which espoused the official doctrine of Ismāʿīlī Shīʿism—the branch that held all authority to inhere in the line of Ismāʿīl, who had predeceased both his father, the sixth ʿAlid *imām* Jaʿfar ibn Muḥammad, and his own son, Muḥammad at-Tamm. Because they believed that the Fāṭimid caliph was the only legitimate

leader, the practice of Sunnī (orthodox) Islām was theoretically outlawed in Fāṭimid domains. But the practical difficulties which the Ismāʿīlī minority faced in imposing its will on the Sunnī majority meant that the Muslim population of Egypt remained predominantly Sunnī throughout the Fāṭimid period. Certainly there was no public outcry when Saladin, who founded the Ayyūbid dynasty, restored Egypt to Sunnī rule in 1171. Regarding non-Muslims, the Fāṭimids, with one notable exception, were known for their tolerance, and the Copts continued to serve in the bureaucracy. Several Copts held the highest administrative post—the vizierate—without changing their religion. Jews also figured prominently in the government; in fact, a Jewish convert to Islām, Ibn Killis, was the first Fāṭimid vizier and is credited with laying the foundations of the Fāṭimid administrative system. Christians and Jews even managed to survive the reign of the mad caliph al-Ḥākim (ruled 996–1021), who ordered the destruction of Christian churches in Fāṭimid territory, including the Church of the Holy Sepulchre in Jerusalem, and offered his non-Muslim subjects the choice of conversion to Islām or expulsion from Fāṭimid territory. This period of persecution undoubtedly accelerated the rate of conversion to Islām, if only on a temporary and superficial level.

Lack of literature and learning

In comparison with Iraq, Egypt contributed relatively little to Arabic literature and Islāmic learning during the early ʿAbbāsid period. But the Fāṭimids' intense interest in propagating Ismāʿīlī Shīʿism through a network of missionary propagandists made Egypt an important religious and intellectual centre. The foundation of the mosque-college of al-Azhar as well as of other academies drew Shīʿite scholars to Egypt from all over the Muslim world and stimulated the production of original contributions in literature, philosophy, and the Islāmic sciences.

Arabization. The Arabization of Egypt continued at a gradual pace. The early Fāṭimids' reliance on Berber troops was soon balanced by the importation of Turkish, Sudanese, and Arab contingents. The Fāṭimids are said to have used thousands of nomadic Arabs in the Egyptian cavalry and to have further stimulated Arabization by settling large numbers of Arabian tribesmen in Upper Egypt to deprive the Qarmaṭians—their Ismāʿīlī enemies in Iraq and Arabia—of Arab tribal support. On the other hand, the Fāṭimids reduced the Arab population of Egypt in the mid-11th century, when they incited the Banū Hilāl and the Banū Ṣulaym tribes to emigrate from Egypt into the neighbouring Berber kingdom of Ifrīqīyah.

Growth of trade. One of the most far-reaching changes in Fāṭimid times was the growth of Egyptian commerce, especially in Fusṭāṭ, which had become the port city for Cairo, the Fāṭimid capital. Theretofore, Iraq in the east and Tunisia in the west had been flourishing centres for trade conducted both within the Muslim world and between the Muslim and the Christian empires of the West. A number of factors contributed to alter this situation in favour of Egypt. As centralized power declined in Iraq, Mesopotamia, and Syria during the 9th and 10th centuries, traffic on the trade routes across these areas also declined. In Egypt, however, the establishment of a strong government, which soon controlled the Red Sea and maintained a strong navy in the eastern Mediterranean, offered an attractive alternative for the international transit trade between the Orient and Christendom. In addition to having the political stability essential for trade, the Fāṭimids encouraged commerce by their low tariff policy and their noninterference in the affairs of merchants who did business in Egypt. These factors, along with increased European mercantile activity in the Italian cities, helped restore Egypt as a great international entrepôt.

Egyptian commerce

The end of the Fāṭimid dynasty. The Fāṭimid achievement in restoring to Egypt a measure of its ancient glory was remarkable but brief. Halfway through their history the political-religious authority of the Fāṭimid caliphs was vitiated by military uprisings that could be put down only by force. By 1163 the Fāṭimid caliph had been shunted aside in a power struggle between the vizier and the chamberlain, who were themselves so impotent that they had to seek help from the Sunnī and even from the crusader powers of Syria and Palestine. Thus began a series of invasions at the behest of Fāṭimid officials, which ended in 1169 with the occupation of Egypt by an army from Syria, one of whose commanders—Saladin—was appointed Fāṭimid vizier. Two years later Saladin restored Egypt to ʿAbbāsid allegiance, abolished the Fāṭimid caliphate, and, in effect, established the Ayyūbid dynasty.

The Ayyūbid dynasty (1171–1250). Under Saladin and his descendants, Egypt was reintegrated into the Sunnī world of the Eastern caliphate. Indeed, Egypt became champion of that world against the crusaders and, as such, chief target of the crusader armies. But this was a gradual process that required Saladin first to build an army strong enough to establish his power in Egypt and then to unite the factions of Syria and Mesopotamia under his leadership against the Franks. By so doing he reconstituted the Egyptian empire, which included, in addition to the areas just named, Yemen, the Hejaz, and, with the fall of Jerusalem (1187), a major part of the Holy Land.

Return to the Eastern caliphate under Saladin

The abolition of the Fāṭimid caliphate and the official reinstitution of Sunnī Islām seems to have caused little perturbation in Egypt except for an uprising by the Fāṭimid palace guard, quickly suppressed. This undoubtedly means that Ismāʿīlī Shīʿism was confined to Fāṭimid ruling circles.

Saladin's policies. Saladin's remission of all taxes not explicitly sanctioned by Islāmic law must have contributed to his own popularity as well as to the stability of his regime. To ensure the defense of his state against both internal and external enemies, he strengthened the fortifications of Cairo by building a citadel and extending the Fāṭimid city walls. Despite the major military and propagandistic efforts mounted against the crusaders, Saladin continued to treat the Christians of Egypt with tolerance; the Coptic Church thrived under the Ayyūbids, and Copts still served the government. Saladin also treated the Christians of Jerusalem with magnanimity after the conquest of that city.

Much to the consternation of the popes, trade between Egypt and the Italian city-states remained brisk, and the Egyptians were able to use raw materials provided by the Italian merchants to forge weapons against the crusaders. The administration of Egypt stayed in the hands of the vast, mainly civilian, bureaucracy, but was supervised by military officials.

Power struggles. The Ayyūbids introduced a significant change in the governance of their empire that was decisive for the history of their rule in Egypt. Though the Ayyūbids were themselves of Kurdish descent, Saladin followed the Turkish practice of assigning the provinces as fiefdoms to members of his family. In theory, such a measure would ensure the loyalty of the provinces to the central government of Egypt through the loyalty of Ayyūbid kinsmen to their family leader. In practice, however, the measure led to recurrent power struggles in which each governor used his province as a base from which to defy the supreme Ayyūbid power of Egypt. The sultans al-Malik al-ʿĀdil (died 1218) and al-Malik al-Kāmil (died 1238) each succeeded in reuniting Syria and Egypt under his own leadership. Kāmil, especially, was able to exploit Frankish attacks—in the form of the Fifth Crusade, directed against Damietta—to rally family and provincial support for the defense of Egypt. Nevertheless, given the dissension within the Ayyūbid empire, it was clearly in the interest of the Egyptian sultan to reach a peaceful settlement with the crusaders; this was achieved in 1229 by a truce between Kāmil and the Holy Roman emperor Frederick II. The agreement stipulated that Kāmil exchange possession of Jerusalem and other territory in the Holy Land for Frederick's guarantee to support the sultan against aggression from any source.

Growth of Mamlūk armies. The only real security for Ayyūbid Egypt lay in its independent military strength. This explains why one of the last sultans, al-Malik aṣ-Ṣāliḥ Ayyūb (died 1249), resorted to increased purchase of Turkish slaves—called Mamlūks, a name derived from the Arabic word for slave—as a means of manning his armies. Although slave troops had formed an important part of Egyptian armies since the time of Aḥmad ibn Ṭūlūn, their strength had been checked by racial dissension

among the various slave units and by the presence of nonslave elements. But after the death of aṣ-Ṣāliḥ Ayyūb in the course of the Sixth Crusade, which the Egyptians defeated thanks to the Mamlūk corps, the Mamlūks were able to exploit a palace feud and to elevate a member of their own ranks to the sultanate. Thus was established the Mamlūk sultanate, which lasted for two and a half centuries and brought Egypt to the peak of its evolution in the medieval period.

THE MAMLŪK AND OTTOMAN PERIODS (1250–1800)

The Mamlūk dynasty (1250–1517). During the Mamlūk period Egypt became the unrivaled political, economic, and cultural centre of the eastern Arabic-speaking zone of the Muslim world. Symbolic of this development was the reestablishment in 1261 under the Mamlūks of the 'Abbāsid caliphate in Cairo (the Mongols had abolished the caliphate when they invaded Baghdad in 1258). Although the caliph enjoyed little authority and had no power, the mere fact that the Mamlūks chose to maintain the institution in Cairo is a measure of their determination to dominate Arabic Islām. It is curious that the Mamlūks—all of whom were of non-Arab, non-Muslim origin and some of whom knew little if any Arabic—established a regime that saved a substantial portion of Muslim territory from pagan domination and established Egypt's supremacy in Arabic culture.

Egypt as the centre of eastern Islām under the Mamlūks

Political life. The political history of the Mamlūk state is complex; during their 264-year reign, no fewer than 45 Mamlūks gained the sultanate, and once, in desperate circumstances, a caliph (in 1412) was briefly installed as sultan. At times individual Mamlūks succeeded in establishing dynasties, most notably Sultan Qalā'ūn (ruled 1279–90), whose progeny ruled Egypt, with two short interruptions, until 1382. Often the Mamlūks chose to allow a sultan's son to succeed his father only for as long as it took another Mamlūk to build up enough support to seize the throne for himself. In reality there was no principle of legitimacy other than force, for without sufficient military power a sultan could expect to be overthrown by a stronger Mamlūk. (D.P.L.)

Nevertheless, several sultans succeeded in harnessing the energies of the Mamlūk system to establish internal stability and to embark on foreign conquests. Soon after the Mamlūk victory over the Mongols at 'Ayn Jālūt in 1260, Baybars I seized power. He was the true founder of the Mamlūk state, and he compaigned actively and with success against the remaining crusader possessions in Palestine and Syria. He ruled until 1277. During the long reign of al-Malik an-Nāṣir (ruled 1293–1341), the Mamlūks concluded a truce with the Mongols (1323) after several major battles and, despite widespread famine, outbreaks of religious strife, and Bedouin uprisings, maintained economic prosperity in Egypt and peaceful relations with foreign powers, both Muslim and Christian. (D.P.L./D.S.Ri.)

Although the state began to decline politically and economically after the death of Nāṣir in 1341, Egypt continued to dominate Eastern Arabdom. But the cumulative effect of the plague, which swept Egypt in 1348 and on many occasions subsequently; Timur's victory in Syria in 1400; and Egypt's loss to the Portuguese of control over the Indian trade, along with the sultans' inability to keep their refractory Mamlūk corps under control, gradually sapped the strength of the state. The best efforts of such a vigorous sultan as Qā'it Bāy (ruled 1468–96) failed to make Egypt strong enough to defend its Syrian empire against raids by the Turkoman states of Anatolia and Azerbaijan and campaigns of the Ottoman Turks.

Contributions to Arabic culture. By the time of the Mamlūks, the Arabization of Egypt must have been almost complete. Arabic had been the language of the bureaucracy since the early 8th century and the language of religion and culture even longer. Moreover, the prevalence of Arabic as a written and spoken language is attested by the discovery in the geniza (storeroom) of a Cairo synagogue of thousands of letters and documents—called the "Geniza Documents"—dating from the 11th through the 13th century. Though often written in Hebrew characters, the actual language of most of these documents is Arabic, which proves that Arabic was widely used even by non-Muslims. The main incentive for learning Arabic must have come from the desire of a subject population to learn the language of the ruling elite. The immigration of Arab tribesmen during the early centuries of the occupation, and their intermarriage with the indigenous inhabitants, must also have contributed to the gradual spread of Arabic in Egypt.

Prevalence of Arabic in Mamlūk Egypt

The specific Mamlūk contribution to Arabic culture, however, lay above all in the military achievement. By defeating the Mongols, the Mamlūks provided a haven in Syria and in Egypt for Muslims fleeing from Mongol devastation. The extent of this haven was narrowed by subsequent Mongol attacks against Syria, one of which led to a brief Mongol occupation of Damascus in 1294–95, so that Egypt received an influx of refugees from Syria itself as well as from areas farther east.

This accidental displacement of scholars and artisans into Egypt does not, however, wholly account for the efflorescence of certain types of cultural activity under the Mamlūks. In the same way as they supported the caliphate as a visible symbol of their legitimate claim to rule Islāmic territory, the Mamlūks cultivated and patronized religious leaders whose skills they needed in administering their empire and in directing the religious sentiments of the masses into safe (*i.e.,* nondisruptive) channels. Those divines who cooperated with the state were rewarded with government offices, in the case of the *'ulamā'* (religious scholars), and with endowed monasteries, in the case of the Ṣūfīs (mystics). On the other hand, those who dared criticize the prevailing social and moral order were thrown into prison (such was the fate of the famous legist, Ibn Taymīyah, who, having emigrated from Mesopotamia in order to escape the Mongols, was incarcerated in Cairo by the Mamlūks and their religious functionaries for spreading seditious doctrines).

Concrete evidence of the stimulus the Mamlūks gave to cultural life can be found chiefly in the fields of architecture and historiography. Dozens of public buildings erected under Mamlūk patronage are still standing in Cairo and include mosques, colleges, hospitals, monasteries, and caravansaries. Historical writing under the Mamlūks was equally monumental, in the form of immense chronicles, biographical dictionaries, and encyclopaedias.

Religious life. The Mamlūk period is also important in Egyptian religious history. With few and therefore notable exceptions, the Muslim rulers of Egypt had seldom interfered with the lives of their Christian and Jewish subjects so long as these groups paid the special taxes levied on them in exchange for state protection. Indeed, both Copts and Jews had always served in the Muslim bureaucracy, sometimes in the very highest administrative positions. Even the Crusades apparently failed to upset the delicate balance between Muslims and Christians. Trade with the Italian city-states had certainly continued, and there is no evidence that the local Christians were held accountable for the crusader invasions of Egypt. While it is true that Saladin dismissed all Copts from the bureaucracy and imposed sumptuary laws on them, this policy was abandoned by his successors in their desire to reach an accommodation with the crusaders.

With the establishment of the Mamlūk dynasty, however, it is generally agreed that the lot of the Christians, both in Egypt and in Syria, took a distinct turn for the worse. One indication of this change is the increased production of anti-Christian polemics written by Muslim theologians. A possible reason for the change may have been the association of Christians with the Mongol peril. Because the Mongols used Christian auxiliaries in their armies—Georgians and Armenians in particular—they often spared the Christian populations of towns they conquered, while slaughtering the Muslims. Also, the diplomatic efforts aimed at uniting the Mongols with Christian European powers in a joint crusade against the Muslims might have contributed to the Mamlūks' distrust of the Christians. But the dissatisfaction seems to have originated not so much with the Mamlūk rulers as with the masses, and it seems to have been directed not so much against Chris-

Anti-Christian feelings

tians' sympathy for the Mongols as against their privileged position and role in the Mamlūk state.

On several occasions popular resentment against the Copts' conspicuous wealth and their employment in the government was manifested in public demonstrations. Both Muslims and Christians resorted to arson, burning the others' sanctuaries, to express their hatred. Under such pressure, the Mamlūk government dismissed Christians from the bureaucracy on no fewer than nine occasions between 1279 and 1447, and in 1301 it ordered all the churches in Egypt closed. As a result of these intermittent persecutions and the destruction of churches, it is believed that the rate of conversion to Islām accelerated markedly in the Mamlūk period and that Coptic virtually disappeared except as a liturgical language. By the end of the Mamlūk dynasty, the Muslims may well have reached the same numerical superiority that they enjoy in modern times—a ratio of more than 10 to one.

Economic life. In trade and commerce, the Mamlūk period marks the zenith of medieval Egyptian economic history. During the 13th and 14th centuries (as long, that is, as the sultanate was able to maintain order in Egypt), trade was heavy with Mediterranean and Black Sea ports and with India. The Oriental trade was controlled largely by a group of Muslim merchants known as the Kārimīs; the Mediterranean trade was left to European traders, whom the Mamlūks allowed certain privileges in Alexandria. By the 15th century, however, Egypt's commercial importance rapidly deteriorated as the result of population losses, increased government interference in commerce, Bedouin raiding, and Portuguese competition in the Indian trade.

The Ottomans (1517–1798). With the Ottomans' defeat of the Mamlūks in 1516–17, Egyptian medieval history had come full circle, as Egypt reverted to the status of a province governed from Istanbul. Again the country was exploited as a source of taxation for the benefit of an imperial government and as a base for foreign expansion. The economic decline that had begun under the late Mamlūks continued, and with it came a decline in Egyptian culture.

Economic decline under Mamlūks

Some historians attribute the lethargy of Ottoman Egypt solely to Ottoman domination. But although Ottoman policy was geared to imperial, not Egyptian, needs, it was obviously to the rulers' benefit to provide a stable government that would maintain Egyptian agriculture at a high level of productivity and would promote the transit trade. To a certain extent Ottoman actions served these purposes. The decisive factor that ultimately undermined Ottoman policies was the perpetuation of the former Mamlūk elite; though they collaborated with the Ottoman government, they often defied it and in the end they dominated it. By and large the history of Ottoman Egypt concerns the process by which the conquered Mamlūks reasserted their power within the Egyptian state.

The Ottoman conquest. From the conquest itself, the Ottoman presence in Egypt was entangled with Mamlūk factionalism. There is no doubt that the Ottomans invaded Syria in 1516 to break an incipient coalition against Ottoman expansion between the Ṣafavids of Persia and the Mamlūks of Egypt and Syria. The long-standing enmity between the Ottomans and the Mamlūks arose from their contest to control the Turkoman frontier states north of Syria. After the Ottomans strengthened their hold over eastern Anatolia in 1514, it was only natural that the Mamlūks should attempt to bolster their forces in northern Syria and exchange diplomatic missions with the Ṣafavids. The Ottoman sultan Selim the Grim responded by attacking the reinforced Mamlūk army in Syria, probably as a preliminary step in a new campaign against the Ṣafavids. In 1516, after Selim had defeated the Mamlūks at Marj Dābiq (north of Aleppo), Ottoman goals had probably been met, especially since the Mamlūk sultan Qānṣūh al-Ghaurī died in the battle. But the Mamlūks rallied around a new sultan in Cairo, who refused to accept Selim's terms for a settlement. Spurred on by the Mamlūk traitor Khair Bey, Selim marched against Egypt in 1517, defeated the Mamlūks, and installed Khair Bey as Ottoman governor. Khair Bey died in 1552; thereafter, the Ottoman viceroy (called *vali*), with the title of pasha, was sent from Istanbul.

Mamlūk factionalism

Ottoman administration. In 1525 the Ottoman administration of Egypt was defined and codified by the Ottoman grand vizier, Ibrahim Paşa, who was dispatched to Egypt for this purpose by the sultan Süleyman the Magnificent. According to the terms of Ibrahim Paşa's decree (*qanuṇname*), Egypt was to be ruled by a viceroy aided by an advisory council (divan) and an army comprising both Ottoman and local corps. The collection of taxes and the administration of the four provinces into which Egypt was divided were assigned to inspectors (*kashifs*). Although the Egyptian government was headed by bureaucratic officials sent from Istanbul, and supported by Ottoman troops, the Mamlūks were able to penetrate both the bureaucracy and the army. The *kashifs* were often drawn from Mamlūk ranks; three of the seven military corps formed by the Ottomans in the 16th century were recruited in Egypt, one of which—the Circassians—was composed of Circassian Mamlūks. Their service in the army enabled the Mamlūk amirs to secure high-ranking military posts that entitled them to serve on the divan itself.

By the 17th century a distinct elite bearing the title of bey had emerged, which consisted largely of Mamlūk amirs. These beys held no specific offices but were nevertheless paid a salary by the Ottoman government. The elite was perpetuated through the old Mamlūk system of purchasing slaves, giving them military training, then freeing them and attaching them to one of the great Mamlūk houses of Egypt. Thus, for all practical purposes, the Mamlūks maintained themselves as an elite throughout the Ottoman period. They were no longer the only political-military elite, as they had been in the past, but they ultimately succeeded in reestablishing their dominance. Yet the chief obstacle to the growth of their power was not so much the Ottoman ruling hierarchy as it was their own factionalism. During the 17th and 18th centuries the Mamlūks were divided into two great rival houses—the Faqariyya and the Qasimiyya—whose mutual hostility often broke out into fighting and impaired the strength of Mamlūks as a bloc.

The beys

Mamlūk power under the Ottomans. In spite of internal dissension and the resistance of the non-Mamlūk hierarchy, the Mamlūks had emerged by the early 18th century as the supreme power in Egyptian politics. While the beys continued to acknowledge the authority of the Ottoman viceroy and to send tribute to Istanbul, the strongest single figure in Egypt was the bey who held the newly coined title of *shaykh al-balad* ("chief of the city"), which signified that he was recognized by the other beys as their chief. The Mamlūks' rise to power was climaxed by the careers of two amirs—'Alī Bey and Abū Dhahab—both of whom secured from the Sublime Porte (Ottoman government) de facto recognition of their autonomy in Egypt (1768–76) and even undertook military campaigns in Syria and the Hejaz. The Ottomans attempted to end the Mamlūk domination by sending an army to Egypt in 1786. Although it was initially successful, this attempt failed and the troops were withdrawn a year later. A Mamlūk duumvirate was reestablished, and it lasted until Napoleon invaded Egypt in 1798.

Expansion. During the 16th century, when their regime in Egypt was strongest, the Ottomans used Egypt as a base for expansion to the south. Like the Mamlūk rulers before them, they attempted to control the southern approaches to Egypt by instituting their authority in Nubia; this they achieved by annexing Nubia as far south as the Third Cataract. Elsewhere, they undertook to reassert Egyptian command of the Red Sea, which the Portuguese had begun to contest during the early 16th century. Ottoman fleets and troops captured Yemen and Aden (1536–46) and thus dominated the lower Red Sea; in 1557 they strengthened this position by setting up a colony on the Abyssinian coast at Mitsiwa (Massawa). In the 17th century these outposts began to lose their importance as Ottoman and Portuguese power began to decline and the Dutch took over the spice trade.

Culture. Given the political instability and the economic decline that had prevailed in Egypt since late Mamlūk times, it is not surprising that the culture of Ottoman Egypt lacked vitality. Perhaps the most telling example of intellectual quiescence was the dramatic decline in the

Impact of political instability

quantity of historical works produced in Egypt. As already noted, the Mamlūk period is renowned for the number and quality of its historians, partly because the amirs patronized court historians; by contrast, in almost three centuries of Ottoman rule Egypt produced only one historian worthy of note, al-Jabartī (died 1825), famous for his observations on the French occupation. The Ottomans also fell short of the Mamlūks' achievement in architecture; there is no lack of public buildings erected under Ottoman patronage, but even the best of these are imitations of the Byzantine basilica, which had been adopted as the model for mosques.

Religious affairs. Like all previous Muslim governments, the Ottomans continued to employ Copts in the financial offices of the bureaucracy. The Ottomans allowed the caliphate, so assiduously preserved in its nominal form by the Mamlūks, to lapse. At first the caliph was installed in Istanbul by Selim the Grim. Later the caliph—the last of the ʿAbbāsid line—returned to Egypt, where he died in the reign of Süleyman. The claim that the caliph had transferred his authority to the Ottoman sultan is an 18th-century invention. (D.P.L.)

FROM THE FRENCH TO THE BRITISH OCCUPATION (1798–1882)

The French occupation and its consequences (1798–1805). Although several projects for a French occupation of Egypt had been advanced in the 17th and 18th centuries, the purpose of the expedition that sailed under Napoleon Bonaparte from Toulon in May 1798 was specifically connected with the war against Britain. Bonaparte had discounted the feasibility of an invasion of England but hoped, by occupying Egypt, to damage British trade, to threaten India, and to obtain assets for bargaining in any future peace settlement. Meanwhile, as a colony under the benevolent and progressive administration of Revolutionary France, Egypt would be regenerated and regain its ancient prosperity. The military and naval forces were therefore accompanied by a commission of scholars and scientists to investigate and report the past and present condition of the country.

Eluding the British Mediterranean fleet under Lord Nelson, the French landed at Abū Qīr (Aboukir) Bay on July 1 and took Alexandria the next day. In an Arabic proclamation, Bonaparte assured the Egyptians that he came as a friend to Islām and the Ottoman sultan, to punish the usurping Mamlūks and to liberate the people. From Alexandria the French advanced on Cairo, defeating Murad Bey at Shubrākhīt (July 13), and again decisively at Imbābah, opposite Cairo in the so-called Battle of the Pyramids on July 21. Murad fled to Upper Egypt, while his colleague, Ibrāhīm Bey, together with the Ottoman viceroy, made his way to Syria.

Battle of the Pyramids

After entering Cairo (July 25), Bonaparte sought to conciliate the population, especially the religious leaders (*ʿulamāʾ*), by demonstrating his sympathy with Islām and by establishing councils (divans) as a means of consulting Egyptian opinion. The destruction of the French fleet at Abū Qīr by Nelson in the so-called Battle of the Nile on August 1 virtually cut Bonaparte's communications and made it necessary for him to consolidate his rule and to make the expeditionary force as self-sufficient as possible. The savants, organized in the Institut d'Égypte, played their part in this. Meanwhile, Egyptian resentment at alien rule, administrative innovations, and the growing fiscal burden of military occupation was exacerbated when the Ottoman sultan, Selim III (1789–1807), declared war on France on September 11. An unforeseen revolt in Cairo on October 21 was suppressed after an artillery bombardment that ended any hopes of cordial Franco-Egyptian coexistence.

Ottoman Syria, dominated by Aḥmad al-Jazzār, the governor of Acre, was the base from which French-occupied Egypt might most easily be threatened, and Bonaparte resolved to deny it to his enemies. His invasion force crossed the frontier in February 1799 but failed to take Acre after a protracted siege (March 19–May 20), and Bonaparte evacuated Syrian territory. A seaborne Ottoman invading force landed at Abū Qīr in July but failed to maintain its bridgehead. At this point Bonaparte resolved to return to France and succeeded in slipping away on August 22, past the British fleet.

His successor as general in chief, Jean-Baptiste Kléber, viewed the situation of the expeditionary force with pessimism and, like many of the soldiers, wished to return to the theatre of war in Europe. He therefore entered into negotiations with the Ottomans and by the Convention of al-ʿArīsh (Jan. 24, 1800) agreed to evacuate Egypt. Sir Sydney Smith, the British naval commander in the eastern Mediterranean, sponsored the convention, but in this he had exceeded his powers and was instructed by his superior officer, Admiral Lord Keith, to require the French to surrender as prisoners of war. Although the Ottoman reoccupation was well underway, Kléber and the French determined on resistance and defeated the Turkish forces at the Battle of Heliopolis (March 20). A second revolt of Cairo, fomented by Ottoman fugitives, took about a month to suppress; but French authority had been restored when Kléber was assassinated by a Syrian Muslim, Sulaymān al-Ḥalabī, on June 14.

His successor, ʿAbd Allāh Jacques Menou, a French officer (and former nobleman) who had turned Muslim, was determined to maintain the occupation and administered at first a tolerably settled country, although he lacked the prestige of his two predecessors. In 1801 a threefold invasion of Egypt began. British troops were landed at Abū Qīr in March, while the Ottomans advanced from Syria. Shortly afterward, British Indian forces were landed at Quṣayr on the Red Sea coast. The French garrison in Cairo capitulated in June and Menou himself at Alexandria in September.

Surrender of the French

The brief episode of the French occupation was to be significant for Egypt in several ways. The arrival of a European army accompanied by scholars and scientists appropriately inaugurated the impact of the West, which was to be felt increasingly in the next 150 years. Egypt, protected for five centuries by the Mamlūk and Ottoman sultanates, was no longer immune from European attack: it had become an object of the contending policies of France and Britain, a part of the "Eastern Question." Bonaparte's savants had little success in interpreting Western culture to the traditionalist *ʿulamāʾ* of Cairo; their achievement was rather to unveil Egypt to Europe. They uncovered the celebrated Rosetta Stone, which held a trilingual inscription making it possible to decipher hieroglyphs and which thus laid the foundation of modern Egyptology. Their reports and monographs were collected in the monumental *Description de l'Égypte* ("Description of Egypt"), which was published in parts from 1809 to 1828 in Paris.

Of more immediate consequence for Egypt was the effect of the French occupation upon internal politics. The Mamlūk ascendancy was fatally weakened. Murad Bey, who had made his peace with the French, died shortly before their capitulation in 1801; and Ibrāhīm Bey, who returned to Egypt with the Ottomans, had henceforward little power. The new Mamlūk leaders, ʿUthmān Bey al-Bardīsī and Muḥammad Bey al-Alfī, former retainers of Murad, headed rival factions and had in any case to reckon with the British and Ottoman occupation forces. In March 1803 the British were evacuated in accordance with the Peace of Amiens. But the Ottomans, determined to reassert their control over Egypt, remained, establishing their power through a viceroy and an occupying army, in which the most effective fighting force was an Albanian contingent. The Albanians, however, acted as an independent party and in May 1803 mutinied and installed their own leader as acting viceroy. When he was assassinated shortly afterward, the command of the Albanians passed to his lieutenant, Muḥammad ʿAlī (born 1769), who, during the ensuing two years, cautiously strengthened his own position at the expense of both the Mamlūks and the Ottomans.

Ottomans remain in Egypt

Muḥammad ʿAlī and his successors (1805–82). In May 1805 a revolt broke out in Cairo against the Ottoman viceroy, Khūrshīd Pasha. The *ʿulamāʾ* invested Muḥammad ʿAlī as viceroy. For some weeks there was street fighting, and Khūrshīd was besieged in the Citadel. In July Sultan Selim III confirmed Muḥammad ʿAlī in office and the revolt ended.

Muḥammad ʿAlī's viceroyalty was marked by a series of military successes, some of which were attended by political failures that frustrated his wider aims. After the renewal of war between Britain and Napoleonic France in 1803, Egypt again became an area of strategic significance. A British expedition occupied Alexandria in 1807 but failed to capture Rosetta and, after a defeat at the hands of Muḥammad ʿAlī's forces, was allowed to withdraw.

Military expansion. In Arabia, the domination of Mecca and Medina by puritanical Wahhābī Muslims was a serious embarrassment to the Ottoman sultan, who was the titular overlord of the Arabian territory of the Hejaz and the leading Muslim sovereign. At the invitation of Sultan Mahmud II (1808–39), Muḥammad ʿAlī sent an expedition to Arabia that between 1811 and 1813 expelled the Wahhābīs from the Hejaz. In a further campaign (1816–18), Ibrāhīm Pasha, the viceroy's eldest son, defeated the Wahhābīs in their homeland of Najd and brought central Arabia within Egyptian control. In 1820–21 Muḥammad ʿAlī sent an expedition up the Nile and conquered much of what is now the northern Sudan. By so doing, he made himself master of one of the principal channels of the slave trade and began an African empire that was to be expanded under his successors.

After the outbreak of the Greek insurrection against Ottoman rule, Muḥammad ʿAlī, at Sultan Mahmud II's request, suppressed the Cretan revolt in 1822. In 1825 Ibrāhīm began a victorious campaign in the Morea in southern Greece, where his military success provoked intervention by the European powers and brought on the destruction of the Ottoman and Egyptian fleets at the Battle of Navarino in October 1827. The Morea was evacuated the following year.

Muḥammad ʿAlī's invasion of Syria

In 1831 Muḥammad ʿAlī embarked upon the invasion of Syria. His pretext was a quarrel with the governor of Acre, but deeper considerations were involved, particularly the growing strength of the Sultan, which might threaten his own autonomy. Syria, moreover, was strategically important; and its products, especially timber, usefully complemented the Egyptian economy. The Ottoman army was defeated near Konya in Anatolia (December 1832), and in 1833 the Sultan ceded the Syrian provinces to Muḥammad ʿAlī.

In 1839 Ottoman forces reentered Syria but were defeated by Ibrāhīm at the Battle of Nizip (Nezib). A fortnight later Mahmud II died, and the Ottoman Empire seemed on the verge of dissolution; it was saved only by European intervention. In 1840 Ibrāhīm was compelled to evacuate Syria. Muḥammad ʿAlī's Arabian empire (which since 1833 had extended into the Yemen) crumbled at the same time. Although in June 1841 the new sultan, Abdülmecid I (1839–61), conferred on the family of Muḥammad ʿAlī the hereditary rule of Egypt, the viceroy's powers were declining. Because of his growing senility, Ibrāhīm succeeded him (July 1848) but his reign lasted only a few months until his death the following November. The next viceroy was ʿAbbās I, the eldest grandson of Muḥammad ʿAlī. The old viceroy himself died in 1849.

Administrative changes. Muḥammad ʿAlī's military exploits would not have been possible but for radical changes in the administration of Egypt itself. Muḥammad ʿAlī was a pragmatic statesman whose principal object was to secure himself and his family in the unchallenged possession of Egypt. His immediate problem on his accession was to deal with the Mamlūks, who still dominated much of the country, and the *ʿulamāʾ*, who had helped him to power. The strength of these two groups rested largely on their control of the agricultural land of Egypt and the revenues arising therefrom. Gradually, between 1805 and 1815, Muḥammad ʿAlī eroded the system of tax farming that had diverted most of the revenues to the Mamlūks and other notables, imposed the direct levy of taxes, expropriated the landholders, and carried out a new tax survey. In 1809 he defeated the *ʿulamāʾ*, and in 1811 he massacred many of the Mamlūk leaders in Cairo, while Ibrāhīm expelled their survivors from Upper Egypt.

Restructuring of taxation

Muḥammad ʿAlī thus became effectively the sole landholder, with a monopoly over trade in crops, in Egypt, although later in his reign he made considerable grants of land to his family and dependents. The monopoly system was extended in due course from primary materials to manufactures, with the establishment of state control over the textile industry. Muḥammad ʿAlī's ambitious hopes of promoting an industrial revolution in Egypt were not realized, fundamentally because of the lack of available sources of power. The monopolies were resented by European merchants in Egypt and clashed with the economic doctrine of free trade upheld by the British government. Although a free-trade convention that was concluded between Britain and the Ottoman Empire in 1838 (the Convention of Balta Liman) was technically binding on Egypt, Muḥammad ʿAlī succeeded in evading its application up to and even after the reversal of his fortunes in 1840–41.

Reform of the military

The old-style military forces (including the Albanians), on whom Muḥammad ʿAlī relied against his internal opponents and who conquered the Hejaz, Najd, and the northern Sudan, were heterogeneous and unruly. An attempt to introduce Western methods of training in 1815 provoked a mutiny. Muḥammad ʿAlī then decided to form an army of slave-troops dependent wholly upon himself and trained by European instructors. The conquest of the Sudan was intended to provide the recruits. But the slaves, encamped at Aswān, died wholesale, and Muḥammad ʿAlī had to look elsewhere for the mass of his troops. In 1823 he took the momentous step of conscripting Egyptian peasants for the rank and file of his "new model army." On the other hand, the officers were mostly Turkish-speaking Ottomans, while the director of the whole enterprise, Sulaymān Pasha (Colonel Sève), was a former French officer. The conscription was brutally administered and military life harsh. There were several ineffective peasant revolts, while flight to the towns and (before 1831) to Syria produced rural depopulation and a decline in cultivation.

As reorganization proceeded, the viceroy gradually built a new administrative structure. While institutions were created and discarded according to his changing needs, Muḥammad ʿAlī depended essentially upon the members of his own family, particularly Ibrāhīm, and loyal servants, such as his Armenian confidant Boghos Bey. Characteristic of his governmental system were councils of officials, convened to deliberate on public business, and administrative departments (divans) that bore some resemblance to the ministries of European governments. In local administration, Muḥammad ʿAlī established a highly centralized system with a clear chain of command from Cairo through the provincial governors, down to the village headmen. Initiative was not encouraged, but firm control had taken the place of anarchy.

These changes necessitated the training of officers and officials in the new Europeanized ways of working; and this in turn resulted in the creation of a range of educational institutions alongside the traditional Muslim schools that prepared the *ʿulamāʾ*. Much of the foundation work was done by expatriates, while missions of Egyptian students were sent to Europe, especially to Paris. One of these, Rifāʿah Rāfiʿ aṭ-Ṭahṭāwī (1801–73), played the leading part in inaugurating the translation of European works into Arabic and so was a pioneer both in the interpretation of European culture to Egypt and in the renaissance of literary Arabic. The establishment of a government printing press in 1815 soon made possible the wide dissemination of the new books.

ʿAbbās I and Saʿīd, 1848–63. The reign of ʿAbbās I (1848–54) indicates how precarious was the advance of westernization in Egypt. The effort had already been relaxed in the last decade of Muḥammad ʿAlī's rule, and ʿAbbās showed himself to be a traditionalist. It was typical of his policy that he closed the school of languages and the translation bureau and sent their director, aṭ-Ṭahṭāwī, to virtual exile in the Sudan. The French, who had played so large a part in Muḥammad ʿAlī's reforms, fell into disfavour, and for diplomatic support ʿAbbās turned to their British rivals, whose support was needed against the Ottomans. Although initially ʿAbbās was ostentatiously loyal to the Sultan, he resented an attempt made at this time to curtail his autonomy. The British, for their part, had their communications with India facilitated by the

grant of a concession to build a railway from Alexandria to Cairo; the line was completed between 1851 and 1856 and was extended to Suez two years later. Saʿīd (1854–63), who succeeded on ʿAbbās' mysterious and violent death, inaugurated another reversal of policy. While he lacked Muḥammad ʿAlī's energy and ability, he was not unsympathetic to the westernizers. To his French friend Ferdinand de Lesseps (who had been a friend to Muḥammad ʿAlī as well) he granted in 1854 a concession for the cutting of a canal across the isthmus of Suez. This embroiled him both with the Sultan, whose prerogative had been encroached upon, and the British, whose overland railway route was threatened by the project; a deadlock lasted throughout his reign.

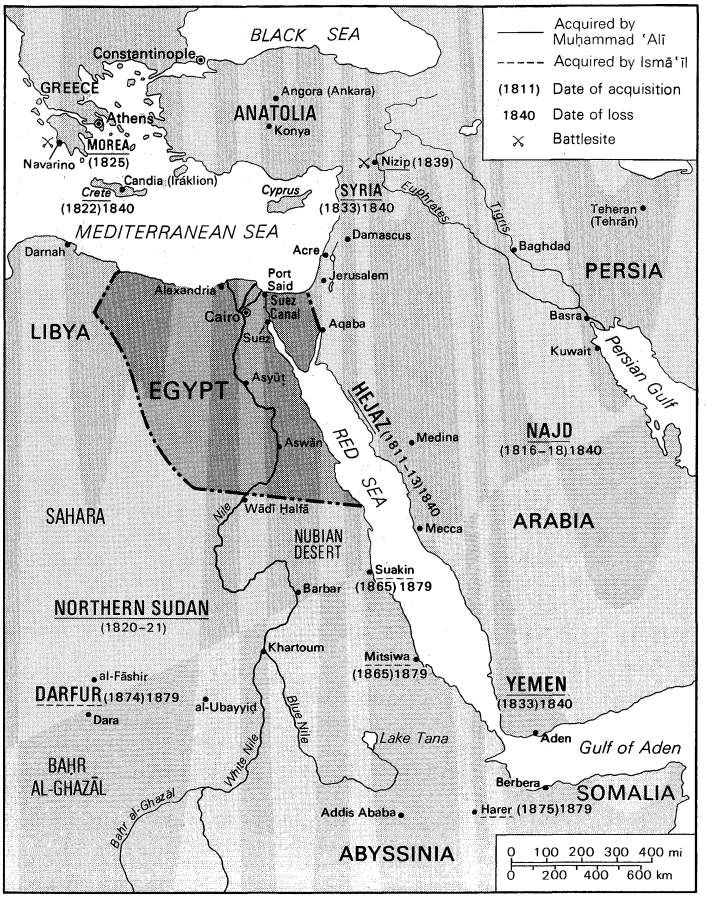
The concession to Ferdinand de Lesseps

Ismāʿīl, 1863–79. Ismāʿīl, the son of Ibrāhīm Pasha, who succeeded on the death of Saʿīd, displayed some of his grandfather's dynamic energy and enthusiasm for modernization. He lacked caution, however, and his reign ended in catastrophe. From his predecessors he inherited a precarious economy and a burden of debt. The American Civil War (1861–65) produced a boom in Egyptian long-staple cotton. This had been introduced and developed in Muḥammad ʿAlī's time, but its production had languished until the interruption of supplies of American cotton caused a fourfold increase in price during the war years. When peace returned, prices collapsed with disastrous consequences for the Egyptian economy. In the management of his finances, Ismāʿīl was both extravagant and unwise and laid himself open to unscrupulous exploitation. Ismāʿīl was committed to the Suez Canal project, but he modified the grant in two important respects: by withdrawing the cession of a strip of land from the Nile to the Suez isthmus, along which a freshwater canal was to be constructed, and by refusing to provide unlimited peasant labour for the project. The matter was submitted to arbitration; an indemnity of more than £3,000,000 was imposed on Ismāʿīl, who also agreed to pay for a large block of shares put by de Lesseps to Saʿīd's account. French pressure on the Sultan succeeded at last in overcoming resistance to the canal project at Istanbul, and a firman (decree from the sultan) authorizing its construction was granted in March 1866. Work had in fact already been going on for seven years, and in November 1869 the Suez Canal was opened to shipping by the empress Eugénie, the wife of Napoleon III of France. The incident symbolized the political and cultural orientation of Egypt in the middle decades of the 19th century.

Ismāʿīl, in other ways, presented himself as the ruler of a new and important state. Although his relations with his suzerain, Sultan Abdülaziz (1861–76), were normally friendly, he was no less anxious than his predecessors to secure the autonomy of his dynasty. In 1866 he obtained a firman establishing the succession by primogeniture in his own line—abandoning the contemporary Ottoman rule of succession by the eldest male. A year later a firman conferred upon Ismāʿīl the special title of khedive, which had in fact been used unofficially since Muḥammad ʿAlī's time and which distinguished the viceroy of Egypt from other Ottoman governors. A period of strained relations developed between the Khedive and the Sultan arising from Ismāʿīl's implied pretensions to sovereignty at the time of the opening of the Suez Canal in 1869, but the two were later reconciled; a firman reconfirmed the Khedive's privileges in 1873. These concessions by the Sultan, however, cost Ismāʿīl heavy expenditure and an increase in the annual Egyptian tribute and formed another factor in the growth of Ismāʿīl's indebtedness.

Ismāʿīl had inherited an African empire in the northern Sudan. Since the middle of the century, in consequence of the abolition of the monopolies, merchants had penetrated south and southwest, up the White Nile and the Baḥr al-Ghazāl, in search of ivory. An ancillary slave trade had developed that was repugnant to the European conscience. Humanitarian and expansionist motives thus coincided to persuade Ismāʿīl to extend Egyptian rule into these remoter regions. He made considerable use of expatriates, notably the Englishmen Sir Samuel Baker and Charles George ("Chinese") Gordon, who extended the Khedive's nominal authority to the African Great Lakes.

Penetration southward



Expansion of Egypt under Muḥammad ʿAlī and Ismāʿīl.

Another series of events led to the conquest in 1874 of the sultanate of Darfur in the west. The Khedive also wished to make Egypt the dominant power in the Red Sea region. The Sultan granted him the old Ottoman ports of Suakin and Mitsiwa in 1865. Egyptian control was established on the Somali coast, and in 1875 Harer was captured. Attempts to invade Abyssinia in 1875 and 1876 were, however, unsuccessful and marked the limits of Ismāʿīl's imperial expansion.

Like other parts of the Ottoman Empire, Egypt was bound by the Capitulations—a system of privileges derived from ancient treaties with former sultans. Under the Capitulations, European and American residents in Egypt were exempt from local taxation and were subject only to their own consular courts. By patient negotiations over several years, Nūbār Pasa, Ismāʿīl's Armenian minister, succeeded in establishing the Mixed Courts in 1875. These had jurisdiction in cases involving Egyptians and foreigners, or foreigners of different nationalities, and had both foreign and Egyptian judges, who administered codes based on French law.

By this time the social consequences of the agrarian and political changes inaugurated by Muḥammad ʿAlī were clearly appearing. The Khedive and his family were the principal landholders in Egypt, possessing extensive personal estates quite apart from the state lands. Around the khedivial family was a parvenu aristocracy that held the principal civil and military offices. Many of its members were also great landowners; most of them were Turkish or Circassian by origin. Although the condition of the peasantry had been adversely affected by military conscription, by corvées for public works (including large-scale demands for labour on the railways and the Suez Canal), and by ill-considered economic and industrial experiments, the rights of cultivators on their land gradually increased. The richer peasants, from whom the village headmen were recruited, in particular increased in importance. When in November 1866 Ismāʿīl set up the consultative council known as the Assembly of Delegates, the members of which were chosen

Creation of the Assembly of Delegates

by indirect election, the great majority of those chosen were village headmen. While Ismāʿīl did not intend that the Assembly should limit his power, its establishment and composition were indications of the political development of the Egyptians in 60 years. Conscription had affected the political significance of the army. The ascendancy of the entrenched Turco-Circassians was challenged by native Egyptian officers, who resented the privileged position of their foreign colleagues. The defeat of the Circassian commander in chief, Rātib Pasha, by the Abyssinians in 1876 was a blow from which the prestige of the old officer group never recovered.

In the Assembly and the army, and among the westernized intelligentsia, politically conscious individuals and groups began to emerge who drew their ideas from both Western and Islāmic sources. Their organization was for the most part small-scale and ephemeral, and their outlook was subversive, being hostile to the autocracy of the Khedive, the ascendancy of the Turco-Circassians, and the pervasive power of the Europeans.

Political tension increased in the last years of Ismāʿīl's reign. Various expedients to postpone bankruptcy (*e.g.*, the sale in 1875 of his Suez Canal shares to Britain) had failed, and in 1876 the Caisse de la Dette Publique (Commission of the Public Debt) was established for the service of the Egyptian debt. Its members were nominated by France, Britain, Austria, and Italy. In the same year, Egyptian revenue and expenditure were placed under the supervision of a British and a French controller (the Dual Control). After an international enquiry in 1878, Ismāʿīl accepted the principle of ministerial responsibility for government and authorized the formation of an international ministry under Nūbār. Ismāʿīl, however, was not prepared to yield his autocracy tamely. In 1879 he profited from an army demonstration against the European ministers to dismiss Nūbār, and he worked in alliance with the Assembly of Delegates to destroy international control over Egypt. By this time, however, his standing outside Eygpt had been lost; and in June 1879, Sultan Abdülhamid II (1876–1908), at the instigation of France and Britain, deposed him in favour of his son, Tawfīq.

Renewed European intervention, 1879–82. European domination was immediately reasserted. The Dual Control was revived, the British controller being Evelyn Baring. By the Law of Liquidation (July 1880), the annual revenues were divided into two approximately equal portions, one of which was assigned to the Caisse de la Dette. The Assembly of Delegates was dissolved. The forces of resistance that Ismāʿīl had stimulated were not, however, allayed by these means. There had already come into existence a nationalist group within the Assembly, prominent among whom was Sharīf (Cherif) Pasha, prime minister from April to August 1879. In the army a group of Egyptian officers, whose leader was ʿUrābī (Arabi) Pasha, was disaffected from the Khedive and resentful of European control of Egypt. By 1881 these two groups had allied to form the National Party, al-Ḥizb al-Waṭanī.

Open tension appeared with a petition drawn up in January 1881 by ʿUrābī and two of his colleagues against the war minister, Rifqī Pasha, a Circassian. They were arrested and court-martialed but released by mutineers. Tawfīq capitulated, dismissed Rifqī, and appointed Bārūdī Pasha, one of ʿUrābī's friends, as war minister. But the ʿUrābists still felt themselves endangered; a military demonstration in Cairo in September 1881 compelled Tawfīq to appoint a new ministry under Sharīf and to convoke the Assembly. But the alliance between the military group and Sharīf was uneasy.

European intervention

Meanwhile, the European powers were becoming increasingly alarmed. A joint English and French communication sent in January 1882 with the intention of strengthening the Khedive against his opponents had the contrary effect. The Assembly of Delegates swung toward the ʿUrābists. Sharīf resigned and Bārūdī became prime minister with ʿUrābī as war minister. Rioting ensued on June 11 after British and French naval forces had been sent to Alexandria. From this point Britain took the initiative. The French refused participation in a bombardment of Alexandria (July 11), while an international conference held at Istanbul was boycotted by the Turks and produced no solution of the problem. The British government finally resolved on intervention and sent an expeditionary force to the Suez Canal. The ʿUrābists were rapidly defeated at Tall al-Kabīr (Sept. 13, 1882), and Cairo was occupied the next day.

THE PERIOD OF BRITISH DOMINATION (1882–1952)

The British occupation and the Protectorate (1882–1922). The British occupation marked the culmination of developments that had been at work since 1798: the de facto separation of Egypt from the Ottoman Empire, the attempt of European powers to influence or control the country, and the rivalry of France and Britain for ascendancy in the country. Through the last minute withdrawal of the French, the British had secured the sole domination of Egypt. W.E. Gladstone's Liberal government was, however, reluctant to prolong the occupation or to establish formal political control, which it feared would antagonize both the Sultan and the other European powers; but the British were unwilling to evacuate Egypt without securing their strategic interests, and this never seemed possible without maintaining a military presence there.

An incident at the outset of the occupation was significant of future tensions. On British insistence, the Khedive's government was obliged to place ʿUrābī and his associates on public trial and to commute the resulting death sentences to exile. Tawfīq's prestige, slight enough at his accession, and diminished in the three years before the occupation, was still further undermined by this intervention of the British government. Meanwhile, Lord Dufferin, the British ambassador in Istanbul, visited Egypt and prepared a report on measures to be taken for the reconstruction of the administrative system. The projects of reform that he envisaged would necessitate an indefinite continuation of the occupation. The implications of this for British policy were slowly and reluctantly accepted by the ministry in London, under pressure from its representative in Cairo, the British agent and consul general, Sir Evelyn Baring, who in 1891 became Lord Cromer.

Public trial of ʿUrābī

Two principal problems confronted the occupying power: first, the acquisition of some degree of international recognition for its special but ambiguous position in Egypt; second, a definition of its relationship to the khedivial government, which formed the official administration of the country. The main European opponents of recognition of the British position were the French, who resented the abolition of the Dual Control (December 1882). The Caisse de la Dette remained in existence, and until 1904 the British had to tread warily in order to circumvent French opposition in this institution. In the early years of the occupation, when Egyptian finances were in disarray, French hostility was a serious problem, but from 1889 onward there was a budget surplus and consequently greater freedom of action for the Egyptian government. A moderate degree of international agreement over Egypt was attained by the Convention of London (1885), which secured an international loan for the Egyptian government and added two further members (nominated by Germany and Russia) to the Caisse de la Dette. In 1888 the Convention of Constantinople (Istanbul) provided that the Suez Canal should always be open in war and peace alike. This was, however, a statement of principle rather than fact; without British cooperation it remained a dead letter.

In matters concerning the international status of Egypt, the decisions were taken in London, but where the internal administration of the country was concerned, Cromer's opinions were usually conclusive. Although throughout the occupation the facade of khedivial government was retained, British advisers attached to the various ministries were more influential than their ministers, while Cromer himself steadily increased his control over the whole administrative machine. (P.M.Ho.)

Cromer's personal rule

Tawfīq himself gave little trouble, but his prime ministers were more tenacious. Sharīf Pasha, prime minister at the beginning of the occupation until 1884, and his successors Nubar Pasha (1884–88) and Riyāḍ (Riaz) Pasha (1888–91) resigned because of clashes over administrative control. Thereafter, until November 1908, with a break in 1893–

95, the prime minister was Muṣṭafā Fahmī Pasha, who showed himself an obedient instrument of Cromer.

ʿAbbās Ḥilmī II, 1892–1914. The death of Tawfīq and the accession of his 17-year-old son, ʿAbbās Ḥilmī II, in 1892 marked the beginning of a new phase of opposition to the occupation. The new khedive was not content to accept Cromer's tutelage, while the British agent resented the attempts of one so much his junior to play a serious role in Egyptian politics. ʿAbbās dismissed Muṣṭafā Fahmī in January 1893 and tried to appoint his own nominee as prime minister. Cromer, backed by the British government, frustrated his endeavours, and Fahmī returned to office in November 1895. ʿAbbās provoked another crisis in January 1894 by public criticism of British military officers and especially H.H. Kitchener, the sirdar (commander in chief). Once again Cromer intervened, and ʿAbbās was compelled to make amends.

Other considerations apart, the behaviour of ʿAbbās in the early years of his reign indicated the emergence of a new generation who had only been children when the occupation began. One of ʿAbbās' contemporaries was Muṣṭafā Kāmil (1874–1908), who had studied in France and then had entered a circle of Anglophobe writers and politicians. On returning to Egypt in 1894 he had reached an understanding with the Khedive on the basis of their common detestation of the British occupation. By his speeches and writings (in 1900 he founded his own newspaper, *al-Liwā*), he endeavoured to create an Egyptian patriotism that would rally the entire nation around the Khedive. A boost was given to nationalism by the campaigns for the reconquest of the Sudan (1896–98) and still more by the Condominium Agreement of 1899, which nominally gave Egypt and Britain joint responsibility for the administration of the reconquered territory but in effect made the Sudan a British possession.

Muṣṭafā Kāmil

A final episode in the reconquest of the Sudan, the confrontation of British and French at Fashoda on the White Nile in 1898, was followed by the reconciliation of the two powers in the Entente Cordiale (1904), which in effect gave Britain a free hand in Egypt. This was a blow to the hopes of Muṣṭafā Kāmil and to his alliance with the Khedive, who showed himself more willing to cooperate with Cromer. Muṣṭafā Kāmil now turned to Sultan Abdülhamid. When a dispute (the Ṭābah Incident, 1906) arose between the Ottomans and the occupying power over the Sinai Peninsula, Muṣṭafā Kāmil sought to rally Egyptian nationalist opinion in favour of the Sultan, but Muṣṭafā Kāmil died in 1908.

British domination in Egypt and Cromer's personal ascendancy never seemed more secure than in the period following the Entente Cordiale. But the "veiled protectorate" had hidden weaknesses. Cromer was both out of touch and out of sympathy with the new generation of Egyptians. The occupation had become to all intents and purposes permanent, and the consequent growth of the British official establishment created frustration among educated Egyptians. The British, however, saw themselves as the benefactors of the Egyptian peasantry, whom they had delivered from the corvée and the lash. The Dinshawāy Incident showed them in another light. In June 1906 a fracas between villagers at Dinshawāy and a party of British officers out pigeon shooting resulted in the death of a British officer. The special tribunal set up to try the matter imposed exemplary and brutal sentences on the villagers. In the bitter aftermath of this affair, Cromer retired in May 1907.

The Dinshawāy Incident

Sir Eldon Gorst, who succeeded Cromer, had served in Egypt from 1886 to 1904 and brought a fresh mind to bear on the problems of the occupation. He obtained an understanding with the Khedive and endeavoured to diminish the growing power and numbers of the British establishment. At the same time he tried to give more effective authority to Egyptian political institutions. Muṣṭafā Fahmī's long premiership ended and he was followed by a Copt, Buṭrus Ghālī Pasha. When Gorst died prematurely in July 1911, he had attained only limited success. Many British officials resented his policies, which at the same time failed to conciliate the nationalists. A project for the extension of the Suez Canal Company's 99-year concession by 40 years was thrown out by the General Assembly (a quasi-parliamentary body, set up in 1883), while Buṭrus Ghālī, who had advocated it, was assassinated a few days later by a Muslim extremist. The appointment of Lord Kitchener to succeed Gorst portended the end of conciliation of the Khedive. But Kitchener, although autocratic, was not wholly conservative; his attempts to limit the power and influence of ʿAbbās Ḥilmī served the interests of the nationalists. The Organic Law of 1913 created a new and more powerful Legislative Assembly that served as a training ground for the nationalist leaders of the postwar period. At the same time, the peasants were helped by improved agriculture and by legal protection of their holdings from seizure for debt.

World War I and independence. In November 1914 Britain declared war on the Ottoman Empire and in December proclaimed a protectorate over Egypt, deposed ʿAbbās, and appointed his uncle, Ḥusayn Kāmil, with the title of sultan. Kitchener was succeeded by Sir Henry MacMahon, and he by Sir Reginald Wingate, both with the title of high commissioner. Although Egypt was not required to provide troops, the people, and particularly the peasantry, suffered from the effects of war. The declaration of martial law and the suspension of the Legislative Assembly curbed the activities of middle-class nationalists. Ḥusayn Kāmil died in October 1917 and was succeeded by his ambitious brother, Aḥmad Fu'ād.

On Nov. 13, 1918, two days after the Armistice, Wingate was visited by three Egyptian politicians headed by Sa'd Zaghlūl Pasha. Zaghlūl demanded autonomy for Egypt and announced his intention of leading a delegation (Arabic *wafd*) to state his case in England. The British government's refusal to accept a delegation, followed by the arrest of Zaghlūl, produced a widespread revolt in Egypt; and Lord Allenby, the victor over the Turks in Palestine, was sent out as special high commissioner. Allenby insisted on concessions to the nationalists in the hopes of reaching a settlement. Zaghlūl was released, and the Wafd, now a countrywide organization, dominated Egyptian politics. The Milner Commission (1919–20), sent to report on the establishment of constitutional government under the protectorate, was boycotted, but Milner subsequently had private talks with Zaghlūl in London. Finally, hoping to outmaneuver Zaghlūl and to build up a group of pro-British politicians in Egypt, Allenby pressed his government to promise independence without previously securing British interests by a treaty. The declaration of independence (Feb. 28, 1922) ended the protectorate but, pending negotiations, reserved four matters to the discretion of the British government: the security of imperial communications, defense, the protection of foreign interests and of minorities, and the Sudan. On March 15 the Sultan became King Fu'ād I of Egypt.

Attempt of Zaghlūl to secure Egypt's independence

The Kingdom of Egypt (1922–52). The new kingdom was in form a constitutional monarchy. The constitution, based on that of Belgium and promulgated in April 1923, defined the King's executive powers and established a bicameral legislature. An electoral law provided for universal male suffrage and the indirect election of deputies to the lower house: the Senate was half elected and half appointed. But Egyptian constitutionalism was as illusory as Egyptian independence. A political struggle was continually waged among three opportunist contestants—the King, the Wafd, and the British.

The interwar period. Fu'ād was never popular and felt insecure, and was therefore prepared to intrigue with the nationalists or with the British to secure his position and powers. The Wafd, with its mass following, elaborate organization, and (until his death in 1927) charismatic leader in Zaghlūl, was the only truly national party in Egypt. Ideologically, it stood for national independence against British domination and for constitutional government against royal autocracy. In practice—and increasingly as time went on—its leaders were prepared to make deals with the British or the King to obtain or retain power. Personal and political rivalries led to the formation of splinter parties, the first of which, the Liberal Constitutionalist Party, broke off as early as 1922. The primary aim of the British government, represented by its high

commissioner (after 1936, its ambassador), was to secure imperial interests, especially the control of communications through the Suez Canal. The need for a treaty to safeguard these interests led Britain on more than one occasion to conciliate nationalist feeling by supporting the Wafd against the King.

Political crises of the 1920s

The first general election, in January 1924, gave the Wafd a majority, and Zaghlūl became prime minister for a few months marked by unsuccessful treaty discussions with the British and tension with the King. When in November 1924 Sir Lee Stack, the sirdar and governor-general of the Sudan, was assassinated in Cairo, Allenby immediately presented an ultimatum that, though later modified by the British government, caused Zaghlūl to resign. The general election of March 1925 left the Wafd still the strongest party, but the Parliament no sooner met than it was dissolved. For more than a year Egypt was governed by decree. The third general election, in May 1926, again gave the Wafd a majority. The British frowned on a return of Zaghlūl to the premiership, and the office went instead to the Liberal Constitutionalist ʿAdlī Yegen (Yakan), while Zaghlūl held the presidency of the Chamber of Deputies until his death in 1927. Once again tension developed between the Parliament and the King, and in April 1927 ʿAdlī resigned, to be succeeded by another Liberal Constitutionalist, ʿAbd al-Khāliq Tharwat (Sarwat) Pasha, who negotiated a draft treaty with the British foreign secretary. The draft treaty, however, failed to win the approval of the Wafd. Tharwat resigned (March 1928), and Muṣṭafā an-Naḥḥās (Nahas) Pasha, Zaghlūl's successor, became prime minister. But the King dismissed him in June and dissolved the Parliament in July. In effect, the constitution was suspended, and Egypt was again governed by decree under a Liberal Constitutionalist premier, Muḥammad Maḥmūd Pasha.

Draft treaty proposals were agreed upon in June 1929, but since Maḥmūd was unable to overcome Wafdist opposition, British influence was thrown behind a return to constitutional government, hoping that a freely elected Parliament would approve the proposals. In the fourth general election (December 1929), the Wafd won a majority, and an-Naḥḥās again became prime minister. Resumed treaty negotiations broke down over the problem of the Sudan, from which the Egyptians had been virtually excluded since 1924. An-Naḥḥās also clashed with the King, whose influence he sought to curtail. He resigned in June 1930, and Fu'ād appointed Ismāʿīl Ṣidqī (Sidki) Pasha to the premiership. The constitution of 1923 was abrogated, and another was promulgated by royal decree. This, with its accompanying electoral law, strengthened the King's power. By this and other measures, Ṣidqī sought to break the power of the Wafd, which boycotted the general election of June 1931. The strong government of Ṣidqī lasted until September 1933, when he was dismissed by the King. Thereafter, for more than a year, palace-appointed governments ruled Egypt.

But Fu'ād, whose health was failing, could not hold out indefinitely against the internal pressure of the Wafd and the external pressure of Britain, which was becoming increasingly anxious for a treaty with Egypt. In April 1935 the constitution of 1923 was restored, and a general election in May 1936 gave the Wafd a majority once more. Fu'ād had died in the previous month and was succeeded by his son Farouk (Fārūq), still a minor. An-Naḥḥās became prime minister for the third time. Agreement was quickly reached with Britain, and a treaty of mutual defense and alliance was signed in August 1936. At the conference of Montreux, held in the following year, Egypt, with the backing of Britain, obtained the immediate abolition of the Capitulations and the extinction of the Mixed Courts after 12 years. In 1937 also, Egypt became a member of the League of Nations.

Treaty with Britain

An-Naḥḥās had reached the height of his power, but he was soon to be overthrown. In July 1937 the young king Farouk came of age and assumed his full royal powers. He was both popular and ambitious to rule, and tension rapidly developed between him and his prime minister. A split developed in the Wafd: Maḥmūd Fahmī an-Nuqrāshī (Nokrashy) Pasha and Aḥmad Māhir (Maher) Pasha were expelled and formed the Saʿdist Group. The Wafdist youth movement, known as the Blueshirts, was opposed by the Greenshirts of Young Egypt, a fascist organization. In December 1937 King Farouk dismissed an-Naḥḥās. In the ensuing general election (April 1938), the Wafd won only 12 seats.

World War II and its aftermath. Although at the outbreak of World War II in September 1939 Egypt provided facilities for the British war effort, few Egyptians were enthusiastic supporters of Britain and many expected its defeat. In 1940 the British brought pressure on the King to dismiss his prime minister, ʿAlī Māhir, and to appoint a more cooperative government. When, early in 1942, German forces prepared to invade Egypt, a second British intervention compelled King Farouk to accept an-Naḥḥās as prime minister. The Wafd, its power confirmed by overwhelming success in the general election of 1942, cooperated with Britain. Nevertheless, the intervention of February 1942 had disastrous consequences. It confirmed Farouk's hostility to both the British and an-Naḥḥās and tarnished the Wafd's pretensions as the standard-bearer of Egyptian nationalism. The Wafd was damaged also by internal rivalries.

An-Naḥḥās was dismissed by the King in October 1944. His successor, Aḥmad Māhir, was acceptable to the British, but he was assassinated in February 1945, at the moment of Egypt's declaration of war on Germany and Japan. He was succeeded by a Saʿdist, an-Nuqrāshī Pasha.

At the end of World War II, Egypt was in a thoroughly unstable condition. The Wafd declined and its political opponents took up the nationalist demand for a revision of the treaty of 1936—in particular for the complete evacuation of British troops from Egypt and the ending of British control in the Sudan. Politics was passing into the hands of radicals. The Muslim Brotherhood, founded in 1928, developed from an orthodox Islāmic reformist movement into a militant mass organization. Demonstrations in Cairo became increasingly frequent and violent. The pressure rendered it impossible for any Egyptian government to attempt a settlement of its two main external problems: the need to revise the treaty with Britain, and the wish to support the Arab cause in Palestine. Negotiations with Britain, undertaken by an-Nuqrāshī and (after February 1946) by his successor, Ṣidqī, broke down over the British refusal to prejudice the possible independence of the Sudan. Although Egypt referred the dispute to the United Nations in July 1947, the deadlock continued.

Anti-British demonstrations

Until the interwar period neither the Egyptian public nor the politicians had shown much interest in Arab affairs generally; Egyptian nationalism had developed as an indigenous response to local conditions. After 1936, however, Egypt became involved in the Palestine problem, and in 1943–44 it played a leading part in the formation of the Arab League. After World War II, Egypt became increasingly committed to the Arab cause in Palestine, but its unexpected and crushing defeat in the first Arab–Israeli War (1948–49), which had been launched with Syria, Iraq, and Jordan in response to the declaration of the State of Israel in May 1948, contributed to disillusionment and political instability. The Muslim Brotherhood increased its terrorist activities. An-Nuqrāshī, again prime minister, endeavoured to suppress the organization and was assassinated in December 1948. The Brotherhood's leader was murdered two months later.

A general election in January 1950 gave the Wafd a majority, and an-Naḥḥās again formed a government. Failing to reach agreement with Britain, in October 1951 he abrogated both the 1936 treaty and the Condominium Agreement of 1899. Anti-British demonstrations were followed by guerrilla warfare against the British garrison in the Canal Zone. British military action in Ismailia was followed on Jan. 26, 1952, by the burning of Cairo by demonstrators. An-Naḥḥās was dismissed, and there were four prime ministers in the ensuing six months.

(P.M.Ho./Ed.)

THE REVOLUTION AND THE REPUBLIC

The Nasser regime. At mid-century Egypt was ripe for revolution. Political groupings of both right and left pressed

for radical alternatives. From an array of contenders for power, it was a movement of military conspirators—the Free Officers led by Col. Gamal Abdel Nasser—that toppled the monarchy in a coup in July 1952. In broad outline, the history of contemporary Egypt is the story of this coup, which preempted a revolution but then itself became a revolution from above. For three decades rule by Free Officers brought just enough advance at home and enhancement of standing abroad to make Egypt an island of stability in a turbulent Middle East.

The Free Officers

The coup of July 1952 was fueled by a powerful but vague Egyptian nationalism rather than by a coherent ideology. It yielded a regime whose initially reformist character was given more precise form by a domestic power struggle and by the necessity of coming to terms with the British, who still occupied their base at Suez.

The domestic challenge to Nasser came in February–April 1954 from Gen. Mohammad Naguib, an older officer who served as figurehead for the Free Officers. Political parties had been abolished in January 1953. To supplement his power base in the military forces, Nasser drew on the police and on working-class support mobilized by the newly created mass political organization called the National Union. The small middle class, the former political parties, and the Muslim Brotherhood all rallied to Naguib. Nasser's triumph meant that a strong reliance on the military and security apparatus, coupled with carefully controlled manipulation of the civilian population, would be basic to the new system of rule.

Nasser's initial moderation

Obscured in the West was Nasser's initial moderation regarding Egypt's key foreign policy challenges—the Sudan, the British presence, and Israel. An agreement signed in 1954 established a transitional period of self-government for the Sudan, which became an independent republic in January 1956. Prolonged negotiations yielded the Anglo-Egyptian Treaty of 1954, under which British troops were to be evacuated gradually from the Canal Zone. Some Egyptians were critical, finding the treaty unsatisfactory from an Egyptian nationalist perspective. An attempt to assassinate Nasser by a member of the Muslim Brotherhood in October 1954 was used as a pretext to crush that organization.

In retrospect, it is clear that Nasser was the reluctant champion of the Arab struggle against Israel. Domestic development was his priority. A dangerous pattern of violent interactions, however, was evolving that would eventually draw the Egyptians into conflict with Israel. Small groups of Palestinian raiders, including some operating from Egyptian-controlled Gaza, were infiltrating Israel's borders. In October 1953 the Israeli government initiated the policy of large-scale retaliation that it pursued thereafter. One such strike—an attack on Gaza in February 1955 that left 38 Egyptians dead—exposed the military weakness of the Free Officer regime.

In September 1955 Nasser announced that an arms agreement had been signed between Egypt and Czechoslovakia (acting for the Soviet Union). The way to improved Soviet–Egyptian relations had been prepared by Nasser's refusal to join the Baghdad Pact (the Middle East Treaty Organization, later known as the Central Treaty Organization), which had been formed earlier that year by Turkey, Iraq, Iran, Pakistan, and the United Kingdom, with the support of the United States, to counter the threat of Soviet expansion. With the arms agreement of 1955, the Soviet Union eluded efforts to contain its actions and established itself as a force in the Middle East.

The erosion of Nasser's initially pro-Western orientation was accelerated further by the denial of funds previously promised by the United States and Britain for the construction of a high dam at Aswān. Defiantly, Nasser announced the nationalization of the Suez Canal Company in 1956 to finance the dam. In its subsequent attack on Egypt in October 1956, Israel was joined by the British, who were enraged by the nationalization, and the French, who were angered by Egyptian aid to the revolt in Algeria. Pressure on the invading powers by the United States and the Soviet Union, however, soon ended the so-called Suez War, leaving Nasser triumphant (despite his military losses) and with the Suez Canal firmly in Egyptian hands.

The Suez War of 1956

Nasser, who had been elected president in June 1956, pursued a more radical line in the decade following the Suez War. He launched an ambitious program of domestic transformation, a revolution from above that was paralleled by a drive for Egyptian leadership in the Arab world. Early in 1958 Egypt combined with Syria to form the United Arab Republic (U.A.R.), but it was a reluctant marriage of convenience and was dissolved in bitterness in September 1961 (Egypt retained the name United Arab Republic until 1971). The secession of Syria was blamed by Nasser on Syrian "reactionaries," and in direct response he pushed the revolution in Egypt further to the left. The following spring a National Charter proclaimed that Egypt's would be a regime of "scientific socialism" with a new mass organization, the Arab Socialist Union (ASU), to function in place of the National Union.

Impressive domestic gains were registered. In 1950 industry contributed 10 percent to the total national output; by 1970 that figure had increased to 21 percent. Unfortunately, these achievements in industry were not matched in agriculture, and they were further undercut by rapid population growth.

Throughout this period the potential military danger from Israel was a constant factor in the calculations of the U.A.R. government. It was a motive in strengthening ties with the Soviet bloc and producing a series of initiatives for cooperation among the Arab states, which, however, were disappointing. Nasser masked essential Egyptian moderation on the Israeli issue with a militant rhetoric of confrontation that was necessary to preserve his standing in the Arab world.

The failure of the union with Syria had been a blow to Nasser's pan-Arab standing. To regain the initiative, Nasser intervened in 1962–67 on the republican side of the Yemeni civil war. That intervention provoked conflict with Saudi Arabia, which supported the Yemeni royalists, and with the United States, which in turn supported the Saudis. Until then, Nasser had managed to obtain impressive aid from both the Soviet Union and the United States. Because of Egyptian intervention in the Yemen, U.S. aid was cut off in the mid-1960s.

Egyptian intervention in Yemen

This series of reversals was one key factor in the mood of desperation that pushed Nasser to abandon his policy of "militant inaction" toward Israel. For 10 years relative peace on the border with Israel was precariously maintained by the presence of a UN Emergency Force (UNEF) stationed on the Egyptian side. In the Arab summit conferences of the early 1960s Nasser had counseled restraint, but in 1966 events eluded his control. Palestinian incursions against Israel were launched with greater frequency and intensity from bases in Jordan, Lebanon, and, especially, Syria. A radical Syrian regime openly pledged support to the Palestinian guerrilla raids. On Nov. 13, 1966, an Israeli strike into Jordan left 18 dead and 54 wounded. Taunted openly for hiding behind the UNEF, Nasser was forced to act. The Egyptian president requested the withdrawal of the UNEF from the Sinai border. But that would include, as the United Nations interpreted the order, the removal of UN troops stationed at Sharm ash-Shaykh at the head of the Gulf of Aqaba. The posting of Egyptian troops there would mean the closing of the gulf to the Israelis.

Israel had made it clear that the closing of the gulf would be a cause for war. On June 5, 1967, Israel launched a preemptive attack on Egypt and Jordan later known as the June (or Six-Day) War. All of Egypt's airfields were struck, and the bulk of Egyptian planes were demolished on the ground. In the Sinai, Egyptian forces were defeated and put to flight. An estimated 10,000 Egyptians died. The Israelis reached the Suez Canal on June 9. Egypt was crushed and Nasser resigned. A popular outpouring of support, only partially manipulated by the government, refused the President's resignation. But the Nasser era was, in fact, over. In both domestic and foreign affairs, Nasser began a turn to the right that his successor, Anwar el-Sādāt, was to accelerate sharply.

Six-Day War of 1967

The Sādāt regime. Nasser died on Sept. 28, 1970, and was succeeded by his vice president, Sādāt, himself a Free Officer. Although regarded at the time as an interim figure,

Sādāt soon revealed unexpected gifts for political survival. In May 1971 he outmaneuvered a formidable combination of rivals for power, calling his victory the "Corrective Revolution." Sādāt then used his strengthened position to manage a war with Israel in October 1973, thereby setting the stage for a new era in Egypt's history.

October War of 1973

The Sādāt era really began with the October (or Yom Kippur) War of 1973. The concerted Syrian–Egyptian surprise attack on October 6 surprised not only Israel but also the world. There were no illusions that Israel could be vanquished. Rather, the war was launched with the diplomatic aim of convincing a chastened, if still undefeated, Israel to negotiate on terms more favourable to the Arabs. Preparation for the war involved a loosening of ties with the Soviet Union; to that end, in July 1972 Sādāt had announced the withdrawal of all Soviet military advisers who, it was claimed later, had opposed the Egyptian determination to fight.

Egypt did not win the war of 1973 in any conventional sense. As soon as Israel recovered from the initial shock of Arab gains in the first few days of fighting—and once the United States abandoned its early equivocation and resupplied Israel with a massive airlift—the Israelis demonstrated their military superiority. A cease-fire was secured by the United States.

Still, the initial successes in October 1973 were sufficient to allow Sādāt to pronounce the war an Egyptian victory and to openly and honourably seek peace. Egyptian interests, as Sādāt saw them, dictated peace with Israel. Despite almost immediate difficulties with his Syrian allies, Sādāt signed the Sinai I (1974) and Sinai II (1975) disengagement agreements that returned Sinai and secured large foreign assistance commitments to Egypt. When Israeli inflexibility combined with Arab resistance to slow events, Sādāt made his dramatic journey to Jerusalem on Nov. 19, 1977, to address the Israeli Knesset (Parliament). The subsequent meeting in September 1978 of Sādāt, Israeli Prime Minister Menachem Begin, and U.S. Pres. Jimmy Carter at Camp David, Md., led directly to the Israeli–Egyptian peace treaty of March 26, 1979. The treaty provided for Egyptian–Israeli normalization and established a framework for the Palestinian issue. Its provisions included the withdrawal of Israeli armed forces and civilians from Sinai within three years, special security arrangements in Sinai, a buffer zone along the Sinai–Israel border to be manned by United Nations peacekeeping forces, the exchange of ambassadors, and the establishment of normal economic and cultural relations. The status of the Israeli-occupied West Bank and Gaza territories and the question of Palestinian autonomy were to be negotiated.

Peace with Israel

Sādāt linked his peace initiative to the task of economic reconstruction, and an open-door policy was proclaimed. A liberalized Egyptian economy would be revitalized by the inflow of Western and Arab capital. The peace process did produce economic benefits, notably a vast U.S. aid program, begun in 1975, that reached more than $1,000,000,000 a year by the 1980s.

The Sādāt peace with Israel was not without its costs, however. As the narrowness of the Israeli interpretation of Palestinian autonomy under the Camp David agreement became clear, Sādāt found it impossible to convince the Arab world that the accords dealt justly with legitimate Palestinian rights. Egypt lost the financial support of the Arab states and, shortly after signing the peace treaty, was expelled from the Arab League.

At home democratization of political life did not prove to be an acceptable substitute for economic revitalization. On Jan. 18–19, 1977, demonstrations provoked by economic hardship broke out in Egypt's major cities. An estimated 79 persons were killed, 1,000 were wounded, and 1,250 were jailed. The removal of the most oppressive features of Nasser's rule, the return in controlled form to a multiparty system, and (at least initially) the Sādāt peace with Israel were all welcomed. But, as Egypt entered the 1980s, the lack of progress on the Palestinian issue and the failure to relieve mass economic hardships, heightened by widening class gaps, threatened to destabilize the Sādāt regime. In the West, Sādāt's international role initially obscured these danger signs. Then, in September 1981, his arrest of more than 1,300 of the political elite of Egypt signaled the precariousness of his position.

Egypt after Sādāt. Sādāt's assassination on Oct. 6, 1981, by members of the radical fringe of the Muslim religious opposition was greeted in Egypt by a deafening calm. It was with a profound sense of relief that Egyptians brought Hosni Mubarak, Sādāt's handpicked vice president, to power with a mandate for cautious change. As an air force general and hero of the October War, Mubarak had played an important role in Sādāt's rule from the early 1970s. (R.W.Ba.)

During his first year as president, Mubarak struck a moderate note. There was no backing away from the peace with Israel and no loosening of the connection to the United States. By pursuing that steady course, he was able to prevent any delay in the return of the occupied Sinai to Egyptian sovereignty in April 1982. At the same time, Mubarak tried to contain the disaffections that had surfaced in the last year of Sādāt's era. He announced the end of the reign of the privileged minority that had dominated the invigorated private sector during the Sādāt years. He also moved immediately to soften the harsh edges of the authoritarianism of Free Officer rule. Unfortunately, Egypt's worsening economic problems did not lend themselves to rapid improvement. But in his very first speeches Mubarak did frankly and perceptively outline the shortcomings of the Egyptian economy.

These solid beginnings were undercut by the Israeli invasion of Lebanon in June 1982. In Egypt the invasion was seen as an Israeli attempt to destroy Palestinian nationalism, and Mubarak was accused by his detractors of allowing Israel to take advantage of Egypt's position of disengagement. Official relations with Israel were severely strained until Israel began its partial withdrawal from Lebanon in 1985. As a result of Mubarak's cautious policies, on the other hand, Egypt gradually was able to repair its relationships with most of the moderate Arab nations.

Within the country, opposition to a variety of political, economic, and social policies continued, chiefly among discontented labour and religious groups. The government contained labour strikes and other incidents of unrest and adopted several measures aimed at curbing a determined drive by Islāmic fundamentalists to destabilize the regime.

Egypt's economy suffered markedly from a sharp decline in oil prices in 1986 and was further weakened by a drop in the number of remittances from workers abroad. In spite of a rising burden of debt, the government continued to rely heavily on foreign economic aid.

For later developments in the history of Egypt, see the *Britannica Book of the Year* section in the BRITANNICA WORLD DATA ANNUAL.

For coverage of related topics in the *Macropædia* and *Micropædia,* see the *Propædia,* sections 911, 912, 924, 962, 96/11, and 978. (R.W.Ba./D.H./Ed.)

BIBLIOGRAPHY

General works: RICHARD F. NYROP (ed.), *Egypt: A Country Study,* 4th ed. (1983), covering the history, society, economy, and politics of Egypt; SHIRLEY KAY, *The Egyptians: How They Live and Work* (1975), an introductory survey of Egypt's geography, history, government, and culture, as well as transportation; JASPER MORE, *The Land of Egypt* (1980), an illustrated general description of the country; and AHMED FAKHRY, *The Oases of Egypt,* 2 vol. (1973), a description of the oases of the Western Desert.

The land: W.B. FISHER, *The Middle East: A Physical, Social, and Regional Geography,* 7th rev. ed. (1978), basic geographical information; M.S. ABU AL-IZZ, *Landforms of Egypt,* trans. from Arabic (1971), a detailed outline of physiographic regionalization; MARTIN A.J. WILLIAMS and HUGUES FAURE (eds.), *The Sahara and the Nile: Quaternary Environments and Prehistoric Occupation in Northern Africa* (1980), a detailed geologic and anthropological study. Other specialized works include RUSHDI SAID, *The Geology of Egypt* (1962), and *The Geological Evolution of the River Nile* (1981); as well as TOM LITTLE, *High Dam at Aswan: The Subjugation of the Nile* (1965); and JULIAN RZÓSKA, *The Nile: Biology of an Ancient River* (1976), containing discussion of the biological effects of the Aswān High Dam. On plants and animals, see VIVI TÄCKHOLM, GUNNAR TÄCKHOLM, and MOHAMMED DRAR, *Flora of Egypt,* 4 vol. (1941–69, reprinted 1973), the standard work on the subject; RICHARD MEINERTZHAGEN, *Nicoll's Birds of Egypt,* 2 vol. (1930),

a primary source, copiously illustrated; and JOHN ANDERSON, WILLIAM E. DE WINTON, and GEORGE A. BOULENGER, *Zoology of Egypt*, 3 vol. in 4 (1898–1907, reprinted 1965), an authoritative and amply illustrated standard work. HENRY HABIB AYROUT, *The Fellaheen* (1945, reprinted 1981; originally published in French, 1938), contains observations on the customs, dress, and psychology of the Egyptian peasant; and HAMID AMMAR, *Growing Up in an Egyptian Village* (1954, reissued 1973), is an excellent and full account of village life in Egypt.

The people: ABBAS M. AMMAR, *The People of Sharqiya*, 2 vol. (1944), a physical anthropologist's description of the inhabitants of the eastern Delta; ROBERT A. FERNEA, *Nubians in Egypt: Peaceful People* (1973), an illustrated ethnographic essay; and ANWAR G. CHEJNE, *The Arabic Language: Its Role in History* (1969), a discussion of the background of classical Arabic and the dichotomy between it and the various dialects. WILLIAM H. WORRELL, *A Short Account of the Copts* (1945), is a concise study of the indigenous Christian population of Egypt. Other studies of religions of Egypt include OTTO F.A. MEINARDUS, *Christian Egypt, Ancient and Modern*, 2nd rev. ed. (1977), on the Christian communities; MORROE BERGER, *Islam in Egypt Today: Social and Political Aspects of Popular Religion* (1970); and G.H. JANSEN, *Militant Islam* (1979). For a popular introduction to the religions of Egypt, see VERONICA IONS, *Egyptian Mythology*, new ed. (1983).

Administrative and social conditions: HAROLD F. ALDERFER, M. FATHALLA EL KHATIB, and MOUSTAFA AHMED FAHMY, *Local Government in the United Arab Republic* (1963); MORROE BERGER, *Bureaucracy and Society in Modern Egypt* (1957, reprinted 1969); and P.J. VATIKIOTIS, *The Egyptian Army in Politics: Pattern for New Nations?* (1961, reprinted 1975). See also FRANK TACHAU (ed.), *Political Elites and Political Development in the Middle East* (1975); ENID HILL, *Mahkama!: Studies in the Egyptian Legal System: Courts & Crimes, Law & Society* (1979); JAMES B. MAYFIELD, *Local Institutions and Egyptian Rural Development* (1974); and HELMI R. TADROS, *Rural Resettlement in Egypt's Reclaimed Lands* (1978). On education, see AMIR BOKTOR, *The Development and Expansion of Education in the United Arab Republic* (1963), an important general survey; BAYARD DODGE, *Al-Azhar: A Millennium of Muslim Learning* (1961, reissued 1974); and GEORGIE D.M. HYDE, *Education in Modern Egypt: Ideals and Realities* (1978). Other works on social conditions include TOM LITTLE, *Modern Egypt* (1967), a study of social and political structures; PETER MANSFIELD, *Nasser's Egypt*, 2nd ed. (1969), a clear and orderly description of political, economic, and social changes in Egypt after 1952; UNNI WIKAN, *Life Among the Poor in Cairo* (1980; originally published in Norwegian, 1976); ABDEL R. OMRAN (ed.), *Egypt: Population Problems & Prospects* (1973); SAAD M. GADALLA, *Land Reform in Relation to Social Development, Egypt* (1962), and *Is There Hope?: Fertility and Family Planning in a Rural Egyptian Community* (1978); and ANDREA B. RUGH, *Family in Contemporary Egypt* (1984).

Economy: ROBERT L. TIGNOR, *State, Private Enterprise, and Economic Change in Egypt, 1918–1952* (1984); ROBERT MABRO, *The Egyptian Economy, 1952–1972* (1974); and ROBERT MABRO and SAMIR RADWAN, *The Industrialization of Egypt, 1939–1973: Policy and Performance* (1976); KASIM ALRIMAWI (QASIM RIMAWI), *The Challenge of Industrialization, Egypt* (1974); CHARLES ISSAWI, *Egypt in Revolution: An Economic Analysis* (1963, reprinted 1986); MOSTAFA H. NAGI, *Labor Force and Employment in Egypt: A Demographic and Socioeconomic Analysis* (1971); RASHED AL-BARAWY, *Economic Development in the United Arab Republic: Egypt* (1972); K.M. BARBOUR, *The Growth, Location, and Structure of Industry in Egypt* (1972); MAURICE GIRGIS, *Industrialization and Trade Patterns in Egypt* (1977); YUSUF J. AHMAD, *Absorptive Capacity of the Egyptian Economy: An Examination of Problems and Prospects* (1976); DAVID WILLIAM CARR, *Foreign Investment and Development in Egypt* (1979); KHALID IKRAM, *Egypt, Economic Management in a Period of Transition* (1980); and JOHN WATERBURY, *The Egypt of Nasser and Sadat: The Political Economy of Two Regimes* (1983).

Cultural life: MUSTAFA HABIB (ed.), *Cultural Life in the United Arab Republic* (1968); ALBERT HOURANI, *Arabic Thought in the Liberal Age, 1798–1939* (1962, reissued 1983), a study of the interaction of Western and indigenous culture in its historical context; JACOB M. LANDAU, *Studies in the Arab Theatre and Cinema* (1958); ABD AL-MONEM ISMAIL, *Drama and Society in Contemporary Egypt* (1967); FAROUK ABDEL WAHAB (comp.), *Modern Egyptian Drama* (1974); ABDEL-AZIZ ABDEL-MEGUID, *The Modern Arabic Short Story: Its Emergence, Development, and Form* (1950?); HAMDI SAKKUT, *The Egyptian Novel and Its Main Trends from 1913 to 1952* (1971); and HILARY KILPATRICK, *The Modern Egyptian Novel: A Study in Social Criticism* (1974). Other studies include MOUHAN A. KHOURI, *Poetry and the Making of Modern Egypt, 1882–1922* (1971); YVES THORAVAL, *Regards sur le cinéma Égyptien* (1975), on the Egyptian cinema; and PIERRE DU BOURGUET, *Coptic Art* (1971, originally published in French, 1968).

History: (Ancient Egypt): The most detailed presentation of Egyptian history, with full bibliographies arranged by subject, is the multivolume *Cambridge Ancient History,* though volumes 1 and 2 no longer reflect current knowledge. WOLFGANG HELCK, EBERHARD OTTO, and WOLHART WESTENDORF (eds.), *Lexikon der Ägyptologie* (1975–), is the basic reference work in Egyptology, of which 5 volumes had appeared by 1986, with further parts published in fascicles. MICHAEL A. HOFFMAN, *Egypt Before the Pharaohs: The Prehistoric Foundations of Egyptian Civilization* (1979, reissued 1984), is a comprehensive general work on prehistory; while LECH KRZYŻANIAK, *Early Farming Cultures on the Lower Nile: The Predynastic Period in Egypt* (1977), focuses on the transition to agriculture and on Lower Egypt. General studies include CYRIL ALDRED, *The Egyptians,* rev. ed. (1984); and JOHN RUFFLE, *Heritage of the Pharaohs: An Introduction to Egyptian Archaeology* (1977); as well as other works cited below under the specific periods on which they focus. General histories include B.G. TRIGGER *et al., Ancient Egypt: A Social History* (1983), containing four essays on the main periods, concentrating on relations with Africa, and including valuable bibliographies; and SIR ALAN GARDINER, *Egypt of the Pharaohs* (1961), a personal history, notable for the use made of ancient Egyptian texts. WILLIAM W. HALLO and WILLIAM KELLY SIMPSON, *The Ancient Near East: A History* (1971), is a reliable brief introduction; and ÉTIENNE DRIOTON and JACQUES VANDIER, *L'Égypte: des origines à la conquête d'Alexandre,* 4th ed. (1962, reprinted 1984), remains valuable for its critical discussions. JOHN A. WILSON, *The Burden of Egypt: An Interpretation of Ancient Egyptian Culture* (1951, reprinted 1965), is a selective historical study. WILLIAM C. HAYES, *The Scepter of Egypt,* 2 vol. (1953–59), is a detailed cultural history of Egypt to the end of the 20th dynasty, based on the collections in the Metropolitan Museum of Art, New York City. WOLFGANG HELCK, *Geschichte des alten Ägypten* (1968, reprinted 1981), is still the best general history; his *Beziehungen Ägyptens zu Vorderasien im 3. und 2. Jahrtausend v. Chr.,* 2nd ed. (1971), is the fundamental work on foreign relations, and his *Wirtschaftsgeschichte des Alten Ägypten im 3. und 2. Jahrtausend vor Chr.* (1975) covers institutions and economics. ROLF KRAUSS, *Sothis- und Monddaten: Studien zur astronomischen und technischen Chronologie Altägyptens* (1985), is a vital chronological study for the 2nd and 1st millennia BC; its dates are adopted in this article with minor variations. JOHN BAINES and JAROMÍR MÁLEK, *Atlas of Ancient Egypt* (1980), is a concise, geographically oriented survey. HERMANN KEES, *Ancient Egypt: A Cultural Topography* (1961, reprinted 1977; originally published in German, 2nd ed., 1958; 3rd German ed., 1977), studies a number of major sites in depth. KARL W. BUTZER, *Early Hydraulic Civilization in Egypt: A Study in Cultural Ecology* (1976), is a useful discussion of geographic and environmental conditions and their relation to the development of ancient Egyptian civilization. CLAUDE VANDERSLEYEN *et al., Das alte Ägypten* (1975), is the most comprehensive survey of Egyptian art. W. STEVENSON SMITH, *The Art and Architecture of Ancient Egypt,* rev. ed., edited by WILLIAM KELLY SIMPSON (1981), is an excellent general account; and for the Old Kingdom, Smith's *History of Egyptian Sculpture and Painting in the Old Kingdom,* 2nd ed. (1949), is still a fundamental source. MIRIAM LICHTHEIM, *Ancient Egyptian Literature: A Book of Readings,* 3 vol. (1973–80), offers an excellent collection of texts in translation, covering the Old, Middle, and New Kingdoms and the Late Period. A smaller selection of readings is available in WILLIAM KELLY SIMPSON (ed.), *The Literature of Ancient Egypt: An Anthology of Stories, Instructions, and Poetry,* new ed. (1973); while JAMES B. PRITCHARD (ed.), *Ancient Near Eastern Texts Relating to the Old Testament,* 3rd ed. (1969), contains a wide selection of Egyptian material in translation. Studies of administration include KLAUS BAER, *Rank and Title in the Old Kingdom* (1960, reprinted 1974); to which NIGEL STRUDWICK, *The Administration of Egypt in the Old Kingdom: The Highest Titles and Their Holders* (1985), adds a vast amount of detail. WOLFGANG HELCK, *Zur Verwaltung des Mittleren und Neuen Reichs* (1958), with a separately published index volume (1975), is the basic work on the succeeding periods.

(Egypt from the 18th dynasty to 332 BC): The rise of the New Kingdom is treated in JÜRGEN VON BECKERATH, *Untersuchungen zur politischen Geschichte der Zweiten Zwischenzeit in Ägypten* (1964). DONALD B. REDFORD, *History and Chronology of the Eighteenth Dynasty of Egypt: Seven Studies* (1967), includes a reevaluation of Hatshepsut. An informative account of the New Kingdom empire at its height is ELIZABETH RIEFSTAHL, *Thebes in the Time of Amunhotep III* (1964, reprinted 1971). For the controversial Amarna period, ROLF KRAUSS, *Das Ende der Amarnazeit: Beitr. zur Geschichte u. Chronologie d. Neuen Reiches* (1978); and DONALD B. REDFORD, *Akhenaten, the Heretic King* (1984), offer strongly contrasting interpre-

tations. CYRIL ALDRED, *Akhenaten and Nefertiti* (1973), is a good collection of the artistic evidence for the period. For the Ramesside period, K.A. KITCHEN, *Pharaoh Triumphant: The Life and Times of Ramesses II King of Egypt* (1982), sets its subject in context, presenting the New Kingdom in general as well as Ramses' own reign. EDWARD F. WENTE, *Late Ramesside Letters* (1967), deals with material from the end of the same period. For the economy of this time, see the major work of J.J. JANSSEN, *Commodity Prices from the Ramessid Period: An Economic Study of the Village of Necropolis Workmen at Thebes* (1975). JOHN ROMER, *Ancient Lives: Daily Life in Egypt of the Pharaohs* (1984), presents the life of the same community. T.G.H. JAMES, *Pharaoh's People: Scenes from Life in Imperial Egypt* (1984), is concerned with life-styles of higher ranks of society in the same general period. K.A. KITCHEN, *The Third Intermediate Period in Egypt (1100–650 B.C.)*, 2nd rev. ed. (1986), is the basic work on the period. HERMANN KEES, *Das Priestertum im ägyptischen Staat, vom neuen Reich bis zur Spätzeit* (1953), with an index volume, *Indices und Nachträge* (1958), is a comprehensive analysis of the Egyptian priesthoods. This fundamental institution of the Late Period is also valuably treated in SERGE SAUNERON, *The Priests of Ancient Egypt* (1960, reprinted 1980; originally published in French, 1957). On the period from the Saite 26th dynasty until Alexander the Great, see FRIEDRICH K. KIENITZ, *Die politische Geschichte Ägyptens vom 7. bis 4. Jahrhundert vor der Zeitwende* (1953), based on both Egyptian and classical sources. ALAN B. LLOYD, *Herodotus, Book II*, 2 vol. (1975–76), contains much material on the Late Period.

(*Hellenistic and Roman Egypt*): On the period in general, see HAROLD I. BELL, *Egypt, from Alexander the Great to the Arab Conquest: A Study in the Diffusion and Decay of Hellenism* (1948, reprinted 1980); and ALAN K. BOWMAN, *Egypt After the Pharaohs, 332 B.C.–A.D. 642: From Alexander to the Arab Conquest* (1986). The basic general works on the papyri are L. MITTEIS and U. WILCKEN, *Grundzüge und Chrestomathie der Papyruskunde*, 2 vol. in 4 (1912, reprinted 1963); and E.G. TURNER, *Greek Papyri: An Introduction* (1968, reissued 1980), with its illustrated companion, *Greek Manuscripts of the Ancient World* (1971). On Ptolemaic Egypt, see DOROTHY J. CRAWFORD, *Kerkeosiris: An Egyptian Village in the Ptolemaic Period* (1971); P.M. FRASER, *Ptolemaic Alexandria*, 3 vol. (1972); J. GRAFTON MILNE, *A History of Egypt Under Roman Rule*, 3rd rev. ed. (1924); ORSOLINA MONTEVECCHI, *La papirologia* (1973); ALAN E. SAMUEL, *From Athens to Alexandria: Hellenism and Social Goals in Ptolemaic Egypt* (1983); NAPHTALI LEWIS, *Greeks in Ptolemaic Egypt: Case Studies in the Social History of the Hellenistic World* (1986); E.E. RICE, *The Grand Procession of Ptolemy Philadelphus* (1983); M. ROSTOVTZEFF, *The Social & Economic History of the Hellenistic World*, 3 vol. (1941, reprinted with corrections 1972); and SARAH B. POMEROY, *Women in Hellenistic Egypt: From Alexander to Cleopatra* (1984). On Roman Egypt, see A.C. JOHNSON, *Roman Egypt to the Reign of Diocletian*, vol. 2 in TENNEY FRANK (ed.), *An Economic Survey of Ancient Rome*, 6 vol. (1933–40, reprinted 1975); A.H.M. JONES, *The Cities of the Eastern Roman Provinces*, 2nd ed. (1971, reprinted 1983); and NAPHTALI LEWIS, *Life in Egypt Under Roman Rule* (1983). On Byzantine Egypt, see ALFRED J. BUTLER, *The Arab Conquest of Egypt and the Last Thirty Years of the Roman Dominion*, 2nd ed., revised by P.M. FRASER (1978); EDWARD ROCHIE HARDY, *The Large Estates of Byzantine Egypt* (1931, reprinted 1968), and *Christian Egypt: Church and People: Christianity and Nationalism in the Patriarchate of Alexandria* (1952); ALLAN CHESTER JOHNSON and LOUIS C. WEST, *Byzantine Egypt: Economic Studies* (1949, reprinted 1967); and COLIN H. ROBERTS, *Manuscript, Society, and Belief in Early Christian Egypt* (1979).

(*Egypt from c. 630 to c. 1800*): Two standard works that survey medieval Egyptian history as a whole are STANLEY LANE-POOLE, *A History of Egypt in the Middle Ages*, 4th ed. (1968); and GASTON WIET, *L'Égypte arabe de la conquête arabe à la conquête ottomane, 642–1517 de l'ère chrétienne*, vol. 4 in GABRIEL HANOTAUX, *Histoire de la nation égyptienne*, 7 vol. (1931–40). Each of these is outdated in many respects, but each presents an accurate summary of the political history of the period, based on primary Arabic sources; also, both are strong on Egyptian architecture as an insight into political, social, and economic history. A valuable later reference source with comprehensive coverage of the period is JOAN WUCHER KING, *Historical Dictionary of Egypt* (1984). For the economic history, see SUBHI LABIB, *Handelsgeschichte Ägyptens im Spätmittelalter, 1171–1517* (1965); Labib has summarized this book in English in the form of an article, "Egyptian Commercial Policy in the Middle Ages," in *Studies in the Economic History of the Middle East: From the Rise of Islam to the Present Day*, edited by M.A. COOK, pp. 63–77 (1970). ELIYAHU ASHTOR, *A Social and Economic History of the Near East in the Middle Ages* (1976), and *Levant Trade in the Later Middle Ages* (1983), are also important. AZIZ S. ATIYA, *A History of Eastern Christianity* (1968, reissued 1980), is authoritative for Coptic history. For the beginnings of Muslim Egypt, see FRANCESCO GABRIELI, *Muhammad and the Conquests of Islam* (1968, originally published in Italian, 1967), for the conquest of Egypt; and DANIEL C. DENNETT, *Conversion and the Poll Tax in Early Islam* (1950), for Muslim tax policy in Egypt. For the Ṭūlūnids, see ZAKY MOHAMED HASAN, *Les Tulunides* (1933). Fāṭimid studies have been transformed by S.D. GOITEIN, *A Mediterranean Society: The Jewish Communities of the Arab World as Portrayed in the Documents of the Cairo Geniza* (1968–), of which four volumes had appeared by 1987. Three articles by HAMILTON A.R. GIBB are definitive for Egypt under the Ayyūbids and during the Crusades, all published in *A History of the Crusades*, ed. by KENNETH M. SETTON, 2nd ed., 5 vol. (1958–85): "The Caliphate and the Arab States," 1:81–98; "The Rise of Saladin, 1169–1189," 1:563–589; and "The Aiyūbids," 2:693–714. See also R. STEPHEN HUMPHREYS, *From Saladin to the Mongols: The Ayyubids of Damascus, 1193–1260* (1977). For Mamlūk and Ottoman Egypt, see F.R.C. BAGLEY (ed. and trans.), *The Last Great Muslim Empires*, vol. 3 in *The Muslim World: A Historical Survey*, 3 vol. (1960–69, originally published in German, 1952–59). An account of the early Mamlūk state is found in ROBERT IRWIN, *The Middle East in the Middle Ages: The Early Mamluk Sultanate, 1250–1382* (1986); and for the Ottoman period alone, see STANFORD J. SHAW, *The Financial and Administrative Organization and Development of Ottoman Egypt, 1517–1798* (1962).

(*Egypt since 1800*): EDWARD WILLIAM LANE, *An Account of the Manners and Customs of the Modern Egyptians*, 2 vol. (1836, reissued in 1 vol., 1973), is a classic study of everyday life during the second quarter of the 19th century. An analysis of the political developments of the period is offered in F. ROBERT HUNTER, *Egypt Under the Khedives, 1805–1879: From Household Government to Modern Bureaucracy* (1984). JAMAL M. AHMED, *The Intellectual Origins of Egyptian Nationalism* (1960, reissued 1968), is particularly concerned with the nationalists of the period from 1892 to 1914. Other useful works are GABRIEL BAER, *A History of Landownership in Modern Egypt, 1800–1950* (1962); P.M. HOLT, *Egypt and the Fertile Crescent, 1516–1922* (1966), and P.M. HOLT (ed.), *Political and Social Change in Modern Egypt* (1968); JACOB M. LANDAU, *Parliaments and Parties in Egypt* (1953, reissued 1979); HELEN ANNE B. RIVLIN, *The Agricultural Policy of Muḥammad ʿAlī in Egypt* (1961); AFAF LUFTI AL-SAYYID MARSOT, *Egypt in the Reign of Muhammad Ali* (1984), a sturdy defense by an Egyptian author; ROBERT L. TIGNOR, *Modernization and British Colonial Rule in Egypt, 1882–1914* (1966); and NADAV SAFRAN, *Egypt in Search of Political Community: An Analysis of the Intellectual and Political Evolution of Egypt, 1804–1952* (1961, reprinted 1981). P.J. VATIKIOTIS, *Nasser and His Generation* (1978), offers a fine biography, especially for the years between 1930 and 1952; RAYMOND W. BAKER, *Egypt's Uncertain Revolution Under Nasser and Sadat* (1978), analyzes the effect of the Egyptian revolution on Egyptian society; DAVID HIRST and IRENE BEESON, *Sadat* (1981), is an early assessment of the Sādāt years; RAYMOND A. HINNEBUSCH, JR., *Egyptian Politics Under Sadat: The Post-Populist Development of an Authoritarian-Modernizing State* (1985), is an interesting study; DEREK HOPWOOD, *Egypt. Politics and Society, 1945–1984*, 2nd ed. (1985), is a general comprehensive introduction; and P.J. VATIKIOTIS, *The History of Egypt*, 3rd ed. (1985), together with AFAF LUFTI AL-SAYYID MARSOT, *A Short History of Modern Egypt* (1985), are especially valuable for their analyses of the post-Sādāt period.

Ancient Egyptian Arts and Architecture

In the general tradition of the visual arts of the West, ancient Egypt represents a source of form and technique dating back to the early 3rd millennium BC. For the purposes of definition ancient Egyptian is essentially coterminous with dynastic Egyptian, the dynastic structure of Egyptian history, artificial though it may partly be, providing a convenient chronological framework. The distinctive periods are: Early Dynastic (1st–3rd dynasties, *c.* 2925–*c.* 2575 BC); Old Kingdom (4th–8th dynasties, *c.* 2575–*c.* 2130 BC); First Intermediate (9th–11th dynasties, *c.* 2130–1939 BC); Middle Kingdom (12th–14th dynasties, 1938–*c.* 1600? BC); Second Intermediate (15th–17th dynasties, *c.* 1630–1540 BC); New Kingdom (18th–20th dynasties, 1539–1075 BC); Third Intermediate (21st–25th dynasties, *c.* 1075–656 BC); and Late Dynastic (26th–31st dynasties, 664–332 BC).

Geographical factors were predominant in forming the particular character of Egyptian art. By providing Egypt with the most predictable agricultural system in the ancient world, the Nile afforded a stability of life in which arts and crafts readily flourished. Equally, the deserts and the sea, which protected Egypt on all sides, contributed to this stability by discouraging serious invasion for almost 2,000 years. The desert hills were also rich in minerals and fine stones, ready to be exploited by artists and craftsmen. Only good wood was lacking, and the need for it led the Egyptians to undertake foreign expeditions to Lebanon, to Somalia, and, through intermediaries, to tropical Africa. In general, the search for useful and precious materials determined the direction of foreign policy and the establishment of trade routes and led ultimately to the enrichment of Egyptian material culture. For further treatment, see EGYPT; MIDDLE EASTERN RELIGIONS, ANCIENT.

This article is divided into the following sections:

Predynastic Period

The term predynastic denotes the period of emerging cultures that preceded the establishment of the 1st dynasty in Egypt. In the late 5th millennium BC there began to emerge patterns of civilization that displayed characteristics deserving to be called Egyptian. The accepted sequence of predynastic cultures is based on the excavations of Sir Flinders Petrie at Naqādah, at al-ʿĀmirah (el-ʿÂmra), and at al-Jazīrah (el-Gezira). Another somewhat earlier stage of predynastic culture has been identified at al-Badārī in Upper Egypt.

From graves at al-Badārī, Dayr Tasa, and al-Mustaqiddah evidence of a relatively rich and developed artistic and industrial culture has been retrieved. Pottery of a fine red polished ware with blackened tops already shows distinctive Egyptian shapes. Copper was worked into small ornaments, and beads of steatite (soapstone) show traces of primitive glazing. Subsequently in the Naqādah I and Naqādah II stages predynastic civilization developed steadily. Pottery remains the distinctive product, showing refinement of technique and the development of adventurous decoration. Shapes already found in Badarian graves were produced in Naqādah I with superior skill and decorated with geometric designs of white-filled lines and even simple representations of animals. Later new clays were exploited, and fine buff-coloured wares were decorated in purple pigment with scenes of ships, figures, and a wide variety of symbols.

Refinement of pottery

The working of hard stones also began in earnest in the later Predynastic Period. At first craftsmen were devoted to the fashioning of fine vessels and to the making of jewelry incorporating semiprecious stones.

Sculpture found its best beginnings not so much in representations of the human form (although figurines, mostly female, were made from Badarian times) as in the carving of small animal figures and the making of schist (slate) palettes (intended originally for the preparation of eye paint). The Hunters and Battlefield palettes (British Museum; part of the former in the Louvre; part of the latter in the Ashmolean, Oxford) show two-dimensional representation—a convention that was to last 3,000 years.

The schist palettes

The basic techniques of two-dimensional art—drawing and painting—are exemplified in Upper Egyptian rock drawings and in the painted tomb at Hierakonpolis, now destroyed. Scenes of animals, boats, and hunting, the common subjects of rock drawings, were more finely executed in paint in the tomb, and additional themes, probably of conquest, presaged those found in dynastic art.

Dynastic Egypt

Evidence suggests that the unification of Upper and Lower Egypt drew together the various threads of what was to become the rich tapestry of Egyptian culture and started the intricate weave on the loom of time. Many of the new artistic developments undoubtedly can be traced back to the Naqādah II period; but the abundant evidence from the great tombs of the 1st dynasty at Abydos and Ṣaqqārah far outweighs what was found in the modest burials of earlier times. The impression is certainly one of an extraordinary efflorescence of civilization. Conquest, implicit in unification, is dramatically characterized in the scenes shown on the Narmer Palette (Egyptian Museum, Cairo), where Narmer, probably the founding king of dynastic Egypt, and better known as Menes, is depicted as the triumphant ruler (Figure 1).

The Narmer representations display much of what is typical of Egyptian art of the Dynastic Period. Here is the characteristic image of the king smiting his enemy, depicted with the conventions that distinguish Egyptian two-dimensional art. The head is shown in profile, but the eye in full; the shoulders are frontally represented, while the torso is at three-quarters view; the legs again are in profile. To show as much detail as possible was the principal intention of the artist—to show what he knew was

Conventions of two-dimensional representation

there, not simply what he could see from one viewpoint. Further conventions, well established by the 4th dynasty, included the showing of both hands and feet, right and left, without distinction. Scenes were set on baselines, and the events were placed in sequence, usually from right to left. Unity in a scene was provided by the focal figure of the most important person, the king or tomb owner. Relative size established importance: the ruler dwarfed the high official, while the tomb owner dwarfed his wife and, still more so, his children.

The canon of proportion

Conservatism in artistic matters was nurtured by a relative coherence of culture, strengthened by a vigorous tradition of scribal training, and tempered by a canon of proportion for the representation of the human figure. In the Old Kingdom, walls prepared for decoration were marked out with red horizontal guidelines; in later times vertical lines were added. During much of the Dynastic Period a grid of 18 rows of squares was used to contain the standing figure of a man; from the 26th dynasty, 21 rows of squares were used for the same purpose. At different periods, variations in the placing of specific bodily features produced interesting and subtle nuances. During the so-called Amarna period a distinctive reappraisal of the canon took place. The full range of changes and the many variants still remain to be studied, but it is clear that the basic canon lay deeply rooted in the training of the Egyptian artist.

Figure 1: Slate Narmer Palette, from Hierakonpolis, beginning of 1st dynasty, *c.* 2925 BC. In the Egyptian Museum, Cairo. Height 63.5 cm. (Left) Obverse, divided into three pictorial strips: the king, wearing the crown of Lower Egypt, shown on his way to witness the execution of fettered enemies; two bearded men leading two fabulous animals, perhaps symbolizing the unification of Upper and Lower Egypt; and the king in the form of a wild ox attacking a fortified settlement. (Right) Reverse, showing a victory motive: King Narmer, wearing the crown of Upper Egypt, striking down an enemy held by the hair.

ARCHITECTURE

The two principal building materials used in ancient Egypt were unbaked mud brick and stone. From the Old Kingdom onward stone was generally used for tombs—the eternal dwellings of the dead—and for temples—the eternal houses of the gods. Mud brick remained the domestic material, used even for royal palaces; it was also used for fortresses, the great walls of temple precincts and towns, and for subsidiary buildings in temple complexes.

Most ancient Egyptian towns have been lost because they were situated in the cultivated and flooded area of the Nile Valley; many temples and tombs have survived because they were built on ground unaffected by the Nile flood. Any survey of Egyptian architecture will in consequence be weighted in favour of funerary and religious buildings. Yet the dry, hot climate of Egypt has allowed some mud brick structures to survive where they have escaped the destructive effects of water or man.

Tomb architecture. Mortuary architecture in Egypt was highly developed and often grandiose. The tomb was not simply a place in which a corpse might be protected from desecration. It was the home of the deceased, provided with material objects to ensure continued existence after death. Part of the tomb might reproduce symbolically the earthly dwelling of the dead person; it might be decorated with scenes that would enable the individual to pursue magically an afterlife suitable and similar to his worldly existence. For a king the expectations were quite different; for him the tomb became the vehicle whereby he might achieve his exclusive destiny with the gods in a celestial afterlife.

The tomb as a home

Most tombs comprised two principal parts, the burial chamber (the tomb proper) and the chapel, in which offerings for the deceased could be made. In royal burials the chapel rapidly developed into a temple, which in later times was usually built separately and at some distance from the tomb. In the following discussion, funerary temples built separately will be discussed with temples in general and not as part of the funerary complex.

Royal tombs. In the earliest dynasties the tombs of kings and high officials were made of mud brick and of such similar size that it is difficult to distinguish between them. It is now generally thought that the tombs at Abydos were royal, whereas those at Ṣaqqārah were noble. The latter, better preserved than the former, reveal rectangular superstructures, called mastabas (see below), with sides constructed in the form of paneled niches painted white and decorated with elaborate "matting" designs.

These great superstructures contained many storage chambers stocked with food and equipment for the deceased, who lay in a rectangular burial chamber below ground. Also within the superstructure, but not always clearly evident, was a low mound of earth, possibly representing the primitive grave of earlier times. Sometimes this concealed mound was a low, stepped structure, perhaps the precursor of the first great building constructed of stone in Egypt.

The Step Pyramid of Djoser

The Step Pyramid of Djoser, second king of the 3rd dynasty, was built within a vast enclosure on a commanding site at Ṣaqqārah overlooking the city of Memphis. A high royal official, Imhotep, has traditionally been credited with the design and with the decision to use quarried stone. This first essay in stone is remarkable for its design of six superposed stages of diminishing size, and also for its huge enclosure (1,784 × 909 feet [544 × 277 metres]) surrounded by a paneled wall faced with fine limestone and containing a series of "mock" buildings that probably represent structures associated with the palace in Memphis. There the Egyptian stonemasons made their earliest architectural innovations, using stone to reproduce the forms of primitive wood and brick buildings. Fine reliefs of the king and elaborate wall "hangings" in glazed tiles in parts of the subterranean complexes are among the innovations found in this remarkable monument.

The Great Pyramid of Khufu

For the Old Kingdom the most characteristic form of tomb building was the true pyramid, the finest example of which is the Great Pyramid of King Khufu (Cheops) of the 4th dynasty at al-Jīzah (Giza; Figure 2). The form itself reached its maturity in the reign of Snefru, father of Khufu. Subsequently only the pyramid of Khafre (Chephren), Khufu's successor, approached the size and perfection of the Great Pyramid. The simple measurements of the Great Pyramid indicate very adequately its scale, monumentality, and precision: its sides are 755.43 feet (230.26 metres; north), 756.08 feet (230.45 metres; south), 755.88 feet (230.39 metres; east), 755.77 feet (230.36 metres; west); its orientation on the cardinal points is almost exact; its height upon completion was 481.4 feet (146.7 metres); its area at base is just over 13 acres (5.3 hectares). Other features in its construction contribute substantially to its remarkable character: the lofty, corbeled Grand Gallery and the granite-built King's Chamber with five relieving compartments (empty rooms for reducing pressure) above.

The pyramid formed the focal point of a group of buildings that constituted the funerary complex of a king. Two temples linked by a causeway were essential components. The valley temple, built on the edge of the desert escarp-

Ray Manley—Shostal Assoc.

ment, was the place of reception for the royal body. The most striking valley temple is that of Khafre, a structure of massive granite blocks with huge alabaster flooring slabs, starkly simple but immensely effective. The best preserved causeway serves the pyramid of King Unas of the 5th dynasty; it contains low-relief wall decorations and a ceiling adorned with stars. The pyramid temple of Unas is distinguished by the extensive use of granite for architectural elements, including doorways and splendid monolithic columns with palm capitals.

The pyramids built for the later kings of the Old Kingdom and most kings of the Middle Kingdom were comparatively poor in size, construction, and materials. The tomb of King Mentuhotep II of the 11th dynasty is, however, of exceptional interest. The tomb complex at Dayr al-Baḥrī was once thought to have contained a pyramid, but excavations between 1966 and 1971 have shown that the hypothetical reconstructions were misconceived. Its essential components were a rectangular structure, a series of pillared ambulatories, an open court, and a hypostyle hall tucked into the cliffs.

The monumentality of the pyramid made it not only a potent symbol of royal power but also an obvious target for tomb robbers. During the New Kingdom the wish to halt the robbing and desecration of royal tombs led to their being sited together in a remote valley at Thebes, dominated by a peak that itself resembled a pyramid.

The Valley of the Kings

There, in the Valley of the Kings, tombs were carved deep into the limestone with no outward structure and marked only by a doorway carved in the rock face. They had no common plan, but most consisted of a series of corridors opening out at intervals to form rooms and ending in a large burial chamber deep in the mountain. The finest of the tombs is that of Seti I, second king of the 19th dynasty; it extends 328 feet (100 metres) into the mountain and contains a spectacular burial chamber, the barrel-shaped roof of which represents the vault of heaven.

After the abandonment of the valley at the end of the 20th dynasty, kings of the subsequent two dynasties were buried in very simple tombs within the temple enclosure of the delta city of Tanis. No later royal tombs have ever been identified.

Private tombs. A major distinction between royal and nonroyal tombs lies in the provision of arrangements for the funerary cult of the deceased. The evidence available from the 3rd dynasty onward makes it clear that king and commoner had quite different expectations. In nonroyal tombs a chapel was provided that included a formal tablet or stela on which the deceased was shown seated at a table of offerings. The earliest examples are simple and architecturally undemanding; later a suitable room, the tomb-chapel, was provided for the stela (now incorporated in a false door) in the tomb superstructure, or mastaba.

The mastaba

The term mastaba (Arabic: "bench") was first used archaeologically in the 19th century by workmen on Auguste Mariette's excavation at Ṣaqqārah to describe the rectangular, flat-topped stone superstructures of tombs. Subsequently, mastaba was also used for mud brick superstructures.

In the great cemeteries of the Old Kingdom, changes in size, internal arrangements, and groupings of the burials of nobles indicate the vicissitudes of nonroyal posthumous expectations. In the 3rd dynasty at Ṣaqqārah the most important private burials were at some distance from the step pyramids of Djoser and Sekhemkhet. Their large superstructures incorporated offering niches that were to develop into chapels (as in the tomb of Khabausokar) and corridors that could accommodate paintings of equipment for the afterlife and niches to hold carved representations of the deceased owner (as in the tomb of Hesire). During the 4th dynasty the stone mastabas of the Giza pyramid field were regularly laid out near the pyramids, and, although smaller than those at Ṣaqqārah, they show the true start of the exploitation of space within the superstructure. The niche chapel became a room for the false door and offering table, and there might also be rooms containing scenes of offering and of daily activities.

Nothing indicates more clearly the relaxation of royal authority in the later Old Kingdom than the size and decoration of the mastabas at Ṣaqqārah and Abusīr. Externally they were still rectangular structures, occasionally with a low wall establishing a precinct (as in the tomb of Mereruka). The full exploitation of internal space in the great mastabas at Abusīr (that of Ptahshepses) and Ṣaqqārah (that of Ti and the double mastaba of Akhtihotep and Ptahhotep) made ample room available for the receipt of offerings and for the representation of the milieu in which the dead owner might expect to spend his afterlife. In the mastaba of Mereruka, a vizier of Teti, first king of the 6th dynasty, there were 21 rooms for his own funerary purposes, with six for his wife and five for his son.

Exploitation of internal space

Contemporaneously, the provincial colleagues of the

Memphite nobles developed quite different tombs in Middle and Upper Egypt. Tomb chapels were excavated into the rock of the cliffs overlooking the Nile. Rock-cut tombs subsequently were to become the most common kind of private tomb, although mastabas were built in the royal cemeteries of the 12th dynasty.

Rock-cut tombs

Most rock-cut tombs were fairly simple single chambers serving all the functions of the multiplicity of rooms in a mastaba. Some, however, were excavated with considerable architectural pretensions. At Aswān huge halls, often connecting to form labyrinthine complexes, were partly formal, with columns carefully cut from the rock, and partly rough-hewn. Chapels with false doors were carved out within the halls. In some cases the facades were monumental, with porticoes and inscriptions.

At Beni Hasan the local nobles during the Middle Kingdom cut large and precise tomb chambers in the limestone cliffs. Architectural features—columns, barrel roofs, and porticoes, all carved from the rock—provided fine settings for painted mural decorations. The tombs of Khnumhotep and Amenemhet are outstanding examples of fine design impeccably executed.

The most famous rock-cut private tombs are those of the New Kingdom at Thebes, their fame resting, above all, on their mural decoration. As elsewhere the excavated chambers are the tomb-chapels, mostly taking a simple T-form, in which the crossbar of the T represents the entrance hall, and the upright stroke of the T is the chapel proper. Some of the more important tombs (Rekhmire, Ramose) have open courts before their unelaborate facades and some striking internal features, but most are small in comparison with those of earlier times.

A separate tradition of private tomb design was developed for important officials at Ṣaqqārah in the New Kingdom. Open courts, constructed offering chapels, and elaborate subterranean suites of rooms characterize these Memphite tombs. The tomb for Horemheb, a military commander who became the last king of the 18th dynasty, has remarkable relief decoration. The tomb of Tia (a sister of the 19th-dynasty king Ramses II) has a small pyramid behind the chapel.

Temple architecture. Two principal kinds of temple can be distinguished—cult temples and funerary or mortuary temples. The former accommodated the images of deities, the recipients of the daily cult; the latter were the shrines for the funerary cults of dead kings.

Cult temples. It is generally thought that the Egyptian temple of the Dynastic Period owed most to the cult of the sun god Re at Heliopolis. The temple of Re, however, was probably open in plan and lacked a shrine. Sun temples were unique among cult temples; worship was centred on a cult object, the *benben,* which was a squat obelisk placed in full sunlight. Among the few temples surviving from the Old Kingdom are sun temples of the 5th-dynasty kings at Abū Jirāb (Abu Gurab). That of Neuserre reveals the essential layout: a reception pavilion at the desert edge connected by a covered corridor on a causeway to the open court of the temple high on the desert, within which stood the *benben* of limestone and a huge alabaster altar. Fine reliefs embellished the covered corridor and also corridors on two sides of the court.

Sun temples

The cult temple achieved its most highly developed form in the great sanctuaries erected over many centuries at Thebes. Architecturally the most satisfying, and certainly the most beautiful, is the Luxor Temple, started by Amenhotep III of the 18th dynasty. The original design consists of an imposing open court with colonnades of graceful lotus columns, a smaller offering hall, a shrine for the ceremonial boat of the god, an inner sanctuary for the cult image, and a room in which the divine birth of the king was celebrated. The approach to the temple was made by a colonnade of huge columns with open papyrus-flower capitals, planned by Amenhotep III but decorated with fascinating processional reliefs under Tutankhamen and Horemheb. Later Ramses II built a wide court before the colonnade and two great pylons to form a new entrance.

Temple at Luxor

The necessary elements of an Egyptian temple, most of which can be seen at Luxor, are the following: an approach avenue of sphinxes leading to the great double-towered pylon entrance fitted with flagpoles and pennants; before the pylon a pair of obelisks and colossal statues of the king; within the pylon a court leading to a pillared hall, the hypostyle, beyond which might come a further, smaller hall where offerings could be prepared; and at the heart of the temple, the shrine for the cult image. In addition, there were storage chambers for temple equipment and sometimes a crypt. Outside the main temple building was a lake, or at least a well, for the water needed in the rituals; in later times there might also be a birth house (*mammisi*) to celebrate the king's divine birth. The whole, with service buildings, was contained by a massive mud brick wall.

The great precinct of the Temple of Karnak (the longest side, 1,837 feet [560 metres]) contains whole buildings, or parts of buildings, dating from the early 18th dynasty down to the Roman Period. Modern reconstruction work has even recovered a tiny way station of the 12th dynasty, a gem of temple building decorated with some of the finest surviving relief scenes and texts.

The Karnak complex

Of the structures on the main Karnak axis the most remarkable are the hypostyle hall and the so-called Festival Hall of Thutmose III. The former contained 134 mighty papyrus columns, 12 of which formed the higher central aisle (76 feet [23 metres]). Grill windows allowed some light to enter, but it must be supposed that even on the brightest day most of the hall was in deep gloom.

The Festival Hall is better described as a memorial hall. Its principal room is distinguished by a series of unusual columns with bell-shaped capitals, inspired by the wooden tent poles used in primitive buildings. Their lightness contrasts strikingly with the massive supports of the hypostyle hall.

Near Karnak Temple, King Akhenaton and his wife, Nefertiti, built a number of temples, later dismantled, to the sun god Aton. The vast number of blocks found in modern times indicates that these constructions were essentially open places for worship like the earlier sun temples. So, too, was the great Aton temple at Tell el-Amarna, built later in Akhenaton's reign.

The most interesting and unusual cult temple of the New Kingdom was built at Abydos by Seti I of the 19th dynasty. Principally dedicated to Osiris, it contained seven chapels dedicated to different deities, including the deified Seti himself. These chapels have well-preserved barrel ceilings and are decorated with low-relief scenes retaining much original colour.

The most remarkable monument of Ramses II, the great builder, is undoubtedly the temple of Abu Simbel (Figure 3). Although excavated from the living rock, it follows generally the plan of the usual Egyptian temple: colossal seated statues emerging from the facade, which is the cliff face; a pillared hall followed by a second leading to a vestibule; and a shrine with four statues of divinities, including one of Ramses himself.

Temple of Abu Simbel

Mention should also be made of the immense temple dedicated to the god Amon-Re at Tanis in the delta by the kings of the 21st and 22nd dynasties. Much of the stone for the so-called northern Karnak, along with colossal statues and a dozen obelisks, was appropriated from other sanctuaries in Egypt, making this a remarkable assemblage of earlier work. It was not only a cult temple but the funerary temple for the kings who were buried within the precinct.

Funerary temples. Most of the New Kingdom funerary temples were built along the desert edge in western Thebes. An exception, and by far the most original and beautiful, was Queen Hatshepsut's temple, designed and built by her steward Senenmut near the tomb of Mentuhotep II at Dayr al-Baḥrī. Three terraces lead up to the recess in the cliffs where the shrine was cut into the rock. Each terrace is fronted by colonnades of square pillars protecting reliefs of unusual subjects, including an expedition to Punt and the divine birth of Hatshepsut. Ramps lead from terrace to terrace, and the uppermost level opens into a large court with colonnades. Chapels of Hathor (the principal deity of the temple) and Anubis occupy the south and north ends of the colonnade of the second terrace.

The largest conventionally planned funerary temple was

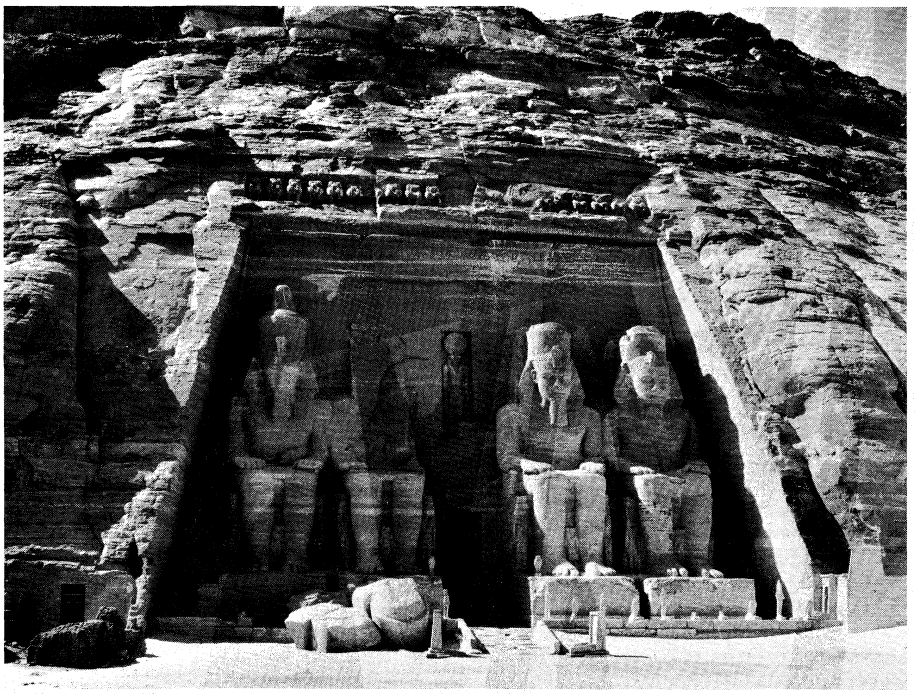

Figure 3: Entrance to the Nubian cliff temple of Ramses II at Abu Simbel, Egypt, c. 1250 BC, New Kingdom, 19th dynasty.
H. Roger-Viollet

probably that of Amenhotep III, now to be judged principally from the two huge quartzite statues, the Colossi of Memnon. These and other royal sculptures found in the ruins of the temple's courts and halls testify to the magnificence now lost. Its design, as well as much of its stone, was used by Ramses II for his own funerary temple, the Ramesseum. The huge enclosure of the latter included not only the temple but also a royal palace (only traces of which can now be seen). The temple itself contained two huge open courts, entered through towering pylons, which led to a lofty hypostyle hall and a smaller hall with astronomical carvings on the ceiling. Statues of vast size stood before the second pylon, one of which, now toppled and ruined, has been estimated as weighing more than 1,000 tons. Mud brick storerooms in the enclosure preserve ample evidence of the use of the vault in the late 2nd millennium BC.

Temple at Madīnat Habu

Ramses III's funerary temple at Madīnat Habu contains the best preserved of Theban mortuary chapels and shrines, as well as the main temple components. The most private parts of the temple, to which few had access apart from the king and his priestly representatives, begin at the sides of the first hypostyle hall, with the temple treasury and a room for the processional boat of Ramses II (a much-honoured ancestor) on the south and shrines for various deities, including Ramses III, on the north. A second pillared hall is flanked by a solar chapel and a small Osiris complex, where the king took on the personae of Re, the sun-god, and of Osiris, god of the underworld, a transfiguration considered necessary for his divine afterlife. Beyond the Osiris complex, along the temple axis, is a third small hall and the main shrine for the Theban god Amon; two lateral shrines were reserved for Amon's consort Mut and their divine child Khons.

As with most New Kingdom temples, the mural decorations on the outer walls of funerary temples, including that at Madīnat Habu, dealt mainly with the military campaigns of the king, while the inner scenes were mostly of ritual significance. Within the temple precinct lived and worked a whole community of priests and state officials. A small palace lay to the south of the main building, and a further suite of rooms for the king was installed in the castellated gate building on the east side of the precinct. The reliefs in this "high gate" suggest that the suite was used for recreational purposes by the king together with his women.

Domestic architecture. Mud brick and wood were the standard materials for houses and palaces throughout the Dynastic Period; stone was used occasionally for such architectural elements as doorjambs, lintels, column bases, and windows.

The workman's house

The best preserved private houses are those of modest size in the workmen's village of Dayr al-Madīnah. Exceptional in that they were built of stone, they typically had three or four rooms, comprising a master bedroom, a reception room, a cellar for storage, and a kitchen open to the sky; accommodation on the roof, reached by a stair, completed the plan.

Villas for important officials in Akhenaton's city of Tell el-Amarna were large and finely decorated with brightly painted murals. The house of the vizier Nakht had at least 30 rooms, including separate apartments for the master, his family, and his guests. Such houses had bathrooms and lavatories. The ceilings of large rooms were supported by painted wooden pillars, and there may have been further rooms above. Where space was restricted (as in Thebes) houses of several stories were built. Tomb scenes that show such houses also demonstrate that windows were placed high to reduce sunlight and that hooded vents on roofs were used to catch the breeze.

Palaces, as far as can be judged from remains at Thebes and Tell el-Amarna, were vast, rambling magnified versions of Nakht's villa, with broad halls, harem suites, kitchen areas, and wide courts. At Tell el-Amarna some monumental formality was introduced in the form of porticoes, colonnades, and statuary. Lavish use was made of mural and floor decoration in which floral themes predominated.

SCULPTURE

The Egyptian artist, whose skills are best exemplified in sculpture, regarded himself essentially as a craftsman. Owing to his discipline and highly developed aesthetic sense, however, the products of his craft deserve to rank as art outstanding by any standards.

Much of the surviving sculpture is funerary—statues for tombs. Most of the remainder was made for placing in temples—votive for private persons and ritual for royal and divine representations. Royal colossi were ritual and also served to proclaim the grandeur and power of the king. By itself, however, a statue could represent no one unless it carried an identification in hieroglyphs.

Types of figures

Emergence of types in the Old Kingdom. The standing male figure with left leg advanced and the seated figure were the most common types of Egyptian statuary. Traces of wooden figures found at Ṣaqqārah show that the first type was being made as early as the 1st dynasty. The earliest seated figures are two of King Khasekhem of the 2nd dynasty (Egyptian Museum, Cairo, and Ashmolean, Oxford), which, although relatively small, already embody the essential monumentality of all royal sculpture.

Supreme sculptural competence was achieved remarkably quickly. The primitive, yet immensely impressive life-size statue of Djoser (Egyptian Museum) pointed the way to the magnificent royal sculptures from the 4th-dynasty pyramid complexes at Giza. For subtlety of carving and true regal dignity scarcely anything of later date surpasses the diorite statue of Khafre (Egyptian Museum). Scarcely less fine are the sculptures of Menkaure (Mycerinus). The pair statue of the king and his wife (Museum of Fine Arts, Boston) exemplifies wonderfully both dignity and marital affection (Figure 4); the triads showing the king with goddesses and nome (provincial) deities exhibit a complete mastery of carving hard stone in many planes.

This union of skill and genius was achieved in nonroyal statuary more frequently in the Old Kingdom than later. The painted limestone statues of Prince Rahotep and his wife, Nofret (Egyptian Museum), exemplify this achievement in the formal category of seated figures. They also display the Egyptian's unsurpassed skill in inlaying eyes into sculptures, a skill further demonstrated in the wooden figure of Ka'aper, known as Shaykh al-Balad (Egyptian Museum), the very epitome of the self-important official (see Figure 8).

Scribal statues

Among additions to the sculptural repertoire during the Old Kingdom was the scribal statue. Examples in the Louvre and in the Egyptian Museum express brilliantly the alert vitality of the bureaucrat, squatting on the ground with brush poised over papyrus. The heads of such figures possess striking individuality, even if they are not true portraits.

Figure 4: King Menkaure and Queen Khamerernebty II, slate sculpture from Giza, Egypt, *c.* 2525 BC, Old Kingdom, 4th dynasty. In the Museum of Fine Arts, Boston. Height 1.42 m.

Refinements of the Middle Kingdom. Changes in funerary practices during the Middle Kingdom led to a reduction in the number of sculptures. Royal sculptures, particularly of Sesostris III and Amenemhet III (British Museum), achieved a high degree of realism, even of portraiture. The first true royal colossi were produced in the 12th dynasty (if the Great Sphinx of Giza is discounted) for the embellishment of cult temples. Colossi of Amenemhet I and Sesostris I (Egyptian Museum) exhibit a hard, uncompromising style said to typify the ruthless drive of the 12th-dynasty kings.

In this period, too, the sphinx—the recumbent lion with head or face of the king—became a commonly used image of the king as protector. The great red granite sphinx of Amenemhet II from Tanis (Louvre) expresses the idea most potently.

In private sculpture during the Middle Kingdom the subject is usually portrayed seated or squatting, occasionally standing, and wearing an all-enveloping cloak. The body was mostly concealed, but its contours were often subtly suggested in the carving, as in the figure of Khertyhotep (Ägyptisches Museum, West Berlin). Of female subjects, none is more impressive than that of Sennu (Museum of Fine Arts, Boston), a wonderful example of a figure in repose.

Block statues

The simplification of the human figure was carried to its ultimate in the block statue, a uniquely Egyptian type that represents the subject squatting on the ground with knees drawn up close to his body. The arms and legs may be wholly contained within the cubic form, hands and feet alone discretely protruding. The 12th-dynasty block statue of Sihathor (British Museum) is the earliest dated example.

Innovation, decline, and revival in the New Kingdom. Excellence of craftsmanship is the hallmark of 18th-dynasty sculpture, in a revival of the best traditions of the Middle Kingdom. Wonderfully sensitive statues of Hatshepsut and Thutmose III confirm the return of conditions in which great work can be achieved. A seated limestone statue of Hatshepsut (Metropolitan Museum of Art, New York City) shows the queen as king, but with an expression of consummate grace. A schist statue of Thutmose III (Luxor Museum), in the perfection of its execution and subtlety of its realization, epitomizes regality.

The placing of votive statues in temples led to a proliferation of private sculptures during the New Kingdom. The sculptures of Senenmut, steward of Hatshepsut, exemplify the development. At least 23 votive statues (some fragmentary) of this royal favourite are known, exhibiting many different forms.

Colossal sculpture

Colossal sculpture, which reached its apogee in the reign of Ramses II, was used to splendid, and perhaps less bombastic, effect by Amenhotep III. The great sculptures of his funerary temple, already mentioned, including the immense Colossi of Memnon, were part of the noble designs of his master of works, also called Amenhotep (son of Hapu). Most unusually, this distinguished commoner was allowed a funerary temple for himself and larger-than-life votive sculptures (Egyptian Museum and Luxor Museum) that show him in contrasting attitudes, as stern-faced authoritarian and as submissive scribe.

The realistic portraiture that can be noted in certain sculptures of Amenhotep III (British Museum) hints of an artistic change that was developed in the subsequent reign of Akhenaton. The distinctive style of this period has come to be called Amarna, after the location of Akhenaton's new capital in Middle Egypt. Colossal sculptures of the King from the dismantled Karnak temples (Egyptian Museum) emphasize his bodily peculiarities—elongated facial features, heavy breasts, and swelling hips (Figure 5). Sculptures of Nefertiti, his queen, are often executed in the most remarkably sensual manner (*e.g.*, the Louvre torso). Sculptures from later in the reign display innovations of style with no loss of artistry, at the same time avoiding the grotesqueries of the early years. Of this period is the famous painted bust of Nefertiti (Ägyptisches Museum).

Much of the best of the artistic legacy of Akhenaton's reign persisted in the sculpture of subsequent reigns—Tutankhamen, Horemheb, and the early kings of the 19th dynasty—but a marked change came in the reign of Ramses II. It is a commonplace to decry the quality of his monumental statuary, although little in Egypt is more dra-

The reign of Ramses II

Figure 5: King Akhenaton, sandstone pillar statue from the Temple of Aton at Karnak, Egypt, New Kingdom, 18th dynasty (mid-14th century BC). In the Egyptian Museum, Cairo. Height 4.00 m.

matic and compelling than the great seated figures of this king at Abu Simbel. Nevertheless, there is much truth in the belief that the steady decline in sculpture began during Ramses II's reign. Royal portraiture subsequently became conventional. Occasionally a sculptor might produce some unusual piece, such as the extraordinary figure of Ramses VI with his lion, dragging beside him a Libyan prisoner (Egyptian Museum). Among private sculptures there is the scribal statue of Ramsesnakht (Egyptian Museum); the subject bends over his papyrus while Thoth (the divine scribe), in baboon form, squats behind his head.

A change was to come with the advent of the Kushite (Nubian) kings of the 25th dynasty. The portraiture of the Kushite kings exhibits a brutal realism that may owe much to the royal sculpture of the 12th dynasty; the sphinx of Taharqa, fourth king of the 25th dynasty (British Museum), is a good example.

Archaism is strikingly evident in the private sculpture of the last dynasties. Types of statue common in the Middle Kingdom and 18th dynasty were revived, and many very fine pieces were produced. The sculptures of the mayor of Thebes, Montemhat (Egyptian Museum), display great variety, excellent workmanship, and, in one case, a realism that transcends the dictates of convention.

In considering the clear sculptural qualities of Late Period work one should never overlook the primary purpose of most Egyptian sculpture: to represent the individual in death before Osiris, or in life and death before the deities of the great temples. To this end the statue was not only a physical representation but also a vehicle for appropriate texts, which might be inscribed obtrusively over beautifully carved surfaces. The extreme example of such "disfigurement" is a so-called healing statue (Louvre) of which even the wig is covered with texts.

RELIEF SCULPTURE AND PAINTING

For Egyptians the decoration of tomb walls with reliefs or painted scenes provided some certainty of the perpetuation of life; in a temple, similarly, it was believed that mural decoration magically ensured the performance of important ceremonies and reinforced the memory of royal deeds.

Importance of mural decoration

The beginnings of the dynastic tradition can be found in tombs of the 3rd dynasty, such as that of Hesire at Ṣaqqārah; it contained mural paintings of funerary equipment and wooden panels carrying figures of Hesire in the finest low relief (Egyptian Museum; see Figure 8). Generally speaking, mural decorations were in paint when the ground was mud brick or stone of poor quality, and in relief when the walls were in good stone. Painting and drawing formed the basis of what was to be carved in relief, and the finished carving was itself commonly painted.

In tombs the mural decorations might be left unfinished, being only partly sketched or partly carved by the time of the burial. Uncompleted scenes reveal clearly the methods of laying out walls for decoration. The prepared wall was marked out with red guidelines, the grid described earlier being used for major human figures and sometimes for minor ones. Preliminary outlines were corrected and paint was applied usually in tempera, pigments being mostly mineral-based.

In the Old Kingdom pure painting of the highest quality is found as early as the 4th dynasty in the scene of geese from the tomb of Nefermaat and Atet at Maydum. But the glory of Old Kingdom mural decoration is the low-relief work in the royal funerary monuments of the 5th dynasty and in the private tombs of the 5th and 6th dynasties in the Memphite necropolis. Outstanding are the reliefs from the sun temple of King Neuserre at Abu Jīrab (Ägyptisches Museum, East and West Berlin) and the scenes of daily life in the tombs of Ptahhotep and Ti at Ṣaqqārah.

The tradition of fine painting was continued in the Middle Kingdom. At Beni Hasan the funerary chambers are crowded with paintings exhibiting fine draftsmanship and use of colour. The best relief work of the period, reviving the Memphite tradition, is found at Thebes in the tomb of Mentuhotep II at Dayr al-Baḥrī and in the little shrine of Sesostris I at Karnak, where the fine carving is greatly enhanced by a masterly use of space in the disposition of figures and text.

In the early 18th dynasty the relief tradition was revived at Thebes and can best be observed in the carvings in Hatshepsut's temple at Dayr al-Baḥrī. Later royal reliefs of Amenhotep III and of the post-Amarna kings show a stylistic refinement that was carried to its best in the reign of Seti I, at Karnak, at Abydos, and in his tomb at Thebes.

The 18th dynasty also saw Egyptian painting reach its highest achievement in the tombs of the nobles at Thebes (Figure 6). The medium of decoration and an apparently

High point of Egyptian painting

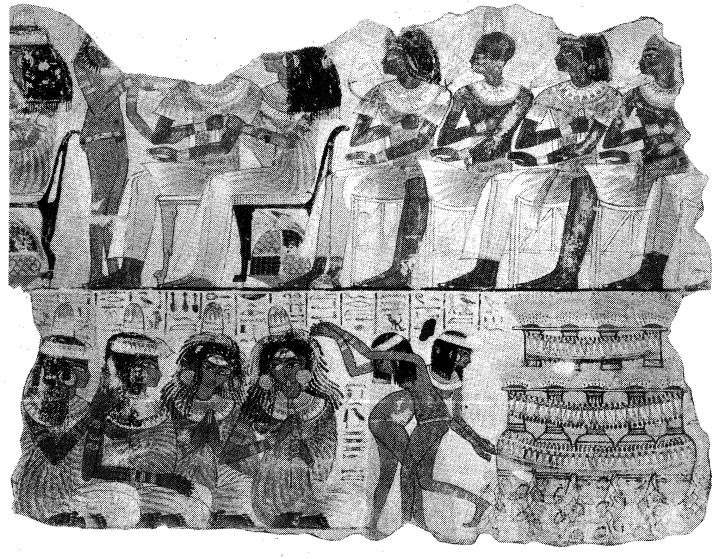

Figure 6: Banquet scene with musicians, tempera painting on gesso from the tomb of Nebamun at Thebes, 18th dynasty (*c.* 1400 BC). In the British Museum.

greater artistic freedom led to the introduction of small, often entertaining details into standard scenes. The tiny tombs of Menna and Nakht are full of such playful vignettes. The paintings in great tombs, such as that of Rekhmire, are more formal but still crammed with unusual detail. Fragments of mural and floor paintings from palaces and houses at Thebes and Tell el-Amarna provide tantalizing glimpses of the marsh and garden settings of everyday upper-class life.

The fine royal reliefs of the late 18th dynasty were matched by those in private tombs at Thebes (Ramose and Kheruef) and Ṣaqqārah (Horemheb); these are breathtaking in execution and, in the case of Horemheb, both moving and original. Interest in relief subsequently passed to the work in the temples of the 19th and 20th dynasties. The most dramatic subject was war, whether the so-called triumph of Ramses II at Kadesh (Thebes and Abu Simbel), or the more genuine successes of Ramses III against the Libyans and the Sea Peoples (Madīnat Habu). The size and vitality of these ostentatious scenes are stupendous, even if their execution tends to be slapdash.

The artistic renaissance of the 25th and 26th dynasties is less evident in painting and relief than in sculpture. Although the fine work in the tomb of Montemhat at Thebes is distinctly archaizing, it is, nevertheless, exceptional in quality. The skills of the Egyptian draftsman, nurtured by centuries of exercise at large and small scale, remained highly professional. This skill is seen at its most consistent level in the illumination of papyruses. The practice of including drawings, often painted, in religious papyruses flourished from the time of the 18th dynasty and reached a high point around 1300 BC. The peak of achievement is probably represented by the *Book of the Dead* of the scribe Ani (British Museum), in the vignettes of which both technique and the use of colour are outstanding. Subsequently, and especially in the Late Period, pure line drawing was increasingly employed.

Illumination of papyruses

PLASTIC ARTS

In Egypt pottery provided the basic material for vessels of all kinds. Fine wares and many other small objects were made from faience. Glass arrived late on the scene and was used somewhat irregularly from the New Kingdom onward.

Pottery. Generally speaking, Egyptian pottery had few artistic pretensions. In the tomb of Tutankhamen most of the pottery vessels were simple wine jars in the form of amphorae. It is surprising that no finer pottery vessels were found, because high-quality ware was made during the late 18th and 19th dynasties, often brightly painted with floral designs.

Pottery was rarely modeled, although human and animal figures occur in small numbers throughout the Dynastic Period. Small vessels in animal form were also made, especially during the Middle and New Kingdoms, and a fine category of highly burnished red pottery vases in female form was produced during the 18th dynasty.

Faience. The place of pottery for modeling was filled with faience (a glazed composition of ground quartz), most commonly blue or green in colour. In the Early Dynastic Period it was much used for the making of small animal and human figures, and throughout the Dynastic Period it continued to be used in this way, among the most striking results being the blue-glazed hippopotamus figures of Middle Kingdom date.

Hippopotamus figures

In the Late Period, in particular, the making of amulets and divine figurines in faience was highly developed, and many pieces display a high standard of modeling and perfection of glazing. The vast quantities of *ushabti* (*shabti*, or *shawabti*) figures provided as parts of funerary equipments are mostly routine work, but the finest examples from the New Kingdom, and some of Saite date, show complete mastery of a difficult technique.

Faience tiles were also first made in the early dynasties and were used chiefly for wall decoration, as in the subterranean chambers of the Step Pyramid. In the New Kingdom, tiles with floral designs were used in houses and palaces in the reigns of Amenhotep III and his successors. During the 19th and 20th dynasties royal palaces at Per Ramessu (modern Qantīr), Tell al-Yahudīyah, and Madīnat Habu were embellished with remarkable polychrome tiles, many of which bear figures of captive foreigners.

Throughout the Dynastic Period faience was regularly used for simple beads, amulets, and other components of jewelry. Quite exceptional is the extraordinary *was*-sceptre (a symbol of divine power) found at Tūkh, near Naqādah (Victoria and Albert Museum, London). It is dated to the reign of Amenhotep II and originally measured about six and a half feet (two metres) in length.

Glass. In the form of glaze, glass was known to the ancient Egyptians from early predynastic times, but the material was not used independently until the 18th dynasty. From the mid-18th dynasty and during the 19th dynasty glass was used for small amulets, beads, inlays, and especially for small vessels. The material was opaque, blue being the predominant colour, although other bright colours were also achieved. The vessels, made around sand cores, were mostly drinking cups or flasks for precious liquids and were often decorated with trailed patterns applied as glass threads. Glass was certainly a material of luxury, a fact confirmed by the presence of two glass goblets with gold rims among a treasure of precious vessels from the reign of Thutmose III (Metropolitan Museum of Art).

The use of glass for inlay is notably demonstrated in Tutankhamen's golden throne, in his solid gold mask, and in much of his jewelry (Figure 7). After the 19th dynasty, glass manufacture seems largely to have been discontinued until the Late Period,when the use of glass for inlays was revived.

Glass inlay

DECORATIVE ARTS

Jewelry. Gold provided Egyptian jewelry with its richness; it was used for settings, cloisonné work, chains, and beads, both solid and hollow. Soldering, granulation, and wire making were practiced. Precious stones were not used, but a wide range of semiprecious stones was exploited: carnelian, amethyst, garnet, red and yellow jasper, lapis lazuli, feldspar, turquoise, agate. Additional colours and textures were provided by faience and glass.

Ancient Egyptian jewelers had a fine eye for colour and an excellent sense of design. From the earliest dynasties come bracelets from the tomb of King Djer at Abydos (Egyptian Museum); from the 4th dynasty, the armlets of Queen Hetepheres, of silver inlaid with carnelian, turquoise, and lapis lazuli (Egyptian Museum and Museum of Fine Arts). There are examples of splendid and delicate jewelry dating from the Middle Kingdom: in particular, pieces found at Dahshūr and al-Lāhūn—circlets of Princess Khnumet

(Egyptian Museum), pectorals of Princess Sithathor and Queen Meret (Egyptian Museum), and girdles of Princess Sithathor-iunet (Metropolitan Museum of Art).

The large and spectacular collection of jewelry buried with Queen Ahhotep of the early 18th dynasty (Egyptian Museum) includes many unusual designs; her gold chain is a masterpiece. Much fine 18th-dynasty jewelry has survived, but all is dominated by that of Tutankhamen (Egyptian Museum). This huge collection demonstrates all the techniques of the goldsmith's and the lapidary's arts.

Copper and bronze. The techniques of metalworking were probably introduced into Egypt from the Middle East at a very early date. At first copper was most commonly used; but from at least the late 3rd millennium it was often alloyed with tin, as bronze.

The skill and artistry of the metalworker is shown in the fine bowls, jugs, and other vessels from all periods, and in statues and statuettes of gods, kings, and ordinary mortals. Most vessels were made by raising from metal ingots, beaten on wooden anvils. In the Late Period many vessels were produced by casting. Huge situlae, vessels used for carrying sacred liquids, are often decorated with scenes and inscriptions.

The earliest and largest metal figure from Egypt is the life-size statue of Pepi I (Egyptian Museum) made of copper plates fitted to a wooden core, the plates probably beaten, not cast. Casting in open molds was developed early for tools and weapons, but the lost-wax process (*cire-perdue*), using closed molds, was not employed until the Middle Kingdom. Even in the 18th dynasty the casting of bronze figures occurred on a relatively small scale.

Casting of figures

The casting of large-scale bronze figures achieved its highest point in the late New Kingdom down to the 25th dynasty. The outstanding example from this period is the figure of Karomama (Louvre). The exceptionally elegant modeling of the female form is greatly enriched by inlays of gold and silver reproducing the feathered pattern of the gown and an elaborate collar of floral motifs.

In the Late Period huge numbers of excellent castings of conventional sacred figures and animals were produced. The so-called Gayer-Anderson cat (British Museum) is technically and artistically without peer.

Gold and silver. Gold was more easily obtainable in ancient Egypt than silver and was therefore less valuable (until the late New Kingdom). Gold was also easier to work and unaffected by environmental conditions. In consequence, many more gold than silver objects have survived.

Decorative uses of gold

Apart from jewelry, gold was lavishly used for many decorative purposes, as thin sheet, leaf, and inlay, in funerary equipment, and for vessels and furniture. The range of uses is best exemplified in the objects from the tomb of Tutankhamen.

The gold-plated, gold-inlaid furniture of Queen Hetepheres of 4th-dynasty date reveals how early Egyptian craftsmen mastered the working of gold. Gold vessels have rarely survived, but those from the royal burials of Tanis (Egyptian Museum) preserve styles and techniques that go back to the traditions of the New Kingdom and earlier. Gold statuettes also are rare, but again, surviving examples, such as the magnificent falcon head of a cult statue of 6th-dynasty date from Hierakonpolis and the divine triad of Osiris, Isis, and Horus of the 22nd dynasty (Louvre), show the achievements of early and late times.

In a hoard of precious vessels found at Bubastis and dated to the 19th dynasty (Egyptian Museum) there were three silver pieces of exceptional interest, in particular a jug the handle of which is of gold and in the shape of a goat. Greater availability of silver in later times is demonstrated by two massive silver coffins and a number of vessels in the royal burials at Tanis (Egyptian Museum).

Wood. The wooden sculpture of the Old Kingdom shows the carver of wood at his most skillful and sensitive (Figure 8). But it is in the field of cabinetmaking that the ancient woodworker excelled. Best known are the many chairs, tables, stools, beds, and chests found in Tutankhamen's tomb. Many of the designs are exceptionally practical and elegant. Techniques of inlay, veneering, and marquetry are completely mastered. One chest is veneered with strips of ivory and inlaid with 33,000 small pieces

Cabinetmaking

of ivory and ebony. Fine furniture was being produced in very early times, as is confirmed by the skillfully restored furniture from the secondary burial of Hetepheres (Egyptian Museum and Museum of Fine Arts).

Among the most charming and delicate products of the Egyptian woodworker are the many toilet spoons and containers in the form of graceful swimming girls, lute players in the marshes, and fishes and animals. At the other extreme, nothing is more remarkable than the great boat, more than 140 feet (43 metres) long, found in a trench by the side of the Great Pyramid.

Ivory and bone. Of the few small ivory figurines to have survived from pharaonic times, two royal representations found in the Early Dynastic temple at Abydos (Egyptian Museum and British Museum) are outstanding. There can be little doubt, in spite of the paucity of survivals, that fine decorative objects of ivory were made at all periods. A gazelle and a grasshopper of the 18th dynasty (Metropolitan Museum of Art and Brooklyn Museum) may truly be described as *objets de vertu.* Many fine examples of the use of ivory were found in Tutankhamen's tomb, from simple geometric marquetry patterns to box panels carved with exquisitely informal scenes of the king with his queen.

Ivory figurines

Greco-Roman Egypt

After the conquest of Egypt by Alexander the Great, the independent rule of Pharaohs in the strict sense came to an end. Under the Ptolemies, whose rule followed Alexander's, profound changes took place in art and architecture.

The most lasting impression of the new period is made by the architectural legacy. Although very little survives of important funerary architecture, there is a group of tombs at Tunah al-Jabal of unusual form and great importance. Most interesting is the tomb of Petosiris, high priest of Thoth in nearby Hermopolis Magna in the late 4th century BC. It is in the form of a small temple with pillared portico, elaborate column capitals, and a large forecourt. In its mural decorations a strong Greek influence merges with the traditional Egyptian modes of expression.

A boom in temple building of a more conventional kind followed the establishment of the Ptolemaic regime. At Dandarah, Esna, Idfū, Kawm Umbū (Kôm Ombo), and

Ptolemaic temples

Philae the Egyptian cult temple can be studied better than at almost any earlier temple. The temple of Horus at Idfū is the most complete, displaying all the essentials of the classical Egyptian temple. The common judgment on these late temples is adverse, but for exploitation of setting and richness of detail it is difficult to fault the temples of Philae and Kawm Umbū, in particular.

In relief carving a noticeable change had taken place in the conventional proportions of human figures during the Saite Period, and subsequently, with added influences from Greek art, a more voluptuous style of human representation developed. There is also undoubtedly some coarseness in much of the new work. Nevertheless, there is much to admire in the best reliefs of the Hathor Temple at Dandarah and in the double cult temple of Sebek and Horus at Kawm Umbū.

Generous representation of the human form, especially the female form, also characterizes the sculpture of the Ptolemaic Period, and there is little to match the figure of Queen Arsinoe II (State Hermitage Museum, Leningrad). It is in the treatment of the head, however, that the greatest changes took place. It is a matter of debate whether the new emphasis on portraiture was attributable to influences from the classical world or was a development of earlier Egyptian sculptural tendencies. Fine pieces such as the schist "green" head of a man (Ägyptisches Museum) could not have failed to impress the observer from the Ptolemaic court or the later Roman administration. One of the finest surviving heads, in diorite, slightly larger than life-size and of dominating appearance, is the "black" head in The Brooklyn Museum (Figure 9).

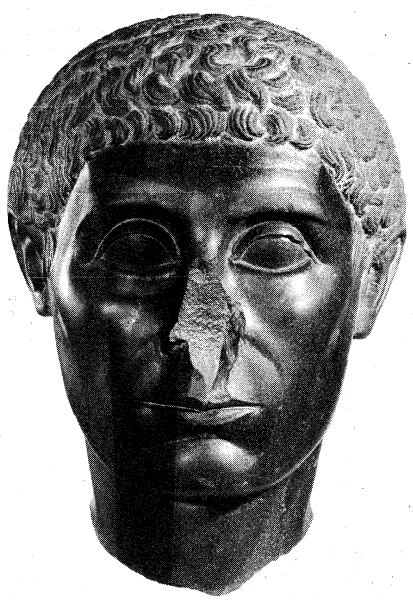

Figure 9: Black diorite head of a high official, possibly a high priest of Ptah of Memphis, Ptolemaic Period (c. 75 BC). In The Brooklyn Museum. Height 41.4 cm.

Throughout the Ptolemaic Period votive sculpture of private persons was made in great quantity. After the Roman conquest it became rare and of indifferent quality. Such Egyptian art as can be isolated in the Roman Period is found in funerary equipment—in coffins, shrouds, and panel portraits. A mixture of Egyptian and classical styles and of diverse symbolisms can be observed. The great shroud showing the deceased and his mummy protected by the mortuary deity, Anubis (Louvre), while harking back to the traditions of pharaonic Egypt, also displays in the figure of the deceased a style that points to Byzantium.

Mummy portraits

The mummy, or Fayum, portraits are Egyptian only in that they are associated with essentially Egyptian burial customs. Painted in an encaustic technique, they represent mostly Greek inhabitants of Egypt. Seen properly in context, as in the complete mummy of Artemidorus (British Museum), they provide a strange epilogue to the funerary art of 3,000 years of pharaonic Egypt. In this field and in a few others the vigour of the native tradition persisted artistically up to the Roman conquest. Thereafter the decline was rapid and complete. By the 3rd century AD Egypt was on the way to becoming a Christian country. The old tradition was not only destroyed, it was no longer valued. Coptic art was to find its inspiration elsewhere.

BOTHMER (comp.), *Egyptian Sculpture of the Late Period, 700 B.C. to A.D. 100* (1969). Excellent reproductions of paintings and drawings are to be found in NINA M. DAVIES and ALAN H. GARDINER, *Ancient Egyptian Paintings,* 3 vol. (1936); good surveys and some unusual material are in EMMA BRUNNER-TRAUT, *Egyptian Artists' Sketches* (1979). Also see T.G.H. JAMES, *Egyptian Painting* (1985); ARPAG MEKHITARIAN, *Egyptian Painting* (1954, reissued 1978; originally published in French, 1954); and WILLIAM H. PECK, *Drawings from Ancient Egypt* (1978). A good survey of the whole range of pottery is JANINE BOURRIAU, *Umm el-Ga'ab: Pottery from the Nile Valley Before the Arab Conquest* (1981). On glassware, see JOHN D. COONEY, *Glass* (1976). Jewelry is well treated artistically and technically in CYRIL ALDRED, *Jewels of the Pharaohs* (1971, reissued 1978); and technically and archaeologically in ALIX WILKINSON, *Ancient Egyptian Jewellery* (1971, reissued 1975). An excellent general account of furniture is contained in HOLLIS S. BAKER, *Furniture in the Ancient World: Origins and Evolution 3100–475 B.C.* (1966); for a reliable technical study, see G. KILLEN, *Ancient Egyptian Furniture,* vol. 1 (1980). On Greco-Roman art there is an excellent summary in GÜNTHER GRIMM, *Kunst der Ptolemäer- und Römerzeit im Ägyptischen Museum Kairo* (1975); for useful background essays, see HERWIG MAEHLER and VOLKER MICHAEL STROCKA (eds.), *Das ptolemäische Ägypten* (1978); and on reliefs in Greco-Roman temples, see ERICH WINTER, *Untersuchungen zu den ägyptischen Tempelreliefs der griechisch-römischen Zeit* (1968). The essential work on Fayum portraits is KLAUS PARLASCA, *Mumienporträts und verwandte Denkmäler* (1966).

(T.G.H.J.)

Einstein

Recognized in his own time as one of the most creative intellects in human history, Albert Einstein, in the first 15 years of the 20th century, advanced a series of theories that for the first time asserted the equivalence of mass and energy and proposed entirely new ways of thinking about space, time, and gravitation. His theories of relativity and gravitation were a profound advance over the old Newtonian physics and revolutionized scientific and philosophic inquiry.

Herein lay the unique drama of Einstein's life. He was a self-confessed lone traveller; his mind and heart soared with the cosmos, yet he could not armour himself against the intrusion of the often horrendous events of the human community. Almost reluctantly he admitted that he had a "passionate sense of social justice and social responsibility." His celebrity gave him an influential voice that he used to champion such causes as pacifism, liberalism, and Zionism. The irony for this idealistic man was that his famous postulation of an energy–mass equation, which states that a particle of matter can be converted into an enormous quantity of energy, had its spectacular proof in the creation of the atomic and hydrogen bombs, the most destructive weapons ever known.

Einstein.

By courtesy of the Nobelstiftelsen, Stockholm

Early life and career. Albert Einstein was born in Ulm, Germany, on March 14, 1879. The following year his family moved to Munich, where Hermann Einstein, his father, and Jakob Einstein, his uncle, set up a small electrical plant and engineering works. In Munich Einstein attended rigidly disciplined schools. Under the harsh and pedantic regimentation of 19th-century German education, which he found intimidating and boring, he showed little scholastic ability. At the behest of his mother, Einstein also studied music; though throughout life he played exclusively for relaxation, he became an accomplished violinist. It was then only Uncle Jakob who stimulated in Einstein a fascination for mathematics and Uncle Cäsar Koch who stimulated a consuming curiosity about science.

By the age of 12 Einstein had decided to devote himself to solving the riddle of the "huge world." Three years later, with poor grades in history, geography, and languages, he left school with no diploma and went to Milan to rejoin his family, who had recently moved there from Germany because of his father's business setbacks. Albert Einstein resumed his education in Switzerland, culminating in four years of physics and mathematics at the renowned Federal Polytechnic Academy in Zürich.

After his graduation in the spring of 1900, he became a Swiss citizen, worked for two months as a mathematics teacher, and then was employed as examiner at the Swiss patent office in Bern. With his newfound security, Einstein married his university sweetheart, Mileva Marić, in 1903.

First contributions to science

Early in 1905 Einstein published in the prestigious German physics monthly *Annalen der Physik* a thesis, "A New Determination of Molecular Dimensions," that won him a Ph.D. from the University of Zürich. Four more important papers appeared in *Annalen* that year and forever changed man's view of the universe.

The first of these, "Über die von der molekularkinetischen Theorie der Wärme geforderte Bewegung von in ruhenden Flüssigkeiten suspendierten Teilchen" ("On the Motion—Required by the Molecular Kinetic Theory of Heat—of Small Particles Suspended in a Stationary Liquid"), provided a theoretical explanation of Brownian motion. In "Über einen die Erzeugung und Verwandlung des Lichtes betreffenden heuristischen Gesichtspunkt" ("On a Heuristic Viewpoint Concerning the Production and Transformation of Light"), Einstein postulated that light is composed of individual quanta (later called photons) that, in addition to wavelike behaviour, demonstrate certain properties unique to particles. In a single stroke he thus revolutionized the theory of light and provided an explanation for, among other phenomena, the emission of electrons from some solids when struck by light, called the photoelectric effect.

Einstein's special theory of relativity, first printed in "Zur Elektrodynamik bewegter Körper" ("On the Electrodynamics of Moving Bodies"), had its beginnings in an essay Einstein wrote at age 16. The precise influence of work by other physicists on Einstein's special theory is still controversial. The theory held that, if, for all frames of reference, the speed of light is constant and if all natural laws are the same, then both time and motion are found to be relative to the observer.

In the mathematical progression of the theory, Einstein published his fourth paper, "Ist die Trägheit eines Körpers von seinem Energieinhalt abhängig?" ("Does the Inertia of a Body Depend Upon Its Energy Content?"). This mathematical footnote to the special theory of relativity established the equivalence of mass and energy, according to which the energy E of a quantity of matter, with mass m, is equal to the product of the mass and the square of the velocity of light, c. This relationship is commonly expressed in the form $E = mc^2$.

Public understanding of this new theory and acclaim for its creator were still many years off, but Einstein had won a place among Europe's most eminent physicists, who increasingly sought his counsel, as he did theirs. While Einstein continued to develop his theory, attempting now to encompass with it the phenomenon of gravitation, he left the patent office and returned to teaching—first in Switzerland, briefly at the German University in Prague, where he was awarded a full professorship, and then, in the winter of 1912, back at the Polytechnic in Zürich. He was later remembered from this time as a very happy man, content in his marriage and delighted with his two young sons, Hans Albert and Edward.

In April 1914 the family moved to Berlin, where Einstein had accepted a position with the Prussian Academy of Sciences, an arrangement that permitted him to continue his researches with only the occasional diversion of lecturing at the University of Berlin. His wife and two sons vacationed in Switzerland that summer and, with the eruption of World War I, were unable to return to Berlin. A few years later this enforced separation was to lead to divorce. Einstein abhorred the war and was an outspoken critic of German militarism among the generally acquiescent academic community in Berlin, but he

was primarily engrossed in perfecting his general theory of relativity, which he published in *Annalen der Physik* as "Die Grundlagen der allgemeinen Relativitätstheorie" ("The Foundation of the General Theory of Relativity") in 1916. The heart of this postulate was that gravitation is not a force, as Newton had said, but a curved field in the space–time continuum, created by the presence of mass. This notion could be proved or disproved, he suggested, by measuring the deflection of starlight as it travelled close by the Sun, the starlight being visible only during a total eclipse. Einstein predicted twice the light deflection that would be accountable under Newton's laws.

General theory of relativity

His new equations also explained for the first time the puzzling irregularity—that is, the slight advance—in the planet Mercury's perihelion, and they demonstrated why stars in a strong gravitational field emitted light closer to the red end of the spectrum than those in a weaker field.

While Einstein awaited the end of the war and the opportunity for his theory to be tested under eclipse conditions, he became more and more committed to pacifism, even to the extent of distributing pacifist literature to sympathizers in Berlin. His attitudes were greatly influenced by the French pacifist and author Romain Rolland, whom he met on a wartime visit to Switzerland. Rolland's diary later provided the best glimpse of Einstein's physical appearance as he reached his middle 30s:

> Einstein is still a young man, not very tall, with a wide and long face, and a great mane of crispy, frizzled and very black hair, sprinkled with gray and rising high from a lofty brow. His nose is fleshy and prominent, his mouth small, his lips full, his cheeks plump, his chin rounded. He wears a small cropped mustache. (By permission of Madame Marie Romain Rolland.)

Einstein's view of humanity during the war period appears in a letter to his friend, the Austrian-born Dutch physicist Paul Ehrenfest:

> The ancient Jehovah is still abroad. Alas, he slays the innocent along with the guilty, whom he strikes so fearsomely blind that they can feel no sense of guilt. . . . We are dealing with an epidemic delusion which, having caused infinite suffering, will one day vanish and become a monstrous and incomprehensible source of wonderment to later generations. (From Otto Nathan and Heinz Norden [eds.], *Einstein on Peace;* Simon and Schuster, 1960.)

It would be said often of Einstein that he was naïve about human affairs; for example, with the proclamation of the German Republic and the armistice in 1918, he was convinced that militarism had been thoroughly abolished in Germany.

International acclaim. International fame came to Einstein in November 1919, when the Royal Society of London announced that its scientific expedition to Príncipe Island, in the Gulf of Guinea, had photographed the solar eclipse on May 29 of that year and completed calculations that verified the predictions made in Einstein's general theory of relativity. Few could understand relativity, but the basic postulates were so revolutionary and the scientific community was so obviously bedazzled that the physicist was acclaimed the greatest genius on Earth. Einstein himself was amazed at the reaction and apparently displeased, for he resented the consequent interruptions of his work. After his divorce he had, in the summer of 1919, married Elsa, the widowed daughter of his late father's cousin. He lived quietly with Elsa and her two daughters in Berlin, but, inevitably, his views as a foremost savant were sought on a variety of issues.

Proof of the general theory of relativity

Despite the now deteriorating political situation in Germany, Einstein attacked nationalism and promoted pacifist ideals. With the rising tide of anti-Semitism in Berlin, Einstein was castigated for his "Bolshevism in physics," and the fury against him in right-wing circles grew when he began publicly to support the Zionist movement. Judaism had played little part in his life, but he insisted that, as a snail can shed his shell and still be a snail, so a Jew can shed his faith and still be a Jew.

Although Einstein was regarded warily in Berlin, such was the demand for him in other European cities that he travelled widely to lecture on relativity, usually arriving at each place by third-class rail carriage, with a violin tucked under his arm. So successful were his lectures that one enthusiastic impresario guaranteed him a three-week booking at the London Palladium. He ignored the offer, but, at the request of the Zionist leader Chaim Weizmann, toured the United States in the spring of 1921 to raise money for the Palestine Foundation Fund. Frequently treated like a circus freak and feted from morning to night, Einstein nevertheless was gratified by the standards of scientific research and the "idealistic attitudes" that he found prevailing in the United States.

During the next three years Einstein was constantly on the move, journeying not only to European capitals but also to the Orient, to the Middle East, and to South America. According to his diary notes, he found nobility among the Hindus of Ceylon, a pureness of soul among the Japanese, and a magnificent intellectual and moral calibre among the Jewish settlers in Palestine. His wife later wrote that, on steaming into one new harbour, Einstein had said to her, "Let us take it all in before we wake up."

In Shanghai a cable reached him announcing that he had been awarded the 1921 Nobel Prize for Physics "for your photoelectric law and your work in the field of theoretical physics." Relativity, still the centre of controversy, was not mentioned.

The Nobel Prize

Though the 1920s were tumultuous times of wide acclaim, and some notoriety, Einstein did not waver from his new search—to find the mathematical relationship between electromagnetism and gravitation. This would be a first step, he felt, in discovering the common laws governing the behaviour of everything in the universe, from the electron to the planets. He sought to relate the universal properties of matter and energy in a single equation or formula, in what came to be called a unified field theory. This turned out to be a fruitless quest that occupied the rest of his life. Einstein's peers generally agreed quite early that his search was destined to fail because the rapidly developing quantum theory uncovered an uncertainty principle in all measurements of the motion of particles: the movement of a single particle simply could not be predicted because of a fundamental uncertainty in measuring simultaneously both its speed and its position, which means, in effect, that the future of any physical system at the subatomic level cannot be predicted. While fully recognizing the brilliance of quantum mechanics, Einstein rejected the idea that these theories were absolute and persevered with his theory of general relativity as the more satisfactory foundation to future discovery. He was widely quoted on his belief in an exactly engineered universe: "God is subtle but he is not malicious." On this point, he parted company with most theoretical physicists. The distinguished German quantum theorist Max Born, a close friend of Einstein, said at the time: "Many of us regard this as a tragedy, both for him, as he gropes his way in loneliness, and for us, who miss our leader and standard-bearer." This appraisal, and others pronouncing his work in later life as largely wasted effort, will have to await the judgment of later generations.

The year of Einstein's 50th birthday, 1929, marked the beginning of the ebb flow of his life's work in a number of aspects. Early in the year the Prussian Academy published the first version of his unified-field theory, but, despite the sensation it caused, its very preliminary nature soon became apparent. The reception of the theory left him undaunted, but Einstein was dismayed by the preludes to certain disaster in the field of human affairs: Arabs launched savage attacks on Jewish colonists in Palestine; the Nazis gained strength in Germany; the League of Nations proved so impotent that Einstein resigned abruptly from its Committee on Intellectual Cooperation as a protest to its timidity; and the stock market crash in New York City heralded worldwide economic crisis.

Crushing Einstein's natural gaiety more than any of these events was the mental breakdown of his younger son, Edward. Edward had worshipped his father from a distance but now blamed him for deserting him and for ruining his life. Einstein's sorrow was eased only slightly by the amicable relationship he enjoyed with his older son, Hans Albert.

As visiting professor at Oxford University in 1931, Ein-

stein spent as much time espousing pacifism as he did discussing science. He went so far as to authorize the establishment of the Einstein War Resisters' International Fund in order to bring massive public pressure to bear on the World Disarmament Conference, scheduled to meet in Geneva in February 1932. When these talks foundered, Einstein felt that his years of supporting world peace and human understanding had accomplished nothing. Bitterly disappointed, he visited Geneva to focus world attention on the "farce" of the disarmament conference. In a rare moment of fury, Einstein stated to a journalist,

Einstein War Resisters' International Fund

> They [the politicians and statesmen] have cheated us. They have fooled us. Hundreds of millions of people in Europe and in America, billions of men and women yet to be born, have been and are being cheated, traded and tricked out of their lives and health and well-being.

Shortly after this, in a famous exchange of letters with the Austrian psychiatrist Sigmund Freud, Einstein suggested that people must have an innate lust for hatred and destruction. Freud agreed, adding that war was biologically sound because of the love–hate instincts of man and that pacifism was an idiosyncrasy directly related to Einstein's high degree of cultural development. This exchange was only one of Einstein's many philosophic dialogues with renowned men of his age. With Rabindranath Tagore, Hindu poet and mystic, he discussed the nature of truth. While Tagore held that truth was realized through man, Einstein maintained that scientific truth must be conceived as a valid truth that is independent of humanity. "I cannot prove that I am right in this, but that is my religion," said Einstein. Firmly denying atheism, Einstein expressed a belief in "Spinoza's God who reveals himself in the harmony of what exists." The physicist's breadth of spirit and depth of enthusiasm were always most evident among truly intellectual men. He loved being with the physicists Paul Ehrenfest and Hendrick A. Lorentz at The Netherlands' Leiden University, and several times he visited the California Institute of Technology in Pasadena to attend seminars at the Mt. Wilson Observatory (now part of Hale Observatories), which had become world renowned for astrophysical research. At Mt. Wilson he heard the Belgian scientist Abbé Georges Lemaître detail his theory that the universe had been created by the explosion of a "primeval atom" and was still expanding. Gleefully, Einstein jumped to his feet, applauding. "This is the most beautiful and satisfactory explanation of creation to which I have ever listened," he said.

In 1933, soon after Adolf Hitler became chancellor of Germany, Einstein renounced his German citizenship and left the country. He later accepted a full-time position as a foundation member of the school of mathematics at the new Institute for Advanced Study in Princeton, New Jersey. In reprisal, Nazi storm troopers ransacked his beloved summer house at Caputh, near Berlin, and confiscated his sailboat. Einstein was so convinced that Nazi Germany was preparing for war that, to the horror of Romain Rolland and his other pacifist friends, he violated his pacifist ideals and urged free Europe to arm and recruit for defense.

Flight from Europe

Although his warnings about war were largely ignored, there were fears for Einstein's life. He was taken by private yacht from Belgium to England. By the time he arrived in Princeton in October 1933, he had noticeably aged. A friend wrote,

> It was as if something had deadened in him. He sat in a chair at our place, twisting his white hair in his fingers and talking dreamily about everything under the sun. He was not laughing any more.

Later years in the United States. In Princeton Einstein set a pattern that was to vary little for more than 20 years. He lived with his wife in a simple, two-story frame house and most mornings walked a mile or so to the Institute, where he worked on his unified-field theory and talked with colleagues. For relaxation he played his violin and sailed on a local lake. Only rarely did he travel, even to New York. In a letter to Queen Elisabeth of Belgium, he described his new refuge as a "wonderful little spot, . . . a quaint and ceremonious village of puny demigods on stilts." Eventually he acquired American citizenship, but he always continued to think of himself as a European. Pursuing his own line of theoretical research outside the mainstream of physics, he took on an air of fixed serenity. "Among my European friends, I am now called *Der grosse Schweiger* ("The Great Stone Face"), a title I well deserve," he said. Even his wife's death late in 1936 did not disturb his outward calm. "It seemed that the difference between life and death for Einstein consisted only in the difference between being able and not being able to do physics," wrote Leopold Infeld, the Polish physicist who arrived in Princeton at this time.

Development of the atomic bomb

Niels Bohr, the great Danish atomic physicist, brought news to Einstein in 1939 that the German refugee physicist Lise Meitner had split the uranium atom, with a slight loss of total mass that had been converted into energy. Meitner's experiments, performed in Copenhagen, had been inspired by similar, though less precise, experiments done months earlier in Berlin by two German chemists, Otto Hahn and Fritz Strassmann. Bohr speculated that, if a controlled chain-reaction splitting of uranium atoms could be accomplished, a mammoth explosion would result. Einstein was skeptical, but laboratory experiments in the United States showed the feasibility of the idea. With a European war regarded as imminent and fears that Nazi scientists might build such a "bomb" first, Einstein was persuaded by colleagues to write a letter to President Franklin D. Roosevelt urging "watchfulness and, if necessary, quick action" on the part of the United States in atomic-bomb research. This recommendation marked the beginning of the Manhattan Project.

Although he took no part in the work at Los Alamos, New Mexico, and did not learn that a nuclear-fission bomb had been made until Hiroshima was razed in 1945, Einstein's name was emphatically associated with the advent of the atomic age. He readily joined those scientists seeking ways to prevent any future use of the bomb, his particular and urgent plea being the establishment of a world government under a constitution drafted by the United States, Britain, and Russia. With the spur of the atomic fear that haunted the world, he said "we must not be merely willing, but actively eager to submit ourselves to the binding authority necessary for world security." Once more, Einstein's name surged through the newspapers. Letters and statements tumbled out of his Princeton study, and in the public eye Einstein the physicist dissolved into Einstein the world citizen, a kind "grand old man" devoting his last years to bringing harmony to the world.

The rejection of his ideals by statesmen and politicians did not break him, because his prime obsession still remained with physics. "I cannot tear myself away from my work," he wrote at the time. "It has me inexorably in its clutches." In proof of this came his new version of the unified field in 1950, a most meticulous mathematical essay that was immediately but politely criticized by most physicists as untenable.

New version of the unified field

Compared with his renown of a generation earlier, Einstein was virtually neglected and said himself that he felt almost like a stranger in the world. His health deteriorated to the extent that he could no longer play the violin or sail his boat. Many years earlier, chronic abdominal pains had forced him to give up smoking his pipe and to watch his diet carefully.

On April 18, 1955, Einstein died in his sleep at Princeton Hospital. On his desk lay his last incomplete statement, written to honour Israeli Independence Day. It read in part: "What I seek to accomplish is simply to serve with my feeble capacity truth and justice at the risk of pleasing no one." His contribution to man's understanding of the universe was matchless, and he is established for all time as a giant of science. Broadly speaking, his crusades in human affairs seem to have had no lasting impact. Einstein perhaps anticipated such an assessment of his life when he said, "Politics are for the moment. An equation is for eternity." (P.Mi.)

Electricity and Magnetism

Electricity and magnetism are two aspects of electromagnetism, the science of charge and of the forces and fields associated with charge. Electricity and magnetism were long thought to be separate forces. It was not until the 19th century that they were finally treated as interrelated phenomena. In 1905 Albert Einstein's special theory of relativity established beyond a doubt that both are aspects of one common phenomenon. At a practical level, however, electric and magnetic forces behave quite differently and are described by different equations. Electric forces are produced by electric charges either at rest or in motion. Magnetic forces, on the other hand, are produced only by moving charges and act solely on charges in motion.

Electric phenomena occur even in neutral matter because the forces act on the individual charged constituents. The electric force, in particular, is responsible for most of the physical and chemical properties of atoms and molecules. It is enormously strong compared with gravity. For example, the absence of only one electron out of every billion molecules in two 70-kilogram (154-pound) persons standing two metres (two yards) apart would repel them with a 30,000-ton force. On a more familiar scale, electric phenomena are responsible for the lightning and thunder accompanying certain storms.

Electric and magnetic forces can be detected in regions called electric and magnetic fields. These fields are fundamental in nature and can exist in space far from the charge or current that generated them. Remarkably, electric fields can produce magnetic fields and vice versa, independent of any external charge. A changing magnetic field produces an electric field, as the English physicist Michael Faraday discovered in work that forms the basis of electric power generation. Conversely, a changing electric field produces a magnetic field, as the Scottish physicist James Clerk Maxwell deduced. The mathematical equations formulated by Maxwell incorporated light and wave phenomena into electromagnetism. He showed that electric and magnetic fields travel together through space as waves of electromagnetic radiation, with the changing fields mutually sustaining each other. Examples of electromagnetic waves traveling through space independent of matter are radio and television waves, microwaves, infrared rays, visible light, ultraviolet light, X rays, and gamma rays. All of these waves travel at the same speed—namely, the velocity of light (roughly 300,000 kilometres, or 186,000 miles, per second). They differ from each other only in the frequency at which their electric and magnetic fields oscillate.

Maxwell's equations still provide a complete and elegant description of electromagnetism down to, but not including, the subatomic scale. The interpretation of his work, however, was broadened in the 20th century. Einstein's special relativity theory merged electric and magnetic fields into one common field and limited the velocity of all matter to the velocity of electromagnetic radiation. During the late 1960s, physicists discovered that other forces in nature have fields with a mathematical structure similar to that of the electromagnetic field. These other forces are the nuclear force, responsible for the energy released in nuclear fusion, and the weak force, observed in the radioactive decay of unstable atomic nuclei. In particular, the weak and electromagnetic forces have been combined into a common force called the electroweak force. The goal of many physicists to unite all of the fundamental forces, including gravity, into one grand unified theory has not been attained to date.

An important aspect of electromagnetism is the science of electricity, which is concerned with the behaviour of aggregates of charge, including the distribution of charge within matter and the motion of charge from place to place. Different types of materials are classified as either conductors or insulators on the basis of whether charges can move freely through their constituent matter. Electric current is the measure of the flow of charges; the laws governing currents in matter are important in technology, particularly in the production, distribution, and control of energy.

The concept of voltage, like those of charge and current, is fundamental to the science of electricity. Voltage is a measure of the propensity of charge to flow from one place to another; positive charges generally tend to move from a region of high voltage to a region of lower voltage. A common problem in electricity is determining the relationship between voltage and current or charge in a given physical situation.

This article seeks to provide a qualitative understanding of electromagnetism as well as a quantitative appreciation for the magnitudes associated with electromagnetic phenomena.

For coverage of related topics in the *Macropædia* and *Micropædia,* see the *Propædia,* sections 127 and 128, and the *Index.*

The article is divided into the following sections:

General considerations

Everyday modern life is pervaded by electromagnetic phenomena. When a light bulb is switched on, a current flows through a thin filament in the bulb; the current heats the filament to such a high temperature that it glows, illuminating its surroundings. Electric clocks and connections link simple devices of this kind into complex systems such as traffic lights that are timed and synchronized with the speed of vehicular flow. Radio and television sets receive information carried by electromagnetic waves traveling through space at the speed of light. To start an automobile, currents in an electric starter motor generate magnetic fields that rotate the motor shaft and drive engine pistons to compress an explosive mixture of gasoline and air; the spark initiating the combustion is an electric discharge, which makes up a momentary current flow.

Many of these devices and phenomena are complex, but they derive from the same fundamental laws of electromagnetism. One of the most important of these is Coulomb's law, which describes the electric force between charged objects. Formulated by the 18th-century French physicist Charles-Augustin de Coulomb, it is analogous to Newton's law for the gravitational force. Both gravitational and electric forces decrease with the square of the distance between the objects, and both forces act along a line between them. In Coulomb's law, however, the magnitude and sign of the electric force are determined by the charge, rather than the mass, of an object. Thus, charge determines how electromagnetism influences the motion of charged objects. (Charge is a basic property of matter. Every constituent of matter has an electric charge with a value that can be positive, negative, or zero. For example, electrons are negatively charged, and atomic nuclei are positively charged. Most bulk matter has an equal amount of positive and negative charge and thus has zero net charge.)

Coulomb's law

According to Coulomb, the electric force for charges at rest has the following properties:

(1) Like charges repel each other; unlike charges attract. Thus, two negative charges repel one another, while a positive charge attracts a negative charge.

(2) The attraction or repulsion acts along the line between the two charges.

(3) The size of the force varies inversely as the square of the distance between the two charges. Therefore, if the distance between the two charges is doubled, the attraction or repulsion becomes weaker, decreasing to one-fourth of the original value. If the charges come 10 times closer, the size of the force increases by a factor of 100.

(4) The size of the force is proportional to the value of each charge. The unit used to measure charge is the coulomb (C). If there were two positive charges, one of 0.1 coulomb and the second of 0.2 coulomb, they would repel each other with a force that depends on the product 0.2×0.1. If each of the charges were reduced by one-half, the repulsion would be reduced to one-quarter of its former value.

Static cling is a practical example of the Coulomb force. In static cling, garments made of synthetic material collect a charge, especially in dry winter air. A plastic or rubber comb passed quickly through hair also becomes charged and will pick up bits of paper. The synthetic fabric and the comb are insulators; charge on these objects cannot move easily from one part of the object to another. Similarly, an office copy machine uses electric force to attract particles of ink to paper.

Like Coulomb's law, the principle of charge conservation is a fundamental law of nature. According to this principle, the charge of an isolated system cannot change. If an additional positively charged particle appears within a system, a particle with a negative charge of the same magnitude will be created at the same time; thus, the principle of conservation of charge is maintained. In nature, a pair of oppositely charged particles is created when high-energy radiation interacts with matter; an electron and a positron are created in a process known as pair production.

Principle of charge conservation

The smallest subdivision of the amount of charge that a particle can have is the charge of one proton, $+1.602 \times 10^{-19}$ coulomb. The electron has a charge of the same magnitude but opposite sign—*i.e.*, -1.602×10^{-19} coulomb. An ordinary flashlight battery delivers a current that provides a total charge flow of approximately 5,000 coulomb, which corresponds to more than 10^{22} electrons, before it is exhausted.

Electric current is a measure of the flow of charge, as, for example, charge flowing through a wire. The size of the current is measured in amperes and symbolized by *i*. An ampere of current represents the passage of one coulomb of charge per second, or 6.2 billion billion electrons (6.2×10^{18} electrons) per second. A current is positive when it is in the direction of the flow of positive charges; its direction is opposite to the flow of negative charges.

The force and conservation laws are only two aspects of electromagnetism, however. Electric and magnetic forces are caused by electromagnetic fields. The term field denotes a property of space, so that the field quantity has a numerical value at each point of space. These values may also vary with time. The value of the electric or magnetic field is a vector—*i.e.*, a quantity having both magnitude and direction. The value of the electric field at a point in space, for example, equals the force that would be exerted on a unit charge at that position in space.

Every charged object sets up an electric field in the surrounding space. A second charge "feels" the presence of this field. The second charge is either attracted toward the initial charge or repelled from it, depending on the signs of the charges. Of course, since the second charge also has an electric field, the first charge feels its presence and is either attracted or repelled by the second charge, too.

Electric fields and forces

The electric field from a charge is directed away from the charge when the charge is positive and toward the charge when it is negative. The electric field from a charge at rest is shown in Figure 1 for various locations in space. The arrows point in the direction of the electric field, and the length of the arrows indicates the strength of the field at the midpoint of the arrows.

If a positive charge were placed in the electric field, it would feel a force in the direction of the field. A negative charge would feel a force in the direction opposite the direction of the field.

In calculations, it is often more convenient to deal directly with the electric field than with the charges; fre-

quently, more is known about the field than about the distribution of charges in space. For example, the distribution of charges in conductors is generally unknown because the charges move freely within the conductor. In static situations, however, the electric field in a conductor in equilibrium has a definite value, zero, because any force on the charges inside the conductor redistributes them until the field vanishes. The unit of electric field is newtons per coulomb, or volts per metre.

Electric potential

The electric potential is another useful field. It provides an alternative to the electric field in electrostatics problems. The potential is easier to use, however, because it is a single number, a scalar, instead of a vector. The difference in potential between two places measures the degree to which charges are influenced to move from one place to another. If the potential is the same at two places (*i.e.*, if the places have the same voltage), charges will not be influenced to move from one place to the other. The potential on an object or at some point in space is measured in volts; it equals the electrostatic energy that a unit charge would have at that position. In a typical 12-volt car battery, the battery terminal that is marked with a + sign is at a potential 12 volts greater than the potential of the terminal marked with the − sign. When a wire, such as the filament of a car headlight, is connected between the + and the − terminals of the battery, charges move through the filament as an electric current and heat the filament; the hot filament radiates light.

Magnetic fields and forces

The magnetic force influences only those charges that are already in motion. It is transmitted by the magnetic field. Both magnetic fields and magnetic forces are more complicated than electric fields and electric forces. The magnetic field does not point along the direction of the source of the field; instead, it points in a perpendicular direction. In addition, the magnetic force acts in a direction that is perpendicular to the direction of the field. In comparison, both the electric force and the electric field point directly toward or away from the charge.

The present discussion will deal with simple situations in which the magnetic field is produced by a current of charge in a wire. Certain materials, such as copper, silver, and aluminum, are conductors that allow charge to flow freely from place to place. If an external influence establishes a current in a conductor, the current generates a magnetic field. For a long straight wire, the magnetic field has a direction that encircles the wire on a plane perpendicular to the wire. The strength of the magnetic field decreases with distance from the wire. The arrows in Figure 2 represent the size and direction of the magnetic field for a current moving in the direction indicated. Figure 2A shows an end view with the current coming toward the reader, while Figure 2B provides a three-dimensional view of the magnetic field at one position along the wire.

In subsequent figures, continuous lines will be used to represent the direction of electric and magnetic fields. These lines emphasize the important fact that electric fields begin on positive charges and end on negative charges, while magnetic fields do not have beginnings or ends and close on themselves. The magnetic field shown in Figure 2

is unusually simple. Highly complex and useful magnetic fields can be generated by the proper choice of conductors to carry electric currents. Under development are thermonuclear fusion reactors for obtaining energy from the fusion of light nuclei in the form of very hot plasmas of hydrogen isotopes. The plasmas have to be confined by magnetic fields (dubbed "magnetic bottles") as no material container can withstand such high temperatures. Charged particles are also confined by magnetic fields in nature. Large numbers of charged particles, mostly protons and electrons, are trapped in huge bands around the Earth by its magnetic field. These bands are known as the Van Allen radiation belts. Disturbance of the Earth's confining magnetic field produces spectacular displays, the so-called northern lights, in which trapped charged particles are freed and crash through the atmosphere to Earth.

Interaction of a magnetic field with charge

How does the magnetic field interact with a charged object? If the charge is at rest, there is no interaction. If the charge moves, however, it is subjected to a force, the size of which increases in direct proportion with the velocity of the charge. The force has a direction that is perpendicular both to the direction of motion of the charge and to the direction of the magnetic field. There are two possible precisely opposite directions for such a force for a given direction of motion. This apparent ambiguity is resolved by the fact that one of the two directions applies to the force on a moving positive charge while the other direction applies to the force on a moving negative charge. Figure 3 illustrates the directions of the magnetic force on positive charges and on negative charges as they move in a magnetic field that is perpendicular to the motion.

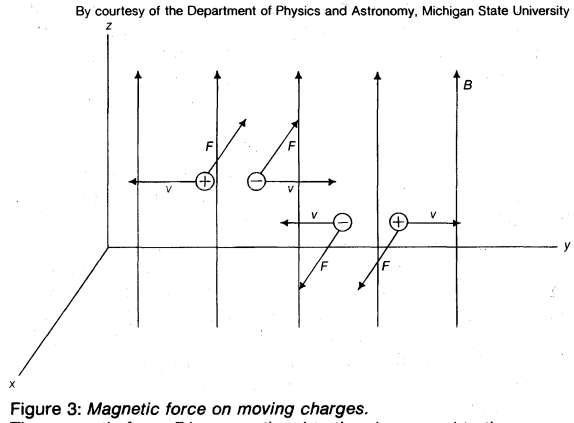

Figure 3: *Magnetic force on moving charges.*
The magnetic force ***F*** is proportional to the charge and to the magnitude of velocity ***v*** times the magnetic field ***B***.

Depending on the initial orientation of the particle velocity to the magnetic field, charges having a constant speed in a uniform magnetic field will follow a circular or helical path.

Electric currents in wires are not the only source of magnetic fields. Naturally occurring minerals exhibit magnetic properties and have magnetic fields. These magnetic fields result from the motion of electrons in the atoms of the material. They also result from a property of electrons called the magnetic dipole moment, which is related to the intrinsic spin of individual electrons (see the article ATOMS: *Electrons*). In most materials, little or no field is observed outside the matter because of the random orientation of the various constituent atoms. In some materials such as iron, however, atoms within certain distances tend to become aligned in one particular direction.

Magnets have numerous applications, ranging from use as toys and paper holders on home refrigerators to essential components in electric generators and machines that can accelerate particles to speeds approaching that of light. The practical application of magnetism in technology is greatly enhanced by using iron and other ferromagnetic materials with electric currents in devices like motors. These materials amplify the magnetic field produced by the currents and thereby create more powerful fields (see below *Ferromagnetism*).

While electric and magnetic effects are well separated in many phenomena and applications, they are coupled

Time-varying magnetic field

closely together when there are rapid time fluctuations. Faraday's law of induction describes how a time-varying magnetic field produces an electric field (see below *Faraday's law of induction*). Important practical applications include the electric generator and transformer. In a generator, the physical motion of a magnetic field produces electricity for power. In a transformer, electric power is converted from one voltage level to another by the magnetic field of one circuit inducing an electric current in another circuit.

The existence of electromagnetic waves depends on the interaction between electric and magnetic fields. Maxwell postulated that a time-varying electric field produces a magnetic field. His theory predicted the existence of electromagnetic waves in which each time-varying field produces the other field. For example, radio waves are generated by electronic circuits known as oscillators that cause rapidly oscillating currents to flow in antennas; the rapidly varying magnetic field has an associated varying electric field. The result is the emission of radio waves into space (see ELECTROMAGNETIC RADIATION).

Many electromagnetic devices can be described by circuits consisting of conductors and other elements. These circuits may operate with a steady flow of current, as in a flashlight, or with time-varying currents. Important elements in circuits include sources of power called electromotive forces; resistors, which control the flow of current for a given voltage; capacitors, which store charge and energy temporarily; and inductors, which also store electrical energy for a limited time. Circuits with these elements can be described entirely with algebra. (For more complicated circuit elements such as transistors, see ELECTRONICS: *Semiconductor devices* and *Integrated circuits*).

Fluxes and line integrals of vector fields

Two mathematical quantities associated with vector fields, like the electric field $\boldsymbol{E}$ and the magnetic field $\boldsymbol{B}$, are useful for describing electromagnetic phenomena. They are the flux of such a field through a surface and the line integral of the field along a path. The flux of a field through a surface measures how much of the field penetrates through the surface; for every small section of the surface, the flux is proportional to the area of that section and depends also on the relative orientation of the section and the field. The line integral of a field along a path measures the degree to which the field is aligned with the path; for every small section of path, it is proportional to the length of that section and is also dependent on the alignment of the field with that section of path. When the field is perpendicular to the path, there is no contribution to the line integral. The fluxes of $\boldsymbol{E}$ and $\boldsymbol{B}$ through a surface and the line integrals of these fields along a path play an important role in electromagnetic theory. As examples, the flux of the electric field $\boldsymbol{E}$ through a closed surface measures the amount of charge contained within the surface; the flux of the magnetic field $\boldsymbol{B}$ through a closed surface is always zero because there are no magnetic monopoles (magnetic charges consisting of a single pole) to act as sources of the magnetic field in the way that charge is a source of the electric field.

Electricity

ELECTROSTATICS

Use of mathematical methods

Electrostatics is the study of electromagnetic phenomena that occur when there are no moving charges—*i.e.*, after a static equilibrium has been established. Charges reach their equilibrium positions rapidly because the electric force is extremely strong. The mathematical methods of electrostatics make it possible to calculate the distributions of the electric field and of the electric potential from a known configuration of charges, conductors, and insulators. Conversely, given a set of conductors with known potentials, it is possible to calculate electric fields in regions between the conductors and to determine the charge distribution on the surface of the conductors. The electric energy of a set of charges at rest can be viewed from the standpoint of the work required to assemble the charges; alternatively, the energy also can be considered to reside in the electric field produced by this assembly of charges. Finally, energy can be stored in a capacitor; the energy required to charge such a device is stored in it as electrostatic energy of the electric field.

Static electricity. This is a familiar electric phenomenon in which friction transfers charged particles from one body to another. If two objects are rubbed together, especially if the objects are insulators and the surrounding air is dry, the objects acquire equal and opposite charges and an attractive force develops between them. The object that loses electrons becomes positively charged, and the other becomes negatively charged. The force is simply the attraction between charges of opposite sign. The properties of this force were described above; they are incorporated in the mathematical relationship known as Coulomb's law. The electric force on a charge Q_1 under these conditions, due to a charge Q_2 at a distance r, is given by Coulomb's law,

$$\boldsymbol{F} = k\frac{Q_1 Q_2}{r^2}\hat{\boldsymbol{r}} \qquad (1)$$

The bold characters in the equation indicate the vector nature of the force, and the unit vector $\hat{\boldsymbol{r}}$ is a vector that has a size of one and that points from charge Q_2 to charge Q_1. The proportionality constant k equals $10^{-7}c^2$, where c is the speed of light in a vacuum; k has the numerical value of 8.99×10^9 newtons-square metre per coulomb squared (Nm^2/C^2). Figure 4 shows the force on Q_1 due to Q_2. A numerical example will help to illustrate this force. Both Q_1 and Q_2 are chosen arbitrarily to be positive charges, each with a magnitude of 10^{-6} coulomb. The charge Q_1 is located at coordinates x, y, z with values of 0.03, 0, 0, respectively, while Q_2 has coordinates 0, 0.04, 0. All coordinates are given in metres. Thus, the distance between Q_1 and Q_2 is 0.05 metre.

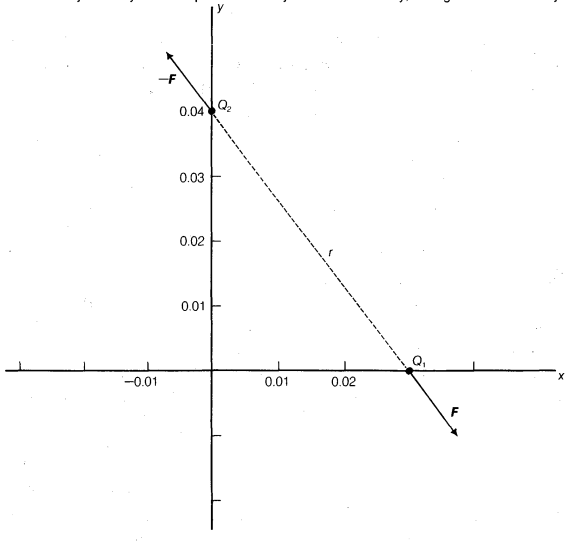

Figure 4: Electric force between two charges (see text).

The magnitude of the force $\boldsymbol{F}$ on charge Q_1 as calculated using equation (1) is 3.6 newtons; its direction is shown in Figure 4. The force on Q_2 due to Q_1 is $-\boldsymbol{F}$, which also has a magnitude of 3.6 newtons; its direction, however, is opposite to that of $\boldsymbol{F}$. The force $\boldsymbol{F}$ can be expressed in terms of its components along the x and y axes, since the force vector lies in the xy plane. This is done with elementary trigonometry from the geometry of Figure 4, and the results are shown in Figure 5. Thus,

$$\boldsymbol{F} = 2.16\hat{\boldsymbol{x}} - 2.88\hat{\boldsymbol{y}} \qquad (2)$$

in newtons. Coulomb's law describes mathematically the properties of the electric force between charges at rest. If the charges have opposite signs, the force would be attractive; the attraction would be indicated in equation (1) by the negative coefficient of the unit vector $\hat{\boldsymbol{r}}$. Thus, the electric force on Q_1 would have a direction opposite to the unit vector $\hat{\boldsymbol{r}}$ and would point from Q_1 to Q_2. In Cartesian coordinates, this would result in a change of the signs of both the x and y components of the force in equation (2).

How can this electric force on Q_1 be understood? Fun-

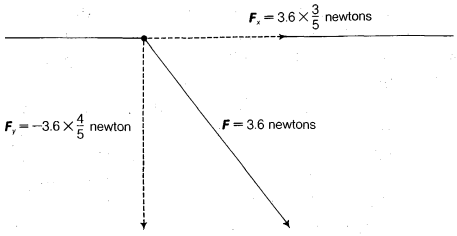

Figure 5: The x and y components of the force F in Figure 4 (see text).

By courtesy of the Department of Physics and Astronomy, Michigan State University

damentally, the force is due to the presence of an electric field at the position of Q_1. The field is caused by the second charge Q_2 and has a magnitude proportional to the size of Q_2. In interacting with this field, the first charge some distance away is either attracted to or repelled from the second charge, depending on the sign of the first charge.

Calculating the value of an electric field

In the example, the charge Q_1 is in the electric field produced by the charge Q_2. This field has the value

$$E = k\frac{Q_2}{r^2}\hat{r} \qquad (3)$$

in newtons per coulomb (N/C). (Electric field can also be expressed in volts per metre [V/m], which is the equivalent of newtons per coulomb.) The electric force on Q_1 is given by

$$F = Q_1 E \qquad (4)$$

in newtons. This equation can be used to define the electric field of a point charge. The electric field E produced by charge Q_2 is a vector. The magnitude of the field varies inversely as the square of the distance from Q_2; its direction is away from Q_2 when Q_2 is a positive charge and toward Q_2 when Q_2 is a negative charge. Using equations (2) and (4), the field produced by Q_2 at the position of Q_1 is

$$E = 2.16 \times 10^6\hat{x} - 2.88 \times 10^6\hat{y}$$

in newtons per coulomb.

When there are several charges present, the force on a given charge Q_1 may be simply calculated as the sum of the individual forces due to the other charges Q_2, Q_3, . . . , etc., until all the charges are included. This sum requires that special attention be given to the direction of the individual forces since forces are vectors. The force on Q_1 can be obtained with the same amount of effort by first calculating the electric field at the position of Q_1 due to Q_2, Q_3, . . . , etc. To illustrate this, a third charge is added to the example above. There are now three charges, $Q_1 = +10^{-6}$ C, $Q_2 = +10^{-6}$ C, and $Q_3 = -10^{-6}$ C. The locations of the charges, using Cartesian coordinates [x, y, z] are, respectively, [0.03, 0, 0], [0, 0.04, 0], and [−0.02, 0, 0] metre, as shown in Figure 6. The goal is to find the force on Q_1. From the sign of the charges, it can be seen that Q_1 is repelled by Q_2 and attracted by Q_3. It is also clear that these two forces act along different directions. The electric field at the position of Q_1 due to charge Q_2 is, just as in the example above,

$$E_{1,2} = 2.16 \times 10^6\hat{x} - 2.88 \times 10^6\hat{y}$$

in newtons per coulomb. The electric field at the location of Q_1 due to charge Q_3 is

$$E_{1,3} = -3.6 \times 10^6\hat{x}$$

in newtons per coulomb. Thus, the total electric field at position 1 (*i.e.*, at [0.03, 0, 0]) is the sum of these two fields $E_{1,2} + E_{1,3}$ and is given by

$$E_1\ (total) = -1.44 \times 10^6\hat{x} - 2.88 \times 10^6\hat{y}.$$

The fields $E_{1,2}$ and $E_{1,3}$, as well as their sum, the total electric field at the location of Q_1, E_1 (*total*), are shown in Figure 6. The total force on Q_1 is then obtained from equation (4) by multiplying the electric field E_1 (*total*) by Q_1. In Cartesian coordinates, this force, expressed in newtons, is given by its components along the x and y axes by

$$F_1\ (total) = -1.44\hat{x} - 2.88\hat{y}.$$

The resulting force on Q_1 is in the direction of the total electric field at Q_1, shown in Figure 6. The magnitude of the force, which is obtained as the square root of the sum of the squares of the components of the force given in the above equation, equals 3.22 newtons.

Superposition principle

This calculation demonstrates an important property of the electromagnetic field known as the superposition principle. According to this principle, a field arising from a number of sources is determined by adding the individual fields from each source. The principle is illustrated by Figure 6, in which an electric field arising from several sources is determined by the superposition of the fields from each of the sources. In this case, the electric field at the location of Q_1 is the sum of the fields due to Q_2 and Q_3. Studies of electric fields over an extremely wide range of magnitudes have established the validity of the superposition principle.

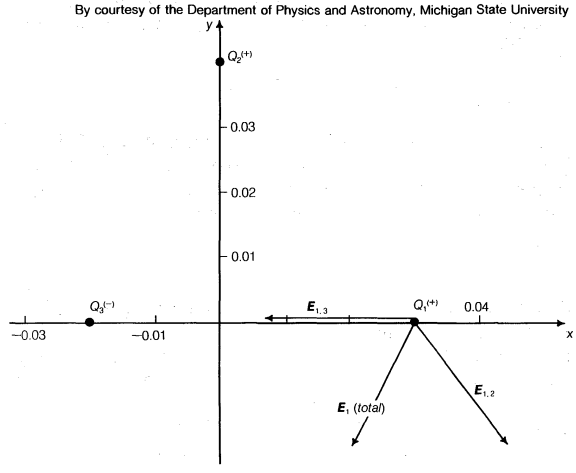

Figure 6: Electric field at the location of Q_1 (see text).

The vector nature of an electric field produced by a set of charges introduces a significant complexity. Specifying the field at each point in space requires giving both the magnitude and the direction at each location. In the Cartesian coordinate system, this necessitates knowing the magnitude of the x, y, and z components of the electric field at each point in space. It would be much simpler if the value of the electric field vector at any point in space could be derived from a scalar function with magnitude and sign.

The electric potential is just such a scalar function. Electric potential is related to the work done by an external force when it transports a charge slowly from one position to another in an environment containing other charges at rest. The difference between the potential at point A and the potential at point B is defined by the equation

$$V_A - V_B = \frac{\text{work to move charge } q \text{ from B to A}}{q}. \qquad (5)$$

As noted above, electric potential is measured in volts. Since work is measured in joules in the Système Internationale d'Unités (SI), one volt is equivalent to one joule per coulomb. The charge q is taken as a small test charge; it is assumed that the test charge does not disturb the distribution of the remaining charges during its transport from point B to point A.

To illustrate the work in equation (5), Figure 7 shows a positive charge $+Q$. Consider the work involved in moving a second charge q from B to A. Along path 1, work is done to offset the electric repulsion between the two charges. If path 2 is chosen instead, no work is done in moving q from B to C, since the motion is perpendicular to the electric force; moving q from C to D, the work is, by symmetry, identical as from B to A, and no work is required from D to A. Thus, the total work done in moving q from B to A is the same for either path. It can be shown easily that the same is true for any path going from B to A. When the initial and final positions of the charge q are located on a sphere centred on the location of the $+Q$ charge, no work is done; the electric potential at the initial position has the same value as at the final position. The

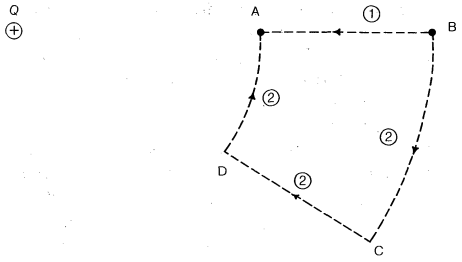

Figure 7: Positive charge +Q and two paths in moving a second charge, q, from B to A (see text).

sphere in this example is called an equipotential surface. When equation (5), which defines the potential difference between two points, is combined with Coulomb's law, it yields the following expression for the potential difference $V_A - V_B$ between points A and B:

$$V_A - V_B = k\frac{Q}{r_a} - k\frac{Q}{r_b}, \qquad (6)$$

where r_a and r_b are the distances of points A and B from Q. Choosing B far away from the charge Q and arbitrarily setting the electric potential to be zero far from the charge results in a simple equation for the potential at A:

$$V_A = k\frac{Q}{r_a}. \qquad (7)$$

The contribution of a charge to the electric potential at some point in space is thus a scalar quantity directly proportional to the magnitude of the charge and inversely proportional to the distance between the point and the charge. For more than one charge, one simply adds the contributions of the various charges. The result is a topological map that gives a value of the electric potential for every point in space.

Figure 8 provides three-dimensional views illustrating the effect of the positive charge $+Q$ located at the origin on either a second positive charge q (Figure 8A) or on a negative charge $-q$ (Figure 8B); the potential energy "landscape" is illustrated in each case. The potential energy of a charge q is the product qV of the charge and of the electric potential at the position of the charge. In Figure 8A, the positive charge q would have to be pushed by some external agent in order to get close to the location of $+Q$ because, as q approaches, it is subjected to an increasingly repulsive electric force. For the negative charge $-q$, the potential energy in Figure 8B shows, instead of a steep hill, a deep funnel. The electric potential due to $+Q$ is still positive, but the potential energy is negative, and the negative charge $-q$, in a manner quite analogous to a particle under the influence of gravity, is attracted toward the origin where charge $+Q$ is located.

The electric field is related to the variation of the electric potential in space. The potential provides a convenient tool for solving a wide variety of problems in electrostatics. In a region of space where the potential varies, a charge is subjected to an electric force. For a positive charge the direction of this force is opposite the gradient of the potential—that is to say, in the direction in which the potential decreases the most rapidly. A negative charge would be subjected to a force in the direction of the most rapid increase of the potential. In both instances, the magnitude of the force is proportional to the rate of change of the potential in the indicated directions. If the potential in a region of space is constant, there is no force on either positive or negative charge. In a 12-volt car battery, positive charges would tend to move away from the positive terminal and toward the negative terminal, while negative charges would tend to move in the opposite direction—*i.e.,* from the negative to the positive terminal. The latter occurs when a copper wire, in which there are electrons that are free to move, is connected between the two terminals of the battery.

The electric field has already been described in terms of the force on a charge. If the electric potential is known at every point in a region of space, the electric field can be derived from the potential. In vector calculus notation, the electric field is given by the negative of the gradient of the electric potential, $\boldsymbol{E} = -\mathbf{grad}\ V$. This expression specifies how the electric field is calculated at a given point. Since the field is a vector, it has both a direction and magnitude. The direction is that in which the potential decreases most rapidly, moving away from the point. The magnitude of the field is the change in potential across a small distance in the indicated direction divided by that distance.

Deriving electric field from potential

To become more familiar with the electric potential, a numerically determined solution is presented for a two-dimensional configuration of electrodes. A long, circular conducting rod is maintained at an electric potential of −20 volts. Next to the rod, a long L-shaped bracket, also made of conducting material, is maintained at a potential of +20 volts. Both the rod and bracket are placed inside a long, hollow metal tube with a square cross section; this enclosure is at a potential of zero (*i.e.,* it is at "ground" potential). Figure 9 shows the geometry of the problem. Because the situation is static, there is no electric field inside the material of the conductors. If there were such a field, the charges that are free to move in a conducting material would do so until equilibrium was reached. The

charges are arranged so that their individual contributions to the electric field at points inside the conducting material add up to zero. In a situation of static equilibrium, excess charges are located on the surface of conductors. Because there are no electric fields inside the conducting material, all parts of a given conductor are at the same potential; hence, a conductor is an equipotential in a static situation.

In Figure 10, the numerical solution of the problem gives the potential at a large number of points inside the cavity. The locations of the +20-volt and −20-volt electrodes can be recognized easily. In carrying out the numerical solution of the electrostatic problem in the figure, the electrostatic potential was determined directly by means of one of its important properties: in a region where there is no charge (in this case, between the conductors), the value of the potential at a given point is the average of the values of the potential in the neighbourhood of the point. This follows from the fact that the electrostatic potential in a charge-free region obeys Laplace's equation, which in vector calculus notation is *div* **grad** $V = 0$. This equation is a special case of Poisson's equation *div* **grad** $V = \rho$, which is applicable to electrostatic problems in regions where the volume charge density is ρ. Laplace's

equation states that the divergence of the gradient of the potential is zero in regions of space with no charge. In the example of Figure 10, the potential on the conductors remains constant. Arbitrary values of potential are initially assigned elsewhere inside the cavity. To obtain a solution, a computer replaces the potential at each coordinate point that is not on a conductor by the average of the values of the potential around that point; it scans the entire set of points many times until the values of the potentials differ by an amount small enough to indicate a satisfactory solution. Clearly, the larger the number of points, the more accurate the solution will be. The computation time as well as the computer memory size requirement increase rapidly, however, especially in three-dimensional problems with complex geometry. This method of solution is called the "relaxation" method.

In Figure 11, points with the same value of electric potential have been connected to reveal a number of important properties associated with conductors in static situations. The lines in the figure represent equipotential surfaces. The distance between two equipotential surfaces tells how rapidly the potential changes, with the smallest distances corresponding to the location of the greatest rate of change and thus to the largest values of the electric field. Looking at the +20-volt and +15-volt equipotential surfaces, one observes immediately that they are closest to each other at the sharp external corners of the right-

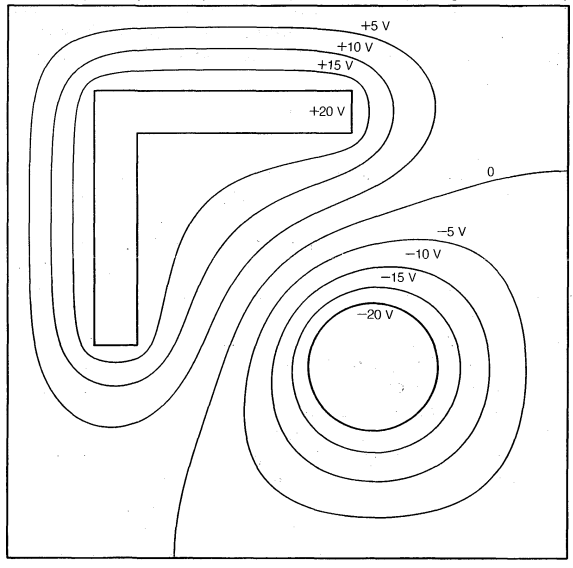

Figure 11: *Equipotential surfaces.*
The distance between two equipotential surfaces, represented by the lines, indicates how rapidly the potential changes. The smallest distances correspond to the location of the greatest rate of change and therefore to the largest values of the electric field.

angle conductor. This shows that the strongest electric fields on the surface of a charged conductor are found on the sharpest external parts of the conductor; electrical breakdowns are most likely to occur there. It also should be noted that the electric field is weakest in the inside corners, both on the inside corner of the right-angle piece and on the inside corners of the square enclosure.

In Figure 12, dashed lines indicate the direction of the electric field. The strength of the field is reflected by the density of these dashed lines. Again, it can be seen that the field is strongest on outside corners of the charged L-shaped conductor; the largest surface charge density must occur at those locations. The field is weakest in the inside corners. The signs of the charges on the conducting surfaces can be deduced from the fact that electric fields point away from positive charges and toward negative charges. The magnitude of the surface charge density σ on the conductors is measured in coulombs per metre squared and is given by

$$\sigma = \varepsilon_0 E, \qquad (8)$$

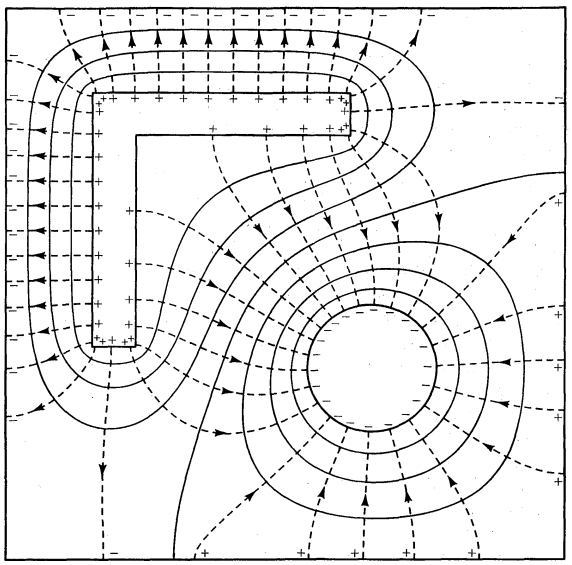

Figure 12: *Electric field lines.*
The density of the dashed lines indicates the strength of the field (see text).

where ε_0 is called the permittivity of free space and has the value of 8.854×10^{-12} coulomb squared per newton-square metre. In addition, ε_0 is related to the constant k in Coulomb's law by

$$k = \frac{1}{4\pi\varepsilon_0}. \tag{9}$$

Field lines and equipotential surfaces

Figure 12 also illustrates an important property of an electric field in static situations: field lines are always perpendicular to equipotential surfaces. The field lines meet the surfaces of the conductors at right angles, since these surfaces also are equipotentials. Figure 13 completes this example by showing the potential energy landscape of a small positive charge q in the region. From the variation in potential energy, it is easy to picture how electric forces tend to drive the positive charge q from higher to lower potential—*i.e.*, from the L-shaped bracket at +20 volts toward the square-shaped enclosure at ground (0 volts) or toward the cylindrical rod maintained at a potential of −20 volts. It also graphically displays the strength of force near the sharp corners of conducting electrodes.

Capacitance. A useful device for storing electrical energy consists of two conductors in close proximity and insulated from each other. A simple example of such a storage device is the parallel-plate capacitor. If positive charges with total charge $+Q$ are deposited on one of the conductors and an equal amount of negative charge $-Q$ is deposited on the second conductor, the capacitor is said to have a charge Q. As shown in Figure 14, it consists of two flat conducting plates, each of area A, parallel to each other and separated by a distance d.

By courtesy of the Department of Physics and Astronomy, Michigan State University

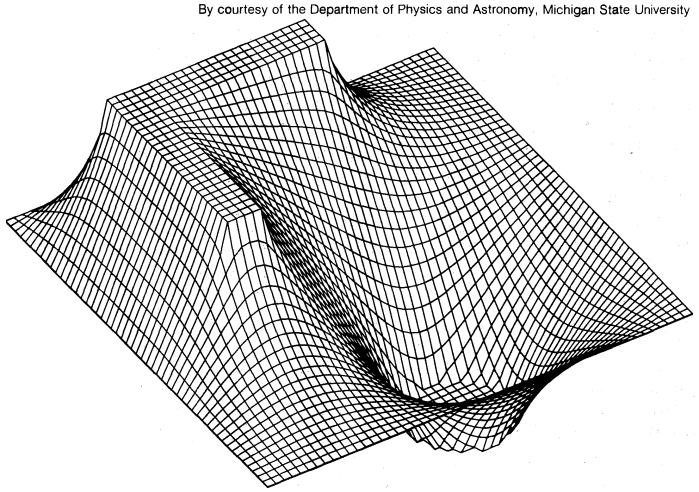

Figure 13: Potential energy for a positive charge (see text).

Principle of the capacitor

To understand how a charged capacitor stores energy, consider the following charging process. With both plates of the capacitor initially uncharged, a small amount of negative charge is removed from the lower plate and placed on the upper plate. Thus, little work is required to make the lower plate slightly positive and the upper plate slightly negative. As the process is repeated, however, it becomes increasingly difficult to transport the same amount of negative charge, since the charge is being moved toward a plate that is already negatively charged and away from a plate that is positively charged. The negative charge on the upper plate repels the negative charge moving toward it, and the positive charge on the lower plate exerts an attractive force on the negative charge being moved away. Therefore, work has to be done to charge the capacitor.

Where and how is this energy stored? The negative charges on the upper plate are attracted toward the positive charges on the lower plate and could do work if they could leave the plate. Because they cannot leave the plate, however, the energy is stored. A mechanical analogy is the potential energy of a stretched spring. Another way to understand the energy stored in a capacitor is to compare an uncharged capacitor with a charged capacitor. In the uncharged capacitor, there is no electric field between the plates; in the charged capacitor, because of the positive and negative charges on the inside surfaces of the plates, there is an electric field between the plates with the field lines pointing from the positively charged plate to the negatively charged one. The energy stored is the energy that

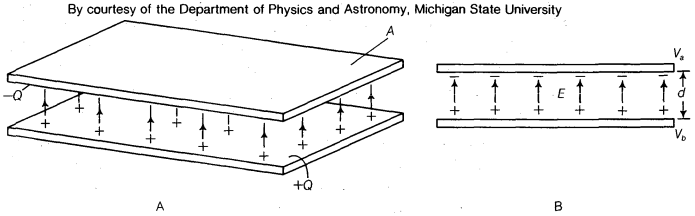

Figure 14: *Parallel-plate capacitor.*
(A) This storage device consists of two flat conducting plates, each of area *A*. (B) These plates are parallel and separated by a small distance *d* (see text).

was required to establish the field. In the simple geometry of Figure 14, it is apparent that there is a nearly uniform electric field between the plates; the field becomes more uniform as the distance between the plates decreases and the area of the plates increases. It was explained above how the magnitude of the electric field can be obtained from the electric potential. In summary, the electric field is the change in the potential across a small distance in a direction perpendicular to an equipotential surface divided by that small distance. In Figure 14, the upper plate is assumed to be at a potential of V_a volts, and the lower plate at a potential of V_b volts. The size of the electric field is

$$E = \frac{V_b - V_a}{d} \tag{10}$$

in volts per metre, where d is the separation of the plates. If the charged capacitor has a total charge of $+Q$ on the inside surface of the lower plate (it is on the inside surface because it is attracted to the negative charges on the upper plate), the positive charge will be uniformly distributed on the surface with the value

$$\sigma = \frac{Q}{A} \tag{11}$$

in coulombs per metre squared. Equation (8) gives the electric field when the surface charge density is known as $E = \sigma/\varepsilon_0$. This, in turn, relates the potential difference to the charge on the capacitor and the geometry of the plates. The result is

$$V_b - V_a = \frac{Qd}{\varepsilon_0 A} = \frac{Q}{C}. \tag{12}$$

The quantity C is termed capacity; for the parallel-plate capacitor, C is equal to $\varepsilon_0 A/d$. The unit used for capacity

is the farad (F); one farad equals one coulomb per volt. In equation (12), only the potential difference is involved. The potential of either plate can be set arbitrarily without altering the electric field between the plates. Often one of the plates is grounded—*i.e.*, its potential is set at the Earth potential, which is referred to as zero volts. The potential difference is then denoted as ΔV, or simply as V.

Three equivalent formulas for the total energy W of a capacitor with charge Q and potential difference V are

$$W=\frac{1}{2}\frac{Q^2}{C}=\frac{1}{2}CV^2=\frac{1}{2}QV. \quad (13)$$

All are expressed in joules. The stored energy in the parallel-plate capacitor also can be expressed in terms of the electric field; it is, in joules,

$$W=\frac{1}{2}\varepsilon_0 E^2\,(Ad). \quad (14)$$

The quantity Ad, the area of each plate times the separation of the two plates, is the volume between the plates. Thus, the energy per unit volume (*i.e.*, the energy density of the electric field) is given by $\frac{1}{2}\varepsilon_0 E^2$ in units of joules per metre cubed.

The amount of charge stored in a capacitor is the product of the voltage and the capacity. What limits the amount of charge that can be stored on a capacitor? The voltage can be increased, but electric breakdown will occur if the electric field inside the capacitor becomes too large. The capacity can be increased by expanding the electrode areas and by reducing the gap between the electrodes. In general, capacitors that can withstand high voltages have a relatively small capacity. If only low voltages are needed, however, compact capacitors with rather large capacities can be manufactured. One method for increasing capacity is to insert between the conductors an insulating material that reduces the voltage because of its effect on the electric field. Such materials are called dielectrics (substances with no free charges). When the molecules of a dielectric are placed in the electric field, their negatively charged electrons separate slightly from their positively charged cores. With this separation, referred to as polarization, the molecules acquire an electric dipole moment. A cluster of charges with an electric dipole moment is often called an electric dipole.

Polarization and electric dipole moment

Is there an electric force between a charged object and uncharged matter, such as a piece of wood? Surprisingly, the answer is yes, and the force is attractive. The reason is that under the influence of the electric field of a charged object, the negatively charged electrons and positively charged nuclei within the atoms and molecules are subjected to forces in opposite directions. As a result, the negative and positive charges separate slightly. Such atoms and molecules are said to be polarized and to have an electric dipole moment. The molecules in the wood acquire an electric dipole moment in the direction of the external electric field. The polarized molecules are attracted toward the charged object because the field increases in the direction of the charged object.

The electric dipole moment $\boldsymbol{p}$ of two charges $+q$ and $-q$ separated by a distance l is a vector of magnitude $p=ql$ with a direction from the negative to the positive charge. An electric dipole in an external electric field is subjected to a torque $\tau=pE\sin\theta$, where θ is the angle between $\boldsymbol{p}$ and $\boldsymbol{E}$. The torque tends to align the dipole moment $\boldsymbol{p}$ in the direction of $\boldsymbol{E}$. The potential energy of the dipole is given by $U_e=-pE\cos\theta$, or in vector notation $U_e=-\boldsymbol{p}\cdot\boldsymbol{E}$. In a nonuniform electric field, the potential energy of an electric dipole also varies with position, and the dipole can be subjected to a force. The force on the dipole is in the direction of increasing field when $\boldsymbol{p}$ is aligned with $\boldsymbol{E}$, since the potential energy U_e decreases in that direction.

The polarization of a medium $\boldsymbol{P}$ gives the electric dipole moment per unit volume of the material; it is expressed in units of coulombs per metre squared. When a dielectric is placed in an electric field, it acquires a polarization that depends on the field. The electric susceptibility χ_e relates the polarization to the electric field as $\boldsymbol{P}=\chi_e\boldsymbol{E}$. In general, χ_e varies slightly depending on the strength of the electric field, but for some materials, called linear dielectrics, it is a constant. The dielectric constant κ of a substance is related to its susceptibility as $\kappa=1+\chi_e/\varepsilon_0$; it is a dimensionless quantity. Table 1 lists the dielectric constants of a few substances.

Table 1: Dielectric Constants of Some Materials (at room temperature)

material	dielectric constant (κ)
Vacuum	1.0
Air	1.0006
Oil	2.2
Polyethylene	2.26
Beeswax	2.8
Fused quartz	3.78
Water	80
Calcium titanate	168
Barium titanate	1,250

The presence of a dielectric affects many electric quantities. A dielectric reduces by a factor K the value of the electric field and consequently also the value of the electric potential from a charge within the medium. As seen in Table 1, a dielectric can have a large effect. The insertion of a dielectric between the electrodes of a capacitor with a given charge reduces the potential difference between the electrodes and thus increases the capacitance of the capacitor by the factor K. For a parallel-plate capacitor filled with a dielectric, the capacity becomes $C=K\varepsilon_0 A/d$. A third and important effect of a dielectric is to reduce the speed of electromagnetic waves in a medium by the factor $\sqrt{K}$.

Effects of dielectrics

Capacitors come in a wide variety of shapes and sizes. Not all have parallel plates; some are cylinders, for example. If two plates, each one square centimetre in area, are separated by a dielectric with $K=2$ of one millimetre thickness, the capacity is 1.76×10^{-12} F, about two picofarads. Charged to 20 volts, this capacitor would store about 40 picocoulombs of charge; the electric energy stored would be 400 picojoules. Even small-sized capacitors can store enormous amounts of charge. Modern techniques and dielectric materials permit the manufacture of capacitors that occupy less than one cubic centimetre and yet store 10^{10} times more charge and electric energy than in the above example.

Capacitors have many important applications. They are used, for example, in digital circuits so that information stored in large computer memories is not lost during a momentary electric power failure; the electric energy stored in such capacitors maintains the information during the temporary loss of power. Capacitors play an even more important role as filters to divert spurious electric signals and thereby prevent damage to sensitive components and circuits caused by electric surges. How capacitors provide such protection is discussed below in the section *Transient response.*

DIRECT ELECTRIC CURRENT

Basic phenomena and principles. Many electric phenomena occur under what is termed steady-state conditions. This means that such electric quantities as current, voltage, and charge distributions are not affected by the passage of time. For instance, because the current through a filament inside a car headlight does not change with time, the brightness of the headlight remains constant. An example of a nonsteady-state situation is the flow of charge between two conductors that are connected by a thin conducting wire and that initially have an equal but opposite charge. As current flows from the positively charged conductor to the negatively charged one, the charges on both conductors decrease with time, as does the potential difference between the conductors. The current therefore also decreases with time and eventually ceases when the conductors are discharged.

Steady-state phenomena

In an electric circuit under steady-state conditions, the flow of charge does not change with time and the charge distribution stays the same. Since charge flows from one location to another, there must be some mechanism to keep the charge distribution constant. In turn, the values

of the electric potentials remain unaltered with time. Any device capable of keeping the potentials of electrodes unchanged as charge flows from one electrode to another is called a source of electromotive force, or simply an emf.

Figure 15 shows a wire made of a conducting material such as copper. By some external means, an electric field is established inside the wire in a direction along its length.

By courtesy of the Department of Physics and Astronomy, Michigan State University

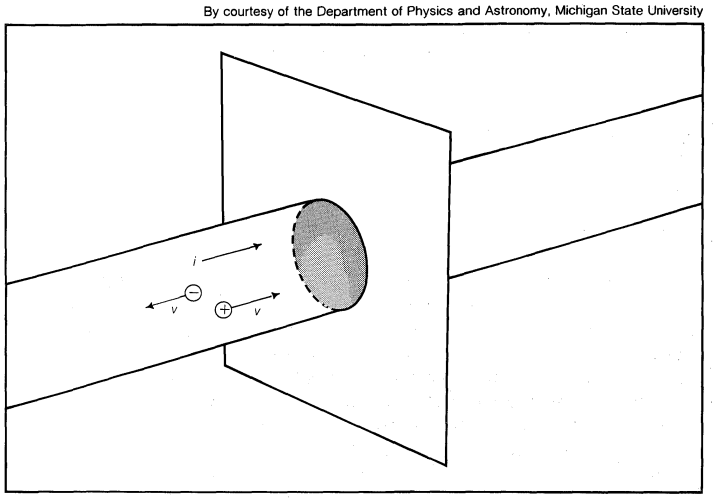

Figure 15: Motion of charge in electric current i (see text).

The electrons that are free to move will gain some speed. Since they have a negative charge, they move in the direction opposite that of the electric field. The current i is defined to have a positive value in the direction of flow of positive charges. If the moving charges that constitute the current i in a wire are electrons, the current is a positive number when it is in a direction opposite to the motion of the negatively charged electrons. (If the direction of motion of the electrons were also chosen to be the direction of a current, the current would have a negative value.) The current is the amount of charge crossing a plane transverse to the wire per unit time—*i.e.*, in a period of one second. If there are n free particles of charge q per unit volume with average velocity v and the cross-sectional area of the wire is A, the current i, in elementary calculus notation, is

$$i = \frac{dQ}{dt} = nevA, \tag{15}$$

where dQ is the amount of charge that crosses the plane in a time interval dt. The unit of current is the ampere (A); one ampere equals one coulomb per second. A useful quantity related to the flow of charge is current density, the flow of current per unit area. Symbolized by $\boldsymbol{J}$, it has a magnitude of i/A and is measured in amperes per square metre.

Wires of different materials have different current densities for a given value of the electric field $\boldsymbol{E}$; for many materials, the current density is directly proportional to the electric field. This behaviour is represented by Ohm's law:

$$\boldsymbol{J} = \sigma_J \boldsymbol{E}. \tag{16}$$

The proportionality constant σ_J is the conductivity of the material. In a metallic conductor, the charge carriers are electrons and, under the influence of an external electric field, they acquire some average drift velocity in the direction opposite the field. In conductors of this variety, the drift velocity is limited by collisions, which heat the conductor.

If the wire in Figure 15 has a length l and area A and if an electric potential difference of V is maintained between the ends of the wire, a current i will flow in the wire. The electric field $\boldsymbol{E}$ in the wire has a magnitude V/l. The equation for the current, using Ohm's law, is

$$i = JA = \frac{\sigma_J V}{l} A \tag{17}$$

or

$$V = i\frac{l}{\sigma_J A}. \tag{18}$$

The quantity $l/\sigma_J A$, which depends on both the shape and material of the wire, is called the resistance R of the wire. Resistance is measured in ohms (Ω). The equation for resistance,

$$R = \frac{l}{\sigma_J A}, \tag{19}$$

is often written as

$$R = \frac{\rho l}{A}, \tag{20}$$

where ρ is the resistivity of the material and is simply $1/\sigma_J$. The geometric aspects of resistance in equation (20) are easy to appreciate: the longer the wire, the greater the resistance to the flow of charge. A greater cross-sectional area results in a smaller resistance to the flow. Resistivity

The resistive strain gauge is an important application of equation (20). Strain, $\delta l/l$, is the fractional change in the length of a body under stress, where δl is the change of length and l is the length. The strain gauge consists of a thin wire or narrow strip of a metallic conductor such as constantan, an alloy of nickel and copper. A strain changes the resistance because the length, area, and resistivity of the conductor change. In constantan, the fractional change in resistance $\delta R/R$ is directly proportional to the strain with a proportionality constant of approximately 2.

A common form of Ohm's law is Ohm's law

$$V = iR, \tag{21}$$

where V is the potential difference in volts between the two ends of an element with an electric resistance of R ohms and where i is the current through that element.

Table 2 lists the resistivities of certain materials at room temperature. These values depend to some extent on temperature; therefore, in applications where the temperature is very different from room temperature, the proper values of resistivities must be used to calculate the resistance. As an example, equation (20) shows that a copper wire 59 metres long and with a cross-sectional area of one square millimetre has an electric resistance of one ohm at room temperature.

Table 2: Electric Resistivities
(at room temperature)

material	resistivity ρ (ohm metre)
Silver	$1.6 \cdot 10^{-8}$
Copper	$1.7 \cdot 10^{-8}$
Aluminum	$2.7 \cdot 10^{-8}$
Carbon (graphite)	$1.4 \cdot 10^{-5}$
Germanium*	$4.7 \cdot 10^{-1}$
Silicon*	$2 \cdot 10^{3}$
Carbon (diamond)	$5 \cdot 10^{12}$
Polyethylene	$1 \cdot 10^{17}$
Fused quartz	$> 1 \cdot 10^{19}$

*Values very sensitive to purity.

Conductors, insulators, and semiconductors. Materials are classified as conductors, insulators, or semiconductors according to their electric conductivity. The classifications can be understood in atomic terms. Electrons in an atom can have only certain well-defined energies, and, depending on their energies, the electrons are said to occupy particular energy levels. In a typical atom with many electrons, the lower energy levels are filled, each with the number of electrons allowed by a quantum mechanical rule known as the Pauli exclusion principle. Depending on the element, the highest energy level to have electrons may or may not be completely full. If two atoms of some element are brought close enough together so that they interact, the two-atom system has two closely spaced levels for each level of the single atom. If 10 atoms interact, the 10-atom system will have a cluster of 10 levels corresponding to each single level of an individual atom. In a solid, the number of atoms and hence the number of levels is extremely large; most of the higher energy levels overlap in a continuous fashion except for certain energies in which there are no levels at all. Energy regions with levels are called energy bands, and regions that have no levels are referred to as band gaps. Energy bands and band gaps

The highest energy band occupied by electrons is the valence band. In a conductor, the valence band is partially filled, and since there are numerous empty levels, the electrons are free to move under the influence of an electric field; thus, in a metal the valence band is also the conduction band. In an insulator, electrons completely fill the valence band; and the gap between it and the next band, which is the conduction band, is large. The electrons cannot move under the influence of an electric field unless they are given enough energy to cross the large energy gap to the conduction band. In a semiconductor, the gap to the conduction band is smaller than in an insulator. At room temperature, the valence band is almost completely filled. A few electrons are missing from the valence band because they have acquired enough thermal energy to cross the band gap to the conduction band; as a result, they can move under the influence of an external electric field. The "holes" left behind in the valence band are mobile charge carriers but behave like positive charge carriers.

For many materials, including metals, resistance to the flow of charge tends to increase with temperature. For example, an increase of 5° C (9° F) increases the resistivity of copper by 2 percent. In contrast, the resistivity of insulators and especially of semiconductors such as silicon and germanium decreases rapidly with temperature; the increased thermal energy causes some of the electrons to populate levels in the conduction band where, influenced by an external electric field, they are free to move. The energy difference between the valence levels and the conduction band has a strong influence on the conductivity of these materials, with a smaller gap resulting in higher conduction at lower temperatures.

Range of resistivities in different materials

The values of electric resistivities listed in Table 2 show an extremely large variation in the capability of different materials to conduct electricity. The principal reason for the large variation is the wide range in the availability and mobility of charge carriers within the materials. The copper wire in Figure 15, for example, has many extremely mobile carriers; each copper atom has approximately one free electron, which is highly mobile because of its small mass. An electrolyte, such as a saltwater solution, is not as good a conductor as copper. The sodium and chlorine ions in the solution provide the charge carriers. The large mass of each sodium and chlorine ion increases as other attracted ions cluster around them. As a result, the sodium and chlorine ions are far more difficult to move than the free electrons in copper. Pure water also is a conductor, although it is a poor one because only a very small fraction of the water molecules are dissociated into ions. The oxygen, nitrogen, and argon gases that make up the atmosphere are somewhat conductive because a few charge carriers form when the gases are ionized by radiation from radioactive elements on the Earth as well as from extraterrestrial cosmic rays (*i.e.*, high-speed atomic nuclei and electrons). Electrophoresis is an interesting application based on the mobility of particles suspended in an electrolytic solution. Different particles (proteins, for example) move in the same electric field at different speeds; the difference in speed can be utilized to separate the contents of the suspension.

A current flowing through a wire heats it. This familiar phenomenon occurs in the heating coils of an electric range or in the hot tungsten filament of an electric light bulb. This ohmic heating is the basis for the fuses used to protect electric circuits and prevent fires; if the current exceeds a certain value, a fuse, which is made of an alloy with a low melting point, melts and interrupts the flow of current. The power P dissipated in a resistance R through which current i flows is given by

$$P = i^2R, \tag{22}$$

where P is in watts (one watt equals one joule per second), i is in amperes, and R is in ohms. According to Ohm's law, the potential difference V between the two ends of the resistor is given by $V = iR$, and so the power P can be expressed equivalently as

$$P = iV = \frac{V^2}{R}. \tag{23}$$

Superconductivity

In certain materials, however, the power dissipation that manifests itself as heat suddenly disappears if the conductor is cooled to a very low temperature. The disappearance of all resistance is a phenomenon known as superconductivity. As mentioned earlier, electrons acquire some average drift velocity v under the influence of an electric field in a wire. Normally the electrons, subjected to a force because of an electric field, accelerate and progressively acquire greater speed. Their velocity is, however, limited in a wire because they lose some of their acquired energy to the wire in collisions with other electrons and in collisions with atoms in the wire. The lost energy is either transferred to other electrons, which later radiate, or the wire becomes excited with tiny mechanical vibrations referred to as phonons. Both processes heat the material. The term phonon emphasizes the relationship of these vibrations to another mechanical vibration—namely, sound. In a superconductor, a complex quantum mechanical effect prevents these small losses of energy to the medium. The effect involves interactions between electrons and also those between electrons and the rest of the material. It can be visualized by considering the coupling of the electrons in pairs with opposite momenta; the motion of the paired electrons is such that no energy is given up to the medium in inelastic collisions or phonon excitations. One can imagine that an electron about to "collide" with and lose energy to the medium could end up instead colliding with its partner so that they exchange momentum without imparting any to the medium.

A superconducting material widely used in the construction of electromagnets is an alloy of niobium and titanium. This material must be cooled to a few degrees above absolute zero temperature, −263.66° C (or 9.5 K), in order to exhibit the superconducting property. Such cooling requires the use of liquefied helium, which is rather costly. During the late 1980s, materials that exhibit superconducting properties at much higher temperatures were discovered. These temperatures are higher than the −196° C of liquid nitrogen, making it possible to use the latter instead of liquid helium. Since liquid nitrogen is plentiful and cheap, such materials may provide great benefits in a wide variety of applications, ranging from electric power transmission to high-speed computing.

Electromotive force. A 12-volt automobile battery can deliver current to a circuit such as that of a car radio for a considerable length of time, during which the potential difference between the terminals of the battery remains close to 12 volts. The battery must have a means of continuously replenishing the excess positive and negative charges that are located on the respective terminals and that are responsible for the 12-volt potential difference between the terminals. The charges must be transported from one terminal to the other in a direction opposite to the electric force on the charges between the terminals. Any device that accomplishes this transport of charge constitutes a source of electromotive force. A car battery, for example, uses chemical reactions to generate electromotive force. The Van de Graaff generator shown in Figure 16 is a mechanical device that produces an electromotive force. Invented by the American physicist Robert J. Van de Graaff in the 1930s, this type of particle accelerator has been widely used to study subatomic particles. Because it is conceptually simpler than a chemical source of electromotive force, the Van de Graaff generator will be discussed first.

Sources of electromotive force

An insulating conveyor belt carries positive charge from the base of the Van de Graaff machine to the inside of a large conducting dome. The charge is removed from the belt by the proximity of sharp metal electrodes called charge remover points. The charge then moves rapidly to the outside of the conducting dome. The positively charged dome creates an electric field, which points away from the dome and provides a repelling action on additional positive charges transported on the belt toward the dome. Thus, work is done to keep the conveyor belt turning. If a current is allowed to flow from the dome to ground and if an equal current is provided by the transport of charge on the insulating belt, equilibrium is established and the potential of the dome remains at a constant positive value.

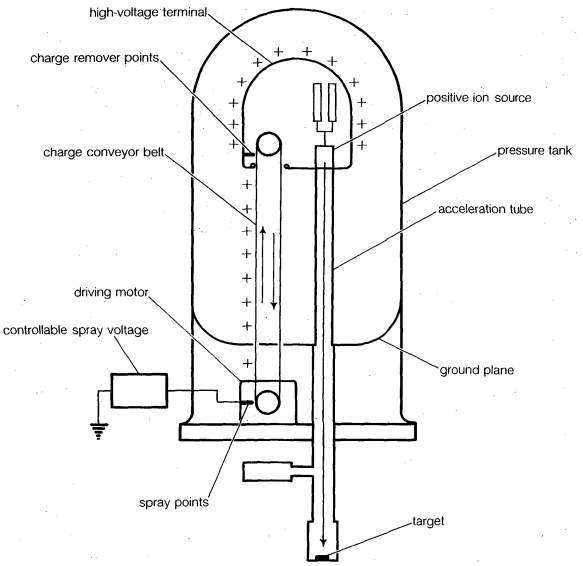

Figure 16: Van de Graaff accelerator.

From I. Kaplan, *Nuclear Physics*, © 1962, Addison-Wesley Publishing Co., Inc., Reading, Mass.; reprinted with permission of the publisher

In this example, the current from the dome to ground consists of a stream of positive ions inside the accelerating tube, moving in the direction of the electric field. The motion of the charge on the belt is in a direction opposite to the force that the electric field of the dome exerts on the charge. This motion of charge in a direction opposite the electric field is a feature common to all sources of electromotive force.

In the case of a chemically generated electromotive force, chemical reactions release energy. If these reactions take place with chemicals in close proximity to each other (*e.g.*, if they mix), the energy released heats the mixture. To produce a voltaic cell, these reactions must occur in separate locations. A copper wire and a zinc wire poked into a lemon make up a simple voltaic cell. The potential difference between the copper and the zinc wires can be measured easily and is found to be 1.1 volts; the copper wire acts as the positive terminal. Such a "lemon battery" is a rather poor voltaic cell capable of supplying only small amounts of electric power. Another kind of 1.1-volt battery constructed with essentially the same materials can provide much more electricity. In this case, a copper wire is placed in a solution of copper sulfate and a zinc wire in a solution of zinc sulfate; the two solutions are connected electrically by a potassium chloride salt bridge. (A salt bridge is a conductor with ions as charge carriers.) In both kinds of batteries, the energy comes from the difference in the degree of binding between the electrons in copper and those in zinc. Energy is gained when copper ions from the copper sulfate solution are deposited on the copper electrode as neutral copper ions, thus removing free electrons from the copper wire. At the same time, zinc atoms from the zinc wire go into solution as positively charged zinc ions, leaving the zinc wire with excess free electrons. The result is a positively charged copper wire and a negatively charged zinc wire. The two reactions are separated physically, with the salt bridge completing the internal circuit.

Figure 17 illustrates a 12-volt lead-acid battery, using standard symbols for depicting batteries in a circuit. The battery consists of six voltaic cells, each with an electromotive force of approximately two volts; the cells are connected in series, so that the six individual voltages add up to about 12 volts (Figure 17A). As shown in Figure 17B, each two-volt cell consists of a number of positive and negative electrodes connected electrically in parallel. The parallel connection is made to provide a large surface area of electrodes, on which chemical reactions can take place. The higher rate at which the materials of the electrodes are able to undergo chemical transformations allows the battery to deliver a larger current.

In the lead-acid battery, each voltaic cell consists of a negative electrode of pure, spongy lead (Pb) and a positive electrode of lead oxide (PbO_2). Both the lead and lead oxide are in a solution of sulfuric acid (H_2SO_4) and water (H_2O). At the positive electrode, the chemical reaction is $PbO_2 + SO_4^{--} + 4H^+ + 2e^- \rightarrow PbSO_4 + 2H_2O + (1.68\ V)$. At the negative terminal, the reaction is $Pb + SO_4^{--} \rightarrow PbSO_4 + 2e^- + (0.36\ V)$. The cell potential is $1.68 + 0.36 = 2.04$ volts. The 1.68 and 0.36 volts in the above equations are, respectively, the reduction and oxidation potentials; they are related to the binding of the electrons in the chemicals. When the battery is recharged, either by a car generator or by an external power source, the two chemical reactions are reversed.

Direct-current circuits. The simplest direct-current (DC) circuit consists of a resistor connected across a source of electromotive force. The symbol for a resistor is shown in Figure 18; here the value of R, 60Ω, is given by the numerical value adjacent to the symbol. The symbol for a source of electromotive force, E, is shown with the associated value of the voltage. Convention gives the terminal with the long line a higher (*i.e.*, more positive) potential than the terminal with the short line. Straight lines connecting various elements in a circuit are assumed to have negligible resistance, so that there is no change in potential across these connections. The circuit shows a 12-volt electromotive force connected to a 60Ω resistor. The letters *a*, *b*, *c*, and *d* on the diagram are reference points.

Circuit elements

The function of the source of electromotive force is to maintain point *a* at a potential 12 volts more positive than point *d*. Thus, the potential difference $V_a - V_d$ is 12 volts. The potential difference across the resistance is $V_b - V_c$. From Ohm's law, the current i flowing through the resistor is

$$i = \frac{V_b - V_c}{R} = \frac{V_b - V_c}{60}. \qquad (24)$$

Since points *a* and *b* are connected by a conductor of negligible resistance, they are at the same potential. For the same reason, *c* and *d* are at the same potential. Therefore, $V_b - V_c = V_a - V_d = 12$ volts. The current in the circuit is given by equation (24). Thus, $i = 12/60 = 0.2$ ampere. The power dissipated in the resistor as heat is easily calculated using equation (22):

$$P = i^2R = (0.02)^2 \times 60 = 2.4 \text{ watts}.$$

Where does the energy that is dissipated as heat in the resistor come from? It is provided by a source of elec-

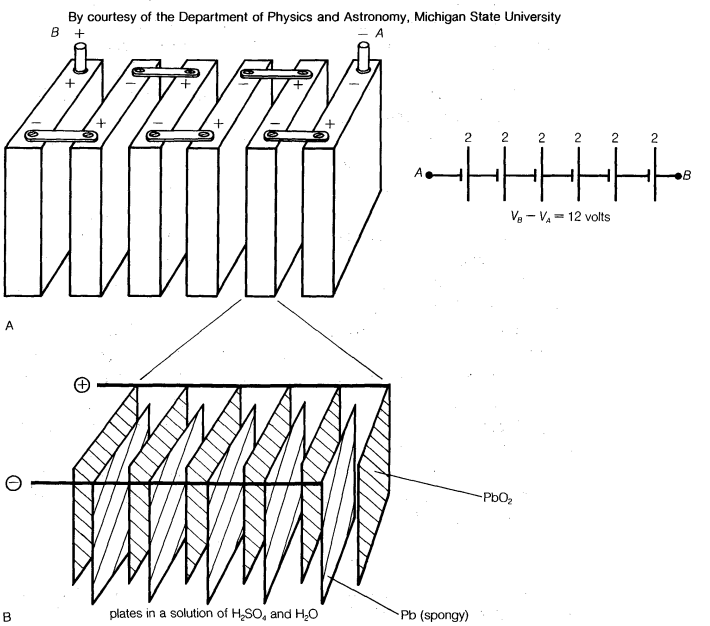

Figure 17: *Voltaic cells and electrodes of a 12-volt lead-acid battery.*
(A) The battery consists of six two-volt cells connected in series. (B) Each component cell is composed of several negative and positive electrodes made of pure spongy lead and lead oxide, respectively; the electrodes, connected in parallel, are immersed in a dilute solution of sulfuric acid.

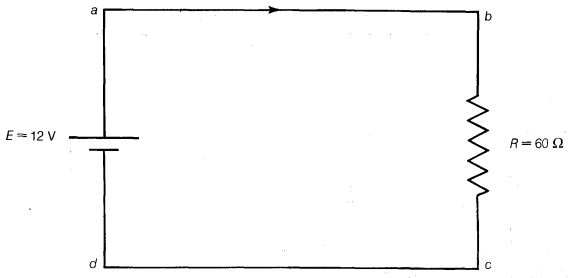

Figure 18: Direct-current circuit (see text).

tromotive force (*e.g.*, a lead-acid battery). Within such a source, for each amount of charge dQ moved from the lower potential at d to the higher potential at a, an amount of work is done equal to $dW = dQ(V_a - V_d)$. If this work is done in a time interval dt, the power delivered by the battery is obtained by dividing dW by dt. Thus, the power delivered by the battery (in watts) is

$$\frac{dW}{dt} = (V_a - V_d)\frac{dQ}{dt} = (V_a - V_d)i.$$

Using the values $i = 0.2$ ampere and $V_a - V_d = 12$ volts makes $dW/dt = 2.4$ watts. As expected, the power delivered by the battery is equal to the power dissipated as heat in the resistor.

Resistors in series and parallel. If two resistors are connected in Figure 19A so that all of the electric charge must traverse both resistors in succession, the equivalent resistance to the flow of current is the sum of the resistances.

By courtesy of the Department of Physics and Astronomy, Michigan State University

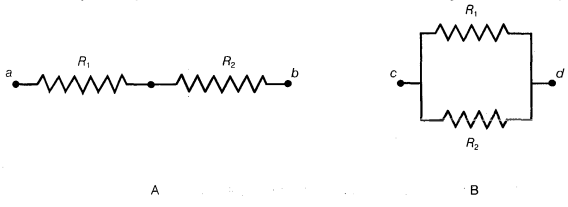

Figure 19: *Resistors.*
(A) In series. (B) In parallel.

Using R_1 and R_2 for the individual resistances, the resistance between a and b is given by

$$R_{ab} = R_1 + R_2. \qquad (25a)$$

This result can be appreciated by thinking of the two resistors as two pieces of the same type of thin wire. Connecting the wires in series as shown simply increases their length to equal the sum of their two lengths. As equation (20) indicates, the resistance is the same as that given by equation (25a). The resistances R_1 and R_2 can be replaced in a circuit by the equivalent resistance R_{ab}. If $R_1 = 5\Omega$ and $R_2 = 2\Omega$, then $R_{ab} = 7\Omega$. If two resistors are connected as shown in Figure 19B, the electric charges have alternate paths for flowing from c to d. The resistance to the flow of charge from c to d is clearly less than if either R_1 or R_2 were missing. Anyone who has ever had to find a way out of a crowded theatre can appreciate how much easier it is to leave a building with several exits than one with a single exit. The value of the equivalent resistance for two resistors in parallel is given by the equation

$$\frac{1}{R_{cd}} = \frac{1}{R_1} + \frac{1}{R_2}. \qquad (25b)$$

This relationship follows directly from the definition of resistance in equation (20), where $1/R$ is proportional to the area. If the resistors R_1 and R_2 are imagined to be wires of the same length and material, they would be wires with different cross-sectional areas. Connecting them in parallel is equivalent to placing them side by side, increasing the total area available for the flow of charge. Clearly, the equivalent resistance is smaller than the resistance of either resistor individually. As a numerical example, for $R_1 = 5\Omega$ and $R_2 = 2\Omega$, $1/R_{cd} = 1/5 + 1/2 = 0.7$. Therefore, $R_{cd} = 1/0.7 = 1.43\Omega$. As expected, the equivalent resistance of 1.43 ohms is smaller than either 2 ohms or 5 ohms. It should be noted that both equations (25a) and (25b) are given in a form in which they can be extended easily to any number of resistances.

Kirchhoff's laws of electric circuits. Two simple relationships can be used to determine the value of currents in circuits. They are useful even in rather complex situations such as circuits with multiple loops. The first relationship deals with currents at a junction of conductors. Figure 20 shows three such junctions, with the currents assumed to flow in the directions indicated.

Determining the value of currents in circuits

By courtesy of the Department of Physics and Astronomy, Michigan State University

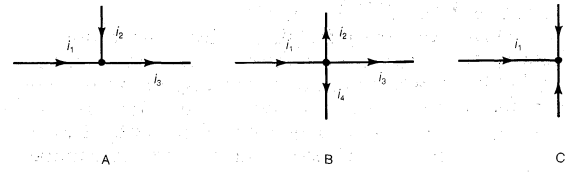

Figure 20: Electric currents at a junction (see text).

Simply stated, the sum of currents entering a junction equals the sum of currents leaving that junction. This statement is commonly called Kirchhoff's first law (after the German physicist Gustav Robert Kirchhoff, who formulated it). For Figure 20A, the sum is $i_1 + i_2 = i_3$. For Figure 20B, $i_1 = i_2 + i_3 + i_4$. For Figure 20C, $i_1 + i_2 + i_3 = 0$. If this last equation seems puzzling because all the currents appear to flow in and none flows out, it is because of the choice of directions for the individual currents. In solving a problem, the direction chosen for the currents is arbitrary. Once the problem has been solved, some currents have a positive value, and the direction arbitrarily chosen is the one of the actual current. In the solution some currents may have a negative value, in which case the actual current flows in a direction opposite that of the arbitrary initial choice.

Kirchhoff's second law is as follows: the sum of electromotive forces in a loop equals the sum of potential drops in the loop. When electromotive forces in a circuit are symbolized as circuit components as in Figure 18, this law can be stated quite simply: the sum of the potential differences across all the components in a closed loop equals zero. To illustrate and clarify this relation, one can consider a single circuit with two sources of electromotive forces E_1 and E_2, and two resistances R_1 and R_2, as shown in Figure 21. The direction chosen for the current i also is indicated. The letters a, b, c, and d are used to indicate certain locations around the circuit. Applying Kirchhoff's second law to the circuit,

$$(V_b - V_a) + (V_c - V_b) + (V_d - V_c) + (V_a - V_d) = 0. \qquad (26)$$

Referring to the circuit in Figure 21, the potential differences maintained by the electromotive forces indicated are $V_b - V_a = E_1$, and $V_c - V_d = -E_2$. From Ohm's law, $V_b - V_c = iR_1$, and $V_d - V_a = iR_2$. Using these four relationships in equation (26), the so-called loop equation becomes $E_1 - E_2 - iR_1 - iR_2 = 0$.

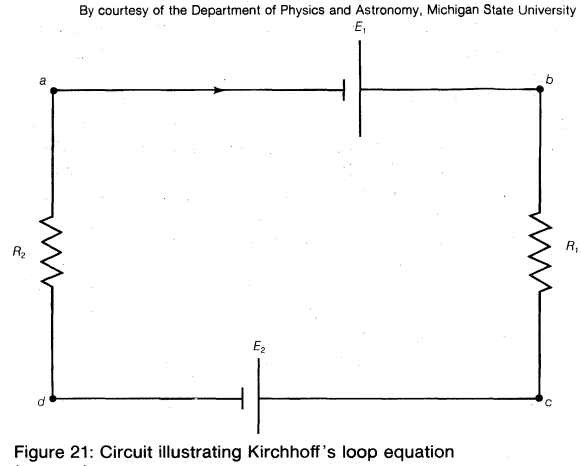

Figure 21: Circuit illustrating Kirchhoff's loop equation (see text).

Given the values of the resistances R_1 and R_2 in ohms and of the electromotive forces E_1 and E_2 in volts, the value of the current i in the circuit is obtained. If E_2 in the circuit had a greater value than E_1, the solution for the current i would be a negative value for i. This negative sign indicates that the current in the circuit would flow in a direction opposite the one indicated in Figure 21.

Kirchhoff's laws can be applied to circuits with several connected loops. The same rules apply, though the algebra required becomes rather tedious as the circuits increase in complexity.

ALTERNATING ELECTRIC CURRENTS

Use in power transmission and in radio and television broadcasting

Basic phenomena and principles. Many applications of electricity and magnetism involve voltages that vary in time. Electric power transmitted over large distances from generating plants to users involves voltages that vary sinusoidally in time, at a frequency of 60 hertz (Hz) in the United States and Canada and 50 hertz in Europe. (One hertz equals one cycle per second.) This means that in the United States, for example, the current alternates its direction in the electric conducting wires so that each second it flows 60 times in one direction and 60 times in the opposite direction. Alternating currents (AC) are also used in radio and television transmissions. In an AM (amplitude-modulation) radio broadcast, electromagnetic waves with a frequency of around one million hertz are generated by currents of the same frequency flowing back and forth in the antenna of the station. The information transported by these waves is encoded in the rapid variation of the wave amplitude. When voices and music are broadcast, these variations correspond to the mechanical oscillations of the sound and have frequencies from 50 to 5,000 hertz. In an FM (frequency-modulation) system, which is used by both television and FM radio stations, audio information is contained in the rapid fluctuation of the frequency in a narrow range around the frequency of the carrier wave.

Circuits that can generate such oscillating currents are called oscillators; they include, in addition to transistors and vacuum tubes, such basic electrical components as resistors, capacitors, and inductors. As was mentioned above, resistors dissipate heat while carrying a current. Capacitors store energy in the form of an electric field in the volume between oppositely charged electrodes. Inductors are essentially coils of conducting wire; they store magnetic energy in the form of a magnetic field generated by the current in the coil. All three components provide some impedance to the flow of alternating currents. In the case of capacitors and inductors, the impedance depends on the frequency of the current. With resistors, impedance is independent of frequency and is simply the resistance. This is easily seen from Ohm's law, equation (21), when it is written as $i = V/R$. For a given voltage difference V between the ends of a resistor, the current varies inversely with the value of R. The greater the value R, the greater is the impedance to the flow of electric current. Before proceeding to circuits with resistors, capacitors, inductors, and sinusoidally varying electromotive forces, the behaviour of a circuit with a resistor and a capacitor will be discussed to clarify transient behaviour and the impedance properties of the capacitor.

Impedance

Transient response. Consider a circuit consisting of a capacitor and a resistor that are connected as shown in Figure 22. What will be the voltage at point b if the voltage at a is increased suddenly from $V_a = 0$ to $V_a = +50$ volts? Closing the switch produces such a voltage because it connects the positive terminal of a 50-volt battery to point a while the negative terminal is at ground (point c). Figure 23 (left) graphs this voltage V_a as a function of the time.

Initially, the capacitor has no charge and does not affect the flow of charge. The initial current is obtained from Ohm's law, $V = iR$, where $V = V_a - V_b$, V_a is 50 volts and V_b is zero. Using 2,000 ohms for the value of the resistance in Figure 22, there is an initial current of 25 milliamperes in the circuit. This current begins to charge the capacitor, so that a positive charge accumulates on the plate of the capacitor connected to point b and a negative charge accumulates on the other plate. As a result, the potential at point b increases from zero to a positive value. As more charge accumulates on the capacitor, this positive potential continues to increase. As it does so, the value of the potential across the resistor is reduced; consequently, the current decreases with time, approaching the value of zero as the capacitor potential reaches 50 volts. The behaviour of the potential at b in Figure 23 (right) is described by the equation $V_b = V_a(1 - e^{-t/RC})$ in volts. For $R = 2{,}000\,\Omega$ and capacitance $C = 2.5$ microfarads, $V_b = 50(1 - e^{-t/0.005})$ in volts. The potential V_b at b in Figure 23 (right) increases from zero when the capacitor is uncharged and reaches the ultimate value of V_a when equilibrium is reached.

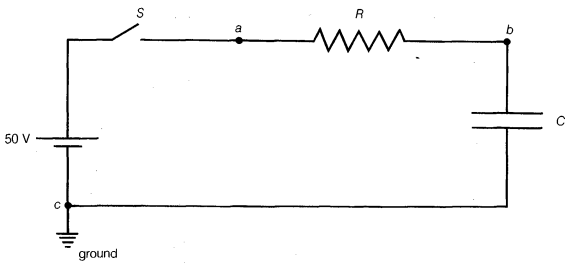

Figure 22: *An RC circuit.*
This type of electric circuit consists of both a resistor and a capacitor connected as shown (see text).

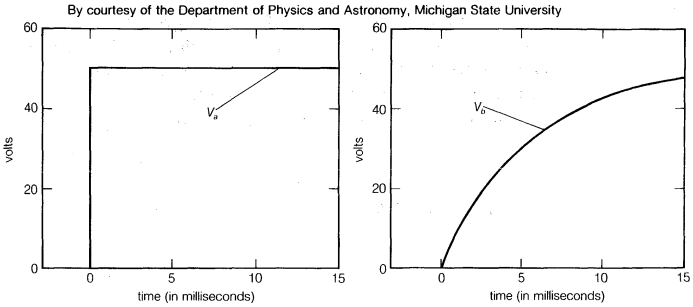

Figure 23: Voltage as a function of time (see text).

How would the potential at point b vary if the potential at point a, instead of being maintained at +50 volts, were to remain at +50 volts for only a short time, say, one millisecond, and then return to zero? The superposition principle (see above) is used to solve the problem. The voltage at a starts at zero, goes to +50 volts at $t = 0$, then returns to zero at $t = +0.001$ second. This voltage can be viewed as the sum of two voltages, $V_{1a} + V_{2a}$, where V_{1a} becomes +50 volts at $t = 0$ and remains there indefinitely, and V_{2a} becomes −50 volts at $t = 0.001$ second and remains there indefinitely. This superposition is shown graphically on the left side of Figure 24. Since the solutions for V_{1b} and V_{2b} corresponding to V_{1a} and V_{2a} are known from the previous example, their sum V_b is the answer to the problem. The individual solutions and their sum are given graphically on the right side of Figure 24.

The voltage at b reaches a maximum of only 9 volts. The superposition illustrated in Figure 24 also shows that the shorter the duration of the positive "pulse" at a, the smaller is the value of the voltage generated at b. Increasing the size of the capacitor also decreases the maximum voltage at b. This decrease in the potential of a transient explains the "guardian role" that capacitors play in protecting delicate and complex electronic circuits from damage by large transient voltages. These transients, which generally occur at high frequency, produce effects similar to those produced by pulses of short duration. They can damage equipment when they induce circuit components to break down electrically. Transient voltages are often introduced into electronic circuits through power supplies. A concise way to describe the role of the capacitor in the above example is to say that its impedance to an electric signal decreases with increasing frequency. In the example, much of the signal is shunted to ground instead of appearing at point b.

Transient voltages and their effects

Alternating-current circuits. Certain circuits include

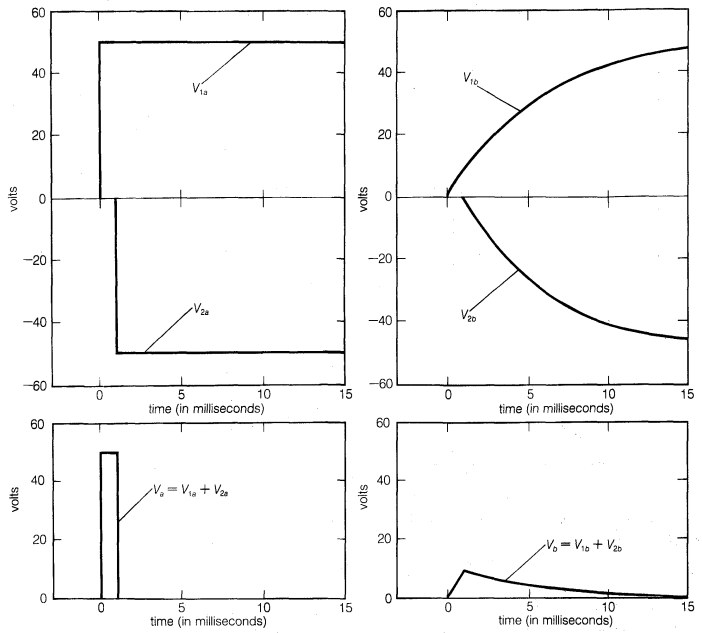

Figure 24: Application of the superposition principle to a problem concerned with voltages as a function of time (see text).
By courtesy of the Department of Physics and Astronomy, Michigan State University

sources of alternating electromotive forces of the sinusoidal form $V = V_0 \cos(\omega t)$ or $V = V_0 \sin(\omega t)$. The sine and cosine functions have values that vary between +1 and −1; either of the equations for the voltage represents a potential that varies with respect to time and has values from $+V_0$ to $-V_0$. The voltage varies with time at a rate given by the numerical value of ω; ω, which is called the angular frequency, is expressed in radians per second. Figure 25 shows an example with $V_0 = 170$ volts and $\omega = 377$ radians per second, so that $V = 170 \cos(377t)$. The time interval required for the pattern to be repeated is called the period T, given by $T = 2\pi/\omega$. In Figure 25, the pattern is repeated every 16.7 milliseconds, which is the period. The frequency of the voltage is symbolized by f and given by $f = 1/T$. In terms of ω, $f = \omega/2\pi$, in hertz.

The root-mean-square (rms) voltage of a sinusoidal source of electromotive force (V_{rms}) is used to characterize the source. It is the square root of the time average of the voltage squared. The value of V_{rms} is $V_0/\sqrt{2}$, or, equivalently, $0.707V_0$. Thus, the 60-hertz, 120-volt alternating current, which is available from most electric outlets in U.S. homes and which is illustrated in Figure 25, has $V_0 = 120/0.707 = 170$ volts. The potential difference at the outlet varies from +170 volts to −170 volts and back to +170 volts 60 times each second. The rms values of voltage and current are especially useful in calculating average power in AC circuits.

A sinusoidal electromotive force can be generated using

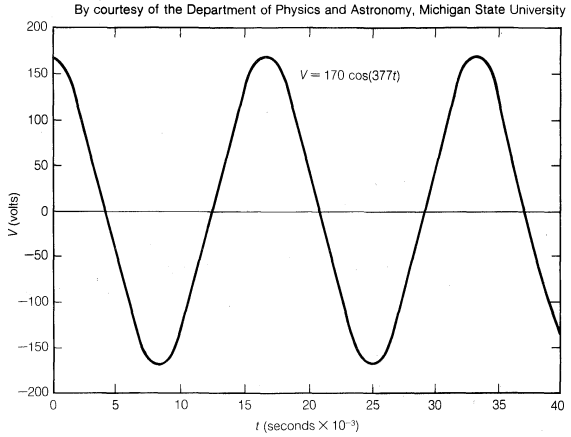

Figure 25: A sinusoidal voltage (see text).

the principles described in Faraday's law of electromagnetic induction (see below *Faraday's law of induction*). Briefly, an alternating electromotive force can be induced in a loop of conducting wire by rotating the loop of wire in a uniform magnetic field.

In AC circuits, it is often necessary to find the currents as a function of time in the various parts of the circuit for a given source of sinusoidal electromotive force. While the problems can become quite complex, the solutions are based on Kirchhoff's two laws discussed above (see *Kirchhoff's laws of electric circuits*). The solution for the current in a given loop takes the form $i = i_0 \cos(\omega t - \varphi)$. The current has the same frequency as the applied voltage but is not necessarily "in phase" with that voltage. When the phase angle φ does not equal zero, the maximum of the current does not occur when the driving voltage is at its maximum.

Behaviour of an AC circuit

The way an AC circuit functions can be better understood by examining one that includes a source of sinusoidally varying electromotive force, a resistor, a capacitor, and an inductor, all connected in series. For this single-loop problem, only the second of Kirchhoff's laws is needed since there is only one current. The circuit is shown in Figure 26 with the points *a, b, c,* and *d* at various positions in the circuit located between the various elements. The letters *R, L,* and *C* represent, respectively, the values of

By courtesy of the Department of Physics and Astronomy, Michigan State University

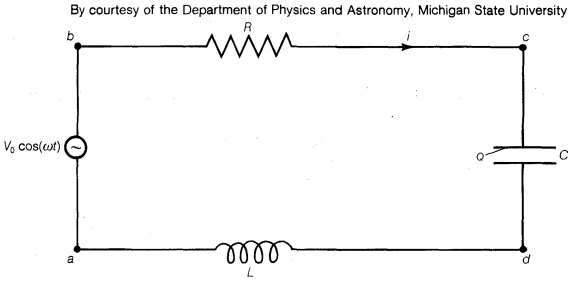

Figure 26: *A series LRC circuit.*
This type of electric circuit has an inductor, resistor, and capacitor connected in series (see text).

the resistance in ohms, the inductance in henrys, and the capacitance in farads. The source of the AC electromotive force is located between *a* and *b*. The wavy symbol is a reminder of the sinusoidal nature of the voltage that is responsible for making the current flow in the loop. For the potential between *b* and *a*,

$$V_b - V_a = V_0 \cos \omega t. \qquad (27a)$$

Equation (27a) represents a potential difference that has its maximum positive value at $t = 0$.

The direction chosen for the current i in the circuit in Figure 26 represents the direction of that current at some particular time, since AC circuits feature continuous reversals of the direction of the flow of charge. The direction chosen for the current is important, however, because the loop equation must consider all the elements at the same instant in time. The potential difference across the resistor is given by Ohm's law as

$$V_b - V_c = iR. \qquad (27b)$$

For equation (27b), the direction of the current is important. The potential difference across the capacitor, $V_c - V_d$, depends on the charge on the capacitor. When the charge on the upper plate of the capacitor in Figure 26 has a value Q, the potential difference across the capacitor is

$$V_c - V_d = \frac{Q}{C}, \qquad (27c)$$

which is a variant of equation (12). One must be careful labeling the charge and the direction of the current, since the charge on the other plate is $-Q$. For the choices shown in the figure, the current in the circuit is given by the rate of change of the charge Q—that is, $i = dQ/dt$. Finally, the value of the potential difference $V_d - V_a$ across the inductor depends on the rate of change of the current through the inductor, di/dt. For the direction chosen for i, the value is

$$V_d - V_a = +L\frac{di}{dt}. \tag{27d}$$

The result of combining equations (27a, b, c, d) in accordance with Kirchhoff's second law for the loop in Figure 26 is

$$V_0 \cos(\omega t) = L\frac{di}{dt} + iR + \frac{Q}{C}. \tag{28}$$

Both the current i and the rate of change of the current di/dt can be eliminated from equation (28), since $i = dQ/dt$, and $di/dt = d^2Q/dt^2$. The result is a linear, inhomogeneous, second-order differential equation with well-known solutions for the charge Q as a function of time. The most important solution describes the current and voltages after transient effects have been dampened; the transient effects last only a short time after the circuit is completed. Once the charge is known, the current in the circuit can be obtained by taking the first derivative of the charge. The expression for the current in the circuit is

$$i = \frac{V_0}{Z}\cos(\omega t - \varphi) = i_0 \cos(\omega t - \varphi). \tag{29}$$

In equation (29), Z is the impedance of the circuit; impedance, like resistance, is measured in units of ohms. Z is a function of the frequency of the source of applied electromotive force. The equation for Z is

$$Z = \sqrt{R^2 + \left(\omega L - \frac{1}{\omega C}\right)^2}. \tag{30}$$

If the resistor were the only element in the circuit, the impedance would be $Z = R$, the resistance of the resistor. For a capacitor alone, $Z = 1/\omega C$, showing that the impedance of a capacitor decreases as the frequency increases. For an inductor alone, $Z = \omega L$; the reason why the impedance of the inductor increases with frequency will become clear once Faraday's law of magnetic induction is discussed in detail below. Here it is sufficient to say that an induced electromotive force in the inductor opposes the change in current, and it is directly proportional to the frequency.

The phase angle φ in equation (29) gives the time relationship between the current in the circuit and the driving electromotive force, $V_0 \cos(\omega t)$. The tangent of the angle φ is

$$\tan\varphi = \frac{\left(\omega L - \frac{1}{\omega C}\right)}{R}. \tag{31}$$

Depending on the values of ω, L, and C, the angle φ can be positive, negative, or zero. If φ is positive, the current "lags" the voltage, while for negative values of φ, the current "leads" the voltage.

The power dissipated in the circuit is the same as the power delivered by the source of electromotive force, and both are measured in watts. Using equation (23), the power is given by

$$P = iV = i_0 \cos(\omega t - \varphi) V_0 \cos(\omega t). \tag{32}$$

An expression for the average power dissipated in the circuit can be written either in terms of the peak values i_0 and V_0 or in terms of the rms values i_{rms} and V_{rms}. The average power is

$$P_{ave} = I_{rms} V_{rms} \cos\varphi = \frac{1}{2} i_0 V_0 \cos\varphi. \tag{33}$$

The cos φ in equation (33) is called the power factor. It is evident that the only element that can dissipate energy is the resistance.

Resonance

A most interesting condition known as resonance occurs when the phase angle is zero in equation (31), or equivalently, when the angular frequency ω has the value $\omega = \omega_r = \sqrt{1/LC}$. The impedance in equation (30) then has its minimum value and equals the resistance R. The amplitude of the current in the circuit, i_0, is at its maximum value (see equation [29]). Figure 27 shows the dependence of i_0 on the angular frequency ω of the source of alternating electromotive force. The values of the electric parameters for the figure are $V_0 = 50$ volts, $R = 25$ ohms,

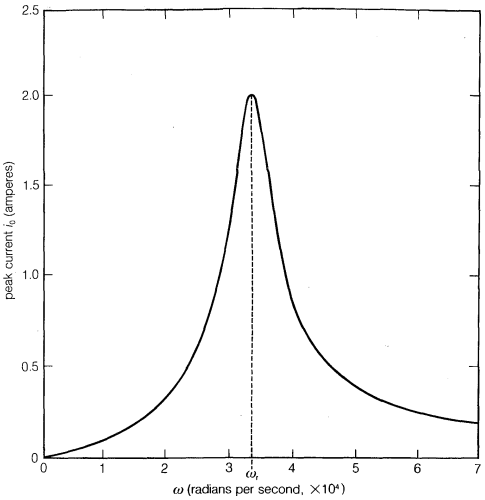

Figure 27: Current amplitude (peak current) as a function of ω (see text).

By courtesy of the Department of Physics and Astronomy, Michigan State University

$L = 4.5$ millihenrys, and $C = 0.2$ microfarad. With these values, the resonant angular frequency ω_r of the circuit in Figure 26 is 3.33×10^4 radians per second.

The peaking in the current shown in Figure 27 constitutes a resonance. At the resonant frequency, in this case when ω_r equals 3.33×10^4 radians per second, the impedance Z of the circuit is at a minimum and the power dissipated is at a maximum. The phase angle φ is zero so that the current is in phase with the driving voltage, and the power factor, cos φ, is 1. Figure 28 illustrates the variation of the average power with the angular frequency of the sinusoidal electromotive force. The resonance is seen to be even more pronounced. The quality factor Q for the circuit is the electric energy stored in the circuit divided by the energy dissipated in one period. The Q of a circuit is an important quantity in certain applications, as in the case of electromagnetic waveguides and radio-frequency cavities where Q has values around 10,000 and where high voltages and electric fields are desired. For the present circuit, $Q = \omega_r L/R$. Q also can be obtained from the average power graph as the ratio $\omega_r/(\omega_2 - \omega_1)$, where ω_1 and ω_2 are the angular frequencies at which the average power dissipated in the circuit is one-half its maximum value. For the circuit here, $Q = 6$.

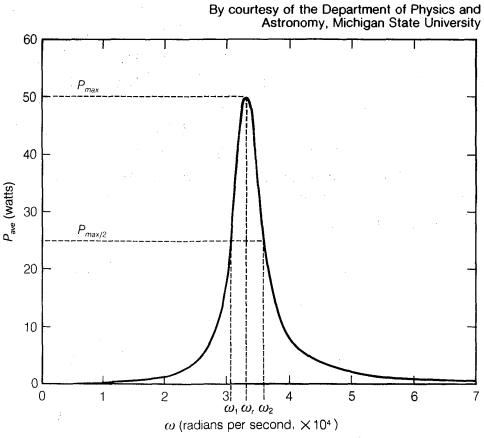

Figure 28: Average power dissipation versus ω (see text).

What is the maximum value of the potential difference across the inductor? Since it is given by Ldi/dt, it will occur when the current has the maximum rate of change. Figure 29 shows the amplitude of the potential difference as a function of ω.

The maximum amplitude of the voltage across the inductor, 300 volts, is much greater than the 50-volt amplitude of the driving sinusoidal electromotive force. This result is typical of resonance phenomena. In a familiar mechanical system, children on swings time their kicks to attain very

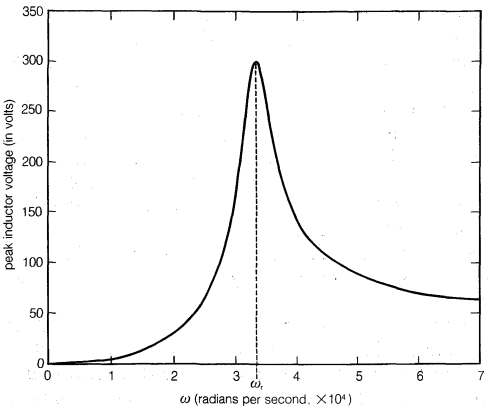

Figure 29: Electromotive force across L versus ω (see text).

large swings (much larger than they could attain with a single kick). In a more spectacular, albeit costly, example, the collapse of the Tacoma Narrows Bridge (a suspension bridge across the Narrows of Puget Sound, Wash.) on Nov. 7, 1940, was the result of the large amplitudes of oscillations that the span attained as it was driven in resonance by high winds. A ubiquitous example of electric resonance occurs when a radio dial is turned to receive a broadcast. Turning the dial changes the value of the tuning capacitor of the radio. When the circuit attains a resonance frequency corresponding to the frequency of the radio wave, the voltage induced is enhanced and processed to produce sound.

Magnetism

FUNDAMENTALS

Magnetism is a phenomenon associated with the motion of charge. This motion can take many forms. It can be an electric current in a conductor or charged particles moving through space, or it can be the motion of an electron in atomic orbit. Magnetism is also associated with elementary particles, such as the electron, that have a property called spin.

Effects of a magnetic field

Basic to magnetism are magnetic fields and their effects on matter, as, for instance, the deflection of moving charges and torques on other magnetic objects. Evidence for the presence of a magnetic field is the magnetic force on charges moving in that field; the force is at right angles to both the field and the velocity of the charge. This force deflects the particles without changing their speed. The deflection can be observed in the electron beam of a television tube when a permanent magnet is brought near the tube. A more familiar example is the torque on a compass needle that acts to align the needle with the magnetic field of the Earth. The needle is a thin piece of iron that has been magnetized—*i.e.*, a small bar magnet. One end of the magnet is called a north pole and the other end a south pole. The force between a north and a south pole is attractive, whereas the force between like poles is repulsive. The magnetic field is sometimes referred to as magnetic induction or magnetic flux density; it is always symbolized by $\boldsymbol{B}$. Magnetic fields are measured in units of tesla (T). (Another unit of measure commonly used for $\boldsymbol{B}$ is the gauss, though it is no longer considered a standard unit. One gauss equals 10^{-4} tesla.)

A fundamental property of a magnetic field is that its flux through any closed surface vanishes. (A closed surface is one that completely surrounds a volume.) This is expressed mathematically by div $\boldsymbol{B} = 0$ and can be understood physically in terms of the field lines representing $\boldsymbol{B}$. These lines always close on themselves, so that if they enter a certain volume at some point, they must also leave that volume. In this respect, a magnetic field is quite different from an electric field. Electric field lines can begin and end on a charge, but no equivalent magnetic charge has been found in spite of many searches for so-called magnetic monopoles.

The most common source of magnetic fields is the electric current loop. It may be an electric current in a circular conductor or the motion of an orbiting electron in an atom. Associated with both these types of current loops is a magnetic dipole moment, the value of which is iA, the product of the current and the area of the loop. In addition, electrons, protons, and neutrons in atoms have a magnetic dipole moment associated with their intrinsic spin; such magnetic dipole moments represent another important source of magnetic fields. A particle with a magnetic dipole moment is often referred to as a magnetic dipole. (A magnetic dipole may be thought of as a tiny bar magnet. It has the same magnetic field as such a magnet and behaves the same way in external magnetic fields.) When placed in an external magnetic field, a magnetic dipole can be subjected to a torque that tends to align it with the field; if the external field is not uniform, the dipole also can be subjected to a force.

All matter exhibits magnetic properties to some degree. When placed in an inhomogeneous field, matter is either attracted or repelled in the direction of the gradient of the field. This property is described by the magnetic susceptibility of the matter and depends on the degree of magnetization of the matter in the field. Magnetization depends on the size of the dipole moments of the atoms in a substance and the degree to which the dipole moments are aligned with respect to each other. Certain materials, such as iron, exhibit very strong magnetic properties because of the alignment of the magnetic moments of their atoms within certain small regions called domains. Under normal conditions, the various domains have fields that cancel, but they can be aligned with each other to produce extremely large magnetic fields. Various alloys, like NdFeB (an alloy of neodymium, iron, and boron), keep their domains aligned and are used to make permanent magnets. The strong magnetic field produced by a typical three-millimetre-thick magnet of this material is comparable to an electromagnet made of a copper loop carrying a current of several thousand amperes. In comparison, the current in a typical light bulb is 0.5 ampere. Since aligning the domains of a material produces a magnet, disorganizing the orderly alignment destroys the magnetic properties of the material. Thermal agitation that results from heating a magnet to a high temperature destroys its magnetic properties.

Domains

Magnetic fields vary widely in strength. Some representative values are given in Table 3.

Table 3: Typical Magnetic Fields

Inside atomic nuclei	10^{11} T
In superconducting solenoids	20 T
In a superconducting coil cyclotron	5 T
Near a small ceramic magnet	0.1 T
Earth's field at the equator	4×10^{-5} T
In interstellar space	2×10^{-10} T

MAGNETIC FIELD OF STEADY CURRENTS

Biot–Savart law

Magnetic fields produced by electric currents can be calculated for any shape of circuit using the law of Biot and Savart, named for the early 19th-century French physicists Jean-Baptiste Biot and Félix Savart. A few magnetic field lines produced by a current in a loop are shown in Figure 30. These lines of $\boldsymbol{B}$ form loops around the current. The Biot–Savart law expresses the partial contribution $d\boldsymbol{B}$ from a small segment of conductor to the total $\boldsymbol{B}$ field of a current in the conductor. For a segment of length and orientation $d\boldsymbol{l}$ that carries a current i,

$$d\boldsymbol{B} = \frac{\mu_0}{4\pi} \frac{i d\boldsymbol{l} \times \hat{\boldsymbol{r}}}{r^2}. \qquad (34)$$

In this equation, μ_0 is the permeability of free space and has the value of $4\pi \times 10^{-7}$ newton per square ampere. This equation is illustrated in Figure 31 for a small segment of a wire that carries a current so that, at the origin of the coordinate system, the small segment of length $d\boldsymbol{l}$ of the wire lies along the x axis.

Comparing $d\boldsymbol{B}$ at points 1 and 2 shows the inverse square dependence of the magnitude of the field with distance. The vectors at points 1, 3, and 4, which are all at the

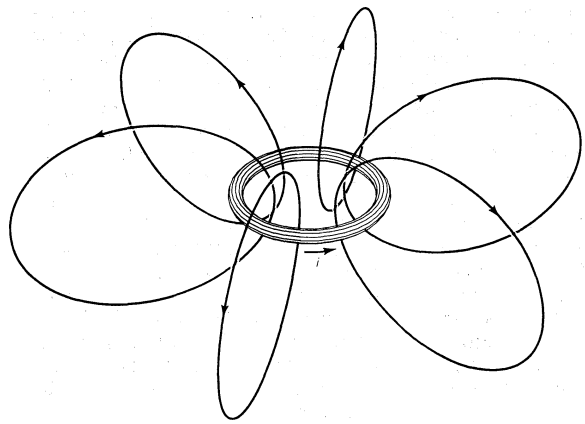

Figure 30: Some lines of the magnetic field $\boldsymbol{B}$ for an electric current i in a loop (see text).
By courtesy of the Department of Physics and Astronomy, Michigan State University

same distance from $d\boldsymbol{l}$, show the direction of $d\boldsymbol{B}$ in a circle around the wire. In position 1, the contribution to the field, $d\boldsymbol{B}_1$, is perpendicular both to the current direction and to the vector r_1. Finally, the vectors at 1, 5, 6, and 7 illustrate the angular dependence of the magnitude of $d\boldsymbol{B}$ at a point. The magnitude of $d\boldsymbol{B}$ varies as the sine of the angle between $d\boldsymbol{l}$ and $\hat{\boldsymbol{r}}$, where $\hat{\boldsymbol{r}}$ is in the direction from $d\boldsymbol{l}$ to the point. It is strongest at 90° to $d\boldsymbol{l}$ and decreases to zero for locations directly in line with $d\boldsymbol{l}$. The magnetic field of a current in a loop or coil is obtained by summing the individual partial contributions of all the segments of the circuits, taking into account the vector nature of the field. While simple mathematical expressions for the magnetic field can be derived for a few current configurations, most of the practical applications require the use of high-speed computers.

The expression for the magnetic field $\boldsymbol{B}$ a distance r from a long straight wire with current i is

$$\boldsymbol{B} = \frac{\mu_0 i}{2\pi r}\hat{\boldsymbol{\theta}}, \tag{35}$$

where $\hat{\boldsymbol{\theta}}$ is a unit vector pointing in a circle around the wire. The $\boldsymbol{B}$ field near a long straight wire with current i can be seen in Figures 2A and 2B. The magnetic field at a distance r from a magnetic dipole with moment $\boldsymbol{m}$ is given by

$$\boldsymbol{B} = \frac{\mu_0 m}{4\pi r^3}(2\cos\theta\,\hat{\boldsymbol{r}} + \sin\theta\,\hat{\boldsymbol{\theta}}). \tag{36}$$

The size of the magnetic dipole moment is m in ampere times square metre (A · m²), and the angle between the direction of $\boldsymbol{m}$ and of $\boldsymbol{r}$ is θ. Both $\hat{\boldsymbol{r}}$ and $\hat{\boldsymbol{\theta}}$ are unit vectors in the direction of $\boldsymbol{r}$ and θ. It is apparent that the magnetic

By courtesy of the Department of Physics and Astronomy, Michigan State University

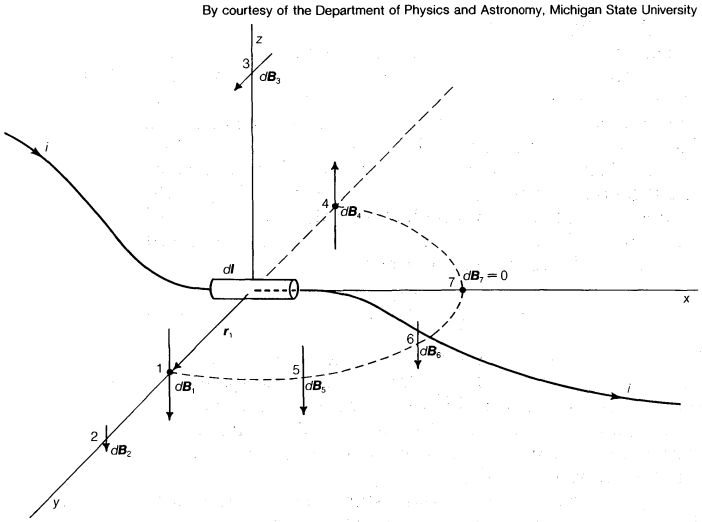

Figure 31: A magnetic field produced by a small section of wire with electric current i (see text).

field decreases rapidly as the cube of the distance from the dipole. Equation (36) is also valid for a small current loop with current i, when the distance r is much greater than the size of the current loop. A loop of area A has a magnetic dipole moment with a magnitude $m = iA$; its direction is perpendicular to the plane of the loop, along the direction of $\boldsymbol{B}$ inside the loop. If the fingers of the right hand are curled and held in the direction of the current in the loop, the extended thumb points in the direction of $\boldsymbol{m}$. In Figure 30, the dipole moment of the current in the loop points up; in Figure 32, $\boldsymbol{m}$ points down because the current flows in a clockwise direction when viewed from above.

The magnetic field of the current loop in Figure 32 at points far from the loop has the same shape as the electric field of an electric dipole; the latter consists of two equal charges of opposite sign separated by a small distance. Magnetic dipoles, like electric dipoles, occur in a variety of situations. Electrons in atoms have a magnetic dipole moment that corresponds to the current of their orbital motion around the nucleus. In addition, the electrons have a magnetic dipole moment associated with their spin. The Earth's magnetic field is thought to be the result of cur-

By courtesy of the Department of Physics and Astronomy, Michigan State University

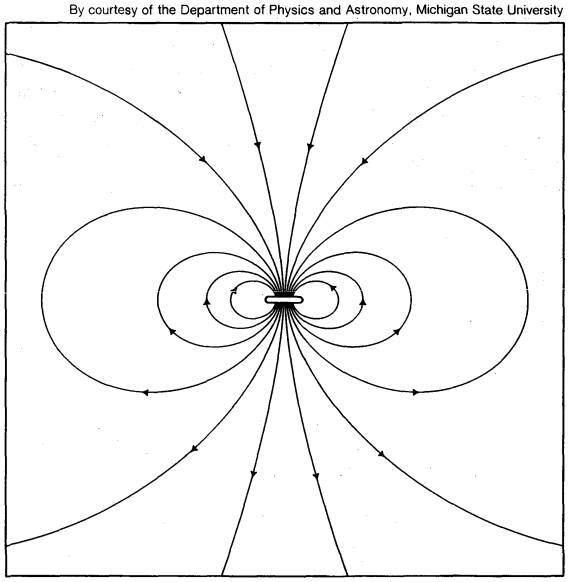

Figure 32: Some of the lines of $\boldsymbol{B}$ from the small current loop in the centre. The current in the loop flows in a clockwise direction when viewed from above.

rents related to the planet's rotation. The magnetic field far from a small bar magnet is well represented by the field of a magnetic dipole. In most of these cases, moving charge produces a magnetic field $\boldsymbol{B}$. Inside a long solenoid with current i and away from its ends, the magnetic field is uniform and directed along the axis of the solenoid. A solenoid of this kind can be made by wrapping some conducting wire tightly around a long hollow cylinder. The value of the field is

$$\boldsymbol{B} = \mu_0 n i, \tag{37}$$

where n is the number of turns per unit length of the solenoid.

MAGNETIC FORCES

A magnetic field $\boldsymbol{B}$ imparts a force on moving charged particles. The entire electromagnetic force on a charged particle with charge q and velocity $\boldsymbol{v}$ is called the Lorentz force (after the Dutch physicist Hendrik A. Lorentz) and is given by

Lorentz force

$$\boldsymbol{F} = q\boldsymbol{E} + q\boldsymbol{v} \times \boldsymbol{B}. \tag{38}$$

The first term is contributed by the electric field. The second term is the magnetic force and has a direction perpendicular to both the velocity $\boldsymbol{v}$ and the magnetic field $\boldsymbol{B}$. The magnetic force is proportional to q and to the magnitude of $\boldsymbol{v} \times \boldsymbol{B}$. In terms of the angle φ between $\boldsymbol{v}$ and $\boldsymbol{B}$, the magnitude of the force equals $qvB \sin \varphi$. An interest-

ing result of the Lorentz force is the motion of a charged particle in a uniform magnetic field. If v is perpendicular to B (*i.e.*, with the angle φ between v and B of 90°), the particle will follow a circular trajectory with a radius of $r = mv/qB$. If the angle φ is less than 90°, the particle orbit will be a helix with an axis parallel to the field lines. If φ is zero, there will be no magnetic force on the particle, which will continue to move undeflected along the field lines. Charged particle accelerators like cyclotrons make use of the fact that particles move in a circular orbit when v and B are at right angles. For each revolution, a carefully timed electric field gives the particles additional kinetic energy, which makes them travel in increasingly larger orbits. When the particles have acquired the desired energy, they are extracted and used in a number of different ways, from fundamental studies of the properties of matter to the medical treatment of cancer.

The magnetic force on a moving charge reveals the sign of the charge carriers in a conductor. A current flowing from right to left in a conductor can be the result of positive charge carriers moving from right to left or negative charges moving from left to right, or some combination of each. When a conductor is placed in a B field perpendicular to the current, the magnetic force on both types of charge carriers is in the same direction. This force, which can be seen in Figure 3, gives rise to a small potential difference between the sides of the conductor. Known as the

Hall effect

Hall effect, this phenomenon (discovered by the American physicist Edwin H. Hall) results when an electric field is aligned with the direction of the magnetic force. As is evident in Figure 3, the sign of the potential differs according to the sign of the charge carrier because, in one case, positive charges are pushed toward the reader and, in the other, negative charges are pushed in that direction. The Hall effect shows that electrons dominate the conduction of electricity in copper. In zinc, however, conduction is dominated by the motion of positive charge carriers. Electrons in zinc that are excited from the valence band leave holes, which are vacancies (*i.e.*, unfilled levels) that behave like positive charge carriers. The motion of these holes accounts for most of the conduction of electricity in zinc.

If a wire with a current i is placed in an external magnetic field B, how will the force on the wire depend on the orientation of the wire? Since a current represents a movement of charges in the wire, the Lorentz force given in equation (38) acts on the moving charges. Because these charges are bound to the conductor, the magnetic forces on the moving charges are transferred to the wire. The force on a small length dl of the wire depends on the orientation of the wire with respect to the field. The magnitude of the force is given by $idlB \sin \varphi$, where φ is the angle between B and dl. There is no force when $\varphi = 0$ or 180°, both of which correspond to a current along a direction parallel to the field. The force is at a maximum when the current and field are perpendicular to each other. The force is obtained from equation (38) and is given by

$$dF = idl \times B. \qquad (39)$$

Again, the cross product denotes a direction perpendicular to both dl and B. The direction of dF is given by the right-hand rule illustrated in Figure 33. As shown, the fingers are in the direction of B; the current (or in the case of a positive moving point charge, the velocity) is in the direction of the thumb, and the force is perpendicular to the palm.

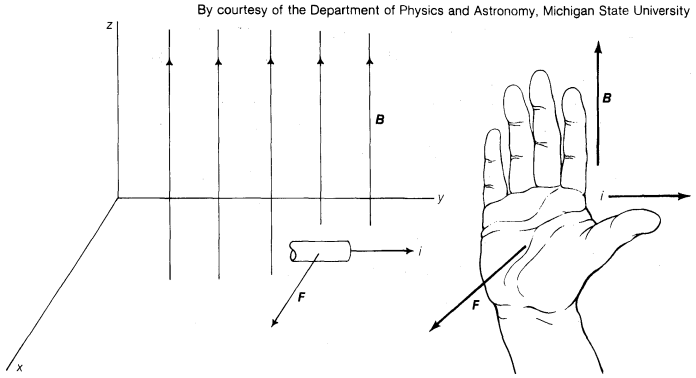

Figure 33: Right-hand rules for the magnetic force on an electric current (see text).

The force between two wires, each of which carries a current, can be understood from the interaction of one of the currents with the magnetic field produced by the other current. For example, the force between two parallel wires carrying currents in the same direction is attractive. It is repulsive if the currents are in opposite directions. Two circular current loops, located one above the other and with their planes parallel, will attract if the currents are in the same directions and will repel if the currents are in opposite directions. The situation is shown on the left side of Figure 34. When the loops are side by side as on the right side of Figure 34, the situation is reversed. For two currents flowing in the same direction, whether clockwise or counterclockwise, the force is repulsive, while for opposite directions, it is attractive. The nature of the force for the loops depicted in Figure 34 can be obtained by considering the direction of the currents in the parts of the loops that are closest to each other: same current direction, attraction; opposite current direction, repulsion. This seemingly complicated force between current loops can be understood more simply by treating the fields as though they originated from magnetic dipoles. As discussed above, the B field of a small current loop is well represented by the field of a magnetic dipole at distances that are large compared to the size of the loop. In another way of looking at the interaction of current loops, the loops of Figure 34A and 34B are replaced in Figure 35A and 35B by small permanent magnets, with the direction of the magnets from south to north corresponding to the direction of the magnetic moment of the loop m. Outside the magnets, the magnetic field lines point away from the north pole and toward the south pole.

By courtesy of the Department of Physics and Astronomy, Michigan State University

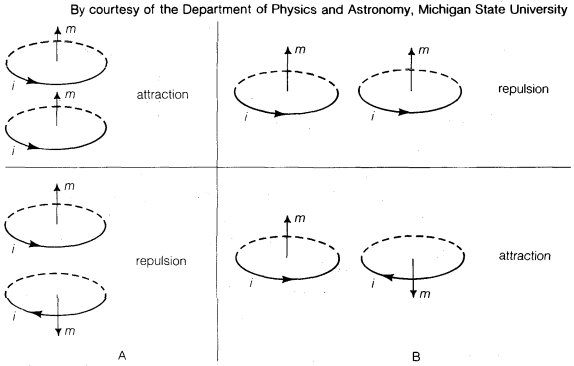

Figure 34: *Magnetic force between current loops.* In each case shown, the arrow indicates the direction of the current i and the magnetic dipole moment m of a loop (see text).

It is easy to understand the nature of the forces in Figures 34 and 35 with the rule that two north poles repulse each other and two south poles repulse each other, while unlike poles attract. As was noted earlier, Coulomb established an inverse square law of force for magnetic poles and electric charges; according to his law, unlike poles attract and like poles repel, just as unlike charges attract and like charges repel. Today, Coulomb's law refers only to charges, but historically it provided the foundation for a magnetic potential analogous to the electric potential.

The alignment of a magnetic compass needle with the direction of an external magnetic field is a good example of the torque to which a magnetic dipole is subjected. The torque has a magnitude $\tau = mB \sin \vartheta$. Here, ϑ is the angle between m and B. The torque τ tends to align m with B. It has its maximum value when ϑ is 90°, and it is zero when the dipole is in line with the external field. Rotating a magnetic dipole from a position where $\vartheta = 0$ to a position where $\vartheta = 180°$ requires work. Thus, the potential energy of the dipole depends on its orientation with respect to the field and is given in units of joules by

$$U_m = -mB \cos \vartheta. \qquad (40)$$

Basis for magnetic resonance imaging

Equation (40) represents the basis for an important medical application—namely, magnetic resonance imaging (MRI), also known as nuclear magnetic resonance imaging. MRI involves measuring the concentration of certain atoms, most commonly those of hydrogen, in body tissue and processing this measurement data to produce high-resolution images of organs and other anatomical structures. When hydrogen atoms are placed in a magnetic field, their nuclei (protons) tend to have their magnetic moments preferentially aligned in the direction of the field. The magnetic potential energy of the nuclei is calculated according to equation (40) as $-mB$. Inverting the direction of the dipole moment requires an energy of $2mB$, since the potential energy in the new orientation is $+mB$. A high-frequency oscillator provides energy in the form of electromagnetic radiation of frequency v, with each quantum of radiation having an energy hv, where h is Planck's constant. The electromagnetic radiation from the oscillator consists of high-frequency radio waves, which are beamed into the patient's body while it is subjected to a strong magnetic field. When the resonance condition $hv = 2mB$ is satisfied, the hydrogen nuclei in the body tissue absorb the energy and reverse their orientation. The resonance condition is met in only a small region of the body at any given time, and measurement of the energy absorption reveals the concentration of hydrogen atoms in that region alone. The magnetic field in an MRI scanner is usually provided by a large solenoid with B of one to three teslas. A number of "gradient coils" insures that the resonance condition is satisfied solely in the limited region inside the solenoid at any particular time; the coils are used to move this small target region, thereby making it possible to scan the patient's body throughout. The frequency of the radiation v is determined by the value of B and is typically 40 to 130 megahertz. The MRI technique does not harm the patient because the energy of the quanta of the electromagnetic radiation is much smaller than the thermal energy of a molecule in the human body.

The direction of the magnetic moment $\boldsymbol{m}$ of a compass needle is from the end marked S for south to the one marked N for north. The lowest energy occurs for $\vartheta = 0$, when $\boldsymbol{m}$ and $\boldsymbol{B}$ are aligned. In a typical situation, the compass needle comes to rest after a few oscillations and points along the $\boldsymbol{B}$ field in the direction called north. It must be concluded from this that the Earth's North Pole is really a magnetic south pole, with the field lines pointing toward that pole, while its South Pole is a magnetic north pole. Put another way, the dipole moment of the Earth currently points north to south. Short-term changes in the Earth's magnetic field are ascribed to electric currents in the ionosphere. There are also longer-term fluctuations in the locations of the poles. The angle between the compass needle and geographic north is called the magnetic declination (see EARTH: *The magnetic field of the Earth*).

The repulsion or attraction between two magnetic dipoles can be viewed as the interaction of one dipole with the magnetic field produced by the other dipole. The magnetic field is not constant, but varies with the distance from the dipole. When a magnetic dipole with moment $\boldsymbol{m}$ is in a $\boldsymbol{B}$ field that varies with position, it is subjected to a force proportional to that variation—*i.e.*, to the gradient of $\boldsymbol{B}$. The direction of the force is understood best by considering the potential energy of a dipole in an external $\boldsymbol{B}$ field, as given by equation (40). The force on the dipole is in the direction in which that energy decreases most rapidly. For example, if the magnetic dipole $\boldsymbol{m}$ is aligned with $\boldsymbol{B}$, then the energy is $-mB$, and the force is in the direction of increasing $\boldsymbol{B}$. If $\boldsymbol{m}$ is directed opposite to $\boldsymbol{B}$, then the potential energy given by equation (40) is $+mB$, and in this case the force is in the direction of decreasing $\boldsymbol{B}$. Both types of forces are observed when various samples of matter are placed in a nonuniform magnetic field. Such a field from an electromagnet is sketched in Figure 36.

Regardless of the direction of the magnetic field in Figure 36, a sample of copper is magnetically attracted toward the low field region to the right in the drawing. This behaviour is termed diamagnetism. A sample of aluminum, however, is attracted toward the high field region in an effect called paramagnetism. A magnetic dipole moment is induced when matter is subjected to an external field.

By courtesy of the Department of Physics and Astronomy, Michigan State University

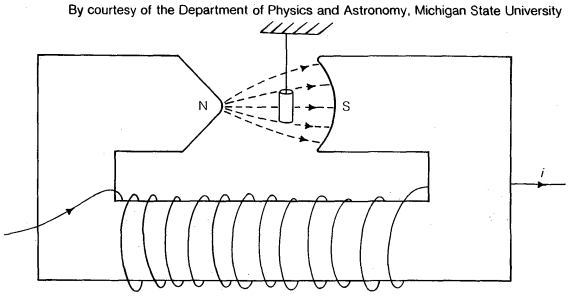

Figure 36: A small sample of copper in an inhomogeneous magnetic field (see text).

For copper, the induced dipole moment is opposite to the direction of the external field; for aluminum, it is aligned with that field. The magnetization $\boldsymbol{M}$ of a small volume of matter is the sum (a vector sum) of the magnetic dipole moments in the small volume divided by that volume. $\boldsymbol{M}$ is measured in units of amperes per metre. The degree of induced magnetization is given by the magnetic susceptibility of the material χ_m, which is commonly defined by the equation

$$\boldsymbol{M} = \chi_m \boldsymbol{H}. \tag{41}$$

The field $\boldsymbol{H}$ is called the magnetic intensity and, like $\boldsymbol{M}$, is measured in units of amperes per metre. (It is sometimes also called the magnetic field, but the symbol $\boldsymbol{H}$ is unambiguous.) The definition of $\boldsymbol{H}$ is

$$\boldsymbol{H} = \frac{\boldsymbol{B}}{\mu_0} - \boldsymbol{M}. \tag{42}$$

Magnetization effects in matter are discussed in some detail below. The permeability μ is often used for ferromagnetic materials such as iron that have a large magnetic susceptibility dependent on the field and the previous magnetic state of the sample; permeability is defined by the equation $\boldsymbol{B} = \mu \boldsymbol{H}$. From equations (41) and (42), it follows that $\mu = \mu_0 (1 + \chi_m)$.

The effect of ferromagnetic materials in increasing the magnetic field produced by current loops is quite large. Figure 37 illustrates a toroidal winding of conducting wire around a ring of iron that has a small gap. The magnetic field inside a toroidal winding similar to the one illustrated in Figure 37 but without the iron ring is given by $B = \mu_0 Ni/2\pi r$, where r is the distance from the axis of the toroid, N is the number of turns, and i is the current in the wire. The value of B for $r = 0.1$ metre, $N = 100$, and $i = 10$ amperes is only 0.002 tesla—about 50 times the magnetic field at the Earth's surface. If the same toroid is wound around an iron ring with no gap, the magnetic field inside the iron is larger by a factor equal to μ/μ_0, where μ is the magnetic permeability of the iron. For low-carbon iron in these conditions, $\mu = 8{,}000\mu_0$. The magnetic field in the iron is then 1.6 tesla. In a typical electromagnet, iron is used to increase the field in a small region, such

as the narrow gap in the iron ring illustrated in Figure 37. If the gap is one centimetre wide, the field in that gap is about 0.12 tesla, a 60-fold increase relative to the 0.002-tesla field in the toroid when no iron is used. This factor is typically given by the ratio of the circumference of the toroid to the gap in the ferromagnetic material. The maximum value of B as the gap becomes very small is of course the 1.6 tesla obtained above when there is no gap.

Energy density in a magnetic field

The energy density in a magnetic field is given in the absence of matter by $\frac{1}{2}B^2/\mu_0$; it is measured in units of joules per cubic metre. The total magnetic energy can be obtained by integrating the energy density over all space. The direction of the magnetic force can be deduced in many situations by studying distribution of the magnetic field lines; motion is favoured in the direction that tends to decrease the volume of space where the magnetic field is strong. This can be understood because the magnitude of B is squared in the energy density. Figure 38 shows some lines of the B field for two circular current loops with currents in opposite directions.

By courtesy of the Department of Physics and Astronomy, Michigan State University

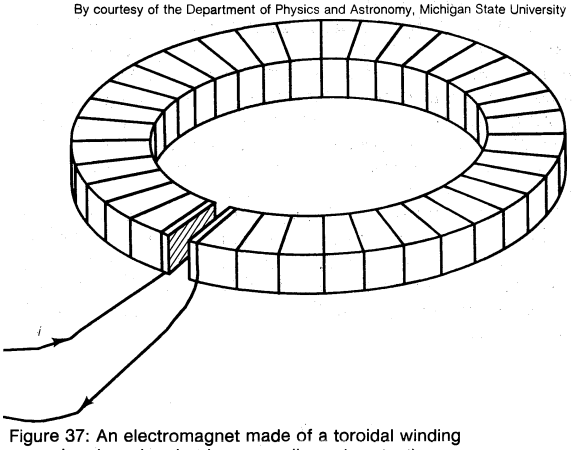

Figure 37: An electromagnet made of a toroidal winding around an iron ring that has a small gap (see text).

Because Figure 38 is a two-dimensional representation of a three-dimensional field, the spacing between the lines reflects the strength of the field only qualitatively. The high values of B between the two loops of the figure show that there is a large energy density in that region and separating the loops would reduce the energy. As discussed above, this is one more way of looking at the source of repulsion between these two loops. Figure 39 shows the B field for two loops with currents in the same direction. The force between the loops is attractive, and the distance separating them is equal to the loop radius. The result

is that the B field in the central region between the two loops is homogeneous to a remarkably high degree. Such a configuration is called a Helmholtz coil. By carefully orienting and adjusting the current in a large Helmholtz coil, it is often possible to cancel an external magnetic field (such as the magnetic field of the Earth) in a region of space where experiments require the absence of all external magnetic fields.

Electromagnetism

The merger of electricity and magnetism from distinct phenomena into electromagnetism is tied to three closely related events. The first was Hans Christian Ørsted's accidental discovery of the influence of an electric current on a magnetic needle—namely, that magnetic fields are produced by electric currents. Ørsted's 1820 report of his observation spurred an intense effort by scientists to prove that magnetic fields can induce currents. The second event was Michael Faraday's experimental proof that a changing magnetic field can induce a current in a circuit. The third was James Clerk Maxwell's prediction that a changing electric field has an associated magnetic field. The technological revolution attributed to the development of electric power and radio communications can be traced to these three landmarks (see below).

EFFECTS OF VARYING MAGNETIC FIELDS

Faraday's law of induction. Faraday's discovery in 1831 of the phenomenon of magnetic induction is one of the great milestones in the quest toward understanding and exploiting nature. Stated simply, Faraday found that (1) a changing magnetic field in a circuit induces an electromotive force in the circuit; and (2) the magnitude of the electromotive force equals the rate at which the flux of the magnetic field through the circuit changes. The flux is a measure of how much field penetrates through the circuit. The electromotive force is measured in volts and is represented by the equation

Magnetic flux

$$\text{emf} = -\frac{d\Phi}{dt}. \qquad (43)$$

Here, Φ, the flux of the vector field B through the circuit, measures how much of the field passes through the circuit. To illustrate the meaning of flux, imagine how much water from a steady rain will pass through a circular ring of area A. When the ring is placed parallel to the path of the water drops, no water passes through the ring. The maximum rate at which drops of rain pass through the ring occurs when the surface is perpendicular to the motion of the drops. The rate of water drops crossing the

surface is the flux of the vector field $\rho \boldsymbol{v}$ through that surface, where ρ is the density of water drops and $\boldsymbol{v}$ represents the velocity of the water. Clearly, the angle between $\boldsymbol{v}$ and the surface is essential in determining the flux. To specify the orientation of the surface, a vector $\boldsymbol{A}$ is defined so that its magnitude is the surface area A in units of square metres and its direction is perpendicular to the surface. The rate at which raindrops pass through the surface is $\rho v \cos \theta A$, where θ is the angle between $\boldsymbol{v}$ and $\boldsymbol{A}$. Using vector notation, the flux is $\rho \boldsymbol{v} \cdot \boldsymbol{A}$. For the magnetic field, the amount of flux through a small area represented by the vector $d\boldsymbol{A}$ is given by $\boldsymbol{B} \cdot d\boldsymbol{A}$. For a circuit consisting of a single turn of wire, adding the contributions from the entire surface that is surrounded by the wire gives the magnetic flux Φ of equation (43). The rate of change of this flux is the induced electromotive force. The units of magnetic flux are webers, with one weber equaling one tesla per square metre. Finally, the minus sign in equation (43) indicates the direction of the induced electromotive force and hence of any induced current. The magnetic flux through the circuit generated by the induced current is in whatever direction will keep the total flux in the circuit from changing. The minus sign in equation (43) is an example of Lenz's law for magnetic systems. This law, deduced by the Russian-born physicist Heinrich Friedrich Emil Lenz, states that "what happens is that which opposes any change in the system."

Faraday's law is valid regardless of the process that causes the magnetic flux to change. It may be that a magnet is moved closer to a circuit or that a circuit is moved closer to a magnet. Figure 40 shows a magnet brought near a conducting ring and gives the direction of the induced current and field, thus illustrating both Faraday's and Lenz's laws. Another alternative is that the circuit may change in size in a fixed external magnetic field or, as in the case of alternating-current generation, that the circuit may be a coil of conducting wire rotating in a magnetic field so that the flux Φ varies sinusoidally in time.

By courtesy of the Department of Physics and Astronomy, Michigan State University

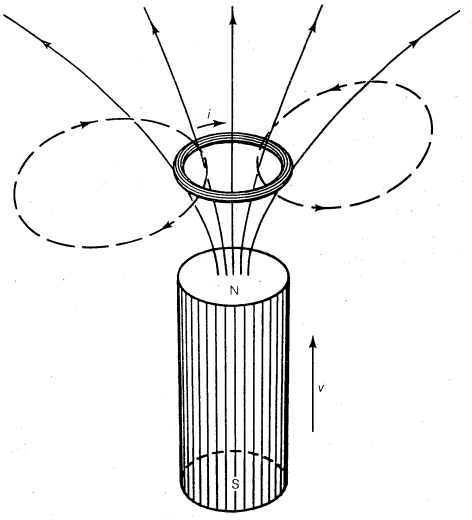

Figure 40: *Demonstration of Faraday's and Lenz's laws.* When a magnet is moved toward a conducting ring, an induced electromotive force causes a current i to flow in a direction such that the magnetic field inside the ring (represented by the two dashed field lines) opposes the increase of flux through the ring from the approaching magnet (see text).

The magnetic flux Φ through a circuit has to be considered carefully in the application of Faraday's law given in equation (43). For example, if a circuit consists of a coil with five closely spaced turns and if φ is the magnetic flux through a single turn, then the value of Φ for the five-turn circuit that must be used in Faraday's law is $\Phi = 5\varphi$. If the five turns are not the same size and closely spaced, the problem of determining Φ can be quite complex.

Self-inductance and mutual inductance. The self-inductance of a circuit is used to describe the reaction of the circuit to a changing current in the circuit, while the mutual inductance with respect to a second circuit describes the reaction to a changing current in the second circuit. When a current i_1 flows in circuit 1, i_1 produces a magnetic field $\boldsymbol{B}_1$; the magnetic flux through circuit 1 due to current i_1 is Φ_{11}. Since $\boldsymbol{B}_1$ is proportional to i_1, Φ_{11} is as well. The constant of proportionality is the self-inductance L_1 of the circuit. It is defined by the equation

$$\Phi_{11} = L_1 i_1. \tag{44}$$

As indicated earlier, the units of inductance are henrys. If a second circuit is present, some of the field $\boldsymbol{B}_1$ will pass through circuit 2 and there will be a magnetic flux Φ_{21} in circuit 2 due to the current i_1. The mutual inductance M_{21} is given by

$$\Phi_{21} = M_{21} i_1. \tag{45}$$

The magnetic flux in circuit 1 due to a current in circuit 2 is given by $\Phi_{12} = M_{12} i_2$. An important property of the mutual inductance is that $M_{21} = M_{12}$. It is therefore sufficient to use the label M without subscripts for the mutual inductance of two circuits.

The value of the mutual inductance of two circuits can range from $+\sqrt{L_1 L_2}$ to $-\sqrt{L_1 L_2}$, depending on the flux linkage between the circuits. If the two circuits are very far apart or if the field of one circuit provides no magnetic flux through the other circuit, the mutual inductance is zero. The maximum possible value of the mutual inductance of two circuits is approached as the two circuits produce $\boldsymbol{B}$ fields with increasingly similar spatial configurations.

If the rate of change with respect to time is taken for the terms on both sides of equation (44), the result is $d\Phi_{11}/dt = L_1 di_1/dt$. According to Faraday's law, $d\Phi_{11}/dt$ is the negative of the induced electromotive force. The result is the equation frequently used for a single inductor in an AC circuit—*i.e.*,

$$\text{emf} = -L\frac{di}{dt}. \tag{46}$$

The phenomenon of self-induction was first recognized by the American scientist Joseph Henry. He was able to generate large and spectacular electric arcs by interrupting the current in a large copper coil with many turns. While a steady current is flowing in a coil, the energy in the magnetic field is given by $\frac{1}{2}Li^2$. If both the inductance L and the current i are large, the amount of energy is also large. If the current is interrupted, as, for example, by opening a knife-blade switch, the current and therefore the magnetic flux through the coil drop quickly. Equation (46) describes the resulting electromotive force induced in the coil, and a large potential difference is developed between the two poles of the switch. The energy stored in the magnetic field of the coil is dissipated as heat and radiation in an electric arc across the space between the terminals of the switch. Due to advances in superconducting wires for electromagnets, it is possible to use large magnets with magnetic fields of several teslas for temporarily storing electric energy as energy in the magnetic field. This is done to accommodate short-term fluctuations in the consumption of electric power.

A transformer is an example of a device that uses circuits with maximum mutual induction. Figure 41 illustrates the configuration of a typical transformer. Here, coils of insulated conducting wire are wound around a ring of iron constructed of thin isolated laminations or sheets. The laminations minimize eddy currents in the iron. Eddy

By courtesy of the Department of Physics and Astronomy, Michigan State University

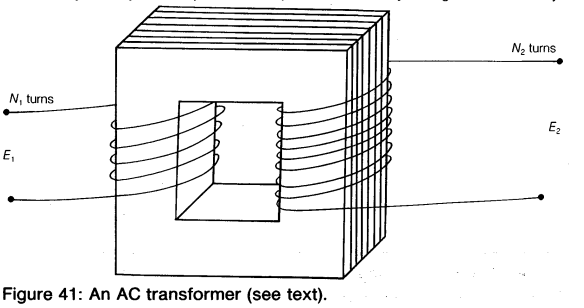

Figure 41: An AC transformer (see text).

Eddy currents

currents are circulatory currents induced in the metal by the changing magnetic field. These currents produce an undesirable by-product—heat in the iron. Energy loss in a transformer can be reduced by using thinner laminations, very "soft" (low-carbon) iron and wire with a larger cross section, or by winding the primary and secondary circuits with conductors that have very low resistance. Unfortunately, reducing the heat loss increases the cost of transformers. Transformers used to transmit and distribute power are commonly 98 to 99 percent efficient. While eddy currents are a problem in transformers, they are useful for heating objects in a vacuum. Eddy currents are induced in the object to be heated by surrounding a relatively nonconducting vacuum enclosure with a coil carrying a high-frequency alternating current.

In a transformer, the iron ensures that nearly all the lines of $\boldsymbol{B}$ passing through one circuit also pass through the second circuit and that, in fact, essentially all the magnetic flux is confined to the iron. Each turn of the conducting coils has the same magnetic flux; thus, the total flux for each coil is proportional to the number of turns in the coil. As a result, if a source of sinusoidally varying electromotive force is connected to one coil, the electromotive force in the second coil is given by

$$\text{emf}_2 = \text{emf}_1 \frac{N_2}{N_1}. \tag{47}$$

Thus, depending on the ratio of N_2 to N_1, the transformer can be either a step-up or a step-down device for alternating voltages. For many reasons, including safety, generation and consumption of electric power occur at relatively low voltages. Step-up transformers are used to obtain high voltages before electric power is transmitted, since for a given amount of power, the current in the transmission lines is much smaller. This minimizes energy lost by resistive heating of the conductors.

Faraday's law constitutes the basis for the power industry and for the transformation of mechanical energy into electric energy. In 1821, a decade before his discovery of magnetic induction, Faraday conducted experiments with electric wires rotating around compass needles. This earlier work, in which a wire carrying a current rotated around a magnetized needle and a magnetic needle was made to rotate around a wire carrying an electric current, provided the groundwork for the development of the electric motor.

EFFECTS OF VARYING ELECTRIC FIELDS

Maxwell's prediction that a changing electric field generates a magnetic field was a masterstroke of pure theory. The Maxwell equations for the electromagnetic field unified all that was hitherto known about electricity and magnetism and predicted the existence of an electromagnetic phenomenon that can travel as waves with the velocity of $1/\sqrt{\varepsilon_0\mu_0}$ in a vacuum. That velocity, which is based on constants obtained from purely electric measurements, corresponds to the speed of light. Consequently, Maxwell concluded that light itself was an electromagnetic phenomenon. Later, Einstein's special relativity theory postulated that the value of the speed of light is independent of the motion of the source of the light. Since then, the speed of light has been measured with increasing accuracy. In 1983 it was defined to be exactly 299,792,458 metres per second. Together with the cesium clock, which has been used to define the second, the speed of light serves as the new standard for length.

The circuit in Figure 42 is an example of a magnetic field generated by a changing electric field. A capacitor with parallel plates is charged at a constant rate by a steady current flowing through the long, straight leads in Figure 42A.

Ampère's law in circuital form

The objective is to apply Ampère's circuital law for magnetic fields to the path P, which goes around the wire in Figure 42A. This law (named in honour of the French physicist André-Marie Ampère) can be derived from the Biot and Savart equation for the magnetic field produced by a current (equation [34]). Using vector calculus notation, Ampère's law states that the integral $\oint \boldsymbol{B} \cdot d\boldsymbol{l}$ along a closed path surrounding the current i is equal to $\mu_0 i$. (An integral is essentially a sum, and, in this case, $\oint \boldsymbol{B} \cdot d\boldsymbol{l}$ is the sum of $B \cos \theta dl$ taken for a small length of the path until the complete loop is included. At each segment of the path dl, θ is the angle between the field $\boldsymbol{B}$ and $d\boldsymbol{l}$.) The current i in Ampère's law is the total flux of the current density $\boldsymbol{J}$ through any surface surrounded by the closed path. In Figure 42A, the closed path is labeled P, and a surface S_1 is surrounded by path P. All the current density through S_1 lies within the conducting wire. The total flux of the current density is the current i flowing through the wire. The result for surface S_1 reflects the value of the magnetic field around the wire in the region of the path P. In Figure 42B, path P is the same but the surface S_2 passes between the two plates of the capacitor. The value of the total flux of the current density through the surface should also be i. There is, however, clearly no motion of charge at all through the surface S_2. The dilemma is that the value of the integral $\oint \boldsymbol{B} \cdot d\boldsymbol{l}$ for the path P cannot be both $\mu_0 i$ and zero.

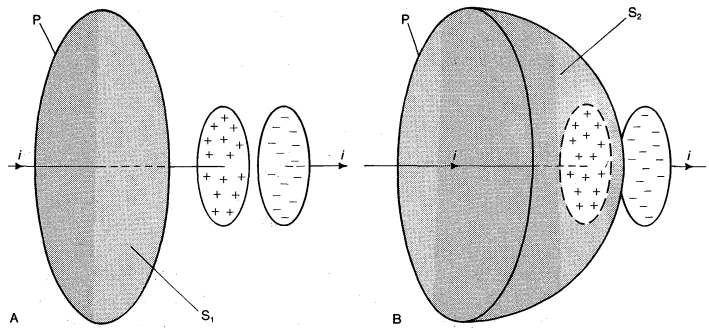

Figure 42: Current i charging a capacitor as an illustration of Maxwell's displacement current (see text).
By courtesy of the Department of Physics and Astronomy, Michigan State University

Maxwell's resolution of this dilemma was his conclusion that there must be some other kind of current density, called the displacement current $\boldsymbol{J}_d$, for which the total flux through the surface S_2 would be the same as the current i through the surface S_1. $\boldsymbol{J}_d$ would take, for the surface S_2, the place of the current density $\boldsymbol{J}$ associated with the movement of charge, since $\boldsymbol{J}$ is clearly zero due to the lack of charges between the plates of the capacitor. What happens between the plates while the current i is flowing? Because the amount of charge on the capacitor increases with time, the electric field between the plates increases with time too. If the current stops, there is an electric field between the plates as long as the plates are charged, but there is no magnetic field around the wire. Maxwell decided that the new type of current density was associated with the changing of the electric field. He found that

$$\boldsymbol{J}_d = \frac{d\boldsymbol{D}}{dt}, \tag{48}$$

where $\boldsymbol{D} = \varepsilon_0 \boldsymbol{E}$ and $\boldsymbol{E}$ is the electric field between the plates. In situations where matter is present, the field $\boldsymbol{D}$ in equation (48) is modified to include polarization effects; the result is $\boldsymbol{D} = \varepsilon_0 \boldsymbol{E} + \boldsymbol{P}$. The field $\boldsymbol{D}$ is measured in coulombs per square metre. Adding the displacement current to Ampère's law represented Maxwell's prediction that a changing electric field also could be a source of the magnetic field $\boldsymbol{B}$. Following Maxwell's predictions of electromagnetic waves, the German physicist Heinrich Hertz initiated the era of radio communications in 1887 by generating and detecting electromagnetic waves.

Maxwell's equations

Using vector calculus notation, the four equations of Maxwell's theory of electromagnetism are

$$\text{I. div } \boldsymbol{D} = \rho, \tag{49}$$

$$\text{II. div } \boldsymbol{B} = 0, \tag{50}$$

$$\text{III. } \textit{curl } \boldsymbol{E} = -\frac{d\boldsymbol{B}}{dt}, \tag{51}$$

$$\text{IV. } \textit{curl } \boldsymbol{H} = \boldsymbol{J} + \frac{d\boldsymbol{D}}{dt}, \tag{52}$$

where $\boldsymbol{D} = \varepsilon_0 \boldsymbol{E} + \boldsymbol{P}$, and $\boldsymbol{H} = \boldsymbol{B}/\mu_0 - \boldsymbol{M}$. The first equation is based on Coulomb's inverse square law for the force between two charges; it is a form of Gauss's law, which

relates the flux of the electric field through a closed surface to the total charge enclosed by the surface. The second equation is based on the fact that apparently no magnetic monopoles exist in nature; if they did, they would be point sources of magnetic field. The third is a statement of Faraday's law of magnetic induction, which reveals that a changing magnetic field generates an electric field. The fourth is Ampère's law as extended by Maxwell to include the displacement current discussed above; it associates a magnetic field to a changing electric field as well as to an electric current.

Maxwell's four equations represent a complete description of the classical theory of electromagnetism. His discovery that light is an electromagnetic wave meant that optics could be understood as part of electromagnetism. Only in microscopic situations is it necessary to modify Maxwell's equations to include quantum effects. That modification, known as quantum electrodynamics (QED), accounts for certain atomic properties to a degree of precision exceeding one part in 100 million.

Sometimes it is necessary to shield apparatus from external electromagnetic fields. For a static electric field, this is a simple matter; the apparatus is surrounded by a shield made of a good conductor (*e.g.*, copper). Shielding apparatus from a steady magnetic field is more difficult because materials with infinite magnetic permeability μ do not exist; for example, a hollow shield made of soft iron will reduce the magnetic field inside to a considerable extent but not completely. As discussed earlier, it is sometimes possible to superpose a field in the opposite direction to produce a very low field region and then to use additional material with a high μ for shielding. In the case of electromagnetic waves, the penetration of the waves in matter varies, depending on the frequency of the radiation and the electric conductivity of the medium. The skin depth δ (which is the distance in the conducting medium traversed for an amplitude decrease of $1/e$, about 1/3) is given by

$$\delta = \sqrt{\frac{2}{\omega \mu_0 \sigma_J}}.$$

At high frequency, the skin depth is small. Therefore, to transmit electronic messages through seawater, for example, a very low frequency must be used to get a reasonable fraction of the signal far below the surface.

A metal shield can have some holes in it and still be effective. For instance, a typical microwave oven has a frequency of 2.5 gigahertz, which corresponds to a wavelength of about 12 centimetres for the electromagnetic wave inside the oven. The metal shield on the door has small holes about two millimetres in diameter; the shield works because the wavelength of the microwave radiation is much greater than the size of the holes. On the other hand, the same shield is not effective with radiation of a much shorter wavelength. Visible light passes through the holes in the shield, as evidenced by the fact that it is possible to see inside a microwave oven when the door is closed. (E.Ka./S.McG.)

Electric properties of matter

PIEZOELECTRICITY

Some solids, notably certain crystals, have permanent electric polarization. Other crystals become electrically polarized when subjected to stress. In electric polarization, the centre of positive charge within an atom, molecule, or crystal lattice element is separated slightly from the centre of negative charge. Piezoelectricity (literally "pressure electricity") is observed if a stress is applied to a solid, for example, by bending, twisting, or squeezing it. If a thin slice of quartz is compressed between two electrodes, a potential difference occurs; conversely, if the quartz crystal is inserted into an electric field, the resulting stress changes its dimensions. Piezoelectricity is responsible for the great precision of clocks and watches equipped with quartz oscillators. It also is used in electric guitars and various other musical instruments to transform mechanical vibrations into corresponding electric signals, which are then amplified and converted to sound by acoustical speakers.

Electric polarization due to mechanical stress

A crystal under stress exhibits the direct piezoelectric effect; a polarization P, proportional to the stress, is produced. In the converse effect, an applied electric field produces a distortion of the crystal, represented by a strain proportional to the applied field. The basic equations of piezoelectricity are $P = d \times stress$ and $E = strain/d$. The piezoelectric coefficient d (in metres per volt) is approximately 3×10^{-12} for quartz, 5×-10^{-11} for ammonium dihydrogen phosphate, and 3×10^{-10} for lead zirconate titanate.

For an elastic body, the stress is proportional to the strain—*i.e.*, $stress = Y_e \times strain$. The proportionality constant is the coefficient of elasticity Y_e, also called Young's modulus for the English physicist Thomas Young. Using that relation, the induced polarization can be written as $P = dY_e \times strain$, while the stress required to keep the strain constant when the crystal is in an electric field is $stress = -dY_eE$. The strain in a deformed elastic body is the fractional change in the dimensions of the body in various directions; the stress is the internal pressure along the various directions. Both are second-rank tensors, and, since electric field and polarization are vectors, the detailed treatment of piezoelectricity is complex. The equations above are oversimplified but can be used for crystals in certain orientations.

The polarization effects responsible for piezoelectricity arise from small displacements of ions in the crystal lattice. Such an effect is not found in crystals with a centre of symmetry. The direct effect can be quite strong; a potential $V = Y_e d\delta/\varepsilon_0 K$ is generated in a crystal compressed by an amount δ, where K is the dielectric constant. If lead zirconate titanate is placed between two electrodes and a pressure causing a reduction of only 1/20th of one millimetre is applied, a 100,000-volt potential is produced. The direct effect is used, for example, to generate an electric spark with which to ignite natural gas in a heating unit or an outdoor cooking grill.

In practice, the converse piezoelectric effect, which occurs when an external electric field changes the dimensions of a crystal, is small because the electric fields that can be generated in a laboratory are minuscule compared to those existing naturally in matter. A static electric field of 10^6 volts per metre produces a change of only about 0.001 millimetre in the length of a one-centimetre quartz crystal. The effect can be enhanced by the application of an alternating electric field of the same frequency as the natural mechanical vibration frequency of the crystal. Many of the crystals have a quality factor Q of several hundred, and, in the case of quartz, the value can be 10^6. The result is a piezoelectric coefficient a factor Q higher than for a static electric field. The very large Q of quartz is exploited in electronic oscillator circuits to make remarkably accurate timepieces. The mechanical vibrations that can be induced in a crystal by the converse piezoelectric effect are also used to generate ultrasound, which is sound with a frequency far higher than frequencies audible to the human ear—above 20 kilohertz. The reflected sound is detectable by the direct effect. Such effects form the basis of ultrasound systems used to fathom the depths of lakes and waterways and to locate fish. Ultrasound has found application in medical imaging (*e.g.*, fetal monitoring and the detection of abnormalities such as prostate tumours). The use of ultrasound makes it possible to produce detailed pictures of organs and other internal structures because of the variation in the reflection of sound from various body tissues. Thin films of polymeric plastic with a piezoelectric coefficient of about 10^{-11} metres per volt are being developed and have numerous potential applications as pressure transducers.

Generation of ultrasound

ELECTRO-OPTIC PHENOMENA

The index of refraction n of a transparent substance is related to its electric polarizability and is given by $n^2 = 1 + \chi_e/\varepsilon_0$. As discussed earlier, χ_e is the electric susceptibility of a medium, and the equation $\boldsymbol{P} = \chi_e \boldsymbol{E}$ relates the polarization of the medium to the applied electric field. For most matter, χ_e is not a constant independent of the value of the electric field, but rather depends to a small degree on the value of the field. Thus, the index of

refraction can be changed by applying an external electric field to a medium. In liquids, glasses, and crystals that have a centre of symmetry, the change is usually very small. Called the Kerr effect (for its discoverer, the Scottish physicist John Kerr), it is proportional to the square of the applied electric field. In noncentrosymmetric crystals, the change in the index of refraction n is generally much greater; it depends linearly on the applied electric field and is known as the Pockels effect (after the German physicist F. R. Pockels).

Modulation of the index of refraction

A varying electric field applied to a medium will modulate its index of refraction. This change in the index of refraction can be used to modulate light and make it carry information. A crystal widely used for its Pockels effect is potassium dihydrogen phosphate, which has good optical properties and low dielectric losses even at microwave frequencies.

An unusually large Kerr effect is found in nitrobenzene, a liquid with highly "acentric" molecules that have large electric dipole moments. Applying an external electric field partially aligns the otherwise randomly oriented dipole moments and greatly enhances the influence of the field on the index of refraction. The length of the path of light through nitrobenzene can be adjusted easily because it is a liquid.

THERMOELECTRICITY

When two metals are placed in electric contact, electrons flow out of the one in which the electrons are less bound and into the other. The binding is measured by the location of the so-called Fermi level of electrons in the metal; the higher the level, the lower is the binding. The Fermi level represents the demarcation in energy within the conduction band of a metal between the energy levels occupied by electrons and those that are unoccupied. The energy of an electron at the Fermi level is $-W$ relative to a free electron outside the metal. The flow of electrons between the two conductors in contact continues until the change in electrostatic potential brings the Fermi levels of the two metals (W_1 and W_2) to the same value. This electrostatic potential is called the contact potential φ_{12} and is given by $e\varphi_{12} = W_1 - W_2$, where e is 1.6×10^{-19} coulomb.

If a closed circuit is made of two different metals, there will be no net electromotive force in the circuit because the two contact potentials oppose each other and no current will flow. There will be a current if the temperature of one of the junctions is raised with respect to that of the second.

Generation of a thermal electromotive force

There is a net electromotive force generated in the circuit, as it is unlikely that the two metals will have Fermi levels with identical temperature dependence. To maintain the temperature difference, heat must enter the hot junction and leave the cold junction; this is consistent with the fact that the current can be used to do mechanical work. The generation of a thermal electromotive force at a junction is called the Seebeck effect (after the Estonian-born German physicist Thomas Johann Seebeck). The electromotive force is approximately linear with the temperature difference between two junctions of dissimilar metals, which are called a thermocouple. For a thermocouple made of iron and constantan (an alloy of 60 percent copper and 40 percent nickel), the electromotive force is about five millivolts when the cold junction is at 0° C and the hot junction at 100° C. One of the principal applications of the Seebeck effect is the measurement of temperature. The chemical properties of the medium, the temperature of which is measured, and the sensitivity required dictate the choice of components of a thermocouple.

The absorption or release of heat at a junction in which there is an electric current is called the Peltier effect (after the French physicist Jean-Charles Peltier). Both the Seebeck and Peltier effects also occur at the junction between a metal and a semiconductor and at the junction between two semiconductors. The development of semiconductor thermocouples (*e.g.*, those consisting of *n*-type and *p*-type bismuth telluride) has made the use of the Peltier effect practical for refrigeration. Sets of such thermocouples are connected electrically in series and thermally in parallel. When an electric current is made to flow, a temperature difference, which depends on the current, develops between the two junctions. If the temperature of the hotter junction is kept low by removing heat, the second junction can be tens of degrees colder and act as a refrigerator. Peltier refrigerators are used to cool small bodies; they are compact, have no moving mechanical parts, and can be regulated to maintain precise and stable temperatures. They are employed in numerous applications, as, for example, to keep the temperature of a sample constant while it is on a microscope stage.

THERMIONIC EMISSION

A metal contains mobile electrons in a partially filled band of energy levels—*i.e.*, the conduction band. These electrons, though mobile within the metal, are rather tightly bound to it. The energy that is required to release a mobile electron from the metal varies from about 1.5 to approximately six electron volts, depending on the metal. In thermionic emission, some of the electrons acquire enough energy from thermal collisions to escape from the metal. The number of electrons emitted and therefore the thermionic emission current depend critically on temperature.

In a metal the conduction-band levels are filled up to the Fermi level, which lies at an energy $-W$ relative to a free electron outside the metal. The work function of the metal, which is the energy required to remove an electron from the metal, is therefore equal to W. At a temperature of 1,000 K only a small fraction of the mobile electrons have sufficient energy to escape. The electrons that can escape are moving so fast in the metal and have such high kinetic energies that they are unaffected by the periodic potential caused by atoms of the metallic lattice. They behave like electrons trapped in a region of constant potential. Because of this, when the rate at which electrons escape from the metal is calculated, the detailed structure of the metal has little influence on the final result. A formula known as Richardson's law (first proposed by the English physicist Owen W. Richardson) is roughly valid for all metals. It is usually expressed in terms of the emission current density (J) as

$$J = AT^2e^{-W/kT}$$

in amperes per square metre. The Boltzmann constant k has the value 8.62×10^{-5} electron volts per kelvin, and temperature T is in kelvins. The constant A is 1.2×10^6 ampere degree squared per square metre, and varies slightly for different metals. For tungsten, which has a work function W of 4.5 electron volts, the value of A is 7×10^5 amperes per square metre kelvin squared and the current density at T equaling 2,400 K is 0.14 ampere per square centimetre. J rises rapidly with temperature. If T is increased to 2,600 K, J rises to 0.9 ampere per square centimetre. Tungsten does not emit appreciably at 2,000 K or below (less than 0.05 milliampere per square centimetre) because its work function of 4.5 electron volts is large compared to the thermal energy kT, which is only 0.16 electron volt. In vacuum tubes, the cathode usually is coated with a mixture of barium and strontium oxides. At 1,000 K the oxide has a work function of approximately 1.3 electron volts and is a reasonably good conductor. Currents of several amperes per square centimetre can be drawn from oxide cathodes, but in practice the current density is generally less than 0.2 ampere per square centimetre. The oxide layer deteriorates rapidly when higher current densities are drawn.

SECONDARY ELECTRON EMISSION

If electrons with energies of 10 to 1,000 electron volts strike a metal surface in a vacuum, their energy is lost in collisions in a region near the surface, and most of it is transferred to other electrons in the metal. Because this occurs near the surface, some of these electrons may be ejected from the metal and form a secondary emission current. The ratio of secondary electrons to incident electrons is known as the secondary emission coefficient. For low-incident energies (below about one electron volt), the primary electrons tend to be reflected and the secondary emission coefficient is near unity. With increasing energy, the coefficient at first falls and then at about 10 elec-

tron volts begins to rise again, usually reaching a peak of value between 2 and 4 at energies of a few hundred electron volts. At higher energies, the primary electrons penetrate so far below the surface before losing energy that the excited electrons have little chance of reaching the surface and escaping. The secondary emission coefficients fall and, when the electrons have energies exceeding 20 kiloelectron volts, are usually well below unity. Secondary emission also can occur in insulators. Because many insulators have rather high secondary emission coefficients, it is often useful when high secondary emission yields are required to coat a metal electrode with a thin insulator layer a few atoms thick.

PHOTOELECTRIC CONDUCTIVITY

If light with a photon energy hv that exceeds the work function W falls on a metal surface, some of the incident photons will transfer their energy to electrons, which then will be ejected from the metal. Since hv is greater than W, the excess energy $hv - W$ transferred to the electrons will be observed as their kinetic energy outside the metal. The relation between electron kinetic energy E and the frequency v (that is, $E = hv - W$) is known as the Einstein relation, and its experimental verification helped to establish the validity of quantum theory. The energy of the electrons depends on the frequency of the light, while the intensity of the light determines the rate of photoelectric emission.

In a semiconductor the valence band of energy levels is almost completely full while the conduction band is almost empty. The conductivity of the material derives from the few holes present in the valence band and the few electrons in the conduction band. Electrons can be excited from the valence to the conduction band by light photons having an energy hv that is larger than energy gap E_g between the bands. The process is an internal photoelectric effect. The value of E_g varies from semiconductor to semiconductor. For lead sulfide, the threshold frequency occurs in the infrared, whereas for zinc oxide it is in the ultraviolet. For silicon, E_g equals 1.1 electron volts, and the threshold wavelength is in the infrared, about 1,100 nanometres. Visible radiation produces electron transitions with almost unity quantum efficiency in silicon. Each transition yields a hole–electron pair (*i.e.,* two carriers) that contributes to electric conductivity. For example, if one milliwatt of light strikes a sample of pure silicon in the form of a thin plate one square centimetre in area and 0.03 centimetre thick (which is thick enough to absorb all incident light), the resistance of the plate will be decreased by a factor of about 1,000. In practice, photoconductive effects are not usually as large as this, but this example indicates that appreciable changes in conductivity can occur even with low illumination. Photoconductive devices are simple to construct and are used to detect visible, infrared, and ultraviolet radiation.

Internal photoelectric effect

ELECTROLUMINESCENCE

Conduction electrons moving in a solid under the influence of an electric field usually lose kinetic energy in low-energy collisions as fast as they acquire it from the field. Under certain circumstances in semiconductors, however, they can acquire enough energy between collisions to excite atoms in the next collision and produce radiation as the atoms de-excite. A voltage applied across a thin layer of zinc sulfide powder causes just such an electroluminescent effect. Electroluminescent panels are of more interest as signal indicators and display devices than as a source of general illumination.

A somewhat similar effect occurs at the junction in a reverse-biased semiconductor p–n junction diode—*i.e.,* a p–n junction diode in which the applied potential is in the direction of small current flow. Electrons in the intense field at the depleted junction easily acquire enough energy to excite atoms. Little of this energy finally emerges as light, though the effect is readily visible under a microscope.

When a junction between a heavily doped n-type material and a less doped p-type material is forward-biased so that a current will flow easily, the current consists mainly of electrons injected from the n-type material into the conduction band of the p-type material. These electrons ultimately drop into holes in the valence band and release energy equal to the energy gap of the material. In most cases, this energy E_g is dissipated as heat, but in gallium phosphide and especially in gallium arsenide, an appreciable fraction appears as radiation, the frequency v of which satisfies the relation $hv = E_g$. In gallium arsenide, though up to 30 percent of the input electric energy is available as radiation, the characteristic wavelength of 900 nanometres is in the infrared. Gallium phosphide gives off visible green light but is inefficient; other related III-V compound semiconductors emit light of different colours. Electroluminescent injection diodes of such materials, commonly known as light-emitting diodes (LEDs), are employed mainly as indicator lamps and numeric displays. Semiconductor lasers built with layers of indium phosphide and of gallium indium arsenide phosphide have proved more useful. Unlike gas or optically pumped lasers, these semiconductor lasers can be modulated directly at high frequencies. Not only are they used in devices such as compact digital disc players but also as light sources for long-distance optical fibre communications systems (see ELECTRONICS: *Light-emitting diodes and semiconductor lasers*).

BIOELECTRIC EFFECTS

Bioelectricity refers to the generation or action of electric currents or voltages in biological processes. Bioelectric phenomena include fast signaling in nerves and the triggering of physical processes in muscles or glands. There is some similarity among the nerves, muscles, and glands of all organisms, possibly because fairly efficient electrochemical systems evolved early. Scientific studies tend to focus on the following: nerve or muscle tissue; such organs as the heart, brain, eye, ear, stomach, and certain glands; electric organs in some fish; and potentials associated with damaged tissue.

Electric activity in living tissue is a cellular phenomenon, dependent on the cell membrane. The membrane acts like a capacitor, storing energy as electrically charged ions on opposite sides of the membrane. The stored energy is available for rapid utilization and stabilizes the membrane system so that it is not activated by small disturbances.

Cells capable of electric activity show a resting potential in which their interiors are negative by about 0.1 volt or less compared with the outside of the cell. When the cell is activated, the resting potential may reverse suddenly in sign; as a result, the outside of the cell becomes negative and the inside positive. This condition lasts for a short time, after which the cell returns to its original resting state. This sequence, called depolarization and repolarization, is accompanied by a flow of substantial current through the active cell membrane, so that a "dipole-current source" exists for a short period. Small currents flow from this source through the aqueous medium containing the cell and are detectable at considerable distances from it. These currents, originating in active membrane, are functionally significant very close to their site of origin but must be considered incidental at any distance from it. In electric fish, however, adaptations have occurred, and this otherwise incidental electric current is actually utilized. In some species the external current is apparently used for sensing purposes, while in others it is used to stun or kill prey. In both cases, voltages from many cells add up in series, thus assuring that the specialized functions can be performed. Bioelectric potentials detected at some distance from the cells generating them may be as small as the 20 or 30 microvolts associated with certain components of the human electroencephalogram or the millivolt of the human electrocardiogram. On the other hand, electric eels can deliver electric shocks with voltages as large as 1,000 volts.

Depolarization and repolarization in cells

In addition to the potentials originating in nerve or muscle cells, relatively steady or slowly varying potentials (often designated dc) are known. These dc potentials occur in the following cases: in areas where cells have been damaged and where ionized potassium is leaking (as much as 50 millivolts); when one part of the brain is compared with another part (up to one millivolt); when different areas of the skin are compared (up to 10 millivolts); within pockets in active glands, *e.g.,* follicles in the thyroid (as

high as 60 millivolts); and in special structures in the inner ear (about 80 millivolts).

A small electric shock caused by static electricity during cold, dry weather is a familiar experience. While the sudden muscular reaction it engenders is sometimes unpleasant, it is usually harmless. Even though static potentials of several thousand volts are involved, a current exists for only a brief time and the total charge is very small. A steady current of two milliamperes through the body is barely noticeable. Severe electrical shock can occur above 10 milliamperes, however. Lethal current levels range from 100 to 200 milliamperes. Larger currents, which produce burns and unconsciousness, are not fatal if the victim is given prompt medical care. (Above 200 milliamperes, the heart is clamped during the shock and does not undergo ventricular fibrillation.) Prevention clearly includes avoiding contact with live electric wiring; risk of injury increases considerably if the skin is wet, as the electric resistance of wet skin may be hundreds of times smaller than that of dry skin. (F.N.H.R./E.E.S./E.Ka.)

Magnetic properties of matter

All matter exhibits magnetic properties when placed in an external magnetic field. Even substances like copper and aluminum that are not normally thought of as having magnetic properties are affected by the presence of a magnetic field such as that produced by either pole of a bar magnet. Depending on whether there is an attraction or repulsion by the pole of a magnet, matter is classified as being either paramagnetic or diamagnetic, respectively. A few materials, notably iron, show a very large attraction toward the pole of a permanent bar magnet; materials of this kind are called ferromagnetic.

Classification of matter as paramagnetic, diamagnetic, or ferromagnetic

In 1845 Faraday became the first to classify substances as either diamagnetic or paramagnetic. He based this classification on his observation of the force exerted on substances in an inhomogeneous magnetic field. At moderate field strengths, the magnetization $\boldsymbol{M}$ of a substance is linearly proportional to the strength of the applied field $\boldsymbol{H}$. The magnetization is specified by the magnetic susceptibility χ (previously labeled χ_m), defined by the relation $\boldsymbol{M} = \chi \boldsymbol{H}$. A sample of volume V placed in a field $\boldsymbol{H}$ directed in the x-direction and increasing in that direction at a rate $d\boldsymbol{H}/dx$ will experience a force in the x-direction of $\boldsymbol{F} = \chi \mu_0 V H\ (d\boldsymbol{H}/dx)$. If the magnetic susceptibility χ is positive, the force is in the direction of increasing field strength, whereas if χ is negative, it is in the direction of decreasing field strength. Measurement of the force $\boldsymbol{F}$ in a known field $\boldsymbol{H}$ with a known gradient $d\boldsymbol{H}/dx$ is the basis of a number of accurate methods of determining χ.

Substances for which the magnetic susceptibility is negative (*e.g.*, copper and silver) are classified as diamagnetic. The susceptibility is small, on the order of -10^{-5} for solids and liquids and -10^{-8} for gases. A characteristic feature of diamagnetism is that the magnetic moment per unit mass in a given field is virtually constant for a given substance over a very wide range of temperatures. It changes little between solid, liquid, and gas; the variation in the susceptibility between solid or liquid and gas is almost entirely due to the change in the number of molecules per unit volume. This indicates that the magnetic moment induced in each molecule by a given field is primarily a property characteristic of the molecule.

Substances for which the magnetic susceptibility is positive are classed as paramagnetic. In a few cases (including most metals), the susceptibility is independent of temperature, but in most compounds it is strongly temperature dependent, increasing as the temperature is lowered. Measurements by the French physicist Pierre Curie in 1895 showed that for many substances the susceptibility is inversely proportional to the absolute temperature T; that is, $\chi = C/T$. This approximate relationship is known as Curie's law and the constant C as the Curie constant. A more accurate equation is obtained in many cases by modifying the above equation to $\chi = C/(T - \theta)$, where θ is a constant. This equation is called the Curie–Weiss law (after Curie and Pierre-Ernest Weiss, another French physicist). From the form of this last equation, it is clear that at the temperature $T = \theta$, the value of the susceptibility becomes infinite. Below this temperature, the material exhibits spontaneous magnetization—*i.e.*, it becomes ferromagnetic. Its magnetic properties are then very different from those in the paramagnetic or high-temperature phase. In particular, although its magnetic moment can be changed by the application of a magnetic field, the value of the moment attained in a given field is not always the same; it depends on the previous magnetic, thermal, and mechanical treatment of the sample.

Curie–Weiss law

INDUCED AND PERMANENT ATOMIC MAGNETIC DIPOLES

Whether a substance is paramagnetic or diamagnetic is determined primarily by the presence or absence of free magnetic dipole moments (*i.e.*, those free to rotate) in its constituent atoms. When there are no free moments, the magnetization is produced by currents of the electrons in their atomic orbits. The substance is then diamagnetic, with a negative susceptibility independent of both field strength and temperature.

In matter with free magnetic dipole moments, the orientation of the moments is normally random and, as a result, the substance has no net magnetization. When a magnetic field is applied, the dipoles are no longer completely randomly oriented; more dipoles point with the field than against the field. When this results in a net positive magnetization in the direction of the field, the substance has a positive susceptibility and is classified as paramagnetic.

The forces opposing alignment of the dipoles with the external magnetic field are thermal in origin and thus weaker at low temperatures. The excess number of dipoles pointing with the field is determined by (mB/kT), where mB represents the magnetic energy and kT the thermal energy. When the magnetic energy is small compared to the thermal energy, the excess number of dipoles pointing with the field is proportional to the field and inversely proportional to the absolute temperature, corresponding to Curie's law. When the value of (mB/kT) is large enough to align nearly all the dipoles with the field, the magnetization approaches a saturation value.

There is a third category of matter in which intrinsic moments are not normally present but appear under the influence of an external magnetic field. The intrinsic moments of conduction electrons in metals behave this way. One finds a small positive susceptibility independent of temperature comparable with the diamagnetic contribution, so that the overall susceptibility of a metal may be positive or negative. The molar susceptibility of elements is shown in Figure 43.

In addition to the forces exerted on atomic dipoles by an external magnetic field, mutual forces exist between the dipoles. Such forces vary widely for different substances. Below a certain transition temperature depending on the substance, they produce an ordered arrangement of the orientations of the atomic dipoles even in the absence of an external field. The mutual forces tend to align neighbouring dipoles either parallel or antiparallel to one another. Parallel alignment of atomic dipoles throughout large volumes of the substance results in ferromagnetism, with a permanent magnetization on a macroscopic scale. On the other hand, if equal numbers of atomic dipoles are aligned in opposite directions and the dipoles are of the same size, there is no permanent macroscopic magnetization, and this is known as antiferromagnetism. If the atomic dipoles are of different magnitudes and those pointing in one direction are all different in size from those pointing in the opposite direction, there exists permanent magnetization on a macroscopic scale in an effect known as ferrimagnetism. A simple schematic representation of these different possibilities is shown in Figure 44.

Mutual forces between dipoles

In all cases, the material behaves as a paramagnet above the characteristic transition temperature; it acquires a macroscopic magnetic moment only when an external field is applied.

DIAMAGNETISM

When an electron moving in an atomic orbit is in a magnetic field $\boldsymbol{B}$, the force exerted on the electron pro-

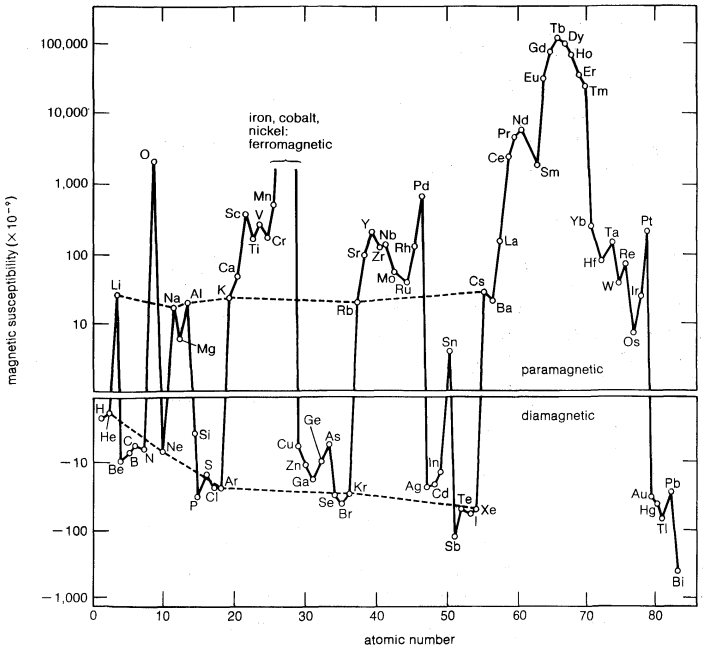

Figure 43: The susceptibility of a kilogram mole of the elements. Broken lines connect the alkali metals (paramagnetic) and the rare gases of the atmosphere (diamagnetic).

duces a small change in the orbital motion; the electron orbit precesses about the direction of $\boldsymbol{B}$. As a result, each electron acquires an additional angular momentum that contributes to the magnetization of the sample. The susceptibility χ is given by

$$\chi = -\mu_0 N \left(\frac{e^2}{6m}\right) \Sigma < r^2 >,$$

where $\Sigma < r^2 >$ is the sum of the mean square radii of all electron orbits in each atom, e and m are the charge and mass of the electron, and N is the number of atoms per unit volume. The negative sign of this susceptibility is a direct consequence of Lenz's law (see above). When $\boldsymbol{B}$ is switched on, the change in motion of each orbit is equivalent to an induced circulating electric current in such a direction that its own magnetic flux opposes the change in magnetic flux through the orbit; *i.e.*, the induced magnetic moment is directed opposite to $\boldsymbol{B}$.

Since the magnetization $\boldsymbol{M}$ is proportional to the number N of atoms per unit volume, it is sometimes useful to give the susceptibility per mole, χ_{mole}. For a kilogram mole (the molecular weight in kilograms), the numerical value of the molar susceptibility is

By courtesy of *Electrical Engineering*

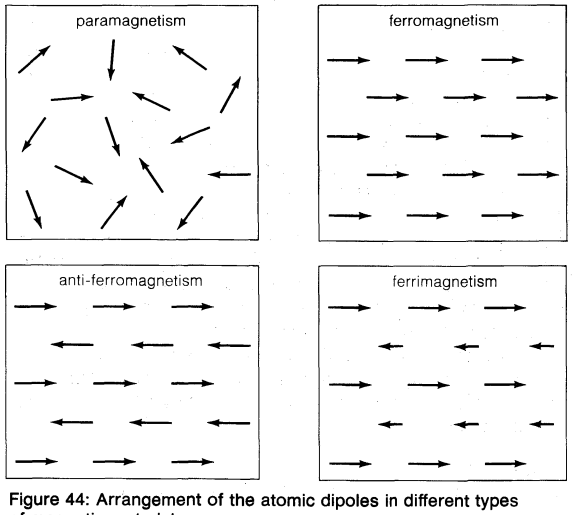

Figure 44: Arrangement of the atomic dipoles in different types of magnetic materials.

$$\chi_{mole} = -3.55 \times 10^{12} \Sigma < r^2 >.$$

For an atom, the mean value of $\Sigma < r^2 >$ is about 10^{-21} square metre and χ_{mole} has values of 10^{-9} to 10^{-10}; the atomic number Z equals the number of electrons in each atom. The quantity $\Sigma < r^2 >$ for each atom, and therefore the diamagnetic susceptibility, is essentially independent of temperature. It is also not affected by the surroundings of the atom.

Diamagnetism in superconductors

A different kind of diamagnetism occurs in superconductors. The conduction electrons are spread out over the entire metal, and so the induced magnetic moment is governed by the size of the superconducting sample rather than by the size of the individual constituent atoms (a very large effective $< r^2 >$). The diamagnetism is so strong that the magnetic field is kept out of the superconductor.

PARAMAGNETISM

Paramagnetism occurs primarily in substances in which some or all of the individual atoms, ions, or molecules possess a permanent magnetic dipole moment. The magnetization of such matter depends on the ratio of the magnetic energy of the individual dipoles to the thermal energy. This dependence can be calculated in quantum theory and is given by the Brillouin function, which depends only on the ratio (B/T). At low magnetic fields, the magnetization is linearly proportional to the field and reaches its maximum saturation value when the magnetic energy is much greater than the thermal energy. Figure 45 shows the dependence of the magnetic moment per ion in units of Bohr magnetons as a function of B/T. (One Bohr magneton equals 9.274×10^{-24} ampere times square metre.)

In substances that have a nuclear magnetic dipole moment, there is a further contribution to susceptibility. The size of the nuclear magnetic moment is only about one-thousandth that of an atom. Per kilogram mole, χ_n is on the order of $10^{-8}/T$; in solid hydrogen this just exceeds the electronic diamagnetism of 1 K.

Curie's law should hold when mB is much smaller than kT, provided that no other forces act on the atomic dipoles. In many solids, the presence of internal forces may cause the susceptibility to vary in a complicated way. If the forces orient the dipoles parallel to each other, the behaviour is ferromagnetic (see below). The forces may orient the dipoles so that the normal state has no free moment. If the force is sufficiently weak, a small magnetic field can reorient the dipoles, resulting in a net magnetization. This type of paramagnetism occurs for conduction electrons in a metal. In normal metals, each occupied electron state has two electrons with opposite spin orientation. This is a consequence of the Pauli principle of quantum mechanics, which permits no greater occupancy of the energetically favoured states. In the presence of a magnetic field, however, it is energetically more favourable for some of the electrons to move to higher states. With only single electrons in these states, the electron moments can be oriented along the field. The resulting paramagnetic susceptibility is independent of temperature. The net susceptibility is independent of temperature. The net susceptibility of a metal can be of either sign, since the diamagnetic and paramagnetic contributions are of comparable magnitudes.

FERROMAGNETISM

A ferromagnetic substance contains permanent atomic magnetic dipoles that are spontaneously oriented parallel to one another even in the absence of an external field. The magnetic repulsion between two dipoles aligned side by side with their moments in the same direction makes it difficult to understand the phenomenon of ferromagnetism. It is known that within a ferromagnetic material, there is a spontaneous alignment of atoms in large clusters. A new type of interaction, a quantum mechanical effect known as the exchange interaction, is involved. A highly simplified description of how the exchange interaction aligns electrons in ferromagnetic materials is given here.

Role of the exchange interaction

The magnetic properties of iron are thought to be the result of the magnetic moment associated with the spin

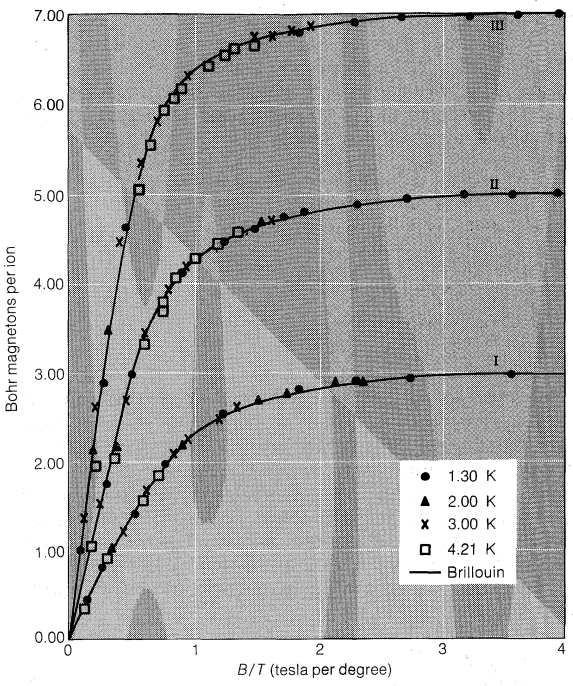

Figure 45: *The approach to saturation in the magnetization of a paramagnetic substance following a Brillouin curve.* The curves I, II, and III refer to ions of chromium, potassium alum, iron ammonium alum, and gadolinium sulfate octahydrate for which $g = 2$ and $j = 3/2$, 5/2, and 7/2, respectively.

of an electron in an outer atomic shell—specifically, the third *d* shell. Such electrons are referred to as magnetization electrons. The Pauli exclusion principle prohibits two electrons from having identical properties; for example, no two electrons can be in the same location and have spins in the same direction. This exclusion can be viewed as a "repulsive" mechanism for spins in the same direction; its effect is opposite that required to align the electrons responsible for the magnetization in the iron domains. However, other electrons with spins in the opposite direction, primarily in the fourth *s* atomic shell, interact at close range with the magnetization electrons, and this interaction is attractive. Because of the attractive effect of their opposite spins, these *s*-shell electrons influence the magnetization electrons of a number of the iron atoms and align them with each other.

A simple empirical representation of the effect of such exchange forces invokes the idea of an effective internal, or molecular, field $\boldsymbol{H}_{int}$, which is proportional in size to the magnetization $\boldsymbol{M}$; that is, $\boldsymbol{H}_{int} = \lambda \boldsymbol{M}$ in which λ is an empirical parameter. The resulting magnetization $\boldsymbol{M}$ equals $\chi_p(\boldsymbol{H} + \lambda \boldsymbol{M})$, in which χ_p is the susceptibility that the substance would have in the absence of the internal field. Assuming that $\chi_p = C/T$, corresponding to Curie's law, the equation $M = C(H + \lambda M)/T$ has the solution $\chi = M/H = C/(T - C\lambda) = C/(T - Tc)$. This result, the Curie–Weiss law, is valid at temperatures greater than the Curie temperature T_c (see below); at such temperatures the substance is still paramagnetic because the magnetization is zero when the field is zero. The internal field, however, makes the susceptibility larger than that given by the Curie law. A plot of $1/\chi$ against T still gives a straight line, as shown in Figure 46, but $1/\chi$ becomes zero when the temperature reaches the Curie temperature.

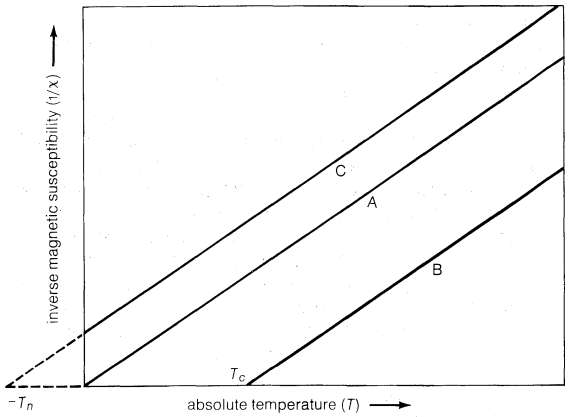

Figure 46: Plot of $1/\chi$. (A) Curie's law. (B) Curie–Weiss law for a ferromagnet with Curie temperature T_c. (C) Curie–Weiss law for an antiferromagnetic substance.

Since $1/\chi = H/M$, $\boldsymbol{M}$ at this temperature must be finite even when the magnetic field is zero. Thus, below the Curie temperature, the substance exhibits a spontaneous magnetization $\boldsymbol{M}$ in the absence of an external field, the essential property of a ferromagnet. Table 4 gives Curie temperature values for various ferromagnetic substances.

Curie temperature as the point of transition

Table 4: Curie Temperatures for Some Ferromagnetic Substances

Iron (Fe)	1,043 K
Cobalt (Co)	1,404 K
Nickel (Ni)	631 K
Gadolinium (Gd)	293 K
"Bismanol" (MnBi)	633 K
Manganese arsenide (MnAs)	318 K

In the ferromagnetic phase below the Curie temperature, the spontaneous alignment is still resisted by random thermal energy, and the spontaneous magnetization $\boldsymbol{M}$ is a function of temperature. The magnitude of $\boldsymbol{M}$ can be found from the paramagnetic equation for the reduced magnetization $M/M_s = f(mB/kT)$ by replacing B with $\mu(H + \lambda M)$. This gives an equation that can be solved numerically if the function f is known. When H equals zero, the curve of (M/M_s) should be a unique function of the ratio (T/T_c) for all substances that have the same function f. Such a curve is shown in Figure 47, together with experimental results for nickel and a nickel–copper alloy.

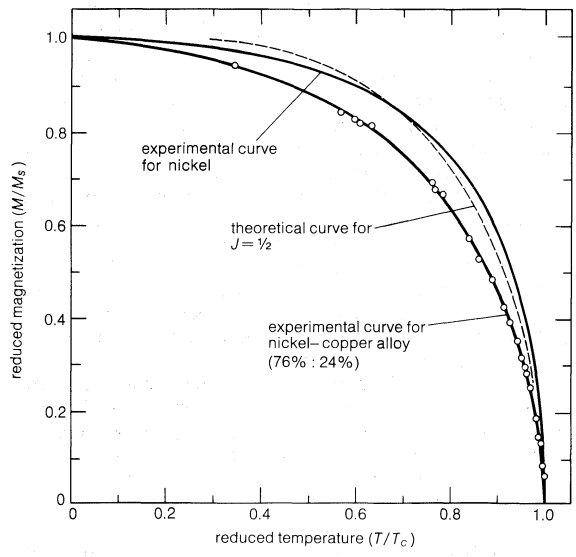

Figure 47: The reduced magnetization M/M_s as a function of reduced temperature T/T_c for a magnet.

The molecular field theory explains the existence of a ferromagnetic phase and the presence of spontaneous magnetization below the Curie temperature. The dependence of the magnetization on the external field is, however, more complex than the Curie–Weiss theory predicts. The magnetization curve is shown in Figure 48 for iron, with the field B in the iron plotted against the external field H. The variation is nonlinear, and B reaches its saturation value S in small fields. The relative permeability $B/\mu_0 H$ attains values of 10^3 to 10^4 in contrast to an ordinary paramagnet, for which μ is about 1.001 at room temperature. On reducing the external field H, the field B does not return along the magnetization curve. Even at $H = 0$, its value is not far below the saturation value.

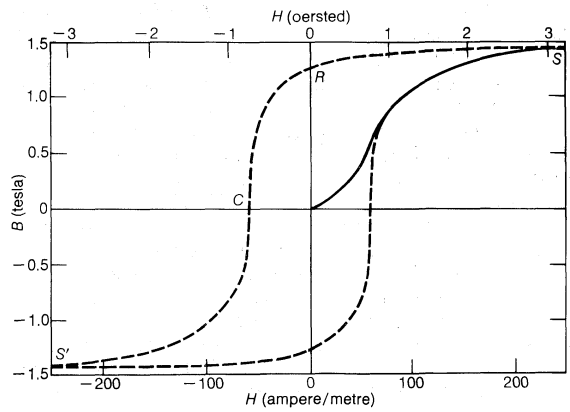

Figure 48: The magnetization curve (solid curve) and hysteresis loop (broken curve) for a ferromagnet.

When $H = 0$ (labeled R in the figure), the magnetic field constitutes what is termed the residual flux density, and the retention of magnetization in zero field is called remanence. When the external field is reversed, the value of B falls and passes through zero (point C) at a field strength known as the coercive force. Further increase in the reverse field H sets up a reverse field B that again quickly reaches a saturation value S'. Finally, as the reverse field is removed and a positive field applied, B traces out the lower broken line back to a positive saturation value. Further cycles of H retrace the broken curve, which is known as the hysteresis curve, because the change in B always lags behind the change in H. The hysteresis curve is not unique unless saturation is attained in each direction; interruption and reversal of the cycle at an intermediate field strength results in a hysteresis curve of smaller size.

Remanence

To explain ferromagnetic phenomena, Weiss suggested that a ferromagnetic substance contains many small regions (called domains), in each of which the substance is magnetized locally to saturations in some direction. In the unmagnetized state, such directions are distributed at random or in such a way that the net magnetization of the whole sample is zero. Application of an external field changes the direction of magnetization of part or all of the domains, setting up a net magnetization parallel to the field. In a paramagnetic substance, atomic dipoles are oriented on a microscopic scale. In contrast, the magnetization of a ferromagnetic substance involves the reorientation of the magnetization of the domains on a macroscopic scale; large changes occur in the net magnetization even when very small fields are applied. Such macroscopic changes are not immediately reversed when the size of the field is reduced or when its direction is changed. This accounts for the presence of hysteresis and for the finite remanent magnetization.

The technological applications of ferromagnetic substances are extensive, and the size and shape of the hysteresis curve are of great importance. A good permanent magnet must have a large spontaneous magnetization in zero field (*i.e.*, a high retentivity) and a high coercive force to prevent its being easily demagnetized by an external field. Both of these imply a "fat," almost rectangular hysteresis loop, typical of a hard magnetic material. On the other hand, ferromagnetic substances subjected to alternating fields, as in a transformer, must have a "thin" hysteresis loop because of an energy loss per cycle that is determined by the area enclosed by the hysteresis loop. Such substances are easily magnetized and demagnetized and are known as soft magnetic materials.

ANTIFERROMAGNETISM

Differences between ferromagnetic and antiferromagnetic substances

In substances known as antiferromagnets, the mutual forces between pairs of adjacent atomic dipoles are caused by exchange interactions, but the forces between adjacent atomic dipoles have signs opposite those in ferromagnets. As a result, adjacent dipoles tend to line up antiparallel to each other instead of parallel. At high temperatures the material is paramagnetic, but below a certain characteristic temperature the dipoles are aligned in an ordered and antiparallel manner. The transition temperature T_n is known as the Néel temperature, after the French physicist Louis-Eugène-Félix Néel, who proposed this explanation of the magnetic behaviour of such materials in 1936. Values of the Néel temperature for some typical antiferromagnetic substances are given in Table 5.

Table 5: Néel Temperature of Antiferromagnetic Substances

Chromium (Cr)	311 K
Manganese fluoride (MnF_2)	67 K
Nickel fluoride (NiF_2)	73 K
Manganese oxide (MnO)	116 K
Ferrous oxide (FeO)	198 K

The ordered antiferromagnetic state is naturally more complicated than the ordered ferromagnetic state, since there must be at least two sets of dipoles pointing in opposite directions. With an equal number of dipoles of the same size on each set, there is no net spontaneous magnetization on a macroscopic scale. For this reason, antiferromagnetic substances have few commercial applications. In most insulating chemical compounds, the exchange forces between the magnetic ions are of an antiferromagnetic nature.

FERRIMAGNETISM

Lodestone, or magnetite (Fe_3O_4), belongs to a class of substances known as ferrites. Ferrites and some other classes of magnetic substances discovered more recently possess many of the properties of ferromagnetic materials, including spontaneous magnetization and remanence. Unlike the ferromagnetic metals, they have low electric conductivity, however. In alternating magnetic fields, this greatly reduces the energy loss resulting from eddy currents. Since these losses rise with the frequency of the alternating field, such substances are of much importance in the electronics industry.

Low electric conductivity of ferrites

A notable property of ferrites and associated materials is that the bulk spontaneous magnetization, even at complete magnetic saturation, does not correspond to the value expected if all the atomic dipoles are aligned parallel to each other. The explanation was put forward in 1948 by Néel, who suggested that the exchange forces responsible for the spontaneous magnetization were basically antiferromagnetic in nature and that in the ordered state they contained two (or more) sublattices spontaneously magnetized in opposite directions. In contrast to the simple antiferromagnetic substances considered above, however, the sizes of the magnetization on the two sublattices are unequal, giving a resultant net magnetization parallel to that of the sublattice with the larger moment. For this phenomenon Néel coined the name ferrimagnetism, and substances that exhibit it are called ferrimagnetic materials.

Historical survey

Electric and magnetic forces have been known since antiquity, but they were regarded as separate phenomena for centuries. Magnetism was studied experimentally at least as early as the 13th century; the properties of the magnetic compass undoubtedly aroused interest in the phenomenon. Systematic investigations of electricity were delayed until the invention of practical devices for producing electric charge and currents. As soon as inexpensive, easy-to-use sources of electricity became available, scientists produced a wealth of experimental data and theoretical insights. As technology advanced, they studied, in turn, magnetism and electrostatics, electric currents and conduction, electrochemistry, magnetic and electric induction, the interrelationship between electricity and magnetism, and finally the fundamental nature of electric charge.

EARLY OBSERVATIONS AND APPLICATIONS OF ELECTRIC AND MAGNETIC PHENOMENA

The ancient Greeks knew about the attractive force of both magnetite and rubbed amber. Magnetite, a magnetic

oxide of iron mentioned in Greek texts as early as 800 BC, was mined in the province of Magnesia in Thessaly. Thales of Miletus, who lived nearby, may have been the first Greek to study magnetic forces. He apparently knew that magnetite attracts iron and that rubbing amber (a fossil tree resin that the Greeks called *ēlektron*) would make it attract such lightweight objects as feathers. According to Lucretius, the Roman author of the philosophical poem *De rerum natura* ("On the Nature of Things") in the 1st century BC, the term magnet was derived from the province of Magnesia. Pliny the Elder, however, attributes it to the supposed discoverer of the mineral, the shepherd Magnes, "the nails of whose shoes and the tip of whose staff stuck fast in a magnetic field while he pastured his flocks."

The magnetic compass

The oldest practical application of magnetism was the magnetic compass, but its origin remains unknown. Some historians believe it was used in China as far back as the 26th century BC; others contend that it was invented by the Italians or Arabs and introduced to the Chinese during the 13th century AD. The earliest extant European reference is by Alexander Neckam (*d.* 1217) of England.

The first experiments with magnetism are attributed to Petrus Peregrinus de Maricourt, a French crusader and engineer. In his oft-cited *Epistola de magnete* (1269; "Letter on the Magnet"), Peregrinus describes having placed a thin iron rectangle on different parts of a spherically shaped piece of magnetite (or lodestone) and marked the lines along which it set itself. The lines formed a set of meridians of longitude passing through two points at opposite ends of the stone, in much the same way as the lines of longitude on the Earth's surface intersect at the North and South poles. By analogy, Peregrinus called the points the poles of the magnet. He further noted that, when a magnet is cut into pieces, each piece still has two poles. He also observed that unlike poles attract each other and that a strong magnet can reverse the polarity of a weaker one.

EMERGENCE OF THE MODERN SCIENCES OF ELECTRICITY AND MAGNETISM

The founder of the modern sciences of electricity and magnetism was William Gilbert, physician to both Elizabeth I and James I of England. Gilbert spent 17 years experimenting with magnetism and, to a lesser extent, electricity. He assembled the results of his experiments and all of the available knowledge on magnetism in the treatise *De Magnete, Magneticisque Corporibus, et de Magno Magnete Tellure* ("On the Magnet and Magnetic Bodies, and on That Great Magnet the Earth"). As suggested by the title, Gilbert described the Earth as a huge magnet. He introduced the term electric for the force between two objects charged by friction and showed that frictional electricity occurs in many common materials. He also noted one of the primary distinctions between magnetism and electricity: the force between magnetic objects tends to align the objects relative to each other and is affected only slightly by most intervening objects, while the force between electrified objects is primarily a force of attraction or repulsion between the objects and is grossly affected by intervening matter. Gilbert attributed the electrification of a body by friction to the removal of a fluid, or "humour," which then left an "effluvium," or atmosphere, around the body. The language is quaint, but, if the "humour" is renamed "charge" and the "effluvium" renamed "electric field," Gilbert's notions closely approach modern ideas.

Pioneering efforts. During the 17th and early 18th centuries, as better sources of charge were developed, the study of electric effects became increasingly popular. The first machine to generate an electric spark was built in 1663 by Otto von Guericke, a German physicist and engineer. Guericke's electric generator consisted of a sulfur globe mounted on an iron shaft. The globe could be turned with one hand and rubbed with the other. Electrified by friction, the sphere alternately attracted and repulsed light objects from the floor.

Stephen Gray, a British chemist, is credited with discovering that electricity can flow (1729). He found that corks stuck in the ends of glass tubes become electrified when the tubes are rubbed. He also transmitted electricity approximately 150 metres through a hemp thread supported by silk cords and, in another demonstration, sent electricity even farther through metal wire. Gray concluded that electricity flowed everywhere.

From the mid-18th through the early 19th centuries, scientists believed that electricity was composed of fluid. In 1733 Charles François de Cisternay DuFay, a French chemist, announced that electricity consisted of two fluids: "vitreous" (from the Latin for "glass"), or positive, electricity; and "resinous," or negative, electricity. When DuFay electrified a glass rod, it attracted nearby bits of cork. Yet, if the rod touched the pieces of cork, the cork fragments were repelled and also repelled one another. DuFay accounted for this phenomenon by explaining that, in general, matter was neutral because it contained equal quantities of both fluids; if, however, friction separated the fluids in a substance and left it imbalanced, the substance would attract or repel other matter.

Invention of the Leyden jar. In 1745 a cheap and convenient source of electric sparks was invented by Pieter van Musschenbroek, a physicist and mathematician in Leiden, Neth. Later called the Leyden jar, it was the first device that could store large amounts of electric charge. (E. Georg von Kleist, a German cleric, independently developed the idea for such a device, but did not investigate it as thoroughly as did Musschenbroek.) The Leyden jar devised by the latter consisted of a glass vial that was partially filled with water and contained a thick conducting wire capable of storing a substantial amount of charge. One end of this wire protruded through the cork that sealed the opening of the vial. The Leyden jar was charged by bringing this exposed end of the conducting wire into contact with a friction device that generated static electricity.

Within a year after the appearance of Musschenbroek's device, William Watson, an English physician and scientist, constructed a more sophisticated version of the Leyden jar; he coated the inside and outside of the container with metal foil to improve its capacity to store charge. Watson transmitted an electric spark from his device through a wire strung across the River Thames at Westminster Bridge in 1747.

The Leyden jar revolutionized the study of electrostatics. Soon "electricians" were earning their living all over Europe demonstrating electricity with Leyden jars. Typically, they killed birds and animals with electric shock or sent charges through wires over rivers and lakes. In 1746 the abbé Jean-Antoine Nollet, a physicist who popularized science in France, discharged a Leyden jar in front of King Louis XV by sending current through a chain of 180 Royal Guards. In another demonstration, Nollet used wire made of iron to connect a row of Carthusian monks more than a kilometre long; when a Leyden jar was discharged, the white-robed monks reportedly leapt simultaneously into the air.

In the United States, Benjamin Franklin sold his printing house, newspaper, and almanac to spend his time conducting electricity experiments. In 1752 Franklin proved that lightning was an example of electric conduction by flying a silk kite during a thunderstorm. He collected electric charge from a cloud by means of wet twine attached to a key and thence to a Leyden jar. He then used the accumulated charge from the lightning to perform electric experiments. Franklin enunciated the law now known as the conservation of charge (the net sum of the charges within an isolated region is always constant). Like Watson, he disagreed with DuFay's two-fluid theory. Franklin argued that electricity consisted of two states of one fluid, which is present in everything. A substance containing an unusually large amount of the fluid would be "plus," or positively charged. Matter with less than a normal amount of fluid would be "minus," or negatively charged.

Franklin's one-fluid theory

Franklin's one-fluid theory, which dominated the study of electricity for 100 years, is essentially correct because most currents are the result of moving electrons. At the same time, however, fundamental particles have both negative and positive charges and, in this sense, DuFay's two-fluid picture is correct.

Joseph Priestley, an English physicist, summarized all available data on electricity in his book *History and Present*

State of Electricity (1767). He repeated one of Franklin's experiments, in which the latter had dropped small corks into a highly electrified metal container and found that they were neither attracted nor repelled. The lack of any charge on the inside of the container caused Priestley to recall Newton's law that there is no gravitational force on the inside of a hollow sphere. From this, Priestley inferred that the law of force between electric charges must be the same as the law for gravitational force—*i.e.,* that the force between masses diminishes with the inverse square of the distance between the masses. Although they were expressed in qualitative and descriptive terms, Priestley's laws are still valid today. Their mathematics was clarified and developed extensively between 1767 and the mid-19th century as electricity and magnetism became precise, quantitative sciences.

Formulation of the quantitative laws of electrostatics and magnetostatics. Charles-Augustin de Coulomb established electricity as a mathematical science during the latter half of the 18th century. He transformed Priestley's descriptive observations into the basic quantitative laws of electrostatics and magnetostatics. He also developed the mathematical theory of electric force and invented the torsion balance that was to be used in electricity experiments for the next 100 years. Coulomb used the balance to measure the force between magnetic poles and between electric charges at varying distances. In 1785 he announced his quantitative proof that electric and magnetic forces vary, like gravitation, inversely as the square of the distance (see above *General considerations*). Thus, according to Coulomb's law, if the distance between two charged masses is doubled, the electric force between them is reduced to a fourth. (The English physicist Henry Cavendish, as well as John Robison of Scotland, had made quantitative determinations of this principle before Coulomb, but they had not published their work.)

The mathematicians Siméon-Denis Poisson of France and Carl Friedrich Gauss of Germany extended Coulomb's work during the 18th and early 19th centuries. Poisson's equation (published in 1813) and the law of charge conservation contain in two lines virtually all the laws of electrostatics. The theory of magnetostatics, which is the study of steady-state magnetic fields, also was developed from Coulomb's law. Magnetostatics uses the concept of a magnetic potential analogous to the electric potential (*i.e.,* magnetic poles are postulated with properties analogous to electric charges).

Faraday's verification of the inverse square law

Michael Faraday built upon Priestley's work and conducted an experiment that verified quite accurately the inverse square law. Faraday's experiment involving the use of a metal ice pail and a gold-leaf electroscope was the first precise quantitative experiment on electric charge. In Faraday's time, the gold-leaf electroscope was used to indicate the electric state of a body. This type of apparatus consists of two thin leaves of gold hanging from an insulated metal rod that is mounted inside a metal box. When the rod is charged, the leaves repel each other and the deflection indicates the size of the charge. Faraday began his experiment by charging a metal ball suspended on an insulating silk thread. He then connected the gold-leaf electroscope to a metal ice pail resting on an insulating block and lowered the charged ball into the pail. The electroscope reading increased as the ball was lowered into the pail and reached a steady value once the ball was within the pail. When the ball was withdrawn without touching the pail, the electroscope reading fell to zero. Yet, when the ball touched the bottom of the pail, the reading remained at its steady value. On removal, the ball was found to be completely discharged. Faraday concluded that the electric charge produced on the outside of the pail, when the ball was inside but not in contact with it, was exactly equal to the initial charge on the ball. He then inserted into the pail other objects, such as a set of concentric pails separated from one another with various insulating materials like sulfur. In each case, the electroscope reading was the same once the ball was completely within the pail. From this, Faraday concluded that the total charge of the system was an invariable quantity equal

Figure 49: *Widespread use of electricity in the 19th century.*
The study and use of electricity affected nearly every area of 19th-century life, even grand opera. In 1888 two singers in a performance of Charles Gounod's *Faust* staged a spectacular duel scene by forming an electric circuit. Their swords were connected to the poles of a battery under the stage floor via wires hidden beneath their costumes, copper nails in their shoes, and metal plates on the stage floor. Each time the swords touched, they sparkled and crackled like lightning.

to the initial charge of the ball. The present-day belief that conservation is a fundamental property of charge rests not only on the experiments of Franklin and Faraday but also on its complete agreement with all observations in electric engineering, quantum electrodynamics, and experimental electricity. With Faraday's work, the theory of electrostatics was complete.

FOUNDATIONS OF ELECTROCHEMISTRY AND ELECTRODYNAMICS

Development of the battery. The invention of the battery in 1800 made possible for the first time major advances in the theories of electric current and electrochemistry. Both science and technology developed rapidly as a direct result, leading some to call the 19th century the age of electricity.

The development of the battery was the accidental result of biological experiments conducted by Luigi Galvani. Galvani, a professor of anatomy at the Bologna Academy of Science, was interested in electricity in fish and other animals. One day he noticed that electric sparks from an electrostatic machine caused muscular contractions in a dissected frog that lay nearby. At first, Galvani assumed that the phenomenon was the result of atmospheric electricity because similar effects could be observed during lightning storms. Later, he discovered that whenever a piece of metal connected the muscle and nerve of the frog, the muscle contracted. Although Galvani realized that some metals appeared to be more effective than others in producing this effect, he concluded incorrectly that the metal was transporting a fluid, which he identified with animal electricity, from the nerve to the muscle. Galvani's observations, published in 1791, aroused considerable controversy and speculation.

Alessandro Volta, a physicist at the nearby University of Pavia, had been studying how electricity stimulates the senses of touch, taste, and sight. When Volta put a metal coin on top of his tongue and another coin of a different metal under his tongue and connected their surfaces with a wire, the coins tasted salty. Like Galvani, Volta assumed that he was working with animal electricity until 1796 when he discovered that he could also produce a current when he substituted a piece of cardboard soaked in brine for his tongue. Volta correctly conjectured that the effect was caused by the contact between metal and a moist body. Around 1800 he constructed what is now known as a voltaic pile consisting of layers of silver, moist cardboard, and zinc, repeated in that order, beginning and ending with a different metal. When he joined the silver and the zinc with a wire, electricity flowed continuously through the wire. Volta confirmed that the effects of his pile were equivalent in every way to those of static electricity. Within 20 years, galvanism, as electricity produced by a chemical reaction was then called, became unequivocally linked to static electricity. More important, Volta's invention provided the first source of continuous electric current. This rudimentary form of battery produced a smaller voltage than the Leyden jar, but it was easier to use because it could supply a steady current and did not have to be recharged.

Voltaic pile

The controversy between Galvani, who mistakenly thought that electricity originated in the animal's nerve, and Volta, who realized that it came from the metal, divided scientists into two camps. Galvani was supported by Alexander von Humboldt in Germany, while Volta was backed by Coulomb and other French physicists.

Within six weeks of Volta's report, two English scientists, William Nicholson and Anthony Carlisle, used a chemical battery to discover electrolysis (the process in which an electric current produces a chemical reaction) and initiate the science of electrochemistry. In their experiment the two employed a voltaic pile to liberate hydrogen and oxygen from water. They attached each end of the pile to brass wires and placed the opposite ends of the wires into salt water. The salt made the water a conductor. Hydrogen gas accumulated at the end of one wire; the end of the other wire was oxidized. Nicholson and Carlisle discovered that the amount of hydrogen and oxygen set free by the current was proportional to the amount of current used.

Discovery of electrolysis

By 1809 the English chemist Humphry Davy had used a stronger battery to free for the first time several very active metals—sodium, potassium, calcium, strontium, barium, and magnesium—from their liquid compounds. Faraday, who was Davy's assistant at the time, studied electrolysis quantitatively and showed that the amount of energy needed to separate a gram of a substance from its compound is closely related to the atomic weight of the substance. Electrolysis became a method of measuring electric current; and the quantity of charge that releases a gram atomic weight of a simple element is now called a faraday in his honour.

Once scientists were able to produce currents with a battery, they could study the flow of electricity quantitatively. Because of the battery, the German physicist Georg Simon Ohm was able experimentally in 1827 to quantify precisely a problem that Cavendish could only investigate qualitatively some 50 years earlier—namely, the ability of a material to conduct electricity. The result of this work—Ohm's law—explains how the resistance to the flow of charge depends on the type of conductor and on its length and diameter. According to Ohm's formulation, the current flow through a conductor is directly proportional to the potential difference, or voltage, and inversely proportional to the resistance—that is, $i = V/R$. Thus, doubling the length of an electric wire doubles its resistance, while doubling the cross-sectional area of the wire reduces the resistance by a half. Ohm's law is probably the most widely used equation in electric design.

Experimental and theoretical studies of electromagnetic phenomena. One of the great turning points in the development of the physical sciences was Hans Christian Ørsted's announcement in 1820 that electric currents produce magnetic effects. (Ørsted made his discovery while lecturing to a class of physics students. He placed by chance a wire carrying current near a compass needle and was surprised to see the needle swing at right angles to the wire.) Ørsted's fortuitous discovery proved that electricity and magnetism are linked. His finding, together with Faraday's subsequent discovery that a changing magnetic field produces an electric current in a nearby circuit, formed the basis of both James Clerk Maxwell's unified theory of electromagnetism and most of modern electrotechnology.

Verification of the link between electricity and magnetism

Once Ørsted's experiment had revealed that electric currents have magnetic effects, scientists realized that there must be magnetic forces between the currents. They began studying the forces immediately. A French physicist, François Arago, observed in 1820 that an electric current will orient unmagnetized iron filings in a circle around the wire. That same year, another French physicist, André-Marie Ampère, developed Ørsted's observations in quantitative terms. Ampère showed that two parallel wires carrying electric currents attract and repel each other like magnets. If the currents flow in the same direction, the wires attract each other; if they flow in opposite directions, the wires repel each other. From this experiment, Ampère was able to express the right-hand rule for the direction of the force on a current in a magnetic field. He also established experimentally and quantitatively the laws of magnetic force between electric currents. He suggested that internal electric currents are responsible for permanent magnets and for highly magnetizable materials like iron. With Arago, he demonstrated that steel needles become more strongly magnetic inside a coil carrying an electric current. Experiments on small coils showed that, at large distances, the forces between two such coils are similar to those between two small bar magnets and, moreover, that one coil can be replaced by a bar magnet of suitable size without changing the forces. The magnetic moment of this equivalent magnet was determined by the dimensions of the coil, its number of turns, and the current flowing around it.

William Sturgeon of England and Joseph Henry of the United States used Ørsted's discovery to develop electromagnets during the 1820s. Sturgeon wrapped 18 turns of bare copper wire around a U-shaped iron bar. When he turned on the current, the bar became an electromagnet capable of lifting 20 times its weight. When the current was turned off, the bar was no longer magnetized. Henry

repeated Sturgeon's work in 1829, using insulated wire to prevent short-circuiting. Using hundreds of turns, Henry created an electromagnet that could lift more than one ton of iron.

Ørsted's experiment showing that electricity could produce magnetic effects raised the opposite question as well: Could magnetism induce an electric current in another circuit? The French physicist Augustin-Jean Fresnel argued that since a steel bar inside a metallic helix can be magnetized by passing a current through the helix, the bar magnet in turn should create a current in an enveloping helix. In the following decade many ingenious experiments were devised, but the expectation that a steady current would be induced in a coil near the magnet resulted in experimenters either accidentally missing or not appreciating any transient electric effects caused by the magnet.

Faraday's discovery of electric induction

Faraday, the greatest experimentalist in electricity and magnetism of the 19th century and one of the greatest experimental physicists of all time, worked on and off for 10 years trying to prove that a magnet could induce electricity. In 1831 he finally succeeded by using two coils of wire wound around opposite sides of a ring of soft iron (Figure 50). The first coil was attached to a battery; when a current passed through the coil, the iron ring became magnetized. A wire from the second coil was extended to a compass needle a metre away, far enough so that it was not affected directly by any current in the first circuit. When the first circuit was turned on, Faraday observed a momentary deflection of the compass needle and its immediate return to its original position. When the primary current was switched off, a similar deflection of the compass needle occurred but in the opposite direction. Building on this observation in other experiments, Faraday showed that changes in the magnetic field around the first coil are responsible for inducing the current in the second coil. He also demonstrated that an electric current can be induced by moving a magnet, by turning an electromagnet on and off, and even by moving an electric wire in the Earth's magnetic field. Within a few months, Faraday built the first, albeit primitive, electric generator.

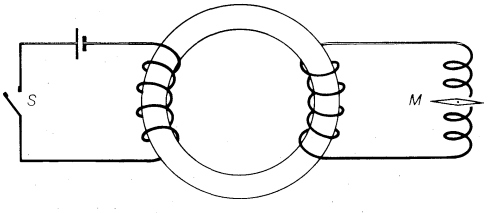

Figure 50: Faraday's magnetic induction experiment. When the switch S is closed in the primary circuit, a momentary current flows in the secondary circuit, giving a transient deflection of the compass needle M.

Henry had discovered electric induction quite independently in 1830, but his results were not published until after he had received news of Faraday's 1831 work, nor did he develop the discovery as fully as Faraday. In his paper of July 1832, Henry reported and correctly interpreted self-induction. He had produced large electric arcs from a long helical conductor when it was disconnected from a battery. When he had opened the circuit, the rapid decrease in the current had caused a large voltage between the battery terminal and the wire. As the wire lead was pulled away from the battery, the current continued to flow for a short time in the form of a bright arc between the battery terminal and the wire.

Faraday's thinking was permeated by the concept of electric and magnetic lines of force. He visualized that magnets, electric charges, and electric currents produce lines of force. When he placed a thin card covered with iron filings on a magnet, he could see the filings form chains from one end of the magnet to the other. He believed that these lines showed the directions of the forces and that electric current would have the same lines of force. The tension they build explains the attraction and repulsion of magnets and electric charges. Faraday had visualized magnetic curves as early as 1831 while working on his induction experiments; he wrote in his notes, "By magnetic curves I mean lines of magnetic forces which would be depicted by iron filings." Faraday opposed the prevailing idea that induction occurred "at a distance"; instead, he held that induction occurs along curved lines of force because of the action of contiguous particles. Later, he explained that electricity and magnetism are transmitted through a medium that is the site of electric or magnetic "fields," which make all substances magnetic to some extent.

Faraday was not the only researcher laying the groundwork for a synthesis between electricity, magnetism, and other areas of physics. On the continent of Europe, primarily in Germany, scientists were making mathematical connections between electricity, magnetism, and optics. The work of the physicists Franz Ernst Neumann, Wilhelm Eduard Weber, and H.F.E. Lenz belongs to this period. At the same time, Helmholtz and the English physicists William Thomson (later Lord Kelvin) and James Prescott Joule were clarifying the relationship between electricity and other forms of energy. Joule investigated the quantitative relationship between electric currents and heat during the 1840s and formulated the theory of the heating effects that accompany the flow of electricity in conductors. Helmholtz, Thomson, Henry, Gustav Kirchhoff, and Sir George Gabriel Stokes also extended the theory of the conduction and propagation of electric effects in conductors. In 1856 Weber and his German colleague, Rudolf Kohlrausch, determined the ratio of electric and magnetic units and found that it has the same dimensions as light and that it is almost exactly equal to its velocity. In 1857 Kirchhoff used this finding to demonstrate that electric disturbances propagate on a highly conductive wire with the speed of light.

Formulation of the classical theory of electromagnetism

The final steps in synthesizing electricity and magnetism into one coherent theory were made by Maxwell. He was deeply influenced by Faraday's work, having begun his study of the phenomena by translating Faraday's experimental findings into mathematics. (Faraday was self-taught and had never mastered mathematics.) In 1856 Maxwell developed the theory that the energy of the electromagnetic field is in the space around the conductors as well as in the conductors themselves. By 1864 he had formulated his own electromagnetic theory of light, predicting that both light and radio waves are electric and magnetic phenomena. While Faraday had discovered that changes in magnetic fields produce electric fields, Maxwell added the converse: changes in electric fields produce magnetic fields even in the absence of electric currents. Maxwell predicted that electromagnetic disturbances traveling through empty space have electric and magnetic fields at right angles to each other and that both fields are perpendicular to the direction of the wave. He concluded that the waves move at a uniform speed equal to the speed of light and that light is one form of electromagnetic wave. Their elegance notwithstanding, Maxwell's radical ideas were accepted by few outside England until 1886, when the German physicist Heinrich Hertz verified the existence of electromagnetic waves traveling at the speed of light; the waves he discovered are known now as radio waves.

Maxwell's four field equations (see above) represent the pinnacle of classical electromagnetic theory. Subsequent developments in the theory have been concerned either with the relationship between electromagnetism and the atomic structure of matter or with the practical and theoretical consequences of Maxwell's equations. His formulation has withstood the revolutions of relativity and quantum mechanics. His equations are appropriate for distances as small as 10^{-10} centimetres—100 times smaller than the size of an atom. The fusion of electromagnetic theory and quantum theory, known as quantum electrodynamics, is required only for smaller distances.

While the mainstream of theoretical activity concerning electric and magnetic phenomena during the 19th century was devoted to showing how they are interrelated, some scientists made use of them to discover new properties of materials and heat. Weber developed Ampère's suggestion that there are internal circulating currents of molecular size in metals. He explained how a substance loses its magnetic properties when the molecular magnets point in

random directions. Under the action of an external force, they may turn to point in the direction of the force; when all point in this direction, the maximum possible degree of magnetization is reached, a phenomenon known as magnetic saturation. In 1895 Pierre Curie of France discovered that a ferromagnetic substance has a specific temperature above which it ceases to be magnetic. Finally, superconductivity was discovered in 1900 by the German physicist Heike Kammerlingh-Onnes. In superconductivity electric conductors lose all resistance at very low temperatures.

Discovery of the electron and its ramifications. Although little of major importance was added to electromagnetic theory in the 19th century after Maxwell, the discovery of the electron in 1898 opened up an entirely new area of study: the nature of electric charge and of matter itself.

Studies of currents in vacuum tubes

The discovery of the electron grew out of studies of electric currents in vacuum tubes. Heinrich Geissler, a glassblower who assisted the German physicist Julius Plücker, improved the vacuum tube in 1854. Four years later, Plücker sealed two electrodes inside the tube, evacuated the air, and forced electric currents between the electrodes; he attributed the green glow that appeared on the wall of the tube to rays emanating from the cathode. From then until the end of the century, the properties of cathode-ray discharges were studied intensively. The work of the English physicist Sir William Crookes in 1879 indicated that the luminescence was a property of the electric current itself. Crookes concluded that the rays were composed of electrified charged particles. In 1898 another English physicist, Sir J.J. Thomson, identified a cathode ray as a stream of negatively charged particles, each having a mass $^1/_{1,836}$ smaller than that of a hydrogen ion. Thomson's discovery established the particulate nature of charge; his particles were later dubbed electrons.

Following the discovery of the electron, electromagnetic theory became an integral part of the theories of the atomic, subatomic, and subnuclear structure of matter. This shift in focus occurred as the result of an impasse between electromagnetic theory and statistical mechanics over attempts to understand radiation from hot bodies. Thermal radiation had been investigated in Germany by the physicist Wilhelm Wien between 1890 and 1900. Wien had virtually exhausted the resources of thermodynamics in dealing with this problem. Two British scientists, Lord Rayleigh (John William Strutt) and Sir James Hopwood Jeans, had by 1900 applied the newly developed science of statistical mechanics to the same problem. They obtained results that, though in agreement with Wien's thermodynamic conclusions (as distinct from his speculative extensions of thermodynamics), only partially agreed with experimental observations. The German physicist Max Planck attempted to combine the statistical approach with a thermodynamic approach. By concentrating on the necessity of fitting together the experimental data, he was led to the formulation of an empirical law that satisfied Wien's thermodynamic criteria and accommodated the experimental data. When Planck interpreted this law in terms of Rayleigh's statistical concepts, he concluded that radiation of frequency ν exists only in quanta of energy. Planck's result, including the introduction of the new universal constant $h\nu$ in 1900, marked the foundation of quantum mechanics and initiated a profound change in physical theory (see ATOMS: *Bohr's shell model*).

By 1900 it was apparent that Thomson's electrons were a universal constituent of matter and, thus, that matter is essentially electric in nature. As a result, in the early years of the 20th century, many physicists attempted to construct theories of the electromagnetic properties of metals, insulators, and magnetic materials in terms of electrons. In 1909 the Dutch physicist Hendrik Antoon Lorentz succeeded in doing so in *The Theory of Electrons and Its Applications to the Phenomena of Light and Radiant Heat;* his work has since been modified by quantum theory.

Special theory of relativity. The other major conceptual advance in electromagnetic theory was the special theory of relativity. In Maxwell's time, a mechanistic view of the universe held sway. Sound was interpreted as an undulatory motion of the air, while light and other electromagnetic waves were regarded as undulatory motions of an intangible medium called ether. The question arose as to whether the velocity of light measured by an observer moving relative to ether would be affected by his motion. Albert Abraham Michelson and Edward W. Morley of the United States had demonstrated in 1887 that light in a vacuum on Earth travels at a constant speed which is independent of the direction of the light relative to the direction of the Earth's motion through the ether. Lorentz and Henri Poincaré, a French physicist, showed between 1900 and 1904 that the conclusions of Michelson and Morley were consistent with Maxwell's equations. On this basis, Lorentz and Poincaré developed a theory of relativity in which the absolute motion of a body relative to a hypothetical ether is no longer significant. Poincaré named the theory the principle of relativity in a lecture at the St. Louis Exposition in September 1904. Planck gave the first formulation of relativistic dynamics two years later. The most general formulation of the special theory of relativity, however, was put forth by Einstein in 1905, and the theory of relativity is usually associated with his name. Einstein postulated that the speed of light is a constant, independent of the motion of the source of the light, and showed how the Newtonian laws of mechanics would have to be modified. While Maxwell had synthesized electricity and magnetism into one theory, he had regarded them as essentially two interdependent phenomena; Einstein showed that they are two aspects of the same phenomenon.

Lorentz's and Poincaré's principle of relativity

Maxwell's equations, the special theory of relativity, the discovery of the electronic structure of matter, and the formulation of quantum mechanics all occurred before 1930. The quantum electrodynamics theory, developed between 1945 and 1955, subsequently resolved some minute discrepancies in the calculations of certain atomic properties. For example, the accuracy with which it is now possible to calculate one of the numbers describing the magnetic moment of the electron is comparable to measuring the distance between New York City and Los Angeles to within the thickness of a human hair. As a result, quantum electrodynamics is the most complete and precise theory of any physical phenomenon. The remarkable correspondence between theory and observation makes it unique among human endeavours.

DEVELOPMENT OF ELECTROMAGNETIC TECHNOLOGY

Electromagnetic technology began with Faraday's discovery of induction in 1831 (see above). His demonstration that a changing magnetic field induces an electric current in a nearby circuit showed that mechanical energy can be converted to electric energy. It provided the foundation for electric power generation, leading directly to the invention of the dynamo and the electric motor. Faraday's finding also proved crucial for lighting and heating systems.

The early electric industry was dominated by the problem of generating electricity on a large scale. Within a year of Faraday's discovery, a small hand-turned generator in which a magnet revolved around coils was demonstrated in Paris. In 1833 there appeared an English model that featured the modern arrangement of rotating the coils in the field of a fixed magnet. By 1850 generators were manufactured commercially in several countries. Permanent magnets were used to produce the magnetic field in generators until the principle of the self-excited generator was discovered in 1866. (A self-excited generator has stronger magnetic fields because it uses electromagnets powered by the generator itself.) In 1870 Zénobe Théophile Gramme, a Belgian manufacturer, built the first practical generator capable of producing a continuous current. It was soon found that the magnetic field is more effective if the coil windings are embedded in slots in the rotating iron armature. The slotted armature, still in use today, was invented in 1880 by the Swedish engineer Jonas Wenström. Faraday's 1831 discovery of the principle of the AC transformer was not put to practical use until the late 1880s when the heated debate over the merits of direct-current and alternating-current systems for power transmission was settled in favour of the latter.

Self-excited generator

At first, the only serious consideration for electric power was arc lighting, in which a brilliant light is emitted by

an electric spark between two electrodes. The arc lamp was too powerful for domestic use, however, and so it was limited to large installations like lighthouses, train stations, and department stores. Commercial development of an incandescent filament lamp, first invented in the 1840s, was delayed until a filament could be made that would heat to incandescence without melting and until a satisfactory vacuum tube could be built. The mercury pump, invented in 1865, provided an adequate vacuum, and a satisfactory carbon filament was developed independently by the English physicist Sir Joseph Wilson Swan and the American inventor Thomas A. Edison during the late 1870s. By 1880 both had applied for patents for their incandescent lamps, and the ensuing litigation between the two men was resolved by the formation of a joint company in 1883. Thanks to the incandescent lamp, electric lighting became an accepted part of urban life by 1900. Since then, the tungsten filament lamp, introduced during the early 1900s, has become the principal form of electric lamp, though more efficient fluorescent gas discharge lamps have found widespread use as well.

Electricity took on a new importance with the development of the electric motor. This machine, which converts electric energy to mechanical energy, has become an integral component of a wide assortment of devices ranging from kitchen appliances and office equipment to industrial robots and rapid-transit vehicles. Although the principle of the electric motor was devised by Faraday in 1821, no commercially significant unit was produced until 1873. In fact, the first important AC motor, built by the Serbian-American inventor Nikola Tesla, was not demonstrated in the United States until 1888. Tesla began producing his motors in association with the Westinghouse Electric Company a few years after DC motors had been installed in trains in Germany and Ireland. By the end of the 19th century, the electric motor had taken a recognizably modern form. Subsequent improvements have rarely involved radically new ideas; however, the introduction of better designs and new bearing, armature, magnetic, and contact materials has resulted in the manufacture of smaller, cheaper, and more efficient and reliable motors.

The modern communications industry is among the most spectacular products of electricity. Telegraph systems using wires and simple electrochemical or electromechanical receivers proliferated in western Europe and the United States during the 1840s. An operable cable was installed under the English Channel in 1865, and a pair of transatlantic cables were successfully laid a year later. By 1872 almost all of the major cities of the world were linked by telegraph.

Alexander Graham Bell patented the first practical telephone in the United States in 1876, and the first public telephone services were operating within a few years. In 1895 the British physicist Sir Ernest Rutherford advanced Hertz's scientific investigations of radio waves and transmitted radio signals for more than one kilometre. Guglielmo Marconi, an Italian physicist and inventor, established wireless communications across the Atlantic employing radio waves of approximately 300- to 3,000-metre wavelength in 1901. Broadcast radio transmissions were established during the 1920s.

Transmission of radio signals

Telephone transmissions by radio waves, the electric recording and reproduction of sound, and television were made possible by the development of the triode tube. This three-electrode tube, invented by the American engineer Lee De Forest, permitted for the first time the amplification of electric signals. Known as the Audion, this device played a pivotal role in the early development of the electronics industry.

The first telephone transmission via radio signals was made from Arlington, Va., to the Eiffel Tower in Paris in 1915; and a commercial radio telephone service between New York City and London was begun in 1927. Besides such efforts, most of the major developmental work of this period was tied to the radio and phonograph entertainment industries and the sound film industry. Rapid progress was made toward transmitting moving pictures, especially in Great Britain; just before World War II, the British Broadcasting Corporation inaugurated the first public television service. Today, many regions of the electromagnetic spectrum are used for communications, including microwaves in the frequency range of approximately 7×10^9 hertz for satellite communication links and infrared light at a frequency of about 3×10^{14} hertz for optical fibre communications systems.

Until 1939 the electronics industry was almost exclusively concerned with communications and broadcast entertainment. Scientists and engineers in Britain, Germany, France, and the United States did initiate research on radar systems capable of aircraft detection and antiaircraft fire-control during the 1930s, however, and this marked the beginning of a new direction for electronics. During World War II and after, the electronics industry made strides paralleled only by those of the chemical industry. Television became commonplace; and a broad array of new devices and systems, most notably the electronic digital computer, emerged.

The electronic revolution of the last half of the 20th century has been made possible in large part by the invention of the transistor (1947) and such subsequent developments as the integrated circuit. (For detailed coverage of these and other major advances, see ELECTRONICS.) This miniaturization and integration of circuit elements has led to a remarkable diminution in the size and cost of electronic equipment and an equally impressive increase in its reliability. TROTTER, JR., "Capacitors," *Scientific American,* 259(1):86–90B (July 1988), provides insight into capacitor functions and their role in technology. DAVID N. SCHRAMM and GARY STEIGMAN, "Particle Accelerators Test Cosmological Theory," *Scientific American,* 258(6):66–72 (June 1988), discusses the fundamental constituents of nature. EDWARD M. PURCELL, *Electricity and Magnetism,* 2nd ed. (1985), is superbly illustrated and treats key principles and phenomena with remarkable insight. Many examples and problems on electricity and magnetism, as well as elementary discussions of vectors and other aspects of physics, are found in DAVID HALLIDAY and ROBERT RESNICK, *Fundamentals of Physics,* 3rd ed. (1988). Useful physics textbooks with illustrations, examples, and problems include RICHARD WOLFSON and JAY M. PASACHOFF, *Physics* (1987); and FRANCIS W. SEARS, MARK W. ZEMANSKY, and HUGH D. YOUNG, *University Physics,* 7th ed. (1987).

Electromagnetism: RICHARD P. FEYNMAN, ROBERT B. LEIGHTON, and MATTHEW SANDS, *The Feynman Lectures on Physics,* vol. 2, *The Electromagnetic Field* (1964, reprinted 1977), is highly recommended for its lucid discussion of fundamentals. JOHN R. REITZ, FREDERICK J. MILFORD, and ROBERT W. CHRISTY, *Foundations of Electromagnetic Theory,* 3rd ed. (1979), is a fine, compact, college-level text using vector calculus; while JOHN DAVID JACKSON, *Classical Electrodynamics,* 2nd ed. (1975), is written at the graduate level. E. DURAND, *Électrostatique,* 3 vol. (1964–66), and *Magnétostatique* (1968), exhaustively treat analytical methods and solutions of a variety of problems in electrostatics and magnetostatics, including dielectric and magnetic materials and conduction.

Electric and magnetic properties of matter: HARALD A. ENGE, *Introduction to Nuclear Physics* (1966), provides an overview. The magnetic properties of solids are discussed in CHARLES KITTEL, *Introduction to Solid State Physics,* 6th ed. (1986). ROBERT EISBERG and ROBERT RESNICK, *Quantum Physics of Atoms, Molecules, Solids, Nuclei, and Particles,* 2nd ed. (1985), broadly treats quantum mechanical effects in various phenomena, including magnetic properties such as ferromagnetism and electric properties such as conduction in solids. Reference books include *Reference Data for Engineers: Radio, Electronics, Computer, and Communications,* 7th ed. (1985), with data and discussion about electric and magnetic properties of matter; and *CRC Handbook of Chemistry and Physics* (annual), an indispensable handbook.

History: J.L. HEILBRON, *Electricity in the 17th and 18th Centuries: A Study of Early Modern Physics* (1979), provides a readable survey of significant developments, as does EDMUND WHITTAKER, *A History of the Theories of Aether and Electricity,* rev. and enlarged ed., 2 vol. (1951–53, reprinted 1973). CHARLES SINGER and T.I. WILLIAMS (eds.), *A History of Technology,* 8 vol. (1954–84), begins in the prehistoric period and concludes around 1950. (E.Ka./ S.McG.)

Electromagnetic Radiation

In terms of classical theory, electromagnetic radiation is the flow of energy through space at the universal speed of light in the form of electric and magnetic fields that make up an electromagnetic wave. In such a wave, time-varying electric and magnetic fields are mutually linked with each other at right angles and perpendicular to the direction of motion. An electromagnetic wave is characterized by its intensity and the frequency ν of the time variation of the electric and magnetic fields.

In terms of the modern quantum theory, electromagnetic radiation is the flow of photons (also called light quanta) through space. Photons are packets of energy $h\nu$ that always move with the universal speed of light. The symbol h is Planck's constant, while the value of ν is the same as that of the frequency of the electromagnetic wave of classical theory. Photons having the same energy $h\nu$ are all alike, and their number density corresponds to the intensity of the radiation. Electromagnetic radiation exhibits a multitude of phenomena as it interacts with charged particles in atoms, molecules, and larger objects of matter. These phenomena as well as the ways in which electromagnetic radiation is created and observed, the manner in which such radiation occurs in nature, and its technological uses depend on its frequency ν. The spectrum of frequencies of electromagnetic radiation extends from very low values over the range of radio waves, television waves, and microwaves to visible light and beyond to the substantially higher values of ultraviolet light, X rays, and gamma rays.

The basic properties and behaviour of electromagnetic radiation are discussed in this article, as are its various forms, including their sources, distinguishing characteristics, and practical applications. The article also traces the development of both the classical and quantum theories of radiation.

For coverage of related topics in the *Macropædia* and *Micropædia,* see the *Propædia,* sections 111, 112, 127, 128, and 131, and the *Index.*

The article is divided into the following sections:

General considerations

OCCURRENCE AND IMPORTANCE

Close to 0.01 percent of the mass/energy of the entire universe occurs in the form of electromagnetic radiation. All human life is immersed in it and modern communications technology and medical services are particularly dependent on one or another of its forms. In fact, all living things on Earth depend on the electromagnetic radiation received from the Sun and on the transformation of solar energy by photosynthesis into plant life or by biosynthesis into zooplankton, the basic step in the food chain in oceans. The eyes of many animals, including those of humans, are adapted to be sensitive to and hence to see the most abundant part of the Sun's electromagnetic radiation—namely, light, which comprises the visible portion of its wide range of frequencies. Green plants also have high sensitivity to the maximum intensity of solar electromagnetic radiation, which is absorbed by a substance called chlorophyll that is essential for plant growth via photosynthesis.

Importance to life

Practically all the fuels that modern society uses—gas, oil, and coal—are stored forms of energy received from the Sun as electromagnetic radiation millions of years ago. Only the energy from nuclear reactors does not originate from the Sun.

Everyday life is pervaded by man-made electromagnetic radiation: food is heated in microwave ovens, airplanes are guided by radar waves, television sets receive electromagnetic waves transmitted by broadcasting stations, and infrared waves from heaters provide warmth. Infrared waves also are given off and received by automatic self-focusing cameras that electronically measure and set the correct distance to the object to be photographed. As soon as the Sun sets, incandescent or fluorescent lights are turned on to provide artificial illumination, and cities glow brightly with the colourful fluorescent and neon lamps of advertisement signs. Familiar too is ultraviolet radiation, which the eyes cannot see but whose effect is felt as pain from sunburn. Ultraviolet light represents a kind of electromagnetic radiation that can be harmful to life. Such is also true of X rays, which are important in medicine as they allow physicians to observe the inner parts of the body but exposure to which should be kept to a minimum. Less familiar are gamma rays, which come from nuclear reactions and radioactive decay and are part of the harmful high-energy radiation of radioactive materials and nuclear weapons.

THE ELECTROMAGNETIC SPECTRUM

The brief account of familiar phenomena given above surveyed electromagnetic radiation from small frequencies ν (long wave radios) to exceedingly high values of ν (gamma rays). Going from the ν values of radio waves to those of visible light is like comparing the thickness of this page with the distance of the Earth from the Sun, which represents an increase by a factor of a million billion. Similarly, going from the ν values of visible light to the very much larger ones of gamma rays represents another increase in frequency by a factor of a million billion. This extremely large range of ν values, called the electromagnetic spec-

Vast range of frequencies

trum, is shown in Figure 1, together with the common names used for its various parts, or regions.

The number ν is shared by both the classical and the modern interpretation of electromagnetic radiation. In classical language, ν is the frequency of the temporal changes in an electromagnetic wave. The frequency of a wave is related to its speed c and wavelength λ in the following way. If 10 complete waves pass by in one second, one observes 10 wriggles, and one says that the frequency of such a wave is $\nu = 10$ cycles per second (10 hertz [Hz]). If the wavelength of the wave is, say, $\lambda = 3$ centimetres, then it is clear that a wave train 30 centimetres long has passed in that one second to produce the 10 wriggles that were observed. Thus, the speed of the wave is 30 centimetres per second, and one notes that in general the speed is $c = \lambda\nu$. The speed of electromagnetic radiation of all kinds is the same universal constant that is defined to be exactly $c = 299{,}792{,}458$ metres per second (186,282 miles per second). The wavelengths of the classical electromagnetic waves in free space calculated from $c = \lambda\nu$ are also shown on the spectrum in Figure 1, as is the energy $h\nu$ of modern-day photons. One commonly uses as the unit of energy electron volt (eV), which is the energy that can be given to an electron by a one-volt battery. It is clear that the range of wavelengths λ and of photon energies $h\nu$ are equally as large as the spectrum of ν values.

Because the wavelengths and energy quanta $h\nu$ of electromagnetic radiation of the various parts of the spectrum are so different in magnitude, the sources of the radiations, the interactions with matter, and the detectors employed are correspondingly different. This is why the same electromagnetic radiation is called by different names in various regions of the spectrum.

In spite of these obvious differences of scale, all forms of electromagnetic radiation obey certain general rules that are well understood and that allow one to calculate with very high precision their properties and interactions with charged particles in atoms, molecules, and large objects.

Electric and magnetic fields

Electromagnetic radiation is, classically speaking, a wave of electric and magnetic fields propagating at the speed of light c through empty space. In this wave the electric and magnetic fields change their magnitude and direction each second. This rate of change is the frequency ν measured in cycles per second—namely, in hertz. The electric and magnetic fields are always perpendicular to one another and at right angles to the direction of propagation, as shown in Figure 2. There is as much energy carried by the electric component of the wave as by the magnetic component, and the energy is proportional to the square of the field strength.

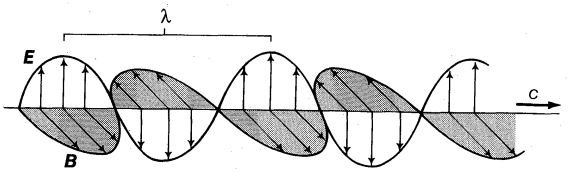

Figure 2: Radiation fields in which vectors ***E*** and ***B*** are perpendicular to each other and to the direction of propagation (see text).

GENERATION OF ELECTROMAGNETIC RADIATION

Electromagnetic radiation is produced whenever a charged particle, such as an electron, changes its velocity—*i.e.*, whenever it is accelerated or decelerated. The energy of the electromagnetic radiation thus produced comes from the charged particle and is therefore lost by it. A common example of this phenomenon is the oscillating charge or current in a radio antenna. The antenna of a radio transmitter is part of an electric resonance circuit in which the charge is made to oscillate at a desired frequency. An electromagnetic wave so generated can be received by a similar antenna connected to an oscillating electric circuit in the tuner that is tuned to that same frequency. The electromagnetic wave in turn produces an oscillating motion of charge in the receiving antenna. In general, one can say that any system which emits electromagnetic radiation of a given frequency can absorb radiation of the same frequency.

Such man-made transmitters and receivers become smaller with decreasing wavelength of the electromagnetic wave and prove impractical in the millimetre range. At even shorter wavelengths down to the wavelengths of X rays, which are one million times smaller, the oscillating charges arise from moving charges in molecules and atoms.

Systems or processes that generate electromagnetic radiation

One may classify the generation of electromagnetic radiation into two categories: (1) systems or processes that produce radiation covering a broad continuous spectrum of frequencies and (2) those that emit (and absorb) radiation of discrete frequencies that are characteristic of particular systems. The Sun with its continuous spectrum is an example of the first, while a radio transmitter tuned to one frequency exemplifies the second category.

Continuous spectra of electromagnetic radiation. Such spectra are emitted by any warm substance. Heat is the irregular motion of electrons, atoms, and molecules; the higher the temperature, the more rapid is the motion. Since electrons are much lighter than atoms, irregular thermal motion produces irregular oscillatory charge motion, which reflects a continuous spectrum of frequencies. Each oscillation at a particular frequency can be considered a tiny "antenna" that emits and receives electromagnetic radiation. As a piece of iron is heated to increasingly high temperatures, it first glows red, then yellow, and finally white. In short, all the colours of the visible spectrum are represented. Even before the iron begins to glow red, one can feel the emission of infrared waves by the heat sensation on the skin. A white-hot piece of iron also emits ultraviolet radiation, which can be detected by a photographic film.

Not all materials heated to the same temperature emit the same amount and spectral distribution of electromagnetic waves. For example, a piece of glass heated next to iron looks nearly colourless, but it feels hotter to the skin (it emits more infrared rays) than does the iron. This observation illustrates the rule of reciprocity: a body radiates strongly at those frequencies that it is able to absorb, because for both processes it needs the tiny antennas of that range of frequencies. Glass is transparent in the visible range of light because it lacks possible electronic absorption at these particular frequencies. As a consequence,

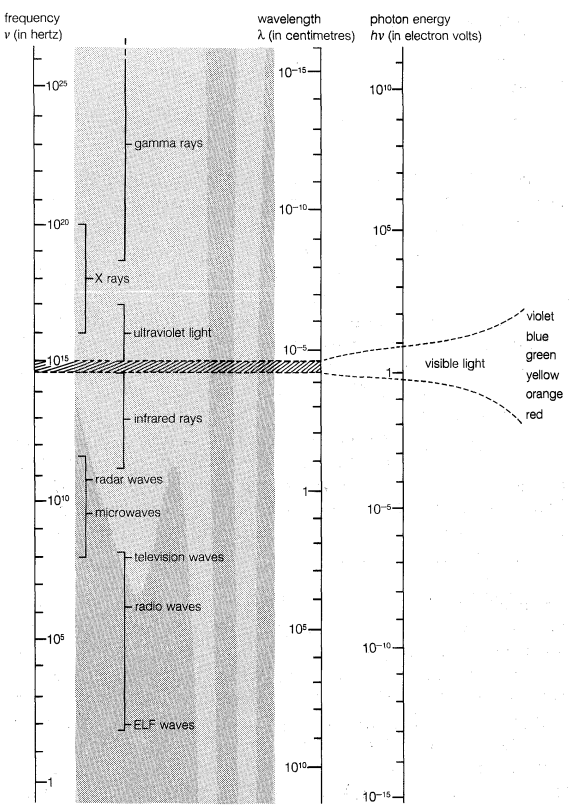

Figure 1: *Electromagnetic spectrum.*
The small visible range (shaded) is shown enlarged at the right.

glass cannot glow red because it cannot absorb red. On the other hand, glass is a better emitter/absorber in the infrared than iron or any other metal that strongly reflects such lower frequency electromagnetic waves. This selective emissivity and absorptivity is important for understanding the greenhouse effect (see below *The greenhouse effect of the atmosphere*) and many other phenomena in nature. The tungsten filament of a light bulb has a temperature of 2,500 K (4,040° F) and emits large amounts of visible light but relatively little infrared because metals, as mentioned above, have small emissivities in the infrared range. This is of course fortunate, since one wants light from a light bulb but not much heat. The light emitted by a candle originates from very hot carbon soot particles in the flame, which strongly absorb and thus emit visible light. By contrast, the gas flame of a kitchen range is pale, even though it is hotter than a candle flame, because of the absence of soot. Light from the stars originates from the high temperature of the gases at their surface. A wide spectrum of radiation is emitted from the Sun's surface, the temperature of which is about 6,000 K. The radiation output is 60 million watts for every square metre of solar surface, which is equivalent to the amount produced by an average-size commercial power-generating station that can supply electric power for about 30,000 households.

Blackbody radiation

The spectral composition of a heated body depends on the materials of which the body consists. That is not the case for an ideal radiator or absorber. Such an ideal object absorbs and thus emits radiation of all frequencies equally and fully. A radiator/absorber of this kind is called a blackbody, and its radiation spectrum is referred to as blackbody radiation, which depends on only one parameter, its temperature. Scientists devise and study such ideal objects because their properties can be known exactly. This information can then be used to determine and understand why real objects, such as a piece of iron or glass, a cloud, or a star, behave differently.

A good approximation of a blackbody is a piece of coal or, better yet, a cavity in a piece of coal that is visible through a small opening. There is one property of blackbody radiation which is familiar to everyone but which is actually quite mysterious. As the piece of coal is heated to higher and higher temperatures, one first observes a dull red glow, followed by a change in colour to bright red; as the temperature is increased further, the colour changes to yellow and finally to white. White is not itself a colour but rather the visual effect of the combination of all primary colours. The fact that white glow is observed at high temperatures means that the colour blue has been added to the ones observed at lower temperatures. This colour change with temperature is mysterious because one would expect, as the energy (or temperature) is increased, just more of the same and not something entirely different. For example, as one increases the power of a radio amplifier, one hears the music louder but not at a higher pitch.

Antennas of vibrating changes

The change in colour or frequency distribution of the electromagnetic radiation coming from heated bodies at different temperatures remained an enigma for centuries. The solution of this mystery by the German physicist Max Planck initiated the era of modern physics at the beginning of the 20th century. He explained the phenomenon by proposing that the tiny antennas in the heated body are quantized, meaning that they can emit electromagnetic radiation only in finite energy quanta of size hv. The universal constant h is called Planck's constant in his honour. For blue light $hv = 3$ eV, whereas $hv = 1.8$ eV for red light. Since high-frequency antennas of vibrating charges in solids have to emit larger energy quanta hv than lower-frequency antennas, they can only do so when the temperature, or the thermal atomic motion, becomes high enough. Hence, the average pitch, or peak frequency, of blackbody electromagnetic radiation increases with temperature.

The many tiny antennas in a heated chunk of material are, as noted above, to be identified with the accelerating and decelerating charges in the heat motion of the atoms of the material. There are other sources of continuous spectra of electromagnetic radiation that are not associated with heat but still come from accelerated or decelerated charges. X rays are, for example, produced by abruptly stopping rapidly moving electrons. This deceleration of the charges produces bremsstrahlung ("braking radiation"). In an X-ray tube, electrons moving with an energy of $E_{max} = 10{,}000$ to 50,000 eV (10–50 keV) are made to strike a piece of metal. The electromagnetic radiation produced by this sudden deceleration of electrons is a continuous spectrum extending up to the maximum photon energy $hv = E_{max}$.

By far the brightest continuum spectra of electromagnetic radiation come from synchrotron radiation sources. These are not well known because they are predominantly used for research and only recently have they been considered for commercial and medical applications. Because any change in motion is an acceleration, circulating currents of electrons produce electromagnetic radiation. When these circulating electrons move at relativistic speeds (*i.e.*, those approaching the speed of light), the brightness of the radiation increases enormously. This radiation was first observed at the General Electric Company in 1947 in an electron synchrotron (hence the name of this radiation), which is a type of particle accelerator that forces relativistic electrons into circular orbits using powerful magnetic fields. The intensity of synchrotron radiation is further increased more than a thousandfold by wigglers and undulators that move the beam of relativistic electrons to and fro by means of other magnetic fields.

The conditions for generating bremsstrahlung as well as synchrotron radiation exist in nature in various forms. Acceleration and capture of charged particles by the gravitational field of a star, black hole, or galaxy is a source of energetic cosmic X rays. Gamma rays are produced in other kinds of cosmic objects—namely, supernovae, neutron stars, and quasars.

Discrete-frequency sources and absorbers of electromagnetic radiation. These are commonly encountered in everyday life. Familiar examples of discrete-frequency electromagnetic radiation include the distinct colours of lamps filled with different fluorescent gases characteristic of advertisement signs, the colours of dyes and pigments, the bright yellow of sodium lamps, the blue-green hue of mercury lamps, and the specific colours of lasers.

Internal energy states

Sources of electromagnetic radiation of specific frequency are typically atoms or molecules. Every atom or molecule can have certain discrete internal energies, which are called quantum states. An atom or molecule can therefore change its internal energy only by discrete amounts. By going from a higher to a lower energy state, a quantum hv of electromagnetic radiation is emitted of a magnitude that is precisely the energy difference between the higher and lower state. Absorption of a quantum hv brings the atom from a lower to a higher state if hv matches the energy difference. All like atoms are identical, but all different chemical elements of the periodic table have their own specific set of possible internal energies. Therefore, by measuring the characteristic and discrete electromagnetic radiation that is either emitted or absorbed by atoms or molecules, one can identify which kind of atom or molecule is giving off or absorbing the radiation. This provides a means of determining the chemical composition of substances. Since one cannot subject a piece of a distant star to conventional chemical analysis, studying the emission or absorption of starlight is the only way to determine the composition of stars or of interstellar gases and dust.

The Sun, for example, not only emits the continuous spectrum of radiation that originates from its hot surface but also emits discrete radiation quanta hv that are characteristic of its atomic composition. Many of the elements can be detected at the solar surface, but the most abundant is helium. This is so because helium is the end product of the nuclear fusion reaction that is the fundamental energy source of the Sun. This particular element was named helium (from the Greek word *helios,* meaning "Sun") because its existence was first discovered by its characteristic absorption energies in the Sun's spectrum. The helium of the cooler outer parts of the solar atmosphere absorbs the characteristic light frequencies from the lower and hotter regions of the Sun.

The characteristic and discrete energies $h\nu$ found as emission and absorption of electromagnetic radiation by atoms and molecules extend to X-ray energies. As high-energy electrons strike the piece of metal in an X-ray tube, electrons are knocked out of the inner energy shell of the atoms. These vacancies are then filled by electrons from the second or third shell; emitted in the process are X rays having $h\nu$ values that correspond to the energy differences of the shells. One therefore observes not only the continuous spectrum of the bremsstrahlung discussed above but also X-ray emissions of discrete energies $h\nu$ that are characteristic of the specific elemental composition of the metal struck by the energetic electrons in the X-ray tube.

The discrete electromagnetic radiation energies $h\nu$ emitted or absorbed by all substances reflect the discreteness of the internal energies of all material things. This means that window glass and water are transparent to visible light; they cannot absorb these visible light quanta because their internal energies are such that no energy difference between a higher and a lower internal state matches the energy $h\nu$ of visible light. Figure 3 shows as an example the coefficient of absorption of water as a function of frequency ν of electromagnetic radiation. Above the scale of frequencies, the corresponding scales of photon energy $h\nu$ and wavelength λ are given. An absorption coefficient $\alpha = 10^{-4}$ cm^{-1} means that the intensity of electromagnetic radiation is only one-third its original value after passing through 100 metres of water. When $\alpha = 1$ cm^{-1}, only a layer one centimetre thick is needed to decrease the intensity to one-third its original value, and, for $\alpha = 10^3$ cm, a layer of water having a thickness of this page is sufficient to attenuate electromagnetic radiation by that much. The transparency of water to visible light, marked by the vertical dashed lines, is a remarkable feature that is significant for life on Earth.

Transparency of water to visible light

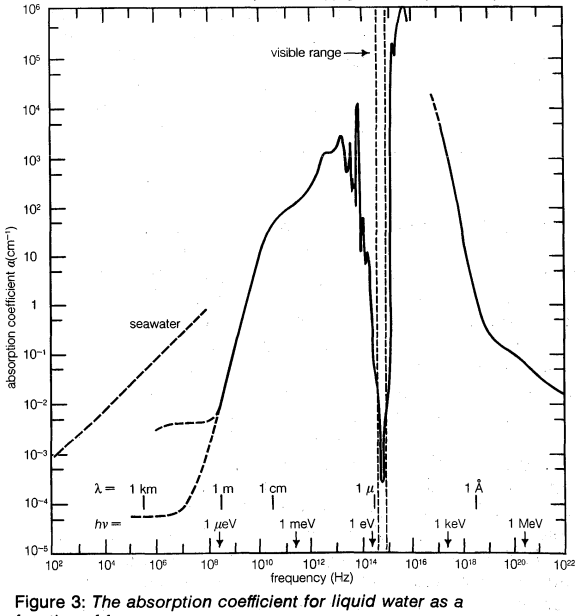

Figure 3: *The absorption coefficient for liquid water as a function of frequency.*
Also shown as abscissas are an energy scale (arrows) and a wavelength scale (vertical lines). The visible region of the frequency spectrum is indicated by the vertical dashed lines. The absorption coefficient for seawater is denoted by the dashed diagonal line at the left. The scales are logarithmic in both directions.

All things look so different and have different colours because of their different sets of internal discrete energies, which determine their interaction with electromagnetic radiation. The words *looking* and *colours* are associated with the human detectors of electromagnetic radiation, the eyes. Since there are instruments available for detecting electromagnetic radiation of any frequency, one can imagine that things "look" different at all energies of the spectrum because different materials have their own characteristic sets of discrete internal energies. Even the nuclei of atoms are composites of other elementary particles and thus can be excited to many discrete internal energy states. Since nuclear energies are much larger than atomic energies, the energy differences between internal energy states are substantially larger, and the corresponding electromagnetic radiation quanta $h\nu$ emitted or absorbed when nuclei change their energies are even bigger than those of X rays. Such quanta given off or absorbed by atomic nuclei are called gamma rays (see *The electromagnetic spectrum* above).

PROPERTIES AND BEHAVIOUR

Scattering, reflection, and refraction. If a charged particle interacts with an electromagnetic wave, it experiences a force proportional to the strength of the electric field and thus is forced to change its motion in accordance with the frequency of the electric field wave. In doing so, it becomes a source of electromagnetic radiation of the same frequency, as described in the previous section. The energy for the work done in accelerating the charged particle and emitting this secondary radiation comes from and is lost by the primary wave. This process is called scattering.

Since the energy density of the electromagnetic radiation is proportional to the square of the electric field strength and the field strength is caused by acceleration of a charge, the energy radiated by such a charge oscillator increases with the square of the acceleration. On the other hand, the acceleration of an oscillator depends on the frequency of the back-and-forth oscillation. The acceleration increases with the square of the frequency. This leads to the important result that the electromagnetic energy radiated by an oscillator increases very rapidly—namely, with the square of the square or, as one says, with the fourth power of the frequency. Doubling the frequency thus produces an increase in radiated energy by a factor of 16.

This rapid increase in scattering with the frequency of electromagnetic radiation can be seen on any sunny day: it is the reason the sky is blue and the setting Sun is red. The higher-frequency blue light from the Sun is scattered much more by the atoms and molecules of the Earth's atmosphere than is the lower-frequency red light. Hence the light of the setting Sun, which passes through a thick layer of atmosphere, has much more red than yellow or blue light, while light scattered from the sky contains much more blue than yellow or red light.

The process of scattering, or reradiating part of the electromagnetic wave by a charge oscillator, is fundamental to understanding the interaction of electromagnetic radiation with solids, liquids, or any matter that contains a very large number of charges and thus an enormous number of charge oscillators. This also explains why a substance that has charge oscillators of certain frequencies absorbs and emits radiation of those frequencies.

Significance of the scattering process

When electromagnetic radiation falls on a large collection of individual small charge oscillators, as in a piece of glass or metal or a brick wall, all of these oscillators perform oscillations in unison, following the beat of the electric wave. As a result, all the oscillators emit secondary radiation in unison (or coherently), and the total secondary radiation coming from the solid consists of the sum of all these secondary coherent electromagnetic waves. This sum total yields radiation that is reflected from the surface of the solid and radiation that goes into the solid at a certain angle with respect to the normal of (*i.e.*, a line perpendicular to) the surface. The latter is the refracted radiation that may be attenuated (absorbed) on its way through the solid.

Superposition and interference. When two electromagnetic waves of the same frequency superpose in space, the resultant electric and magnetic field strength of any point of space and time is the sum of the respective fields of the two waves. When one forms the sum, both the magnitude and the direction of the fields need be considered, which means that they sum like vectors. In the special case when two equally strong waves have their fields in the same direction in space and time (*i.e.*, when they are in phase), the resultant field is twice that of each individual wave. The resultant intensity, being proportional to the square of the field strength, is therefore not two but four times the intensity of each of the two superposing waves.

By contrast, the superposition of a wave that has an electric field in one direction (positive) in space and time with a wave of the same frequency having an electric field in the opposite direction (negative) in space and time leads to cancellation and no resultant wave at all (zero intensity). Two waves of this sort are termed out of phase. The first example, that of in-phase superposition yielding four times the individual intensity, constitutes what is called constructive interference. The second example, that of out-of-phase superposition yielding zero intensity, is destructive interference. Since the resultant field at any point and time is the sum of all individual fields at that point and time, these arguments are easily extended to any number of superposing waves. One finds constructive, destructive, or partial interference for waves having the same frequency and given phase relationships.

Constructive and destructive interference

Propagation and coherence. Once generated, an electromagnetic wave is self-propagating because a time-varying electric field produces a time-varying magnetic field and vice versa. When an oscillating current in an antenna is switched on for, say, eight minutes, then the beginning of the electromagnetic train reaches the Sun just when the antenna is switched off because it takes a few seconds more than eight minutes for electromagnetic radiation to reach the Sun. This eight-minute wave train, which is as long as the Sun–Earth distance, then continues to travel with the speed of light past the Sun into the space beyond.

Except for radio waves transmitted by antennas that are switched on for many hours, most electromagnetic waves comes in many small pieces. The length and duration of a wave train are called coherence length and coherence time, respectively. Light from the Sun or from a light bulb comes in many tiny bursts lasting about a millionth of a millionth of a second and having a coherence length of about one centimetre. The discrete radiant energy emitted by an atom as it changes its internal energy can have a coherence length several hundred times longer (one to 10 metres) unless the radiating atom is disturbed by a collision.

Coherence length and coherence time

The time and space at which the electric and magnetic fields have a maximum value or are zero between the reversal of their directions are different for different wave trains. It is therefore clear that the phenomenon of interference can arise only from the superposition of part of a wave train with itself. This can be accomplished, for instance, with a half-transparent mirror that reflects half the intensity and transmits the other half of each of the billion billion wave trains of a given light source, say, a yellow sodium discharge lamp. One can allow one of these half beams to travel in direction A and the other in direction B, as shown in Figure 4. By reflecting each half beam back, one can then superpose the two half beams and observe the resultant total. If one half beam has to travel a path ½ wavelength or ³⁄₂ or ⁵⁄₂ wavelength longer than the other, then the superposition yields no light at all because the electric and magnetic fields of every half wave train in the two half beams point in opposite directions and their sum is therefore zero. The important point is that cancellation occurs between each half wave train and its mate. This is an example of destructive interference. By adjusting the path lengths A and B such that they are equal or differ by λ, 2λ, $3\lambda \ldots$, the electric and magnetic fields of each half wave train and its mate add when they are superposed. This is constructive interference, and, as a result, one sees strong light.

The interferometer discussed above and represented in Figure 4 was designed by the American physicist Albert A. Michelson in 1880 (while he was studying with Hermann von Helmholtz in Berlin) for the purpose of measuring the effect on the speed of light of the motion of the ether through which light was believed to travel (see below *The electromagnetic wave and field concept*).

Speed of electromagnetic radiation and the Doppler effect. Electromagnetic radiation, or in modern terminology the photons $h\nu$, always travel in free space with the universal speed c—*i.e.*, the speed of light. This is actually a very puzzling situation which was first experimentally verified by Michelson and Edward Williams Morley, another American scientist, in 1887 and which is the basic

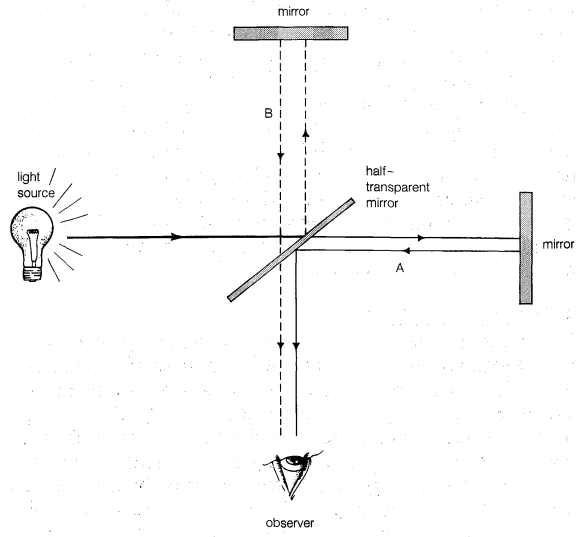

Figure 4: Michelson interferometer.

axiom of Albert Einstein's theory of relativity. Although there is no doubt that it is true, the situation is puzzling because it is so different from the behaviour of normal particles; that is to say, for little or not so little pieces of matter. When one chases behind a normal particle (*e.g.*, an airplane) or moves in the opposite direction toward it, one certainly will measure very different speeds of the airplane relative to oneself. One would detect a very small relative speed in the first case and a very large one in the second. Moreover, a bullet shot forward from the airplane and another toward the back would appear to be moving with different speeds relative to oneself. This would not at all be the case when one measures the speed of electromagnetic radiation: irrespective of one's motion or that of the source of the electromagnetic radiation, any measurement by a moving observer will result in the universal speed of light. This must be accepted as a fact of nature.

What happens to pitch or frequency when the source is moving toward the observer or away from him? It has been established from sound waves that the frequency is higher when a sound source is moving toward the observer and lower when it is moving away from him. This is the Doppler effect, named after the Austrian physicist Christian Doppler, who first described the phenomenon in 1842. Doppler predicted that the effect also occurs with electromagnetic radiation and suggested that it be used for measuring the relative speeds of stars. This means that a characteristic blue light emitted, for example, by an excited helium atom as it changes from a higher to a lower internal energy state would no longer appear blue when one looks at this light coming from helium atoms that move very rapidly away from the Earth with, say, a galaxy. When the speed of such a galaxy away from the Earth is large, the light may appear yellow; if the speed is still larger, it may appear red or even infrared. This is actually what happens, and the speed of galaxies as well as of stars relative to the Earth is measured from the Doppler shift of characteristic atomic radiation energies $h\nu$.

COSMIC BACKGROUND ELECTROMAGNETIC RADIATION

As one measures the relative speeds of galaxies using the Doppler shift of characteristic radiation emissions, one finds that all galaxies are moving away from one another. Those that are moving the fastest are systems that are the farthest away (Hubble's law). The speeds and distances give the appearance of an explosion. Extrapolating backward in time, one obtains an estimate as to when this explosion, dubbed the big bang, might have occurred. This time is calculated to be somewhere between 15 and 20 billion years ago, which is considered to be the age of the universe. From this early stage onward, the universe expanded and cooled. The American scientists Robert W. Wilson and Arno Penzias determined in 1965 that the whole universe can be conceived of as an expanding blackbody filled with electromagnetic radiation which now

The universe as an expanding blackbody

corresponds to a temperature of 2.74 K, only a few degrees above absolute zero. Because of this low temperature, most of the radiation energy is in the microwave region of the electromagnetic spectrum. The intensity of this radiation corresponds, on average, to about 400 photons in every cubic centimetre of the universe. It has been estimated that there are about one billion times more photons in the universe than electrons, nuclei, and all other things taken together. The presence of this microwave cosmic background radiation supports the predictions of big-bang cosmology. (For more specific information on these and related matters, see COSMOS, THE.)

EFFECT OF GRAVITATION

The energy of the quanta of electromagnetic radiation is subject to gravitational forces just like a mass of magnitude $m = h\nu/c^2$. This is so because the relationship of energy E and mass m is $E = mc^2$. As a consequence, light traveling toward the Earth gains energy and its frequency is shifted toward the blue (shorter wavelengths), whereas light traveling "up" loses energy and its frequency is shifted toward the red (longer wavelengths). These shifts are very small but have been detected by the American physicists Robert V. Pound and Glen A. Rebka.

The effect of gravitation on light increases with the strength of the gravitational attraction. Thus, a light beam from a distant star does not travel along a straight line when passing a star like the Sun but is deflected toward it. This deflection can be strong around very heavy cosmic objects, which then distort the light path acting as a gravitational lens.

Under extreme conditions the gravitational force of a cosmic object can be so strong that no electromagnetic radiation can escape the gravitational pull. Such an object, called a black hole, is therefore not visible and its presence can only be detected by its gravitational effect on other visible objects in its vicinity. (For additional information, see COSMOS, THE; PHYSICAL SCIENCES, THE: *Astronomy.*)

THE GREENHOUSE EFFECT OF THE ATMOSPHERE

The temperature of the terrestrial surface environment is controlled not only by the Sun's electromagnetic radiation but also in a sensitive way by the Earth's atmosphere. As noted earlier, each substance absorbs and emits electromagnetic radiation of some energies $h\nu$ and does not do so in other ranges of energy. These regions of transparency and opaqueness are governed by the particular distribution of internal energies of the substance.

The Earth's atmosphere acts much like the glass panes of a greenhouse: it allows sunlight, particularly its visible range, to reach and warm the Earth, but it largely inhibits the infrared radiation emitted by the heated terrestrial surface from escaping into space. Figure 5 shows the absorption of the Earth's atmosphere for various frequencies and wavelengths of electromagnetic radiation. Since the atmosphere becomes thinner and thinner with increasing altitude above the Earth, there is less atmospheric absorption in the higher regions of the atmosphere. At an altitude of 100 kilometres, the fraction of atmosphere is one 10-millionth of that on the ground. Figure 5 shows the altitude at which the intensity of electromagnetic radiation of certain frequencies coming from space is attenuated to one-half of its original value. There are regions of strong absorption and "windows" of transmission. Below 10 million hertz (10^7 Hz), the absorption is caused by the ionosphere, a layer in which atoms and molecules in the atmosphere are ionized by the Sun's ultraviolet radiation. In the infrared region, the absorption is caused by molecular vibrations and rotations. In the ultraviolet and X-ray regions, the absorption is due to electronic excitations in atoms and molecules. The window of transmission for visible light can be seen near the centre of the diagram.

Infrared-absorbing gases in the atmosphere

Without water vapour and carbon dioxide (CO_2), which are, together with certain industrial pollutants, the main infrared-absorbing species in the atmosphere, the Earth would experience the extreme temperature variations between night and day that occur on the Moon. The Earth would then be a frozen planet, like Mars, with an average temperature of 200 K, and not be able to support life.

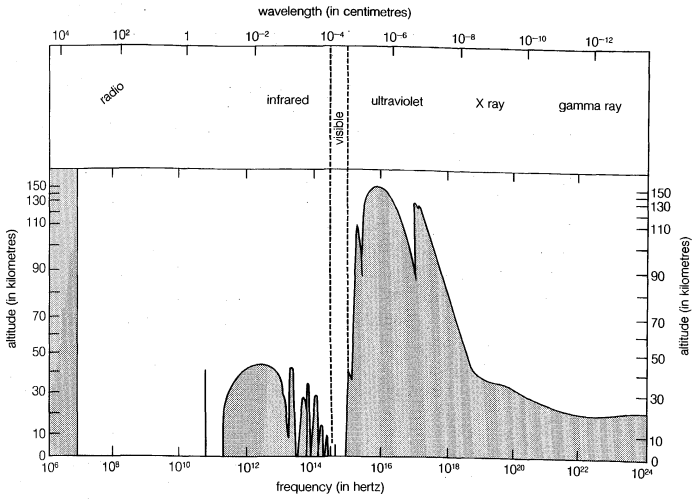

Figure 5: *Atmospheric absorption of electromagnetic radiation.* The intensity of electromagnetic radiation of certain frequencies coming from space is attenuated by the Earth's atmosphere to half of its original value at the altitudes shown here.

Adapted from "The New Astrophysics" by M. Longair in P. Davies (ed.), *The New Physics*, © Cambridge University Press, 1989; after R. Giacconi, H. Gurksy, and L.P. van Speybroeck in "Observational Techniques in X-Ray Astronomy," reproduced, with permission, from the *Annual Review of Astronomy and Astrophysics*, vol. 6, © 1968 by Annual Reviews Inc.

Scientists believe that the Earth's temperature and climate in general will be affected as the composition of the atmosphere is altered by an increased release and accumulation of carbon dioxide and other gaseous pollutants (for a detailed discussion, see CLIMATE AND WEATHER: *Climate and life: Impact of human activities on climate;* HYDROSPHERE, THE: *Impact of human activities on the hydrosphere: Buildup of greenhouse gases*).

Forms of electromagnetic radiation

Electromagnetic radiation appears in a wide variety of forms and manifestations. Yet, these diverse phenomena are understood to comprise a single aspect of nature, following simple physical principles. Common to all forms is the fact that electromagnetic radiation interacts with and is generated by electric charges. The apparent differences in the phenomena arise from the question in which environment and under what circumstances can charges respond on the time scale of the frequency ν of the radiation.

At smaller frequencies ν (smaller than 10^{12} hertz), electric charges typically are the freely moving electrons in the metal components of antennas or the free electrons and ions in space that give rise to phenomena related to radio waves, radar waves, and microwaves. At higher frequencies (10^{12} to 5×10^{14} hertz), in the infrared region of the spectrum, the moving charges are primarily associated with the rotations and vibrations of molecules and the motions of atoms bonded together in materials. Electromagnetic radiation in the visible range to X rays have frequencies that correspond to charges within atoms, whereas gamma rays are associated with frequencies of charges within atomic nuclei. The characteristics of electromagnetic radiation occurring in the different regions of the spectrum are described in this section.

RADIO WAVES

Radio waves are used for wireless transmission of sound messages, or information, for communication, as well as for maritime and aircraft navigation. The information is imposed on the electromagnetic carrier wave as amplitude modulation (AM) or as frequency modulation (FM) or in digital form (pulse modulation). Transmission therefore involves not a single-frequency electromagnetic wave but rather a frequency band whose width is proportional to the information density. The width is about 10,000 Hz for telephone, 20,000 Hz for high-fidelity sound, and five megahertz (MHz = one million hertz) for high-definition television. This width and the decrease in efficiency of generating electromagnetic waves with decreasing fre-

quency sets a lower frequency limit for radio waves near 10,000 Hz.

Because electromagnetic radiation travels in free space in straight lines, scientists questioned the efforts of the Italian physicist and inventor Guglielmo Marconi to develop long-range radio. The curvature of the Earth limits the line-of-sight distance from the top of a 100-metre (330-foot) tower to about 30 kilometres (19 miles). Marconi's unexpected success in transmitting messages over more than 2,000 kilometres led to the discovery of the Kennelly–Heaviside layer, more commonly known as the ionosphere. This region is an approximately 300-kilometre-thick layer starting about 100 kilometres above the Earth's surface in which the atmosphere is partially ionized by ultraviolet light from the Sun, giving rise to enough electrons and ions to affect radio waves. Because of the Sun's involvement, the height, width, and degree of ionization of the stratified ionosphere vary from day to night and from summer to winter.

Radio waves transmitted by antennas in certain directions are bent or even reflected back to Earth by the ionosphere, as illustrated in Figure 6. They may bounce off the Earth and be reflected by the ionosphere repeatedly, making radio transmission around the globe possible. Long-distance communication is further facilitated by the so-called ground wave. This form of electromagnetic wave closely follows the surface of the Earth, particularly over water, as a result of the wave's interaction with the terrestrial surface. The range of the ground wave (up to 1,600 kilometres) and the bending and reflection of the sky wave by the ionosphere depend on the frequency of the waves. Under normal ionospheric conditions 40 MHz is the highest-frequency radio wave that can be reflected from the ionosphere. The strong absorption of the ionosphere below 10 MHz is shown in Figure 5. In order to accommodate the large band width of transmitted signals, television frequencies are necessarily higher than 40 MHz. Television transmitters must therefore be placed on high towers or on hilltops.

Ground waves

As a radio wave travels from the transmitting to the receiving antenna, it may be disturbed by reflections from buildings and other large obstacles. Disturbances arise when several such reflected parts of the wave reach the receiving antenna and interfere with the reception of the wave. Radio waves can penetrate nonconducting materials such as wood, bricks, and concrete fairly well.

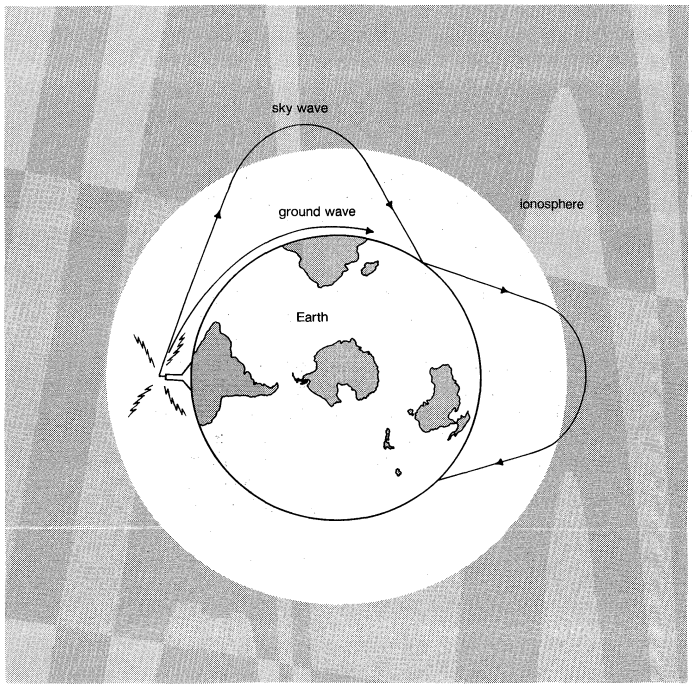

Figure 6: Radio-wave transmission reaching beyond line of sight by means of the sky wave reflected by the ionosphere and by means of the ground wave (see text).

They cannot pass through electrical conductors such as water or metals. Above $\nu = 40$ MHz, radio waves from deep space can penetrate the Earth's atmosphere. This makes radio astronomy observations with ground-based telescopes possible.

Whenever transmission of electromagnetic energy from one location to another is required with minimal energy loss and disturbance, the waves are confined to a limited region by means of wires, coaxial cables, and, in the microwave region, waveguides. Unguided or wireless transmission is naturally preferred when the locations of receivers are unspecified or too numerous, as in the case of radio and television communications. Cable television, as the name implies, is an exception. In this case electromagnetic radiation is transmitted by a coaxial cable system to users either from a community antenna or directly from broadcasting stations. The shielding of this guided transmission from disturbances provides high-quality signals.

Transmission via wires, coaxial cables, and waveguides

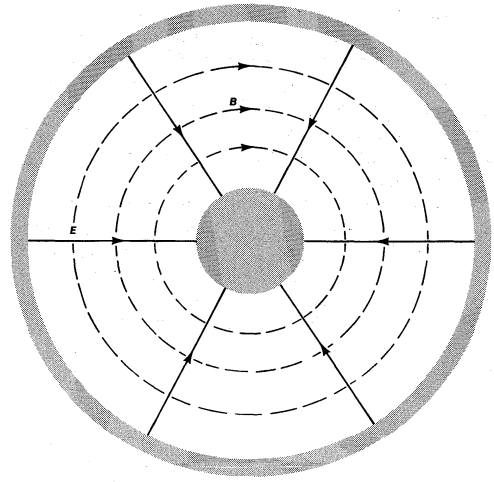

Figure 7: *Cross section of a coaxial cable carrying high-frequency current.*
Electric field lines ***E*** (solid) and magnetic field lines ***B*** (dashed) are mutually perpendicular and perpendicular to the electromagnetic wave propagation, which is toward the viewer.

Figure 7 shows the electric field ***E*** (solid lines) and the magnetic field ***B*** (dashed lines) of an electromagnetic wave guided by a coaxial cable. There is a potential difference between the inner and outer conductors and so electric field lines ***E*** extend from one conductor to the other, represented here in cross section. The conductors carry opposite currents that produce the magnetic field lines ***B***. The electric and magnetic fields are perpendicular to each other and perpendicular to the direction of propagation, as is characteristic of the electromagnetic waves illustrated in Figure 2. At any cross section viewed, the directions of the ***E*** and ***B*** field lines change to their opposite with the frequency ν of the radiation. This direction reversal of the fields does not change the direction of propagation along the conductors. The speed of propagation is again the universal speed of light if the region between the conductors consists of air or free space.

A combination of radio waves and strong magnetic fields is used by magnetic resonance imaging (MRI) to produce diagnostic pictures of parts of the human body and brain without apparent harmful effects. This imaging technique has thus found increasingly wider application in medicine (see also RADIATION: *Imaging techniques*).

Extremely low-frequency (ELF) waves are of interest for communications systems for submarines. The relatively weak absorption by seawater of electromagnetic radiation at low frequencies and the existence of prominent resonances of the natural cavity formed by the Earth and the ionosphere make the range between 5 and 100 Hz attractive for this application.

There is evidence that ELF waves and the oscillating magnetic fields that occur near electric power transmission lines or electric heating blankets have adverse effects on human health and the electrochemical balance of the

brain. Prolonged exposure to low-level and low-frequency magnetic fields have been reported to increase the risk of developing leukemia, lymphoma, and brain cancer in children.

MICROWAVES

The microwave region extends from 1,000 to 300,000 MHz (or 30-centimetre to one-millimetre wavelengths). Although microwaves were first produced and studied in 1886 by Hertz, their practical application had to await the invention of suitable generators, such as the klystron and magnetron.

Use in high-speed telegraphic data transmissions

Microwaves are the principal carriers of high-speed telegraphic data transmissions between stations on the Earth and also between ground-based stations and satellites and space probes. A system of synchronous satellites about 36,000 kilometres above the Earth is used for international broadband telegraphy of all kinds of communications—*e.g.*, television, telephone, and telefacsimile (FAX).

Microwave transmitters and receivers are parabolic dish antennas. They produce microwave beams whose spreading angle is proportional to the ratio of the wavelength of the constituent waves to the diameter of the dish. The beams can thus be directed like a searchlight. Radar beams consist of short pulses of microwaves. One can determine the distance of an airplane or ship by measuring the time it takes such a pulse to travel to the object and, after reflection, back to the radar dish antenna. Moreover, by making use of the change in frequency of the reflected wave pulse caused by the Doppler effect (see above), one can measure the speed of objects. Microwave radar is therefore widely used for guiding airplanes and vessels and for detecting speeding motorists. Microwaves can penetrate clouds of smoke, but are scattered by water droplets, and so are used for mapping meteorologic disturbances and in weather forecasting (see CLIMATE AND WEATHER: *Meteorological measurement and weather forecasting*).

Microwaves play an increasingly wide role in heating and cooking food. They are absorbed by water and fat in foodstuffs (*e.g.*, in the tissue of meats) and produce heat from the inside. In most cases, this reduces the cooking time a hundredfold. Such dry objects as glass and ceramics, on the other hand, are not heated in the process, and metal foils are not penetrated at all.

The heating effect of microwaves destroys living tissue when the temperature of the tissue exceeds 43° C (109° F). Accordingly, exposure to intense microwaves in excess of 20 milliwatts of power per square centimetre of body surface is harmful. The lens of the human eye is particularly affected by waves with a frequency of 3,000 MHz, and repeated and extended exposure can result in cataracts. Radio waves and microwaves of far less power (microwatts per square centimetre) than the 10–20 milliwatts per square centimetre needed to produce heating in living tissue can have adverse effects on the electrochemical balance of the brain and the development of a fetus if these waves are modulated or pulsed at low frequencies between 5 and 100 hertz, which are of the same magnitude as brain wave frequencies.

Microwave sources

Various types of microwave generators and amplifiers have been developed. Vacuum-tube devices, the klystron and the magnetron, continue to be used on a wide scale, especially for higher-power applications. Klystrons are primarily employed as amplifiers in radio relay systems and for dielectric heating, while magnetrons have been adopted for radar systems and microwave ovens. (For a detailed discussion of these devices, see ELECTRONICS: *Principal devices and components: Electron tubes.*) Solid-state technology has yielded several devices capable of producing, amplifying, detecting, and controlling microwaves. Notable among these are the Gunn diode and the tunnel (or Esaki) diode. Another type of device, the maser (acronym for "microwave amplification by stimulated emission of radiation") has proved useful in such areas as radio astronomy, microwave radiometry, and long-distance communications.

Astronomers have discovered what appears to be natural masers in some interstellar clouds. Observations of radio radiation from interstellar hydrogen (H_2) and certain other molecules indicate amplification by the maser process. Also, as was mentioned above, microwave cosmic background radiation has been detected and is considered by many to be the remnant of the primeval fireball postulated by the big-bang cosmological model.

INFRARED RADIATION

Beyond the red end of the visible range but at frequencies higher than those of radar waves and microwaves is the infrared region of the electromagnetic spectrum, between frequencies of 10^{12} and 5×10^{14} Hz (or wavelengths from 0.1 to 7.5×10^{-5} centimetre). William Herschel, a German-born British musician and self-taught astronomer, discovered this form of radiation in 1800 by exploring, with the aid of a thermometer, sunlight dispersed into its colours by a glass prism. Infrared radiation is absorbed and emitted by the rotations and vibrations of chemically bonded atoms or groups of atoms and thus by many kinds of materials. For instance, window glass that is transparent to visible light absorbs infrared radiation by the vibration of its constituent atoms. Infrared radiation is strongly absorbed by water and by the atmosphere, as shown in Figures 3 and 5, respectively. Although invisible to the eye, infrared radiation can be detected as warmth by the skin. Nearly 50 percent of the Sun's radiant energy is emitted in the infrared region of the electromagnetic spectrum, with the rest primarily in the visible region.

Atmospheric haze and certain pollutants that scatter visible light are nearly transparent to parts of the infrared spectrum because the scattering efficiency increases with the fourth power of the frequency. Infrared photography of distant objects from the air takes advantage of this phenomenon. For the same reason, infrared astronomy enables researchers to observe cosmic objects through large clouds of interstellar dust that scatter infrared radiation substantially less than visible light. However, since water vapour, ozone, and carbon dioxide in the atmosphere absorb large parts of the infrared spectrum most infrared astronomical observations are carried out at high altitude by balloons, rockets, or spacecraft.

An infrared photograph of a landscape enhances objects according to their heat emission: blue sky and water appear nearly black, whereas green foliage and unexposed skin show up brightly. Infrared photography can reveal pathological tissue growths (thermography) and defects in electronic systems and circuits due to their increased emission of heat.

The infrared absorption and emission characteristics of molecules and materials yield important information about the size, shape, and chemical bonding of molecules and of atoms and ions in solids. The energies of rotation and vibration are quantized in all systems. The infrared radiation energy $h\nu$ emitted or absorbed by a given molecule or substance is therefore a measure of the difference of some of the internal energy states. These in turn are determined by the atomic weight and molecular bonding forces. For this reason, infrared spectroscopy is a powerful tool for determining the internal structure of molecules and substances or, when such information is already known and tabulated, for identifying the amounts of those species in a given sample. Infrared spectroscopic techniques are often used to determine the composition and hence the origin and age of archaeological specimens and for detecting forgeries of art and other objects, which, when inspected under visible light, resemble the originals.

Infrared radiation plays an important role in heat transfer and is integral to the so-called greenhouse effect (see above), influencing the thermal radiation budget of the Earth on a global scale and affecting nearly all biospheric activity. Virtually every object at the Earth's surface emits electromagnetic radiation primarily in the infrared region of the spectrum.

Infrared LEDs and lasers

Man-made sources of infrared radiation include, besides hot objects, infrared light-emitting diodes (LEDs) and lasers. LEDs are small, inexpensive optoelectronic devices made of such semiconducting materials as gallium arsenide. Infrared LEDs are employed as optoisolators and as light sources in some fibre-optics-based communications systems (see ELECTRONICS: *Principal devices and compo-*

nents: Optoelectronic devices). Powerful optically pumped infrared lasers have been developed using carbon dioxide and carbon monoxide. Carbon dioxide infrared lasers are used to induce and alter chemical reactions and in isotope separation. They also are employed in LIDAR (light radar) systems. Other applications of infrared light include its use in the rangefinders of automatic self-focusing cameras, security alarm systems, and night-vision optical instruments.

Instruments for detecting infrared radiation include heat-sensitive devices such as thermocouple detectors, bolometers (some of these are cooled to temperatures close to absolute zero so that the thermal radiation of the detector system itself is greatly reduced), photovoltaic cells, and photoconductors. The latter are made of semiconductor materials (*e.g.,* silicon and lead sulfide) whose electrical conductance increases when exposed to infrared radiation.

VISIBLE RADIATION

Visible light is the most familiar form of electromagnetic radiation and makes up that portion of the spectrum to which the eye is sensitive. This span is very narrow; the frequencies of violet light are only about twice those of red. The corresponding wavelengths extend from 7×10^{-5} centimetre (red) to 4×10^{-5} centimetre (violet). The energy of a photon from the centre of the visible spectrum (yellow) is $h\nu = 2.2$ eV. This is one million times larger than the energy of a photon of a television wave and one billion times larger than that of radio waves in general (see Figure 1).

Life on Earth could not exist without visible light, which represents the peak of the Sun's spectrum and close to one-half of all of its radiant energy. Visible light is essential for photosynthesis, which enables plants to produce the carbohydrates and proteins that are the food sources for animals. Coal and oil are sources of energy accumulated from sunlight in plants and microorganisms millions of years ago, and hydroelectric power is extracted from one step of the hydrologic cycle kept in motion by sunlight at the present time.

Considering the importance of visible sunlight for all aspects of terrestrial life, one cannot help being awed by the dramatically narrow window in the atmospheric absorption shown in Figure 5 and in the absorption spectrum of water in Figure 3. The remarkable transparency of water centred in the narrow regime of visible light, indicated by vertical dashed lines in Figure 3, is the result of the characteristic distribution of internal energy states of water. Absorption is strong toward the infrared on account of molecular vibrations and intermolecular oscillations. In the ultraviolet region, absorption of radiation is caused by electronic excitations. Light of frequencies having absorption coefficients larger than $\alpha = 10$ cm^{-1} cannot even reach the retina of the human eye because its constituent liquid consists mainly of water that absorbs such frequencies of light.

Conversion of solar energy into electricity

Since the 1970s an increasing number of devices have been developed for converting sunlight into electricity. Unlike various conventional energy sources, solar energy does not become depleted by use and does not pollute the environment. Two branches of development may be noted—namely, photothermal and photovoltaic technologies. In photothermal devices, sunlight is used to heat a substance, as, for example, water, to produce steam with which to drive a generator. Photovoltaic devices, on the other hand, convert the energy in sunlight directly to electricity by use of the photovoltaic effect in a semiconductor junction. Solar panels consisting of photovoltaic devices made of gallium arsenide have conversion efficiencies of more than 20 percent and are used to provide electric power in many satellites and space probes. Large-area solar panels can be made with amorphous semiconductors that have conversion efficiencies of about 10 percent. Solar cells have replaced dry cell batteries in some portable electronic instruments, and solar energy power stations of one- to six-megawatts capacity have been built.

The intensity and spectral composition of visible light can be measured and recorded by essentially any process or property that is affected by light. Detectors make use of a photographic process based on silver halide, the photoemission of electrons from metal surfaces, the generation of electric current in a photovoltaic cell, and the increase in electrical conduction in semiconductors.

Glass fibres constitute an effective means of guiding and transmitting light. A beam of light is confined by total internal reflection to travel inside such an optical fibre, whose thickness may be anywhere between one hundredth of a millimetre and a few millimetres. Many thin optical fibres can be combined into bundles to achieve image reproduction. The flexibility of these fibres or fibre bundles permits their use in medicine for optical exploration of internal organs. Optical fibres connecting the continents provide the capability to transmit substantially larger amounts of information than other systems of international telecommunications. Another advantage of optical fibre communication systems is that transmissions cannot easily be intercepted and are not disturbed by lower atmospheric and stratospheric disturbances.

Optical fibres integrated with miniature semiconductor lasers and light-emitting diodes, as well as with light detector arrays and photoelectronic imaging and recording materials, form the building blocks of a new optoelectronics industry. Some familiar commercial products are optoelectronic copying machines, laser printers, compact disc players, FAX machines, optical recording media, and optical disc mass-storage systems of exceedingly high bit density.

ULTRAVIOLET RADIATION

The German physicist Johann Wilhelm Ritter, having learned of Herschel's discovery of infrared waves, looked beyond the violet end of the visible spectrum of the Sun and found (in 1801) that there exist invisible rays that darken silver chloride even more efficiently than visible light. This spectral region extending between visible light and X rays is designated ultraviolet. Sources of this form of electromagnetic radiation are hot objects like the Sun, synchrotron radiation sources, mercury or xenon arc lamps, and gaseous discharge tubes filled with gas atoms (*e.g.,* mercury, deuterium, or hydrogen) that have internal electron energy levels which correspond to the photons of ultraviolet light.

Fluorescence

When ultraviolet light strikes certain materials, it causes them to fluoresce—*i.e.,* they emit electromagnetic radiation of lower energy, such as visible light. The spectrum of fluorescent light is characteristic of a material's composition and thus can be used for screening minerals, detecting bacteria in spoiled food, identifying pigments, or detecting forgeries of artworks and other objects (the aged surfaces of ancient marble sculptures, for instance, fluoresce yellow-green, whereas a freshly cut marble surface fluoresces bright violet).

Optical instruments for the ultraviolet region are made of special materials, such as quartz, certain silicates, and metal fluorides, which are transparent at least in the near ultraviolet. Far-ultraviolet radiation is absorbed by nearly all gases and materials and thus requires reflection optics in vacuum chambers.

Ultraviolet radiation is detected by photographic plates and by means of the photoelectric effect in photomultiplier tubes. Also, ultraviolet radiation can be converted to visible light by fluorescence before detection.

The relatively high energy of ultraviolet light gives rise to certain photochemical reactions. This characteristic is exploited to produce cyanotype impressions on fabrics and for blueprinting design drawings. Here, the fabric or paper is treated with a mixture of chemicals that react upon exposure to ultraviolet light to form an insoluble blue compound. Electronic excitations caused by ultraviolet radiation also produce changes in the colour and transparency of photosensitive and photochromic glasses. Photochemical and photostructural changes in certain polymers constitute the basis for photolithography and the processing of the microelectronic circuits.

Although invisible to the eyes of humans and most vertebrates, near-ultraviolet light can be seen by many insects. Butterflies and many flowers that appear to have identical colour patterns under visible light are distinctly

different when viewed under the ultraviolet rays perceptible to insects.

An important difference between ultraviolet light and electromagnetic radiation of lower frequencies is the ability of the former to ionize, meaning that it can knock an electron out from atoms and molecules. All high-frequency electromagnetic radiation beyond the visible—*i.e.*, ultraviolet light, X rays, and gamma rays—is ionizing and therefore harmful to body tissues, living cells, and DNA (deoxyribonucleic acid). The harmful effects of ultraviolet light to humans and larger animals are mitigated by the fact that this form of radiation does not penetrate much further than the skin.

The body of a sunbather is struck by 10^{21} photons every second, and 1 percent of these, or more than a billion billion per second, are photons of ultraviolet radiation. Tanning and natural body pigments help to protect the skin to some degree, preventing the destruction of skin cells by ultraviolet light. Nevertheless, overexposure to the ultraviolet component of sunlight can cause skin cancer, cataracts of the eyes, and damage to the body's immune system. Fortunately a layer of ozone (O_3) in the stratosphere absorbs the most damaging ultraviolet rays, which have wavelengths of 2000 and 2900 angstroms (one angstrom [Å] = 10^{-10} metre), and attenuates those with wavelengths between 2900 and 3150 Å, as shown in Figure 5. Without this protective layer of ozone, life on Earth would not be possible. The ozone layer is produced at an altitude of about 10 to 50 kilometres above the Earth's surface by a reaction between upward-diffusing molecular oxygen (O_2) and downward-diffusing ionized atomic oxygen (O^+). Many scientists believe that this life-protecting stratospheric ozone layer is being reduced by chlorine atoms in chlorofluorocarbon (or Freon) gases released into the atmosphere by aerosol propellants, air-conditioner coolants, solvents used in the manufacture of electronic components, and other sources. (For more specific information, see ATMOSPHERE: *Composition of the present atmosphere: Effects of human activity on atmospheric composition and their ramifications: Depletion of stratospheric ozone.*)

Protective ozone layer

Ionized atomic oxygen, nitrogen, and nitric oxide are produced in the upper atmosphere by absorption of solar ultraviolet radiation. This ionized region is the ionosphere, which affects radio communications and reflects and absorbs radio waves of frequencies below 40 MHz (see Figure 5).

X RAYS

The German physicist Wilhelm Conrad Röntgen discovered X rays in 1895 by accident while studying cathode rays in a low-pressure gas discharge tube. (A few years later J.J. Thomson of England showed that cathode rays were electrons emitted from the negative electrode [cathode] of the discharge tube.) Röntgen noticed the fluorescence of a barium platinocyanide screen that happened to lie near the discharge tube. He traced the source of the hitherto undetected form of radiation to the point where the cathode rays hit the wall of the discharge tube, and mistakenly concluded from his inability to observe reflection or refraction that his new rays were unrelated to light. Because of his uncertainty about their nature, he called them X-radiation. This early failure can be attributed to the very short wavelengths of X rays (10^{-8} to 10^{-11} centimetre), which correspond to photon energies from 200 to 100,000 eV. In 1912 another German physicist, Max von Laue, realized that the regular arrangement of atoms in crystals should provide a natural grating of the right spacing (about 10^{-8} centimetre) to produce an interference pattern on a photographic plate when X rays pass through such a crystal. The success of this experiment, carried out by Walter Friedrich and Paul Knipping, not only identified X rays with electromagnetic radiation but also initiated the use of X rays for studying the detailed atomic structure of crystals. The interference of X rays diffracted in certain directions from crystals in so-called X-ray diffractometers, in turn, permits the dissection of X-radiation into its different frequencies, just as a prism diffracts and spreads the various colours of light. The spectral composition and characteristic frequencies of X rays emitted by a given X-ray source can thus be measured. As in optical spectroscopy, the X-ray photons emitted correspond to the differences of the internal electronic energies in atoms and molecules. Because of their much higher energies, however, X-ray photons are associated with the inner-shell electrons close to the atomic nuclei, whereas optical absorption and emission are related to the outermost electrons in atoms or in materials in general. Since the outer electrons are used for chemical bonding while the energies of inner-shell electrons remain essentially unaffected by atomic bonding, the identity and quantity of elements that make up a material are more accurately determined by the emission, absorption, or fluorescence of X rays than of photons of visible or ultraviolet light.

Röntgen's X-radiation

The contrast between body parts in medical X-ray photographs (radiographs) is produced by the different scattering and absorption of X rays by bones and tissues. Within months of Röntgen's discovery of X rays and his first X-ray photograph of his wife's hand, this form of electromagnetic radiation became indispensable in orthopedic and dental medicine. The use of X rays for obtaining images of the body's interior has undergone considerable development over the years and has culminated in the highly sophisticated procedure known as computerized axial tomography (CAT; see RADIATION: *Applications of radiation: Medical applications: Imaging techniques*).

Notwithstanding their usefulness in medical diagnosis, the ability of X rays to ionize atoms and molecules and their penetrating power make them a potential health hazard. Exposure of body cells and tissue to large doses of such ionizing radiation can result in abnormalities in DNA that may lead to cancer and birth defects. (For a detailed treatment of the effects of X rays and other forms of ionizing radiation on human health and the levels of such radiation encountered in daily life, see RADIATION: *Biologic effects of ionizing radiation.*)

X rays are produced in X-ray tubes by the deceleration of energetic electrons (bremsstrahlung) as they hit a metal target or by accelerating electrons moving at relativistic velocities in circular orbits (synchrotron radiation; see above). They are detected by their photochemical action in photographic emulsions or by their ability to ionize gas atoms: every X-ray photon produces a burst of electrons and ions, resulting in a current pulse. By counting the rate of such current pulses per second, the intensity of a flux of X rays can be measured. Instruments used for this purpose are called Geiger counters.

Cosmic X-ray sources

X-ray astronomy has revealed very strong sources of X rays in deep space. In the Milky Way Galaxy, of which the solar system is a part, the most intense sources are certain double star systems in which one of the two stars is thought to be either a compact neutron star or a black hole. The ionized gas of the circling companion star falls by gravitation into the compact star, generating X rays that may be more than 1,000 times as intense as the total amount of light emitted by the Sun. At the moment of their explosion, supernovae emit a good fraction of their energy in a burst of X rays.

GAMMA RAYS

Six years after the discovery of radioactivity (1896) by Henri Becquerel of France, the New Zealand-born British physicist Ernest Rutherford found that three different kinds of radiation are emitted in the decay of radioactive substances; these he called alpha, beta, and gamma rays in sequence of their ability to penetrate matter. The alpha particles were found to be identical with the nuclei of helium atoms and the beta rays were identified as electrons. In 1912 it was shown that the much more penetrating gamma rays have all the properties of very energetic electromagnetic radiation, or photons. Gamma-ray photons are between 10,000 and 10,000,000 times more energetic than the photons of visible light when they originate from radioactive atomic nuclei. Gamma rays with a million million times higher energy make up a very small part of the cosmic rays that reach the Earth from supernovae or from other galaxies. The origin of the most energetic gamma rays is not yet known.

During radioactive decay, an unstable nucleus usually emits alpha particles, electrons, gamma rays, and neutrinos spontaneously. In nuclear fission, the unstable nucleus breaks into fragments, which are themselves complex nuclei, along with such particles as neutrons and protons. The resultant stable nuclei or nuclear fragments are usually in a highly excited state and then reach their low-energy ground state by emitting one or more gamma rays. Such a decay scheme is shown schematically in Figure 8 for the unstable nucleus sodium-24 (^{24}Na). Much of what is known about the internal structure and energies of nuclei has been obtained from the emission or resonant absorption of gamma rays by nuclei. Absorption of gamma rays by nuclei can cause them to eject neutrons or alpha particles or it can even split a nucleus like a bursting bubble in what is called photodisintegration. A gamma particle hitting a hydrogen nucleus (that is, a proton), for example, produces a positive pi-meson and a neutron or a neutral pi-meson and a proton. Neutral pi-mesons, in turn, have a very brief mean life of 1.8×10^{-16} second and decay into two gamma rays of energy $h\nu \approx 70$ MeV. When an energetic gamma ray $h\nu > 1.02$ MeV passes a nucleus, it may disappear while creating an electron–positron pair. Gamma photons interact with matter by discrete elementary processes that include resonant absorption, photodisintegration, ionization, scattering (Compton scattering), or pair production.

Photodisintegration

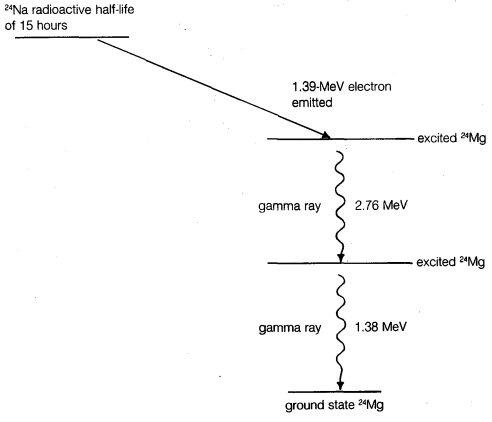

Figure 8: Decay scheme of a radioactive sodium-24 (^{24}Na) nucleus. With a half-life of 15 hours, it decays by beta decay to an excited magnesium-24 (^{24}Mg) nucleus. Two gamma rays are rapidly emitted and the excitation energy is carried off, whereby the stable ground state of magnesium-24 is reached.

Gamma rays are detected by their ability to ionize gas atoms or to create electron–hole pairs in semiconductors or insulators. By counting the rate of charge pulses or voltage pulses or by measuring the scintillation of the light emitted by the subsequently recombining electron–hole pairs, one can determine the number and energy of gamma rays striking an ionization detector or scintillation counter.

Both the specific energy of the gamma-ray photon emitted as well as the half-life of the specific radioactive decay process that yields the photon identify the type of nuclei at hand and their concentrations. By bombarding stable nuclei with neutrons, one can artificially convert more than 70 different stable nuclei into radioactive nuclei and use their characteristic gamma emission for purposes of identification, for impurity analysis of metallurgical specimens (neutron-activation analysis), or as radioactive tracers with which to determine the functions or malfunctions of human organs, to follow the life cycles of organisms, or to determine the effects of chemicals on biological systems and plants.

Penetrating power of gamma rays

The great penetrating power of gamma rays stems from the fact that they have no electric charge and thus do not interact with matter as strongly as do charged particles. Because of their penetrating power gamma rays can be used for radiographing holes and defects in metal castings and other structural parts. At the same time, this property makes gamma rays extremely hazardous. The lethal effect of this form of ionizing radiation makes it useful for sterilizing medical supplies that cannot be sanitized by boiling or for killing organisms that cause food spoilage. More than 50 percent of the ionizing radiation to which humans are exposed comes from natural radon gas, which is an end product of the radioactive decay chain of natural radioactive substances in minerals. Radon escapes from the ground and enters the environment in varying amounts.

Historical survey

DEVELOPMENT OF THE CLASSICAL RADIATION THEORY

The classical electromagnetic radiation theory "remains for all time one of the greatest triumphs of human intellectual endeavor." So said Max Planck in 1931, commemorating the 100th anniversary of the birth of the Scottish physicist James Clerk Maxwell, the prime originator of this theory. The theory was indeed of great significance, for it not only united the phenomena of electricity, magnetism, and light in a unified framework but also was a fundamental revision of the then-accepted Newtonian way of thinking about the forces in the physical universe. The development of the classical radiation theory constituted a conceptual revolution that lasted for nearly half a century. It began with the seminal work of the British physicist and chemist Michael Faraday, who published his article "Thoughts on Ray Vibrations" in *Philosophical Magazine* in May 1846, and came to fruition in 1888 when Hertz succeeded in generating electromagnetic waves at radio and microwave frequencies and measuring their properties.

Wave theory and corpuscular theory. The Newtonian view of the universe may be described as a mechanistic interpretation. All components of the universe, small or large, obey the laws of mechanics, and all phenomena are in the last analysis based on matter in motion. A conceptual difficulty in Newtonian mechanics, however, is the way in which the gravitational force between two massive objects acts over a distance across empty space. Newton did not address this question, but many of his contemporaries hypothesized that the gravitational force was mediated through an invisible and frictionless medium which Aristotle had called the ether (or aether). The problem is that everyday experience of natural phenomena shows mechanical things to be moved by forces which make contact. Any cause and effect without a discernable contact, or "action at a distance," contradicts common sense and has been an unacceptable notion since antiquity. Whenever the nature of the transmission of certain actions and effects over a distance was not yet understood, the ether was resorted to as a conceptual solution of the transmitting medium. By necessity, any description of how the ether functioned remained vague, but its existence was required by common sense and thus not questioned.

Notion of the ether

In Newton's day, light was one phenomenon, besides gravitation, whose effects were apparent at large distances from its source. Newton contributed greatly to the scientific knowledge of light. His experiments revealed that white light is a composite of many colours, which can be dispersed by a prism and reunited to again yield white light. The propagation of light along straight lines convinced him that it consists of tiny particles which emanate at high or infinite speed from the light source. The first observation from which a finite speed of light was deduced was made soon thereafter, in 1676, by the Danish astronomer Ole Rømer (see *Speed of light* below).

Observations of two phenomena strongly suggested that light propagates as waves. One of these involved interference by thin films, which was discovered in England independently by Robert Boyle and Robert Hooke. The other had to do with the diffraction of light in the geometric shadow of an opaque screen. The latter was also discovered by Hooke, who published a wave theory of light in 1665 to explain it.

The Dutch scientist Christiaan Huygens greatly improved the wave theory and explained reflection and refraction in terms of what is now called Huygens' principle. According to this principle (published in 1690), each point on a wave front in the hypothetical ether or in an optical medium is a source of a new spherical light wave and the wave front

Huygens' principle

is the envelope of all the individual wavelets that originate from the old wave front.

In 1669 another Danish scientist, Erasmus Bartholin, discovered the polarization of light by double refraction in Iceland spar (calcite). This finding had a profound effect on the conception of the nature of light. At that time, the only waves known were those of sound, which are longitudinal. It was inconceivable to both Newton and Huygens that light could consist of transverse waves in which vibrations are perpendicular to the direction of propagation. Huygens gave a satisfactory account of double refraction by proposing that the asymmetry of the structure of Iceland spar causes the secondary wavelets to be ellipsoidal instead of spherical in his wave front construction. Since Huygens believed in longitudinal waves, he failed, however, to understand the phenomena associated with polarized light. Newton, on the other hand, used these phenomena as the bases for an additional argument for his corpuscular theory of light. Particles, he argued in 1717, have "sides" and can thus exhibit properties that depend on the directions perpendicular to the direction of motion.

It may be surprising that Huygens did not make use of the phenomenon of interference to support his wave theory; but for him waves were actually pulses instead of periodic waves with a certain wavelength. One should bear in mind that the word wave may have a very different conceptual meaning and convey different images at various times to different people.

It took nearly a century before a new wave theory was formulated by the physicists Thomas Young of England and Augustin-Jean Fresnel of France. Based on his experiments on interference, Young realized for the first time that light is a transverse wave. Fresnel then succeeded in explaining all optical phenomena known at the beginning of the 19th century with a new wave theory. No proponents of the corpuscular light theory remained. Nonetheless, it is always satisfying when a competing theory is discarded on grounds that one of its principal predictions is contradicted by experiment. The corpuscular theory explained the refraction of light passing from a medium of given density to a denser one in terms of the attraction of light particles into the latter. This means the light velocity should be larger in the denser medium. Huygens' construction of wave fronts waving across the boundary between two optical media predicted the opposite—that is to say, a smaller light velocity in the denser medium. The measurement of the light velocity in air and water by Armand-Hippolyte-Louis Fizeau and independently by Jean-Bernard-Léon Foucault during the mid-19th century decided the case in favour of the wave theory (see *Speed of light* below).

The transverse wave nature of light implied that the ether must be a solid elastic medium. The larger velocity of light suggested, moreover, a great elastic stiffness of this medium; yet, it was recognized that all celestial bodies move through the ether without encountering such difficulties as friction. These conceptual problems remained unsolved until the beginning of the 20th century. (Ht.F.)

Relation between electricity and magnetism. As early as 1760 the Swiss-born mathematician Leonhard Euler suggested that the same ether that propagates light is responsible for electrical phenomena. In comparison with both mechanics and optics, however, the science of electricity was slow to develop. Magnetism was the one science that made progress in the Middle Ages, following the introduction from China into the West of the magnetic compass, but electromagnetism played little part in the scientific revolution of the 17th century. It was, however, the only part of physics in which very significant progress was made during the 18th century. By the end of that century the laws of electrostatics—the behaviour of charged particles at rest—were well known, and the stage was set for the development of the elaborate mathematical description first made by the French mathematician Siméon-Denis Poisson. There was no apparent connection of electricity with magnetism, except that magnetic poles, like electric charges, attract and repel with an inverse-square law force.

Following the discoveries in electrochemistry (the chemical effects of electrical current) by the Italian investigators Luigi Galvani, a physiologist, and Alessandro Volta, a physicist, interest turned to current electricity. A search was made by the Danish physicist Hans Christian Ørsted for some connection between electric currents and magnetism, and during the winter of 1819–20 he observed the effect of a current on a magnetic needle. Members of the French Academy learned about Ørsted's discovery in September 1820, and several of them began to investigate it further. Of these, the most thorough in both experiment and theory was the physicist André-Marie Ampère, who may be called the father of electrodynamics. The magnetic effect of a current had been observed earlier (1802) by an Italian jurist, Gian Domenico Romagnosi, but the announcement was published in an obscure newspaper.

The list of four fundamental empirical laws of electricity and magnetism was made complete with the discovery of electromagnetic induction by both Faraday and Joseph Henry in about 1831. In brief, a change in magnetic flux through a conducting circuit produces a current in the circuit. The observation that the induced current is in a direction to oppose the change that produces it, now known as Lenz's law, was formulated by a Russian-born physicist, Heinrich Friedrich Emil Lenz, in 1834. When the laws were put into mathematical form by Maxwell, the law of induction was generalized to include the production of electric force in space, independent of actual conducting circuits, but was otherwise unchanged. On the other hand, Ampère's law describing the magnetic effect of a current required amendment in order to be consistent with the conservation of charge (the total charge must remain constant) in the presence of changing electric fields, and Maxwell introduced the idea of "displacement current" to make the set of equations logically consistent. As a result, he found on combining the equations that he arrived at a wave equation, according to which transverse electric and magnetic disturbances were propagated with a velocity that could be calculated from electrical measurements. These measurements were available to Maxwell, having been made in 1856 by the German physicists Rudolph Hermann Arndt Kohlrausch and Wilhelm Eduard Weber, and his calculation gave him a result that was the same, within the limits of error, as the speed of light in vacuum. It was the coincidence of this value with the velocity of the waves predicted by his theory that convinced Maxwell of the electromagnetic nature of light. (M.Ph./Ht.F.)

Electromagnetic induction

The electromagnetic wave and field concept. Faraday introduced the concept of field and of field lines of force that exist outside material bodies. As he explained it, the region around and outside a magnet or an electric charge contains a field that describes at any location the force experienced by another small magnet or charge placed there. The lines of force around a magnet can be made visible by iron filings sprayed on a paper that is held over the magnet. The concept of field, specifying as it does a certain possible action or force at any location in space, was the key to understanding electromagnetic phenomena. It should be mentioned parenthetically that the field concept also plays (in varied forms) a pivotal role in modern theories of particles and forces.

Besides introducing this important concept of electric and magnetic field lines of force, Faraday had the extraordinary insight that electrical and magnetic actions are not transmitted instantaneously but after a certain lag in time, which increases with distance from the source. Moreover, he realized the connection between magnetism and light after observing that a substance such as glass can rotate the plane of polarization of light in the presence of a magnetic field. This remarkable phenomenon is known as the Faraday effect.

Faraday effect

As noted above, Maxwell formulated a quantitative theory that linked the fundamental phenomena of electricity and magnetism and that predicted electromagnetic waves propagating with a speed, which, as well as one could determine at that time, was identical with the speed of light. He concluded his paper "On the Physical Lines of Force" (1861–62) by saying that electricity may be disseminated through space with properties identical with those of light. In 1864 Maxwell wrote that the numerical factor linking the electrostatic and the magnetic units was very close to

the speed of light and that these results "show that light and magnetism are affections of the same substance, and that light is an electromagnetic disturbance propagated through the field according to [his] electromagnetic laws."

What more was needed to convince the scientific community that the mystery of light was solved and the phenomena of electricity and magnetism were unified in a grand theory? Why did it take 25 more years for Maxwell's theory to be accepted? For one, there was little direct proof of the new theory. Furthermore, Maxwell not only had adopted a complicated formalism but also explained its various aspects by unusual mechanical concepts. Even though he stated that all such phrases are to be considered as illustrative and not as explanatory, the French mathematician Henri Poincaré remarked in 1899 that the "complicated structure" which Maxwell attributed to the ether "rendered his system strange and unattractive."

The ideas of Faraday and Maxwell that the field of force has a physical existence in space independent of material media were too new to be accepted without direct proof. On the Continent, particularly in Germany, matters were further complicated by the success of Carl Friedrich Gauss and Wilhelm Eduard Weber in developing a potential field theory for the phenomena of electrostatics and magnetostatics and their continuing effort to extend this formalism to electrodynamics.

Hertz's contributions

It is difficult in hindsight to appreciate the reluctance to accept the Faraday–Maxwell theory. The impasse was finally removed by Hertz's work. In 1884 Hertz derived Maxwell's theory by a new method and put its fundamental equations into their present-day form. In so doing, he clarified the equations, making the symmetry of electric and magnetic fields apparent. The German physicist Arnold Sommerfeld spoke for most of his learned colleagues when, after reading Hertz's paper, he remarked, "the shades fell from my eyes," and admitted that he understood electromagnetic theory for the first time. Four years later, Hertz made a second major contribution: he succeeded in generating electromagnetic radiation of radio and microwave frequencies, measuring their speed by a standing-wave method and proving that these waves have the properties of reflection, diffraction, refraction, and interference common to light. He showed that such electromagnetic waves can be polarized, that the electric and magnetic fields oscillate in directions that are mutually perpendicular and transverse to the direction of motion, and that their velocity is the same as the speed of light, as predicted by Maxwell's theory.

Hertz's ingenious experiments not only settled the theoretical misconceptions in favour of Maxwell's electromagnetic field theory but also opened the way for building transmitters, antennas, coaxial cables, and detectors for radio-frequency electromagnetic radiation. In 1896 Marconi received the first patent for wireless telegraphy, and in 1901 he achieved transatlantic radio communication.

The Faraday–Maxwell–Hertz theory of electromagnetic radiation, which is commonly referred to as Maxwell's theory, makes no reference to a medium in which the electromagnetic waves propagate. A wave of this kind is produced, for example, when a line of charges is moved back and forth along the line. Moving charges represent an electric current. In this back-and-forth motion, the current flows in one direction and then in another. As a consequence of this reversal of current direction, the magnetic field around the current (discovered by Ørsted and Ampère) has to reverse its direction. The time-varying magnetic field produces perpendicular to it a time-varying electric field, as discovered by Faraday (Faraday's law of induction). These time-varying electric and magnetic fields spread out from their source, the oscillating current, at the speed of light in free space. The oscillating current in this discussion is the oscillating current in a transmitting antenna, and the time-varying electric and magnetic fields that are perpendicular to one another propagate at the speed of light and constitute an electromagnetic wave. Its frequency is that of the oscillating charges in the antenna. Once generated, it is self-propagating because a time-varying electric field produces a time-varying magnetic field, and vice versa. Electromagnetic radiation travels through space by itself. The belief in the existence of an ether medium, however, was at the time of Maxwell as strong as at the time of Plato and Aristotle. It was impossible to visualize ether because contradictory properties had to be attributed to it in order to explain the phenomena known at any given time. In his article ETHER in the ninth edition of the *Encyclopædia Britannica,* Maxwell described the vast expanse of the substance, some of it possibly even inside the planets, carried along with them or passing through them as the "water of the sea passes through the meshes of a net when it is towed along by a boat."

If one believes in the ether, it is, of course, of fundamental importance to measure the speed of its motion or the effect of its motion on the speed of light. One does not know the absolute velocity of the ether, but as the Earth moves through its orbit around the Sun there should be a difference in ether velocity along and perpendicular to the Earth's motion equal to its speed. If such is the case, the velocity of light and of any other electromagnetic radiation along and perpendicular to the Earth's motion should, predicted Maxwell, differ by a fraction that is equal to the square of the ratio of the Earth's velocity to that of light. This fraction is one part in 100 million.

Michelson set out to measure this effect and, as noted above, designed for this purpose the interferometer sketched in Figure 4. If it is assumed that the interferometer is turned so that half beam A is oriented parallel to the Earth's motion and half beam B is perpendicular to it, then the idea of using this instrument for measuring the effect of the ether motion is best explained by Michelson's words to his children:

> Two beams of light race against each other, like two swimmers, one struggling upstream and back, while the other, covering the same distance, just crosses the river and returns. The second swimmer will always win, if there is any current in the river.

Michelson–Morley experiment

An improved version of the interferometer, in which each half beam traversed its path eight times before both were reunited for interference, was built in 1887 by Michelson in collaboration with Morley. A heavy sandstone slab holding the interferometer was floated on a pool of mercury to allow rotation without vibration. Michelson and Morley could not detect any difference in the two light velocities parallel and perpendicular to the Earth's motion to an accuracy of one part in four billion. This negative result did not, however, shatter the belief in the existence of an ether because the ether could possibly be dragged along with the Earth and thus be stationary around the Michelson–Morley apparatus. Hertz's formulation of Maxwell's theory made it clear that no medium of any sort was needed for the propagation of electromagnetic radiation. In spite of this, ether-drift experiments continued to be conducted until about the mid-1920s. All such tests confirmed Michelson's negative results, and scientists finally came to accept the idea that no ether medium was needed for electromagnetic radiation.

Speed of light. Much effort has been devoted to measuring the speed of light, beginning with the aforementioned work of Rømer in 1676. Rømer noticed that the orbital period of Jupiter's first moon, Io, is apparently slowed as the Earth and Jupiter move away from each other. The eclipses of Io occur later than expected when Jupiter is at its most remote position. This effect is understandable if light requires a finite time to reach the Earth from Jupiter. From this effect, Rømer calculated the time required for light to travel from the Sun to the Earth as 11 minutes. In 1728 James Bradley, an English astronomer, determined the speed of light from the apparent orbital motion of stars that is produced by the orbital motion of the Earth. He computed the time for light to reach the Earth from the Sun as eight minutes, 12 seconds. The first terrestrial measurements were made in 1849 by Fizeau and a year later by Foucault. Michelson improved on Foucault's method and obtained an accuracy of one part in 100,000.

Any measurement of velocity requires, however, a definition of the measure of length and of time. Current techniques allow a determination of the velocity of electromagnetic radiation to a substantially higher degree of precision than permitted by the unit of length that scien-

tists had applied earlier. In 1983 the value of the speed of light was fixed at exactly 299,792,458 metres per second, and this value was adopted as a new standard. As a consequence, the metre was redefined as the length of the path traveled by light in a vacuum over a time interval of 1/299,792,458 of a second. Furthermore, the second—the international unit of time—has been based on the frequency of electromagnetic radiation emitted by a cesium-133 atom.

DEVELOPMENT OF THE QUANTUM THEORY OF RADIATION

After a long struggle electromagnetic wave theory had triumphed. The Faraday–Maxwell–Hertz theory of electromagnetic radiation seemed to be able to explain all phenomena of light, electricity, and magnetism. The understanding of these phenomena enabled one to produce electromagnetic radiation of many different frequencies which had never been observed before and which opened a world of new opportunities. No one suspected that the conceptional foundations of physics were about to change again.

Radiation laws and Planck's light quanta. The quantum theory of absorption and emission of radiation announced in 1900 by Planck ushered in the era of modern physics. He proposed that all material systems can absorb or give off electromagnetic radiation only in "chunks" of energy, quanta E, and that these are proportional to the frequency of that radiation $E = h\nu$. (The constant of proportionality h is, as noted above, called Planck's constant.)

Planck was led to this radically new insight by trying to explain the puzzling observation of the amount of electromagnetic radiation emitted by a hot body and, in particular, the dependence of the intensity of this incandescent radiation on temperature and on frequency. The quantitative aspects of the incandescent radiation constitute the radiation laws.

The Austrian physicist Josef Stefan found in 1879 that the total radiation energy per unit time emitted by a heated surface per unit area increases as the fourth power of its absolute temperature T (Kelvin scale). This means that the Sun's surface, which is at $T = 6{,}000$ K, radiates per unit area $(6{,}000/300)^4 = 20^4 = 160{,}000$ times more electromagnetic energy than does the same area of the Earth's surface, which is taken to be $T = 300$ K. In 1889 another Austrian physicist, Ludwig Boltzmann, used the second law of thermodynamics to derive this temperature dependence for an ideal substance that emits and absorbs all frequencies. Such an object that absorbs light of all colours looks black, and so was called a blackbody. The Stefan–Boltzmann law is written in quantitative form $W = \sigma T^4$, where W is the radiant energy emitted per second and per unit area and the constant of proportionality is $\sigma = 0.136$ calories per metre^2-second-K^4.

Stefan–Boltzmann law

The wavelength or frequency distribution of blackbody radiation was studied in the 1890s by Wilhelm Wien of Germany. It was his idea to use as a good approximation for the ideal blackbody an oven with a small hole. Any radiation that enters the small hole is scattered and reflected from the inner walls of the oven so often that nearly all incoming radiation is absorbed and the chance of some of it finding its way out of the hole again can be made exceedingly small. The radiation coming out of this hole is then very close to the equilibrium blackbody electromagnetic radiation corresponding to the oven temperature. Wien found that the radiative energy dW per wavelength interval $d\lambda$ has a maximum at a certain wavelength λ_m and that the maximum shifts to shorter wavelengths as the temperature T is increased, as illustrated in Figure 9. He found that the product $\lambda_m T$ is an absolute constant: $\lambda_m T = 0.2898$ centimetre-degree Kelvin.

Wien's law of the shift of the radiative power maximum to higher frequencies as the temperature is raised expresses in a quantitative form commonplace observations. Warm objects emit infrared radiation, which is felt by the skin; near $T = 950$ K a dull red glow can be observed; and the colour brightens to orange and yellow as the temperature is raised. The tungsten filament of a light bulb is $T = 2{,}500$ K hot and emits bright light, yet the peak of its spectrum is still in the infrared according to Wien's law.

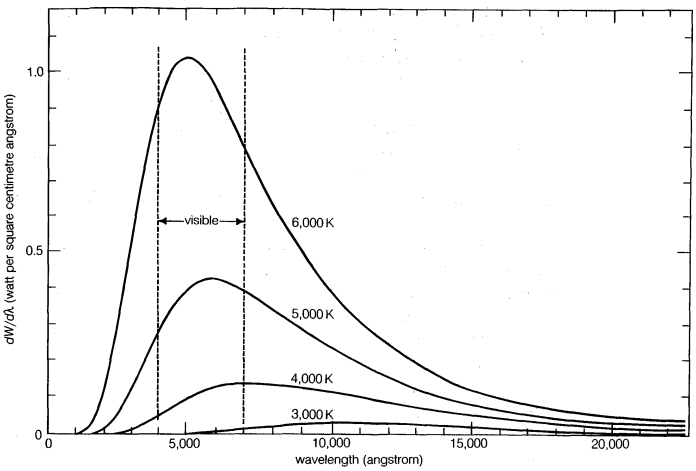

Figure 9: Electromagnetic energy dW emitted per unit area and per second into a wavelength interval, $d\lambda$ = one angstrom, by a blackbody at various temperatures between 3,000 and 6,000 K as a function of wavelength. The range of visible light is between the vertical dashed lines.

The peak shifts to the visible yellow when the temperature is $T = 6{,}000$ K, like that of the Sun's surface.

It was the shape of Wien's radiative energy distribution as a function of frequency that Planck tried to understand. The decrease of the radiation output at low frequency had already been explained by Lord Rayleigh (John William Strutt) in terms of the decrease, with lowering frequency, in the number of modes of electromagnetic radiation per frequency interval. Rayleigh assumed that all possible frequency modes could radiate with equal probability, following the principle of equipartition of energy. Since the number of frequency modes per frequency interval continues to increase without limit with the square of the frequency, Rayleigh's formula predicted an ever-increasing amount of radiation of higher frequencies instead of the observed maximum and subsequent fall in radiative power. A possible way out of this dilemma was to deny the high-frequency modes an equal chance to radiate. To achieve this, Planck postulated that the radiators or oscillators can only emit electromagnetic radiation in finite amounts of energy of size $E = h\nu$. At a given temperature T, there is then not enough thermal energy available to create and emit many large radiation quanta $h\nu$. More large energy quanta $h\nu$ can be emitted, however, when the temperature is raised. Quantitatively the probability of emitting at temperature T an electromagnetic energy quantum $h\nu$ is

$$\frac{1}{e^{h\nu/kT} - 1},$$

where k is Boltzmann's constant, well known from thermodynamics. With $c = \lambda\nu$, Planck's radiation law then becomes

Planck's radiation law

$$dW = \frac{8\pi ch\lambda^{-5} d\lambda}{e^{hc/\lambda kT} - 1}.$$

This is in superb agreement with Wien's experimental results when the value of h is properly chosen to fit the results. It should be pointed out that Planck's quantization refers to the oscillators of the blackbody or of heated substances. These oscillators of frequency ν are incapable of absorbing or emitting electromagnetic radiation except in energy chunks of size $h\nu$. To explain quantized absorption and emission of radiation, it seemed sufficient to quantize only the energy levels of mechanical systems. Planck did not mean to say that electromagnetic radiation itself is quantized, or as Einstein later put it, "The sale of beer in pint bottles does not imply that beer exists only in indivisible pint portions." The idea that electromagnetic radiation itself is quantized was proposed by Einstein in 1905, as described in the subsequent section.

Photoelectric effect. Hertz discovered the photoelectric effect (1887) quite by accident while generating elec-

tromagnetic waves and observing their propagation. His transmitter and receiver were induction coils with spark gaps. He measured the electromagnetic field strength by the maximum length of the spark of his detector. In order to observe this more accurately, he occasionally enclosed the spark gap of the receiver in a dark case. In doing so, he observed that the spark was always smaller with the case than without it. He concluded correctly that the light from the transmitter spark affected the electrical arcing of the receiver. He used a quartz prism to disperse the light of the transmitter spark and found that the ultraviolet part of the light spectrum was responsible for enhancing the receiver spark. Hertz took this discovery seriously because the only other effect of light on electrical phenomena known at that time was the increase in electrical conductance of the element selenium with light exposure.

A year after Hertz's discovery, it became clear that ultraviolet radiation caused the emission of negatively charged particles from solid surfaces. Thomson's discovery of electrons (1897) and his ensuing measurement of the ratio m/e (the ratio of mass to charge) finally made it possible to identify the negative particles emitted in the photoelectric effect with electrons. This was accomplished in 1899 by J.J. Thomson and independently by Philipp Lenard, one of Hertz's students. Lenard discovered that for a given frequency of ultraviolet radiation the maximum kinetic energy of the emitted electrons depends on the metal used rather than on the intensity of the ultraviolet light. The light intensity increases the number but not the energy of emitted electrons. Moreover, he found that for each metal there is a minimum light frequency that is needed to induce the emission of electrons. Light of a frequency lower than this minimum frequency has no effect regardless of its intensity.

In 1905 Einstein published an article entitled "On a Heuristic Point of View about the Creation and Conversion of Light." Here he deduced that electromagnetic radiation itself consists of "particles" of energy $h\nu$. He arrived at this conclusion by using a simple theoretical argument comparing the change in entropy of an ideal gas caused by an isothermal change in volume with the change in entropy of an equivalent volume change for electromagnetic radiation in accordance with Wien's or Planck's radiation law. This derivation and comparison made no references to substances and oscillators. At the end of this paper, Einstein concluded that if electromagnetic radiation is quantized, the absorption processes are thus quantized too, yielding an elegant explanation of the threshold energies and the intensity dependence of the photoelectric effect. He then predicted that the kinetic energy of the electrons emitted in the photoelectric effect increases with light frequency ν proportional to $h\nu - P$, where P is "the amount of work that the electron must produce on leaving the body." This quantity P, now called work function, depends on the kind of solid used, as discovered by Lenard.

Reaction to Einstein's idea of light quanta

Einstein's path-breaking idea of light quanta was not widely accepted by his peers. Planck himself stated as late as 1913 in his recommendation for admitting Einstein to the Prussian Academy of Sciences "the fact that he [Einstein] may occasionally have missed the mark in his speculations, as, for example, with his hypothesis of light quanta, ought not to be held too much against him, for it is impossible to introduce new ideas, even in the exact sciences, without taking risks." In order to explain a quantized absorption and emission of radiation by matter, it seemed sufficient to quantize the possible energy states in matter. The resistance against quantizing the energies of electromagnetic radiation itself is understandable in view of the incredible success of Maxwell's theory of electromagnetic radiation and the overwhelming evidence of the wave nature of this radiation. Moreover, a formal similarity of two theoretical expressions, in Einstein's 1905 paper, of the entropy of an ideal gas and the entropy of electromagnetic radiation was deemed insufficient evidence for a real correspondence.

Einstein's prediction of the linear increase of the kinetic energy of photoemitted electrons with frequency of light, $h\nu - P$, was verified by Arthur Llewelyn Hughes, Owen Williams Richardson, and Karl Taylor Compton in 1912. In 1916 Robert Andrews Millikan measured both the frequency of the light and the kinetic energy of the electron emitted by the photoelectric effect and obtained a value for Planck's constant h in close agreement with the value that had been arrived at by fitting Planck's radiation law to the blackbody spectrum obtained by Wien.

Compton effect. Convincing evidence of the particle nature of electromagnetic radiation was found in 1922 by the American physicist Arthur Holly Compton. While investigating the scattering of X rays, he observed that such rays lose some of their energy in the scattering process and emerge with slightly decreased frequency. This energy loss increases with the scattering angle, θ, measured from the direction of an unscattered X ray. This so-called Compton effect can be explained, according to classical mechanics, as an elastic collision of two particles comparable to the collision of two billiard balls. In this case, an X-ray photon of energy $h\nu$ and momentum $h\nu/c$ collides with an electron at rest. The recoiling electron was observed and measured by Compton and Alfred W. Simon in a Wilson cloud chamber. If one calculates the result of such an elastic collision using the relativistic formulas for the energy and momentum of the scattered electron, one finds that the wavelength of an X ray after (λ') and before (λ) the scattering event differ by $\lambda' - \lambda = (h/mc)(1 - \cos\theta)$. Here m is the rest mass of the electron and h/mc is called Compton wavelength. It has the value 0.0243 angstrom. The energy $h\nu$ of a photon of this wavelength is equal to the rest mass energy mc^2 of an electron. One might argue that electrons in atoms are not at rest, but their kinetic energy is very small compared to that of energetic X rays and can be disregarded in deriving Compton's equation.

Resonance absorption and recoil. During the mid-1800s the German physicist Gustav Robert Kirchhoff observed that atoms and molecules emit and absorb electromagnetic radiation at characteristic frequencies and that the emission and absorption frequencies are the same for a given substance. Such resonance absorption should, strictly speaking, not occur if one applies the photon picture due to the following argument. Since energy and momentum have to be conserved in the emission process, the atom recoils to the left as the photon is emitted to the right, just as a cannon recoils backward when a shot is fired. Because the recoiling atom carries off some kinetic recoil energy E_R, the emitted photon energy is less than the energy difference of the atomic energy states by the amount E_R. When a photon is absorbed by an atom, the momentum of the photon is likewise transmitted to the atom, thereby giving it a kinetic recoil energy E_R. The absorbing photon must therefore supply not only the energy difference of the atomic energy states but the additional amount E_R as well. Accordingly, resonance absorption should not occur because the emitted photon is missing $2E_R$ to accomplish it.

Nevertheless, ever since Kirchhoff's finding, investigators have observed resonance absorption for electronic transitions in atoms and molecules. This is because for visible light the recoil energy E_R is very small compared with the natural energy uncertainty of atomic emission and absorption processes. The situation is, however, quite different for the emission and absorption of gamma-ray photons by nuclei. The recoil energy E_R is more than 10,000 times as large for gamma-ray photons as for photons of visible light, and the nuclear energy transitions are much more sharply defined because their lifetime can be one million times longer than for electronic energy transitions. The particle nature of photons therefore prevents resonance absorption of gamma-ray photons by free nuclei.

Recoil-free gamma-ray resonance absorption

In 1958 the German physicist Rudolf Ludwig Mössbauer discovered that recoilless gamma-ray resonance absorption is, nevertheless, possible if the emitting as well as the absorbing nuclei are embedded in a solid. In this case, there is a strong probability that the recoil momentum during absorption and emission of the gamma photon is taken up by the whole solid (or more precisely by its entire lattice). This then reduces the recoil energy to nearly zero and thus allows resonance absorption to occur even for gamma rays.

Wave–particle duality. How can electromagnetic radi-

ation behave like a particle in some cases while exhibiting wavelike properties that produce the interference and diffraction phenomena in others? This paradoxical behaviour came to be known as the wave–particle duality. Bohr rejected the idea of light quanta, and he searched for ways to explain the Compton effect and the photoelectric effect by arguing that the momentum and energy conservation laws need to be satisfied only statistically in the time average. In 1923 he stated that the hypothesis of light quanta excludes, in principle, the possibility of a rational definition of the concepts of frequency and wavelength that are essential for explaining interference.

The following year, the conceptual foundations of physics were shaken by the French physicist Louis-Victor de Broglie, who suggested in his doctoral dissertation that the wave–particle duality applies not only to light but to a particle as well. De Broglie proposed that any object has wavelike properties. In particular, he showed that the orbits and energies of the hydrogen atom, as described by Bohr's atomic model, correspond to the condition that the circumference of any orbit precisely matches an integral number of wavelengths λ of the matter waves of electrons. Any particle such as an electron moving with a momentum p has, according to de Broglie, a wavelength $\lambda = h/p$. This idea required a conceptual revolution of mechanics, which led to the wave and quantum mechanics of Erwin Schrödinger, Werner Heisenberg, and Max Born.

Verification of de Broglie's idea of the wavelike behaviour of particles

De Broglie's idea of the wavelike behaviour of particles was quickly verified experimentally. In 1927 Clinton Joseph Davisson and Lester Germer of the United States observed diffraction and hence interference of electron waves by the regular arrangement of atoms in a crystal of nickel. That same year S. Kikuchi of Japan obtained an electron diffraction pattern by shooting electrons with an energy of 68 keV through a thin mica plate and recording the resultant diffraction pattern on a photographic plate. The observed pattern corresponded to electron waves having the wavelength predicted by de Broglie. The diffraction effects of helium atoms were found in 1930, and neutron diffraction has today become an indispensable tool for determining the magnetic and atomic structure of materials.

The interference pattern that results when a radiation front hits two slits in an opaque screen is often cited to explain the conceptual difficulty of the wave–particle duality. Consider an opaque screen with two openings A and B, called double slit, and a photographic plate or a projection screen, as shown in Figure 10. A parallel wave with a wavelength λ passing through the double slit will produce the intensity pattern on the plate or screen as shown at the right of the figure. The intensity is greatest at the centre. It falls to zero at all locations x_0, where the distances to the openings A and B differ by odd-number multiples of a half wavelength, as, for instance, $\lambda/2$, $3\lambda/2$, and $5\lambda/2$. The condition for such destructive interference is the same as for Michelson's interferometer illustrated in Figure 4. Whereas a half-transparent mirror in Figure 4 divides the amplitude of each wave train in half, the division in Figure 10 through openings A and B is spatial. The latter is called division of wave front. Constructive interference or intensity maxima are observed on the screen at all positions whose distances from A and B differ by zero or an integer multiple of λ. This is the wave interpretation of the observed double-slit interference pattern.

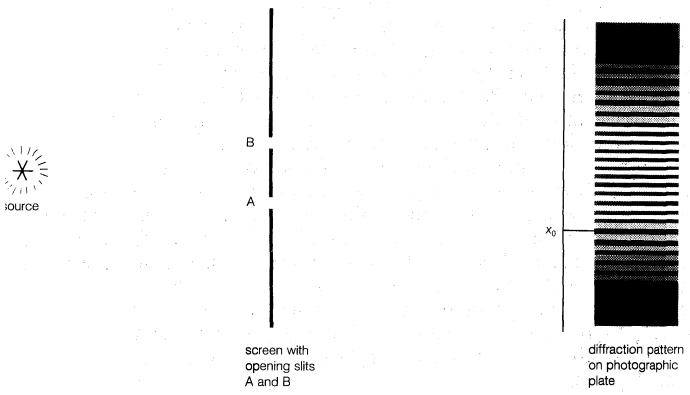

Figure 10: Double-slit interference.

The description of photons is necessarily different because a particle can obviously only pass through opening A or alternatively through opening B. Yet, no interference pattern is observed when either A or B is closed. Both A and B must be open simultaneously. It was thought for a time that one photon passing through A might interfere with another photon passing through B. That possibility was ruled out after the British physicist Geoffrey Taylor demonstrated in 1909 that the same interference pattern can be recorded on a photographic plate even when the light intensity is so feeble that only one photon is present in the apparatus at any one time.

Another attempt to understand the dual nature of electromagnetic radiation was to identify the photon with a wave train whose length is equal to its coherence length $c\tau$, where τ is the coherence time, or the lifetime of an atomic transition from a higher to a lower internal atomic energy state, and c is the light velocity. This is the same as envisioning the photon to be an elongated wave packet, or "needle radiation." Again, the term "photon" had a different meaning for different scientists, and wave nature and quantum structure remained incompatible. It was time to find a theory of electromagnetic radiation that would fuse the wave theory and the particle theory. Such a fusion was accomplished by quantum electrodynamics (QED).

Quantum electrodynamics. Among the most convincing phenomena that demonstrate the quantum nature of light are the following. As the intensity of light is dimmed further and further, one can see individual quanta being registered in light detectors. If the eyes were about 10 times more sensitive, one would perceive the individual light pulses of fainter and fainter light sources as fewer and fewer flashes of equal intensity. Moreover, a movie has been made of the buildup of a two-slit interference pattern by individual photons, such as shown in Figure 10. Photons are particles, but they behave differently from ordinary particles like billiard balls. The rules of their behaviour and their interaction with electrons and other charged particles, as well as the interactions of charged particles with one another, constitute QED.

Subject of QED

Photons are created by perturbances in the motions of electrons and other charged particles; and, in reverse, photons can disappear and thereby create a pair of oppositely charged particles, usually a particle and its antiparticle (*e.g.*, an electron and a positron). A description of this intimate interaction between charged particles and electromagnetic radiation requires a theory that includes both quantum mechanics and special relativity. The foundations of such a theory, known as relativistic quantum mechanics, were laid beginning in 1929 by Paul A.M. Dirac, Heisenberg, and Wolfgang Pauli.

The discussion that follows explains in brief the principal conceptual elements of QED. Further information on the subject can be found in SUBATOMIC PARTICLES: *The development of modern theory;* and MECHANICS: *Quantum mechanics.*

Many phenomena in nature do not depend on the reference scale of scientific measurements. For instance, in electromagnetism the difference in electrical potentials is relevant but not its absolute magnitude. During the 1920s, even before the emergence of quantum mechanics, the German physicist Hermann Weyl discussed the problem of constructing physical theories that are independent of certain reference bases or absolute magnitudes of certain parameters not only locally but everywhere in space. He called this property "Eich Invarianz," which is the conceptual origin of the term "gauge invariance" that plays a crucial role in all modern quantum field theories.

In quantum mechanics all observable quantities are calculated from so-called wave functions, which are complex mathematical functions that include a phase factor. The absolute magnitude of this phase is irrelevant for the observable quantities calculated from these wave functions; hence, the theory describing, for example, the motion of an electron should be the same when the phase of its wave function is changed everywhere in space. This requirement of phase invariance, or gauge invariance, is

Gauge invariance

equivalent to demanding that the total charge is conserved and does not disappear in physical processes or interactions. Experimentally one does indeed observe that charge is conserved in nature.

It turns out that a relativistic quantum theory of charged particles can be made gauge invariant if the interaction is mediated by a massless and chargeless entity which has all the properties of photons. Coulomb's law of the force between charged particles can be derived from this theory, and the photon can be viewed as a "messenger" particle that conveys the electromagnetic force between charged particles of matter. In this theory, Maxwell's equations for electric and magnetic fields are quantized.

The range of a force produced by a particle with nonzero mass is its Compton wavelength h/mc, which for electrons is about 2×10^{-10} centimetre. Since this length is large compared with distances over which stronger nuclear forces act, QED is a very precise theory for electrons.

Despite the conceptual elegance of the QED theory, it proved difficult to calculate the outcome of specific physical situations through its application. Richard P. Feynman and, independently, Julian S. Schwinger and Freeman Dyson of the United States and Tomonaga Shin'ichirō of Japan showed in 1948 that one could calculate the effects of the interactions as a power series in which the coupling constant is called the fine structure constant and has a value close to $1/137$. A serious practical difficulty arose when each term in the series, which had to be summed to obtain the value of an observed quantity, turned out to be infinitely large. In short, the results of the calculations were meaningless. It was eventually found, however, that these divergences could be avoided by introducing "renormalized" couplings and particle masses, an idea conceived by the Dutch physicist Hendrik A. Kramers. Just as a ship moving through water has an enhanced mass due to the fluid that it drags along, so will an electron dragging along and interacting with its own field have a different mass and charge than it would without it. By adding appropriate electromagnetic components to the bare mass and charge—that is, by using renormalized quantities—the disturbing infinities could be removed from the theory. Using this method of renormalization and the perturbation theory, Feynman developed an elegant form for calculating the likelihood of observing processes that are related to the interaction of electromagnetic radiation with matter to any desired degree of accuracy. For example, the passage of an electron or a photon through the double slit illustrated in Figure 10 will, in this QED formalism, produce the observed interference pattern on a photographic plate because of the superposition of all the possible paths these particles can take through the slits.

The success of unifying electricity, magnetism, and light into one theory of electromagnetism and then with the interaction of charged particles into the theory of quantum electrodynamics suggests the possibility of understanding all the forces in nature (gravitational, electromagnetic, weak nuclear, and strong nuclear) as manifestations of a grand unified theory (GUT). The first step in this direction was taken during the 1960s by Abdus Salam, Steven Weinberg, and Sheldon Glashow, who formulated the electroweak theory, which combines the electromagnetic force and the weak nuclear force. This theory predicted that the weak nuclear force is transmitted between particles of matter by three messenger particles designated W^+, W^-, and Z, much in the way that the electromagnetic force is conveyed by photons. The three new particles were discovered in 1983 during experiments at the European Organization for Nuclear Research (CERN), a large accelerator laboratory near Geneva. This triumph for the electroweak theory represented another stepping stone toward a deeper understanding of the forces and interactions that yield the multitude of physical phenomena in the universe. GUT

Electronics

Electronics encompasses an exceptionally broad range of technology having to do with the motion of electrons and its control for useful purposes. The term originally was applied to the study of electron behaviour and movement. It came to be used in its broader sense with advances in knowledge about the fundamental nature of electrons and about the way in which the motion of these particles could be utilized. Today many scientific and technical disciplines—including physics, chemistry, materials science, mathematics, and electrical and electronic engineering—deal with different aspects of electronics.

Research in these fields has resulted in the development of such key devices as transistors, integrated circuits, lasers, and optical fibres. These in turn have made it possible to manufacture a wide array of electronic consumer, industrial, and military products. Such products range from cellular radiotelephone systems and videocassette recorders to high-performance supercomputers and sophisticated weapons systems. By the mid-1980s the electronics industry had become the largest manufacturing industry in the United States. Japan and the industrialized nations of western Europe also had flourishing electronics industries, while various developing countries—including South Korea, Taiwan, Israel, and Yugoslavia—had experienced significant advances as well.

The impact of electronics on modern life has been pervasive. It can be said that the world is in the midst of an electronic revolution at least as significant as the industrial revolution of the 19th century. Evidence of this is apparent everywhere.

Electronics is essential, for example, in telecommunications. Today an increasing volume of information is transmitted in digital form. Digital techniques, in which signals are converted into groups of pulses, allow the intermingling of voice, television, and computer signals into one very rapid series of pulses on a single channel that can be separated at the receiving end and reconstituted into the signals originally sent. Because the digital pulses can be regenerated perfectly after they become attenuated with distance, no noise or other degradation is apparent at the receiving end.

Electronic controls for industrial machines and processes have made possible dramatic improvements in productivity and quality. Computer-aided design tools facilitate the designing of parts that have complex shapes, such as aircraft wings, or intricate structures, such as integrated circuits. The production of designs of this sort is done by computer-controlled machines that receive instructions directly from the design tools.

Access to knowledge has been made far easier by computerized indexes of scientific and technical journals, which are accessible from centralized services over telephone lines. These central databases are being supplemented by new techniques derived from digital audio and video disc technology, which provide locally at low cost access to vast amounts of information in both text and graphic form.

This article reviews the historical development of electronics, highlighting major discoveries and advances. It also describes some key electronic functions and the manner in which various devices carry out these functions.

For coverage of other related topics in the *Macropædia* and *Micropædia,* see the *Propædia,* sections 125, 127, 712, 721, 735, and 738.

The article is divided into the following sections:

History of electronics

EARLY DEVELOPMENTS

Theoretical and experimental studies of electricity during the 18th and 19th centuries led to the development of the first electrical machines and the beginning of the widespread use of electricity. The history of electronics began to evolve separately from that of electricity late in the 19th century with the identification of the electron by the English physicist J.J. Thomson and the measurement of its electric charge by the American physicist Robert A. Millikan in 1909.

At the time of Thomson's work, the American inventor Thomas A. Edison had observed a bluish glow in some of his early light bulbs under certain conditions, and found that a current would flow from one electrode in the lamp to another if the second one (anode) were made positively charged with respect to the first (cathode). Work by Thomson and his students and by the English engineer John Ambrose Fleming revealed that this so-called Edison effect was the result of the emission of electrons from the cathode, the hot filament in the lamp. The motion of the electrons to the anode, a metal plate, constituted an electric current that would not exist if the anode were negatively charged.

This discovery provided impetus for the development of electron tubes, including an improved version of the X-ray tube by the American engineer William D. Coolidge, and

Fleming's thermionic valve

the use of Fleming's thermionic valve (a two-electrode vacuum tube) in radio receivers. The detection of a radio signal, which is a very-high-frequency alternating current, requires that the signal be rectified (*i.e.*, the alternating current must be converted into a direct current by a device that conducts only when the signal has one polarity but not when it has the other). This is precisely what Fleming's valve (patented in 1904) was able to do. Previously, radio signals had been detected by various empirically developed devices such as the "cat whisker" detector, which was composed of a fine wire (the whisker) in delicate contact with the surface of a natural crystal of lead sulfide (galena) or other semiconductor material. These devices were undependable, lacked sufficient sensitivity, and required constant adjustment of the whisker-to-crystal contact to produce the desired result. Yet, these were the forerunners of today's solid-state devices. The fact that crystal rectifiers worked at all encouraged scientists to continue studying them and gradually to obtain the fundamental understanding of the electrical properties of semiconducting materials necessary to permit the invention of the transistor.

In 1906 Lee De Forest, an American engineer, developed a type of vacuum tube that was capable of amplifying radio signals. De Forest added a grid of fine wire between the cathode and anode of the two-electrode thermionic valve constructed by Fleming. The new device, which

De Forest's Audion

De Forest dubbed the Audion, was thus a three-electrode vacuum tube. In operation, the anode in such a vacuum tube is given a positive potential (positively biased) with respect to the cathode, while the grid is negatively biased. A large negative bias on the grid prevents any electrons emitted from the cathode from reaching the anode; however, because the grid is largely open space, it permits some electrons to pass through it and reach the anode at a less negative bias. Small variations in the grid potential can thus control large amounts of anode current.

ERA OF THE ELECTRON TUBE

Impact of the vacuum tube

The first half of the 20th century was the era of the vacuum tube in electronics. This variety of electron tube permitted the development of radio broadcasting, long-distance telephony, television, and the first electronic digital computers. These early electronic computers were, in fact, the largest vacuum-tube systems ever built. Perhaps the best-known representative is the ENIAC (Electronic Numerical Integrator and Calculator; completed in 1946), which was equipped with 17,468 tubes.

The special requirements of the many different applications led to numerous improvements in vacuum tubes, enabling them to handle large amounts of power, operate at very high frequencies, have greater than average reliability, or be made very compact (the size of a thimble).

The cathode-ray tube, originally developed for displaying electrical wave forms on a screen for engineering measurements, evolved into the television picture tube. Such tubes operate by forming the electrons emitted from the cathode into a thin beam that impinges on a fluorescent screen at the end of the tube. The screen emits light that can be viewed from outside the tube. By deflecting the beam, patterns of light are produced on the screen, creating the desired optical images.

Other specialized types of vacuum tubes, developed or refined during World War II for military purposes, are still used today in microwave ovens and as extremely high-frequency transmitters aboard space satellites. Notwithstanding the remarkable success of solid-state devices in most electronic applications, there are certain specialized functions that only vacuum tubes can perform. These usually involve operation at extremes of power or frequency (see below *Electron tubes*). Vacuum tubes continue to be used as display devices for television sets and computer monitors because other means of providing the function are more expensive, though even this situation is changing.

Vacuum tubes are fragile and ultimately wear out in service. Failure occurs in normal usage either by the effects of repeated heating up and cooling down as equipment is switched on and off (thermal fatigue), which ultimately causes a physical fracture in some part of the interior structure of the tube, or by degradation of the properties of the cathode by the residual gases in the tube. Vacuum tubes also take time (from a few seconds to several minutes), to heat up to operating temperature. This is at least an inconvenience and in some cases a serious limitation to their use. These shortcomings motivated scientists at Bell Telephone Laboratories to seek an alternative to the vacuum tube and led to the development of the transistor.

INVENTION OF THE TRANSISTOR: THE SOLID-STATE REVOLUTION

The invention of the transistor in 1947 by John Bardeen, Walter H. Brattain, and William B. Shockley of the Bell research staff provided the first of a series of new devices with remarkable potential for expanding the utility of electronic equipment. Transistors, along with such subsequent developments as integrated circuits (see below), are made of crystalline solid materials called semiconductors, which have electrical properties that can be varied over an extremely wide range by the addition of minuscule quantities of other elements. The electric current in semiconductors is carried by electrons, which have a negative charge, and also by holes, analogous entities that carry a positive charge. The availability of two kinds of charge carriers in semiconductors is a valuable property exploited in many electronic devices made of such materials.

Exploiting the properties of semiconductors

Early transistors were produced using germanium as the semiconductor material, because methods of purifying it to the required degree had been developed during and shortly after World War II. As the electrical properties of semiconductors are extremely sensitive to the presence of the slightest trace of certain other elements, only about 1 part per 1,000,000,000 of such elements can be tolerated in material to be used for making semiconductor devices.

During the late 1950s research on the purification of silicon succeeded in producing material of a quality suitable for semiconductor devices, and new devices made of silicon were manufactured from about 1960. Silicon quickly became the preferred raw material, because it is much more abundant than germanium and thus intrinsically less expensive. In addition, silicon retains its semiconducting properties at higher temperatures than does germanium. For this reason, silicon diodes can be operated at temperatures up to 200° C (392° F), whereas germanium diodes cannot be operated above 85° C. There was one other important property of silicon that was not appreciated at the time but that proved to be crucial to the development of low-cost transistors and integrated circuits: silicon, unlike germanium, forms a tenaciously adhering oxide film with excellent electrical insulating properties when it is heated to high temperatures in the presence of oxygen. This film is utilized extensively as a mask to permit the desired impurities that modify the electrical properties of silicon to be introduced into it during manufacture of semiconductor devices. The mask pattern, formed by a photolithographic process, permits the creation of tiny transistors and other electronic components in the silicon.

Advantages of silicon over germanium

By 1960 vacuum tubes were rapidly being supplanted by transistors because the latter had become less expensive, did not burn out in service, and were much smaller and more reliable. Computers employed hundreds of thousands of transistors each. This fact, together with the need for compact, lightweight electronic missile guidance systems, led to the invention of the integrated circuit (IC) independently by Jack Kilby of Texas Instruments Incorporated in 1958 and by Jean Hoerni and Robert Noyce of Fairchild Semiconductor Corporation in 1959. Kilby is usually credited with having developed the concept of integrating device and circuit elements onto a single silicon chip, while Noyce is given credit for having conceived the method for integrating the separate elements.

Invention of the integrated circuit

Early ICs contained about 10 individual components on a silicon chip three millimetres (0.12 inch) square. By 1970 the number was up to 1,000 on a chip the same size at no increase in cost. Late in the following year the first microprocessor was introduced. The device contained all the arithmetic, logic, and control circuitry required to perform the functions of a computer's central processing unit. This type of large-scale IC was developed by a team at

Intel Corporation, the same company that also introduced the memory integrated circuit in 1971. The stage was now set for the computerization of small electronic equipment.

Until the microprocessor appeared on the scene, computers were essentially discrete pieces of equipment used primarily for data processing and scientific calculations. They ranged in size from minicomputers, comparable in dimensions to a microwave oven, to mainframe systems that took up enough space to fill a large room. The microprocessor enabled computer engineers to develop microcomputers—systems about the size of a lunch box or smaller but with enough computing power to perform many kinds of business, industrial, and scientific tasks. Such systems made it possible to control a host of small instruments or devices (*e.g.*, numerically controlled lathes and one-armed robotic devices for spot welding) by using standard components programmed to do a specific job. The very existence of computer hardware inside such devices is not apparent to the user.

Microprocessors and microcomputers

The large demand for microprocessors generated by these initial applications led to high-volume production and a dramatic reduction in cost. This in turn promoted the use of the devices in many other applications, as, for example, in household appliances and automobiles, for which electronic controls had previously been too expensive to consider. Continued advances in IC technology gave rise to very-large-scale integration (VLSI), which substantially increased the circuit density of microprocessors. This technological advance, coupled with further cost reductions stemming from improved manufacturing methods, made feasible the mass production of personal computers for use in schools and homes, as well as in offices.

Very-large-scale integration

By the mid-1980s inexpensive microprocessors of high-function densities also stimulated computerization of an enormous variety of consumer products. Common examples included programmable microwave ovens and thermostats, clothes washers and dryers, self-tuning television sets and self-focusing cameras, videocassette recorders and video games, telephones and answering machines, musical instruments, watches, and security systems. Microelectronics also came to the fore in business, industry, government, and other sectors. Microprocessor-based equipment proliferated, ranging from automatic teller machines and point-of-sale terminals in retail stores to automated factory assembly systems and office workstations.

By mid-1986 memory integrated circuits with a capacity of 262,144 bits (binary digits) were available. Within a short time, circuits of this kind that had four times that capacity were being produced. By the late 1980s microprocessors capable of handling 16-bit words were common, and 32-bit versions were even available. The larger memories and microprocessors contained more than 3,000,000 transistors on a silicon chip less than two centimetres square. In addition, literally tens of thousands of other kinds of integrated circuits for various applications were available, varying in complexity from a few dozen transistors upward.

DIGITAL ELECTRONICS

Reference was made earlier to digital forms of communication. These arose largely because of the way computers operate—*i.e.*, by using digital representations of numbers. Computers understand only two numbers, 0 and 1, and do all of their arithmetic operations in the binary mode. Many electrical and electronic devices have two states: they are either off or on. A light switch is a familiar example, as are vacuum tubes and transistors. Because computers have been a major application for integrated circuits from their beginning, digital integrated circuits have become commonplace. It has thus become easy to design electronic systems that use digital language to control their functions and to communicate with other systems.

A major advantage in using digital methods is that the correctness of a stream of digital signals can be verified, and, if necessary, errors can be corrected. In contrast, signals that vary in proportion to, say, the sound of an orchestra can be corrupted by "noise," which once present cannot be removed. An example is the sound from a conventional phonograph record, which always contains some extraneous sound from the surface of the recording groove even when the record is new. The noise becomes more pronounced with wear. Contrast this with the sound from a digital compact disc recording. No sound is heard that was not present in the recording studio. The disc and the player contain error-correcting features that remove any incorrect pulses (perhaps arising from dust on the disc) from the information as it is read from the disc.

Error-correcting capability

As electronic systems become more complex, it is essential that errors produced by noise be removed, otherwise, the systems may malfunction. Many electronic systems are required to operate in electrically noisy environments, such as in an automobile. The only practical way to assure immunity from noise is to make such a system operate digitally. That alone may be insufficient, since error-correcting procedures have limits. In principle, it is possible to correct for any arbitrary number of errors, but in practice this may not be possible. The amount of extra information that must be handled to correct for large rates of error reduces the capacity of the system to handle the desired information, and so tradeoffs are necessary.

A consequence of the veritable explosion in the number and kinds of electronic systems has been a sharp growth in the electrical noise level of the environment. Any electrical system generates some noise, and all electronic systems are to some degree susceptible to disturbance from noise. The noise may be conducted along wires connected to the system, or it may be radiated through the air. Care is necessary in the design of systems to limit the amount of noise that is generated and to shield the system properly to protect it from external noise sources.

OPTOELECTRONICS

Many semiconductor materials other than silicon and germanium exist, and they have different useful properties. Compounds formed by the elements from column III of the periodic table, such as aluminum, gallium, and indium, with those from column V, such as phosphorus, arsenic, and antimony, are of particular interest. These so-called III-V compounds are used to make semiconductor devices that emit light efficiently or that operate at exceptionally high frequencies (see below).

Use of III-V compounds

A remarkable characteristic of these compounds is that they can, in effect, be mixed together. One can produce gallium arsenide, or substitute aluminum for some of the gallium, or also substitute phosphorus for some of the arsenic. When this is done, the electrical and optical properties of the material are subtly changed in a continuous fashion in proportion to the amount of aluminum or phosphorus used.

All of these compounds have the same crystal structure. This makes possible the gradation of composition, and thus the properties, of the semiconductor material within one continuous crystalline body. Modern material-processing techniques allow these compositional changes to be controlled accurately on an atomic scale.

These characteristics are exploited in making semiconductor lasers that produce light of any given wavelength within a considerable range. Such lasers are used, for example, in compact digital audio disc players and as light sources for optical fibre communication (see below).

A new direction in electronics curiously does not make use of electrons but instead employs photons (packets of light). By common consent these new approaches are included in electronics because the functions that are performed are, at least for the present, the same as those performed by electronic systems and because these functions usually are embedded in a largely electronic environment. This new direction is called optical electronics, or optoelectronics.

In 1966 it was proposed on theoretical grounds that glass fibres could be made with such high purity that light could travel through them for great distances. Such fibres were produced during the early 1970s. They contain a central core in which the light travels. The outer cladding is made of glass of a different chemical formulation and has a lower optical index of refraction. This difference in refractive index indicates that light travels faster in the cladding than it does in the core. Thus, if the light beam begins to

Development of optical fibres

move from the core into the cladding, its path is bent so as to move it back into the core. The light is constrained within the core even if the fibre is bent into a circle.

The core of early optical fibres was of such a diameter (several micrometres, or about 1/10 the diameter of a human hair) that the various rays of light in the core could travel in slightly different paths, the shortest directly down the axis and other longer paths wandering back and forth across the core. This limited the maximum distance that a pulse of light could travel without becoming unduly spread by the time it arrived at the receiving end of the fibre, with the central ray arriving first and others later. In a digital communications system, successive pulses can overlap one another and be indistinguishable at the receiving end. Such fibres are called multimode fibres, in reference to the various paths (or modes) that the light can follow (see below *Optical fibres*).

During the late 1970s fibres were made with smaller core diameters in which the light was constrained to follow only one path. This occurs if the core has a diameter about the same as the wavelength of the light traveling in it—*i.e.*, about one or two micrometres (0.001 or 0.002 millimetre, or 0.000039 or 0.000078 inch). These single-mode fibres avoid the difficulty described above. By 1985 optical fibres of this kind capable of carrying light signals more than 160 kilometres (100 miles) became available.

Advantages of optical fibres

Optical fibres have several advantages over the copper wires or coaxial cables so widely used in the past. They can carry information at a much higher rate, occupy less space (an important feature in large cities and in buildings), and are quite insensitive to electrical noise. Moreover, it is virtually impossible to make unauthorized connections to them. Costs, initially high, had dropped by 1985 to the point where most new installations of telephone circuits between central telephone offices and longer distances consisted of optical fibres.

Nearly all current installations use a single light signal traveling in one direction within an optical fibre. The light is provided by a solid-state laser and detected at the receiving end by a semiconductor diode. There is no reason that more than one light signal cannot be present at one time in a fibre; up to 10 such signals have been sent down a single fibre in laboratory tests. Each signal is of a slightly different wavelength and can be separated from the others at the receiving end. Signals also have been sent in both directions simultaneously in the laboratory. New terminal equipment can be retrofitted to allow fibres now in service to carry much more information than they were originally intended to do. The cost of long-distance communication can then be significantly reduced and thereby encourage the use of these circuits for more purposes than at present.

A second phase of optoelectronics was being developed during the late 1980s, but the improved system was not expected to be in service for several years. Given the fact that communication signals arrive at a central switching office in optical form, it is attractive to consider switching them from one route to another by optical means rather than electrically, as is done today. The distances between central offices in most cases are substantially less than the distance light can travel within a fibre. Optical switching would make unnecessary the detection and regeneration of the light signals, steps that are presently required. The principles of an optical central-office switch are already understood, though much research is still needed to provide the new optical components and new manufacturing technology required to produce such a switch.

A third direction in optoelectronics builds in part on the foregoing but to a quite different end. A key problem in developing faster computers and faster integrated circuits to use in them is related to the time required for electrical signals to travel over wire interconnections. This is a difficulty both on the integrated circuits themselves as well as between them. Under the best circumstances, electrical signals can travel in a wire at about 90 percent of the speed of light. A more usual rate is 50 percent. Light, fast as it is, travels about 30 centimetres in a billionth of a second. Modern supercomputers operate at speeds of more than 1,000,000,000 operations per second. Thus, if two signals that start simultaneously from different sites are to arrive at their destination simultaneously, the paths they travel must not differ in length by more than a few centimetres.

Two approaches can be envisioned. In one, all of the integrated circuits are placed as close together as possible to minimize the distances that signals must travel. This creates a cooling problem because the integrated circuits generate heat. In the other possible approach, all the paths for signals are made equal to the longest path. This requires the use of much more wire, because most paths are longer than they would otherwise be. All this wire takes space, which means that the integrated circuits have to be placed farther apart than is preferable.

Ultimately, as computers operate even faster, neither approach will work, and a radically new technique must be used. Optical communication between integrated circuits is one possible answer. Light beams do not take up space or interfere with cooling air. If the communication is optical, then the computation might be done optically as well. Optical computation will require a radically different form of integrated circuit. Such integrated circuits can in principle be made of gallium arsenide and related III-V compounds. Some of these integrated circuits may be useful in an optical central-office switch. These matters are presently under serious study in research laboratories.

Optical computers as a possibility

TRENDS IN MICROELECTRONICS

Microprocessors (see above) have been produced in the past as standard products. A growing trend is toward customizing such standard designs for specific applications. Some microprocessors contain an on-board memory that can be programmed at the time of manufacture to provide specific, fixed properties of the device. It is much less expensive to provide unique microprocessors by this tailoring process than to custom-design new microprocessors from scratch.

Another way to provide customized integrated circuits quickly and at modest cost (as compared with a completely new design) is to provide a stock integrated-circuit design having an array of standard functions that can be interconnected in various ways depending on the user's specific needs. Interconnections are formed at the late stages of manufacture, so stock designs can be tailored quickly and inexpensively.

Electrons move much faster in some III-V compound semiconductors than they do in silicon. Microcircuits made from these materials can thus operate at higher speeds and can be used to produce extremely fast computers. These materials are not yet available in as pure a state as silicon and are much more difficult to process: consequently, integrated circuits using III-V materials are not as complex as those made of silicon. Exploitation of these high-speed properties is expected to continue briskly.

SUPERCONDUCTING ELECTRONICS

Numerous metals completely lose their resistance to the flow of electric current at temperatures approaching absolute zero (0 K, or −273° C) and become superconducting. Other equally dramatic changes in electrical properties occur as well. One of these is the Josephson effect, named for the British physicist Brian D. Josephson, who predicted and then discovered the phenomenon in 1962. The Josephson effect governs the passage of current from one superconducting metal to another through a very thin insulating film between them (the Josephson junction), and the effects of small magnetic fields on this current.

Josephson-junction devices

Josephson-junction devices change from one electrical state to another in extraordinarily short times, offering the possibility of producing superconducting microcircuits that operate faster than any other known kind. Serious efforts have been made to construct a computer on this basis, but most of the projects have been either discontinued or sharply cut back due to technical difficulties. Interest in the approach has also waned because of increases in the speed of III-V semiconductor microcircuits.

Josephson junctions have other uses in science. They make extremely sensitive detectors of small magnetic fields, for example. The voltage across a Josephson junction is known on theoretical grounds to be dependent only

on the values of certain basic physical constants. Since these constants are known to great accuracy, Josephson junctions are now used to provide the absolute standard of direct-current voltage.

Other important applications of Josephson junctions have to do with the metrology of very high-speed signals. Measurements of fast phenomena require the use of even faster measurement tools, which Josephson devices provide.

The science of electronics

FUNDAMENTALS

Since electronics is concerned with the control of the motion of electrons, one must keep in mind that electrons, being negatively charged, are attracted to positive charges and repelled by other negative charges. Thus, in a vacuum electrons tend to space themselves apart from one another and form a cloud, subject to the influences of other charges that may be present. An electric current is created by the motion of electrons, whether in a vacuum, in a wire, or in any other electrically conducting medium. In each of these cases, electrons move as a result of their attraction to positive charges or repulsion from negative ones.

An atom consists of a nucleus of protons and neutrons around which electrons, equal in number to the protons in the nucleus, travel in orbits much like those of the planets around the Sun. Because of this equality in the number of positively and negatively charged constituent particles, the atom as a whole is electrically uncharged. When atoms are combined into certain solids called covalent solids (notably the elements of column IV of the periodic table), the valence (or outer) electrons are shared between neighbouring atoms and the atoms thereby become bound together. This occurs not only in elemental solids, wherein all the atoms are of the same kind, but also in chemical compounds (*e.g.*, the III-V compounds).

Variation in conductivity

Different materials vary greatly in their ability to conduct electricity, depending directly on the ease or difficulty of setting electrons free from their atoms. In insulating materials all the outermost electrons of the atoms (the only ones available for electrical conduction in most cases) are tightly bound in the chemical bonds between atoms and are not free to move. In metals there are more valence electrons than are required for bonding, and these excess electrons are freely available for electrical conduction.

Most insulators and metals are crystalline materials, but are composed of a great many very small crystals. The properties of such materials are not much affected by the size of these small crystals. In all crystals, the atoms are positioned in a regularly spaced three-dimensional array.

Semiconducting solids for electronic applications are prepared as single large crystals. In semiconductors the fact that the atoms are in a periodic, three-dimensional array of large size (large, that is, in comparison with an atom) makes the atoms appear nearly invisible to electrons moving within a crystal. The reasons for this behaviour are too complex to explain here, but this property allows electrons to be quite mobile in semiconductors. (For a detailed treatment of the properties of semiconductors, see MATTER: *Semiconductors and insulators.*)

Conduction in semiconductors. In semiconductors such as silicon (which is used as the example here), each constituent atom has four outer electrons, each of which pairs with an electron from one of the four neighbouring atoms to form the interatomic bonds. Completely pure silicon thus has essentially no electrons available at room temperature for electronic conduction, making it a very poor conductor. If an atom from column V of the periodic table, such as phosphorus, is substituted for an atom of silicon, four of its five outer electrons are used for bonding, but the fifth is free to move within the crystal.

If the replacement atom comes from column III of the periodic table, say, boron, it will have only three outer electrons, one too few to complete the four interatomic bonds. The fact that the crystal would be electrically neutral were this bond complete means that if an electron is missing, the vacancy will have a positive charge. A neighbouring electron can move into the vacancy, leaving another vacancy in the electron's former place. This vacancy, with its positive charge, is thus mobile and is called a "hole." Holes in semiconductors move about as readily as electrons do, but because they are positively charged they move in directions opposite to the motion of electrons.

Movement of electrons and holes

Semiconductors whose principal charge carriers are electrons are called *n*-type (*n* standing for negative). If the charge carriers are mainly holes, the material is *p*-type (*p* for positive). The process of substituting elements for the silicon (in this example) is called doping, while the elements are referred to as dopants. The amount of dopant that is required in practical devices is very small, ranging from about 100 dopant atoms per 1,000,000 silicon atoms downward to 1 per 1,000,000,000.

Producing single-crystal silicon

Dopants may be added to the silicon either during the crystal growth process or later. Growth of silicon crystals begins with the preparation of extremely pure polycrystalline silicon having fewer than 1 dopant atom per 10,000,000,000 silicon atoms. This silicon is melted in a quartz-lined furnace. The temperature of the molten silicon is reduced to just above the melting point, and a small bar (the seed) of silicon in single-crystal form is introduced into the surface of the melt. The molten silicon freezes slowly onto the seed with a crystalline structure that is continuous with the structure of the seed. The seed is slowly withdrawn, usually while rotating, under carefully controlled conditions, and it brings with it a cylindrical ingot of silicon that is a single crystal throughout. This ingot may be up to 200 millimetres in diameter and weigh up to 100 kilograms (220 pounds).

After growth, the silicon crystal is ground to a smooth cylindrical shape and sliced into thin wafers approximately 0.6 millimetre thick using diamond tools. The surfaces of the wafers are polished flat by a series of successively finer abrasives until one side has a perfect mirror finish.

The process of fabricating semiconductor devices is a complex series of more than 200 sequential steps, all of which must be done with utmost precision in an environment cleaner than a hospital operating room. The objective is to add the correct dopants in the proper amounts in the right places. The scale of lateral dimensions in integrated circuits ranges down to one micrometre. A high-power semiconductor device for industrial use, on the other hand, may be so large as to require a slice of silicon measuring well over 125 millimetres in diameter (see also below *Integrated circuits*).

Other considerations. The importance of having a thorough, detailed understanding of all the physical effects related to materials, fabrication processes, and device structures cannot be overstated.

The motion of electrons and holes in semiconductors is governed by the theory of quantum mechanics, which was developed during the 1920s and '30s as a much more general theory of the behaviour of all the elementary particles that make up matter. The electrical and optical effects observed in semiconductor materials, their interactions, and the effects of temperature on them are all understood in considerable detail. This understanding not only makes it possible to explain quantitatively what is observed in laboratory experiments but is essential for predicting how new processes and devices work.

The research necessary to develop such a detailed theoretical and experimental body of knowledge was initiated during the late 1940s and has continued in industrial, university, and government laboratories ever since. It is now possible to design new semiconductor devices to perform in a completely predictable fashion by calculating their performance from theory and from their physical configuration with the aid of computers.

The fabrication processes used to make real devices are not as well understood, although much has been learned. Theoretical designs incorporate assumptions that the materials are entirely pure, that dopants exist only in the proper amounts and distributions, and that the dimensions of structures have the intended values. These assumptions are true in practice only to a limited degree. The success of today's semiconductor industry in manufacturing its products is due in large part to the intuition and experience of process engineers, which enable them to cope with

these practical limitations. Large sums of money are spent to provide equipment and manufacturing environments that adequately control each process step and protect the material being processed from contamination.

BASIC ELECTRONIC FUNCTIONS

Rectification. The process of rectification, or conversion of alternating current (AC) to direct current (DC), was briefly mentioned earlier in the discussion of vacuum tubes. A diode, or two-terminal, device is required for this process. Semiconductor diodes consist of a crystal, part of which is *n*-type and part *p*-type. The boundary between the two parts is called a *p–n* junction. As noted above, there is a population of holes on the *p*-type side of the junction and a population of electrons on the *n*-type side.

Use of semiconductor diodes

If a negative voltage is applied to the *p*-type side, implying a positive voltage applied to the *n*-type side, the holes in the *p*-type region will be attracted away from the *p–n* junction, as will the electrons on the *n*-type side. A region on either side of the *p–n* junction will be depleted of charge carriers, thus becoming effectively an insulator. In this condition, called reverse bias, only a very small leakage current flows.

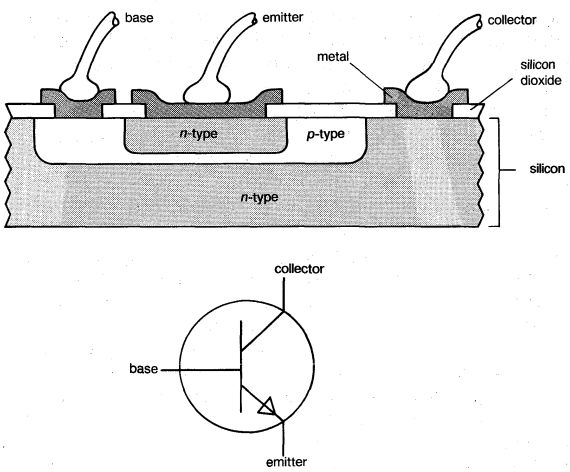

Figure 1: (Top) Cross section of an *n–p–n* transistor and (bottom) its electronic symbol.

If these voltages are reversed (forward bias), the positive voltage on the *p*-type side repels holes across the *p–n* junction; the negative voltage also repels the electrons on the *n*-type side. Both holes and electrons cross the *p–n* junction in opposing directions, creating an electric current.

There are many details of the motion of the holes and electrons that have been omitted in this simple description, but the principle seems clear. The *p–n* junction in a semiconductor diode conducts current with one polarity of applied voltage but not with the other polarity. Typical small diodes will conduct about 0.1 ampere (A) with roughly a 1.5-volt (V) forward bias and withstand 100 or more volts with negligible current flow in the reverse direction. Large industrial diodes can carry up to 5,000 amperes and block several thousand volts.

Amplification. A transistor is constructed with two *p–n* junctions parallel and very close to one another. Figure 1 (top) shows an *n–p–n* transistor with a connection to each of the three regions thus defined. The corresponding electronic symbol for an *n–p–n* transistor is also given in Figure 1 (bottom). The device is not symmetrical but has different levels of doping in the two *n*-type regions and other features that improve its efficiency.

An *n–p–n* transistor

The three regions are labeled as emitter, base, and collector in Figure 1. In normal operation, such as in the amplifier circuit shown in Figure 2, there are provisions (batteries in this case) for applying a small forward bias to the base–emitter junction and a larger reverse bias to the base–collector junction. Resistors are shown in series with each battery to establish the steady-state operating conditions of the circuit. In the base lead is an AC signal source.

If the AC signal source is switched off, the battery in the emitter–base circuit causes a small current to flow

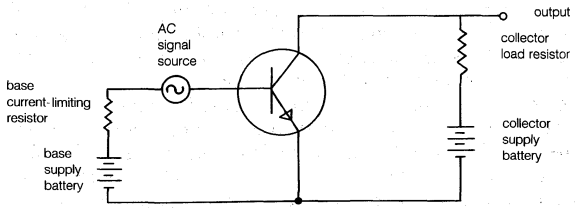

Figure 2: Amplifier using an *n–p–n* transistor.

through the series resistor and the forward-biased emitter–base junction. This results in excess electrons being present in the *p*-type base region of the transistor. Many more of these electrons are attracted to the collector region by the strong reverse bias on the collector than are attracted to the base connection. In an average *n–p–n* transistor more than 100 electrons pass from the emitter to the collector for each one that passes from the emitter to the base.

If the AC signal source is switched on, the base current is increased and decreased alternately. The collector current varies in the same way but to a hundredfold larger extent; in effect, the signal has been amplified. The varying collector current through the collector series resistor causes a varying voltage drop, which may be used as the signal source for a subsequent amplifying circuit. This example employs an *n–p–n* transistor. With a *p–n–p* transistor, the action is similar except that holes are the primary charge carriers, and the voltages of the batteries and thus the direction of current are reversed.

Another important type of transistor that was developed by the early 1960s is the field-effect transistor, illustrated in Figure 3. The physical structure is shown at the top and the electronic symbol at the bottom. The example is a metal-oxide-semiconductor field-effect transistor, or MOSFET. Another type, the junction field-effect transistor, works in a similar fashion but is much less frequently used. The MOSFET consists of two regions: the source (here shown connected to the silicon substrate) and the drain of one conductivity type embedded in a body of the opposite conductivity type. The space between the source and the drain is covered by a thin layer of silicon dioxide formed by heating the silicon in an oxidizing atmosphere. A third part of the device, the gate, is a thin metal layer deposited on the silicon dioxide.

Field-effect transistors

The MOSFET shown in Figure 3 is an *n*-channel type. It is so designated because, when in operation, the application of a positive voltage to the gate with respect to the *p*-type region causes a thin conducting region containing mostly electrons to form in the *p*-type region just beneath the gate. The gate voltage repels holes and attracts electrons from the *p*-type region, in which there are some electrons even though the principal charge carriers are holes.

The thin layer of electron-rich material, the channel, connects the source and drain electrically and permits current to flow between them when the drain is biased positively

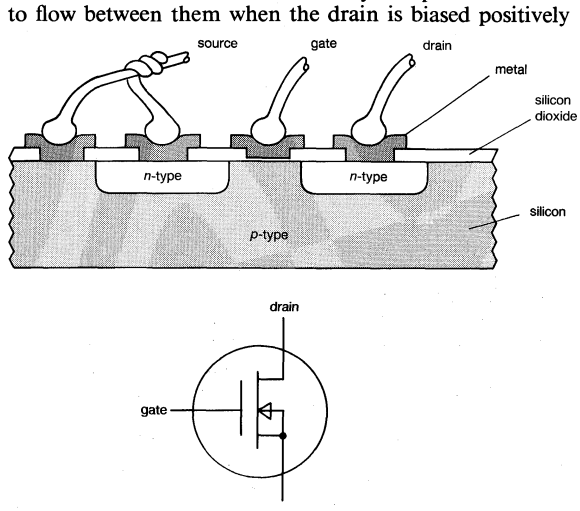

Figure 3: (Top) Cross section of an *n*-channel MOSFET and (bottom) its electronic symbol.

with respect to the source. The amount of current is controlled by the gate voltage. Without gate voltage, no current flows, because the *p–n* junction around the drain region is reverse biased and because no channel exists. MOSFETs are widely used in integrated circuits.

Flexibility in designing solid-state circuits

The existence of more than one type of transistor gives the circuit designer additional freedom not available for vacuum-tube circuits and allows many clever circuits to be constructed. This becomes readily apparent in the direct coupling of successive amplifier stages. There are many ways to couple a signal from one circuit to another. Each has its advantages and disadvantages. Consideration must be given to the voltage levels in the circuits. If both amplifiers were designed as the one in Figure 2, the voltage level at the collector of the first amplifier would be different from that at the base of the second. A direct connection thus could not be used. A transformer could be employed for coupling, with its primary in the collector circuit of the first amplifier and its secondary in the base circuit of the second one. However, transformers often do not exhibit uniform behaviour over a wide range of frequencies, which can be a problem. Transformers also are expensive and bulky. Similarly, a capacitor could be inserted between the collector of the first amplifier and the base of the second. This works well for many applications, providing uniform coupling inexpensively over a wide frequency range. At low frequencies capacitive coupling becomes ineffective, however.

The use of a *p–n–p* second amplifier allows direct connection between the amplifiers, as shown in Figure 4. If properly designed, this arrangement provides useful amplifying properties from direct current to quite high frequencies. Care is required to avoid any changes in the DC operating conditions of the first amplifier, which will cause an amplified change in the DC conditions of the second one. Changes in temperature, in particular, can cause changes in resistor values and changes in the amplification properties of transistors. These factors must be carefully taken into account. Judicious use of feedback from later parts of a circuit to earlier ones can be utilized to stabilize such circuits or to perform various other useful functions (see below). In negative feedback, the feedback signal is of a sense opposite to the signal present at the point in the circuit where the feedback signal is applied. While this has the effect of reducing the overall gain of the circuit, it also corrects numerous small distortions that may have occurred in the signal. For example, if the amplifier does not amplify large signals as much as small ones, the feedback from larger signals will be less, as will the reduction in gain, and the larger signals will be increased in the output of the circuit. Thus the distortion is reduced.

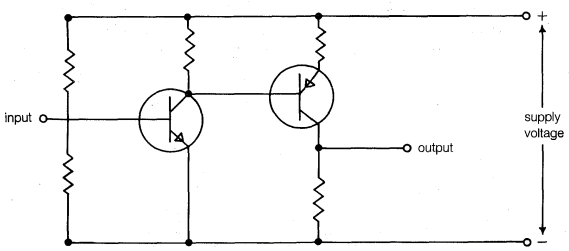

Figure 4: Direct-coupled *n–p–n—p–n–p* amplifier.

Oscillation. If feedback is positive, the feedback signal reinforces the original one, and an amplifier can be made to oscillate, or generate an AC signal. Such signals are needed for many purposes and are created in numerous kinds of oscillator circuits. An example of a tunable oscillator, such as that required for a radio receiver, is shown in Figure 5A. The parallel combination of an inductor and a capacitor is a tuned circuit; at one frequency, and only one, the inductive effects and the capacitive effects balance. At this frequency the voltage developed across the tuned circuit is a maximum. In the oscillator of Figure 5A, positive feedback is provided by the inductor in the collector circuit, which is magnetically coupled to the inductor of the tuned circuit. The connections to these inductors are arranged so that, when the collector current

Tuned circuits

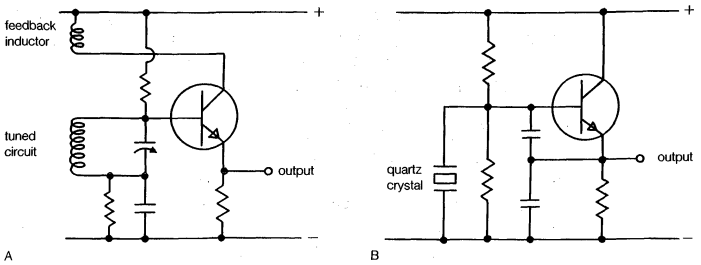

Figure 5: (A) Tunable oscillator; (B) quartz crystal oscillator.

increases, the voltage at the base also increases, thus causing the collector current to rise further. The action of the tuned circuit reverses this sequence after a time and causes the base voltage to start to fall. This reduces the collector current; the positive feedback then further reduces the base voltage, and so on.

The circuit is in fact an amplifier whose output provides the input signal. The tuned circuit affects the feedback process in such a way that the circuit responds to an input signal at only one frequency—namely, the frequency to which the inductor and capacitor are tuned. The variable capacitor provides a way to adjust the frequency of oscillation. The output signal is obtained from the emitter resistor, through which the current rises and falls in synchrony with the collector current.

Oscillators that produce a single, accurate frequency are often needed. Such an oscillator is used in electronic watches. Other circuits in the watch count the output signals from the oscillator to determine the passage of time. These oscillators use a quartz crystal instead of a tuned circuit to establish the operating frequency.

Quartz crystal oscillators

Quartz has the useful property of changing its dimensions slightly if an electric field is applied to it and, conversely, of producing a small electrical voltage when pressure is applied (the piezoelectric effect). In a quartz crystal oscillator a small plate of quartz is provided with metal electrodes on its faces. Just as a bell rings when struck, the quartz plate also "rings," but at a very high frequency, and produces an AC voltage between the electrodes at this mechanically resonant frequency. When used in an oscillator, positive feedback provides energy to the quartz crystal to keep it ringing, and the oscillator output frequency is precisely controlled by the quartz crystal. An oscillator circuit of this kind is shown in Figure 5B.

Quartz is not the only crystalline material that exhibits a piezoelectric effect, but it is used in this application because its oscillation frequency can be rendered to be quite insensitive to temperature changes. Quartz-controlled oscillators are able to produce output frequencies from about 10 kilohertz to more than 200 megahertz and, in carefully controlled environments, can have a precision of one part in 100,000,000,000, though one part in 10,000,000 is more common. The circuit of Figure 5B resembles that of Figure 5A in that the output is taken from the emitter resistor and the tuned circuit is in the base circuit, though the tuned circuit in the crystal oscillator is the quartz crystal. The feedback path is different, however. The feedback signal comes from the emitter and is coupled to the base and to the quartz crystal by the two small capacitors connected in series from the base to the negative supply connection.

Switching and timing. Switching in electronic circuits can be considered in two distinct ways—namely, in terms of digital and non-digital applications.

Non-digital applications. Transistors in amplifier circuits are used as linear devices; *i.e.*, the input signal and the output signal are nearly exact replicas of one another except that the output signal is of a greater amplitude in most cases. Transistors and other semiconductor devices may also be used as switches. In such applications the base or gate of a transistor, depending on the type of transistor in use, is employed as a control element to switch on or off the current between the emitter and collector or the source and drain. The purpose may be as simple as lighting an indicator lamp or it may be of a much more complex nature.

An example of a moderately sophisticated application is in a backup, or "uninterruptible," power source for a computer. Such equipment consists of a storage battery (which is normally kept charged by rectifying the power coming from the AC power line), a circuit for converting the battery power into alternating current, and the necessary control circuits. The control circuits monitor the voltage supplied from the power line. If this voltage varies significantly either upward or downward from its normal values, the control circuit causes the power supply lines to the computer to be switched from the incoming power line to an alternate source of AC derived from the battery.

Inversion by means of transistors

Batteries are usually low-voltage DC sources. Consequently, their energy has to be converted to AC and applied to a transformer, which is useful only in AC circuits, so as to raise the voltage to the proper level for operating the computer. The conversion from DC to AC, a process known as inversion, is often done with high-power transistors operated as switches. The battery is connected to the primary coil of the transformer through the transistors, first in one polarity and then in the other, at a frequency identical to the normal power-line frequency—usually 50 or 60 hertz.

The same result could in principle be obtained by operating the transistors as an oscillator powered by the battery and supplying a smoothly varying AC voltage to the transformer rather than the square pulses obtained via the switching process. This is a much less efficient procedure, however. A transistor operated as a switch is quite efficient, because in its "off" condition very little current flows (a slight leakage through the reverse-biased collector junction) at a relatively high voltage, while in the "on" condition the collector-emitter voltage is very low even though the current is large. In both conditions, the power lost is the product of the voltage and the current. Given this fact, the loss is small because at any instant either the voltage or the current is small.

On the other hand, if the transistor is used as an oscillator, the voltage between the collector and emitter is large most of the time, as is the current, resulting in a substantial loss of power in the transistor as heat. To provide a given amount of power to the computer for a comparable amount of time, a much larger battery and larger and more expensive power transistors would be required, as compared with those needed for a switching mode of operation.

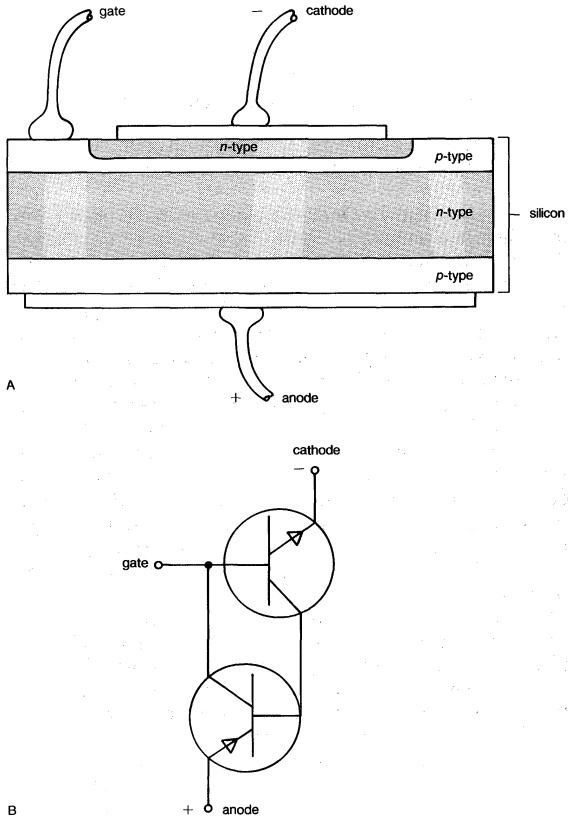

Figure 6: (A) Cross section and (B) *n–p–n—p–n–p* analog of a thyristor.

When the battery is supplying power, the frequency of operation of the power circuits is controlled by a low-power oscillator circuit, which generates timing signals to switch the transistors on at the correct rate. The control circuits monitor the output voltage from the transformer and adjust the "on" period of the transistors by switching them off at the proper time to keep the voltage at the correct level as the power demands of the computer vary.

Use of thyristors in switching applications

Thyristors form another important class of semiconductor devices used in switching applications. Figure 6A illustrates the structure of the simplest of these devices, the controlled rectifier, made of silicon. It may be regarded as two transistors connected, as represented in Figure 6B. If the polarity of the voltage applied between the anode and cathode were the reverse of that shown, the device would not conduct except for minor leakage current across the reverse-biased anode *p–n* junction.

As shown, however, the device will start to conduct if a suitable amount of gate current is applied, but otherwise it will not. The gate current is the equivalent of base current for the *n–p–n* transistor; the resulting larger collector current is the base current for the *p–n–p* transistor. The *p–n–p* transistor has an unusually wide base region, so its gain is small, especially at low currents. Its collector current augments the initial gate current, however. This positive feedback increases the current levels throughout the thyristor, increasing the gain of the *p–n–p* transistor, and at a certain point the combined currents through the *n–p–n* and *p–n–p* transistors are sufficient to maintain conduction through the device even if the gate current is removed. The transistors drive each other into a saturated condition such that the thyristor conducts a large current with a very low voltage drop, typically about one volt. The device remains in this conducting state for an arbitrary period and cannot be turned off under control of the gate. Conduction will cease if the anode polarity becomes negative with respect to the cathode.

Suitability of thyristors for AC circuits

Thyristors are thus well suited for operation in AC rather than DC circuits. They can be switched on during the appropriate half-cycle of voltage (anode positive) and will automatically switch off when the polarity reverses. A single thyristor can be used as a rectifier to produce a variable DC output from a fixed AC input. Adjustment of the DC output is made by modifying the time at which the gate current is applied after the AC voltage crosses zero and becomes the right polarity for conduction. Two thyristors connected in antiparallel (*i.e.*, the anode of each is connected to the cathode of the other) form an AC switch, one thyristor being able to conduct on one half-cycle and the other on the alternate half-cycle. The amount of AC power delivered to the load may be adjusted to any level between zero and full power by appropriate timing of the gate signals to the two thyristors.

Thyristors are designed to handle both small and large amounts of power; the largest ones can withstand up to 5,000 volts in the "off" state and can conduct up to 2,000 amperes in the "on" state. Such a device is contained in an enclosure approximately 150 millimetres in diameter and about 30 millimetres thick and is fitted with either large fins or a water-based cooling arrangement, depending on the application. The power loss in the thyristor in such cases may be as much as four kilowatts, but the total amount of power handled may be up to 1,000 times as large. The efficiency is thus very high.

Other types of thyristors include those in which the gate is able to turn off the thyristor (a useful feature for some applications) and those that can be switched on in either direction of current flow. The latter, called a triac (short for triode alternating current switch), finds wide use in light-duty applications, as, for example, in variable-speed home appliances and light dimmers.

Thyristors have many applications in industrial equipment where substantial amounts of power must be controlled electronically. These applications range from transmission of large amounts of electric power over long

distances, which is more efficient if done as DC rather than AC, to control of heating elements in furnaces and supplying power for electronic equipment. The very large thyristors mentioned earlier are employed in power conversion for DC transmission, both from AC to DC and vice versa.

Other functions. Electronic devices provide a host of different functions too numerous to describe here. Many of these are logical functions that are the basis for the digital integrated circuits discussed later in this article. Others form the interface between integrated circuits and power devices, such as thyristors. When using computers and electronic measuring instruments to control industrial processes, large amounts of power often have to be controlled. The interface circuits are designed to link the "brains" of the computer, for example, with the "muscle" of thyristors.

Interface circuits

Other applications depend on the interactions between light and semiconductor materials mentioned above in connection with optical communication. Such applications include the conversion of sunlight to electricity in solar cells. Most cells of this type consist of silicon diodes in specially designed enclosures to allow sunlight to illuminate them. Silicon is transparent to infrared light; this component of solar radiation passes through a solar cell without generating electricity. The waves of visible light, however, have enough energy to create hole–electron pairs in silicon (the mechanism that results in the absorption of the light). In the vicinity of the *p–n* junction, the holes are attracted toward the electrons on the *n*-type side and the electrons are attracted to the holes on the *p*-type side. This constitutes a current that can be used to power small electric appliances or to charge storage batteries.

There are available special thyristors that use light instead of a gate signal to initiate conduction. They have application in high-voltage systems wherein many thyristors in series must be employed to withstand the voltage. The practical difficulties involved in providing gate signals to all of these thyristors, each at a different electrical potential, are simplified by using optical fibres (which are electrical insulators) to conduct pulses of light to the thyristors. The interaction of the light with the silicon produces carriers just as in a solar cell; these carriers provide the gate signal to switch on the thyristors.

Light-emitting diodes (LEDs) are used in many electronic systems as visual indicators. The first LEDs produced red light, but varieties that emit yellow and green light have become common. These LEDs are made from III-V compounds related to gallium arsenide; the ones that generate red light are usually composed of gallium arsenide phosphide.

Laser diodes

Laser diodes, also made of III-V compounds, are used in digital audio and video disc players to read the minuscule tracks molded into the disc and containing the digitally recorded information. Lasers are employed because laser light can be focused into an extremely tiny spot (substantially smaller than can be obtained with conventional light sources) of great brightness. The light scattered from the markings on the disc is detected by semiconductor photodiodes (see below *Light-emitting diodes and semiconductor lasers*).

Electronic devices must perform their functions over a very wide range of frequencies—from DC to tens of billions of operations per second. Individual types of devices vary greatly in their speed of operation, which is one reason why there are so many types. Thyristors are intrinsically slow, for example, and are primarily used at power-line frequencies. Ordinary small transistors are useful at frequencies up to perhaps 300 megahertz, but power transistors such as those employed in stereo amplifiers are not useful much beyond a few megahertz.

In general, small devices operate better at high frequencies than do large ones, principally because unavoidable parasitic internal series resistances and parallel capacitances that limit high-frequency performance can be better dealt with in small devices. One approach to overcoming the problems of high-frequency, high-power operation involves designing large devices as assemblages of very small ones. This is the approach employed with both metal-oxide-semiconductor (MOS) power transistors and conventional bipolar (*n–p–n* or *p–n–p*) transistors for use at higher frequencies. In effect, hundreds of thousands of identical, small transistors are integrated on a single semiconductor chip and perform as one. The use of III-V compounds, in which electrons move more rapidly than in silicon, can also extend the upper limit of operating frequency. The additional cost of manufacturing these unusual devices generally limits their use to specialized applications, such as in mobile radio transmitters, in which their extra performance level is essential.

In summary, it can be said that present-day electronic devices incorporate exotic materials processed with utmost care and function by the manipulation of electrons and holes via electrical and optical means. The conversion of electronic charge carriers into light and the reverse provide remarkable flexibility for many applications. All of these, taken in combination, have resulted in marvels not even dreamed of only a few years ago. (R.I.S.)

Principal devices and components

ELECTRON TUBES

The term electron tube, as suggested earlier, is the generic name for a class of devices that includes vacuum tubes, phototubes, gas-filled tubes, cathode-ray tubes, and photoelectric tubes. An electron tube typically consists of two or more electrodes enclosed in a glass or metal-ceramic envelope, which is wholly or partially evacuated. Its operation depends on the generation and transfer of electrons through the vacuum from one electrode to another, as shown in Figure 7.

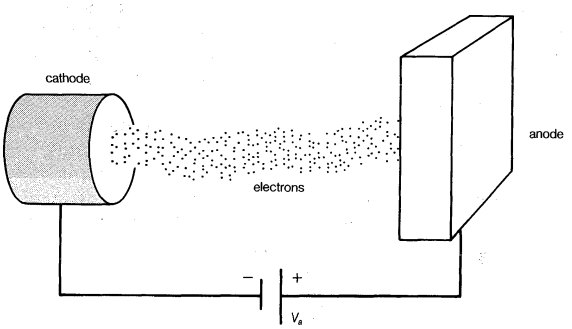

Figure 7: Elements of the simplest electron tube, the diode.

The source of electrons is the cathode, usually a metallic electrode that releases a stream of electrons by one of several mechanisms (*e.g.*, thermionic, secondary, or field emission; see below). Once the electrons have been emitted, their movement is controlled by either an electric field or a magnetic field. An electric field is established by the application of a voltage between the electrodes in the tube (Figure 7), while a magnetic field may be produced external to the tube by an electromagnet or a permanent magnet whose field penetrates the vacuum envelope and influences the emitted electrons. In its simplest form, an electron, being negatively charged, is attracted and accelerated by an electric field from the positive electrode and is repelled and slowed by the field from the negative electrode. The electric fields therefore can be used to change the path of the electron stream, alter the number of electrons flowing (and thereby change the current), and modify their speed. The magnetic field serves primarily to control the movement of the electrons from one electrode to another.

Electron tubes have certain unique properties that cannot be surpassed by solid-state devices for particular applications. Their thermal ruggedness, operating efficiency, and high-power capabilities are features well beyond those provided by the solid-state devices. As components of electronic systems, electron tubes are used as amplifiers, rectifiers, signal generators, and switches. Their applications are extensive, covering a wide range of power levels and frequencies. Electron tubes remain the dominant devices for applications requiring microwave frequencies (above 1,000 megahertz) and moderate- to high-power output.

Electron emission. In its most general sense, electron emission results from directing energy in the form of light, heat, high electric fields, or collisions to a material such that electrons within the material are given enough energy to overcome an energy barrier. Electron emission by application of heat is the mechanism most widely used in electron tubes. The energy barrier is a unique property of a solid and is known as the work function. Thus the ideal materials for use as cathodes in electron tubes are those that yield the lowest work functions. Materials commonly employed for thermionic emission are barium, strontium, and thorium because, when their oxides are combined with base metals of nickel and tungsten, work functions of 1.2 to 3.5 electron volts (eV) are produced. For example, the work functions of tungsten (4.5 eV) and barium (2.3 eV) are reduced significantly through the action of adsorbed atoms on the surface of the emitter where dipoles are formed between the surface and a monolayer of adsorbed atoms (*i.e.*, a single continuous layer of such atoms that is one atom in thickness). In this manner, a tungsten–osmium matrix yields a work function of 1.8 eV when a monolayer of barium oxide is adsorbed on the surface.

Work function

Thermionic emission. When solids are heated to high temperatures, about 1,000° C or higher, electrons can be emitted from the surface. Thermionic emission is not thoroughly understood, but researchers have been able to describe mathematically the emission phenomena using wave mechanics. The most popular models rest on the Richardson–Dushman equation derived in the 1920s and the Langmuir–Child equation formulated shortly thereafter. The former states that the current per unit of area, J, is given by

$$J = AT^2 e^{-W/kT}, \tag{1}$$

where k is Boltzman's constant, A is a constant of the material and its surface finish and is theoretically about 120 amperes per square centimetre per degree Kelvin, T is the temperature of the solid, and W is its work function. When enough electrons are emitted from the cathode of an electron tube, an electron cloud can form in front of the cathode. Such a cloud acts to repel low-energy electrons, and these return to the cathode. This limiting mechanism is aptly referred to as the space-charge-limited operation.

Space-charge-limited operation

In a device such as the diode, the positive voltage applied to the anode attracts electrons from the cloud. The higher the voltage, the more electrons flow to the anode. The higher the voltage, the more electrons flow to the anode. The current density, J, in the space-charge-limited operation, is described by the Langmuir–Child law

$$J = 2.33 \times 10^{-6} \frac{V_a^{3/2}}{d^2}, \tag{2}$$

where V_a is the anode voltage and d is the distance between the anode and the cathode. The key characteristics of thermionic emission, as observed and predicted by equations (1) and (2), are the two regions of emission shown in Figure 8. Much research has been concerned with the transition between the regions and with decreasing the work function of the cathode materials.

Secondary emission. When a metal or dielectric is bombarded by ions or electrons, electrons may be emitted from the surface of the material. The bombarding electrons are called primary and the emitted electrons are designated secondary. Electrons beneath the surface are emitted when they acquire kinetic energy from the primary electrons. The amount of secondary emission depends on the properties of the material, the energy of the primaries, and their angle of incidence. Material properties are characterized by the secondary-emission ratio, which is defined as the number of secondary electrons per primary electron. Typically, the maximum secondary-emission ratio lies between 0.5 and 1.5 for pure metals and occurs for incident electron energies between 200 and 1,000 electron volts. The approximate energy distribution of secondary electrons emitted from a pure metal is skewed such that about 85 percent of the electrons have energies less than 20 electron volts. Positive ion bombardment also can cause secondary emission, but it is much less efficient than electron bombardment. This is because the ions are heavy compared to electrons, and only a small fraction of an ion's energy can be imparted to an electron. Rough or carbon-coated surfaces have relatively small secondary emission.

Secondary-emission ratio

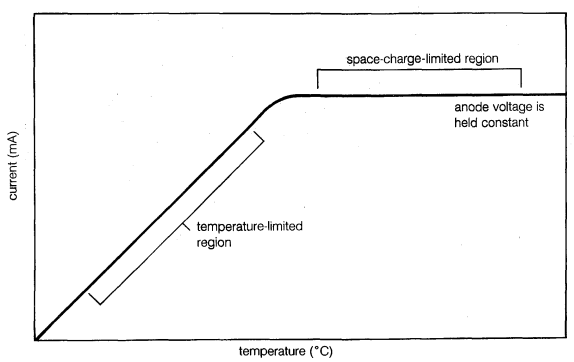

Figure 8: Typical emission characteristic of a thermionic emitter.

Field emission. Electron emission is influenced by an electric field applied at the cathode. For very strong electric fields, the electron emission becomes independent of temperature because the potential barrier at the surface of the cathode is made extremely narrow and electrons tunnel through the barrier even when they have low kinetic energy. Electric fields must be on the order of 10^9 volts per metre in order to cause field emission.

Electron motion in vacuum. Fundamental to all electron devices are the dynamics of charged particles under different electric- and magnetic-field configurations. The charged particles that predominate in the vast majority of applications are electrons (in vacuum). Theoretical treatment of electron trajectories in an evacuated space has made significant strides since the advent of high-speed computers. The fundamental physical laws that serve as the backdrop for the numerical analysis performed by computers are explained below.

The motion of an electron in a uniform field is given by the simple application of Newton's second law, Force = mass × acceleration, in which the force is that exerted on the electron by an applied electric field, $\boldsymbol{E}$. Mathematically, the equation of motion of an electron in a uniform field is given by

$$\boldsymbol{F} = -e\boldsymbol{E} = m\frac{d\upsilon}{dt}, \tag{3}$$

in which e is electron charge 1.60×10^{-19} coulombs, $\boldsymbol{E}$ denotes the field in volts per metre, m is the electron mass 9.107×10^{-31} kilogram, and $d\upsilon/dt$ denotes the rate of change of velocity, which is the electron's acceleration.

When there is a magnetic field present, the electron experiences a second force but only when the electron is in motion. The force is proportional to the product of charge and the velocity component perpendicular to the $\boldsymbol{E}$ field and the magnetic flux density, $\boldsymbol{B}$. The force is directed perpendicular to both the electric field and the electron velocity. Thus an electron traveling at right angles to a uniform magnetic field is deflected in a direction perpendicular to both magnetic and electric fields.

Because the force is always perpendicular to the velocity, the electron trajectory will trace out a perfect circle and maintain that motion at a rate called the cyclotron frequency, ω_c, given by $e/m\boldsymbol{B}$. The circle traced out by the electron has a radius equal to $m\upsilon/e\boldsymbol{B}$. This circular motion is exploited in many electron devices for generating or amplifying radio-frequency (rf) power.

An electron traveling parallel to a uniform magnetic field is unaffected, but any departure from parallelism gives rise to a perpendicular component of velocity and thus a force. This force gives the nearly parallel electron a helical motion about the direction of the magnetic field, keeping it from diverging far from the parallel path. The equation of motion in any of these instances is

$$m\frac{d\upsilon}{dt} = \boldsymbol{B}e\upsilon \sin\theta, \tag{4}$$

where υ is the velocity of the electron in metres per second

in the perpendicular direction to the plane of $\boldsymbol{B}$ and v, and θ is the angle between the directions of $\boldsymbol{B}$ and v. The magnetic flux density is expressed in webers per square centimetre (one weber per centimetre^2 = 10^4 gauss = $10^7/4\pi$ amperes per metre).

Of interest, too, is the situation when the $\boldsymbol{B}$ and the $\boldsymbol{E}$ fields are perpendicular to each other. This configuration is used in beam-focusing devices as well as in a class of devices called magnetrons (see below). In this case, the motion of the electrons is a combination of translation and circular trajectories. The resultant electron trajectory is a cycloid.

Equations 3 and 4 are sufficient to solve for the path and time of transit of electrons in an electron tube except that they require $\boldsymbol{E}$ and $\boldsymbol{B}$ to be known, and these may depend on the presence of electrons or ions. The currents in electron tubes are small enough in most cases that their effect on the magnetic field is usually negligible. The cumulative effect of the electron or ion charge (called space charge) on the electric field cannot always be neglected, however, and this introduces computational difficulty unless the geometry is simple. Furthermore, the electrode currents are so dependent on space charges that the performance characteristics of electron tubes are largely determined by these charges. The electric field with or without space charge can be determined by Gauss's theorem of electrostatics, which states how electric fields are associated with charges. Basically, the rate of change of $\boldsymbol{E}$ with distance is equal to ρ/ε_0 in which ρ is the electric charge density in coulombs per metre, and ε_0 is the permittivity 8.95×10^{-12} farads per metre.

Significance of space charge

The current per unit area, i, entering any surface, as that of an electrode in a tube, is the time rate of change of charge at that surface. This current is the sum of two components, one constituting the actual arrival of electrons at the electrode and the other resulting from the change of induced charge by any change of the electric field with time. Thus, i is the sum of $\rho v + \varepsilon_0 d\boldsymbol{E}/dt$, where v is the electron density and $d\boldsymbol{E}/dt$ is the time-varying electric field. At low frequencies of operation or under steady conditions, the second term is not important. The contrary is true at high frequencies. This equation and the one relating the electric fields to the charges are fundamental to all high-vacuum electron tube phenomena and are sufficient to obtain theoretical solutions.

Energy transfer. The fundamental importance of a large class of electron tubes lies in their ability to amplify power. This power amplification results from the conversion of the energy stored in an external supply via the kinetic energy of electrons to an output energy in the load circuit of the amplifier. The mechanism that makes this conversion possible is electron transport. The underlying principle involved here is that an electron caused to accelerate or decelerate by an electric field will gain or lose kinetic energy. Because energy is conserved, the rf field will increase if the electrons lose kinetic energy, and, conversely, decrease if the electrons gain energy.

The role of electron transport

If a modulated electron convection current flows in an electric field of the same modulation frequency, the power transfer, P, between the field and the electron is

$$P = \frac{1}{2} l_c \boldsymbol{E}, \tag{5}$$

where l_c is the electron convection current and $\boldsymbol{E}$ is the electric field. Both l_c and $\boldsymbol{E}$ are complex quantities, which can be expressed as

$$l_c = l_0(\cos \varphi_l + j \sin \varphi_l) \tag{6}$$

$$\boldsymbol{E} = \boldsymbol{E}_0(\cos \varphi_E + j \sin \varphi_E), \tag{7}$$

in which φ_l and φ_E are the phase angles of the modulated convection current and electric field, respectively. By substituting equations 6 and 7 into 5 and separating the real and imaginary parts, one obtains

$$P_{\text{real}} = \frac{1}{2} l_c E \cos(\varphi_l - \varphi_E) \tag{8}$$

$$P_{\text{imag}} = \frac{1}{2} l_c E \sin(\varphi_l - \varphi_E). \tag{9}$$

Insight into the meaning of equations 8 and 9 may be obtained by considering a physical picture. The negative electron flow (convection current) may be supposed to induce positive charges on the electrodes from which the $\boldsymbol{E}$ field emanates. If the phase is proper, meaning that the induced charges constructively add to the current associated with the modulated E field, the $\boldsymbol{E}$ field grows. Thus, in equations 8 and 9, $P_{\text{real}} = \frac{1}{2} l_c E$, and P_{imag} becomes zero. Conversely, if the phases are 180° apart, P_{real} goes to zero and $P_{\text{imag}} = \frac{1}{2} l_c E$ and power is transferred from the field to the electron current. In practice, different methods are used to produce density modulation in an electron beam (see below).

General applications. The application of vacuum electronics is widespread and involves many types of electron tubes. Another class of electron tubes consists of the tubes employed for rectification and switching. All such vacuum and gas devices make use of a cathode to generate an electron beam and either employ the energy-exchange mechanism or merely illuminate a target, as in the case of a television or X-ray tube. These illuminator tubes are treated in BROADCASTING: *Principles of picture transmission and reception;* RADIATION; and MEASUREMENT AND OBSERVATION. The present discussion focuses on those electron tubes that serve as circuit elements, functioning as rectifiers, microwave rf sources, and amplifiers. Of these, the most important are the latter two types because they constitute most of the electron tubes manufactured since the late 1960s. Within this category the main varieties are magnetrons, klystrons, and traveling-wave tubes. Another notable type is the crossed-field amplifier. Special applications have given impetus to the development of microwave power sources capable of generating tremendous amounts of power (up to billions of watts). These devices, called fast-wave tubes, make up a small but potentially significant element of the electron-tube industry.

Vacuum and gas tubes

Until the late 1950s, electron tubes had been used in virtually every kind of electronic device—computers, radios, transmitters, components of high-fidelity sound systems, etc. After World War II the transistor was perfected and solid-state technology came to be used in all low-frequency (below one gigahertz) and low-power applications. The common conception in the early 1960s was that solid-state technology would rapidly take over microwave applications and thereby render the electron tube obsolete. Such has not been the case, however, and what might be termed a quasi-equilibrium has been established between the solid-state and vacuum-electronic technologies, with each occupying a niche where its technological advantages dominate a particular frequency and power range. The ranges for the various technologies are shown in Figure 9, plotted as domains within the power and frequency spectrum. It will be noted that the higher power levels are dominated by electron tubes, and the lower levels by solid-state devices. High power levels have always been required for transmitters, radar systems, and implements

Use of electron tubes in high-power applications

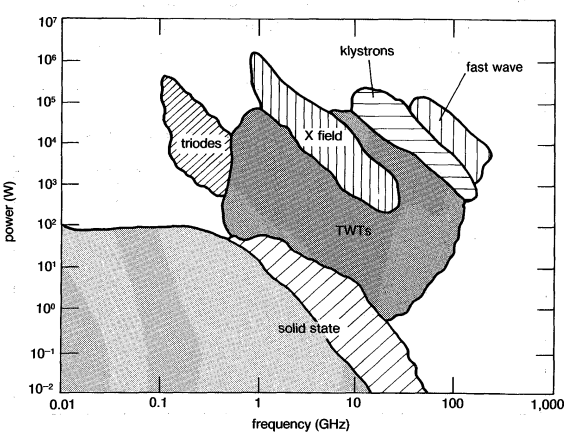

Figure 9: Power and frequency spectrum for sources and amplifiers (see text).

of electronic warfare. Microwave communications systems require power levels of a few watts to hundreds of watts. They include both terrestrial and space microwave links. Extremely high power levels, 10^9 watts, are used primarily for deep-space radars, microwave weapons, and drivers for high-energy particle accelerators.

The prevailing trends in microwave tubes entail improving the amount of bandwidth over which they operate, increasing the efficiency with which DC power is converted to rf power, and enhancing the ability to handle reliably the high power levels. New materials are continually finding use in electron tubes, and this in turn stimulates technological advances. Impressive gains have been scored in cathode technology, in magnets for focusing electron beams in high-thermal conductivity materials, in low secondary-emission materials, and in power-generation techniques.

Electron tubes for rf applications fall into three general categories: (1) space-charge controlled, (2) drift-space, and (3) growing-wave. The space-charge controlled tubes are the triodes, tetrodes, and pentodes. These are low-frequency devices for use below microwave frequencies. A prime example of the drift-space tube is the klystron, which has long been employed in many electronic systems. Two devices, the magnetron and the traveling-wave tube, represent most of the tubes of the growing-wave variety. Some of these and other significant vacuum tubes are delineated below, as are gas tubes employed for rectification and switching.

Klystrons. Devices of this kind are used as amplifiers at microwave frequencies (*e.g.,* in radio relay systems and for dielectric heating) and also as oscillators (*e.g.,* in continuous-wave Doppler radar systems). In klystrons the velocities of electrons emitted from the cathode are modulated to produce a density-modulated electron beam. The principle of operation involved here can be explained in terms of a two-cavity klystron amplifier, the basic structure of which is shown in Figure 10.

Two-cavity klystron amplifier

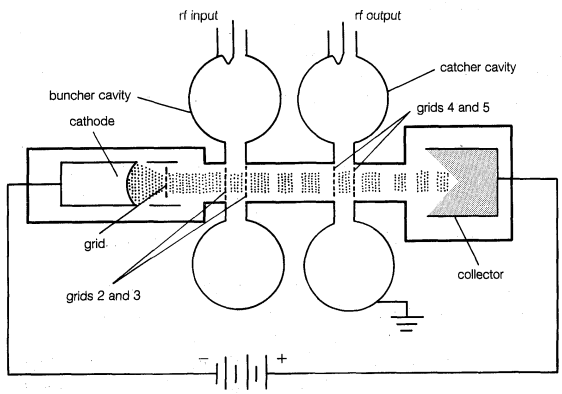

Figure 10: Two-cavity klystron.

The first grid next to the cathode controls the number of electrons in the electron beam and focuses the beam. The voltage between the cathode and the cavity resonators (the buncher and the catcher, which serve as reservoirs of electromagnetic oscillations) is the accelerating potential and is commonly referred to as the beam voltage. This voltage accelerates the DC electron beam to a high velocity before injecting it into the grids of the buncher cavity. The grids of the cavity enable the electrons to pass through but confine the magnetic fields within the cavity. The space between the grids is referred to as the interaction space, or gap. When the electrons traverse this space, they are subjected to rf potentials at a frequency determined by the resonant frequency of the buncher cavity and the input-signal frequency. The amplitude of the rf voltage between the grids is determined by the amplitude of the incoming signal in the case of an amplifier (or by the amplitude of the feedback signal from the second, or catcher, cavity if the klystron is used as an oscillator). Electrons traversing the interaction space when the rf potential on grid 3 is positive with respect to grid 2 are accelerated by the field, while those crossing the gap one half-cycle later are decelerated. In this process, essentially no energy is taken from the buncher cavity, since the average number of electrons slowed down is equal to the average number of electrons speeded up. The decelerated electrons give up energy to the fields inside the cavity, while those that have been accelerated absorb energy from its fields.

Upon leaving the interaction gap, the electrons enter a region called the drift, or bunching, space in which the electrons that were speeded up overtake the slower-moving ones. This causes the electrons to bunch and results in the density modulation of the beam, with the electron bunches representing an rf current in the beam. The catcher is located at a point where the bunching is maximum. This cavity is tuned to the same frequency as the input frequency of the input cavity resonator. The power output at the catcher is obtained by slowing down the electron bunches. If an alternating field exists at the output cavity resonator and grid 4 is positive with respect to grid 5, the electron bunches passing through the grids are decelerated, and they deliver energy to the output cavity. The electron bunches induce an rf current on the walls of the cavity identical to the rf current in the beam. At resonance, the oscillation in the output cavity builds up in proper phase to retard the electron bunches. The power output is equal to the difference in the kinetic energy of the electrons averaged before and after passing the interaction gap. The positive electrode, or collector, located beyond the catcher collects the electrons; it is so designed to minimize secondary emission. (Such emission occurs because of the impact of electrons that reach the end wall.)

Use of the klystron as an oscillator

The klystron amplifier can be converted into an oscillator by employing feedback from the output cavity to the input cavity in proper phase and of sufficient amplitude to overcome the losses in the system. The oscillations are initiated by random fluctuations of the electron beam current and by the noise voltages that generate an alternating field in the cavity. For high-power applications, grids are not used because they would be destroyed by the electron beam.

The output power capability of klystrons is shown in Figure 9. Their power levels are achieved through the use of very high beam voltages and currents. In simple terms the output power is given by $P_o = efficiency \times I_o E_o$, where I_o and E_o are the beam current and voltage and the efficiency is how well the DC power supplied is converted to rf power. For klystrons, the efficiency can be as high as 70 percent. By collecting the spent electron beam at a potential significantly below that of the cavities, higher efficiency can even be achieved—perhaps by as much as 10 to 15 percentage points.

The power gain of the klystron is dependent on the voltage and current as well as on the number of cavities used. The larger the number of cavities employed, the larger the gain that can be obtained. There is, however, a practical limit imposed by the onset of rf instability.

Magnetrons. Electron tubes of this type are primarily used to generate power at microwave frequencies for radar systems and microwave ovens. Magnetrons can be manufactured relatively inexpensively because they require so few parts—namely, a cathode, anode, tank circuit, and magnet. A typical magnetron, shown in Figure 11 in cutaway view, is described below.

The cylindrical anode structure contains a number of equally spaced cavity resonators with slots along the anode surface adjacent to the cylindrical cathode. A permanent

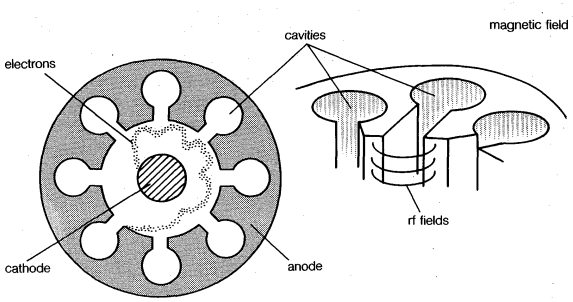

Figure 11: Typical elements of a magnetron.

magnet is usually used to provide the necessary magnetic field. The power output can be coupled through a slot in the cavity or by means of a coupling loop.

As in other types of oscillators, the oscillation originates in random phenomena in the electron space charge and in the cavity resonators. The cavity oscillations produce electric fields that spread outward into the interaction space from the slots in the anode structure, as shown in Figure 11. Energy is transferred from the radial DC field to the rf field by interaction of the electrons with the fringing rf field. The first orbit of an electron in Figure 11 occurs when the rf field across the gap is in a direction to retard the electron. The transfer of energy is from the electron to the tangential component of the rf field. The electron comes to a stop and is again accelerated by the radial DC field, making an orbit adjacent to the next cavity slot. If the rf field across the next cavity slot has changed phase by 180 degrees, the direction of the rf field is in the same direction as that of the electron, which moves in synchrony with the rf field. The electron gives up most of its energy to the cavities before it finally terminates on the anode surface. There is a net delivery of energy to the cavity resonators because electrons that absorb energy from the rf field are quickly returned to the cathode. By contrast, the energy in the rotational component of motion of the electrons in the retarding rf field remains practically unaffected, and the electrons may orbit around the cathode many times.

The phase relationship of the rf fields appearing across adjacent slots is used as a means of defining different modes of oscillation. The mechanism by which electron bunches are formed and by which electrons are kept in synchrony with the rf field is called phase focusing.

Phase focusing

Magnetrons have a wide range of output powers—from that used for cooking, which is about 600 watts, to special ones capable of generating pulsed power levels up to 10^7 watts. The DC-to-rf power-conversion efficiency typically ranges from 50 to 85 percent.

Crossed-field amplifiers. The crossed-field amplifier (CFA) shares several characteristics with the magnetron. Both contain a cylindrical cathode coaxial with an rf structure. Also, each of these tubes constitutes a diode in which a magnetic field is established perpendicular to an electric field between the cathode and anode. Still another similarity between the CFA and magnetron is that the rf structure serves as the electron collector and must therefore be very rugged. The key difference between the CFA and the magnetron is in the rf structure. The CFA uses a delay line that slows down the rf, thereby allowing it to interact more efficiently with the electron stream. With this scheme, CFAs are capable of achieving very high conversion efficiencies of up to 70 percent. Additionally, the output power of CFAs is obtained with relatively low beam voltage, two to three times lower than other devices at the same power level. The gain characteristic of CFAs is a highly nonlinear one and relatively low (one to two orders of magnitude lower) compared with other electron tubes. Bandwidths of CFAs are typically 10 to 20 percent.

Traveling-wave tubes. These are generally used to amplify microwave signals over broad bandwidths. The main elements of a traveling-wave tube (TWT) are (1) an electron gun, (2) a focusing structure that keeps the electrons in a linear path, (3) an rf circuit that causes rf fields to interact with the electron beam, and (4) a collector with which to collect the electrons. There are two main types of TWTs, and these are differentiated by the rf structure. One uses a slow-wave circuit called a helix for propagating the rf wave for electron–rf field interaction, and the other employs a series of staggered cavities coupled to each other for wave propagation. Each type has different characteristics and finds its use in different applications. The helix TWT is distinct from other electron tubes as it is the only one that does not use rf cavities. Because cavities have bandwidth limitations, the coupled-cavity TWT also is bandwidth-limited to typically 10 to 15 percent. The helix TWT, however, has no particular bandwidth limitations and, for all practical purposes, an octave bandwidth (100 percent) is attainable.

Helix and coupled-cavity TWTs

The basic helix TWT is shown schematically in Figure 12. The electron gun contains a cathode that emits electrons, and these are formed by the gun electrodes into a beam that is injected into the opening of the helix.

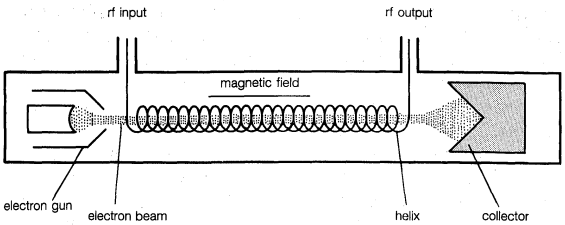

Figure 12: Elements of the traveling-wave tube (TWT).

Because space-charge forces tend to make the electrons diverge radially, a focusing structure is used to keep the beam at a desired diameter by causing diverging electrons to be sent toward the axis of the helix. In this manner, the electron beam is maintained at the desired diameter all along the length of the helix. This is necessary because the electron–rf field interaction takes place continuously over the length of the helix within the helix diameter. In order to achieve this interaction, the diameter and pitch of the helix must be such that the rf wave traveling on the helix wire at the speed of light (*i.e.*, 2.997925×10^8 metres per second) is slowed down in its axial travel to be in synchrony with the velocity of the electrons in the beam. The axial phase velocity of the wave is approximated by multiplying the speed of light by the ratio of the pitch to the circumference of the helix. The axial phase velocity is relatively constant over a wide range of frequencies, and this characteristic provides for the large bandwidths of helix TWTs. For typical applications, the electrons travel down the helix axis at about $1/10$ the speed of light. The voltage required to impart this velocity to the electrons is on the order of 10,000 volts. The rf output power and frequency required determine the actual voltage and current to be used.

The amplifying action of the TWT occurs via a continuous interaction between the axial component of the electric field wave traveling down the centre of the helix and the electron beam moving along the axis of the helix at the same time. The electrons are continually slowed down, and their energy is transferred to the wave along the helix. The electrons tend to bunch in regions where the rf field ahead is decelerating and the field behind is accelerating. The interaction between a bunched electron beam and a helix may be viewed in terms of induced currents. The bunches of electrons induce positive charges on the helix, and these charges move in phase with the bunches. If the phase is proper, this current adds to the current associated with the rf wave flowing in the helix and causes the wave to grow. The interaction is continuous along the length of the helix. The wave amplitude growing on the helix, in turn, causes the electrons to bunch more, and the growing bunches of electrons result in a continuous exponential growth of the helix wave with distance. Typical gains are on the order of four decibels per centimetre, and overall gains are 40 to 50 decibels for helix tubes of practical sizes and applications. The DC-to-rf conversion efficiency of TWTs, both helix and coupled-cavity, is similar and is in the range of 20 to 60 percent, depending on the power level and bandwidth.

A special application of helix TWTs is its use in communications or scientific satellites and other spacecraft. The helix is ideal for this application because of its small size and weight, high efficiency, and low rf-distortion characteristics. TWTs in space have demonstrated ultrareliable operation, amassing millions of hours of operation.

Suitability for use in space vehicles

Fast-wave electron tubes. Conventional electron tubes are designed to produce electron–field interaction by slowing down the rf wave to about $1/10$ the speed of light. A different way of creating the electron–field interaction is to allow the rf wave to propagate at essentially the speed of light by letting it pass, for example, through a section of a wave guide. Electrons used for energy transfer to the fast rf wave are bunched either by rippled magnetic fields or by rf fields that induce angular-velocity modulation.

The bunched electrons give part of their energy to a properly phased microwave field. The advantage of fast-wave devices is that the rf circuits are large compared to the wavelength of a signal. Thus, such devices can be manufactured with large dimensions and still operate at exceedingly high frequencies—*e.g.*, 100 gigahertz or higher. The fast-wave tubes typically operate at very high voltages to generate the high electron velocities required for resonance conditions, thereby permitting an energy exchange to take place. In fact, it is the resonance due to the electrons in a magnetic field that determines the frequency and not a cavity structure, as in a klystron. The high-voltage AC currents used are the main reason that fast-wave devices produce exceedingly high rf power levels, up to millions of watts at very high frequencies (more than 100 gigahertz).

Gyrotrons

One major type of fast-wave electron tube is the gyrotron. Sometimes called the cyclotron resonance maser, this device can generate megawatts of pulsed rf power at millimetre and submillimetre wavelengths. Gyrotrons and other fast-wave tubes are used in certain radar applications, communications, and plasma heating in some experimental controlled-fusion systems.

The gyrotron makes use of an energy-transfer mechanism between an electron orbiting in a magnetic field and an electromagnetic field at the cyclotron frequency (see above; Figure 13). At a very high electron velocity, the electron increases in mass (due to relativistic effects), and this increase lowers the cyclotron frequency. The interaction between the orbiting electron and the electromagnetic field is such that, if energy is given to the field, the electron loses some mass and the phase of the cyclotron wave changes. This results in a form of electron bunching analogous to the bunching in a klystron (see above).

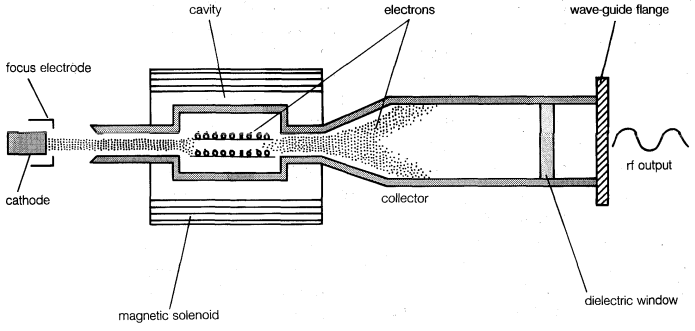

Figure 13: In a gyrotron, electrons from the cathode acquire cyclotron rotation in the cavity (see text).

In another major type of fast-wave tube, an electromagnetic wave travels down a circular or rectangular wave guide and interacts with an undulating electron beam. The undulating motion of the electron beam is produced by a periodic magnetic field. The electrons bunch up as in the klystron process. When the bunches interact with the traveling wave, the electron energy is converted to rf energy, resulting in amplification. Beam voltages in these devices are on the order of 100 kilovolts; and, with electron currents of about 35 amperes, one can generate steady-state power levels of 300 watts or pulsed peak power levels of 200 kilowatts at millimetre wavelengths.

Gas electron tubes. In gas tubes the conductivity between the electrodes differs from that of a vacuum due to the presence of a small amount of gas. Common uses of such devices are rectification and switching (*e.g.*, opening inductive energy-storage circuits, on–off modulations, and closing applications).

Characteristic configuration

The modern gas tube is typically a coaxial, four-electrode device that contains hydrogen gas at a pressure of 50–400 millitorrs (0.000066–0.00053 atmosphere). A low-voltage discharge is initiated near the cathode by the electrons that it generates, and the hydrogen gas molecules are ionized by collisions with the electrons. The electrons released by the ionized hydrogen bombard the cathode, giving rise to secondary electrons. This secondary electron emission sustains the low-voltage discharge. Some primary and secondary electrons are accelerated from the cathode and undergo more collisions with the hydrogen gas molecules. The plasma formed near the cathode can be enlarged so that contact is made with the electrode serving as the anode, and the conduction plasma path is established. The resulting current can be interrupted by means of a control grid with small apertures that pinch off the flow of plasma. (E.N.So.)

SEMICONDUCTOR DEVICES

Semiconductor devices are electronic components fabricated from materials whose electrical conductivity is intermediate between that of an insulator and that of a conductor (see below). They have found wide applications because of their compactness, reliability, and low cost. As discrete components, they can be used to accommodate much of the electromagnetic spectrum—from direct current to ultraviolet frequencies. They have a wide range of current- and voltage-handling capabilities, with current ratings from a few nanoamperes (10^{-9} ampere) to more than 5,000 amperes and voltage ratings extending above 100,000 volts. In addition, semiconductor devices lend themselves to integration into complex but readily manufacturable microelectronic circuits. They are, and will be in the foreseeable future, the key elements for the majority of electronic systems, including communications, consumer, data-processing, and industrial control equipment.

Semiconductor and junction principles. *Semiconductor materials.* Solid-state materials are commonly grouped into three classes: insulators, semiconductors, and conductors. (At low temperatures some conductors, semiconductors, and insulators may become superconductors.) Figure 14 shows the conductivities σ (and the corresponding resistivities $\rho = 1/\sigma$) that are associated with some important materials in each of the three classes. Insulators, such as fused quartz and glass, have very low conductivities on the order of 10^{-18} to 10^{-10} siemens per centimetre; and conductors, such as aluminum and silver, have high conductivities typically from 10^4 to 10^6 siemens per centimetre.The conductivities of semiconductors are between these extremes.

The conductivity of a semiconductor is generally sensitive to temperature, illumination, magnetic fields, and minute amounts of impurity atoms. For example, the addition of less than 0.01 percent of a particular type of impurity can increase the electrical conductivity of a semiconductor by five or more orders of magnitude (*i.e.*, 100,000 times). The ranges of semiconductor conductivity due to impurity atoms for five common semiconductors are given in Figure 14.

Types of semiconductor materials

The study of semiconductor materials began in the early 19th century. Over the years, many semiconductors have been investigated. The Table shows a portion of the periodic table related to semiconductors. The elemental semiconductors are those composed of single species of atoms, such as silicon (Si), germanium (Ge), and gray tin (Sn) in column IV and selenium (Se) and tellurium (Te) in column VI. There are, however, numerous compound semiconductors that are composed of two or more elements. They are called binary compounds (for two elements), ternary compounds (for three elements), and so

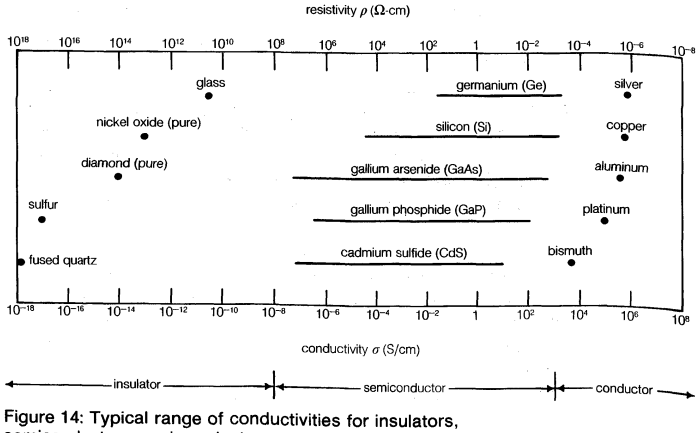

Figure 14: Typical range of conductivities for insulators, semiconductors, and conductors.

Portion of the Periodic Table of Elements Related to Semiconductors

	column				
period	II	III	IV	V	VI
2		boron B	carbon C	nitrogen N	
3	magnesium Mg	aluminum Al	silicon Si	phosphorus P	sulfur S
4	zinc Zn	gallium Ga	germanium Ge	arsenic As	selenium Se
5	cadmium Cd	indium In	tin Sn	antimony Sb	tellurium Te
6	mercury Hg		lead Pb		

forth. Gallium arsenide (GaAs), for example, is a binary III-V compound, which is a combination of gallium (Ga) from column III and arsenic (As) from column V.

Ternary compounds can be formed by elements from three different columns, as, for instance, mercury indium telluride ($HgIn_2Te_4$), a II-III-VI compound. They also can be formed by elements from two columns, such as aluminum gallium arsenide ($Al_xGa_{1-x}As$), which is a ternary III-V compound, where both Al and Ga are from column III and the subscript x is related to the composition of the two elements from 100 percent Al ($x = 1$) to 100 percent Ga ($x = 0$).

Prior to the invention of the bipolar transistor in 1947, semiconductors were used only as two-terminal devices, such as rectifiers and photodiodes. During the early 1950s germanium was the major semiconductor material. However, it proved unsuitable for many applications because devices made of the material exhibited high leakage currents (see below) at only moderately elevated temperatures. Since the early 1960s silicon has become a practical substitute, virtually supplanting germanium as a material for semiconductor fabrication. The main reasons for this are twofold: (1) silicon devices exhibit much lower leakage currents, and (2) high-quality silicon dioxide (SiO_2), which is an insulator, is easy to produce. At present, silicon technology is by far the most advanced among all semiconductor technologies, and silicon-based devices constitute more than 95 percent of all semiconductor hardware sold worldwide.

Many of the compound semiconductors have electrical and optical properties that are absent in silicon. These semiconductors, especially gallium arsenide, are used mainly for high-speed and optoelectronic applications (see below *Optoelectronic devices*).

Electronic properties. The semiconductor materials treated here are single crystals—*i.e.,* the atoms are arranged in a three-dimensional periodic fashion. Figure 15A shows a simplified two-dimensional representation of an intrinsic silicon crystal that is very pure and contains a negligibly small amount of impurities. Each silicon atom in the crystal is surrounded by four of its nearest neighbours. Each atom has four electrons in its outer orbit and shares these electrons with its four neighbours. This sharing of electrons is known as covalent bonding, and each electron pair constitutes a covalent bond. The force of attraction for the electrons by both nuclei holds the two atoms together.

At low temperatures the electrons are bound in their respective positions in the crystal; consequently, they are not available for electrical conduction. At higher temperatures thermal vibration may break some of the covalent bonds. The breaking of a bond yields a free electron that can participate in current conduction. Once an electron moves away from a covalent bond, there is an electron deficiency in that bond. This deficiency may be filled by one of the neighbouring electrons, which results in a shift of the deficiency location from one site to another. This deficiency may thus be regarded as a particle similar to an electron. This fictitious particle, dubbed a hole, carries a positive charge and moves, under the influence of an applied electric field, in a direction opposite to that of an electron. The concept of a hole is analogous to that of a bubble in a liquid. Although it is actually the liquid that moves, it is much easier to talk about the motion of the bubble in the opposite direction.

For an isolated atom, the electrons of the atom can have only discrete energy levels. When a large number of atoms are brought together to form a crystal, the interaction between the atoms causes the discrete energy levels to spread out into energy bands. When there is no thermal vibration, the electrons in a semiconductor will completely fill a number of energy bands, leaving the rest of the energy bands empty. The highest filled band is called the valence band. The next higher band is the conduction band, which is separated from the valence band by an energy gap. This energy gap, also called a bandgap, is a region that designates energies that the electrons in the semiconductor cannot possess. Most of the important semiconductors have bandgaps in the range 0.25 to 2.5 eV. The bandgap of silicon, for example, is 1.12 eV and that of gallium arsenide is 1.42 eV.

Bandgaps of semiconductors

As discussed above, at finite temperatures thermal vibrations will break some bonds. When a bond is broken, a free electron, along with a free hole, results. Because of the relatively small bandgaps of semiconductors, some electrons are able to move from the valence band to the conduction band, leaving holes in the former. When an electric field is applied to the semiconductor, both the electrons in the conduction band and the holes in the valence band gain kinetic energy and conduct electricity.

The electrical conductivity of a material depends on the number of charge carriers (*i.e.,* free electrons and free holes) per unit volume and on the rate at which these carriers move under the influence of an electric field. In an intrinsic semiconductor there exists an equal number of free electrons and free holes. The electrons and holes, however, have different mobilities—that is to say, they move with different velocities in an electric field. For example, for intrinsic silicon at room temperature, the electron mobility is 1,500 square centimetres per volt second ($cm^2/V \cdot s$; *i.e.,* an electron will move at a velocity of 1,500 centimetres per second under an electric field of one volt per centimetre), while the hole mobility is 500 $cm^2/V \cdot s$. The mobilities of a given semiconductor generally decrease with increasing temperature or with increased impurity concentration.

Electrical conduction in intrinsic semiconductors is quite poor. To produce higher conduction, one can intentionally introduce impurities (typically to a concentration of one part per million host atoms). This is the so-called doping process. For example, when a silicon atom is replaced by an atom with five outer electrons such as arsenic, Figure

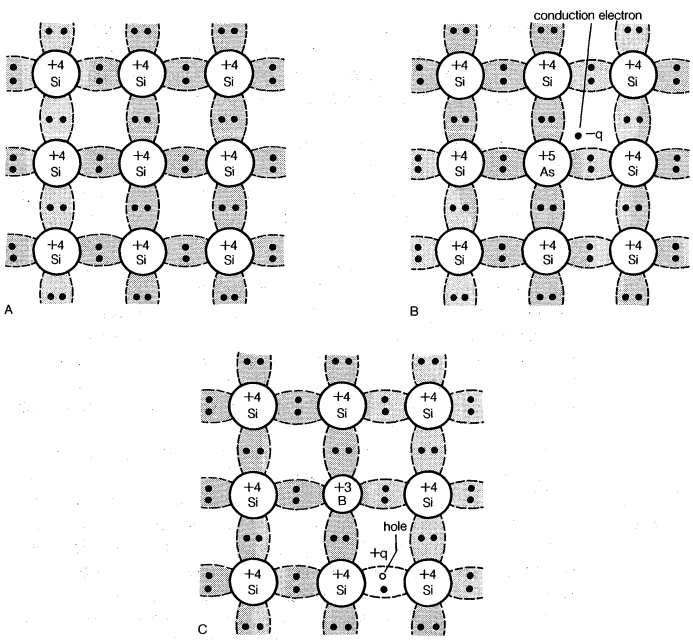

Figure 15: *Three bond pictures of a semiconductor.*
(A) Intrinsic with negligible impurities; (B) *n*-type with donor (arsenic); (C) *p*-type with acceptor (boron).

15B, the arsenic atom forms covalent bonds with its four neighbouring silicon atoms. The fifth electron becomes a conduction electron that is "donated" to the conduction band. The silicon becomes an *n*-type semiconductor because of the addition of the electron. The arsenic atom is the donor. Similarly, Figure 15C shows that, when an atom with three outer electrons such as boron is substituted for a silicon atom, an additional electron is "accepted" to form four covalent bonds around the boron atom, and a positively charged hole is created in the valence band. This is a *p*-type semiconductor, with the boron constituting an acceptor.

The p–n junction. If an abrupt change in impurity type from acceptors (*p*-type) to donors (*n*-type) occurs within a single crystal structure, a *p–n* junction is formed (see the insets of Figure 16). On the *p* side, the holes constitute the dominant carriers and so are called majority carriers. A few thermally generated electrons will also exist in the *p* side; these are termed minority carriers. On the *n* side the electrons are the majority carriers, while the holes are the minority carriers. Near the junction is a region having no free-charge carriers. This region, called the depletion layer, behaves as an insulator.

Majority and minority carriers

The most important characteristic of *p–n* junctions is that they rectify; that is to say, they allow current to flow easily in only one direction. Figure 16 shows the current-voltage characteristics of a typical silicon *p–n* junction. When a forward bias is applied to the *p–n* junction (*i.e.*, a positive voltage applied to the *p*-side with respect to the *n*-side, as shown in the second quadrant), the majority charge carriers move across the junction so that a large current can flow. However, when a reverse bias is applied (in the third quadrant), the charge carriers introduced by the impurities move in opposite directions away from the junction and only a small leakage current flows initially. As the reverse bias is increased, the current remains very small until a critical voltage is reached, at which point the current suddenly increases. This sudden increase in current is referred to as the junction breakdown, usually a nondestructive phenomenon if the resulting power dissipation is limited to a safe value. The applied forward voltage is usually less than one volt, but the reverse critical voltage, called the breakdown voltage, can vary from less than one volt to many thousands of volts, depending on the impurity concentration of the junction and other device parameters.

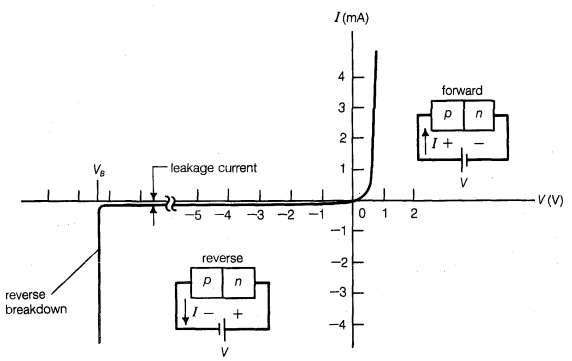

Figure 16: Current-voltage characteristics of a typical silicon *p–n* junction. Insets show forward-bias and reverse-bias conditions.

Two-terminal junction devices. A *p–n* junction diode is a solid-state device that has two terminals. Depending on impurity distribution, device geometry, and biasing condition, a junction diode can perform various functions. There are more than 50,000 types of diodes with voltage ratings from less than one volt to more than 2,000 volts and current ratings from less than one milliampere to more than 5,000 amperes. A *p–n* junction also can generate and detect light and convert optical radiation into electrical energy (see below *Optoelectronic devices*). The circuit symbols of various junction diodes and related semiconductor devices are given in Figure 17.

Junction diodes

Rectifier. This type of *p–n* junction diode is specifically designed to rectify an alternating current—*i.e.*, to give a low resistance to current flow in one direction and a very high resistance in the other direction. Such diodes are generally designed for use as power-rectifying devices that operate at frequencies from 50 hertz to 50 kilohertz. The majority of rectifiers have power-dissipation capabilities from 0.1 to 10 watts and a reverse breakdown voltage from 50 to more than 5,000 volts. (A high-voltage rectifier is made from two or more *p–n* junctions connected in series.)

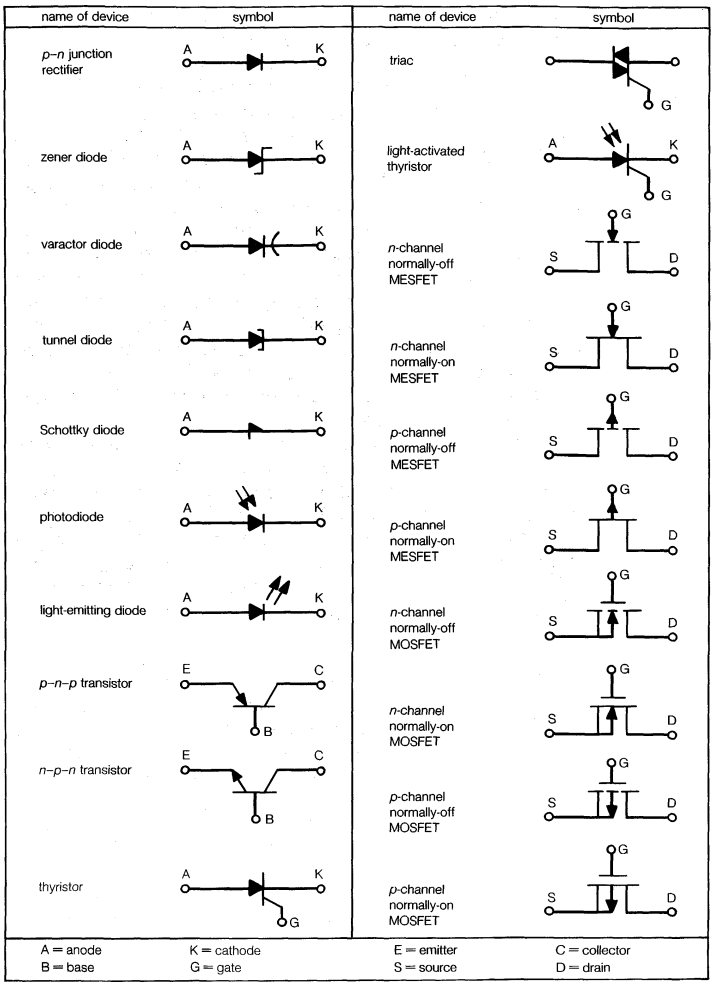

Figure 17: Names and circuit symbols for various semiconductor devices.

Zener diode. This voltage regulator is a *p–n* junction diode that has a precisely tailored impurity distribution to provide a well-defined breakdown voltage. It can be designed to have a breakdown voltage over a wide range from 0.1 volt to thousands of volts. The Zener diode is operated in the reverse direction to serve as a constant voltage source, as a reference voltage for a regulated power supply, and as a protective device against voltage and current transients.

Varactor diode. The varactor (variable reactor) is a device whose reactance can be varied in a controlled manner with a bias voltage. It is a *p–n* junction with a special impurity profile, and its capacitance variation is very sensitive to reverse-biased voltage. Varactors are widely used in parametric amplification, harmonic generation, mixing, detection, and voltage-variable tuning applications.

High sensitivity to reverse-biased voltage

Tunnel diode. A tunnel diode consists of a single *p–n* junction in which both the *p* and *n* sides are heavily doped with impurities. The depletion layer is very narrow (about 100 angstroms). Under forward biases the electrons can tunnel or pass directly through the junction, producing a negative resistance effect (*i.e.*, the current decreases with increasing voltage). Because of its short tunneling time across the junction and its inherent low noise (random fluctuations either of current passing through a device or of voltage developed across it), the tunnel diode is used in

special low-power microwave applications, such as a local oscillator and a frequency-locking circuit.

Schottky diode. Such a diode is one that has a metal–semiconductor contact (*e.g.*, an aluminum layer in intimate contact with a *n*-type silicon substrate). It is named for the German physicist Walter H. Schottky, who in 1938 explained the rectifying behaviour of this kind of contact. The Schottky diode is electrically similar to a *p–n* junction, though the current flow in the diode is due primarily to majority carriers having an inherently fast response. It is used extensively for high-frequency, low-noise mixer and switching circuits. Metal–semiconductor contacts can also be non-rectifying; *i.e.*, the contact has a negligible resistance regardless of the polarity of the applied voltage. Such a contact is called an ohmic contact.

Ohmic contacts

All semiconductor devices as well as integrated circuits need ohmic contacts to make connections to other devices in an electronic system.

The p–i–n diode. A *p–i–n* diode is a *p–n* junction with an impurity profile tailored so that an intrinsic layer, the "*i* region," is sandwiched between a *p* layer and an *n* layer. The *p–i–n* diode has found wide application in microwave circuits. It can be used as a microwave switch with essentially constant depletion-layer capacitance (equal to that of a parallel-plate capacitor having a distance between the plates equal to the *i*-region thickness) and high power-handling capability.

Transferred-electron diode. The transferred-electron diode (TED) is made from *n*-type compound semiconductors (such as gallium arsenide and indium phosphide [InP]) with two ohmic contacts. When an electric field is applied across the diode, it shows a negative resistance due to a field-induced transfer of electrons from high-mobility, lower energy levels to low-mobility, higher energy levels in the conduction band. TEDs have been used as local oscillators and power amplifiers, which cover the microwave frequency range from 1 to 100 gigahertz. They have become important solid-state microwave sources for use in radar, intrusion alarms, and microwave test instruments.

IMPATT diode. The IMPATT (impact ionization avalanche transit time) diode is another important solid-state source of microwave power. It employs impact ionization (a phenomenon related to reverse junction breakdown) and transit-time properties (*i.e.*, charge carriers travel across the depletion layer of a *p–n* junction) to produce negative resistance at microwave frequencies. The negative resistance of the type found in IMPATT diodes can be obtained from a conventional *p–n* junction, a Schottky diode, and many junction diodes that have special impurity profiles. Among solid-state devices, the IMPATT diode can generate the highest continuous-wave power output at millimetre-wave frequencies (*i.e.*, above 30 gigahertz).

Use of impact ionization and transit-time properties

Bipolar transistors. This type of transistor is one of the most important of the semiconductor devices. It is a bipolar device in that both electrons and holes are involved in the conduction process. The bipolar transistor delivers a change in output voltage in response to a change in input current. The ratio of these two changes has resistance dimensions and is a "transfer" property (input-to-output), hence the name transistor.

A perspective view of a silicon *p–n–p* bipolar transistor is shown in Figure 18A. Basically the bipolar transistor is fabricated by first forming an *n*-type region in the *p*-type substrate; subsequently a p^+ region (very heavily doped *p*-type) is formed in the *n* region. Ohmic contacts are made to the top p^+ and *n* regions through the windows opened in the oxide layer (an insulator) and to the *p* region at the bottom.

An idealized, one-dimensional structure of the bipolar transistor, shown in Figure 18B, can be considered as a section of the device along the dashed lines in Figure 18A. The heavily doped p^+ region is called the emitter, the narrow central *n* region is the base, and the *p* region is the collector. The circuit arrangement illustrated in Figure 18B is known as a common-base configuration. The arrows indicate the directions of current flow under normal operating conditions—namely, the emitter–base junction is forward biased and the base–collector junction is reverse

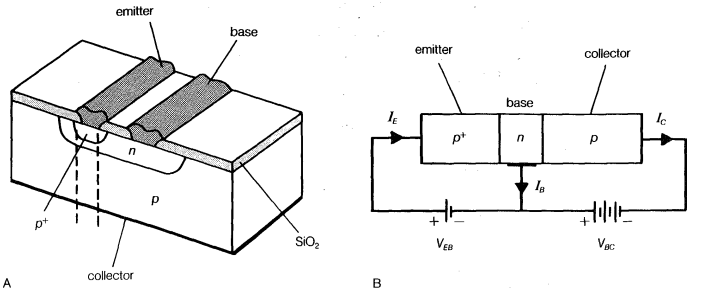

Figure 18: (A) Perspective of a *p–n–p* bipolar transistor; (B) idealized one-dimensional transistor.

biased. The complementary structure of the *p–n–p* bipolar transistor is the *n–p–n* bipolar transistor, which is obtained by interchanging *p* for *n* and *n* for *p* in Figure 18A. The current flow and voltage polarity are all reversed. The circuit symbols for *p–n–p* and *n–p–n* transistors are given in Figure 17.

The bipolar transistor is composed of two closely coupled *p–n* junctions. The emitter–base p^+–*n* junction is forward biased and has low resistance. The majority carriers (holes) in the p^+-emitter are injected (or emitted) into the base region. The base–collector *n–p* junction is reverse biased. It has high resistance, and only a small leakage current will flow across the junction. If the base width is sufficiently narrow, however, most of the holes injected from the emitter can flow through the base and reach the collector. This transport mechanism gives rise to the prevailing nomenclature: emitter, which emits or injects carriers, and collector, which collects these carriers injected from a nearby junction.

The current gain for the common-base configuration is defined as the change in collector current divided by the change in emitter current when the base-to-collector voltage is constant. Typical common-base current gain in a well-designed bipolar transistor is very close to unity.

The most useful amplifier circuit is the common-emitter configuration, as shown in Figure 19A, in which a small change in the input current to the base requires little power but can result in much greater current in the output circuit. A typical output current-voltage characteristic for the common-emitter configuration is shown in Figure 19B, where the collector current I_C is plotted against the emitter–collector voltage V_{EC} for various base currents. A numerical example is provided using Figure 19B. If V_{EC} is fixed at five volts and the base current I_B is varied from 10 to 15 microamperes (μA; 1 μA = 10^{-6} A), the collector current I_C will change from about four to six milliamperes (mA; 1 mA = 10^{-3} A), as can be read from the left axis. Therefore an increment of 5 μA in the input-base current gives rise to an increment of 2 mA in the output circuit—an increase of 400 times, with the input signal thus being substantially amplified. In addition to their use as amplifiers, bipolar transistors are key components for oscillators and pulse and switching circuits, as well as for high-speed integrated circuits. There are more than 45,000 types of bipolar transistors for low-frequency operation,

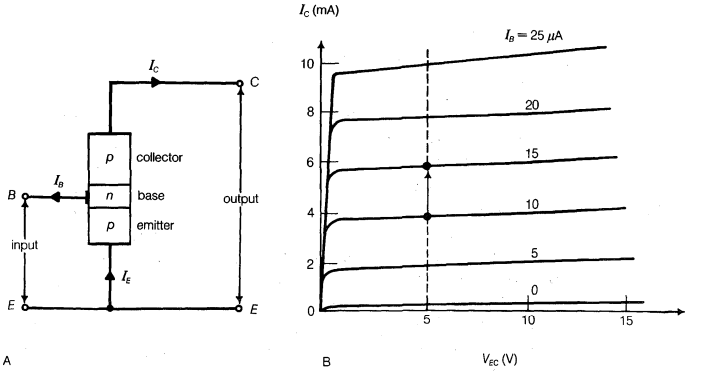

Figure 19: (A) Common-emitter configuration of a *p–n–p* transistor; (B) output characteristics for a *p–n–p* transistor in the common-emitter configuration.

with power outputs up to 3,000 watts and a current rating of more than 1,000 amperes. At microwave frequencies, bipolar transistors have power outputs of more than 200 watts at one gigahertz and about 10 watts at 10 gigahertz.

Thyristors. The thyristors constitute a family of semiconductor devices that exhibit bistable characteristics and can be switched between a high-resistance, low-current "off" state and a low-resistance, high-current "on" state.

Similarity to the bipolar transistor

The operation of thyristors is intimately related to the bipolar transistor, in which both electrons and holes are involved in the conduction processes. The name thyristor is derived from the electron tube called the gas thyratron, since the electrical characteristics of both devices are similar in many respects. Because of their two stable states (on and off) and low power dissipations in these states, thyristors are used in applications ranging from speed control in home appliances to switching and power conversion in high-voltage transmission lines. More than 40,000 types of thyristors are available, with current ratings from a few milliamperes to more than 5,000 amperes and voltage ratings extending to 900,000 volts.

Figure 20A provides a perspective view of a thyristor structure. An *n*-type wafer is generally chosen as the starting material. Then, a diffusion step is used to form the *p*1 and *p*2 layers simultaneously by diffusing the wafer from both sides. (Diffusion is the movement of impurity atoms into the crystalline structure of a semiconductor.) Finally, *n*-type impurity atoms are diffused through a ring-shaped window in an oxide into the *p*2 region to form the *n*2 layer.

A cross section of the thyristor along the dashed lines is shown in Figure 20B. The thyristor is a four-layer *p–n–p–n* diode with three *p–n* junctions in series. The contact electrode to the outer *p* layer (*p*1) is called the anode and that to the outer *n* layer (*n*2) is designated the cathode. An additional electrode, known as the gate electrode, is connected to the inner *p* layer (*p*2).

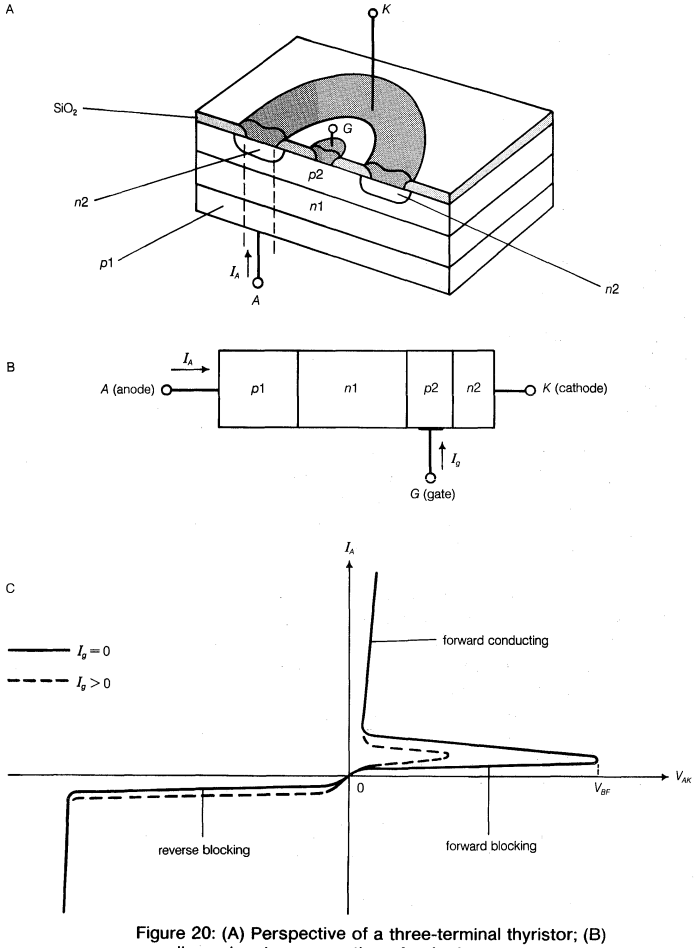

Figure 20: (A) Perspective of a three-terminal thyristor; (B) one-dimensional cross section of a thyristor; (C) current-voltage characteristics of a thyristor.

The basic current-voltage characteristic of a thyristor is illustrated in Figure 20C. It exhibits three distinct regions: the forward-blocking (or off) state, the forward-conducting (or on) state, and the reverse-blocking state, which is similar to that of a reverse-biased *p–n* junction. Thus, a thyristor operated in the forward region is a bistable device that can switch from a high-resistance, low-current off state to a low-resistance, high-current on state, or vice versa.

In the forward off state most of the voltage drops across the centre *n*1–*p*2 junction, while in the forward on state all three junctions are forward biased. The forward current-voltage characteristic can be explained using the method of a two-transistor analog, that is, to consider the device as a *p–n–p* transistor and an *n–p–n* transistor connected with the base of one transistor (*n*1) attached to the collector of the other. As the voltage V_{AK} in Figure 20C increases from zero, the current I_A will increase. This in turn causes the current gains of both transistors to increase. Because of the regenerative nature of these processes, switching eventually occurs and the device is in its on state. The maximum forward voltage that can be applied to the device prior to switching is called the forward-breakover voltage V_{BF}. The magnitude of V_{BF} depends on the gate current. Higher gate currents cause the current I_A to increase faster, enhance the regeneration process, and switch at lower breakover voltages. The effect of gate current on the switching behaviour is shown in Figure 20C (dotted line).

Triac

A bidirectional, three-terminal thyristor is called a triac. This device can switch the current in either direction by applying a small current of either polarity between the gate and one of the two main terminals. The triac is fabricated by integrating two thyristors in an inverse parallel connection. It is used extensively in AC applications such as light dimming, motor-speed control, and temperature control. There also are many light-activated thyristors that use an optical signal to control the switching behaviour of devices. The circuit symbols for some devices in the thyristor family are given in Figure 17.

Metal-semiconductor field-effect transistors. The metal-semiconductor field-effect transistor (MESFET) is a unipolar device because its conduction process involves predominantly only one kind of carrier. The MESFET offers many attractive features for applications in both analog and digital circuits. It is particularly useful for microwave amplifications and high-speed integrated circuits, since it can be made from semiconductors with high electron mobilities (*e.g.*, gallium arsenide, whose mobility is five times that of silicon). Because the MESFET is a unipolar device, it does not suffer from minority-carrier effects and so has higher switching speeds and higher operating frequencies than do bipolar transistors.

A perspective view of a MESFET is given in Figure 21A. It consists of a conductive channel with two ohmic contacts, one acting as the source and the other as the drain. The conductive channel is formed in a thin *n*-type layer supported by a high-resistivity semi-insulating (non-conducting) substrate. When a positive voltage is applied to the drain with respect to the source, electrons flow from the source to the drain. Hence, the source serves as the origin of the carriers and the drain serves as the sink. The third electrode, the gate, forms a rectifying metal–semiconductor contact with the channel. The shaded area underneath the gate electrode is the depletion region of the metal–semiconductor contact. An increase or decrease of the gate voltage with respect to the source causes the depletion region to expand or shrink; this in turn changes the cross-sectional area available for current flow from source to drain. The MESFET thus can be considered a voltage-controlled resistor.

A typical current-voltage characteristic of a MESFET is shown in Figure 21B, where the drain current I_D is plotted against the drain voltage V_D for various gate voltages. For a given gate voltage (*e.g.*, $V_G = 0$) the drain current initially increases linearly with drain voltage, indicating that the conductive channel acts as a constant resistor. As the drain voltage increases, however, the cross-sectional area of the conductive channel is reduced, causing an increase in the channel resistance. As a result, the current increases at a slower rate and eventually saturates. At a given drain

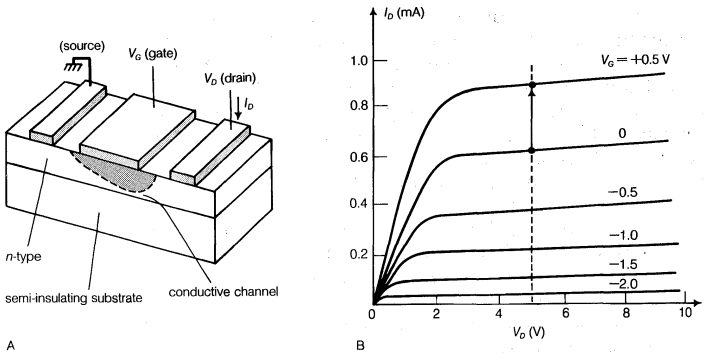

Figure 21: (A) Perspective of a MESFET; (B) current-voltage characteristic of a MESFET.

voltage the current can be varied by varying the gate voltage. For example, for $V_D = 5$ V, one can increase the current from 0.6 to 0.9 mA by forward biasing the gate to 0.5 V, as shown in Figure 21B; or one can reduce the current from 0.6 to 0.2 mA by reverse biasing the gate to −1.0 V.

A device related to the MESFET is the junction field-effect transistor (JFET). The JFET, however, has a *p–n* junction instead of a metal–semiconductor contact for the gate electrode. The operation of a JFET is identical to that of a MESFET.

There are basically four different types of MESFET (or JFET), depending on the type of the conductive channel. If, at zero gate bias, a conductive *n* channel exists and a negative voltage has to be applied to the gate to reduce the channel conductance, as shown in Figure 21B, then the device is an *n*-channel "normally-on" MESFET. If the channel conductance is very low at zero gate bias and a positive voltage must be applied to the gate to form an *n* channel, then the device is an *n*-channel "normally-off" MESFET. Similarly, *p*-channel normally-on and *p*-channel normally-off MESFETs are available. For the circuit symbols of these devices, see Figure 17.

To improve the performance of the MESFET, various heterojunction field-effect transistors (FETs) have been developed. A heterojunction is a junction formed between two dissimilar semiconductors, such as the binary compound GaAs and the ternary compound $Al_xGa_{1-x}As$.

Hetero-junctions

Such junctions have many unique features that are not readily available in the conventional *p–n* junctions discussed previously.

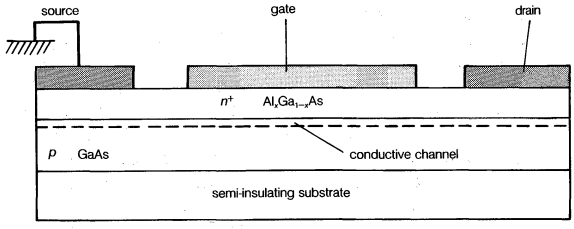

Figure 22: Cross section of a heterojunction FET having a conductive channel at the heterojunction interface.

Figure 22 shows a cross section of a heterojunction FET. The heterojunction is formed between a high-bandgap semiconductor (*e.g.*, $Al_{0.4}Ga_{0.6}As$, with a bandgap of 1.9 eV) and one of a lower bandgap (*e.g.*, GaAs, with a bandgap of 1.42 eV). By proper control of the bandgaps and the impurity concentrations of these two materials, a conductive channel can be formed at the interface of the two semiconductors, as indicated in Figure 22. Because of the high conductivity in the conductive channel, a large current can flow through it from source to drain. When a gate voltage is applied, the conductivity of the channel will be changed by the gate bias, which results in a change of drain current. The current-voltage characteristics are similar to those of the MESFET shown in Figure 21B. If the lower-bandgap semiconductor is a high-purity material, the mobility in the conductive channel will be high. This in turn can give rise to higher operating speed.

Metal-oxide-semiconductor field-effect transistors. The metal-oxide-semiconductor field-effect transistor (MOSFET) is the most important device for very-large-scale integrated circuits (those that contain more than 100,000 semiconductor devices such as diodes and transistors). The MOSFET is a member of the family of field-effect transistors, which includes the aforementioned MESFET and JFET.

A perspective view for an *n*-channel MOSFET is shown in Figure 23. Although it looks similar to a MESFET, there are four major differences: (1) the source and drain of a MOSFET are rectifying *p–n* junctions instead of ohmic contacts; (2) the gate is a metal-oxide-semiconductor structure, meaning that there is an insulator, silicon dioxide (SiO_2), sandwiched between the metal electrode and the semiconductor substrate, while for the MESFET the gate electrode forms a metal–semiconductor contact; (3) the left edge of the gate electrode must be aligned or overlapped with the source contact to facilitate device operation, while in a MESFET there is no overlapping of gate and source contact; and (4) the MOSFET is a four-terminal device, so that there is a fourth substrate contact in addition to the source, drain, and gate electrode, as in the case of a MESFET.

Differences between MOSFETs and MESFETs

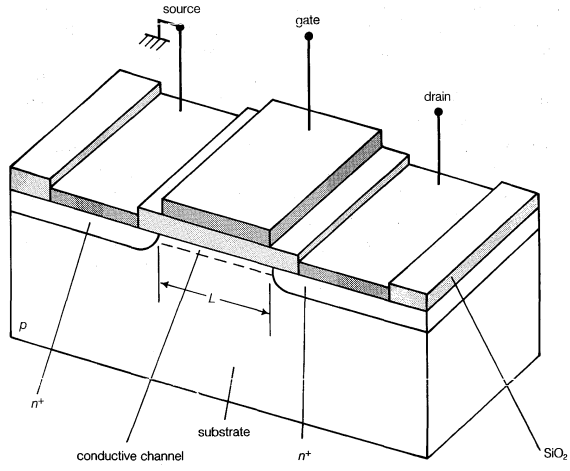

Figure 23: Perspective of a MOSFET.

One of the key device parameters is the channel length, *L*, which is the distance between the two n^+–*p* junctions, as indicated in Figure 23. When the MOSFET was first developed, in 1960, the channel length was longer than 20 micrometres (μm). Today, channel lengths less than I μm have been fabricated in volume productions, and lengths less than 0.1 μm have been created in research laboratories.

The source is generally used as the voltage reference and is grounded. When no voltage is applied to the gate, the source-to-drain electrodes correspond to two *p–n* junctions connected back to back. The only current that can flow from source to drain is a small leakage current. When a high positive bias is applied to the gate, a large number of electrons will be attracted to the semiconductor surface and form a conductive layer just underneath the oxide. The n^+ source and n^+ drain are now connected by a conducting surface *n* layer (or channel) through which a large current can flow. The conductance of this channel can be modulated by varying the gate voltages; the conductance also can be changed by the substrate bias.

The current-voltage characteristic of a MOSFET is similar to that shown in Figure 21B. There are also four different kinds of MOSFETs, depending on the type of conducting layer. The four are *n*-channel normally-off, *n*-channel normally-on, *p*-channel normally-off, and *p*-channel normally-on MOSFETs. They are similar to MESFET varieties. The circuit symbols of these devices are given in Figure 17.

Types of MOSFETs

The main reasons why the MOSFET has surpassed the bipolar transistor and become the dominant device for very-large-scale integrated circuits are (1) the MOSFET can be easily scaled down to smaller dimensions, (2)

it consumes much less power, and (3) it has relatively simple processing steps, which results in a high manufacturing yield (*i.e.*, the ratio of good devices to the total). MOSFETs also are becoming important devices for power applications. This is because the MOSFET has a negative temperature coefficient at high current levels—*i.e.*, the current decreases as temperature increases. This characteristic leads to a more uniform temperature distribution over the device area and reduces MOSFET failures due to the localized heating that occurs in the bipolar transistor.

(S.M.Sz.)

INTEGRATED CIRCUITS

An integrated circuit is an assembly of electrically isolated circuit elements, both active semiconductor devices (transistors and diodes) and passive components (capacitors and resistors), together with electrically conducting interconnections, that are fabricated in place by an iterative process of lithographic definition, deposition, and etching on a common substrate (in most cases, silicon) in such a manner that the resulting interconnected elements perform an electrical circuit function. Many ICs, typically about 0.5 square centimetre each, are fabricated simultaneously on silicon wafers up to 20 centimetres in diameter and subsequently sawed into individual chips (dies) prior to packaging. An IC thus produced is usually sealed in a plastic package with electrical leads that are internally connected by fine wires to output pads on the silicon die and that permit the packaged IC to be plugged into a circuit card.

The integration of a large number of semiconductor devices on a single die of silicon is made possible by the high operational efficiency of the individual devices. Because of this, power dissipation is minimal and so too are the requirements for heat removal. The result is an IC of high dependability, which is further enhanced by the process of integration itself because the method of manufacturing the electrical interconnections between the devices and circuit elements by metal deposition and etching yields an extremely reliable circuit structure. The number of devices integrated on a single tiny chip has increased from an initial few to nearly 1,000,000 as circuit elements with ever-smaller features are employed. This has, in turn, led to a progressive increase in complexity, as exemplified by the dynamic random-access memory (DRAM) and logic circuits based on metal-oxide-semiconductor (MOS) technology (see Figure 24).

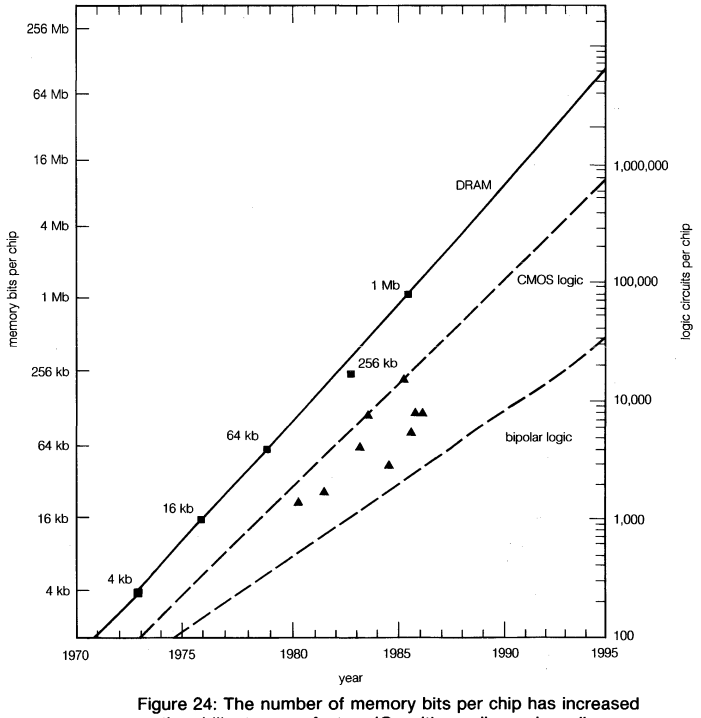

Figure 24: The number of memory bits per chip has increased as the ability to manufacture ICs with smaller and smaller feature sizes has improved. Likewise, the number of logic circuits per chip has increased. Because of the random nature of logic circuits, their density is not as great. Bipolar circuit density is less because of the larger bipolar circuit element and the power dissipation limitation on the number of circuits per chip.

The increase in complexity and resulting functionality has led to a dramatic decrease in cost per transistor and an increase in circuit performance. There are two reasons for the latter: (1) the performance of the individual active devices improves the smaller their internal dimensions become; and (2) the quality of the performance of the entire circuit improves the closer the active devices are positioned to one another. Large-volume applications for ICs have further lowered the manufacturing costs per IC. The cumulative result is that the integrated circuit has become the most pervasive technology of the 20th century. It has provided the cornerstone of modern microelectronics and has promoted the development of the so-called information society. Applications of ICs range from their use in supercomputers, which are bringing about revolutionary advances in medical diagnosis, biotechnology, aeronautical and space engineering, telecommunications, and defense systems, to the development of new consumer products capable of bringing services and information to the home and office environment that otherwise would not have been possible.

Diverse applications of ICs

Device/circuit technology. There are two basic types of transistors that are extensively employed in integrated circuits. They are the bipolar transistor and the MOSFET. (For a detailed discussion of these devices, see above *Bipolar transistors* and *Metal-oxide-semiconductor field-effect transistors.*)

The bipolar transistor is a current-controlled device. As voltage is applied to the base, injecting current into the region, the collector current increases. The ratio of collector current to injected base current is greater than unity, resulting in gain. The transistor can therefore be used as a high-gain amplifier in analog applications. It also should be noted that, for a fixed base current, the collector current saturates and is relatively insensitive to changes in emitter–collector voltage (see Figure 19). Thus, the transistor can also be used as a current switch in digital-circuit applications. The output impedance of the device is low, so that the transistor behaves as a current source and is thus able to drive capacitive loads.

The MOSFET is a voltage-controlled device. As voltage is applied to the gate, conduction begins between the source and the drain, with a consequent voltage gain (see Figure 23). At a fixed gate voltage the drain current saturates and is insensitive to changes in the drain voltage. The output impedance of the device is high, so that the transistor functions as a voltage source. It dissipates much less power than the bipolar transistor and therefore is more suitable for integration than the latter, especially for digital-circuit switching applications. The bipolar device, however, is more proficient in analog and current-driver applications. The MOSFET and bipolar transistor complement each other in the two principal types of integrated-circuit applications, analog and digital.

Analog circuits. These circuits are designed to respond to an analog input and produce an analog output where information is conveyed by the instantaneous value of the signal. The principal technology for analog applications has been bipolar, largely because bipolar technology generates less noise and allows greater small-signal gain. MOS digital technology, however, is becoming more widely used for analog applications as a result of the increasing capability of digital MOSFET integrated circuits to handle complex functions. Special circuit techniques have been developed to overcome some of the shortcomings of digital MOS devices for such applications. Charge storage on integrated capacitors is one such technique, made possible by the high-input impedance and zero offset of MOS technology. Arrays of integrated capacitors are used to sample and hold the analog signal, permitting it to be digitally encoded. On the other hand, in order to furnish an analog interface to sensors and other "real world" input/output devices for computers and computer-based equipment, bipolar analog functions are being integrated on MOS

Growing use of MOS technology

chips that are largely digital functions. Additionally, bipolar technology is being integrated because its greater capability to drive current is useful for line-driver and output-driver transistors. For very-large-scale integrated circuits a mixed bipolar/complementary MOSFET technology (BIC-MOS) benefits from the advantages of both bipolar and MOSFET technologies within the same integrated circuit. Typical analog applications for integrated circuits include their use as filters, analog-to-digital and digital-to-analog converters, voltage comparators and regulators, and operational amplifiers.

Operational amplifiers constitute the basic building block for analog circuits. The ideal operational amplifier has infinite input impedance, infinite gain, and zero output impedance. Although bipolar-circuit designers have not achieved this ideal, they have approached it closely enough for most practical applications by relying heavily on signal-feedback techniques. A very popular implementation of bipolar technology for general-purpose operational-amplifier application is the circuit shown in Figure 25. A high-impedance input is achieved by the emitter-follower input transistors, T1 and T2, whose output drives the emitters of T3 and T4, configured as a common-base differential amplifier pair. T5 and T6 together constitute an active load for the differential pair. Additional stages supply voltage gain and emitter-follower output to minimize loading and provide for a low-impedance output. A total of 20 bipolar transistors and 11 resistors are integrated onto a single silicon die. The operational amplifier is available for commercial use in an eight-pin plastic package and is characterized for operation over a temperature range of 0 to 70° C.

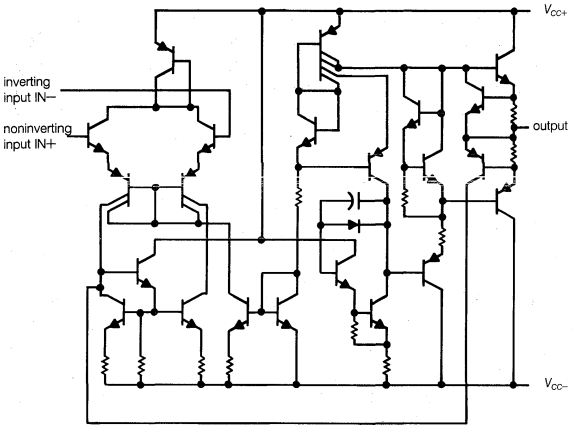

Figure 25: A general-purpose operational amplifier, the uA741C.

Digital circuits. These circuits, based principally on MOS technology, have played the major role in the growth of microelectronics since the concept of the IC was developed. The transistors of a digital circuit are operated as switches having only two states: on and off. They are combined in a manner to perform logic, arithmetic, and memory applications. All four types of MOSFETs, enhancement and depletion *p*-channel metal-oxide-semiconductor (PMOS) transistors and enhancement and depletion *n*-channel metal-oxide-semiconductor (NMOS) transistors, have been used in MOS digital-circuit design as the technology has evolved. Initially PMOS circuits were exclusively employed because of the greater ease of high-yield manufacturing. Later, as manufacturing procedures improved (specifically, airborne particulate and impurity contamination was minimized), NMOS circuits evolved because of their improved performance relative to PMOS circuits. More recently, a complementary MOS (CMOS) technology employing both PMOS and NMOS transistors superseded both previous circuit technologies because of its reduction in power dissipation.

CMOS technology

The algebra for logic design with binary quantities, "on" and "off" representing 1 and 0 (*i.e.*, true and false), was invented by the English mathematician and logician George Boole during the mid-19th century when he also published

A	$\bar{A}$

1	1	1

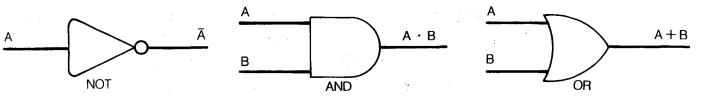

Figure 26: The logic symbol, its corresponding function, and the truth table defining the operation are shown. The NOT function inverts the signal (*i.e.*, a 1 becomes a 0 and a 0 becomes a 1). The AND function generates a true, or 1, if both inputs are 1; otherwise the output is false, or 0. The OR function generates a 1, or true, if either input is a 1, or true, value.

his ideas. The three basic logic functions "NOT," "AND," and "OR" of Boole's system, together with their truth tables, are given in Figure 26. (Arithmetic is performed in the binary number system employing Boolean logic.) The circuit implementation of these functions in both NMOS and CMOS technologies is shown in Figure 27. These basic elements are combined in the design of integrated circuits (for digital computers and associated devices) to perform the desired functions. As an illustration, the circuit for the binary addition of a single place of two binary numbers is shown in Figure 28.

In addition to logic and arithmetic circuits, memory

DRAMs and other memory circuits

circuits that provide for the storage of information are primarily fabricated with MOS technology. Several types of memory circuits have been developed. The simplest and highest-density memories are the DRAMs. They are implemented by storing charge on a capacitor to represent 1 or 0. The charge is stored and sensed by a pass-gate MOSFET to write or read the memory capacitor cell (see Figure 29). The memory consists of an array of these cells, together with the logic circuits that permit random-access addressing of cells in the array. Because the capacitor slowly discharges (*i.e.,* loses its information), the memory must be "refreshed" frequently to restore the charge to its intended value, hence the name dynamic memory. A static memory, one that does not require refreshing, can be constructed from six transistors (see Figure 29). In this kind of memory the information is stored by the state of conduction—*i.e.,* either the right or left path of the cell is conducting. This state may be read or changed by addressing the cell. Both of these memory devices lose the stored information when the electrical power to the circuits is removed. Nonvolatile memories that retain their information by storing a charge on an electrically isolated conductor have been developed: the EPROM (electrically programmable read-only memory), in which the information is electrically written but erased only by the application of ultraviolet light on the IC, and the EEPROM (electrically erasable and programmable read-only memory), in which the information is both written and erased electrically. One other nonvolatile memory, the ROM (read-only memory), in which the information is written at the time of manufacture, provides permanent memory capability.

Very-large-scale integrated circuits perform higher-level functions by combining both logic and memory circuitry on a single silicon chip. Such devices include microprocessors, microcomputers, digital-signal processors, and application-specific integrated circuits for more customized uses. Representative of an IC of this complexity level is the digital signal processor shown in Figure 30.

Designing integrated circuits. Devices produced during the early 1960s, which marked the initial era of integrated circuits, contained fewer than 30 transistors and required only about 1,000 "geometries" (or geometric patterns; see below) to describe the location of the circuit elements on a silicon die. These relatively simple ICs were products of the so-called small-scale integration (SSI) era. By the mid-1980s, the era of very-large-scale integration (VLSI), the number of transistors per integrated circuit exceeded 1,000,000. Each of these ICs required more than 10,000,000 geometries to describe the design. The ever-increasing complexity of integrated circuits is such that computer-aided design (CAD) tools are now required to produce error-free, cost-effective designs.

Reliance on CAD systems

Texas Instruments Inc.

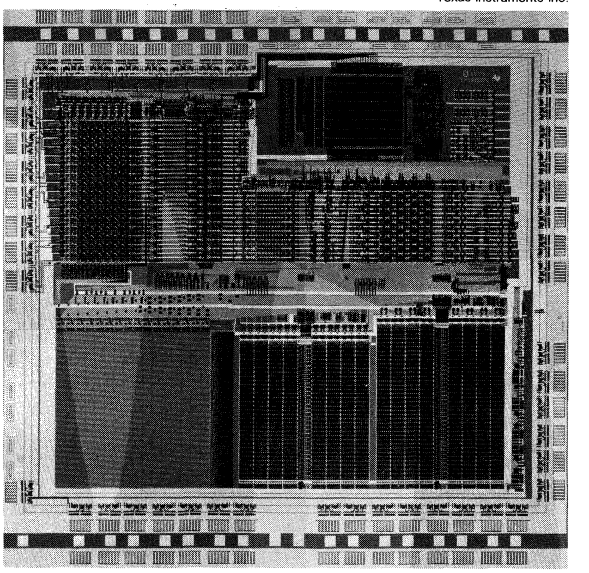

Figure 30: Texas Instruments Incorporated TMS320C25 digital signal processor.

The design process begins with the definition of an IC product or the function to be performed by it. From this definition, a system architect specifies the functional behaviour of the system—say, a supercomputer—and partitions the system into the functional elements needed. Some of these elements may be available from previous designs and are already described at all succeeding levels of design, not requiring further definition for the new design. Other elements, however, do need further defining of their internal operation at the "register-transfer level" to further define their functions. The specific logic description is extracted from this definition, and the design of the electrical circuit follows. This leads to the generation of a data base for the IC design that contains explicit information about the behaviour of the system in response to external stimuli; the architecture of the system, the logic elements, and electrical circuits; a timing analysis of the system's circuits; and all voltages and currents.

From this circuit-level description, designers prepare the physical layout of the geometries from which are produced the photomasks to be used in lithographic patterning during the IC manufacturing process (see below). Design rules specifying the minimum-allowed dimensions of the patterns, along with the device-level descriptions and the

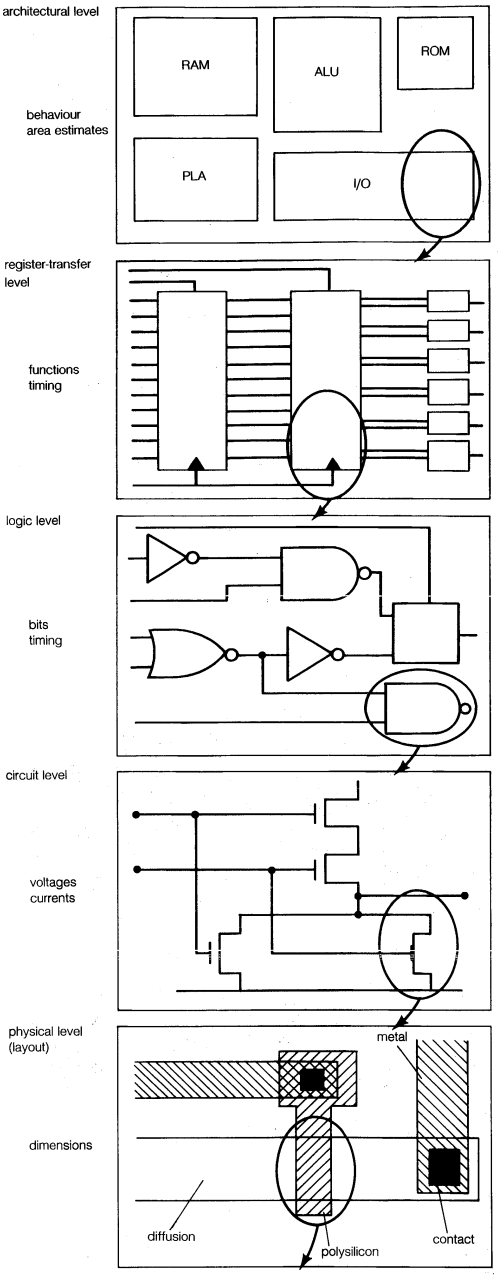

Figure 31: The IC design process.

technology utilized in IC manufacture, are taken into account in producing the layout. The initial specification and the logic implementation provide the basis for test patterns that will be used to determine the functionality of the integrated circuit at the completion of its manufacture. The entire IC design process is depicted in Figure 31.

Manufacturing technology. The fabrication of integrated circuits begins with the preparation of silicon of very high purity. Single-crystal boules with a diameter as large as 20 centimetres are produced from the silicon. The boules are sliced into wafers of a specified crystal orientation. When their surfaces have been polished to a mirrorlike finish that is free of defects, the silicon wafers are ready for fabrication into IC devices.

Basic steps in IC fabrication

This manufacturing process typically involves a sequence of more than 200 specific steps. These steps may be categorized according to function: deposition of thin film, introduction of impurities (doping), lithographic patterning of IC features corresponding to those of the physical layout, etching to define the features of individual circuit elements, and cleaning to prevent contamination and the consequent introduction of defects into circuit elements by particulate matter. These basic operations are repeated again and again in different sequential order until the IC unit is completed.

Film deposition. Several kinds of thin films are deposited on a silicon wafer by different methods during various stages of the fabrication process. The initial step following cleaning is the formation of a silicon dioxide film. This film is grown by placing the silicon wafer in an oxidizing environment at high temperature, as, for example, in a quartz-walled furnace tube. This operation may be followed by the deposition of a film of silicon nitride. Later in the fabrication process, metal films are deposited by means of sputtering. In this technique, a cathode made of the material to be deposited is bombarded with positive ions, resulting in the ejection of atoms from the cathode. These atoms are deposited on the wafer surface and form the desired metal film. Metal and polysilicon films are formed by chemical vapour deposition. Various metal silicide films are deposited and reacted with the surface of the silicon wafer. Glass films also may be deposited, and photoresist films (those of a photosensitive material) are applied by dropping a liquid polymer onto a rapidly rotating wafer.

Impurity doping. Selected impurities (*e.g.*, boron and phosphorus) are introduced into the silicon substrate to control its conductivity in a selective manner. This is accomplished by two methods: ion implantation and thermal diffusion. In the ion implantation process the silicon wafer is exposed to a beam of energetic particles (*i.e.*, high-energy ions) of the substances that are to be incorporated into the silicon. These impurities are driven into the silicon wafer to a depth ranging from a few hundred angstroms to several micrometres, depending on the energy and the mass of the ions in the beam. The wafer is annealed after implantation of the impurity ions in order to eliminate any damage that may have been done to the silicon during the process.

In diffusional doping, specific regions of the silicon wafer are exposed to concentrations of the selected impurities under intense heat in a special high-temperature furnace. At temperatures of about 800° C or higher, the impurity atoms are able to enter the silicon crystal lattice and diffuse into the upper layers of the crystal.

Lithographic patterning. The process of lithographic patterning determines the geometric features specified by the layout as the integrated circuit is fabricated layer by layer. A photomask containing pattern information is prepared for each layer. An image of the photomask is projected onto the surface of the silicon wafer. This is commonly done with an optical projection printer after

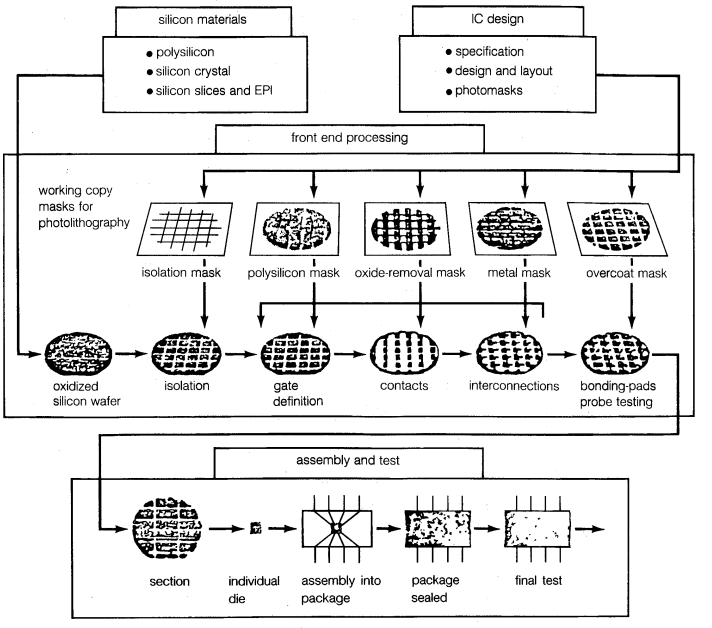

Figure 32: Typical IC design and manufacturing process for NMOS integrated circuits.

the wafer has been coated with a thin layer of photoresist. The pattern image is developed, and the exposed photosensitive material is removed chemically (in the case of a positive photoresist) from the areas that have been exposed to light. The desired pattern is thereby transferred from the photomask to the photoresist on the surface of the partially fabricated integrated circuit. This photoresist pattern serves to define the areas of the wafer where, during a subsequent process step, film is to be deposited, material is to be removed by etching, or impurities are to be introduced. Once the selective deposition or removal of material has been accomplished, the remaining photoresist is cleared off the wafer.

Etching. During this process, material is selectively removed from the wafer surface as defined by the patterned photoresist in order to define the structure of the previously deposited layer. The etching process is accomplished by exposing the wafer to a gas plasma, which both chemically reacts with the material to be removed and physically ablates it.

Manufacturing an NMOS circuit

A representative process sequence. The fabrication of an NMOS circuit can be used to illustrate how the process steps described above might be combined. The sequence of basic steps in manufacturing an NMOS circuit is shown in Figure 32.

Preliminary to these steps is the cleaning of the single-crystal silicon wafer. The fabrication process gets under way with oxidation and nitridation, which are followed by application of the photoresist and photolithographic definition of the mask pattern for electrical isolation between circuit components. After the photoresist has been developed and the isolation oxide/nitride mask defined by etching, the wafer is ion-implanted to electrically isolate the areas where the MOSFETs are to be formed, and oxide is grown over the implanted regions. The oxide/nitride film is then removed and a thin gate oxide is regrown in these regions. Polysilicon is deposited and patterned in the next photolithographic process using a second photomask to define the gate structure of the NMOS transistors. A subsequent ion-implantation process introduces the required impurities into the source/drain regions of the MOSFETs, and silicon oxide is deposited. The positions where electrical contact is to be made to the MOSFETs are defined, using the oxide-removal mask and an etch process. Metal is then deposited into the opened "vias" (passages) in the oxide layer and over its surface. During the subsequent photolithographic process, it is patterned to form the desired electrical interconnections. These two steps are repeated for each succeeding level to produce additional levels of interconnections. Finally, a protective overcoat of oxide/nitride is applied, and vias are opened so that the wires connecting the IC chip to its carrier package can be bonded to output pads.

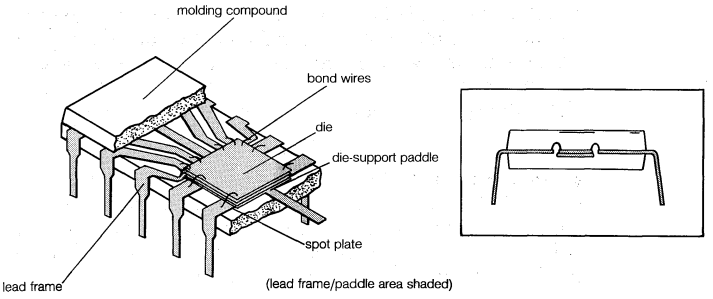

Figure 34: Integrated circuit (cutaway view) in molded plastic package.

The assembly process begins with an electrical test of the ICs die by die on each wafer to determine the location of the good units. The wafer is then sawed into individual dies, and each good unit is installed in a package (made either of plastic or ceramic) by attaching the die to a lead frame and soldering wires between the output pads on the die and the internal leads of the package. A final test is performed on the packaged die to determine whether the unit operates within the specified standards.

These steps, depicted schematically in Figure 32, illustrate the relationship between the design process, which determines the character of the photomasks, and the manufacturing process. Figure 33 shows the resulting vertical profile through a MOSFET structure as the transistor and subsequent electrical interconnections are manufactured. A cutaway view of a finished integrated circuit packaged in a molded plastic enclosure is given in Figure 34.

Possible developments. Silicon integrated-circuit technology, which is based on classical physics, is believed to be viable until the minimum feature size reaches below 0.1 micrometre where quantum mechanical effects begin to be important. However, device structures ranging from 0.01 to 0.1 micrometre, based on quantum domain phenomena, promise to supplant present-day IC technology. Also, other semiconductor materials, particularly those composed of III-V compounds (see above), have the physical properties and flexibility needed to produce novel devices capable of superior performance. Their suitability for integrated circuitry and the viability of their manufacturing techniques, however, remain to be proved. (W.C.Ho.)

OPTOELECTRONIC DEVICES

Major classes of optoelectronic devices

Optoelectronic devices are devices in which the photon, the basic particle of light, is affected. Such devices can be divided into four groups: (1) photodetectors and solar cells that convert photons into electrical current, (2) light-emitting diodes and semiconductor lasers that convert an applied voltage into emitted photons, (3) optical fibres that guide light within a small plastic or glass fibre between a light source and detector, and (4) liquid-crystal displays that use an applied voltage to change the reflection of light. A useful expression when dealing with optoelectronics is the conversion between the wavelength of the light, λ, in micrometres, and the energy of the photon, E, in electron volts:

$$\lambda = 1.24/E.$$

Photodetectors and solar cells. *Photodetectors.* A photodetector is a semiconductor device that transforms light into an electrical signal. Its applications range from sensing the amount of light for control of the shutter in an automatic camera to conversion of an optical signal in an optical communication system into an electrical signal. There are two basic types of photodetectors: photoconductors and photodiodes. Silicon is used for photodiodes in the 0.8- to 0.9-micrometre wavelength region, while germanium and III-V compound semiconductors are employed for those in the 1.0- to 1.6-micrometre wavelength region. At longer wavelengths, narrow-energy-gap compound semiconductors are used; they are cooled to the temperature of liquid nitrogen (77 K) to reduce the leakage current.

Photoconductors

A photoconductor is generally a thin semiconductor layer with ohmic contacts. The basic structure is shown in Figure 35. In this example, a high-resistivity substrate of gallium arsenide has highly doped n^+ regions for ohmic contact to the metal contacts and a lightly doped n^- region where photons with energy larger than the energy gap are absorbed.

The absorption of light is governed by the expression

$$I = I_o \exp(-\alpha x),$$

where I is the light intensity at the depth x, I_o is the incident light intensity, and α is the absorption coefficient at a particular photon energy. The absorption coefficients for commonly used semiconductors in the visible and near-infrared spectral region are shown in Figure 36.

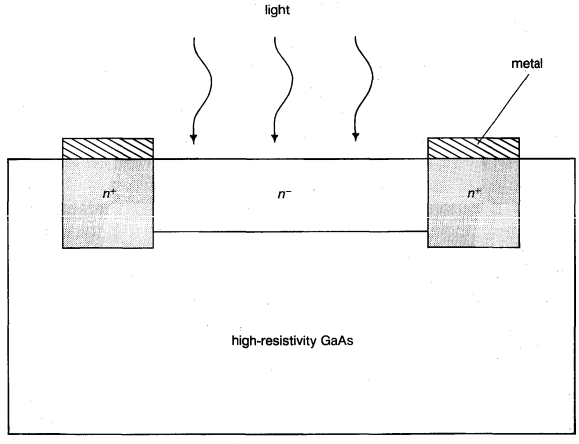

Figure 35: A photoconductor.

A small voltage is applied across the metal contacts, and the absorbed light varies the current that flows in the external circuit. The absorbed light generates free carriers to give the photocurrent I_p. The total number of absorbed photons, when multiplied by the charge q, gives the primary photocurrent I_{ph}. The photoconductor gain is given by

$$\text{gain} = I_p/I_{ph} = \tau/t_r,$$

where τ is the carrier lifetime and t_r is the carrier transit time. For small electrode spacing, the gain can significantly exceed unity. With high carrier mobility and short carrier lifetime, together with small electrode spacing, the sensitivity and speed of response can approach the results obtained with photodiodes. The advantage of photoconductors is the ease of fabrication.

Photodiodes

A photodiode is a p–n junction in which electron–hole pairs are created by photons absorbed near the p–n junction. A schematic representation is shown in Figure 37. These photo-generated carriers result in a current through the external circuit. The photodiode is generally intended to operate only over a narrow wavelength region of a particular optical signal source. The energy gap of the semiconductor should be slightly less than the photon energy. The photodiode can be operated in the photovoltaic mode in which no bias voltage is applied, but the device is connected to a load resistor. The optical signal then appears as a voltage across the load resistor. The diode

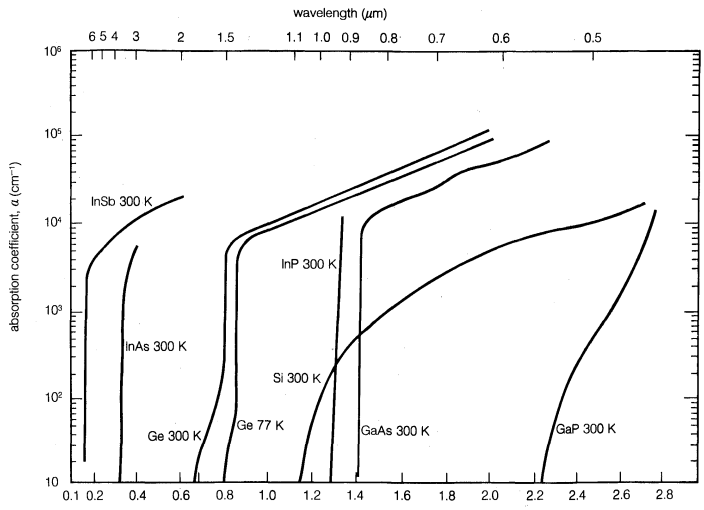

Figure 36: Absorption coefficients for silicon, germanium, and selected III-V compound semiconductors in the visible and near-infrared spectral region (see text).

From G.E. Stillman, V.M. Robbins, and N. Tabatabaie, "III-V Compound Semiconductor Devices: Optical Detectors," IEEE Transactions on Electron Devices, ED-31, 1643, © 1984 IEEE

area is small so that it minimizes the capacitance for better high-frequency response. An important measure of how well the device converts photons to electrons is the quantum efficiency, which is the ratio of the number of electrons flowing in the external circuit to the number of incident photons. With an antireflection coating, the quantum efficiency can exceed 90 percent.

One of the most commonly used photodiodes is the p–i–n diode, which has a very lightly doped i region between the p and n regions (see Figure 38). This structure can enhance the quantum efficiency because more of the light is absorbed in the diode depletion region (between the p and n regions), where it is collected and can flow through the load resistor. Also, because the p and n regions are farther apart than in the p–n-junction photodiode, the capacitance is less and the response speed is faster.

The avalanche photodiode is designed for use at high-reverse bias to provide current gain to the photogenerated hole–electron pairs. When the electric field in the depletion region of the reversed biased p–n-junction photodiode is about 10^5 volts per centimetre, a photogenerated hole or electron can collide with adjacent electron-bonding atoms, break the bond, and create a hole–electron pair. This process is called impact ionization. These newly created pairs can gain enough energy from the electric field to cause further impact ionization until finally an avalanche of carriers is produced. The avalanche gain can increase the signal-to-noise ratio and thus detect lower-intensity light signals than can other photodetectors. The avalanche photodiode, however, will have low noise if only the electron or hole is capable of causing impact ionization. Silicon has a large difference in the ionization rates of electrons

Impact ionization

and holes, while the ionization rates for the III-V semiconductors are nearly equal. Thus only silicon has been extensively used for avalanche photodiodes.

Solar cells. The solar cell was the first optoelectronic device developed and was demonstrated by D.M. Chapin, C.S. Fuller, and G.L. Pearson in 1954 with a diffused silicon *p–n* junction. The solar cell is a large-area photodiode that "detects" the solar emission spectrum rather than a specific optical signal wavelength, as do photodiodes. The solar cell is unbiased, and the load is connected directly across the two terminals of the *p–n* junction. One of the most important parameters is the conversion efficiency, which is the ratio of the maximum power output to the incident power.

Power source for space satellites

The first space satellites were electrically powered by silicon solar cells, and these cells continue to be an important long-duration power source for satellites. The solar cells originally used for this purpose were made with single-crystal silicon and had conversion efficiencies of about 15 percent. For ground applications, lower-cost solar cells have been developed by using large-grained, polycrystalline silicon with efficiencies near 12 percent instead of the more expensive single-crystal silicon. Even thin-film amorphous solar cells with efficiencies of about 6 percent have been investigated for further cost reduction. In each case the lower cost is accompanied by reduced conversion efficiency. Other materials, such as aluminum gallium arsenide or gallium arsenide, have been used in applications where an increased conversion efficiency of more than 25 percent can justify the significantly greater cost.

The design of solar cells is influenced by the solar emission spectrum. The effect of the atmosphere on sunlight at the Earth's surface is defined by the air mass. The solar spectrum outside the atmosphere is the air mass zero (AM0). The solar spectrum at the Earth's surface for the minimum path length with the Sun directly overhead is AM1. The sunlight is attenuated by the atmosphere due to the absorption of infrared rays by ozone and scattering by clouds and airborne particles (*e.g.*, dust). For the Sun at an angle of 60° from the overhead position, the spectrum is AM2. The solar spectral irradiance is given by the power per unit wavelength. These three solar spectral irradiance spectra are shown in Figure 39, together with the 5,800 K emission spectrum of a blackbody that approximates the AM0 spectrum. (A blackbody is a hypothetical ideal body or surface that absorbs and reemits all radiant energy falling upon it.)

From S.M. Sze, *Physics of Semiconductor Devices*, 2nd ed. (1979), John Wiley and Sons, New York

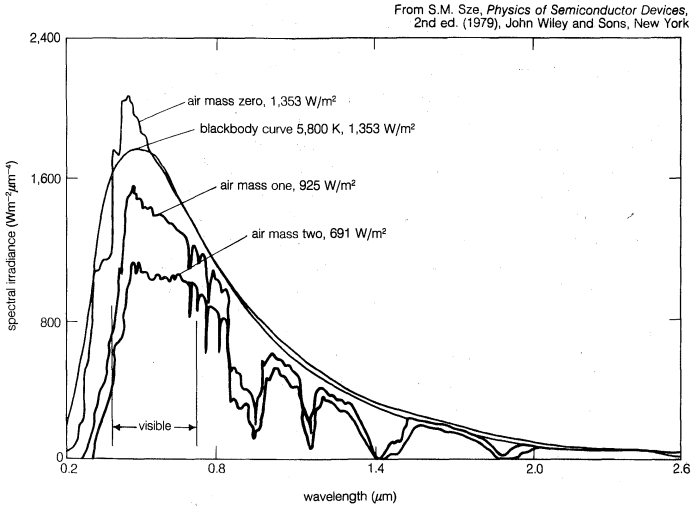

Figure 39: Solar spectral irradiance.

The efficiency of the silicon solar cell is limited to about 15 percent, because the long-wavelength emission is not absorbed near enough to the *p–n* junction for the photogenerated carriers to be collected by the *p–n* junction, and the short-wavelength emission generates carriers so near the top surface that they recombine at the surface rather than being collected by the *p–n* junction.

For satellites and space vehicles, the most important properties are conversion efficiency and reliability. Degradation due to high-energy particle radiation is an important consideration. A schematic representation of the type of solar cell developed for satellite applications is shown in Figure 40. The *p–n* junction is formed very near the front surface by diffusion. The front contact stripe and fingers must be wide enough to have low resistance but not so large as to prevent the sunlight from reaching the *p–n* junction. Thus, the conversion efficiency is decreased by that fraction of the front surface covered by the ohmic contact. The front surface also is covered by an antireflection coating. An ohmic contact covers the entire back surface.

From S.M. Sze, *Physics of Semiconductor Devices*, 2nd ed. (1979); John Wiley and Sons, New York

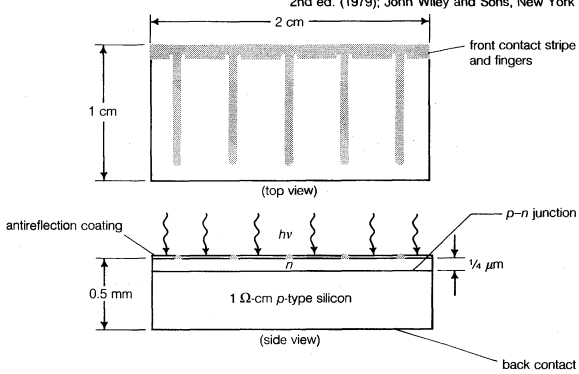

Figure 40: Silicon *p–n* junction solar cell.

A more economical fabrication technology utilizing polycrystalline silicon is shown in Figure 41. This is made by cutting wafers from cast blocks, and it measures 10 centimetres square. The treelike structure is the ohmic contact to the front surface, and the irregular-shaped regions are the silicon grains. These cells are connected in large solar panels for application on the Earth's surface to provide power at remote sites.

Use of polycrystalline silicon

Another technique involves the use of mirrors and lenses to concentrate sunlight and the utilization of a smaller cell area. With silicon cells at a concentration of 1,000 suns, the output is about the same for 1,300 cells at one sun. A gallium arsenide cell with a top layer of aluminum gallium arsenide can be useful with concentrators, and an efficiency of 23 percent close to 1,000 suns gives an output power of 10 watts.

Light-emitting diodes and semiconductor lasers. *Light-emitting diodes.* The familiar light bulb gives off light due to its temperature (incandescence). Luminescence, on the other hand, is the result of electronic excitation of a material. The light-emitting diode is a *p–n* junction in which an applied voltage yields a flow of current, and the recombination of the carriers injected across the junction results in the emission of light. (The process involved here is in effect electroluminescence.) The ratio of the number of emitted photons to the number of electrons crossing

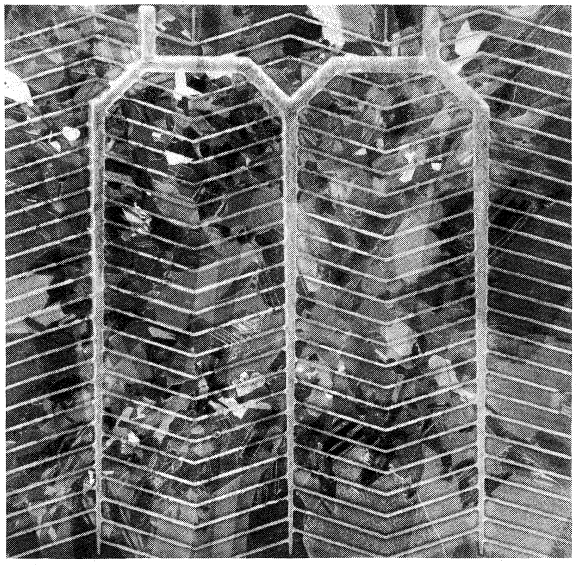

Figure 41: Four-inch-square polycrystalline silicon solar cell.

the p–n junction is the quantum efficiency. LED emission is generally in the visible part of the spectrum with wavelengths from 0.4 to 0.7 μm or in the near infrared with wavelengths between 2.0 and 0.7 μm. Visible LEDs are used as numeric displays or indicator lamps, while the infrared LEDs are employed in opto-isolators or as sources in optical communication systems. The applied voltage is near 1.5 volts. The current would depend on the application and would range from a few milliamperes to several hundred milliamperes.

Use of III-V compound semiconductors

Silicon, the most commonly used semiconductor for electronic devices and integrated circuits, is not suitable for LEDs. In silicon, the electrons in the conduction band and the holes in the valence band do not have the same momentum. Therefore, the recombination of an electron in the conduction band with a hole in the valence band necessary for the emission of a photon cannot readily occur because of the difference in momentum. However, in the III-V compound semiconductors, such as gallium arsenide (GaAs), gallium arsenide phosphide ($GaAs_{1-x}P_x$), aluminum gallium arsenide ($Al_xGa_{1-x}As$), and gallium indium arsenide phosphide ($Ga_xIn_{1-x}As_yP_{1-y}$), radiative recombination can occur with ease because electrons in the conduction band and holes in the valence band have the same momentum. The peak intensity of the emission spectrum occurs at a photon energy slightly less than the semiconductor energy gap. The radiative recombination must compete with various non-radiative recombination processes because of undesirable impurities and crystal defects, including precipitations and dislocations. Careful material processing is necessary to obtain useful LEDs.

From W.O. Groves, A.H. Herzog, and M.G. Craford, "The Effect of Nitrogen Doping on GaAsP Electroluminescent Materials," *Applied Physics Letters*, no. 19 (1970)

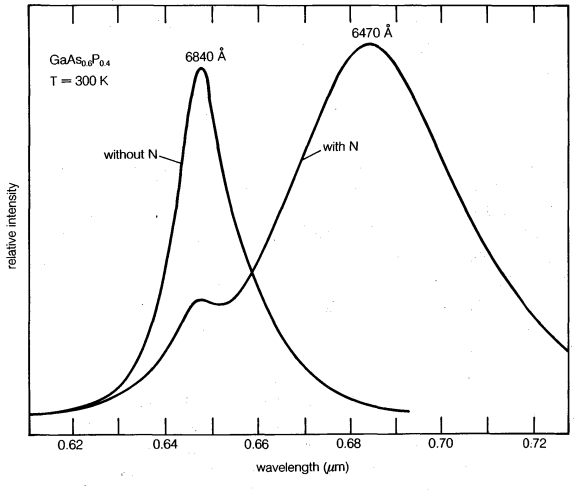

Figure 42: Emission spectra for $GaAs_{0.6}P_{0.4}$ with and without nitrogen.

In the notation used for the ternary solid solutions, the x in $Al_xGa_{1-x}As$ means that x percent of the group III elements are aluminum and $(1-x)$ percent of the group III elements are gallium. For example, with $x = 0.3$, the $Al_{0.3}Ga_{0.7}As$ would have 30 percent aluminum and 70 percent gallium. For quaternary solid solutions such as $Ga_xIn_{1-x}As_yP_{1-y}$, the x represents the percent of group III elements, while the y represents the percent of group V elements. The energy gap, and therefore the wavelength of the emitted light, changes with the composition x or x and y. The wavelength of the emitted light can be changed by varying the semiconductor composition.

The brightness of the light observed from an LED will depend on the power emitted by the LED and the relative sensitivity of the eye at the emitted wavelength. The maximum sensitivity occurs at 0.555 μm, which is in the yellow-orange and green region.

The first visible LED with extensive applications was based on $GaAs_{1-x}P_x$ grown on GaAs substrates. The composition for maximum brightness depends on both the quantum efficiency of the LED and the sensitivity of the eye. The external quantum efficiency for $GaAs_{1-x}P_x$ decreases as composition x increases, but the eye response improves as the emission moves to greater photon energy. The maximum brightness occurs near $x = 0.4$, which is an energy gap of approximately 1.9 eV. At this composition, the external quantum efficiency is about 0.2 percent.

As x increases beyond 0.45, the electron and hole no longer have the same momentum, and the energy gap goes from direct to indirect. An efficient radiative recombination centre in the indirect energy-gap region for $x > 0.45$ is the group V element nitrogen, which replaces phosphorus atoms. A recombination centre of this type is called an isoelectronic centre, and the quantum efficiency is greatly enhanced with nitrogen. Figure 42 shows that the spectrum peak moves to a longer wavelength and the emission spectrum becomes wider with the addition of nitrogen. With the isoelectronic nitrogen centre, efficient LEDs from red to orange, yellow, and green are produced.

Isoelectronic centre

From S. Gage, D. Evans, and M. Hodapp, *Optoelectronics/Fiber-Optics Applications Manual*, 2nd ed. (1977); McGraw-Hill Book Company, New York

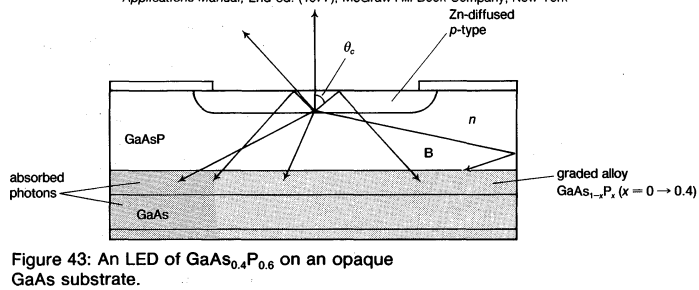

Figure 43: An LED of $GaAs_{0.4}P_{0.6}$ on an opaque GaAs substrate.

The basic configuration of a visible LED of $GaAs_{1-x}P_x$ is illustrated in Figure 43. Gallium arsenide was used as the substrate material, and the composition x varied from $x = 0$ at the substrate to 0.4. Since $GaAs_{0.4}P_{0.6}$ and GaAs do not have the same lattice constant, the composition of the layer is graded to minimize the non-radiative recombination centres that occur as a result of the lattice mismatch. The $GaAs_{1-x}P_x$ is covered with silicon dioxide and holes etched in the oxide, and then zinc is diffused into the n-type $GaAs_{1-x}P_x$ to give the p–n junction. The photons generated by radiative recombination at the p–n junction are emitted in all directions, but only a small fraction escape from the front surface. Because the refractive index of the $GaAs_{1-x}P_x$ is larger than for air, the emitted light is reflected back from the surface. At normal incidence, about 30 percent is reflected. At the critical angle represented by θ_c, all the light is internally reflected. Because the gallium arsenide substrate has a narrower energy gap than does gallium arsenide phosphide, all the light reflected to the substrate is absorbed. This internal absorption causes the internal and external quantum efficiencies to differ by a factor of approximately 10. The use of a substrate transparent to the emitted radiation, such

as gallium phosphide, and a reflecting back contact can greatly enhance the external quantum efficiency.

Any LED may be used as a source with a plastic or glass optical fibre for a short-range optical fibre transmission system over a distance of less than 100 metres. For a long-range optical-fibre transmission system, the emission properties of the source are selected to match the transmission properties of the optical fibre, and the infrared LEDs are a better match than the visible LEDs. Glass optical fibres suffer much less loss than do plastic fibres, and the glass fibres have the lowest transmission loss in the infrared at wavelengths of 1.3 and 1.55 μm. To match the transmission properties of the low-loss glass fibres, the quaternary solid solution gallium indium arsenide phosphide is grown with compositions that have the same lattice constant as the indium phosphide (InP) substrate. The composition of the gallium indium arsenide phosphide may be selected to give emission at 1.3 or 1.55 μm.

Lasers. Optical devices of this kind produce a more directional light beam and a narrow wavelength band. The term laser is an acronym derived from light amplification by stimulated emission of radiation.

Principles of operation

A photon and an electron can interact in two ways. In an absorption process, a photon with an energy slightly larger than the energy gap can interact with an electron in the valence band and raise the electron to the conduction band and create a hole in the valence band. In a stimulated emission process, a photon with an energy slightly greater than the energy gap can interact with an electron in the conduction band and cause the electron to recombine with a hole in the valence band. The recombination process results in the emission of a photon identical to the photon that caused the recombination process, and the number of photons is increased. In absorption a photon is lost, while in stimulated emission an additional photon is created. To have a laser, it is necessary to provide a structure that will make stimulated emission more probable than absorption.

A semiconductor laser requires a p–n junction that provides light emission like an LED (*i.e.,* spontaneous emission) when a voltage is applied and current flows. This radiative recombination has to be confined along the junction plane and must be reflected by parallel, partially reflecting surfaces so as to form a cavity. These parallel mirrors are readily obtained by cleaving along the natural cleavage planes of III-V compound semiconductors. The injected electrons and the light must be confined to the same region, so that they can interact to enhance the stimulated emission.

To provide the carrier and light confinement to the region of the p–n junction and obtain continuous operation at room temperature, it is necessary to use a heterojunction—*i.e.,* the junction in a single crystal between two dissimilar semiconductors. The most significant difference is the energy gap and the refractive index. A double heterostructure made with aluminum gallium arsenide and gallium arsenide is shown in Figure 44A. The left layer is n-type $Al_xGa_{1-x}As$, as the centre layer is p-type GaAs, and the right layer is p-type $Al_xGa_{1-x}As$. The centre layer of GaAs has a smaller energy gap than the two cladding layers of $Al_xGa_{1-x}As$. Typical values for x are 0.3. This gallium arsenide region with a smaller energy gap is where the light is generated due to radiative recombination of the injected carriers; it is called the active region. With an active layer of gallium arsenide, the emission wavelength is in the infrared near 0.9 μm. Other pairs of semiconductors may be used, but all require a smaller-energy-gap active region with larger-energy-gap cladding layers. Also, to prevent non-radiative recombination at the heterojunction interfaces, the active layer and the cladding layers must have the same lattice constant. It is fortunate that GaAs and $Al_xGa_{1-x}As$ closely match as to lattice constant for all compositions of x.

Figure 44B shows the energy gaps of the three regions when a voltage of approximately 1.7 is applied to the heterostructure laser. Electrons are injected from the n-layer of $Al_xGa_{1-x}As$ into the potential well of GaAs formed between the two $Al_xGa_{1-x}As$ layers. The injected carriers are confined to the narrow active layer, which typically

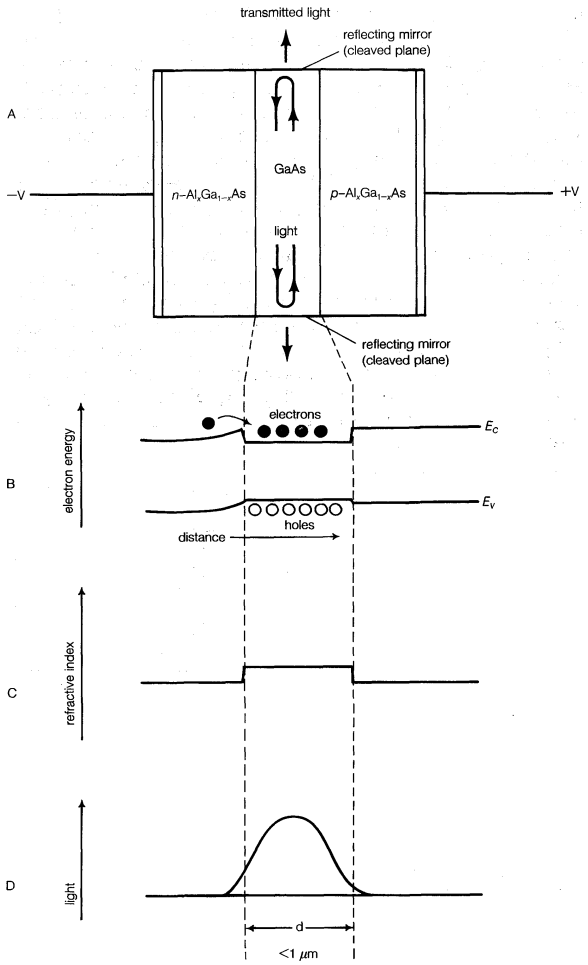

Figure 44: (A) $Al_{0.3}Ga_{0.7}As$-GaAs double heterostructure laser. (B) Energy-band diagram at forward bias. (C) Refractive-index profile. (D) Optical-field distribution.

has a thickness of between 0.1 and 0.2 μm. The refractive index profile is shown in Figure 44C. Because the $Al_xGa_{1-x}As$ layers have a smaller refractive index than the GaAs region, they form an optical wave guide that confines the light due to radiative recombination to the active layer. The light confinement is illustrated in Figure 44D. The carrier and light-confining properties of the heterojunctions permit a high density of injected electrons in the region where the light is confined, so that the photons can interact with the electrons and cause stimulated emission. The oscillation condition requires that the stimulated emission exceed the light lost through the partially reflecting facets and internal absorption.

Epitaxial growth techniques

The layers of $Al_xGa_{1-x}As$ and GaAs are grown on a GaAs substrate by a variety of epitaxial growth techniques, which include liquid-phase epitaxy, molecular-beam epitaxy, and

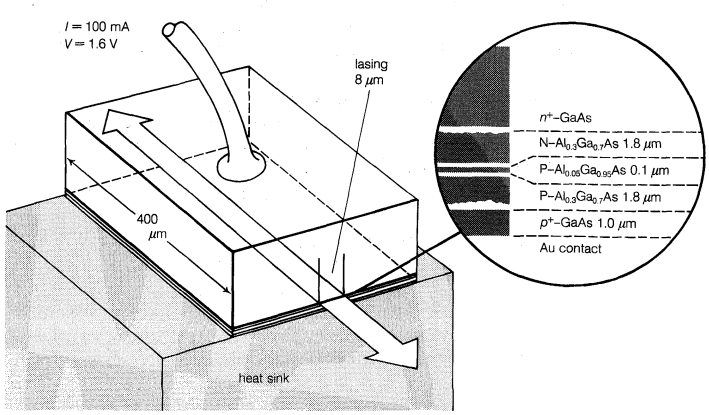

Figure 45: Stripe-geometry laser mounted on a heat sink.

metal-organic chemical-vapour deposition. These techniques permit the growth of the micrometre- and submicrometre-thick layers necessary for heterostructure lasers. Semiconductor lasers use a stripe-geometry that restricts the current along the junction plane to a width of from 1 to 15 μm. The laser chip is mounted upside down so that the heat-generating region, the p–n junction, is close to the heat sink. Figure 45 features a stripe-geometry laser mounted on a heat sink. Figure 46 shows light output as a function of the current. At low current, the light output is small, and this emission results from spontaneous emission, as in an LED. When the stimulated emission exceeds the internal losses and the light emitted from the cleaved facets, the laser threshold is reached and the light output rises rapidly with the current. Above the threshold current, most of the current flowing into the p–n junction results in laser emission, and the quantum efficiency is much higher than for an LED. The emission spectrum is also given in Figure 46.

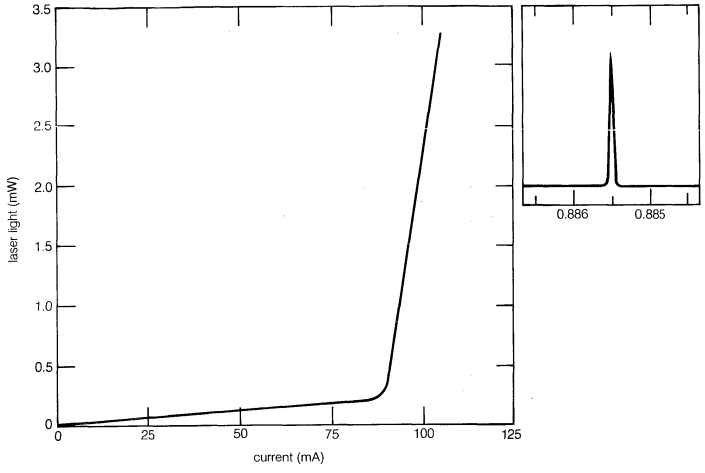

Figure 46: Light output versus the current for a heterostructure laser. The emission spectrum is shown at the upper right.

Stripe-geometry lasers typically have threshold currents near 50 mA, but lasers with threshold currents of less than 1 mA have been demonstrated. The emission may be turned off and on for digital signals by an applied pulse. The frequency response can be very fast, and operation at rates in excess of 1 GHz can readily be obtained. The best match to the transmission properties of optical fibres occurs at wavelengths of 1.3 and 1.55 μm. Heterostructure lasers for emission in this wavelength region have cladding layers made of indium phosphide and active layers consisting of gallium indium arsenide phosphide, which lattice match indium phosphide. These lasers are used as light sources in long-distance optical-fibre communication systems. Such applications include undersea cables.

Major uses of semiconductor lasers

The largest volume use of semiconductor lasers is in compact disc players. In such devices, laser light is focused on a plastic disc coated with a thin metallic film, and digital information is communicated by the presence or absence of "pits." These microscopic holes change the reflectivity of the emitted light, which is detected by light-sensitive diodes.

Optical fibres. Optical fibres are glass or plastic wave guides for transmitting visible or infrared signals. Since plastic fibres have high attenuation and are used only in limited applications, they will not be considered here. Glass fibres are frequently thinner than human hair and are generally used with LEDs or semiconductor lasers that emit in the infrared region. For wavelengths near 0.8 to 0.9 μm, gallium arsenide-aluminum gallium arsenide (GaAs-$Al_xGa_{1-x}As$) sources are used, and for those of 1.3 and 1.55 μm, indium phosphide-gallium indium arsenide phosphide (InP-$Ga_xIn_{1-x}As_yP_{1-y}$) sources are employed. As noted earlier, optical fibres consist of a glass core region that is surrounded by glass cladding. The core region has a larger refractive index than the cladding so that the light is confined to that region as it propagates along the fibre.

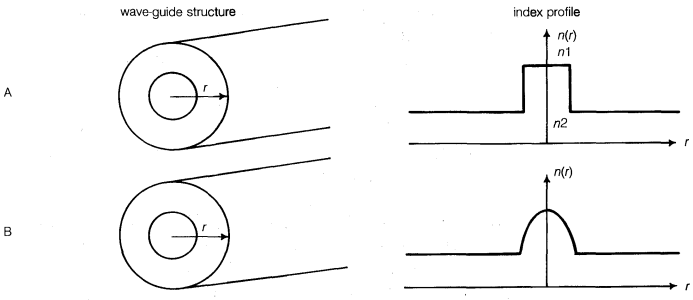

Figure 47: *Optical-fibre wave-guide structures and refractive index profiles.*
(A) Step-index fibre. (B) Graded-index fibre.

Fibre core diameters range between 1 and 100 μm, while cladding diameters are between 100 and 300 μm.

Fibres with a larger core diameter are called multimode fibres, because more than one electromagnetic-field configuration can propagate through such a fibre. A single-mode fibre has a small core diameter, and the difference in refractive index between the core and cladding is smaller than for the multimode fibre. Only one electromagnetic-field configuration propagates through a single-mode fibre. Fibres of this variety have the lowest losses and are the most widely used because they permit longer transmission distances. They have a constant refractive index in the core with a diameter between 1 and 10 μm. The index in the cladding layer decreases by approximately 0.1 to 0.3 percent. This type of fibre is called a step-index fibre and is illustrated in Figure 47A.

Single-mode optical fibres

The multimode fibres may be step-index fibres with diameters between 40 and 100 μm. The refractive index step between the core and cladding is approximately 0.8 to 3 percent. In a graded-index fibre, the core refractive index varies as a function of radial distance, as shown in Figure 47B. In such a fibre, a ray in the centre of the core travels more slowly than one near the edge, because the speed of propagation v is related to refractive index n as $v = c/n$, where c is the speed of light. The ray near the edge has a longer zigzag path than the ray in the centre. The transit times of the rays are thus equalized.

Both single-mode and multimode fibres are made of silica glass. The refractive indexes of the silica are varied with dopants such as germanium dioxide (GeO_2), phosphoric oxide (P_2O_5), and boric oxide (B_2O_3). Vapour-phase growth reactions are used to obtain the "preform" rod, which is then drawn into optical fibres. For example, a GeO_2-SiO_2 film may be deposited inside a silica tube, as shown in Figure 48. In this case, the GeO_2 increases the core refractive index. In another method, preforms for low-loss, single-mode fibres are made by first depositing a low-index borosilicate layer on the inner surface of the silica tube and then depositing a silica layer or inserting a pure fused silica rod before collapsing the preform. The preform is subsequently drawn into the optical fibre and covered with a protective polymer coating.

There are a number of factors that contribute to attenuation in an optical fibre. Rayleigh scattering is caused by microscopic variations in the refractive index of a fibre and is proportional to λ^4. This loss is the limiting loss shown by the dashed line in Figure 49 for fibre loss. Absorption by hydroxyl (OH) ions increases the absorption as shown and gives the minima in loss at 1.3 and 1.55 μm. At

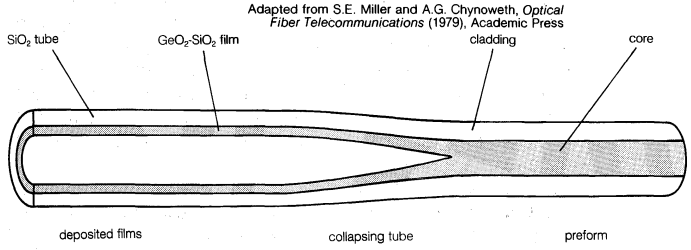

Figure 48: Preparation of the preform rod by vapour deposition. The high-index core is deposited inside the silica tube and becomes the fibre core when the tube collapses.

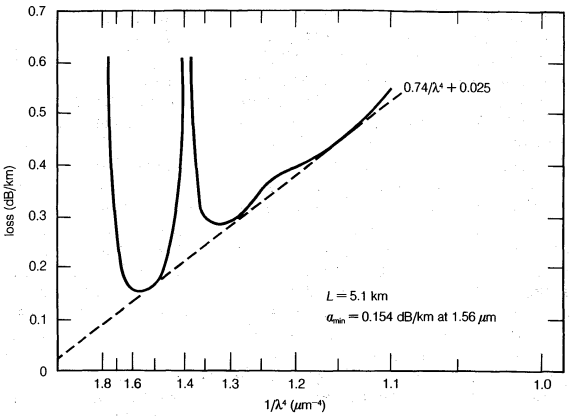

Figure 49: Low-loss, single-mode fibre attenuation plotted as a function of λ^4 (see text).

longer wavelengths, absorption by the atomic vibrations in the silicon-oxygen atoms rapidly increases the loss. Single-mode fibres commercially available for communications systems have losses as low as 0.2 decibel per kilometre. The low fibre loss permits increased repeater spacing and lower system cost. High-bit-rate digital systems without repeaters have been demonstrated for fibre lengths of more than 100 kilometres.

Fibre splicing techniques have been developed so that repairs can be made in the field with losses of only 0.1 to 0.3 decibel. A variety of optical connectors are used, providing both ease of use and low loss of only a few tenths of a decibel. Fibres are combined into many different kinds of cables, which can be laid both in the ground and under the sea.

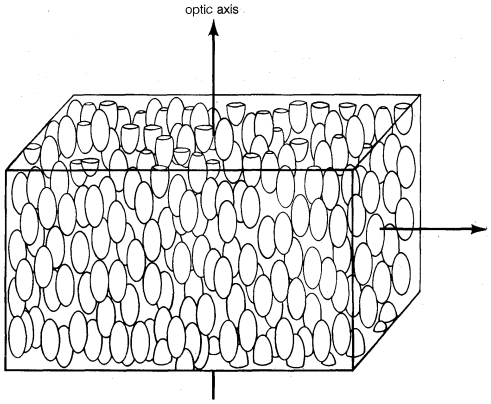

Figure 50: Molecular order in a nematic liquid crystal.

Liquid-crystal displays. Such visual display devices are commonly used as displays for digital wristwatches and pocket calculators, as indicators in automatic cameras, and as flat-panel display screens for portable lap-top computers and pocket televisions. Very little power is required to operate a liquid-crystal display (LCD) because it modifies ambient light instead of generating light. For this reason, it is the only type of electronic display that can operate for more than a year on a small battery.

Liquid crystals have both the fluidity characteristic of liquids and the collective orientation of crystals associated with solids. Their viscosity is similar to that of light machine oil. A widely used variety, the nematic liquid crystal, is composed of elongated organic molecules that align in a preferred direction called the director. This molecular order is shown in Figure 50. The nematic liquids are cloudy, white liquids, but in thin layers they are transparent because incident light will simply pass through them.

Nematic liquid crystals

For use in displays, liquid crystals must be aligned in a particular manner. To align the liquid crystals by a glass surface, an alignment layer is obtained by coating a thin polyimide film on the glass and unidirectionally rubbing the surface with a nylon brush at a precisely controlled pressure and speed. The construction of a liquid-crystal display is shown in Figure 51. The liquid crystal is sandwiched between two glass substrates that have transparent electrode strips. The transparent electrodes are made of indium-tin oxide. Spacer particles keep the plates separated uniformly.

Operation of an LCD is illustrated in Figure 52. In the field-off state (left), no voltage is applied to the electrodes. The glass surfaces at the top and bottom have been rubbed at right angles to each other. Because the liquid crystals align parallel to the rubbing direction at the glass surfaces, the crystals undergo a continuous 90° twist in between the two surfaces. This type of display is known as a twisted nematic display. Polarizing sheets are laminated on the outside of the glass parallel to the rubbing direction. The back glass also has a reflecting mirror surface. The linear

Twisted nematic display

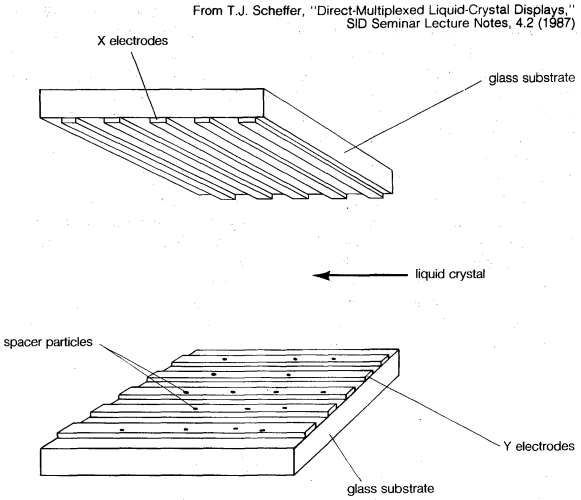

Figure 51: Construction of a liquid-crystal display.

polarized light through the upper polarizer follows the twist in the liquid crystal and passes through the polarizer at the bottom. This light is reflected by the mirror and reverses its path and emerges at the top surface. Because the light has been reflected, the area appears bright. If a small voltage is applied, the resulting electric field causes the molecules to align with the field, as shown at the right of the Figure. Now the polarized light is not rotated by the liquid crystal, and it is absorbed by the polarizer at the bottom. This area will appear dark.

The desired pattern for the display is obtained by an electrode pattern applied to the glass substrates. In a picture display, each picture element, or pixel, must be addressed.

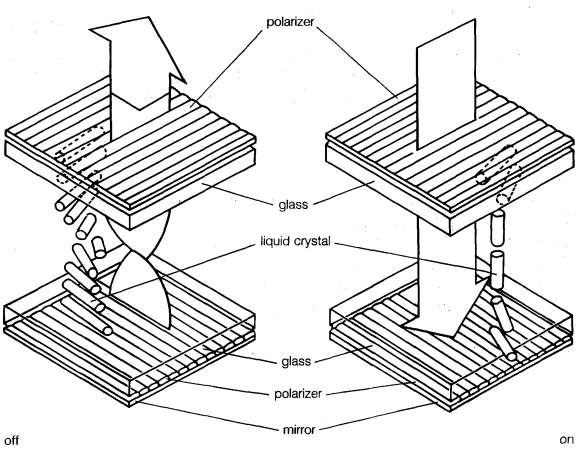

Figure 52: *Operation of a twisted nematic liquid-crystal display.* (Left) The "off" state rotates the polarized light so that it is reflected to give off a bright appearance. (Right) The "on" state with an applied voltage causes the molecules to align with the electric field, and the polarized light is not rotated and is absorbed in the bottom polarizer to give a dark appearance.

An array of 640 × 400 pixels may be involved. Multiplexing schemes are used so that 640 + 400 electrical contacts are required rather than 640 × 400 = 256,000 contacts. Advanced integrated-circuit technology has made it possible to deposit silicon directly on the glass and produce very inexpensive circuitry to drive the display. (H.C.C.)

Elizabeth I of England

Elizabeth I was queen of England from 1558 to 1603. Though her small kingdom was threatened by grave internal divisions, Elizabeth's blend of shrewdness, courage, and majestic self-display inspired ardent expressions of loyalty and helped unify the nation against foreign enemies. The adulation bestowed upon her both in her lifetime and in the ensuing centuries was not altogether a spontaneous effusion; it was the result of a carefully crafted, brilliantly executed campaign in which the queen fashioned herself as the glittering symbol of the nation's destiny. This political symbolism, common to monarchies, had more substance than usual, for the queen was by no means a mere figurehead. While she did not wield the absolute power of which Renaissance rulers dreamed, she tenaciously upheld her authority to make critical decisions and to set the central policies of both state and church. The latter half of the 16th century in England is justly called the Elizabethan era: rarely has the collective life of a whole age been given so distinctively personal a stamp.

From the Woburn Abbey Collection, by kind permission of His Grace, the Duke of Bedford

Elizabeth I, the Armada portrait by Gower (d. 1596). In Woburn Abbey, Bedfordshire.

Childhood. Elizabeth's early years were not auspicious. She was born at Greenwich Palace on Sept. 7, 1533, the daughter of the Tudor king Henry VIII and his second wife, Anne Boleyn. Henry had defied the pope and broken England from the authority of the Roman Catholic church in order to dissolve his marriage with his first wife, Catherine of Aragon, who had borne him a daughter, Mary. Since the king ardently hoped that Anne Boleyn would give birth to the male heir regarded as the key to stable dynastic succession, the birth of a second daughter was a bitter disappointment that dangerously weakened the new queen's position. Before Elizabeth reached her third birthday, her father had her mother beheaded on charges of adultery and treason. Moreover, at Henry's instigation, an act of Parliament declared his marriage with Anne Boleyn invalid from the beginning, thus making their daughter Elizabeth illegitimate, as Roman Catholics had all along claimed her to be. (Apparently the king was undeterred by the logical inconsistency of simultaneously invalidating the marriage and accusing his wife of adultery.) The emotional impact of these events on the little girl, who had been brought up from infancy in a separate household at Hatfield, is not known; presumably no one thought it worth recording. What was noted was her precocious seriousness; at six years old, it was admiringly observed, she had as much gravity as if she had been 40.

Loss of mother

When in 1537 Henry's third wife, Jane Seymour, gave birth to a son, Edward, Elizabeth receded still further into relative obscurity, but she was not neglected. Despite his capacity for monstrous cruelty, Henry VIII treated all his children with what contemporaries regarded as affection; Elizabeth was present at ceremonial occasions and was declared third in line to the throne. She spent much of the time with her half brother Edward and, from her 10th year onward, profited from the loving attention of her stepmother, Catherine Parr, the king's sixth and last wife. Under a series of distinguished tutors, of whom the best known is the Cambridge humanist Roger Ascham, Elizabeth received the rigorous education normally reserved for male heirs, consisting of a course of studies centring on classical languages, history, rhetoric, and moral philosophy. "Her mind has no womanly weakness," Ascham wrote with the unselfconscious sexism of the age, "her perseverance is equal to that of a man, and her memory long keeps what it quickly picks up." In addition to Greek and Latin, she became fluent in French and Italian, attainments of which she was proud and which were in later years to serve her well in the conduct of diplomacy. Thus steeped in the secular learning of the Renaissance, the quick-witted and intellectually serious princess also studied theology, imbibing the tenets of English Protestantism in its formative period. Her association with the Reformation is critically important, for it shaped the future course of the nation, but it does not appear to have been a personal passion: observers noted the young princess's fascination more with languages than with religious dogma.

Education

Position under Edward VI and Mary. With her father's death in 1547 and the accession to the throne of her frail 10-year-old brother Edward, Elizabeth's life took a perilous turn. Her guardian, the dowager queen Catherine Parr, almost immediately married Thomas Seymour, the lord high admiral. Handsome, ambitious, and discontented, Seymour began to scheme against his powerful older brother, Edward Seymour, protector of the realm during Edward VI's minority. In January 1549, shortly after the death of Catherine Parr, Thomas Seymour was arrested for treason and accused of plotting to marry Elizabeth in order to rule the kingdom. Repeated interrogations of Elizabeth and her servants led to the charge that even when his wife was alive Seymour had on several occasions behaved in a flirtatious and overly familiar manner toward the young princess. Under humiliating close questioning and in some danger, Elizabeth was extraordinarily circumspect and poised. When she was told that Seymour had been beheaded, she betrayed no emotion.

The need for circumspection, self-control, and political acumen became even greater after the death of the Protestant Edward in 1553 and the accession of Elizabeth's older half sister Mary, a religious zealot set on returning England, by force if necessary, to the Roman Catholic faith. This attempt, along with her unpopular marriage to the ardently Catholic king Philip II of Spain, aroused bitter Protestant opposition. In a charged atmosphere of treasonous rebellion and inquisitorial repression, Elizabeth's life was in grave danger. For though, as her sister demanded, she conformed outwardly to official Catholic observance, she inevitably became the focus and the obvious beneficiary of plots to overthrow the government and restore Protestantism. Arrested and sent to the Tower of London after Sir Thomas Wyatt's rebellion in January 1554, Elizabeth narrowly escaped her mother's fate. Two months later, after extensive interrogation and spying had revealed no conclusive evidence of treason on her part, she was released from the Tower and placed in close custody for a year at Woodstock. The difficulty of her situation eased somewhat, though she was never far from suspicious scrutiny. Throughout the unhappy years of Mary's childless reign, with its burning of Protestants and its military disasters, Elizabeth had continually to protest her innocence, affirm her unwavering loyalty, and proclaim

Sent to the Tower

her pious abhorrence of heresy. It was a sustained lesson in survival through self-discipline and the tactful manipulation of appearances.

Many Protestants and Roman Catholics alike assumed that her self-presentation was deceptive, but Elizabeth managed to keep her inward convictions to herself, and in religion as in much else they have remained something of a mystery. There is with Elizabeth a continual gap between a dazzling surface and an interior that she kept carefully concealed. Observers were repeatedly tantalized with what they thought was a glimpse of the interior, only to find that they had been shown another facet of the surface. Everything in Elizabeth's early life taught her to pay careful attention to how she represented herself and how she was represented by others. She learned her lesson well.

Accession. At the death of Mary on Nov. 17, 1558, Elizabeth came to the throne amid bells, bonfires, patriotic demonstrations, and other signs of public jubilation. Her entry into London and the great coronation procession that followed were masterpieces of political courtship. "If ever any person," wrote one enthusiastic observer, "had either the gift or the style to win the hearts of people, it was this Queen, and if ever she did express the same it was at that present, in coupling mildness with majesty as she did, and in stately stooping to the meanest sort." Elizabeth's smallest gestures were scrutinized for signs of the policies and tone of the new regime: When an old man in the crowd turned his back on the new queen and wept, Elizabeth exclaimed confidently that he did so out of gladness; when a girl in an allegorical pageant presented her with a Bible in English translation—banned under Mary's reign—Elizabeth kissed the book, held it up reverently, and then laid it on her breast; and when the abbot and monks of Westminster Abbey came to greet her in broad daylight with candles in their hands, she briskly dismissed them with the words "Away with those torches! we can see well enough." Spectators were thus assured that under Elizabeth England had returned, cautiously but decisively, to the Reformation.

The first weeks of her reign were not entirely given over to symbolic gestures and public ceremonial. The queen began at once to form her government and issue proclamations. She reduced the size of the Privy Council, in part to purge some of its Catholic members and in part to make it more efficient as an advisory body; she began a restructuring of the enormous royal household; she carefully balanced the need for substantial administrative and judicial continuity with the desire for change; and she assembled a core of experienced and trustworthy advisers, including William Cecil, Nicholas Bacon, Francis Walsingham, and Nicholas Throckmorton. Chief among these was Cecil (afterward Lord Burghley), whom Elizabeth appointed her principal secretary of state on the morning of her accession and who was to serve her (first in this capacity and after 1571 as lord treasurer) with remarkable sagacity and skill for 40 years.

The woman ruler in a patriarchal world. In the last year of Mary's reign, the Scottish Calvinist preacher John Knox wrote in his *The First Blast of the Trumpet Against the Monstruous Regiment of Women* that "God hath revealed to some in this our age that it is more than a monster in nature that a woman should reign and bear empire above man." With the accession of the Protestant Elizabeth, Knox's trumpet was quickly muted, but there remained a widespread conviction, reinforced by both custom and teaching, that, while men were naturally endowed with authority, women were temperamentally, intellectually, and morally unfit to govern. Men saw themselves as rational beings; they saw women as creatures likely to be dominated by impulse and passion. Gentlemen were trained in eloquence and the arts of war; gentlewomen were urged to keep silent and attend to their needlework. In men of the upper classes a will to dominate was admired or at least assumed; in women it was viewed as dangerous or grotesque.

A woman on the throne

Apologists for the queen countered that there had always been significant exceptions, such as the biblical Deborah, the prophetess who had judged Israel. Crown lawyers, moreover, elaborated a mystical legal theory known as "the king's two bodies." When she ascended the throne, according to this theory, the queen's whole being was profoundly altered: her mortal "body natural" was wedded to an immortal "body politic." "I am but one body, naturally considered," Elizabeth declared in her accession speech, "though by [God's] permission a Body Politic to govern." Her body of flesh was subject to the imperfections of all human beings (including those specific to womankind), but the body politic was timeless and perfect. Hence in theory the queen's gender was no threat to the stability and glory of the nation.

Elizabeth made it immediately clear that she intended to rule in more than name only and that she would not subordinate her judgment to that of any one individual or faction. Since her sister's reign did not provide a satisfactory model for female authority, Elizabeth had to improvise a new model, one that would overcome the considerable cultural liability of her sex. Moreover, quite apart from this liability, any English ruler's power to compel obedience had its limits. The monarch was at the pinnacle of the state, but that state was relatively impoverished and weak, without a standing army, an efficient police force, or a highly developed, effective bureaucracy. To obtain sufficient revenue to govern, the crown had to request subsidies and taxes from a potentially fractious and recalcitrant Parliament. Under these difficult circumstances, Elizabeth developed a strategy of rule that blended imperious command with an extravagant, histrionic cult of love.

The Virgin Queen

The cult of Elizabeth as the Virgin Queen wedded to her kingdom was a gradual creation that unfolded over many years, but its roots may be glimpsed at least as early as 1555. At that time, according to a report that reached the French court, Queen Mary had proposed to marry her sister to the staunchly Catholic duke of Savoy; the usually cautious and impassive Elizabeth burst into tears, declaring that she had no wish for any husband. Other matches were proposed and summarily rejected. But in this vulnerable period of her life there were obvious reasons for Elizabeth to bide her time and keep her options open. No one—not even the princess herself—need have taken very seriously her professed desire to remain single. When she became queen, speculation about a suitable match immediately intensified, and the available options became a matter of grave national concern. Beyond the general conviction that the proper role for a woman was that of a wife, the dynastic and diplomatic stakes in the projected royal marriage were extremely high. If Elizabeth died childless, the Tudor line would come to an end. The nearest heir was Mary, Queen of Scots, the granddaughter of Henry VIII's sister Margaret. Mary, a Catholic whose claim was supported by France and other powerful Catholic states, was regarded by Protestants as a nightmarish threat that could best be averted if Elizabeth produced a Protestant heir.

The queen's marriage was critical not only for the question of succession but also for the tangled web of international diplomacy. England, isolated and militarily weak, was sorely in need of the major alliances that an advantageous marriage could forge. Important suitors eagerly came forward: Philip II of Spain, who hoped to renew the link between Catholic Spain and England; Archduke Charles of Austria; Erik XIV, king of Sweden; Henry, Duke d'Anjou and later king of France; François, Duke d' Alençon; and others. Many scholars think it unlikely that Elizabeth ever seriously intended to marry any of these aspirants to her hand, for the dangers always outweighed the possible benefits, but she skillfully played one off against another and kept the marriage negotiations going for months, even years, at one moment seeming on the brink of acceptance, at the next veering away toward vows of perpetual virginity. "She is a Princess," the French ambassador remarked, "who can act any part she pleases."

English suitors

Elizabeth was courted by English suitors as well, most assiduously by her principal favourite, Robert Dudley, Earl of Leicester. As master of the horse and a member of the Privy Council, Leicester was constantly in attendance on the queen, who displayed toward him all the signs of an ardent romantic attachment. When in September 1560 Leicester's wife, Amy Robsart, died in a suspicious fall, the favourite seemed poised to marry his royal mis-

tress—so at least widespread rumours had it—but, though the queen's behaviour toward him continued to generate scandalous gossip, the decisive step was never taken. Elizabeth's resistance to a marriage she herself seemed to desire may have been politically motivated, for Leicester had many enemies at court and an unsavory reputation in the country at large. But in October 1562 the queen nearly died of smallpox, and, faced with the real possibility of a contested succession and a civil war, even rival factions were likely to have countenanced the marriage.

Probably at the core of Elizabeth's decision to remain single was an unwillingness to compromise her power. Sir Robert Naunton recorded that the queen once said angrily to Leicester, when he tried to insist upon a favour, "I will have here but one mistress and no master." To her ministers she was steadfastly loyal, encouraging their frank counsel and weighing their advice, but she did not cede ultimate authority even to the most trusted. Though she patiently received petitions and listened to anxious advice, she zealously retained her power to make the final decision in all crucial affairs of state. Unsolicited advice could at times be dangerous: when in 1579 a pamphlet was published vehemently denouncing the queen's proposed marriage to the Catholic Duke d'Alençon, its author John Stubbs and his publisher William Page were arrested and had their right hands chopped off.

Elizabeth's performances—her displays of infatuation, her apparent inclination to marry the suitor of the moment—often convinced even close advisers, so that the level of intrigue and anxiety, always high in royal courts, often rose to a feverish pitch. Far from trying to allay the anxiety, the queen seemed to augment and use it, for she was skilled at manipulating factions. This skill extended beyond marriage negotiations and became one of the hallmarks of her regime. A powerful nobleman would be led to believe that he possessed unique influence over the queen, only to discover that a hated rival had been led to a comparable belief. A golden shower of royal favour—apparent intimacies, public honours, the bestowal of such valuable perquisites as land grants and monopolies—would give way to royal aloofness or, still worse, to royal anger. The queen's anger was particularly aroused by challenges to what she regarded as her prerogative (whose scope she cannily left undefined) and indeed by any unwelcome signs of independence. The courtly atmosphere of vivacity, wit, and romance would then suddenly chill, and the queen's behaviour, as her godson Sir John Harington put it, "left no doubtings whose daughter she was." This identification of Elizabeth with her father, and particularly with his capacity for wrath, is something that the queen herself—who never made mention of her mother—periodically invoked.

Relations with Parliament

A similar blend of charm and imperiousness characterized the queen's relations with Parliament, on which she had to depend for revenue. Many sessions of Parliament, particularly in the early years of her rule, were more than cooperative with the queen; they had the rhetorical air of celebrations. But under the strain of the marriage-and-succession question, the celebratory tone, which masked serious policy differences, began over the years to wear thin, and the sessions involved complicated, often acrimonious negotiations between crown and commons. More radical members of Parliament wanted to include in debate broad areas of public policy; the queen's spokesmen struggled to restrict free discussion to government bills. Elizabeth had a rare gift for combining calculated displays of intransigence with equally calculated displays of graciousness and, on rare occasions, a prudent willingness to concede. Whenever possible, she transformed the language of politics into the language of love, likening herself to the spouse or the mother of her kingdom. Characteristic of this rhetorical strategy was her famous "Golden Speech" of 1601, when, in the face of bitter parliamentary opposition to royal monopolies, she promised reforms:

> I do assure you, there is no prince that loveth his subjects better, or whose love can countervail our love. There is no jewel, be it of never so rich a price, which I set before this jewel; I mean, your love: for I do more esteem of it, than of any treasure or riches.

A discourse of rights or interests thus became a discourse of mutual gratitude, obligation, and love. "We all loved her," Harington wrote with just a trace of irony, "for she said she loved us." In her dealings with parliamentary delegations, as with suitors and courtiers, the queen contrived to turn her gender from a serious liability into a distinct advantage.

Religious questions and the fate of Mary, Queen of Scots. Elizabeth restored England to Protestantism. The Act of Supremacy, passed by Parliament and approved in 1559, revived the antipapal statutes of Henry VIII and declared the queen supreme governor of the church, while the Act of Uniformity established a slightly revised version of the second Edwardian prayer book as the official order of worship. Elizabeth's government moved cautiously but steadily to transfer these structural and liturgical reforms from the statute books to the local parishes throughout the kingdom. Priests, temporal officers, and men proceeding to university degrees were required to swear an oath to the royal supremacy or lose their positions; absence from Sunday church service was punishable by a fine; royal commissioners sought to ensure doctrinal and liturgical conformity. Many of the nobles and gentry, along with a majority of the common people, remained loyal to the old faith, but all the key positions in the government and church were held by Protestants who employed patronage, pressure, and propaganda, as well as threats, to secure an outward observance of the religious settlement.

Militant Protestants

But to militant Protestants, including exiles from the reign of Queen Mary newly returned to England from Calvinist Geneva and other centres of continental reform, these measures seemed hopelessly pusillanimous and inadequate. They pressed for a drastic reform of the church hierarchy and church courts, a purging of residual Catholic elements in the prayer book and ritual, and a vigorous searching out and persecution of recusants. Each of these demands was repugnant to the queen. She felt that the reforms had gone far enough and that any further agitation would provoke public disorder, a dangerous itch for novelty, and an erosion of loyalty to established authority. Elizabeth, moreover, had no interest in probing the inward convictions of her subjects; provided that she could obtain public uniformity and obedience, she was willing to let the private beliefs of the heart remain hidden. This policy was consistent with her own survival strategy, her deep conservatism, and her personal dislike of evangelical fervour. When in 1576 the archbishop of Canterbury, Edmund Grindal, refused the queen's orders to suppress certain reformist educational exercises, called "propheseyings," Grindal was suspended from his functions and never restored to them. Upon Grindal's death, Elizabeth appointed a successor, Archbishop Whitgift, who vigorously pursued her policy of an authoritarian ecclesiastical regime and a relentless hostility to Puritan reformers.

The Catholic opposition

If Elizabeth's religious settlement was threatened by Protestant dissidents, it was equally threatened by the recalcitrance and opposition of English Catholics. At first this opposition seemed relatively passive, but a series of crises in the late 1560s and early '70s disclosed its potential for serious, even fatal, menace. In 1569 a rebellion of feudal aristocrats and their followers in the staunchly Catholic north of England was put down by savage military force; while in 1571 the queen's informers and spies uncovered an international conspiracy against her life, known as the Ridolfi Plot. Both threats were linked at least indirectly to Mary, Queen of Scots, who had been driven from her own kingdom in 1568 and had taken refuge in England. The presence, more prisoner than guest, of the woman whom the Roman Catholic church regarded as the rightful queen of England posed a serious political and diplomatic problem for Elizabeth, a problem greatly exacerbated by Mary's restless ambition and penchant for conspiracy. Elizabeth judged that it was too dangerous to let Mary leave the country, but at the same time she firmly rejected the advice of Parliament and many of her councillors that Mary should be executed. So a captive, at once ominous, malevolent, and pathetic, Mary remained.

The alarming increase in religious tension, political intrigue, and violence was not only an internal, English

concern. In 1570 Pope Pius V excommunicated Elizabeth and absolved her subjects from any oath of allegiance that they might have taken to her. The immediate effect was to make life more difficult for English Catholics, who were the objects of a suspicion that greatly intensified in 1572 after word reached England of the St. Bartholomew's Day massacre of Protestants (Huguenots) in France. Tension and official persecution of recusants increased in the wake of the daring clandestine missionary activities of English Jesuits, trained on the Continent and smuggled back to England. Elizabeth was under great pressure to become more involved in the continental struggle between Roman Catholics and Protestants, in particular to aid the rebels fighting the Spanish armies in the Netherlands. But she was very reluctant to become involved, in part because she detested rebellion, even rebellion undertaken in the name of Protestantism, and in part because she detested expenditures. Eventually, after vacillations that drove her councillors to despair, she agreed first to provide some limited funds and then, in 1585, to send a small expeditionary force to the Netherlands.

Fears of an assassination attempt against Elizabeth increased after Pope Gregory XIII proclaimed in 1580 that it would be no sin to rid the world of such a miserable heretic. In 1584 Europe's other major Protestant leader, William of Orange, was assassinated. Elizabeth herself showed few signs of concern—throughout her life she was a person of remarkable personal courage—but the anxiety of the ruling elite was intense. In an ugly atmosphere of intrigue, torture and execution of Jesuits, and rumours of foreign plots to kill the queen and invade England, Elizabeth's Privy Council drew up a Bond of Association, pledging its signers, in the event of an attempt on Elizabeth's life, to kill not only the assassins but also the claimant to the throne in whose interest the attempt had been made. The Association was clearly aimed at Mary, whom government spies, under the direction of Sir Francis Walsingham, had by this time discovered to be thoroughly implicated in plots against the queen's life. When Walsingham's men in 1586 uncovered the Babington Plot, another conspiracy to murder Elizabeth, the wretched Queen of Scots, her secret correspondence intercepted and her involvement clearly proved, was doomed. Mary was tried and sentenced to death. Parliament petitioned that the sentence be carried out without delay. For three months the queen hesitated and then with every sign of extreme reluctance signed the death warrant. When the news was brought to her that on Feb. 8, 1587, Mary had been beheaded, Elizabeth responded with an impressive show of grief and rage. She had not, she wrote to Mary's son, James VI of Scotland, ever intended that the execution actually take place, and she imprisoned the man who had delivered the signed warrant. It is impossible to know how many people believed Elizabeth's professions of grief; Catholics on the Continent wrote bitter denunciations of the queen, while Protestants throughout the kingdom enthusiastically celebrated the death of a woman they had feared and hated.

The Babington Plot

For years Elizabeth had cannily played a complex diplomatic game with the rival interests of France and Spain, a game comparable to her domestic manipulation of rival factions. State-sanctioned privateering raids, led by Sir Francis Drake and others, on Spanish shipping and ports alternated with conciliatory gestures and peace talks. But by the mid-1580s it became increasingly clear that England could not avoid a direct military confrontation with Spain. Word reached London that the Spanish king, Philip II, had begun to assemble an enormous fleet that would sail to the Netherlands, join forces with a waiting Spanish army led by the duke of Parma, and then proceed to an invasion and conquest of Protestant England. Always reluctant to spend money, the queen had nonetheless authorized sufficient funds during her reign to maintain a fleet of maneuverable, well-armed fighting ships, to which could be added other vessels from the merchant fleet. When in July 1588 the Invincible Armada reached English waters, the queen's ships, in one of the most famous naval encounters of history, defeated the enemy fleet, which then in an attempt to return to Spain was all but destroyed by terrible storms.

The Invincible Armada

At the moment when the Spanish invasion was imminently expected, Elizabeth resolved to review in person a detachment of soldiers assembled at Tilbury. Dressed in a white gown and a silver breastplate, she rode through the camp and proceeded to deliver a celebrated speech. Some of her councillors, she said, had cautioned her against appearing before a large, armed crowd, but she did not and would not distrust her faithful and loving people. Nor was she afraid of Parma's army: "I know I have the body of a weak and feeble woman," Elizabeth declared, "but I have the heart and stomach of a king, and of a king of England too." She then promised, "in the word of a Prince," richly to reward her loyal troops, a promise that she characteristically proved reluctant to keep. The scene exemplifies many of the queen's qualities: her courage, her histrionic command of grand public occasions, her rhetorical blending of magniloquence and the language of love, her strategic identification with martial virtues considered male, and even her princely parsimony.

The queen's image. Elizabeth's parsimony did not extend to personal adornments. She possessed a vast repertory of fantastically elaborate dresses and rich jewels. Her passion for dress was bound up with political calculation and an acute self-consciousness about her image. She tried to control the royal portraits that circulated widely in England and abroad, and her appearances in public were dazzling displays of wealth and magnificence. Throughout her reign she moved restlessly from one of her palaces to another—Whitehall, Nonsuch, Greenwich, Windsor, Richmond, Hampton Court, and Oatlands—and availed herself of the hospitality of her wealthy subjects. On her journeys, known as royal progresses, she wooed her people and was received with lavish entertainments. Artists, including poets like Edmund Spenser and painters like Nicholas Hilliard, celebrated her in a variety of mythological guises—as Diana, the chaste goddess of the moon; Astraea, the goddess of justice; Gloriana, the queen of the fairies—and Elizabeth, in addition to adopting these fanciful roles, appropriated to herself some of the veneration that pious Englishmen had directed to the Virgin Mary.

"She imagined," wrote Francis Bacon a few years after the queen's death, "that the people, who are much influenced by externals, would be diverted by the glitter of her jewels, from noticing the decay of her personal attractions." Bacon's cynicism reflects the darkening tone of the last decade of Elizabeth's reign, when her control over her country's political, religious, and economic forces and over her representation of herself began to show severe strains. Bad harvests, persistent inflation, and unemployment caused hardship and a loss of public morale. Charges of corruption and greed led to widespread popular hatred of many of the queen's favourites to whom she had given lucrative and much-resented monopolies. A series of disastrous military attempts to subjugate the Irish culminated in a crisis of authority with her last great favourite, Robert Devereux, the proud Earl of Essex, who had undertaken to defeat rebel forces led by Hugh O'Neill, Earl of Tyrone. Essex returned from Ireland against the queen's orders, insulted her in her presence, and then made a desperate, foolhardy attempt to raise an insurrection. He was tried for treason and executed on Feb. 25, 1601.

The last decade

Elizabeth continued to make brilliant speeches, to exercise her authority, and to receive the extravagant compliments of her admirers, but she was, as Sir Walter Raleigh remarked, "a lady surprised by time," and her long reign was drawing to a close. She suffered from bouts of melancholy and ill health and showed signs of increasing debility. Her more astute advisers—among them Lord Burghley's son, Sir Robert Cecil, who had succeeded his father as her principal counselor—secretly entered into correspondence with the likeliest claimant to the throne, James VI of Scotland. On March 24, 1603, having reportedly indicated James as her successor, Elizabeth died quietly. The nation enthusiastically welcomed its new king. But in a very few years the English began to express nostalgia for the rule of "Good Queen Bess." Long before her death she had transformed herself into a powerful image of female authority, regal magnificence, and national pride, and that image has endured to the present.

BIBLIOGRAPHY

Writings by Elizabeth: Some of Elizabeth's private letters appear in *The Letters of Queen Elizabeth,* ed. by G.B. HARRISON (1935, reprinted 1981); others are included in *The Girlhood of Queen Elizabeth: A Narrative in Contemporary Letters,* ed. by FRANK A. MUMBY (1909). Both of these volumes, however, include letters whose authenticity is doubtful. Elizabeth's translations of classical verse by Boethius, Plutarch, and Horace are published in *Queen Elizabeth's Englishings . . . ,* ed. by CAROLINE PEMBERTON (1899, reprinted 1975); and her poetry appears in *The Poems of Queen Elizabeth I,* ed. by LEICESTER BRADNER (1964). A brief sampling of her speeches may be found in *The Public Speaking of Queen Elizabeth: Selections from the Official Addresses,* ed. by GEORGE P. RICE, JR. (1951, reissued 1966); a more complete selection is available in J.E. NEALE, *Elizabeth I and Her Parliaments,* 2 vol. (1953–57, reissued 1966), which reprints complete transcripts of the queen's known addresses to Parliament. The speeches she made while on royal progresses are included in JOHN NICHOLS, *The Progresses and Public Processions of Queen Elizabeth,* new ed., 3 vol. (1823, reprinted 1966).

Biographies: The standard biography of Elizabeth remains J.E. NEALE, *Queen Elizabeth* (1934, reissued as *Queen Elizabeth I,* 1971). It should be supplemented by other scholarly biographies; among the most useful are J.B. BLACK, *The Reign of Elizabeth, 1558–1603,* 2nd ed. (1959); NEVILLE WILLIAMS, *Elizabeth, Queen of England* (1967; U.S. title, *Elizabeth the First, Queen of England,* 1968), which stresses the formation under Elizabeth of an English national consciousness; and PAUL JOHNSON, *Elizabeth I: A Biography* (U.K. title, *Elizabeth I: A Study in Power and Intellect,* 1974). JASPER RIDLEY, *Elizabeth I* (1987; U.S. title, *Elizabeth I: The Shrewdness of Virtue,* 1988), emphasizes the role of religion in the queen's domestic and foreign policy. Popular biographies of Elizabeth, even when well researched, tend to be highly speculative about Elizabeth's emotions and motivations. Among the more recent biographies are ELIZABETH JENKINS, *Elizabeth the Great* (1958, reissued 1972); LACEY BALDWIN SMITH, *Elizabeth Tudor: Portrait of a Queen* (1975); CAROLLY ERICKSON, *The First Elizabeth* (1983); and ALISON PLOWDEN, *The Young Elizabeth* (1971), and *Elizabeth Regina: The Age of Triumph, 1588–1603* (1980). Selections and extracts of contemporary accounts of Elizabeth may be found in JOSEPH M. LEVINE (ed.), *Elizabeth I* (1969); RICHARD L. GREAVES (ed.), *Elizabeth I, Queen of England* (1974); and LACEY BALDWIN SMITH (ed.), *Elizabeth I* (1980).

Elizabethan government and politics: For the controversy over women's right to rule a nation, see PAULA LOUISE SCALINGI, "The Scepter or the Distaff: The Question of Female Sovereignty, 1515–1607," *Historian,* 41(1):59–75 (1978). The doctrine of the king's two bodies is explained in ERNST H. KANTOROWICZ, *The King's Two Bodies: A Study in Mediaeval Political Theology* (1957, reissued 1987); and applied to the case of Elizabeth in MARIE AXTON, *The Queen's Two Bodies: Drama and the Elizabethan Succession* (1977). ALLISON HEISCH, "Queen Elizabeth I: Parliamentary Rhetoric and the Exercise of Power," *Signs,* 1(1):31–55 (Autumn 1975), analyzes the strategies and effects of Elizabeth's masterful parliamentary speeches.

The structure and practice of Tudor administration is analyzed in PENRY WILLIAMS, *The Tudor Regime* (1979, reissued 1981), which may be supplemented by CHRISTOPHER COLEMAN and DAVID STARKEY (eds.), *Revolution Reassessed: Revisions in the History of Tudor Government and Administration* (1986); and DAVID LOADES, *The Tudor Court* (1986). The operations of Elizabeth's government are treated in detail in WALLACE MACCAFFREY, *The Shaping of the Elizabethan Regime* (1968, reissued 1971), which addresses the early years of her reign, and *Queen Elizabeth and the Making of Policy, 1572–1588* (1981). JOEL HURSTFIELD, *Elizabeth I and the Unity of England* (1960, reissued 1971), deals with Elizabeth's largely successful efforts at creating national unity in the face of profound religious, social, and political changes. For the ways in which Elizabethan politics led to 17th-century revolution, see LAWRENCE STONE, *The Causes of the English Revolution, 1529–1642,* 2nd ed. (1986); and CHRISTOPHER HILL, *Intellectual Origins of the English Revolution* (1965, reprinted 1980).

Aspects of the succession question are addressed by MORTIMER LEVINE, *The Early Elizabethan Succession Question, 1558–1568* (1966); and by JOEL HURSTFIELD, "The Succession Struggle in Late Elizabethan England," in S.T. BINDOFF, JOEL HURSTFIELD, and C.H. WILLIAMS, *Elizabethan Government and Society* (1961), ch. 13, pp. 369–396. Elizabeth's religious policies are studied in WILLIAM P. HAUGAARD, *Elizabeth and the English Reformation: The Struggle for a Stable Settlement of Religion* (1968). The religious affiliations of her councillors are addressed in WINTHROP S. HUDSON, *The Cambridge Connection and the Elizabethan Settlement of 1559* (1980). For foreign policy, see R.B. WERNHAM, *The Making of Elizabethan Foreign Policy, 1558–1603* (1980); and GARRETT MATTINGLY, *Renaissance Diplomacy* (1955, reprinted 1988).

Useful overviews of Elizabethan government are given in ALAN G.R. SMITH, *The Government of Elizabethan England* (1967); S.T. BINDOFF, *Tudor England* (1950, reprinted 1979); and CHRISTOPHER HAIGH (ed.), *The Reign of Elizabeth I* (1984).

The image of Elizabeth: The iconography of the queen's image is examined in ROY STRONG, *Gloriana: The Portraits of Queen Elizabeth I,* rev. ed. (1987), and *The Cult of Elizabeth: Elizabethan Portraiture and Pageantry* (1977, reprinted 1986), which also treats the chivalric revival under Elizabeth. Elizabeth's image in literature is exhaustively treated in ELKIN CALHOUN WILSON, *England's Eliza* (1939, reissued 1966); and in FRANCES YATES, *Astraea: The Imperial Theme in the Sixteenth Century* (1975, reissued 1985). The relations between Elizabeth's image and literary representations of her are investigated in LOUIS ADRIAN MONTROSE, " 'Eliza, Queene of shepheardes,' and the Pastoral of Power," *English Literary Renaissance,* 10(2):153–182 (1980), and " 'Shaping Fantasies': Figurations of Gender and Power in Elizabethan Culture," *Representations,* 1(2):61–94 (Spring 1983). For the staging of the self in this period, see STEPHEN GREENBLATT, *Renaissance Self-Fashioning: From More to Shakespeare* (1980).

Bibliography: A comprehensive bibliography of works relating to Elizabeth and her times is the *Bibliography of British History: Tudor Period 1485–1603,* ed. by CONYERS READ, 2nd ed. (1959, reissued 1978). More recent bibliographies include MORTIMER LEVINE, *Tudor England 1485–1603* (1968); and G.R. ELTON, *Modern Historians on British History, 1485–1945: A Critical Bibliography, 1945–1969* (1970).

Human Emotion

An emotion, as it is commonly known, is a distinct feeling or quality of consciousness, such as joy or sadness, that reflects the personal significance of an emotion-arousing event. In modern times the subject of emotion has become part of the subject matter of several scientific disciplines—biology, psychology, psychiatry, anthropology, and sociology. Emotions are central to the issues of human survival and adaptation. They motivate the development of moral behaviour, which lies at the very root of civilization. Emotions influence empathic and altruistic behaviour, and they play a role in the creative processes of the mind. They affect the basic processes of perception and influence the way humans conceive and interpret the world around them. Evidence suggests that emotions shape many other aspects of human life and human affairs. Clinical psychologists and psychiatrists often describe problems of adjustment and types of psychopathology as "emotional problems," mental conditions that an estimated 1 in 3 Americans, for example, suffers from during his or her lifetime.

The subject of emotion is studied from a wide range of views. Behaviorally oriented neuroscientists study the neurophysiology and neuroanatomy of emotions and the relations between neural processes and the expression and experience of emotion. Social psychologists and cultural anthropologists study similarities and differences among cultures by the way emotions are expressed and conceptualized. Philosophers are interested in the role of emotions in rationality, thought, character development, and values. Novelists, playwrights, and poets are interested in emotions as the motivations and defining features of fictional characters and as vehicles for communicating the meaning and significance of events.

This article will consider the meaning of emotions; the use of emotion concepts in literature and philosophy; the activation, structure, and functions of emotions as conceived by psychologists and neuroscientists; and the causes and consequences of emotions as reflected in individual experience and social relationships.

For coverage of related topics in the *Macropædia* and *Micropædia,* see the *Propædia,* section 433.

The article is divided into the following parts:

Definitions and humanistic background

DEFINITIONS

Emotion has been defined as a particular psychological state of feeling, such as fear, anger, joy, and sorrow. The feeling often includes action tendencies and tends to trigger certain perceptual and cognitive processes. Most experts agree that emotion is a causal factor or influence in thoughts, actions, personalities, and social relationships.

The multilevel concept

The concept of emotion that will be developed here is a multiaspect, or multilevel, one, considering structure and functions at the levels of neurophysiology, emotion expression, and emotion experience (feeling). It should be noted, however, that not all of the numerous definitions that can be found in emotion literature fit into this multilevel concept. The definitions, which reflect differences in the interests and theoretical orientations of the authors, can be reduced to three categories concerned with structure and three concerned with functions. The three structural categories are the three levels, or aspects, that are included in the multilevel concept. The first of these categories of definition focuses on the neurophysiological processes underlying or accompanying emotions, the second on expression, or emotional behaviour, and the third on the subjective experience, or conscious aspect, of emotion.

Of the three categories of definition related to functions, the first defines emotions in terms of their adaptive or disruptive influences. The second category defines emotion in terms of motivation and considers it as part of the same class of phenomena that contains physiological drives, such as pain, thirst, and the need for elimination. The third category concerned with functions consists of definitions that attempt to distinguish between emotion and other psychological processes.

A multilevel definition of emotion essentially subsumes definitions that focus on one of the three structural categories of neural processes, expressive behaviour, and subjective experience, and elaborations and extensions of such a definition would consider concerns of the three categories related to functions. In summary, the foregoing consideration of definitions of emotion suggests that a multilevel concept comes closest to a consensus viewpoint among emotion theorists and provides a way of resolving the complex issue of definition. Thus, a specific emotion is a particular set of neural processes that gives rise to a particular configuration of expressive behaviours and a particular feeling state or quality of consciousness that has motivational and adaptive functions. Under some circumstances extremely intense emotion may become disruptive.

HUMANISTIC BACKGROUND

Orators, literary artists, and philosophers have recognized emotions as part of human nature since recorded history. Homer's *Iliad* contains vivid descriptions of the emotions of the characters; the goddess Athena frequently goes among Agamemnon's troops playing upon their emotions, attempting to allay their fears and bolster their courage for battle. Ancient philosophers discussed the emotions at length, and from these discussions it appears that the basic meanings of emotion concepts are timeless. For example,

Aristotle's views

in the *Rhetoric,* Aristotle described the significance, causes, and consequences of the experiences of anger, fear, and shame in much the same way as contemporary writers. He observed that anger is caused by undeserved slight, fear by the perception of danger, and shame by deeds that bring disgrace or dishonour. His understanding of the relations among emotions also has a modern ring. In contrasting the young and the old, he said of the young,

> And they are more courageous, for they are full of passion and hope, and the former of these prevents them fearing, while the latter inspires them with confidence, for no one fears when angry, and hope of some advantage inspires confidence.

Literature. The use of emotion words in literary works serves several purposes. They help define the motivations and personalities of the characters in a play or novel, and they help the reader to understand and identify with characters and to experience vicariously their emotions.

Shakespeare, for example, was a master at expressing emotion through his characters and eliciting emotions from the audience. His work also contains quite accurate descriptions of emotional expressions. An example in *Henry V* is the king's effort to ready his soldiers for battle:

> Then imitate the action of the tiger;
> Stiffen the sinews, summon up the blood,
> Disguise fair nature with hard-favour'd rage;
> Then lend the eye a terrible aspect;
> Let it pry through the portage of the head
> Like the brass cannon; let the brow o'erwhelm it
> As fearfully as doth a galled rock
> O'erhang and jutty his confounded base,
> Swill'd with the wild and wasteful ocean.
> Now set the teeth and stretch the nostril wide,
> Hold hard the breath and bend up every spirit
> To his full height.
>
> (Act III, scene 1)

James Joyce's use of emotion

In modern times James Joyce used emotion words and words with emotional connotation to powerful effect. In *A Portrait of the Artist as a Young Man,* much of Stephen Dedalus' mood and character are revealed in a few lines describing a time when he was drinking with his cronies and trying to overcome his sense of alienation from his father:

> His mind seemed older than theirs: it shone coldly on their strifes and happiness and regrets like a moon upon a younger earth. . . . Nothing stirred within his soul but a cold and cruel and loveless lust. His childhood was dead or lost and with it his soul capable of simple joys, and he was drifting amid life like the barren shell of the moon.
