As noted earlier, ethics itself is not primarily concerned with the description of moral systems in different societies. That task, which remains on the level of description, is one for anthropology or sociology. In contrast, ethics deals with the justification of moral principles. Nevertheless, ethics must take note of the variations in moral systems because it has often been claimed that this knowledge shows that morality is simply a matter of what is customary and is always relative to a particular society. According to this view, no ethical principles can be valid except in terms of the society in which they are held. Words such as good and bad just mean, it is claimed, "approved in my society" or "disapproved in my society," and so to search for an objective, or rationally justifiable, ethic is to search for what is in fact an illusion.

One way of replying to this position would be to stress the fact that there are some features common to virtually all human moralities. It might be thought that these common features must be the universally valid and objective core of morality. This argument would, however, invoive a fallacy. If the explanation for the common features is simply that they are advantageous in terms of evolutionary theory, that does not make them right. Evolution is a blind force incapable of conferring a moral imprimatur on human behaviour. It may be a fact that concern for kin is in accord with evolutionary theory, but to say that concern for kin is therefore right would be to attempt to deduce values from facts. As will be seen later, it is not possible to deduce values from facts in this manner. In any case, that something is universally approved does not make it right. If all human societies enslaved any tribe they could conquer, some freethinking moralists might still insist that slavery is wrong. They could not be said to be talking nonsense merely because they had few supporters. Similarly, then, universal support for principles of kinship and reciprocity cannot prove that these principles are in some way objectively justified.

This example illustrates the way in which ethics differs from a descriptive science. From the standpoint of ethics, whether human moral codes closely parallel one another or are extraordinarily diverse, the question of how an individual should act remains open. If you are thinking deeply about what you should do, your uncertainty will not be overcome by being told what your society thinks you should do in the circumstances in which you find yourself. Even if you are told that virtually all other human societies agree, you may choose not to go that way. If you are told that there is great variation among human societies over what people should do in your circumstances, you may wonder whether there can be any objective answer, but your dilemma has still not been resolved. In fact, this diversity does not rule out the possibility of an objective answer either: conceivably, most societies simply got it wrong. This, too, is something that will be taken up later in this article, for the possibility of an objective morality is one of the constant themes of ethics.

ANCIENT ETHICS

The first ethical precepts were certainly passed down by word of mouth by parents and elders, but as societies

learned to use the written word, they began to set down their ethical beliefs. These records constitute the first historical evidence of the origins of ethics.

The Middle East. The earliest surviving writings that might be taken as ethics textbooks are a series of lists of precepts to be learned by boys of the ruling class of Egypt, prepared some 3,000 years before the Christian Era. In most cases, they consist of shrewd advice on how to live happily, avoid unnecessary troubles, and advance one's career by cultivating the favour of superiors. There are, however, several passages that recommend more broadly based ideals of conduct, such as the following: Rulers should treat their people justly and judge impartially between their subjects. They should aim to make their people prosperous. Those who have bread are urged to share it with the hungry. Humble and lowly people must be treated with kindness. One should not laugh at the blind or at dwarfs.

Why then should one follow these precepts? Did the ancient Egyptians believe that one should do what is good for its own sake? The precepts frequently state that it will profit a man to act justly, much as we say that "honesty is the best policy." They also emphasize the importance of having a good name. Since these precepts are intended for the instruction of the ruling classes, however, we have to ask why helping the destitute should have contributed to an individual's good reputation among this class. To some degree the authors of the precepts must have thought that to make people prosperous and happy and to be kind to those who have least is not merely personally advantageous but good in itself.

The precepts are not works of ethics in the philosophical sense. No attempt is made to find any underlying principles of conduct that might provide a more systematic understanding of ethics. Justice, for example, is given a prominent place, but there is no elaboration of the notion of justice nor any discussion of how disagreements about what is just and unjust might be resolved. Furthermore, there is no probing of ethical dilemmas that may occur if the precepts should conflict with one another. The precepts are full of sound observations and practical wisdom, but they do not encourage theoretical speculation.

The same practical bent can be found in other early codes or lists of ethical injunctions. The great codification of Babylonian law by Hammurabi is often said to have been based on the principle of "an eye for an eye, a tooth for a tooth," as if this were some fundamental principle of justice, elaborated and applied to all cases. In fact, the code reflects no such consistent principle. It frequently prescribes the death penalty for offenses that do not themselves cause death—*e.g.,* for robbery or for accepting bribes. Moreover, even the eye-for-an-eye rule applies only if the eye of the original victim is that of a member of the patrician class; if it is the eye of a commoner, the punishment is a fine of a quantity of silver. Apparently such differences in punishment were not thought to require justification. At any rate, there are no surviving attempts to defend the principles of justice on which the code was based.

Code of Hammurabi

The Hebrew people were at different times captives of both the Egyptians and the Babylonians. It is therefore not surprising that the law of ancient Israel, which was put into its definitive form during the Babylonian Exile, shows the influence both of the ancient Egyptian precepts and of the Code of Hammurabi. The book of Exodus refers, for example, to the principle of "life for life, eye for eye, tooth for tooth." Hebrew law does not differentiate, as the Babylonian law does, between patricians and commoners, but it does stipulate that in several respects foreigners may be treated in ways that it is not permissible to treat fellow Hebrews; for instance, Hebrew slaves, but not others, had to be freed without ransom in the seventh year. Yet, in other respects Israeli law and morality developed the humane concern shown in the Egyptian precepts for the poor and unfortunate: hired servants must be paid promptly, because they rely on their wages to satisfy their pressing needs; slaves must be allowed to rest on the seventh day; widows, orphans, and the blind and deaf must not be wronged, and the poor man should not be refused a loan. There was even a tithe providing for an incipient welfare state. The spirit of this humane concern was summed up by the injunction to "love thy neighbour as thyself," a sweepingly generous form of the rule of reciprocity.

The famed Ten Commandments are thought to be a legacy of Semitic tribal law when important commands were taught, one for each finger, so that they could more easily be remembered. (Sets of five or 10 laws are common among preliterate civilizations.) The content of the Hebrew commandments differed from other laws of the region mainly in its emphasis on duties to God. In the more detailed laws laid down elsewhere, this emphasis continued with as much as half the legislation concerned with crimes against God and ceremonial and ritualistic matters, though there may be other explanations for some of these ostensibly religious requirements concerning the avoidance of certain foods and the need for ceremonial cleansings.

In addition to lengthy statements of the law, the surviving literature of ancient Israel includes both proverbs and the books of the prophets. The proverbs, like the precepts of the Egyptians, are brief statements without much concern for systematic presentation or overall coherence. They go further than the Egyptian precepts, however, in urging conduct that is just and upright and pleasing to God. There are correspondingly fewer references to what is needed for a successful career, although it is frequently stated that God rewards the just. In this connection the Book of Job is notable as an exploration of the problem raised for those who accept this motive for obeying the moral law: How are we to explain the fact that the best of people may suffer the worst misfortunes? The book offers no solution beyond faith in God, but the sharpened awareness of the problem it offers may have influenced some to adopt belief in reward and punishment in another realm as the only possible solution.

Hebrew proverbs and the books of the prophets

The literature of the prophets contains a good deal of social and ethical criticism, though more at the level of denunciation than discussion about what goodness really is or why there is so much wrongdoing. The Book of Isaiah is especially notable for its early portrayal of a utopia in which "the desert shall blossom as the rose . . . the wolf also shall dwell with the lamb . . . . They shall not hurt or destroy in all my holy mountain."

India. Unlike the ethical teaching of ancient Egypt and Babylon, Indian ethics was philosophical from the start. In the oldest of the Indian writings, the Vedas, ethics is an integral aspect of philosophical and religious speculation about the nature of reality. These writings date from about 1500 BC. They have been described as the oldest philosophical literature in the world, and what they say about how people ought to live may therefore be the first philosophical ethics.

The Vedas

The Vedas are, in a sense, hymns, but the gods to which they refer are not persons but manifestations of ultimate truth and reality. In the Vedic philosophy, the basic principle of the universe, the ultimate reality on which the cosmos exists, is the principle of *Ritam,* which is the word from which the Western notion of right is derived. There is thus a belief in a right moral order somehow built into the universe itself. Hence, truth and right are linked; to penetrate through illusion and understand the ultimate truth of human existence is to understand what is right. To be an enlightened one is to know what is real and to live rightly, for these are not two separate things but one and the same.

The ethic that is thus traced to the very essence of the universe is not without its detailed practical applications. These were based on four ideals, or proper goals, of life: prosperity, the satisfaction of desires, moral duty, and spiritual perfection—*i.e.,* liberation from a finite existence. From these ends follow certain virtues: honesty, rectitude, charity, nonviolence, modesty, and purity of heart. To be condemned, on the other hand, are falsehood, egoism, cruelty, adultery, theft, and injury to living things. Because the eternal moral law is part of the universe, to do what is praiseworthy is to act in harmony with the universe and accordingly will receive its proper reward; conversely, once the true nature of the self is understood, it becomes

apparent that those who do what is wrong are acting self-destructively.

The basic principles underwent considerable modification over the ensuing centuries, especially in the *Upaniṣads*, a body of philosophical literature dating from 800 BC. The Indian caste system, with its intricate laws about what members of each caste may or may not do, is accepted by the *Upaniṣads* as part of the proper order of the universe. Ethics itself, however, is not regarded as a matter of conformity to laws. Instead, the desire to be ethical is an inner desire. It is part of the quest for spiritual perfection, which in turn is elevated to the highest of the four goals of life.

During the following centuries the ethical philosophy of this early period gradually became a rigid and dogmatic system that provoked several reactions. One, which is uncharacteristic of Indian thought in general, was the Cārvāka, or materialist school, which mocked religious ceremonies, saying that they were invented by the Brahmans (the priestly caste) to ensure their livelihood. When the Brahmans defended animal sacrifices by claiming that the sacrificed beast goes straight to heaven, the members of the Cārvāka asked why the Brahmans did not kill their aged parents to hasten their arrival in heaven. Against the postulation of an eventual spiritual liberation, Cārvāka ethics urged each individual to seek his or her pleasure here and now.

The Cārvāka

Jainism, another reaction to the traditional Vedic outlook, went in exactly the opposite direction. The Jaina philosophy is based on spiritual liberation as the highest of all goals and nonviolence as the means to it. In true philosophical manner, the Jainas found in the principle of nonviolence a guide to all morality. First, apart from the obvious application to prohibiting violent acts to other humans, nonviolence is extended to all living things. The Jainas are vegetarian. They are often ridiculed by Westerners for the care they take to avoid injuring insects or other living things while walking or drinking water that may contain minute organisms; it is less well known that Jainas began to care for sick and injured animals thousands of years before animal shelters were thought of in Europe. The Jainas do not draw the distinction usually made in Western ethics between their responsibility for what they do and their responsibility for what they omit doing. Omitting to care for an injured animal would also be in their view a form of violence.

Jaina philosophy

Other moral duties are also derived from the notion of nonviolence. To tell someone a lie, for example, is regarded as inflicting a mental injury on that person. Stealing, of course, is another form of injury, but because of the absence of a distinction between acts and omissions, even the possession of wealth is seen as depriving the poor and hungry of the means to satisfy their wants. Thus nonviolence leads to a principle of nonpossession of property. Jaina priests were expected to be strict ascetics and to avoid sexual intercourse. Ordinary Jainas, however, followed a slightly less severe code, which was intended to give effect to the major forms of nonviolence while still being compatible with a normal life.

The other great ethical system to develop as a reaction to the ossified form of the old Vedic philosophy was Buddhism. The person who became known as the Buddha, which means the "enlightened one," was born about 563 BC, the son of a king. Until he was 29 years old, he lived the sheltered life of a typical prince, with every luxury he could desire. At that time, legend has it, he was jolted out of his idleness by the "Four Signs": he saw in rapid succession a very feeble old man, a hideous leper, a funeral, and a venerable ascetic monk. He began to think about old age, disease, and death, and decided to follow the way of the monk. For six years he led an ascetic life of renunciation, but finally, while meditating under a tree, he concluded that the solution was not withdrawal from the world, but rather a practical life of compassion for all.

Buddhism is often thought to be a religion, and indeed over the centuries it has adopted in many places the trappings of religion. This is an irony of history, however, because the Buddha himself was a strong critic of religion. He rejected the authority of the Vedas and refused to set up any alternative creed. He saw religious ceremonies as a waste of time and theological beliefs as mere superstition. He refused to discuss abstract metaphysical problems such as the immortality of the soul. The Buddha told his followers to think for themselves and take responsibility for their own future. In place of religious beliefs and religious ceremonies, the Buddha advocated a life devoted to universal compassion and brotherhood. Through such a life one might reach the ultimate goal, Nirvāṇa, a state in which all living things are free from pain and sorrow. There are similarities between this ethic of universal compassion and the ethics of the Jainas. Nevertheless, the Buddha was the first historical figure to develop such a boundless ethic.

The teachings of the Buddha

In keeping with his own previous experience, the Buddha proposed a "middle path" between self-indulgence and self-renunciation. In fact, it is not so much a path between these two extremes as one that draws together the benefits of both. Through living a life of compassion and love for all, a person achieves the liberation from selfish cravings sought by the ascetic and a serenity and satisfaction that are more fulfilling than anything obtained by indulgence in pleasure.

It is sometimes thought that because the Buddhist goal is Nirvāṇa, a state of freedom from pain and sorrow that can be reached by meditation, Buddhism teaches a withdrawal from the real world. Nirvāṇa, however, is not to be sought for oneself alone; it is regarded as a unity of the individual self with the universal self in which all things take part. In the Mahāyāna school of Buddhism, the aspirant for Enlightenment even takes a vow not to accept final release until everything that exists in the universe has attained Nirvāṇa.

The Buddha lived and taught in India, and so Buddhism is properly classified as an Indian ethical philosophy. Yet, Buddhism did not take hold in the land of its origin. Instead, it spread in different forms south into Sri Lanka and Southeast Asia, and north through Tibet to China, Korea, and Japan. In the process, Buddhism suffered the same fate as the Vedic philosophy against which it had rebelled: it became a religion, often rigid, with its own sects, ceremonies, and superstitions.

China. The two greatest moral philosophers of ancient China, Lao-tzu (flourished *c.* 6th century BC) and Confucius (551–479 BC), thought in very different ways. Lao-tzu is best known for his ideas about the Tao (literally "Way," the Supreme Principle). The Tao is based on the traditional Chinese virtues of simplicity and sincerity. To follow the Tao is not a matter of keeping to any set list of duties or prohibitions, but rather of living in a simple and honest manner, being true to oneself, and avoiding the distractions of ordinary living. Lao-tzu's classic book on the Tao, *Tao-te Ching*, consists only of aphorisms and isolated paragraphs, making it difficult to draw an intelligible system of ethics from it. Perhaps this is because Lao-tzu was a type of moral skeptic: he rejected both righteousness and benevolence, apparently because he saw them as imposed on individuals from without rather than coming from their own inner nature. Like the Buddha, Lao-tzu found the things prized by the world—rank, luxury, and glamour—to be empty, worthless values when compared with the ultimate value of the peaceful inner life. He also emphasized gentleness, calm, and nonviolence. Nearly 600 years before Jesus, he said: "It is the way of the Tao . . . to recompense injury with kindness." By returning good for good and also good for evil, Lao-tzu believed that all would become good; to return evil for evil would lead to chaos.

Lao-tzu

The lives of Lao-tzu and Confucius overlapped, and there is even an account of a meeting between them, which is said to have left the younger Confucius baffled. Confucius was the more down-to-earth thinker, absorbed in the practical task of social reform. When he was a provincial minister of justice, the province became renowned for the honesty of its people and their respect for the aged and their care for the poor. Probably because of its practical nature, the teachings of Confucius had a far greater influence on China than did those of the more withdrawn Lao-tzu.

Confucius did not organize his recommendations into

The teachings of Confucius

any coherent system. His teachings are offered in the form of sayings, aphorisms, and anecdotes, usually in reply to questions by disciples. They aim at guiding the audience in what is necessary to become a better person, a concept translated as "gentleman" or "the superior man." In opposition to the prevailing feudal ideal of the aristocratic lord, Confucius presented the superior man as one who is humane and thoughtful, motivated by the desire to do what is good rather than by personal profit. Beyond this, however, the concept is not discussed in any detail; it is only shown by diverse examples, some of them trite: "A superior man's life leads upwards . . . . The superior man is broad and fair; the inferior man takes sides and is petty . . . . A superior man shapes the good in man; he does not shape the bad in him."

One of the recorded sayings of Confucius is an answer to a request from a disciple for a single word that could serve as a guide to conduct for one's entire life. He replied: "Is not reciprocity such a word? What you do not want done to yourself, do not do to others." This rule is repeated several times in the Confucian literature and might be considered the supreme principle of Confucian ethics. Other duties are not, however, presented as derivative from this supreme principle, nor is the principle used to determine what is to be done when more specific duties—*e.g.*, duties to parents and duties to friends, both of which were given prominence in Confucian ethics—should clash.

Confucius did not explain why the superior man chose righteousness rather than personal profit. This question was taken up more than 100 years after his death by his follower Mencius, who asserted that humans are naturally inclined to do what is humane and right. Evil is not in human nature but is the result of poor upbringing or lack of education. But Confucius also had another distinguished follower, Hsün-tzu, who said that man's nature is to seek self-profit and to envy others. The rules of morality are designed to avoid the strife that would otherwise follow from this nature. The Confucian school was united in its ideal of the superior man but divided over whether such an ideal was to be obtained by allowing people to fulfill their natural desires or by educating them to control those desires.

Ancient Greece. Early Greece was the birthplace of Western philosophical ethics. The ideas of Socrates, Plato, and Aristotle, who flourished in the 5th and 4th centuries BC, will be discussed in the next section. The sudden blooming of philosophy during that period had its roots in the ethical thought of earlier centuries. In the poetic literature of the 7th and 6th centuries BC, there were, as in the early development of ethics in other cultures, ethical precepts but no real attempts to formulate a coherent overall ethical position. The Greeks were later to refer to the most prominent of these poets and early philosophers as the seven sages, and they are frequently quoted with respect by Plato and Aristotle. Knowledge of the thought of this period is limited, for often only fragments of original writings, along with later accounts of dubious accuracy, remain.

Pythagoras (*c.* 580–*c.* 500 BC), whose name is familiar because of the geometrical theorem that bears his name, is one such early Greek thinker about whom little is known. He appears to have written nothing at all, but he was the founder of a school of thought that touched on all aspects of life and that may have been a kind of philosophical and religious order. In ancient times the school was best known for its advocacy of vegetarianism, which, like that of the Jainas, was associated with the belief that after the death of the body, the human soul may take up residence in the body of an animal. Pythagoreans continued to espouse this view for many centuries, and classical passages in the works of such writers as Ovid and Porphyry opposing bloodshed and animal slaughter can be traced back to Pythagoras.

Pythagorean school of thought

Ironically, an important stimulus for the development of moral philosophy came from a group of teachers to whom the later Greek philosophers—Socrates, Plato, and Aristotle—were consistently hostile: the Sophists. This term was used in the 5th century to refer to a class of professional teachers of rhetoric and argument. The Sophists promised their pupils success in political debate and increased influence in the affairs of the city. They were accused of being mercenaries who taught their students to win arguments by fair means or foul. Aristotle said that Protagoras, perhaps the most famous of them, claimed to teach how "to make the weaker argument the stronger."

The Sophists

The Sophists, however, were more than mere teachers of rhetorical tricks. They saw their role as imparting the cultural and intellectual qualities necessary for success, and their involvement with argument about practical affairs led them to develop views about ethics. The recurrent theme in the views of the better known Sophists, such as Protagoras, Antiphon, and Thrasymachus, is that what is commonly called good and bad or just and unjust does not reflect any objective fact of nature but is rather a matter of social convention. It is to Protagoras that we owe the celebrated epigram summing up this theme, "Man is the measure of all things." Plato represents him as saying "Whatever things seem just and fine to each city, are just and fine for that city, so long as it thinks them so." Protagoras, like Herodotus, was an early social relativist, but he drew a moderate conclusion from his relativism. He argued that while the particular content of the moral rules may vary, there must be rules of some kind if life is to be tolerable. Thus Protagoras stated that the foundations of an ethical system needed nothing from the gods or from any special metaphysical realm beyond the ordinary world of the senses.

The Sophist Thrasymachus appears to have taken a more radical approach—if Plato's portrayal of his views is historically accurate. He explained that the concept of justice means nothing more than obedience to the laws of society, and, since these laws are made by the strongest political group in their own interests, justice represents nothing but the interests of the stronger. This position is often represented by the slogan "Might is right." Thrasymachus was probably not saying, however, that whatever the mightiest do really is right; he is more likely to have been denying that the distinction between right and wrong has any objective basis. Presumably he would then encourage his pupils to follow their own interests as best they could. He is thus an early representative of Skepticism about morals and perhaps of a form of egoism, the view that the rational thing to do is follow one's own interests.

It is not surprising that with ideas of this sort in circulation other thinkers should react by probing more deeply into ethics to see if the potentially destructive conclusions of some of the Sophists could be resisted. This reaction produced works that have served ever since as the cornerstone for the entire edifice of Western ethics.

Western ethics from Socrates to the 20th century

THE CLASSICAL PERIOD OF GREEK ETHICS

Socrates. "The unexamined life is not worth living," Socrates once observed. This thought typifies his questioning, philosophical approach to ethics. Socrates, who lived from about 470 BC until he was put to death in 399 BC, must be regarded as one of the greatest teachers of ethics. Yet, unlike other figures of comparable importance such as the Buddha or Confucius, he did not tell his audience how they should live. What Socrates taught was a method of inquiry. When the Sophists or their pupils boasted that they knew what justice, piety, temperance, or law was, Socrates would ask them to give an account of it and then show that the account offered was entirely inadequate. For instance, against the received wisdom that justice consists in keeping promises and paying debts, Socrates put forth the example of a person faced with an unusual situation: a friend from whom he borrowed a weapon has since become insane but wants the weapon back. Conventional morality gives no clear answer to this dilemma; therefore, the original definition of justice has to be reformulated. So the Socratic dialogue gets under way.

Because his method of inquiry threatened conventional beliefs, Socrates' enemies contrived to have him put to death on a charge of corrupting the youth of Athens. For those who saw adherence to the conventional moral

code as more desirable than the cultivation of an inquiring mind, the charge was appropriate. By conventional standards, Socrates was indeed corrupting the youth of Athens, but he himself saw the destruction of beliefs that could not stand up to criticism as a necessary preliminary to the search for true knowledge. Here, he differed from the Sophists with their moral relativism, for he thought that virtue is something that can be known and that the good person is the one who knows of what virtue, or justice, consists.

It is therefore not entirely accurate to see Socrates as contributing a method of inquiry but no positive views of his own. He believed in goodness as something that can be known, even though he did not himself profess to know it. He also thought that those who know what good is are in fact good. This latter belief seems peculiar today, because we make a sharp distinction between what is good and what is in a person's own interests. Accordingly, it does not seem surprising if people know what they ought morally to do but then proceed to do what is in their own interests instead. How to provide such people with reasons for doing what is right has been a major problem for Western ethics. Socrates did not see a problem here at all; in his view anyone who does not act well must simply be ignorant of the nature of goodness. Socrates could say this because in ancient Greece the distinction between goodness and self-interest was not made, or at least not in the clear-cut manner that it is today. The Greeks believed that virtue is good both for the individual and for the community. To be sure, they recognized that to live virtuously might not be the best way to prosper financially, but then they did not assume, as we are prone to do, that material wealth is a major factor in whether a person's life goes well or ill.

Plato. Socrates' greatest disciple, Plato (428/427–348/347 BC), accepted the key Socratic beliefs in the objectivity of goodness and in the link between knowing what is good and doing it. He also took over the Socratic method of conducting philosophy, developing the case for his own positions by exposing errors and confusions in the arguments of his opponents. He did this by writing his works as dialogues in which Socrates is portrayed as engaging in argument with others, usually Sophists. The early dialogues are generally accepted as reasonably accurate accounts of Socrates' views, but the later ones, written many years after the death of Socrates, use the latter as a mouthpiece for ideas and arguments that were Plato's rather than those of the historical Socrates.

In the most famous of Plato's dialogues, *Politeia* (*The Republic*), the imaginary Socrates is challenged by the following example: Suppose a person obtained the legendary ring of Gyges, which has the magical property of rendering the wearer invisible. Would that person still have any reason to behave justly? Behind this challenge lies the suggestion, made by the Sophists and still heard today, that the only reason for acting justly is that one cannot get away with acting unjustly. Plato's response to this challenge is a long argument developing a position that appears to go beyond anything the historical Socrates asserted. Plato maintained that true knowledge consists not in knowing particular things but in knowing something general that is common to all the particular cases. This is obviously derived from the way in which Socrates would press his opponents to go beyond merely describing particular good, or temperate, or just acts, and to give instead a general account of goodness, or temperance, or justice. The implication is that we do not know what goodness is unless we can give this general account. But the question then arises, what is it that we know when we know this general idea of goodness? Plato's answer seems to be that what we know is some general form or idea of goodness, which is shared by every particular thing that is good. Yet, if we are truly to be able to know this form or idea of goodness, it seems to follow that it must really exist. Plato accepts this implication. His theory of forms is the view that when we know what goodness is, we have knowledge of something that is the common element in virtue of which all good things are good and, at the same time, is some existing thing, the pure form of goodness.

It has been said that all of Western philosophy consists of footnotes to Plato. Certainly the central issue around which all of Western ethics has revolved can be traced back to the debate between the Sophists, on the one hand, with their claims that goodness and justice are relative to the customs of each society or, worse still, merely a disguise for the interests of the stronger, and, on the other, Plato's defense of the possibility of knowledge of an objective form or idea of goodness.

But even if we know what goodness or justice is, why should we act justly if we can profit by doing the opposite? This remaining part of the challenge posed by the legendary ring of Gyges is still to be answered, for even if we accept that goodness is objective, it does not follow that we all have sufficient reason to do what is good. Whether goodness leads to happiness is, as has been seen from the preceding discussion of early ethics in other cultures, a perennial topic for all who think about ethics. Plato's answer is that justice consists in harmony between the three elements of the soul: intellect, emotion, and desire. The unjust person lives in an unsatisfactory state of internal discord, trying always to overcome the discomfort of unsatisfied desire but never achieving anything better than the mere absence of want. The soul of the good person, on the other hand, is harmoniously ordered under the governance of reason, and the good person finds truly satisfying enjoyment in the pursuit of knowledge. Plato remarks that the highest pleasure, in fact, comes from intellectual speculation. He also gives an argument for the belief that the human soul is immortal; therefore, even if just individuals seem to be living in poverty or illness, the gods will not neglect them in the next life, and there they will have the greatest rewards of all. In summary, then, Plato asserts that we should act justly because in doing so we are "at one with ourselves and with the gods."

Plato's concept of justice

Today, this may seem like a strange account of justice and a farfetched view of what it takes to achieve human happiness. Plato does not recommend justice for its own sake, independently of any personal gains one might obtain from being a just person. This is characteristic of Greek ethics, with its refusal to recognize that there could be an irresolvable conflict between one's own interest and the good of the community. Not until Immanuel Kant, in the 18th century, does a philosopher forcefully assert the importance of doing what is right simply because it is right quite apart from self-interested motivation. To be sure, Plato must not be interpreted as holding that the motivation for each and every just act is some personal gain; on the contrary, the person who takes up justice will do what is just because it is just. Nevertheless, Plato accepts the assumption of his opponents that one could not recommend taking up justice in the first place unless doing so could be shown to be advantageous for oneself as well as for others.

In spite of the fact that many people now think differently about this connection between morality and self-interest, Plato's attempt to argue that those who are just are in the long run happier than those who are unjust has had an enormous influence on Western ethics. Like Plato's views on the objectivity of goodness, the claim that justice and personal happiness are linked has helped to frame the agenda for a debate that continues even today.

Aristotle. Plato founded a school of philosophy in Athens known as the Academy. Here Aristotle (384–322 BC), Plato's younger contemporary and only rival in terms of influence on the course of Western philosophy, came to study. Aristotle was often fiercely critical of Plato, and his writing is very different in style and content, but the time they spent together is reflected in a considerable amount of common ground. Thus Aristotle holds with Plato that the life of virtue is rewarding for the virtuous, as well as beneficial for the community. Aristotle also agrees that the highest and most satisfying form of human existence is that in which man exercises his rational faculties to the fullest extent. One major difference is that Aristotle does not accept Plato's theory of common essences, or universal ideas, existing independently of particular things. Thus he does not argue that the path to goodness is through knowledge of the universal form or idea of "the good."

The basis of Aristotle's ethics

Aristotle's ethics are based on his view of the universe. He saw it as a hierarchy in which everything has a function. The highest form of existence is the life of the rational being, and the function of lower beings is to serve this form of life. This led him to defend slavery—because he thought barbarians were less rational than Greeks and by nature suited to be "living tools"—and the killing of nonhuman animals for food or clothing. From this also came a view of human nature and an ethical theory derived from it. All living things, Aristotle held, have inherent potentialities and it is their nature to develop that potential to the full. This is the form of life properly suited to them and constitutes their goal. What, however, is the potentiality of human beings? For Aristotle this question turns out to be equivalent to asking what it is that is distinctive about human beings, and this, of course, is the capacity to reason. The ultimate goal of humans, therefore, is to develop their reasoning powers. When they do this, they are living well, in accordance with their true nature, and they will find this the most rewarding existence possible.

Aristotle thus ends up agreeing with Plato that the life of the intellect is the highest form of life; though having a greater sense of realism than Plato, he tempered this view with the suggestion that the best feasible life for humans must also have the goods of material prosperity and close friendships. Aristotle's argument for regarding the life of the intellect so highly, however, is different from that used by Plato; and the difference is significant because Aristotle committed a fallacy that has often been repeated. The fallacy is to assume that whatever capacity distinguishes humans from other beings is, for that very reason, the highest and best of their capacities. Perhaps the ability to reason is the best of our capacities, but we cannot be compelled to draw this conclusion from the fact that it is what is most distinctive of the human species.

A broader and still more pervasive fallacy underlies Aristotle's ethics. It is the idea that an investigation of human nature can reveal what we ought to do. For Aristotle, an examination of a knife would reveal that its distinctive quality is to cut, and from this we could conclude that a good knife would be a knife that cuts well. In the same way, an examination of human nature should reveal the distinctive quality of human beings, and from this we should be able to conclude what it is to be a good human being. This line of thought makes sense if we think, as Aristotle did, that the universe as a whole has a purpose and that we exist as part of such a goal-directed scheme of things, but its error becomes glaring once we reject this view and come to see our existence as the result of a blind process of evolution. Then we know that the standards of quality for knives are a result of the fact that knives are made with a specific purpose in mind and that a good knife is one that fills this purpose well. Human beings, however, were not made with any particular purpose in mind. Their nature is the result of random forces of natural selection and thus cannot, without further moral premises, determine how they ought to live.

Concept of the final end

It is to Aristotle that we owe the notion of the final end, or, as it was later called by medieval scholars, the *summum bonum*—the overall good for human beings. This can be found, Aristotle wrote, by asking why we do the things that we do. If we ask why we chop wood, the answer may be to build a fire; and if we ask why we build a fire, it may be to keep warm; but, if we ask why we keep warm, the answer is likely to be simply that it is pleasant to be warm and unpleasant to be cold. We can ask the same kind of questions about other activities; the answer always points, Aristotle thought, to what he called *eudaimonia*. This Greek word is usually translated as "happiness," but this is only accurate if we understand that term in its broadest sense to mean living a fulfilling, satisfying life. Happiness in the narrower sense of joy or pleasure would certainly be a concomitant of such a life, but it is not happiness in this narrower sense that is the goal.

In searching for the overall good, Aristotle separates what may be called instrumental goods from intrinsic goods. The former are good only because they lead to something else that is good; the latter are good in themselves. The distinction is neglected in the early lists of ethical precepts that were surveyed above, but it is of the first importance if a firmly grounded answer to questions about how one ought to live is to be obtained.

Aristotle is also responsible for much later thinking about the virtues one should cultivate. In his most important ethical treatise, the *Ethica Nicomachea* (*Nicomachean Ethics*), he sorts through the virtues as they were popularly understood in his day, specifying in each case what is truly virtuous and what is mistakenly thought to be so. Here, he uses the idea of the Golden Mean, which is essentially the same idea as the Buddha's middle path between self-indulgence and self-renunciation. Thus courage, for example, is the mean between two extremes: one can have a deficiency of it, which is cowardice, or one can have an excess of it, which is foolhardiness. The virtue of friendliness, to give another example, is the mean between obsequiousness and surliness.

Aristotle does not intend the idea of the mean to be applied mechanically in every instance: he says that in the case of the virtue of temperance, or self-restraint, it is easy to find the excess of self-indulgence in the physical pleasures, but the opposite error, insufficient concern for such pleasures, scarcely exists. (The Buddha, with his experience of the ascetic life of renunciation, would not have agreed.) This caution in the application of the idea is just as well, for while it may be a useful device for moral education, the notion of a mean cannot help us to discover new truths about virtue. We can only arrive at the mean if we already have a notion as to what is an excess and what is a defect of the trait in question, but this is not something to be discovered by a morally neutral inspection of the trait itself. We need a prior conception of the virtue in order to decide what is excessive and what is defective. To attempt to use the doctrine of the mean to define the particular virtues would be to travel in a circle.

Aristotle's list of the virtues differs from later Christian lists. Courage, temperance, and liberality are common to both periods, but Aristotle also includes a virtue that literally means "greatness of soul." This is the characteristic of holding a high opinion of oneself. The corresponding vice of excess is unjustified vanity, but the vice of deficiency is humility, which for Christians is a virtue.

Aristotle's discussion of the virtue of justice has been the starting point for almost all Western accounts. He distinguishes between justice in the distribution of wealth or other goods and justice in reparation, as, for example, in punishing someone for a wrong he has done. The key element of justice, according to Aristotle, is treating like cases alike—an idea that has set later thinkers the task of working out which similarities (need, desert, talent) are relevant. As with the notion of virtue as a mean, Aristotle's conception of justice provides a framework that needs to be filled in before it can be put to use.

Theoretical and practical reason

Aristotle distinguished between theoretical and practical wisdom. His concept of practical wisdom is significant, for it goes beyond merely choosing the means best suited to whatever ends or goals one may have. The practically wise person also has the right ends. This implies that one's ends are not purely a matter of brute desires or feelings; the right ends are something that can be known. It also gives rise to the problem that faced Socrates: How is it that people can know the difference between good and bad and still choose what is bad? As noted earlier, Socrates simply denied that this could happen, saying that those who did not choose the good must, appearances notwithstanding, be ignorant of what it is. Aristotle said that this view of Socrates was "plainly at variance with the observed facts" and, instead, offered a detailed account of the ways in which one can possess knowledge and yet not act on it because of lack of control or weakness of will.

LATER GREEK AND ROMAN ETHICS

In ethics, as in many other fields, the later Greek and Roman periods do not display the same penetrating insight as the Classic period of 5th- and 4th-century Greek civilization. Nevertheless, the two dominant schools of thought, Stoicism and Epicureanism, represent important approaches to the question of how one ought to live.

The Stoics. Stoicism had its origins in the views of

Socrates and Plato, as modified by Zeno and then by Chrysippus in the 3rd century BC. It gradually gained influence in Rome, chiefly through the teachings of Cicero (106–43 BC) and then later in the 1st century AD through those of Seneca. Remarkably, its chief proponents include both a slave, Epictetus, and an emperor, Marcus Aurelius. This is a fine illustration of the Stoic message that what is important is the pursuit of wisdom and virtue, a pursuit that is open to all human beings owing to their common capacity for reason and that can be carried out no matter what the external circumstances of their lives.

Today, the word stoic conjures up one who remains unmoved by the sorrows and afflictions that distress the rest of humanity. This is an accurate representation of a stoic ideal, but it must be placed in the context of a systematic approach to life. Plato held that human passions and physical desires are in need of regulation by reason (see above). The Stoics went further: they rejected passions altogether as a basis for deciding what is good or bad. Physical desires cannot simply be abolished, but when we become wise we appreciate the difference between wanting something and judging it to be good. Our desires make us want something, but only our reason can judge the goodness of what is wanted. If we are wise, we will identify with our reason, not with our desires; hence, we will not place our hopes on the attainment of our physical desires nor our anxieties on our failure to attain them. Wise Stoics will feel physical pain as others do, but in their minds they will know that physical pain leaves the true reasoning self untouched. The only thing that is truly good is to live in a state of wisdom and virtue. In aiming at such a life, we are not subject to the same play of fortune that afflicts us when we aim at physical pleasure or material wealth, for wisdom and virtue are matters of the intellect and under our own control. Moreover, if matters become too grim, there is always a way of ending the pain of the physical world. The Stoics were not reluctant to counsel suicide as a means of avoiding otherwise inescapable pain.

Rejection of passion in making moral judgments

Perhaps the most important legacy of Stoicism, however, is its conviction that all human beings share the capacity to reason. This led the Stoics to a fundamental sense of equality, which went beyond the limited Greek conception of equal citizenship. Thus Seneca claimed that the wise man will esteem the community of rational beings far above any particular community in which the accident of birth has placed him, and Marcus Aurelius said that common reason makes all individuals fellow citizens. The belief that human reasoning capacities are common to all was also important, because from it the Stoics drew the implication that there is a universal moral law, which all people are capable of appreciating. The Stoics thus strengthened the tradition that sees the universality of reason as the basis on which ethical relativism is to be rejected.

The Epicureans. While the modern use of the term stoic accurately represents at least a part of the Stoic philosophy, anyone taking the present-day meaning of epicure as a guide to the philosophy of Epicurus (341–270 BC) would go astray. True, the Epicureans regarded pleasure as the sole ultimate good and pain as the sole evil; and they did regard the more refined pleasures as superior, simply in terms of the quantity and durability of the pleasure they provided, to the coarser pleasures. To portray them as searching for these more refined pleasures by dining at the best restaurants and drinking the finest wines, however, is the reverse of the truth. By refined pleasures, Epicurus meant pleasures of the mind, as opposed to the coarse pleasures of the body. He taught that the highest pleasure obtainable is the pleasure of tranquillity, which is to be obtained by the removal of unsatisfied wants. The way to do this is to eliminate all but the simplest wants; these are then easily satisfied even by those who are not wealthy.

Epicurus developed his position systematically. To determine whether something is good, he would ask if it increased pleasure or reduced pain. If it did, it was good as a means; if it did not, it was not good at all. Thus justice was good but merely as an expedient arrangement to prevent mutual harm. Why not then commit injustice when we can get away with it? Only because, Epicurus says, the perpetual dread of discovery will cause painful anxiety.

The fundamentals of Epicurean ethics

Epicurus also exalted friendship, and the Epicureans were famous for the warmth of their personal relationships; but, again, they proclaimed that friendship is good only because of its tendency to create pleasure.

Both Stoic and Epicurean ethics can be seen as precursors of later trends in Western ethics: the Stoics of the modern belief in equality and the Epicureans of a Utilitarian ethic based on pleasure. The development of these ethical positions, however, was dramatically affected by the spreading from the East of a new religion that had its roots in a Jewish conception of ethics as obedience to a divine authority. With the conversion of Emperor Constantine I to Christianity by AD 313, the older schools of philosophy lost their sway over the thinking of the Roman Empire.

CHRISTIAN ETHICS FROM THE NEW TESTAMENT TO THE SCHOLASTICS

Ethics in the New Testament. Matthew reports Jesus as having said, in the Sermon on the Mount, that he came not to destroy the law of the prophets but to fulfill it. Indeed, when Jesus is regarded as a teacher of ethics, it is clear that he was more a reformer of the Hebrew tradition than a radical innovator. The Hebrew tradition had a tendency to place great emphasis on compliance with the letter of the law; the Gospel accounts of Jesus portray him as preaching against this "righteousness of the scribes and Pharisees," championing the spirit rather than the letter of the law. This spirit he characterized as one of love, for God and for one's neighbour. But since he was not proposing that the old teachings be discarded, he saw no need to develop a comprehensive ethical system. Christianity thus never really broke with the Jewish conception of morality as a matter of divine law to be discovered by reading and interpreting the word of God as revealed in the Scriptures.

This conception of morality had important consequences for the future development of Western ethics. The Greeks and Romans, and indeed thinkers such as Confucius too, did not have the Western conception of a distinctively moral realm of conduct. For them, everything that one did was a matter of practical reasoning, in which one could do well or poorly. In the more legalistic Judeo-Christian view, however, it is one thing to lack practical wisdom in, say, household budgeting, and a quite different and much more serious matter to fall short of what the moral law requires. This distinction between the moral and the nonmoral realms now affects every question in Western ethics, including the very way the questions themselves are framed.

Another consequence of the retention of the basically legalistic stance of Jewish ethics was that from the beginning Christian ethics had to deal with the question of how to judge the person who breaks the law from good motives or keeps it from bad motives. The latter half of this question was particularly acute because the Gospels describe Jesus as repeatedly warning of a coming resurrection of the dead at which time all would be judged and punished or rewarded according to their sins and virtues in this life. The punishments and rewards were weighty enough to motivate anyone who took this message seriously; and it was given added emphasis by the fact that it was not going to be long in coming. (Jesus said that it would take place during the lifetime of some of those listening to him.) This is, therefore, an ethic that invokes external sanctions as a reason for doing what is right, in contrast to Plato or Aristotle for whom happiness is an internal element of a virtuous life. At the same time, it is an ethic that places love above mere literal compliance with the law. These two aspects do not sit easily together. Can one love God and neighbour in order to be rewarded with eternal happiness in another life?

Basic principles of the Christian ethic

The fact that Jesus and Paul, too, believed in the imminence of the Second Coming led them to suggest ways of living that were scarcely feasible on any other assumption: taking no thought for the morrow; turning the other cheek; and giving away all one has. Even Paul's preference for celibacy rather than marriage and his grudging acceptance of the latter on the basis that "It is better to marry than to burn" makes some sense once we grasp that he was proposing ethical standards for what he thought would be

the last generation on earth. When the expected event did not occur and Christianity became the official religion of the vast and embattled Roman Empire, Christian leaders were faced with the awkward task of reinterpreting these injunctions in a manner more suited for a continuing society.

The new Christian ethical standards did lead to some changes in Roman morality. Perhaps the most vital was a new sense of the equal moral status of all human beings. As previously noted, the Stoics had been the first to elaborate this conception, grounding equality on the common capacity to reason. For Christians, humans are equal because they are all potentially immortal and equally precious in the sight of God. This caused Christians to condemn a wide variety of practices that had been accepted by both Greek and Roman moralists. Many of these related to the taking of innocent human life: from the earliest days Christian leaders condemned abortion, infanticide, and suicide. Even killing in war was at first regarded as wrong, and soldiers converted to Christianity had refused to continue to bear arms. Once the empire became Christian, however, this was one of the inconvenient ideas that had to yield. In spite of what Jesus had said about turning the other cheek, the church leaders declared that killing in a "just war" was not a sin. The Christian condemnation of killing in gladiatorial games, on the other hand, had a more permanent effect. Finally, but perhaps most importantly, while Christian emperors continued to uphold the legality of slavery, the Christian church accepted slaves as equals, admitted them to its ceremonies, and regarded the granting of freedom to slaves as a virtuous, if not obligatory, act. This moral pressure led over several hundred years to the gradual disappearance of slavery in Europe.

The Christian contribution to improving the position of slaves can also be linked with the distinctively Christian list of virtues. Some of the virtues described by Aristotle, as, for example, greatness of soul, are quite contrary in spirit to Christian virtues such as humility. In general, it can be said that the Greeks and Romans prized independence, self-reliance, magnanimity, and worldly success. By contrast, Christians saw virtue in meekness, obedience, patience, and resignation. As the Greeks and Romans conceived virtue, a virtuous slave was almost a contradiction in terms, but for Christians there was nothing in the state of slavery that was incompatible with the highest moral character.

Augustine. Christianity began with a set of scriptures incorporating many ethical injunctions but with no ethical philosophy. The first serious attempt to provide such a philosophy was made by St. Augustine of Hippo (354–430). Augustine was acquainted with a version of Plato's philosophy, and he developed the Platonic idea of the rational soul into a Christian view wherein humans are essentially souls, using their bodies as means to achieve their spiritual ends. The ultimate object remains happiness, as in Greek ethics, but Augustine saw happiness as consisting in a union of the soul with God after the body has died. It was through Augustine, therefore, that Christianity received the Platonic theme of the relative inferiority of bodily pleasures. There was, to be sure, a fundamental difference: whereas Plato saw this inferiority in terms of a comparison with the pleasures of philosophical contemplation in this world, Christians compared them unfavourably with the pleasures of spiritual existence in the next world. Moreover, Christians came to see bodily pleasures not merely as inferior but also as a positive threat to the achievement of spiritual bliss.

It was also important that Augustine could not accept the view, common to so many Greek and Roman philosophers, that philosophical reasoning was the path to wisdom and happiness. For a Christian, of course, the path had to be through love of God and faith in Jesus as the Saviour. The result was to be, for many centuries, a rejection of the use of unfettered reasoning powers in ethics.

Augustine was aware of the tension caused by the dual Christian motivations of love of God and neighbour, on the one hand, and reward and punishment in the afterlife, on the other. He came down firmly on the side of love, insisting that those who keep the moral law through fear of punishment are not really keeping it at all. But it is not ordinary human love, either, that suffices as a motivation for true Christian living. Augustine believed all men bear the burden of Adam's original sin, and so are incapable of redeeming themselves by their own efforts. Only the unmerited grace of God makes possible obedience to the "first greatest commandment" of loving God, and without such, one cannot fulfill the moral law. This view made a clear-cut distinction between Christians and pagan moralists, no matter how humble and pure the latter might be; only the former could be saved because only they could receive the blessing of divine grace. But this gain, as Augustine saw it, was purchased at the cost of denying that man is free to choose good or evil. Only Adam had this choice: he chose for all humanity, and he chose evil.

Aquinas and the moral philosophy of the Scholastics. At this point we may pass over more than 800 years in silence, for there were no major developments in ethics in the West until the rise of Scholasticism in the 12th and 13th centuries. Among the first of the significant works written during this time was a treatise on ethics by the French philosopher and theologian Peter Abelard (1079–1142). His importance in ethical theory lies in his emphasis on intentions. Abelard maintained, for example, that the sin of sexual wrongdoing consists not in the act of illicit sexual intercourse nor even in the desire for it, but in mentally consenting to that desire. In this he was far more modern than Augustine, with his doctrine of grace, and also more thoughtful than those who even today assert that the mere desire for what is wrong is as wrong as the act itself. Abelard saw that there is a problem in holding anyone morally responsible for the existence of mere physical desires. His ingenious solution was taken up by later medieval writers, and traces of it can still be found in modern discussions of moral responsibility.

Aristotle's ethical writings were not known to scholars in western Europe during Abelard's time. Latin translations became available only in the first half of the 13th century, and the rediscovery of Aristotle dominated later medieval philosophy. Nowhere is his influence more marked than in the thought of St. Thomas Aquinas (1225–74), often regarded as the greatest of the Scholastic philosophers and undoubtedly the most influential, since his teachings became the semiofficial philosophy of the Roman Catholic Church. Such is the respect in which Aquinas held Aristotle that he referred to him simply as The Philosopher, and it is not too far from the truth to say that the chief aim of Aquinas' work was to reconcile Aristotle's views with Christian doctrine.

Reconciliation of Aristotelian views with Christian doctrine

Aquinas took from Aristotle the notion of a final end, or *summum bonum,* at which all action is ultimately directed; and, like Aristotle, he saw this end as necessarily linked with happiness. This conception was Christianized, however, by the idea that happiness is to be found in the love of God. Thus a person seeks to know God but cannot fully succeed in this in life on earth. The reward of heaven, where one can know God, is available only to those who merit it, though even then it is given by God's grace rather than obtained by right. Short of heaven, a person can experience only a more limited form of happiness to be gained through a life of virtue and friendship, much as Aristotle had recommended.

The blend of Aristotle's teachings and Christianity is also evident in Aquinas' views about right and wrong, and how we come to know the difference between them. Aquinas is often described as advocating a "natural law" ethic, but this term is easily misunderstood. The natural law to which Aquinas referred does not require a legislator any more than do the laws of nature that govern the motions of the planets. An even more common mistake is to imagine that this conception of natural law relies on contrasting what is natural with what is artificial. Aquinas' theory of the basis of right and wrong developed rather as an alternative to the view that morality is determined simply by the arbitrary will of God. Instead of conceiving of right and wrong in this manner as something fundamentally unrelated to human goals and purposes, Aquinas saw morality as deriving from human nature and the activities that are objectively suited to it.

It is a consequence of this natural law ethic that the difference between right and wrong can be appreciated by the use of reason and reflection on experience. Christian revelation may supplement this knowledge in some respects, but even such pagan philosophers as Aristotle could understand the essentials of virtuous living. We are, however, likely to err when we apply these general principles to the particular cases that confront us in everyday life. Corrupt customs and poor moral education may obscure the messages of natural reason. Hence, societies must enact laws of their own to supplement natural law and, where necessary, to coerce those who, because of their own imperfections, are liable to do what is wrong and socially destructive.

It follows, too, that virtue and human flourishing are linked. When we do what is right, we do what is objectively suited to our true nature. Thus the promise of heaven is no mere external sanction, rewarding actions that would otherwise be indifferent to us or even against our best interests. On the contrary, Aquinas wrote that "God is not offended by us except by what we do against our own good." Reward and punishment in the afterlife reinforce a moral law that all humans, Christian or pagan, have adequate prior reasons for following.

In arguing for his views, Aquinas was always concerned to show that he had the authority of the Scriptures or the Church Fathers on his side, but the substance of his ethical system is to a remarkable degree based on reason rather than revelation. This is strong testimony to the power of Aristotle's example. Nonetheless, Aquinas absorbed the weaknesses as well as the strengths of the Aristotelian system. His attempt to base right and wrong on human nature, in particular, invites the objection that we cannot presuppose our nature to be good. Aquinas might reply that it is good because God made it so, but this merely shifts back one step the issue of the basis of good and bad: Did God make it good in accordance with some independent standard of goodness, or would any human nature made by God be good? If we give the former answer, we need an account of the independent standard of goodness. Because this cannot—if we are to avoid circular argument—be based on human nature, it is not clear what account Aquinas could offer. If we maintain, however, that any human nature made by God would be good, we must accept that if God had made our nature such that we flourish and achieve happiness by torturing the weak and helpless among us, that would have been what we should do in order to live virtuously.

Something resembling this second option—but without the intermediate step of an appeal to human nature—was the position taken by the last of the great Scholastic philosophers, William of Ockham (*c.* 1285–1349?). Ockham boldly broke with much that had been taken for granted by his immediate predecessors. Fundamental to this was his rejection of the central Aristotelian idea that all things have a final end, or goal, toward which they naturally tend. He, therefore, also spurned Aquinas' attempt to base morality on human nature, and with it the idea that happiness is man's goal and closely linked with goodness. This led him to a position in stark contrast to almost all previous Western ethics. Ockham denied all standards of good and evil that are independent of God's will. What God wills is good; what God condemns is evil. That is all there is to say about the matter. This position is sometimes called a divine approbation theory, because it defines "good" as whatever is approved by God. As indicated earlier, when discussing attempts to link morality with religion, it follows from such a position that it is meaningless to describe God himself as good. It also follows that if God had willed us to torture children, it would be good to do so. As for the actual content of God's will, according to Ockham, that is not a subject for philosophy but rather a matter for revelation and faith.

Theory of divine approbation

The rigour and consistency of Ockham's philosophy made it for a time one of the leading schools of Scholastic thought, but eventually it was the philosophy of Aquinas that prevailed in the Roman Catholic Church. After the Reformation, however, Ockham's view exerted influence on Protestant theologians. Meanwhile, it hastened the decline of Scholastic moral philosophy because it effectively removed ethics from the sphere of reason.

RENAISSANCE AND REFORMATION

The revival of Classical learning and culture that began in 15th-century Italy and then slowly spread throughout Europe did not give immediate birth to any major new ethical theories. Its significance for ethics lies, rather, in a change of focus. For the first time since the conversion of the Roman Empire to Christianity, man, not God, became the chief object of interest, and the theme was not religion but humanism—the powers, freedom, and accomplishments of human beings. This does not mean that there was a sudden conversion to atheism. Renaissance thinkers remained Christian and still considered human beings as somehow midway between the beasts and the angels. Yet, even this middle position meant that humans were special. It meant, too, a new conception of human dignity and of the importance of the individual.

Machiavelli. Although the Renaissance did not produce any outstanding moral philosophers, there is one writer whose work is of some importance in the history of ethics: the Italian author and statesman Niccolò Machiavelli. His book *Il principe* (1513; *The Prince*) offered advice to rulers as to what they must do to achieve their aims and secure their power. Its significance for ethics lies precisely in the fact that Machiavelli's advice ignores the usual ethical rules: "It is necessary for a prince, who wishes to maintain himself, to learn how not to be good, and to use this knowledge and not use it, according to the necessities of the case." There had not been so frank a rejection of morality since the Greek Sophists. So startling is the cynicism of Machiavelli's advice that it has been suggested that *Il principe* was an attempt to satirize the conduct of the princely rulers of Renaissance Italy. It may be more accurate, however, to view Machiavelli as an early political scientist, concerned only with setting out what human beings are like and how power is maintained, with no intention of passing moral judgment on the state of affairs described. In any case, *Il principe* gained instant notoriety, and Machiavelli's name became synonymous with political cynicism and deviousness. In spite of the chorus of condemnation, the work has led to a sharper appreciation of the difference between the lofty ethical systems of the philosophers and the practical realities of political life.

The first Protestants. It was left to the 17th-century English philosopher and political theorist Thomas Hobbes to take up the challenge of constructing an ethical system on the basis of so unflattering a view of human nature (see below). Between Machiavelli and Hobbes, however, there occurred the traumatic breakup of Western Christianity known as the Reformation. Reacting against the worldly immorality apparent in the Renaissance church, Martin Luther, John Calvin, and other leaders of the new Protestantism sought to return to the pure early Christianity of the Scriptures, especially the teachings of Paul, and of the Church Fathers, with Augustine foremost among them. They were contemptuous of Aristotle (Luther called him a "buffoon") and of non-Christian philosophers in general. Luther's standard of right and wrong was what God commands. Like William of Ockham, Luther insisted that the commands of God cannot be justified by any independent standard of goodness: good simply means what God commands. Luther did not believe these commands would be designed to satisfy human desires because he was convinced that desires are totally corrupt. In fact, he thought that human nature was totally corrupt. In any case, Luther insisted that one does not earn salvation by good works: one is justified by faith in Christ and receives salvation through divine grace.

Luther's standard of right and wrong

It is apparent that if these premises are accepted, there is little scope for human reason in ethics. As a result, no moral philosophy has ever had the kind of close association with any Protestant church that, say, the philosophy of Aquinas has had with Roman Catholicism. Yet, because Protestants emphasized the capacity of the individual to read and understand the Gospels without obtaining the authoritative interpretation of the church, the ultimate outcome of the Reformation was a greater freedom to

read and write independently of the church hierarchy. This made possible a new era of ethical thought.

From this time, too, distinctively national traditions of moral philosophy began to emerge; the British tradition, in particular, developed largely independently of ethics on the Continent. Accordingly, the present discussion will follow this tradition through the 19th century before returning to consider the different line of development in continental Europe.

THE BRITISH TRADITION: FROM HOBBES TO THE UTILITARIANS

Hobbes. Thomas Hobbes (1588–1679) is an outstanding example of the independence of mind that became possible in Protestant countries after the Reformation. God does, to be sure, play an honourable role in Hobbes's philosophy, but it is a dispensable role. The philosophical edifice stands on its own foundations; God merely crowns the apex. Hobbes was the equal of the Greek philosophers in his readiness to develop an ethical position based only on the facts of human nature and the circumstances in which humans live; and he surpassed even Plato and Aristotle in the extent to which he sought to do this by systematic deduction from clearly set out premises.

Hobbes started with a severe view of human nature: all of man's voluntary acts are aimed at self-pleasure or self-preservation. This position is known as psychological hedonism, because it asserts that the fundamental psychological motivation is the desire for pleasure. Like later psychological hedonists, Hobbes was confronted with the objection that people often seem to act altruistically. There is a story that Hobbes was seen giving alms to a beggar outside St. Paul's Cathedral. A clergyman sought to score a point by asking Hobbes if he would have given the money, had Christ not urged giving to the poor. Hobbes replied that he gave the money because it pleased him to see the poor man pleased. The reply reveals the dilemma that always faces those who propose startling new explanations for all human actions: either the theory is flagrantly at odds with how people really behave or else it must be broadened to such an extent that it loses much of what made it so shocking in the first place.

The psychological hedonism of Hobbes

Hobbes's account of "good" is equally devoid of religious or metaphysical premises. He defined good as "any object of desire," and insisted that the term must be used in relation to a person—nothing is simply good of itself independently of the person who desires it. Hobbes may therefore be considered a subjectivist. If one were to say, for example, of the incident just described, "What Hobbes did was good," this statement would not be objectively true or false. It would be good for the poor man, and, if Hobbes's reply was accurate, it would also be good for Hobbes. But if a second poor person, for instance, was jealous of the success of the first, that person could quite properly say that what Hobbes did was bad.

Remarkably, this unpromising picture of self-interested individuals who have no notion of good apart from their own desires serves as the foundation of Hobbes's account of justice and morality in his masterpiece, *Leviathan* (1651). Starting with the premises that humans are self-interested and the world does not provide for all their needs, Hobbes argued that in the state of nature, without civil society, there will be competition between men for wealth, security, and glory. The ensuing struggle is Hobbes's famous "war of all against all," in which there can be no industry, commerce, or civilization, and the life of man is "solitary, poor, nasty, brutish and short." The struggle occurs because each individual rationally pursues his or her own interests, but the outcome is in no one's interest.

How can this disastrous situation be ended? Not by an appeal to morality or justice; in the state of nature these ideas have no meaning. Yet, we want to survive and we can reason. Our reason leads us to seek peace if it is attainable but to continue to use all the means of war if it is not. How is peace to be obtained? Only by a social contract. We must all agree to give up our rights to attack others in return for their giving up their rights to attack us. By reasoning in order to increase our prospects for survival, we have found the solution.

We know that a social contract will solve our problems. Our reason therefore leads us to desire such an arrangement. But how is it to come about? My reason cannot tell me to accept it while others do not. Nor is Hobbes under the illusion that the mere making of a promise or contract will carry any weight. Since we are self-interested, we will keep our promises only if it is in our interest to do so. A promise that cannot be enforced is worthless. Therefore, in making the social contract, we must establish some means of enforcing it. To do this we must all hand our powers over to some other person or group of persons who will punish anyone who breaches the contract. This person or group of persons Hobbes calls the sovereign. It may be a single person, or an elected legislature, or almost any other form of government; the essence of sovereignty consists only in having sufficient power to keep the peace by punishing those who would break it. When such a sovereign—the Leviathan of his title—exists, justice becomes meaningful in that agreements or promises are necessarily kept. At the same time, each individual has adequate reason to be just, for the sovereign will ensure that those who do not keep their agreements are suitably punished.

Hobbes witnessed the turbulence and near anarchy of the English Civil Wars (1642–51) and was keenly aware of the dangers caused by disputed sovereignty. His solution was to insist that sovereignty must not be divided. Because the sovereign was appointed to enforce the social contract fundamental to peace and everything desired, it can only be rational to resist the sovereign if the sovereign directly threatens one's life. Hobbes was, in effect, a supporter of absolute sovereignty, and this has been the focus of much political discussion of his ideas. His significance for ethics, however, lies rather in his success in dealing with the subject independently of theology and of those quasi-theological or quasi-Aristotelian accounts that see the world as designed for the benefit of human beings. With this achievement, he brought ethics into the modern era.

Early intuitionists: Cudworth, More, and Clarke. There was, of course, immediate opposition to Hobbes's views. Ralph Cudworth (1617–88), one of a group known as the Cambridge Platonists, defended a position in some respects similar to that of Plato. That is to say, Cudworth believed the distinction between good and evil does not lie in human desires but is something objective and can be known by reason, just as the truths of mathematics can be known by reason. Cudworth was thus a forerunner of what has since come to be called intuitionism, the view that there are objective moral truths that can be known by a kind of rational intuition. This view was to attract the support of a line of distinguished thinkers until the 20th century when it became for a time the dominant view in British academic philosophy.

Henry More (1614–87), another leading member of the Cambridge Platonists, attempted to give effect to the comparison between mathematics and morality by listing moral axioms that can be seen as self-evidently true, just as the axioms of geometry are seen to be self-evident. In marked contrast to Hobbes, More included an axiom of benevolence: "If it be good that one man should be supplied with the means of living well and happily, it is mathematically certain that it is doubly good that two should be so supplied, and so on." Here, More was attempting to build on something that Hobbes himself accepted—namely, our own desire to be supplied with the means of living well. More, however, wanted to enlist reason to lead us beyond this narrow egoism to a universal benevolence. There are traces of this line of thought in the Stoics, but it was More who introduced it into British ethical thinking, wherein it is still very much alive.

More's axiom of benevolence

Samuel Clarke (1675–1729), the next major intuitionist, accepted More's axiom of benevolence in slightly different words. He was also responsible for a principle of equity, which, though derived from the Golden Rule so widespread in ancient ethics, was formulated with a new precision: "Whatever I judge reasonable or unreasonable for another to do for me, that by the same judgment I declare reasonable or unreasonable that I in the like case should do for him." As for the means by which these moral truths are known, Clarke accepted Cudworth's and

More's analogy with truths of mathematics and added the idea that what human reason discerns is a certain "fitness or unfitness" about the relationship between circumstances and actions. The right action in a given set of circumstances is the fitting one; the wrong action is unfitting. This is something known intuitively; it is self-evident.

Clarke's notion of fitness is obscure, but intuitionism faces a still more serious problem that has always been a barrier to its acceptance. Suppose we accept the ability of reason to discern that it would be wrong to deceive a person in order to profit from the deception. Why should our discerning this truth provide us with a motive sufficient to override our desire to profit? The intuitionist position divorces our moral knowledge from the forces that motivate us. The former is a matter of reason, the latter of desire.

The punitive power of Hobbes's sovereign is, of course, one way to provide sufficient motivation for obedience to the social contract and to the laws decreed by the sovereign as necessary for the peaceful functioning of society. The intuitionists, however, wanted to show that morality is objective and holds in all circumstances whether there is a sovereign or not. Reward and punishment in the afterlife, administered by an all-powerful God, would provide a more universal motive; and some intuitionists, such as Clarke, did make use of this divine sanction. Other thinkers, however, wanted to show that it is reasonable to do what is good independently of the threats of any external power, human or divine. This desire lay behind the development of the major alternative to intuitionism in 17th- and 18th-century British moral philosophy: moral sense theory. The debate between the intuitionist and moral sense schools of thought aired for the first time the major issue in what is still the central debate in moral philosophy: Is morality based on reason or on feelings?

Shaftesbury and the moral sense school. The term moral sense was first used by the 3rd Earl of Shaftesbury (1671–1713), whose writings reflect the optimistic tone both of the school of thought he founded and of so much of the philosophy of the 18th-century Enlightenment. Shaftesbury believed that Hobbes had erred by presenting a one-sided picture of human nature. Selfishness is not the only natural passion. We also have natural feelings directed to others: benevolence, generosity, sympathy, gratitude, and so on. These feelings give us an "affection for virtue," which leads us to promote the public interest. Shaftesbury called this affection the moral sense, and he thought it created a natural harmony between virtue and self-interest. Shaftesbury was, of course, realistic enough to acknowledge that we also have contrary desires and that not all of us are virtuous all of the time. Virtue could, however, be recommended because—and here Shaftesbury picked up a theme of Greek ethics—the pleasures of virtue are superior to the pleasures of vice.

Harmony between virtue and self-interest through moral sense

Butler on self-interest and conscience. Joseph Butler (1692–1752), a bishop of the Church of England, developed Shaftesbury's position in two ways. He strengthened the case for a harmony between morality and enlightened self-interest by claiming that happiness occurs as a by-product of the satisfaction of desires for things other than happiness itself. Those who aim directly at happiness do not find it; those who have their goals elsewhere are more likely to achieve happiness as well. Butler was not doubting the reasonableness of pursuing one's own happiness as an ultimate aim. He went so far as to say that "... when we sit down in a cool hour, we can neither justify to ourselves this or any other pursuit, till we are convinced that it will be for our happiness, or at least not contrary to it." He held, however, that direct and simple egoism is a self-defeating strategy. Egoists will do better for themselves by adopting immediate goals other than their own interests and living their everyday life in accordance with these more immediate goals.

Butler's second addition to Shaftesbury's account was the idea of conscience. This he saw as a second natural guide to conduct, alongside enlightened self-interest. Butler believed that there is no inconsistency between the two; he admitted, however, that skeptics may doubt "the happy tendency of virtue" and for them conscience can serve as an authoritative guide. Just what reason these skeptics have to follow conscience, if they believe its guidance to be contrary to their own happiness, is something that Butler did not adequately explain. Nevertheless, his introduction of conscience as an independent source of moral reasoning reflects an important difference between ancient and modern ethical thinking. The Greek and Roman philosophers would have had no difficulty in accepting everything Butler said about the pursuit of happiness, but they would not have understood his idea of another independent source of rational guidance. Although Butler insisted that the two operate in harmony, this was for him a fortunate fact about the world and not a necessary principle of reason. Thus his recognition of conscience opened the way for later formulations of a universal principle of conduct at odds with the path indicated by even the most enlightened self-interested reasoning.

Conscience is a rational guide to conduct

The climax of moral sense theory: Hutcheson and Hume. The moral sense school reached its fullest development in the works of two Scottish philosophers, Francis Hutcheson (1694–1746) and David Hume (1711–76). Hutcheson was concerned with showing, against the intuitionists, that moral judgment cannot be based on reason and therefore must be a matter of whether an action is "amiable or disagreeable" to one's moral sense. Like Butler's notion of conscience, Hutcheson's moral sense does not find pleasing only, or even predominantly, those actions that are in one's own interest. On the contrary, Hutcheson conceived moral sense as based on a disinterested benevolence. This led him to state, as the ultimate criterion of the goodness of an action, a principle that was to serve as the basis for the Utilitarian reformers: "that action is best which procures the greatest happiness for the greatest numbers . . . ."

Hume, like Hutcheson, held that reason cannot be the basis of morality. His chief ground for this conclusion was that morality is essentially practical: there is no point in judging something good if the judgment does not incline us to act accordingly. Reason alone, however, Hume regarded as "the slave of the passions." Reason can show us how best to achieve our ends, but it cannot determine our ultimate desires and is incapable of moving us to action except in accordance with some prior want or desire. Hence, reason cannot give rise to moral judgments.

This is an important argument that is still employed in the debate between those who believe that morality is based on reason and those who base it instead on emotion or feelings. Hume's conclusion certainly follows from his premises. Can either premise be denied? We have seen that intuitionists such as Cudworth and Clarke maintained that reason can lead to action. Reason, they would have said, leads us to see a particular action as fitting in given circumstances and therefore to do it. Hume would have none of this. "Tis not contrary to reason," he provocatively asserted, "to prefer the destruction of the whole world to the scratching of my finger." To show that he was not embracing the view that only egoism is rational, Hume continued: "Tis not contrary to reason to choose my total ruin, to prevent the least uneasiness of an Indian or person wholly unknown to me." His point was simply that to have these preferences is to have certain desires or feelings; they are not matters of reason at all. The intuitionists might insist that moral and mathematical reasoning are analogous, but this analogy was not helpful here. We can know a truth of geometry and not be motivated to act in any way.

What of Hume's other premise that morality is essentially practical and moral judgments must lead to action? This can be denied more easily. We could say that moral judgments merely tell us what is right or wrong. They do not lead to action unless we want to do what is right. Then Hume's argument would do nothing to undermine the claim that moral judgments are based on reason. But there is a price to pay. The terms right and wrong lose much of their force. We can no longer assert that those who know what is right but do what is wrong are in any way irrational. They are just people who do not happen to have the desire to do what is right. This desire—because it leads to action—must be acknowledged to be based on feeling rather than reason. Denying that morality is necessarily action-guiding means abandoning the idea, so important

to those defending the objectivity of morality, that some things are objectively required of all rational beings.

Hume's forceful presentation of this argument against a rational basis for morality would have been enough to earn him a place in the history of ethics, but it is by no means his only achievement in this field. In *A Treatise of Human Nature* (1739–40) Hume points, almost as an afterthought, to the fact that writers on morality regularly start by making various observations about human nature or about the existence of a god—all statements of fact about what is the case—and then suddenly switch to statements about what ought or ought not be done. Hume says that he cannot conceive how this new relationship of "ought" can be deduced from the preceding statements that were related by "is"; and he suggests these authors should explain how this deduction is to be achieved. The point has since been called Hume's Law and taken as proof of the existence of a gulf between facts and values, or between "is" and "ought." This places too much weight on Hume's brief and ironic comment, but there is no doubt that many writers, both before and after Hume, have argued as if values could easily be deduced from facts. They can usually be found to have smuggled values in somewhere. Attention to Hume's Law makes it easy for us to detect such logically illicit contraband.

Hume's Law

Hume's positive account of morality is in line with that of the moral sense school: "The hypothesis which we embrace is plain. It maintains that morality is determined by sentiment. It defines virtue to be whatever mental action or quality gives to a spectator the pleasing sentiment of approbation; and vice the contrary." In other words, Hume takes moral judgments to be based on a feeling. They do not reflect any objective state of the world. Having said that, however, it may still be asked whether this feeling is one that is common to all of us or one that varies from individual to individual. If Hume gives the former answer, moral judgments retain a kind of objectivity. While they do not reflect anything out there in the universe apart from human feelings, one's judgments may be true or false depending on whether they capture this universal human moral sentiment. If, on the other hand, the feeling varies from one individual to the next, moral judgments become entirely subjective. People's judgments would express their own feelings, and to reject someone else's judgment as wrong would merely be to say that one's own feelings were different.

Hume does not make entirely clear which of these two views he holds; but if he is to avoid breaching his own rule about not deducing an "ought" from an "is," he cannot hold that a moral judgment can follow logically from a description of the feelings that an action gives to a particular group of spectators. From the mere existence of a feeling we cannot draw the inference that we ought to obey it. For Hume to be consistent on this point—and even with his central argument that moral judgments must move to action—the moral judgment must be based not on the fact that all people, or most people, or even the speaker, have a certain feeling; it must rather be based on the actual experience of the feeling by whoever accepts the judgment. This still leaves it open whether the feeling is common to all or limited to the person accepting the judgment, but it shows that, in either case, the "truth" of a judgment for any individual depends on whether that individual actually has the appropriate feeling. Is this "truth" at all? As will be seen below, 20th-century philosophers with views broadly similar to Hume's have suggested that moral judgments have a special kind of meaning not susceptible of truth or falsity in the ordinary way.

The intuitionist response: Price and Reid. Powerful as they were, Hume's arguments did not end the debate between the moral sense theorists and the intuitionists. They did, however, lead Richard Price (1723–91), Thomas Reid (1710–96), and later intuitionists to abandon the idea that moral truths can be established by some process of demonstrative reasoning akin to that used in mathematics. Instead, these proponents of intuitionism took the line that our notions of right and wrong are simple, objective ideas, directly perceived by us and not further analyzable into anything such as "fitness." We know of these ideas, not through any moral sense based on feelings, but rather through a faculty of reason or of the intellect that is capable of discerning truth. Since Hume, this has been the only plausible form of intuitionism. Yet, Price and Reid failed to explain adequately just what are the objective moral qualities that we perceive directly and how they connect with the actions we choose.

Utilitarianism. At this point the argument over whether morality is based on reason or feelings was temporarily exhausted, and the focus of British ethics shifted from such questions about the nature of morality as a whole to an inquiry into which actions are right and which are wrong. Today, the distinction between these two types of inquiry would be expressed by saying that whereas the 18th-century debate between intuitionism and the moral sense school dealt with questions of metaethics, 19th-century thinkers became chiefly concerned with questions of normative ethics. The positions we take in metaethics over whether ethics is objective or subjective, for example, do not tell us what we ought to do. That task is the province of normative ethics.

Paley. The impetus to the discussion of normative ethics was provided by the challenge of Utilitarianism. The essential principle of Utilitarianism was, as noted above, put forth by Hutcheson. Curiously, it gained further development from the widely read theologian William Paley (1743–1805), who provides a good example of the independence of metaethics and normative ethics. His position on the nature of morality was similar to that of Ockham and Luther—namely, he held that right and wrong are determined by the will of God. Yet, because he believed that God wills the happiness of his creatures, his normative ethics were Utilitarian: whatever increases happiness is right; whatever diminishes it is wrong.

Bentham. Notwithstanding these predecessors, Jeremy Bentham (1748–1832) is properly considered the father of modern Utilitarianism. It was he who made the Utilitarian principle serve as the basis for a unified and comprehensive ethical system that applies, in theory at least, to every area of life. Never before had a complete, detailed system of ethics been so consistently constructed from a single fundamental ethical principle.

Bentham as the father of modern Utilitarianism

Bentham's ethics began with the proposition that nature has placed human beings under two masters: pleasure and pain. Anything that seems good must either be directly pleasurable, or thought to be a means to pleasure or to the avoidance of pain. Conversely, anything that seems bad must either be directly painful, or thought to be a means to pain or to the deprivation of pleasure. From this Bentham argued that the words right and wrong can only be meaningful if they are used in accordance with the Utilitarian principle, so that whatever increases the net surplus of pleasure over pain is right and whatever decreases it is wrong.

Bentham then set out how we are to weigh the consequences of an action, and thereby decide whether it is right or wrong. We must, he says, take account of the pleasures and pains of everyone affected by the action, and this is to be done on an equal basis: "Each to count for one, and none for more than one." (At a time when Britain had a major trade in slaves, this was a radical suggestion; and Bentham went further still, explicitly extending consideration to nonhuman animals as well.) We must also consider how certain or uncertain the pleasures and pains are, their intensity, how long they last, and whether they tend to give rise to further feelings of the same or of the opposite kind.

Bentham did not allow for distinctions in the quality of pleasure or pain as such. Referring to a popular game, he affirmed that "quantity of pleasure being equal, pushpin is as good as poetry." This led his opponents to characterize his philosophy as one fit for pigs. The charge is only half true. Bentham could have defended a taste for poetry on the grounds that whereas one tires of mere games, the pleasures of a true appreciation of poetry have no limit; thus the quantities of pleasure obtained by poetry are greater than those obtained by pushpin. All the same, one of the strengths of Bentham's position is its honest bluntness, which it owes to his refusal to be fazed by the

contrary opinions either of conventional morality or of refined society. He never thought that the aim of Utilitarianism was to explain or justify ordinary moral views; it was, rather, to reform them.

Mill. John Stuart Mill (1806–73), Bentham's successor as the leader of the Utilitarians and the most influential British thinker of the 19th century, had some sympathy for the view that Bentham's position was too narrow and crude. His essay "Utilitarianism" (1861) introduced several modifications, all aimed at a broader view of what is worthwhile in human existence and at implications less shocking to established moral convictions. Although his position was based on the maximization of happiness (and this is said to consist in pleasure and the absence of pain), he distinguished between pleasures that are higher and those that are lower in quality. This enabled him to say that it is "better to be Socrates dissatisfied than a fool satisfied." The fool, he argued, would only be of a different opinion because he did not know both sides of the question.

Mill sought to show that Utilitarianism is compatible with moral rules and principles relating to justice, honesty, and truthfulness by arguing that Utilitarians should not attempt to calculate before each action whether that specific action will maximize utility. Instead, they should be guided by the fact that an action falls under a general principle (such as the principle that we should keep our promises), and adherence to that general principle tends to increase happiness. Only under special circumstances is it necessary to consider whether an exception may have to be made.

Sidgwick. Mill's easily readable prose ensured a wide audience for his exposition of Utilitarianism, but as a philosopher he was markedly inferior to the last of the 19th-century Utilitarians, Henry Sidgwick (1838–1900). Sidgwick's *Methods of Ethics* (1874) is the most detailed and subtle work of Utilitarian ethics yet produced. Especially noteworthy is his discussion of the various principles accepted by what he calls common sense morality—*i.e.,* the morality accepted by most people without systematic thought. Price, Reid, and some adherents of their brand of intuitionism thought that such principles (*e.g.,* those of truthfulness, justice, honesty, benevolence, purity, and gratitude) were self-evident, independent moral truths. Sidgwick was himself an intuitionist as far as the basis of ethics was concerned: he believed that the principle of Utilitarianism must ultimately be based on a self-evident axiom of rational benevolence. Nonetheless, he strongly rejected the view that all principles of common sense morality are themselves self-evident. He went on to demonstrate that the allegedly self-evident principles conflict with one another and are vague in their application. They could only be part of a coherent system of morality, he argued, if they were regarded as subordinate to the Utilitarian principle, which defined their application and resolved the conflicts between them.

Attempt at reconciling common sense morality and Utilitarianism

Sidgwick was satisfied that he had reconciled common sense morality and Utilitarianism by showing that whatever was sound in the former could be accounted for by the latter. He was, however, troubled by his inability to achieve any such reconciliation between Utilitarianism and egoism, the third method of ethical reasoning dealt with in his book. True, Sidgwick regarded it as self-evident that "from the point of view of the universe" one's own good is of no greater value than the like good of any other person, but what could be said to the egoist who expresses no concern for the point of view of the universe, taking his stand instead on the fact that his own good mattered more to him than anyone else's? Bentham had apparently believed either that self-interest and the general happiness are not at odds or that it is the legislator's task to reward or punish actions so as to see that they are not. Mill also had written of the need for sanctions but was more concerned with the role of education in shaping human nature in such a way that one finds happiness in doing what benefits all. By contrast, Sidgwick was convinced that this could lead at best to a partial overlap between what is in one's own interest and what is in the interest of all. Hence, he searched for arguments with which to convince the egoist of the rationality of universal benevolence but failed to find any. *The Methods of Ethics* concludes with an honest admission of this failure and an expression of dismay at the fact that, as a result, ". . . it would seem necessary to abandon the idea of rationalizing [morality] completely."

THE CONTINENTAL TRADITION: FROM SPINOZA TO NIETZSCHE

Spinoza. If Hobbes is to be regarded as the first of a distinctively British philosophical tradition, the Dutch-Jewish philosopher Benedict Spinoza (1632–77) appropriately occupies the same position in continental Europe. Unlike Hobbes, Spinoza did not provoke a long-running philosophical debate. In fact, his philosophy was neglected for a century after his death and was in any case too much of a self-contained system to invite debate. Nevertheless, Spinoza held positions on crucial issues that were in sharp contrast to those taken by Hobbes, and these differences were to grow over the centuries during which British and continental European philosophy followed their own paths.

The first of these contrasts with Hobbes is Spinoza's attitude toward natural desires. As has been noted, Hobbes took self-interested desire for pleasure as an unchangeable fact about human nature and proceeded to build a moral and political system to cope with it. Spinoza did just the opposite. He saw natural desires as a form of bondage. We do not choose to have them of our own will. Our will cannot be free if it is subject to forces outside itself. Thus our real interests lie not in satisfying these desires but in transforming them by the application of reason. Spinoza thus stands in opposition not only to Hobbes but also to the position later to be taken by Hume, for Spinoza saw reason not as the slave of the passions but as their master.

The second important contrast is that while individual humans and their separate interests are always assumed in Hobbes's philosophy, this separation is simply an illusion from Spinoza's viewpoint. Everything that exists is part of a single system, which is at the same time nature and God. (One possible interpretation of this is that Spinoza was a pantheist, believing that God exists in every aspect of the world and not apart from it.) We, too, are part of this system and are subject to its rationally necessary laws. Once we know this, we understand how irrational it would be to desire that things should be different from the way they are. This means that it is irrational to envy, to hate, and to feel guilt, for these emotions presuppose the possibility of things being different. So we cease to feel such emotions and find peace, happiness, and even freedom—in Spinoza's terms the only freedom there can be—in understanding the system of which we are a part.

A view of the world so different from our everyday conceptions as that of Spinoza's cannot be made to seem remotely plausible when presented in summary form. To many philosophers it remains implausible even when complete. Its value for ethics, however, lies not in its validity as a whole, but in the introduction into continental European philosophy of a few key ideas: that our everyday nature may not be our true nature; that we are part of a larger unity; and that freedom is to be found in following reason.

Leibniz. The German philosopher and mathematician Gottfried Wilhelm Leibniz (1646–1716), the next great figure in the Rationalist tradition, gave scant attention to ethics, perhaps because of his belief that the world is governed by a perfect God, and hence must be the best of all possible worlds. As a result of Voltaire's hilarious parody in *Candide* (1758), this position has achieved a certain notoriety. It is not generally recognized, however, that it does at least provide a consistent solution to a problem that has baffled thinking Christians for many centuries: How can there be evil in a world governed by an all-powerful, all-knowing, and all-good God? Leibniz's solution may not be plausible, but there may be no better one if the above premises are allowed to pass unchallenged.

Rousseau. It was the French philosopher and writer Jean-Jacques Rousseau (1712–78) who took the next step. His *Discours sur l'origine et les fondements de l'inégalité parmi les hommes* (1755; *A Discourse upon the Origin and*

Foundation of the Inequality Among Mankind) depicted a state of nature very different from that described by Hobbes as well as from Christian conceptions of original sin. Rousseau's "noble savages" lived isolated, trouble-free lives, supplying their simple wants from the abundance that nature provided and even coming to each other's aid in times of need. Only when someone claimed possession of a piece of land did laws have to be introduced, and with them came civilization and all its corrupting influences. This is, of course, a message that resembles one of Spinoza's key points: The human nature we see before us in our fellow citizens is not the only possibility; somewhere, there is something better. If we can find a way to reach it, we will have found the solution to our ethical and social problems.

Rousseau revealed his route in his *Contrat social* (1762; *A Treatise on the Social Compact*, or *Social Contract*). It required rule by the "general will." This may sound like democracy and, in a sense, it was democracy that Rousseau advocated; but his conception of rule by the general will is very different from the modern idea of democratic government. Today, we assume that in any society the interests of different citizens will be in conflict, and that as a result for every majority that succeeds in having its will implemented there will be a minority that fails to do so. For Rousseau, on the other hand, the general will is not the sum of all the individual wills in the community but the true common will of all the citizens. Even if a person dislikes and opposes a decision carried by the majority, that decision represents the general will, the common will in which he shares. For this to be possible, Rousseau must be assuming that there is some common good in which all human beings share and hence that their true interests coincide. As man passes from the state of nature to civil society, he has to "consult his reason rather than study his inclinations." This is not, however, a sacrifice of his true interests, for in following reason he ceases to be a slave to "physical impulses" and so gains moral freedom.

Rousseau's notion of general will

This leads to a picture of civilized human beings as divided selves. The general will represents the rational will of every member of the community. If an individual opposes the decision of the general will, his opposition must stem from his physical impulses and not from his true, autonomous will. For obvious reasons, this idea was to find favour with such autocratic leaders of the French Revolution as Robespierre. It also had a much less sinister influence on one of the outstanding philosophers of modern times: Immanuel Kant of Germany.

Kant. Interestingly, Kant (1724–1804) acknowledged that he had despised the ignorant masses until he read Rousseau and came to appreciate the worth that exists in every human being. For other reasons too, Kant is part of the tradition deriving from both Spinoza and Rousseau. Like his predecessors, Kant insisted that actions resulting from desires cannot be free. Freedom is to be found only in rational action. Moreover, whatever is demanded by reason must be demanded of all rational beings; hence, rational action cannot be based on a single individual's personal desires, but must be action in accordance with something that he can will to be a universal law. This view roughly parallels Rousseau's idea of the general will as that which, as opposed to the individual will, a person shares with the whole community. Kant extended this community to all rational beings.

Kant's most distinctive contribution to ethics was his insistence that our actions possess moral worth only when we do our duty for its own sake. He first introduced this idea as something accepted by our common moral consciousness and only then tried to show that it is an essential element of any rational morality. In claiming that this idea is central to the common moral consciousness, Kant was expressing in heightened form a tendency of Judeo-Christian ethics and revealing how much the Western ethical consciousness had changed since the time of Socrates, Plato, and Aristotle.

Does our common moral consciousness really insist that there is no moral worth in any action done for any motive other than duty? Certainly we would be less inclined to praise the young man who plunges into the surf to rescue a drowning child if we learned that he did it because he expected a handsome reward from the child's millionaire father. This feeling lies behind Kant's disagreement with all those moral philosophers who have argued that we should do what is right because that is the path to happiness, either on earth or in heaven. But Kant went further than this. He was equally opposed to those who see benevolent or sympathetic feelings as the basis of morality. Here he may be reflecting the moral consciousness of 18th-century Protestant Germany, but it appears that even then the moral consciousness of Britain, as reflected in the writings of Shaftesbury, Hutcheson, Butler, and Hume, was very different. The moral consciousness of Western civilization in the last quarter of the 20th century also appears to be different from the one Kant was describing.

Kant's ethics is based on his distinction between hypothetical and categorical imperatives. He called any action based on desires a hypothetical imperative, meaning by this that it is a command of reason that applies only if we desire the goal. For example, "Be honest, so that people will think well of you!" is an imperative that applies only if you want people to think well of you. A similarly hypothetical analysis can be given of the imperatives suggested by, say, Shaftesbury's ethics: "Help those in distress, if you sympathize with their sufferings!" In contrast to such approaches to ethics, Kant said that the commands of morality must be categorical imperatives: they must apply to all rational beings, regardless of their wants and feelings. To most philosophers this poses an insuperable problem: a moral law that applied to all rational beings, irrespective of their personal wants and desires, could have no specific goals or aims because all such aims would have to be based on someone's wants or desires. It took Kant's peculiar genius to seize upon precisely this implication, which to others would have refuted his claims, and to use it to derive the nature of the moral law. Because nothing else but reason is left to determine the content of the moral law, the only form this law can take is the universal principle of reason. Thus the supreme formal principle of Kant's ethics is: "Act only on that maxim through which you can at the same time will that it should become a universal law."

The dictates of morality as categorical imperatives

Kant still faced two major problems. First, he had to explain how we can be moved by reason alone to act in accordance with this supreme moral law; and, second, he had to show that this principle is able to provide practical guidance in our choices. If we were to couple Hume's theory that reason is always the slave of the passions with Kant's denial of moral worth to all actions motivated by desires, the outcome would be that no actions can have moral worth. To avoid such moral skepticism, Kant maintained that reason alone can lead to action. Unfortunately he was unable to say much in defense of this claim. Of course, the mere fact that we otherwise face so unpalatable a conclusion is in itself a powerful incentive to believe that somehow a categorical imperative must be possible, but this is not convincing to anyone not already wedded to Kant's view of moral worth. At one point Kant appeared to be taking a different line. He wrote that the moral law inevitably produces in us a feeling of reverence or awe. If he meant to say that this feeling then becomes the motivation for obedience, however, he was conceding Hume's point that reason alone is powerless to bring about action. It would also be difficult to accept that anything, even the moral law, can necessarily produce a certain kind of feeling in all rational beings regardless of their psychological constitution. Thus this approach does not succeed in clarifying Kant's position or rendering it plausible.

Kant gave closer attention to the problem of how his supreme formal principle of morality can provide guidance in concrete situations. One of his examples is as follows. Suppose that I plan to get some money by promising to pay it back, although I have no intention of keeping my promise. The maxim of such an action might be "Make false promises when it suits you to do so." Could such a maxim be a universal law? Of course not. If promises were so easily broken, no one would rely on them, and the practice of promising would cease. For this reason,

I know that the moral law does not allow me to carry out my plan.

Not all situations are so easily decided. Another of Kant's examples deals with aiding those in distress. I see someone in distress, whom I could easily help, but I prefer not to do so. Can I will as a universal law the maxim that a person should refuse assistance to those in distress? Unlike the case of promising, there is no strict inconsistency in this maxim being a universal law. Kant, however, says that I cannot will it to be such because I may someday be in distress myself, and I would then want assistance from others. This type of example is less convincing than the previous one. If I value self-sufficiency so highly that I would rather remain in distress than escape from it through the intervention of another, Kant's principle no longer tells me that I have a duty to assist those in distress. In effect, Kant's supreme principle of practical reason can only tell us what to do in those special cases in which turning the maxim of our action into a universal law yields a contradiction. Outside this limited range, the moral law that was to apply to all rational beings regardless of their wants and desires cannot guide us except by appealing to our desires.

Kant does offer alternative formulations of the categorical imperative, and one of these has been seen as providing more substantial guidance than the formulation so far considered. This formulation is: "So act that you treat humanity in your own person and in the person of everyone else always at the same time as an end and never merely as means." The connection between this formulation and the first one is not entirely clear, but the idea seems to be that when I choose for myself I treat myself as an end. If, therefore, in accordance with the principle of universal law, I must choose so that all could choose similarly, I must respect everyone else as an end. Even if this is valid, the application of the principle raises further questions. What is it to treat someone merely as a means? Using a person as a slave is an obvious example; Kant, like Bentham, was making a stand against this kind of inequality while it still flourished as an institution in some parts of the world. But to condemn slavery we have only to give equal weight to the interests of the slaves. Does Kant's principle take us any further than Utilitarianism? Modern Kantians hold that it does because they interpret it as denying the legitimacy of sacrificing the rights of one human being in order to benefit others.

The deontological nature of Kant's ethics

One thing that can be said confidently is that Kant was firmly opposed to the Utilitarian principle of judging every action by its consequences. His ethics is a deontology. In other words, the rightness of an action depends on whether it accords with a rule irrespective of its consequences. In one essay Kant went so far as to say that it would be wrong to tell a lie even to a would-be murderer who came to your door seeking to kill an innocent person hidden in your house. This kind of situation illustrates how difficult it is to remain a strict deontologist when principles may clash. Apparently Kant believed that his principle of universal law required that one never tell lies, but it could also be argued that his principle of treating everyone as an end would necessitate doing everything possible to save the life of an innocent person. Another possibility would be to formulate the maxim of the action with sufficient precision to define the circumstances under which it would be permissible to tell lies—*e.g.*, we could all agree to a universal law that permitted lies to people intending to commit murder. Kant did not explore such solutions.

Hegel. Kant's philosophy deeply affected subsequent German thought, but there were several aspects of it that troubled later thinkers. One of these was his portrayal of human nature as irreconcilably split between reason and emotion. In *Briefe über die ästhetische Erziehung des Menschen* (1795; *Letters on the Aesthetic Education of Man*), the dramatist and literary theorist Friedrich Schiller suggested that while this might apply to modern human beings, it was not the case in ancient Greece where reason and feeling seemed to have been in harmony. (There is, as suggested earlier, some basis for this claim insofar as the Greek moral consciousness did not make the modern distinction between morality and self-interest.) Schiller's suggestion may have been the spark that led Georg Wilhelm Friedrich Hegel (1770–1831) to develop the first philosophical system that has historical change as its core.

As Hegel presents it, all of history is the progress of mind or spirit along a logically necessary path that leads to freedom. Human beings are manifestations of this universal mind, although at first they do not realize this. Freedom cannot be achieved until human beings do realize it, and so feel at home in the universe. There are echoes of Spinoza in Hegel's idea of mind as something universal and also in his conception of freedom as based on knowledge. What is original, however, is the way in which all of history is presented as leading to the goal of freedom. Thus Hegel accepts Schiller's view that for the ancient Greeks, reason and feeling were in harmony, but he sees this as a naive harmony that could exist only as long as the Greeks did not see themselves as free individuals with a conscience independent of the views of the community. For freedom to develop, it was necessary for this harmony to break down. This occurred as a result of the Reformation, with its insistence on the right of individual conscience. But the rise of individual conscience left human beings divided between conscience and self-interest, between reason and feeling. We have seen how many philosophers tried unsuccessfully to bridge this gulf until Kant's insistence that we must do our duty for duty's sake made the division an apparently inevitable part of moral life. For Hegel, however, it can be overcome by a synthesis of the harmonious communal nature of Greek life with the modern freedom of individual conscience.

The concept of the organic community

In *Naturrecht und Staatswissenschaft im Grundrisse*, alternatively entitled *Grundlinien der Philosophie des Rechts* (1821; *The Philosophy of Right*), Hegel described how this synthesis could be achieved in an organic community. The key to his solution is the recognition that human nature is not fixed but is shaped by the society in which one lives. The organic community would foster those desires that most benefit the community. It would imbue its members with the sense that their own identity consists in being a part of the community, so that they would no more think of going off in pursuit of their own private interests than one's left arm would think of going off without the rest of the body. Nor should it be forgotten that such organic relationships are reciprocal: the organic community will no more disregard the interests of its members than an individual would disregard an injury to his or her arm. Harmony would thus prevail but not the naive harmony of ancient Greece. The citizens of Hegel's organic community do not obey its laws and customs simply because they are there. With the independence of mind characteristic of modern times, they can only give their allegiance to institutions that they recognize as conforming to rational principles. The modern organic state, unlike the ancient Greek city-state, is self-consciously based on rationally selected principles.

Hegel provided a new approach to the ancient problem of reconciling morality and self-interest. Others had accepted the problem as part of the inevitable nature of things and looked for ways around it. Hegel looked at it historically and saw it as a problem only in a certain type of society. Instead of solving the problem as it existed, he looked to the emergence of a new form of society in which it would disappear. In this way Hegel claimed to have overcome one great problem that was insoluble for Kant.

Hegel also believed that he had the solution to the other key weakness in Kant's ethics—namely, the difficulty of giving content to the supreme formal moral principle. In Hegel's organic community, the content of our moral duty would be given to us by our position in society. We would know that our duty was to be a good parent, a good citizen, a good teacher, merchant, or soldier, as the case might be. It is an ethic that has been called "my station and its duties." It might be thought that this is a limited, conservative conception of what we ought to do with our lives, especially when compared with Kant's principle of universal law, which does not base what we ought to do on what our particular station in society happens to be. Hegel would have replied that because the organic community is

based on universally valid principles of reason, it complies with Kant's principle of universal law. Moreover, without the specific content provided by the concrete institutions and practices of a society, that principle would remain an empty formula.

Hegel's philosophy has both a conservative and a radical side. The conservative aspect is reflected in the ethic of "my station and its duties," and even more strongly in the significant resemblance between Hegel's detailed description of the organic society and the actual institutions of the Prussian state in which he lived and taught for the last decade of his life. This resemblance, however, was in no way a necessary implication of Hegel's philosophy as a whole. After Hegel's death, a group of his more radical followers known as the Young Hegelians hailed the manner in which he had demonstrated the need for a new form of society to overcome the separation between self and community but scorned the implication that the state in which they were living could be this solution to all the problems of history. Among this group was a young student named Karl Marx.

Marx. Marx (1818–83) has often been presented by his followers as a scientist rather than a moralist. He did not deal directly with the ethical issues that occupied the philosophers so far discussed. His Materialist conception of history is, rather, an attempt to explain all ideas, whether political, religious, or ethical, as the product of the particular economic stage that society has reached. Thus a feudal society will regard loyalty and obedience to one's lord as the chief virtues. A capitalist economy, on the other hand, requires a mobile labour force and expanding markets, so that freedom, especially the freedom to sell one's labour, is its key ethical conception. Because Marx saw ethics as a mere by-product of the economic basis of society, he frequently took a dismissive stance toward it. Echoing the Sophist Thrasymachus, Marx said that the "ideas of the ruling class are in every epoch the ruling ideas." With his coauthor Friedrich Engels, he was even more scornful in the *Manifest der Kommunistischen Partei* (1848; *The Communist Manifesto*), in which morality, law, and religion are referred to as "so many bourgeois prejudices behind which lurk in ambush just as many bourgeois interests."

A sweeping rejection of ethics, however, is difficult to reconcile with the highly moralistic tone of Marx's condemnation of the miseries the capitalist system inflicts upon the working class and with his obvious commitment to hastening the arrival of the Communist society that will end such iniquities. After Marx died, Engels tried to explain this apparent inconsistency by saying that as long as society was divided into classes, morality would serve the interests of the ruling class. A classless society, on the other hand, would be based on a truly human morality that served the interests of all human beings. This does make Marx's position consistent by setting him up as a critic, not of ethics as such, but rather of the class-based moralities that would prevail until the Communist revolution.

By studying Marx's earlier writings—those produced when he was a Young Hegelian—one obtains a slightly different, though not incompatible, impression of the place of ethics in Marx's thought. There seems no doubt that the young Marx, like Hegel, saw human freedom as the ultimate goal. He also held, as did Hegel, that freedom could only be obtained in a society in which the dichotomy between private interest and the general interest had disappeared. Under the influence of socialist ideas, however, he formed the view that merely knowing what was wrong with the world would not achieve anything. Only the abolition of private property could lead to the transformation of human nature and so bring about the reconciliation of the individual and the community. Theory, Marx concluded, had gone as far as it could; even the theoretical problems of ethics, as illustrated in Kant's division between reason and feeling, would remain insoluble unless one moved from theory to practice. This is what Marx meant in the famous thesis that is engraved on his tombstone: "The philosophers have only interpreted the world, in various ways; the point is to change it." The goal of changing the world stemmed from Marx's attempt to overcome one of the central problems of ethics; the means now passed beyond philosophy.

Nietzsche. Friedrich Nietzsche (1844–1900) was a literary and social critic, not a systematic philosopher. In ethics, the chief target of his criticism is the Judeo-Christian tradition. He describes Jewish ethics as a "slave morality" based on envy. Christian ethics is, in his opinion, even worse because it makes a virtue of meekness, poverty, and humility, telling one to turn the other cheek rather than to struggle. It is the ethics of the weak, who hate and fear strength, pride, and self-affirmation. Such an ethics undermines the human drives that have led to the greatest and most noble human achievements.

Nietzsche thought the era of traditional religion to be over: "God is dead," perhaps his most widely repeated aphorism, was his paradoxical way of putting it. Yet, what was to be put in its place? Nietzsche took from Aristotle the concept of greatness of soul, the unchristian virtue that included nobility and a justified pride in one's achievements. He suggested a reevaluation of values that would lead to a new ideal: the *Übermensch,* a term usually translated as "Superman" and given connotations that suggest that Nietzsche would have regarded Hitler as an ideal type. Nietzsche's praise of "the will to power" is taken as further evidence that he would have approved of Hitler. This interpretation owes much to Nietzsche's racist sister, who after his death compiled a volume of his unpublished writings, arranging them to make it appear that he was a forerunner of Nazi thinking. This is at best a partial truth. Nietzsche was almost as contemptuous of pan-German racism and anti-Semitism as he was of the ethics of Judaism and Christianity. What Nietzsche meant by *Übermensch* was a person who could rise above the limitations of ordinary morality; and by "the will to power" it seems that Nietzsche had in mind self-affirmation and not necessarily the use of power to oppress others.

The concept of the *Übermensch* and its implications

Nevertheless, Nietzsche left himself wide open to those who wanted his philosophical imprimatur for their crimes against humanity. His belief in the importance of the *Übermensch* made him talk of ordinary people as "the herd," who did not really matter. In *Jenseits von Gut und Böse* (1886; *Beyond Good and Evil*), he wrote with approval of "the distinguished type of morality," according to which "one has duties only toward one's equals; toward beings of a lower rank, toward everything foreign to one, one may act as one sees fit, 'as one's heart dictates' "—in any event, beyond good and evil. The point is that the *Übermensch* is above all ordinary moral standards: "The distinguished type of human being feels *himself* as value-determining; he does not need to be ratified; he judges 'that which is harmful to me is harmful as such'; he knows that *he* is the something which gives value to objects; he *creates values.*" In this Nietzsche was a forerunner of Existentialism rather than Nazism, but then Existentialism, precisely because it gives no basis for choosing other than authenticity, is not incompatible with Nazism.

Nietzsche's position on ethical matters represents a stark contrast to that of Henry Sidgwick, the last major figure of 19th-century British ethics treated in this article. Sidgwick believed in objective standards for ethical judgments and thought that the subject of ethics had over the centuries made progress toward these standards. He saw his own work as building carefully on that progress. Nietzsche, on the other hand, would have us sweep away everything since Greek ethics and not keep much of that either. The superior types would then be able to freely create their own values as they saw fit.

20th-century Western ethics

The brief historical survey of Western ethics from Socrates to the 20th century provided above has shown three constant themes. Since the Sophists, there have been (1) disagreements over whether ethical judgments are truths about the world or only reflections of the wishes of those who make them; (2) frequent attempts to show, in the face of considerable skepticism, either that it is in one's own interests to do what is good or that, even though this is not necessarily in one's own interests, it is the ratio-

nal thing to do; and (3) repeated debates over just what goodness and the standard of right and wrong might be. The 20th century has seen new twists to these old themes and an increased attention to the application of ethics to practical problems. Each of these major questions is considered below in terms of metaethics, normative ethics, and applied ethics.

METAETHICS

As previously noted, metaethics deals not with substantive ethical theories or moral judgments but rather with questions about the nature of these theories and judgments. Among 20th-century philosophers in English-speaking countries, those defending the objectivity of ethical judgments have most often been intuitionists or naturalists; those taking a different view have been emotivists or prescriptivists.

Moore and the naturalistic fallacy. At first it was the intuitionists who dominated the scene. In 1903 the Cambridge philosopher G.E. Moore presented in *Principia Ethica* his "open question argument" against what he called the naturalistic fallacy. The argument can in fact be found in Sidgwick and to some extent in the 18th-century intuitionists, but Moore's statement of it somehow caught the imagination of philosophers for the first half of the 1900s. Moore's aim was to prove that "good" is the name of a simple, unanalyzable quality. His chief target was the attempt to define good in terms of some natural quality of the world whether it be "pleasure" (he had John Stuart Mill in mind), or "more evolved" (here he refers to Herbert Spencer, who had tried to build an ethical system around Darwin's theory of evolution), or simply the idea of what is natural itself, as in appeals to a law of nature—hence the label naturalistic fallacy (*i.e.*, the fallacy of treating good as if it were the name of a natural property). But the label is not apt because Moore's argument applied, as he acknowledged, to any attempt to define good in terms of something else, including something metaphysical or supernatural such as "what God wills."

The naturalistic fallacy

The so-called open question argument itself is simple enough. It consists of taking the proposed definition of good and turning it into a question. For instance, if the proposed definition is "Good means whatever leads to the greatest happiness of the greatest number," then Moore would ask: "Is whatever leads to the greatest happiness of the greatest number good?" Moore is not concerned whether we answer yes or no. His point is that if the question is at all meaningful—if a negative answer is not plainly self-contradictory—then the definition cannot be right, for a definition is supposed to preserve the meaning of the term defined. If it does, a question of the type Moore asks would be absurd for all who understand the meaning of the term. Compare, for example, "Do all squares have four equal sides?"

Moore's argument does show that definitions of the kind he criticized do not capture all that we ordinarily mean by the term good. It would still be open to a would-be naturalist to admit that the definition does not capture everything that we ordinarily mean by the term, and add that all this shows is that ordinary usage is muddled and in need of revision. (We shall see that J.L. Mackie was later to make this part of his defense of subjectivism.) As for Mill, it is questionable whether he really intended to offer a definition of the term good; he seems to have been more interested in offering a criterion by which we could ascertain which actions are good. As Moore acknowledged, the open question argument does not do anything to show that pleasure, for example, is not the sole criterion of the goodness of an action. It shows only that this cannot be known to be true by definition, and so, if it is to be known at all, it must be known by some other means.

In spite of these doubts, Moore's argument was widely accepted at the time as showing that all attempts to derive ethical conclusions from anything not itself ethical in nature are bound to fail. The point was soon seen to be related to that made by Hume in his remarks on writers who move from "is" to "ought." Moore, however, would have considered Hume's own account of morality to be naturalistic because of its definition of virtue in terms of the sentiments of the spectator. The upshot was that for 30 years after the publication of *Principia Ethica* intuitionism was the dominant metaethical position in British philosophy. In addition to Moore, its supporters included H.A. Prichard and Sir W.D. Ross.

Modern intuitionism. The 20th-century intuitionists were not far removed philosophically from their 18th-century predecessors—those such as Richard Price who had learned from Hume's criticism and did not attempt to reason his way to ethical conclusions but claimed rather that ethical knowledge is gained through an immediate apprehension of its truth. In other words, a true ethical judgment is self-evident as long as we are reflecting clearly and calmly and our judgment is not distorted by self-interest or faulty moral upbringing. Ross, for example, took "the convictions of thoughtful, well-educated people" as "the data of ethics," observing that while some may be illusory, they should only be rejected when they conflict with others that are better able to stand up to "the test of reflection."

The intuitionists differed on the nature of the moral truths that are apprehended in this way. For Moore it was self-evident that certain things are valuable: *e.g.*, the pleasures of friendship and the enjoyment of beauty. On the other hand, Ross thought we know it to be our duty to do acts of a certain type. These differences will be dealt with in the discussion of normative ethics. They are, however, significant to metaethical intuitionism because they reveal the lack of agreement, even among the intuitionists themselves, about moral judgments that each claims to be self-evident.

This disagreement was one of the reasons for the eventual rejection of intuitionism, which, when it came, was as complete as its acceptance had been in earlier decades. But there was also a more powerful philosophical motive working against intuitionism. During the 1930s, Logical Positivism, brought from Vienna by Ludwig Wittgenstein and popularized by A.J. Ayer in his manifesto *Language, Truth and Logic* (1936), became influential in British philosophy. According to the Logical Positivists, all true statements fall into two categories: logical truths and statements of fact. Moral judgments cannot fit comfortably into either category. They cannot be logical truths, for these are mere tautologies that can tell us nothing more than what is already contained in the definitions of the terms. Nor can they be statements of fact because these must, according to the Logical Positivists, be at least in principle verifiable; there is no way of verifying the truths that the intuitionists claimed to apprehend. The truths of mathematics, on which intuitionists had continued to rely as the one clear parallel case of a truth known by its self-evidence, were explained now as logical truths. In this view, mathematics tells us nothing about the world; it is simply a logical system, true by the definitions of the terms involved, which may be useful in our dealings with the world. Thus the intuitionists lost the one useful analogy to which they could appeal in support of the existence of a body of self-evident truths known by reason alone. It seemed to follow that moral judgments could not be truths at all.

Impact of Logical Positivism

Emotivism. In his above-cited *Language, Truth and Logic,* Ayer offered an alternative account: moral judgments are not statements at all. When we say, "You acted wrongly in stealing that money," we are not expressing any fact beyond that stated by "You stole that money." It is, however, as if we had stated this fact with a special tone of abhorrence, for in saying that something is wrong, we are expressing our feelings of disapproval toward it.

This view was more fully developed by Charles Stevenson in *Ethics and Language* (1945). As the titles of books of this period suggest, philosophers were now paying more attention to language and to the different ways in which it could be used. Stevenson distinguished the facts a sentence may convey from the emotive impact it is intended to have. Moral judgments are significant, he urged, because of their emotive impact. In saying that something is wrong, we are not merely expressing our disapproval of it, as Ayer suggested. We are encouraging those to whom we speak to share our attitude. This is why we bother to

argue about our moral views, while on matters of taste we may simply agree to differ. It is important to us that others share our attitudes on war, equality, or killing; we do not care if they prefer to take their tea with lemon and we do not.

Charges of subjectivism

The emotivists were immediately accused of being subjectivists. In one sense of the term subjectivist, the emotivists could firmly reject this charge. Unlike other subjectivists in the past, they did not hold that those who say, for example, "Stealing is wrong," are making a statement of fact about their own feelings or attitudes toward stealing. This view—more properly known as subjective naturalism because it makes the truth of moral judgments depend on a natural, albeit subjective, fact about the world—could be refuted by Moore's open question argument. It makes sense to ask: "I know that I have a feeling of approval toward this, but is it good?" It was the emotivists' view, however, that moral judgments make no statements of fact at all. The emotivists could not be defeated by the open question argument because they agreed that no definition of "good" in terms of facts, natural or unnatural, could capture the emotive element of its meaning. Yet, this reply fails to confront the real misgivings behind the charge of subjectivism: the concern that there are no possible standards of right and wrong other than one's own subjective feelings. In this sense, the emotivists were subjectivists.

Existentialism. About this time a different form of subjectivism was becoming fashionable on the Continent and to some extent in the United States. Existentialism was as much a literary as a philosophical movement. Its leading figure, Jean-Paul Sartre, propounded his ideas in novels and plays as well as in his major philosophical treatise, *L'Être et le néant* (1943; *Being and Nothingness*). For Sartre, because there is no God, human beings have not been designed for any particular purpose. The Existentialists express this by stating that our existence precedes our essence. In saying this, they make clear their rejection of the Aristotelian notion that just as we can recognize a good knife once we know that the essence of a knife is to cut, so we can recognize a good human being once we understand the essence of human nature. Because we have not been designed for any specific end, we are free to choose our own essence, which means to choose how we will live. To say that we are compelled by our situation, our nature, or our role in life to act in a certain way is to exhibit "bad faith." This seems to be the only term of disapproval the Existentialists are prepared to use. As long as we choose "authentically," there are no moral standards by which our conduct can be criticized.

Relativity of all moral standards

This, at least, is the view most widely held by the Existentialists. In one work, a brochure entitled *L'Existentialisme est un humanisme* (1946; "Existentialism Is a Humanism"; Eng. trans., *Existentialism and Humanism*), Sartre backs away from so radical a subjectivism by suggesting a version of Kant's idea that we must be prepared to apply our judgments universally. He does not reconcile this view with conflicting statements elsewhere in his writings, and it is doubtful if it can be regarded as a statement of his true ethical views. It may reflect, however, a widespread postwar reaction to the spreading knowledge of what happened at Auschwitz and other Nazi death camps. One leading German prewar Existentialist, Martin Heidegger, had actually become a Nazi. Was this "authentic choice" just as good as Sartre's own choice to join the French Résistance? Is there really no firm ground from which such a choice could be rejected? This seemed to be the upshot of the pure Existentialist position, just as it was an implication of the ethical emotivism that was dominant among English-speaking philosophers. It is scarcely surprising that many philosophers should search for a metaethical view that did not commit them to this conclusion. The means used by Sartre in *L'Existentialisme est un humanisme* were also to have their parallel, though in a much more sophisticated form, in British moral philosophy.

Universal prescriptivism. In *The Language of Morals* (1952), R.M. Hare supported some of the elements of emotivism but rejected others. He agreed that in making moral judgments we are not primarily seeking to describe anything; but neither, he said, are we simply expressing our attitudes. Instead, he suggested that moral judgments prescribe; that is, they are a form of imperative sentence. Hume's rule about not deriving an "is" from an "ought" can best be explained, according to Hare, in terms of the impossibility of deriving any prescription from a set of descriptive sentences. Even the description "There is an enraged bull bearing down on you" does not necessarily entail the prescription "Run!" because I may have been searching for ways of killing myself in such a way that my children can still benefit from my life insurance. Only I can choose whether the prescription fits what I want. Herein lies moral freedom: because the choice of prescription is individual, no one can tell another what he or she must think right.

Hare's espousal of the view that moral judgments are prescriptions led commentators on his first book to classify him with the emotivists as one who did not believe in the possibility of using reason to arrive at ethical conclusions. That this was a mistake became apparent with the publication of his second book, *Freedom and Reason* (1963). The aim of the book was to show that the moral freedom guaranteed by prescriptivism is, notwithstanding its element of choice, compatible with a substantial amount of reasoning about moral judgments. Such reasoning is possible, Hare wrote, because moral judgments must be "universalizable." This notion owed something to the ancient Golden Rule and even more to Kant's first formulation of the categorical imperative. In Hare's treatment, however, these ideas were refined so as to eliminate their obvious defects. Moreover, for Hare universalizability is not a substantive moral principle but a logical feature of the moral terms. This means that anyone who uses such terms as right and ought is logically committed to universalizability.

Definition of universalizability

To say that a moral judgment must be universalizable means, for Hare, that if I judge a particular action—say, a man's embezzlement of a million dollars from his employer—to be wrong, I must also judge any relevantly similar action to be wrong. Of course, everything will depend on what is allowed to count as a relevant difference. Hare's answer is that all features may count, except those that contain ineliminable uses of words such as I or my, or singular terms such as proper names. In other words, the fact that he embezzled a million dollars in order to be able to take holidays in Tahiti, whereas I embezzled the same sum so as to channel it from my wealthy employer to those starving in Africa, may be a relevant difference; the fact that the man's crime benefitted him, whereas my crime benefitted me, cannot be so.

This notion of universalizability can also be used to test whether a difference that is alleged to be relevant—for instance, skin colour or even the position of a freckle on one's nose—really is relevant. Hare emphasized that the same judgment must be made in all conceivable cases. Thus if a Nazi were to claim that he may kill a person because that person is Jewish, he must be prepared to prescribe that if, somehow, it should turn out that he is himself of Jewish origin, he should also be killed. Nothing turns on the likelihood of such a discovery; the same prescription has to be made in all hypothetically, as well as actually, similar cases. Since only an unusually fanatical Nazi would be prepared to do this, universalizability is a powerful means of reasoning against certain moral judgments, including those made by the Nazis. At the same time, since there could be fanatical Nazis who are prepared to die for the purity of the Aryan race, the argument of *Freedom and Reason* allows that the role played by reason in ethics does have definite limits. Hare's position at this stage, therefore, appeared to be a compromise between the extreme subjectivism of the emotivists and some more objectivist view of ethics. As so often happens with those who try to take the middle ground, Hare was soon to receive criticism from both sides.

Modern naturalism. For a time, Moore's presentation of the naturalistic fallacy halted attempts to define "good" in terms of natural qualities such as happiness. The effect was, however, both local and temporary. In the United States, Ralph Barton Perry was untroubled by Moore's arguments. His *General Theory of Value* (1926) gave an account of value that was objectivist and much less mys-

terious than the intuitionist accounts, which were at that time dominating British philosophy. Perry suggested that there is no such thing as value until a being desires something, and nothing can have intrinsic value considered apart from all desiring beings. A novel, for example, has no value at all unless there is a being who desires to read it or perhaps use it for some other purpose, such as starting a fire on a cold night. Thus Perry is a naturalist, for he defines value in terms of the natural quality of being desired or, as he puts it, being an object of an interest. His naturalism is objectivist, in spite of this dependence of value on desires, because value is defined as any object of any interest. Accordingly, even if I do not desire, say, this encyclopaedia for any purpose at all, I cannot deny that it has some value so long as there is some being who does desire it. Moreover, Perry believed it followed from his theory that the greatest moral value is to be found in whatever leads to the harmonious integration of interests.

In Britain, Moore's impact was for a long time too great for any form of naturalism to be taken seriously. It was only as a response to Hare's intimation that any principle could be a moral principle so long as it satisfied the formal requirement of universalizability that philosophers such as Philippa Foot, Elizabeth Anscombe, and Geoffrey Warnock began to suggest that perhaps a moral principle must also have a particular kind of content—*i.e.,* it must deal, for instance, with some aspect of wants, welfare, or flourishing.

The problem with these suggestions, Hare soon pointed out, is that if we define morality in such a way that moral principles are restricted to those that maximize well-being, then if there is a person who is not interested in maximizing well-being, moral principles, as we have defined them, will have no prescriptive force for that person. This reply elicited two responses—namely, those of Anscombe and Foot.

Anscombe went back to Aristotle, suggesting that we need a theory of human flourishing that will provide an account of what any person must do in order to flourish, and so will lead to a morality that every one of us has reason to follow. No such theory was forthcoming, however, until 1980 when John Finnis offered a theory of basic human goods in his *Natural Law and Natural Rights.* The book was acclaimed by Roman Catholic moral theologians and philosophers, but natural law ethics continues to have few followers outside these circles.

Foot initially attempted to defend a similarly Aristotelian view in which virtue and self-interest are necessarily linked, but she came to the conclusion that this link could not be made. This led her to abandon the assumption that we all have adequate reasons for doing what is right. Like Hume, she suggested that it depends on what we desire and especially on how much we care about others. She observed that morality is a system of hypothetical, not categorical, imperatives.

A much cruder form of naturalism surfaced from a different direction with the publication of Edward O. Wilson's *Sociobiology: The New Synthesis* (1975). Wilson, a biologist rather than a philosopher, claimed that new developments in the application of evolutionary theory to social behaviour would allow ethics to be "removed from the hands of philosophers" and "biologicized." It was not the first time that a scientist, frustrated by the apparent lack of progress in ethics as compared to the sciences, had proposed some way of transforming ethics into a science. In a later book, *On Human Nature* (1978), Wilson suggested that biology justifies specific values (including the survival of the gene pool) and, because man is a mammal rather than a social insect, universal human rights. Other sociobiologists have gone further still, reviving the claims of earlier "social Darwinists" to the effect that Darwin's theory of evolution shows why it is right that there should be social inequality.

Attempt to transform ethics into a science

As the above section on the origin of ethics suggests, evolutionary theory may indeed have something to reveal about the origins and nature of the systems of morality used by human societies. Wilson is, however, plainly guilty of breaching Hume's rule when he tries to draw from a theory of a factual nature ethical premises that tell us what we ought to do. It may be that, coupled with the premise that we wish our species to survive for as long as possible, evolutionary theory will suggest the direction we ought to take, but even that premise cannot be regarded as unquestionable. It is not impossible to imagine circumstances in which life is so grim that extinction is preferable. That choice cannot be dictated by science. It is even less plausible to suppose that more specific choices about social equality can be settled by evolutionary theory. At best, the theory would indicate the costs we might incur by moving to greater equality; it could not conceivably tell us whether incurring those costs is justifiable.

Recent developments in metaethics. In view of the heat of the debate between Hare and his naturalist opponents during the 1960s, the next development was surprising. At first in articles and then in the book *Moral Thinking* (1981), Hare offered a new understanding of what is involved in universalizability that relies on treating moral ideals in a similar fashion to ordinary desires or preferences. In *Freedom and Reason* the universalizability of moral judgments prevented me from giving greater weight to my own interests, simply on the grounds that they are mine, than I was prepared to give to anyone else's interests. In *Moral Thinking* Hare argued that to hold an ideal, whether it be a Nazi ideal such as the purity of the Aryan race or a more conventional ideal such as that justice must be done irrespective of the consequences, is really to have a special kind of preference. When I ask whether I can prescribe a moral judgment universally, I must take into account all the ideals and preferences held by all those who will be affected by the action I am judging; and in taking these into account, I cannot give any special weight to my own ideals merely because they are my own. The effect of this application of universalizability is that for a moral judgment to be universalizable it must ultimately be based on the maximum possible satisfaction of the preferences of all those affected by it. Thus Hare claimed that his reading of the formal property of universalizability inherent in moral language enables him to solve the ancient problem of showing how reason can, at least in principle, resolve ethical disagreement. Moral freedom, on the other hand, has been reduced to the freedom to be an amoralist and to avoid using moral language altogether.

Hare's position was immediately challenged by J.L. Mackie in *Ethics: Inventing Right and Wrong* (1977). In the course of a defense of moral subjectivism, Mackie argued that Hare had stretched the notion of universalizability far beyond anything that is really inherent in moral language. Moreover, even if such a notion were embodied in our way of thinking and talking about morality, Mackie insisted that we would always be free to reject such notions and to decide what to do without concerning ourselves with whether our judgments are universalizable in Hare's, or indeed in any, sense. According to Mackie, our ordinary use of moral language presupposes that moral judgments are statements about something in the universe and, therefore, can be true or false. This is, however, a mistake. Drawing on Hume, Mackie says that there cannot be any matters of fact that make it rational for everyone to act in a certain way. If we do not reject morality altogether, we can only base our moral judgments on our own desires and feelings.

There are a number of contemporary British philosophers who do not accept either Hare's or Mackie's metaethical views. Those who hold forms of naturalism have already been mentioned. Others, including the Oxford philosophers David Wiggins and John McDowell, have employed modern semantic theories of the nature of truth to show that even if moral judgments do not correspond to any objective facts or self-evident truths, they may still be proper candidates for being true or false. This position has become known as moral realism. For some, it makes moral judgments true or false at the cost of taking objectivity out of the notion of truth.

Moral realism

Many modern writers on ethics, including Mackie and Hare, share a view of the nature of practical reason derived from Hume. Our reasons for acting morally, they hold, must depend on our desires because reason in action applies only to the best way of achieving what we desire.

This view of practical reason virtually precludes any general answer to the question "Why should I be moral?" Until very recently, this question had received less attention in the 20th century than in earlier periods. In the early part of the century, such intuitionists as H.A. Prichard had rejected all attempts to offer extraneous reasons for being moral. Those who understood morality would, they said, see that it carried its own internal reasons for being followed. For those who could not see these reasons, the situation was reminiscent of the story of the emperor's new clothes.

The question fared no better with the emotivists. They defined morality so broadly that anything an individual desires can be considered to be moral. Thus there can be no conflict between morality and self-interest, and if anyone asks "Why should I be moral?" the emotivist response would be to say "Because whatever you most approve of doing is, by definition, your morality." Here the question is effectively being rejected as senseless, but this reply does nothing to persuade the questioners to act in a benevolent or socially desirable way. It merely tells them that no matter how antisocial their actions may be, they can still be moral as the emotivists define the term.

For Hare, on the other hand, the question "Why should I be moral?" amounts to asking why I should act only on those judgments that I am prepared to universalize; and the answer he gives is that unless this is what I want to do, it is not always possible to give an adult a reason for doing so. At the same time, Hare does believe that if someone asks why children should be brought up to be morally good, the answer is that they are more likely to be happy if they develop habits of acting morally.

Other philosophers have put the question to one side, saying that it is a matter for psychologists rather than for philosophers. In earlier periods, of course, psychology was considered a branch of philosophy rather than a separate discipline, but in fact psychologists have also had little to say about the connection between morality and self-interest. In *Motivation and Personality* (1954) and other works, Abraham H. Maslow developed a psychological theory reminiscent of Shaftesbury in its optimism about the link between personal happiness and moral values, but Maslow's factual evidence was thin. Victor Emil Frankl, a psychotherapist, has written several popular books defending a position essentially similar to that of Joseph Butler on the attainment of happiness. The gist of this view is known as the paradox of hedonism. In *The Will to Meaning* (1969), Frankl states that those who aim directly at happiness do not find it; those whose lives have meaning or purpose apart from their own happiness find happiness as well.

Psychological theories on the connection between morality and self-interest

The U.S. philosopher Thomas Nagel has taken a different approach to the question of how we may be motivated to act altruistically. Nagel challenges the assumption that Hume was right about reason being subordinate to desires. In *The Possibility of Altruism* (1969), Nagel sought to show that if reason must always be based on desire, even our normal idea of prudence (that we should give the same weight to our future pains and pleasures as we give to our present ones) becomes incoherent. Once we accept the rationality of prudence, however, Nagel argued that a very similar line of argument can lead us to accept the rationality of altruism—*i.e.*, the idea that the pains and pleasures of another individual are just as much a reason for one to act as are one's own pains and pleasures. This means that reason alone is capable of motivating moral action; hence, it is unnecessary to appeal to self-interest or benevolent feelings. Though not an intuitionist in the ordinary sense, Nagel has effectively reopened the 18th-century debate between the moral sense school and the intuitionists who believed that reason alone can play a role in action.

The most influential work in ethics by a U.S. philosopher since the early 1960s, John Rawls's *Theory of Justice* (1971), is for the most part centred on normative ethics, and so will be discussed in the next section; it has, however, had some impact in metaethics as well. To argue for his principles of justice, Rawls uses the idea of a hypothetical contract, in which the contracting parties are behind a "veil of ignorance" that prevent them from knowing any particular details about their own attributes. Thus one cannot try to benefit oneself by choosing principles of justice that favour the wealthy, the intelligent, males, or whites. The effect of this requirement is in many ways similar to Hare's idea of universalizability, but Rawls claims that it avoids, as the former does not, the trap of grouping together the interests of different individuals as if they all belonged to one person. Accordingly, the old social contract model that had largely been neglected since the time of Rousseau has had a new wave of popularity as a form of argument in ethics.

Revival of the notion of social contract

The other aspect of Rawls's thought to have metaethical significance is his so-called method of reflective equilibrium—the idea that a sound moral theory is one that matches reflective moral judgments. In *A Theory of Justice* Rawls uses this method to justify tinkering with the original model of the hypothetical contract until it produces results that are not too much at odds with ordinary ideas of justice. To his critics, this represents a reemergence of a conservative form of intuitionism, for it means that new moral theories are tested against ordinary moral intuitions. If a theory fails to match enough of these, it will be rejected no matter how strong its own foundations may be. In Rawls's defense it may be said that it is only our "reflective moral judgments" that serve as the testing ground—our ordinary moral intuitions may be rejected, perhaps simply because they are contrary to a well-grounded theory. If such be the case, the charge of conservatism may be misplaced, but in the process the notion of some independent standard by which the moral theory may be tested has been weakened, perhaps so far as to become virtually meaningless.

Perhaps the most impressive work of metaethics published in the United States in recent years is R.B. Brandt's *Theory of the Good and the Right* (1979). Brandt returns to something like the naturalism of Ralph Barton Perry but with a distinctive late 20th-century American twist. He spends little time on the concept of good, believing that everything capable of being expressed by this word can be more clearly stated in terms of rational desires. To explicate this notion of a rational desire, Brandt appeals to cognitive psychotherapy. An ideal process of cognitive psychotherapy would eliminate many desires: those based on false beliefs, those which one has only because one is ignoring the feelings or desires that are likely to be expressed in the future, the desires or aversions that are artificially caused by others, desires that are based on early deprivation, and so on. The desires that an individual would still have, undiminished in strength after going through this process, are what Brandt is prepared to call rational desires.

Brandt's notion of rational desire

In contrast to his view of the term good, Brandt does think that the notions of morally right and morally wrong are useful. He suggests that, in calling an action morally wrong, we should mean that it would be prohibited by any moral code that all fully rational people would support for the society in which they are to live. (Brandt then argues that fully rational people would support that moral code which would maximize happiness, but the justification of this claim is a task for normative ethics, not metaethics.)

Brandt's final chapter is an indication of the revival of interest in the question, as he phrases it, "Is it always rational to act morally?" His answer, echoing Shaftesbury in modern guise, is that such desires as benevolence would survive cognitive psychotherapy, and so a rational person would be benevolent. A rational person would also have other moral motives, including an aversion to dishonesty. These motives will occasionally conflict with self-interested desires, and there can be no guarantee that the moral motives will be the stronger. If they are not, and in spite of the fact that a rational person would support a code favouring honesty, Brandt is unable to say that it would be irrational to follow self-interest rather than morality. A fully rational person might support a certain kind of moral code and yet not act in accordance with it on every occasion.

As the century draws to a close, the issues that divided Plato and the Sophists are still dividing moral philoso-

phers. Ironically, the one position that now has few defenders is Plato's view that "good" refers to an idea or property having an objective existence quite apart from anyone's attitudes or desires—on this point the Sophists appear to have won out at last. Yet, this still leaves ample room for disagreement about the extent to which reason can bring about agreed decisions on what we ought to do. There also remains the dispute about whether it is proper to refer to moral judgments as true and false. On the other central question of metaethics, the relationship between morality and self-interest, a complete reconciliation of the two continues to prove—at least for those not prepared to appeal to a belief in reward and punishment in another life—as elusive as it did for Sidgwick at the end of the 19th century.

NORMATIVE ETHICS

The debate over consequentialism. Normative ethics seeks to set norms or standards for conduct. The term is commonly used in reference to the discussion of general theories about what one ought to do, a central part of Western ethics since ancient times. Normative ethics continued to hold the spotlight during the early years of the 20th century, with intuitionists such as W.D. Ross engaged in showing that an ethic based on a number of independent duties was superior to Utilitarianism. With the rise of Logical Positivism and emotivism, however, the logical status of normative ethics seemed doubtful: Was it not simply a matter of whatever one approved? Nor was the analysis of language, which dominated philosophy in English-speaking countries during the 1950s, any more congenial to normative ethics. If philosophy could do no more than analyze words and concepts, how could it offer guidance about what one ought to do? The subject was therefore largely neglected until the 1960s, when emotivism and linguistic analysis were both on the retreat and moral philosophers once again began to think about how individuals ought to live.

A crucial question of normative ethics is whether actions are to be judged right or wrong solely on the basis of their consequences. Traditionally, those theories that judge actions by their consequences have been known as teleological theories, while those that judge actions according to whether they fall under a rule have been referred to as deontological theories. Although the latter term continues to be used, the former has been replaced to a large extent by the more straightforward term consequentialist. The debate over this issue has led to the development of different forms of consequentialist theories and to a number of rival views.

Classical Utilitarianism is the simplest form

Varieties of consequentialism. The simplest form of consequentialism is classical Utilitarianism, which holds that every action is to be judged good or bad according to whether its consequences do more than any alternative action to increase—or, if that is impossible, to limit any unavoidable decrease in—the net balance of pleasure over pain in the universe. This is often called hedonistic Utilitarianism.

G.E. Moore's normative position offers an example of a different form of consequentialism. In the final chapters of the aforementioned *Principia Ethica* and also in *Ethics* (1912), Moore argued that the consequences of actions are decisive for their morality, but he did not accept the classical Utilitarian view that pleasure and pain are the only consequences that matter. Moore asked his readers to picture a world filled with all possible imaginable beauty but devoid of any being who can experience pleasure or pain. Then the reader is to imagine another world, as ugly as can be but equally lacking in any being who experiences pleasure or pain. Would it not be better, Moore asked, that the beautiful world rather than the ugly world exist? He was clear in his own mind that the answer was affirmative, and he took this as evidence that beauty is good in itself, apart from the pleasure it brings. He also considered that the friendship of close personal relationships has a similar intrinsic value independent of its pleasantness. Moore thus judged actions by their consequences but not solely by the amount of pleasure they produced. Such a position was once called ideal Utilitarianism because it was a form of Utilitarianism based on certain ideals. Today, however, it is more frequently referred to by the general label consequentialism, which includes, but is not limited to, Utilitarianism.

R.M. Hare is another example of a consequentialist. His interpretation of universalizability leads him to the view that for a judgment to be universalizable, it must prescribe what is most in accord with the preferences of all those affected by the action. This form of consequentialism is frequently called preference Utilitarianism because it attempts to maximize the satisfaction of preferences, just as classical Utilitarianism endeavours to maximize pleasure or happiness. Part of the attraction of such a view lies in the way in which it avoids making judgments about what is intrinsically good, finding its content instead in the desires that people, or sentient beings generally, do have. Another advantage is that it overcomes the objection, which so deeply troubled Mill, that the production of simple, mindless pleasure becomes the supreme goal of all human activity. Against these advantages we must put the fact that most preference Utilitarians want to base their judgments, not on the desires that people actually have, but rather on those they would have if they were fully informed and thinking clearly. It then becomes essential to discover what people would want under these conditions, and, because most people most of the time are less than fully informed and clear in their thoughts, the task is not an easy one.

Preference Utilitarianism

It may also be noted in passing that Hare claims to derive his version of Utilitarianism from universalizability, which in turn he draws from moral language and moral concepts. Moore, on the other hand, had simply found it self-evident that certain things were intrinsically good. Another Utilitarian, the Australian philosopher J.J.C. Smart, has defended hedonistic Utilitarianism by asserting that he has a favourable attitude to making the surplus of happiness over misery as large as possible. As these differences suggest, consequentialism can be held on the basis of widely differing metaethical views.

Consequentialists may also be separated into those who ask of each individual action whether it will have the best consequences, and those who ask this question only of rules or broad principles and then judge individual actions by whether they fall under a good rule or principle. The distinction having arisen in the specific context of Utilitarian ethics, the former are known as act-Utilitarians and the latter as rule-Utilitarians.

Rule-Utilitarianism developed as a means of making the implications of Utilitarianism less shocking to ordinary moral consciousness. (The germ of this approach is seen in Mill's defense of Utilitarianism.) There might be occasions, for example, when stealing from one's wealthy employer in order to give to the poor would have good consequences. Yet, surely it would be wrong to do so. The rule-Utilitarian solution is to point out that a general rule against stealing is justified on Utilitarian grounds, because otherwise there could be no security of property. Once the general rule has been justified, individual acts of stealing can then be condemned whatever their consequences because they violate a justifiable rule.

This suggests an obvious question, one already raised by the above account of Kant's ethics: How specific may the rule be? Although a rule prohibiting stealing may have better consequences than no rule at all against stealing, would not the best consequences of all follow from a rule that permitted stealing only in those special cases in which it is clear that stealing will have better consequences than not stealing? But what then is the difference between act- and rule-Utilitarianism? In *Forms and Limits of Utilitarianism* (1965), David Lyons argued that if the rule were formulated with sufficient precision to take into account all its causally relevant consequences, rule-Utilitarianism would collapse into act-Utilitarianism. If rule-Utilitarianism is to be maintained as a distinct position, then there must be some restriction on how specific the rule can be so that at least some relevant consequences are not taken into account.

To ignore relevant consequences is to break with the very essence of consequentialism; rule-Utilitarianism is

Rule-Utilitarianism versus act-Utilitarianism

therefore not a true form of Utilitarianism at all. That, at least, is the view taken by Smart, who has derided rule-Utilitarianism as "rule-worship" and consistently defended act-Utilitarianism. Of course, when time and circumstances make it awkward to calculate the precise consequences of an action, Smart's act-Utilitarian will resort to rough and ready "rules of thumb" for guidance; but these rules of thumb have no independent status apart from their usefulness in predicting likely consequences, and if ever we are clear that we will produce better consequences by acting contrary to the rule of thumb, we should do so. If this leads us to do things that are contrary to the rules of conventional morality, then, Smart says, so much the worse for conventional morality.

Today, straightforward rule-Utilitarianism has few supporters. On the other hand, a number of more complex positions have been proposed, bridging in some way the distance between rule-Utilitarianism and act-Utilitarianism.

Intuitive level of moral thought

In *Moral Thinking* Hare distinguished two levels of thought about what we ought to do. At the critical level we may reason about the principles that should govern our action and consider what would be for the best in a variety of hypothetical cases. The correct answer here, Hare believed, is always that the best action will be the one that has the best consequences. This principle of critical thinking is not, however, well-suited for everyday moral decision making. It requires calculations that are difficult to carry out under the most ideal circumstances and virtually impossible to carry out properly when we are hurried or liable to be swayed by our emotions or our interests. Everyday moral decisions are the proper domain of the intuitive level of moral thought. At this intuitive level we do not enter into fine calculations of consequences; instead, we act in accordance with fundamental moral principles that we have learned and accepted as determining, for practical purposes, whether an act is right or wrong. Just what these moral principles should be is a task for critical thinking. They must be the principles that, when applied intuitively by most people, will produce the best consequences overall, and they must also be sufficiently clear and brief to be made part of the moral education of children. Hare therefore can avoid the dilemma of the rule-Utilitarian while still preserving the advantages of that position. Given that ordinary moral beliefs reflect the experience of many generations, Hare believed that judgments made at the intuitive level will probably not be too different from judgments made by conventional morality. At the same time, Hare's restriction on the complexity of the intuitive principles is fully consequentialist in spirit.

Some recently published work has gone further still in this direction. Following on earlier discussions of the difficulties consequentialists may have in trusting one another—since the word of a Utilitarian is only as good as the consequences of keeping the promise appear to him to be—Donald Regan has explored the problems of cooperation among Utilitarians in his *Utilitarianism and Co-operation* (1980) and has come out with a further variation designed to make cooperation feasible and thus to achieve the best consequences on the whole. In *Reasons and Persons* (1984), Derek Parfit argued that to aim always at producing the best consequences would be indirectly self-defeating; we would be cutting ourselves off from some of the greatest goods of human life, including those close personal relationships that demand that we sacrifice the ideal of impartial benevolence to all in order that we may give preference to those we love. We therefore need, Parfit suggested, not simply a theory of what we should all do, but a theory of what motives we should all have. Parfit, like Hare, plausibly contended that recognizing this distinction will bring the practical application of consequentialist theories closer to conventional moral judgments.

An ethic of prima facie duties. In the first third of the 20th century, it was the intuitionists, especially W.D. Ross, who provided the major alternative to Utilitarianism. Because of this situation, the position described below is sometimes called intuitionism, but it seems less likely to cause confusion if we reserve that label for the quite distinct metaethical position held by Ross—and incidentally by Sidgwick as well—and refer to the normative position by the more descriptive label, an "ethic of prima facie duties."

Ross's normative ethic consists of a list of duties, each of which is to be given independent weight: fidelity, reparation, gratitude, beneficence, nonmaleficence, and self-improvement. If an act falls under one and only one of these duties, it ought to be carried out. Often, of course, an act will fall under two or more duties: I may owe a debt of gratitude to someone who once helped me, but beneficence will be better served if I help others in greater need. This is why the duties are, Ross says, prima facie rather than absolute; each duty can be overridden if it conflicts with a more stringent duty.

An ethic structured in this manner may match our ordinary moral judgments more closely than a consequentialist ethic, but it suffers from two serious drawbacks. First, how can we be sure that just those duties listed by Ross are independent sources of moral obligation? Ross could only respond that if we examine them closely we will find that these, and these alone, are self-evident. But others, even other intuitionists, have found that what was self-evident to Ross was not self-evident to them. Second, if we grant Ross his list of independent prima facie moral duties, we still need to know how to decide, in a particular situation, when a less stringent duty is overridden by a more stringent one. Here, too, Ross had no better answer than an unsatisfactory appeal to intuition.

Rawls's theory of justice. When philosophers again began to take an interest in normative ethics in the 1960s after an interval of some 30 years, no theory could rival the ability of Utilitarianism to provide a plausible and systematic basis for moral judgments in all circumstances. Yet, many people found themselves unable to accept Utilitarianism. One common ground for dissatisfaction was that Utilitarianism does not offer any principle of justice beyond the basic idea that everyone's happiness—or preferences, depending on the form of Utilitarianism—counts equally. Such a principle is quite compatible with sacrificing the welfare of some to the greater welfare of others. This situation explains the enthusiastic welcome accorded to Rawls's *Theory of Justice* when it appeared in 1971.

Rawls's theory as an alternative to Utilitarianism

Rawls offered an alternative to Utilitarianism that came close to matching its rival's ability to provide a systematic theory of what one ought to do and, at the same time, led to conclusions about justice very different from those of the Utilitarians.

Rawls asserted that if people had to choose principles of justice from behind a "veil of ignorance" that restricted what they could know of their own position in society, they would not seek to maximize overall utility. Instead, they would safeguard themselves against the worst possible outcome, first, by insisting on the maximum amount of liberty compatible with the like liberty for others; and, second, by requiring that wealth be distributed so as to make the worst-off members of the society as well-off as possible. This second principle is known as the "maximin" principle, because it seeks to maximize the welfare of those at the minimum level of society. Such a principle might be thought to lead directly to an insistence on the equal distribution of wealth, but Rawls points out that if we accept certain assumptions about the effect of incentives and the benefits that may flow to all from the productive labours of the most talented members of society, the maximin principle could allow considerable inequality.

The "maximin" principle

In the decade following its appearance, *A Theory of Justice* was subjected to unprecedented scrutiny by moral philosophers throughout the world. Two major issues emerged: Were the two principles of justice soundly derived from the original contract situation? And did the two principles amount, in themselves, to an acceptable theory of justice?

To the first question, the general verdict was negative. Without appealing to specific psychological assumptions about an aversion to risk—and Rawls disclaimed any such assumptions—there was no convincing way in which Rawls could exclude the possibility that the parties to the original contract would choose to maximize average

utility, thus giving themselves the best possible chance of having a high level of welfare. True, each individual making such a choice would have to accept the possibility that he would end up with a very low level of welfare, but that might be a risk worth running for the sake of a chance at a very high level.

Even if the two principles cannot validly be derived from the original contract, they might be sufficiently attractive to stand on their own either as self-evident moral truths—if we are objectivists—or as principles to which we might have favourable attitudes. Maximin, in particular, has proved attractive in a variety of disciplines, including welfare economics, a field in which preference Utilitarianism once reigned unchallenged. But maximin has also had its critics, who have pointed out that the principle could require us to forgo very great benefits to the vast majority if, for some reason, this would require some loss (no matter how trivial) to the worst-off members of society.

Rights theories. One of Rawls's severest critics, Robert Nozick of the United States, rejected the assumption that lies behind not only the maximin principle but behind any principle that seeks to achieve a pattern of distribution by taking from one group in order to give to another. In attempting to bring about a certain pattern of distribution, Nozick said, these principles ignore the question of how the individuals from whom wealth will be taken acquired their wealth in the first place. If they have done so by wholly legitimate means without violating the rights of others, then Nozick held that no one, not even the state, can have the right to take their wealth from them without their consent.

Although appeals to rights have been common since the great 18th-century declarations of the rights of man, most ethical theorists have treated rights as something that must be derived from more basic ethical principles or else from accepted social and legal practices. Recently, however, there have been attempts to turn this tendency around and make rights the basis of the ethical theory. It is in the United States, no doubt because of its history and constitution, that the appeal to rights as a fundamental moral principle has been most common. Nozick's *Anarchy, State and Utopia* (1974) is one example of a rights-based theory, although it is mostly concerned with the application of the theory in the political sphere and says very little about other areas of normative ethics. Unlike Rawls, who for all his disagreement with Utilitarianism is still a consequentialist of sorts, Nozick is a deontologist. Our rights to life, liberty, and legitimately acquired property are absolute, and no act can be justified if it violates them. On the other hand, we have no duty to assist people in the preservation of their rights. If others go about their own affairs without infringing on the rights of others, I must not infringe on their rights; but if they are starving, I have no duty to share my food with them. We can appeal to the generosity of the rich, but we have absolutely no right to tax them against their will so as to provide relief for the poor. This doctrine has found favour with some Americans on the political right, but it has proved too harsh for most students of ethics.

Rights as the basis of ethical theory

To illustrate the variety of possible theories based on rights, we can take as another example the one propounded by Ronald Dworkin in *Taking Rights Seriously* (1977). Dworkin agreed with Nozick that rights are not to be overridden for the sake of improved welfare: rights are, he said, "trumps" over ordinary consequentialist considerations. Dworkin's view of rights, however, derives from a fundamental right to equal concern and respect. This makes it much broader than Nozick's theory, since respect for others may require us to assist them and not merely leave them to fend for themselves. Accordingly, Dworkin's view obliges the state to intervene in many areas to ensure that rights are respected.

In its emphasis on equal concern and respect, Dworkin's theory is part of a recent revival of interest in Kant's principle of respect for persons as the fundamental principle of ethics. This principle, like the principle of justice, is often said to be ignored by Utilitarians. Rawls invoked it when setting out the underlying rationale of his theory of justice. The concept, however, suffers from vagueness, and attempts to develop it into something more specific that could serve as the basis for a complete ethical theory have not—unless Rawls's theory is to count as one of them—offered a satisfactory basis for ethical decision making.

Natural law ethics. As far as secular moral philosophy is concerned, during most of the 20th century, natural law ethics has been considered a lifeless medieval relic, preserved only in Roman Catholic schools of moral theology. It is still true that the chief proponents of natural law are of that particular religious persuasion, but they have recently begun to defend their position by arguments that make no explicit appeal to their religious beliefs. Instead, they start their ethics with the claim that there are certain basic human goods that we should not act against. In the list offered by John Finnis in *Natural Law and Natural Rights* (1980), for example, these goods are life, knowledge, play, aesthetic experience, friendship, practical reasonableness, and religion. The identification of these goods is a matter of reflection, assisted by the findings of anthropologists. Each of the basic goods is regarded as equally fundamental; there is no hierarchy among them.

It would, of course, be possible to hold a consequentialist ethic that identified several basic human goods of equal importance and judged actions by their tendency to produce or maintain these goods. Thus, if life is a good, any action that led to a preventable loss of life would, other things being equal, be wrong. Natural law ethics, however, rejects this consequentialist approach. It makes the claim that it is impossible to measure the basic goods against each other. Instead of engaging in consequentialist calculations, the natural law ethic is built on the absolute prohibition of any action that aims directly against any basic good. The killing of the innocent, for instance, is always wrong, even if somehow killing one innocent person were to be the only way of saving thousands of innocent people. What is not adequately explained in this rejection of consequentialism is why the life of one innocent person—about whom, let us say, we know no more than that he is innocent—cannot be measured against the lives of a thousand innocent people about whom we have precisely the same information.

The basis of modern natural law ethic

Natural law ethics does allow one means of softening the effect of its absolute prohibitions. This is the doctrine of double effect, traditionally applied by Roman Catholic writers to some cases of abortion. If a pregnant woman is found to have a cancerous uterus, the doctrine of double effect allows a doctor to remove the uterus notwithstanding the fact that such action will kill the fetus. This allowance is made not because the life of the mother is regarded as more valuable than the life of the fetus, but because in removing the uterus the doctor is held not to aim directly at the death of the fetus. Instead, its death is an unwanted and indirect side effect of the laudable act of removing a diseased organ. On the other hand, a different medical condition might mean that the only way of saving the mother's life is by directly killing the fetus. Some years ago before the development of modern obstetric techniques, this was the case if the head of the fetus became lodged during delivery. Then the only way of saving the life of the woman was to crush the skull of the fetus. Such a procedure was prohibited, for in performing it the doctor would be directly killing the fetus. This ruling was applied even to those cases in which the death of the mother would certainly bring about the death of the fetus as well. The claim was that the doctor who killed the fetus directly was responsible for a murder, but the deaths from natural causes of the mother and fetus were not considered to be the doctor's doing. The example is significant because it indicates the lengths to which proponents of the natural law ethics are prepared to go in order to preserve the absolute nature of the prohibitions.

Ethical egoism. All of the normative theories considered so far have had a universal focus—*i.e.*, if they have been consequentialist theories, the goods they sought to achieve were sought for all capable of benefitting from them; and if they were deontological theories, the deontological principles applied equally to whoever might do the act in question. Ethical egoism departs from this consensus, suggesting that we should each consider only

Avoidance of conflict between morality and self-interest

the consequences of our actions for our own interests. The great advantage of such a position is that it avoids any possible conflict between morality and self-interest. If it is rational for us to pursue our own interest, then, if the ethical egoist is right, the rationality of morality is equally clear.

We can distinguish two forms of egoism. The individual egoist says, "Everyone should do what is in my interests." This indeed is egoism, but it is incapable of being couched in a universalizable form, and so it is arguably not a form of ethical egoism. Nor is the individual egoist likely to be able to persuade others to follow a course of action that is so obviously designed to benefit only the person who is advocating it.

Universal egoism is based on the principle "Everyone should do what is in her or his own interests." This principle is universalizable, since it contains no reference to any particular individual and it is clearly an ethical principle. Others may be disposed to accept it because it appears to offer them the surest possible way of furthering their own interests. Accordingly, this form of egoism is from time to time seized upon by some popular writer who proclaims it the obvious answer to all our ills and has no difficulty finding agreement from a segment of the general public. The U.S. writer Ayn Rand is perhaps the best 20th-century example. Rand's version of egoism is expounded in the novel *Atlas Shrugged* (1957) by her hero, John Galt, and in *The Virtue of Selfishness* (1965), a collection of her essays. It is a confusing mixture of appeals to self-interest and suggestions that everyone will benefit from the liberation of the creative energy that will flow from unfettered self-interest. Overlaying all this is the idea that true self-interest cannot be served by stealing, cheating, or similarly antisocial conduct.

As this example illustrates, what starts out as a defense of ethical egoism very often turns into an indirect form of Utilitarianism; the claim is that we will all be better off if each of us does what is in his or her own interest. The ethical egoist is virtually compelled to make this claim because otherwise there is a paradox in the fact that the ethical egoist advocates ethical egoism at all. Such advocacy would be contrary to the very principle of ethical egoism, unless the egoist benefits from others' becoming ethical egoists. If we see our interests as threatened by others' pursuing their own interests, we will certainly not benefit by others' becoming egoists; we would do better to keep our own belief in egoism secret and advocate altruism.

Unfortunately for ethical egoism, the claim that we will all be better off if every one of us does what is in his or her own interest is incorrect. This is shown by what are known as "prisoner's dilemma" situations, which are playing an increasingly important role in discussions of ethical theory. The basic prisoner's dilemma is an imaginary situation in which two prisoners are accused of a crime. If one confesses and the other does not, the prisoner who confesses will be released immediately and the other who does not will spend the next 20 years in prison. If neither confesses, each will be held for a few months and then both will be released. And if both confess, they will each be jailed for 15 years. The prisoners cannot communicate with one another. If each of them does a purely self-interested calculation, the result will be that it is better to confess than not to confess no matter what the other prisoner does. Paradoxical as it might seem, two prisoners, each pursuing his own interest, will end up worse than they would if they were not egoists.

The example might seem bizarre, but analogous situations occur quite frequently on a larger scale. Consider the dilemma of the commuter. Suppose that each commuter finds his or her private car a little more convenient than the bus; but when each of them drives a car, the traffic becomes so congested that everyone would be better off if they all took the bus and the buses moved quickly without traffic holdups. Because private cars are somewhat more convenient than buses, however, and the overall volume of traffic is not appreciably affected by one more car on the road, it is in the interest of each to continue using a private car. At least on the collective level, therefore, egoism is self-defeating—a conclusion well brought out by Parfit in his aforementioned *Reasons and Persons.*

APPLIED ETHICS

The most striking development in the study of ethics since the mid-1960s has been the growth of interest among philosophers in practical, or applied, ethics; *i.e.,* the application of normative theories to practical moral problems. This is not, admittedly, a totally new departure. From Plato onward moral philosophers have concerned themselves with practical questions, including suicide, the exposure of infants, the treatment of women, and the proper behaviour of public officials. Christian philosophers, notably Augustine and Aquinas, examined with great care such matters as when a war was just, whether it could ever be right to tell a lie, or if a Christian woman did wrong to commit suicide in order to save herself from rape. Hobbes had an eminently practical purpose in writing his *Leviathan,* and Hume wrote about the ethics of suicide. Practical concerns continued with the British Utilitarians, who saw reform as the aim of their philosophy: Bentham wrote on an incredible variety of topics, and Mill is celebrated for his essays on liberty and on the subjection of women.

The application of normative theories to practical moral problems

Nevertheless, during the first six decades of the 20th century moral philosophers largely isolated themselves from practical ethics—something that now seems all but incredible, considering the traumatic events through which most of them lived. There were one or two notable exceptions. The philosopher Bertrand Russell was very much involved in practical issues, but his stature among his colleagues was based on his work in logic and metaphysics and had nothing to do with his writings on topics such as disarmament and sexual morality. Russell himself seems to have regarded his practical contributions as largely separate from his philosophical work and did not develop his ethical views in any systematic or rigorous fashion.

The prevailing view of the period was that moral philosophy is quite separate from "moralizing," a task best left to preachers. What was not generally considered was whether moral philosophers could, without merely preaching, make an effective contribution to discussions of practical issues involving difficult ethical questions. The value of such work began to be widely recognized only during the 1960s, when first the U.S. civil rights movement and subsequently the Vietnam War and the rise of student activism started to draw philosophers into discussions of the moral issues of equality, justice, war, and civil disobedience. (Interestingly, there has been very little discussion of sexual morality—an indication that a subject once almost synonymous with the term morals has become marginal to our moral concerns.)

The founding, in 1971, of *Philosophy and Public Affairs,* a new journal devoted to the application of philosophy to public issues, provided both a forum and a new standard of rigour for these contributions. Applied ethics soon became part of the teaching of most philosophy departments of universities in English-speaking countries. Here it is not possible to do more than briefly mention some of the major areas of applied ethics and point to the issues that they raise.

Applications of equality. Since much of the early impetus for applied ethics came from the U.S. civil rights movement, such topics as equality, human rights, and justice have been prominent. We often make statements such as "All humans are equal" without thinking too deeply about the justification for the claims. Since the mid-1960s much has been written about how they can be justified. Discussions of this sort have led in several directions, often following social and political movements. The initial focus, especially in the United States, was on racial equality, and here, for once, there was a general consensus among philosophers on the unacceptability of discrimination against blacks. With so little disagreement about racial discrimination itself, the centre of attention soon moved to reverse discrimination: Is it acceptable to favour blacks for jobs and enrollment in universities and colleges because they had been discriminated against in the past and were generally so much worse off than

Questions related to racial discrimination

whites? Or is this, too, a form of racial discrimination and unacceptable for that reason?

Inequality between the sexes has been another focus of discussion. Does equality here mean ending as far as possible all differences in the sex roles, or could we have equal status for different roles? There has been a lively debate—both between feminists and their opponents and, on a different level, among feminists themselves—about what a society without sexual inequality would be like. Here, too, the legitimacy of reverse discrimination has been a contentious issue. Feminist philosophers have also been involved in debates over abortion and new methods of reproduction. These topics will be covered separately below.

Many discussions of justice and equality are limited in scope to a single society. Even Rawls's theory of justice, for example, has nothing to say about the distribution of wealth between societies, a subject that could make acceptance of his maximin principle much more onerous. But philosophers have now begun to think about the moral implications of the inequality in wealth between the affluent nations (and their citizens) and those living in countries subject to famine. What are the obligations of those who have plenty when others are starving? It has not proved difficult to make a strong case for the view that affluent nations, as well as affluent individuals, ought to be doing much more to help the poor than they are generally now doing.

There is one issue related to equality in which philosophers have led, rather than followed, a social movement. In the early 1970s, a group of young Oxford-based philosophers began to question the assumption that while all humans are entitled to equal moral status, nonhuman animals automatically have an inferior position. The publication in 1972 of *Animals, Men and Morals: An Inquiry into the Maltreatment of Non-humans,* edited by Roslind and Stanley Godlovitch and John Harris, was followed three years later by Peter Singer's *Animal Liberation* and then by a flood of articles and books that established the issue as a part of applied ethics. At the same time, these writings provided the philosophical basis for the animal liberation movement, which has had an effect on attitudes and practices toward animals in many countries.

Environmental ethics. Environmental issues raise a host of difficult ethical questions, including the ancient one of the nature of intrinsic value. Whereas many philosophers in the past have agreed that human experiences have intrinsic value and the Utilitarians at least have always accepted that the pleasures and pains of nonhuman animals are of some intrinsic significance, this does not show why it is so bad if dodos become extinct or a rain forest is cut down. Are these things to be regretted only because of the loss to humans or other sentient creatures? Or is there more to it than that? Some philosophers are now prepared to defend the view that trees, rivers, species (considered apart from the individual animals of which they consist), and perhaps ecological systems as a whole have a value independent of the instrumental value they may have for humans or other sentient creatures.

Issue of obligations to future generations

Our concern for the environment also raises the question of our obligations to future generations. How much do we owe to the future? From a social contract view of ethics or for the ethical egoist, the answer would seem to be: nothing. For we can benefit them, but they are unable to reciprocate. Most other ethical theories, however, do give weight to the interests of coming generations. Utilitarians, for one, would not think that the fact that members of future generations do not exist yet is any reason for giving less consideration to their interests than we give to our own, provided only that we are certain that they will exist and will have interests that will be affected by what we do. In the case of, say, the storage of radioactive wastes, it seems clear that what we do will indeed affect the interests of generations to come.

The question becomes much more complex, however, when we consider that we can affect the size of future generations by the population policies we choose and the extent to which we encourage large or small families. Most environmentalists believe that the world is already dangerously overcrowded. This may well be so, but the notion of overpopulation conceals a philosophical issue that is ingeniously explored by Derek Parfit in *Reasons and Persons* (1984). What is optimum population? Is it that population size at which the average level of welfare will be as high as possible? Or is it the size at which the total amount of welfare—the average multiplied by the number of people—is as great as possible? Both answers lead to counterintuitive outcomes, and the question remains one of the most baffling mysteries in applied ethics.

War and peace. The Vietnam War ensured that discussions as to the justness of a war and of the legitimacy of conscription and civil disobedience were prominent in early writings in applied ethics. There was considerable support for civil disobedience against unjust aggression and against unjust laws even in a democracy.

With the cessation of hostilities in Vietnam and the end of conscription, interest in these questions declined. Concern about nuclear weapons in the early 1980s, however, has caused philosophers to argue about whether nuclear deterrence can be an ethically acceptable strategy if it means using civilian populations as potential nuclear targets. Jonathan Schell's *Fate of the Earth* (1982) raised several philosophical questions about what we ought to do in the face of the possible destruction of all life on our planet.

Abortion, euthanasia, and the value of human life. A number of ethical questions cluster around both ends of the human life span. Whether abortion is morally justifiable has popularly been seen as depending on our answer to the question "When does a human life begin?" Many philosophers believe this to be the wrong question to ask because it suggests that there might be a factual answer that we can somehow discover through advances in science. Instead, these philosophers think we need to ask what it is that makes killing a human being wrong and then consider whether these characteristics, whatever they might be, apply to the fetus in an abortion. There is no generally agreed upon answer, yet some philosophers have presented surprisingly strong arguments to the effect that not only the fetus but even the newborn infant has no right to life. This position has been defended by Jonathan Glover in *Causing Death and Saving Lives* (1977) and in more detail by Michael Tooley in *Abortion and Infanticide* (1984).

Such views have been hotly contested, especially by those who claim that all human life, irrespective of its characteristics, must be regarded as sacrosanct. The task for those who defend the sanctity of human life is to explain why human life, no matter what its characteristics, is specially worthy of protection. Explanation could no doubt be provided in terms of such traditional Christian doctrines as that all humans are made in the image of God or that all humans have an immortal soul. In the current debate, however, the opponents of abortion have eschewed religious arguments of this kind without finding a convincing secular alternative.

Somewhat similar issues are raised by euthanasia when it is nonvoluntary, as, for example, in the case of severely disabled newborn infants. Euthanasia, however, can be voluntary, and this has brought it support from some who hold that the state should not interfere with the free, informed choices of its citizens in matters that do not cause others harm. (The same argument is often invoked in defense of the pro-choice position in the abortion controversy; but it is on much weaker ground in this case because it presupposes what it needs to prove—namely, that the fetus does not count as an "other.") Opposition to voluntary euthanasia has centred on practical matters such as the difficulty of adequate safeguards and on the argument that it would lead to a "slippery slope" that would take us to nonvoluntary euthanasia and eventually to the compulsory involuntary killing of those the state considers to be socially undesirable.

Distinction between killing and allowing to die

Philosophers have also canvassed the moral significance of the distinction between killing and allowing to die, which is reflected in the fact that many physicians will allow a patient with an incurable condition to die when life could still be prolonged, but they will not take active steps to end the patient's life. Consequentialist philosophers, among them both Glover and Tooley, have denied that

this distinction possesses any intrinsic moral significance. For those who uphold a system of absolute rules, on the other hand, a distinction between acts and omissions is essential if they are to render plausible the claim that we must never breach a valid moral rule.

Bioethics. The issues of abortion and euthanasia are included in one of the fastest growing areas of applied ethics, that dealing with ethical issues raised by new developments in medicine and the biological sciences. This subject, known as bioethics, often involves interdisciplinary work, with physicians, lawyers, scientists, and theologians all taking part. Centres for research in bioethics have been established in Australia, Britain, Canada, and the United States. Many medical schools have added the discussion of ethical issues in medicine to their curricula. Governments have sought to deal with the most controversial issues by appointing special committees to provide ethical advice.

Major issues of bioethics

Several key themes run through the subjects covered by bioethics. One, related to abortion and euthanasia, is whether the quality of a human life can be a reason for ending it or for deciding not to take steps to prolong it. Since medical science can now keep alive severely disabled infants who a few years ago would have died soon after birth, pediatricians are regularly faced with this question. The issue received national publicity in Britain in 1981 when a respected pediatrician was charged with murder, following the death of an infant with Down's syndrome. Evidence at the trial indicated that the parents had not wanted the child to live and that the pediatrician had consequently prescribed a narcotic painkiller. The doctor was acquitted. The following year, in the United States, an even greater furor was caused by a doctor's decision to follow the wishes of the parents of a Down's syndrome infant and not carry out surgery without which the baby would die. The doctor's decision was upheld by the Supreme Court of Indiana, and the baby died before an appeal could be made to the U.S. Supreme Court. In spite of the controversy and efforts by government officials to ensure that handicapped infants are given all necessary lifesaving treatment, in neither Britain nor the United States is there any consensus about the decisions that should be made when severely disabled infants are born or by whom these decisions should be made.

Medical advances have raised other related questions. Even those who defend the doctrine of the sanctity of all human life do not believe that doctors have to use extraordinary means to prolong life, but the distinction between ordinary and extraordinary means, like that between acts and omissions, is itself under attack. Critics assert that the wishes of the patient or, if these cannot be ascertained, the quality of the patient's life provides a more relevant basis for a decision than the nature of the means to be used.

Another central theme is that of patient autonomy. This arises not only in the case of voluntary euthanasia but also in the area of human experimentation, which has come under close scrutiny following reported abuses. It is generally agreed that patients must give informed consent to any experimental procedures. But how much and how detailed information is the patient to be given? The problem is particularly acute in the case of randomly controlled trials, which scientists consider the most desirable way of testing the efficacy of a new procedure but which require that the patient agree to being administered randomly one of two or more forms of treatment.

The allocation of medical resources became a life-and-death issue when hospitals obtained dialysis machines and had to choose which of their patients suffering from kidney disease would be able to use the scarce machines. Some argued for "first come, first served," whereas others thought it obvious that younger patients or patients with dependents should have preference. Kidney machines are no longer as scarce, but the availability of various other exotic, expensive lifesaving techniques is limited; hence, the search for rational principles of distribution continues.

New issues arise as further advances are made in biology and medicine. In 1978 the birth of the first human being to be conceived outside the human body initiated a debate about the ethics of in vitro fertilization. This soon led to questions about the freezing of human embryos and what should be done with them if, as happened in 1984 with two embryos frozen by an Australian medical team, the parents should die. The next controversy in this area arose over commercial agencies offering infertile married couples a surrogate mother who would for a fee be impregnated with the sperm of the husband and then surrender the resulting baby to the couple. Several questions emerged: Should we allow women to rent their wombs to the highest bidder? If a woman who has agreed to act as a surrogate changes her mind and decides to keep the baby, should she be allowed to do so?

The culmination of such advances in human reproduction will be the mastery of genetic engineering. Then we will all face the question posed by the title of Jonathan Glover's probing book *What Sort of People Should There Be?* (1984). Perhaps this will be the most challenging issue for 21st-century ethics.

BIBLIOGRAPHY

General works: For an introduction to the major theories of ethics, the reader should consult RICHARD B. BRANDT, *Ethical Theory: The Problems of Normative and Critical Ethics* (1959), an excellent comprehensive textbook. WILLIAM K. FRANKENA, *Ethics,* 2nd ed. (1973), is a much briefer treatment. Another concise work is BERNARD WILLIAMS, *Ethics and the Limits of Philosophy* (1985). There are several useful collections of classical and modern writings; among the better ones are OLIVER A. JOHNSON, *Ethics: Selections from Classical and Contemporary Writers,* 5th ed. (1984); and JAMES RACHELS (ed.), *Understanding Moral Philosophy* (1976), which places greater emphasis on modern writers.

Origins of ethics: JOYCE O. HERTZLER, *The Social Thought of the Ancient Civilizations* (1936, reissued 1961), is a wide-ranging collection of materials. EDWARD WESTERMARCK, *The Origin and Development of the Moral Ideas,* 2 vol., 2nd ed. (1912–17, reprinted 1971), is dated but still unsurpassed as a comprehensive account of anthropological data. MARY MIDGLEY, *Beast and Man: The Roots of Human Nature* (1978, reissued 1980), is excellent on the links between biology and ethics; and EDWARD O. WILSON, *Sociobiology: The New Synthesis* (1975), and *On Human Nature* (1978), contain controversial speculations on the biological basis of social behaviour. RICHARD DAWKINS, *The Selfish Gene* (1976, reprinted 1978), is another evolutionary account, fascinating but to be used with care.

History of Western ethics: HENRY SIDGWICK, *Outlines of the History of Ethics for English Readers,* 6th enlarged ed. (1931, reissued 1967), is a triumph of scholarship and brevity. WILLIAM EDWARD HARTPOLE LECKY, *History of European Morals from Augustus to Charlemagne,* 2 vol., 3rd rev. ed. (1877, reprinted 1975), is fascinating and informative. Among more recent histories, VERNON J. BOURKE, *History of Ethics* (1968, reissued in 2 vol., 1970), is remarkably comprehensive; while ALASDAIRE MACINTYRE, *A Short History of Ethics* (1966), is a readable personal view.

Indian ethics: SURAMA DASGUPTA, *Development of Moral Philosophy in India* (1961, reissued 1965), is a clear discussion of the various schools. SARVEPALLI RADHAKRISHNAN and CHARLES A. MOORE (eds.), *A Source Book in Indian Philosophy* (1957, reprinted 1967), is a collection of key primary sources. For Buddhist texts, see EDWARD CONZE *et al.* (eds.), *Buddhist Texts Through the Ages* (1954, reissued 1964).

Chinese ethics: Standard introductions to the works of classic Chinese authors mentioned in the article are E.R. HUGHES (ed.), *Chinese Philosophy in Classical Times* (1942, reprinted 1966); and FUNG YU-LAN, *A History of Chinese Philosophy,* 2 vol., trans. from the Chinese (1952–53, reprinted 1983).

Ancient Greek and Roman ethics: JONATHAN BARNES, *The Presocratic Philosophers,* rev. ed. (1982), treats Greek ethics before Socrates. The central texts of the Classic period of Greek ethics are PLATO, *Politeia* (*The Republic*), *Euthyphro, Protagoras,* and *Gorgias;* and ARISTOTLE, *Ethica Nicomachea* (*Nicomachean Ethics*). A concise introduction to the ethical thought of this period is provided by PAMELA HUBY, *Greek Ethics* (1967); and CHRISTOPHER ROWE, *An Introduction to Greek Ethics* (1976). Significant writings of the Stoics include MARCUS TULLIUS CICERO, *De officiis* (*On Duties*); LUCIUS ANNAEUS SENECA, *Epistulae morales* (*Moral Essays*); and MARCUS AURELIUS, *D. imperatoris Marci Antonini Commentariorum qvos sibi ipsi scripsit libri XII* (*The Meditations of the Emperor Marcus Antoninus*). From Epicurus only fragments remain; they have been collected in CYRIL BAILEY (ed.), *Epicurus, the Extant Remains* (1926, reprinted 1979). The most complete of the surviving works of the Epicureans is LUCRETIUS, *De rerum natura* (*On the Nature of Things*).

Early and medieval Christian ethics: In addition to the

Gospels and Paul's letters, important writings include ST. AUGUSTINE, *De civitate Dei* (413–426; *The City of God*), and *Enchiridion ad Laurentium de fide, spe, et caritate* (421; *Enchiridion to Laurentius on Faith, Hope and Love*); PETER ABELARD, *Ethica* (*c.* 1135; *Ethics*); and ST. THOMAS AQUINAS, *Summa theologiae* (1265 or 1266–73). On the history of the transition from Roman ethics to Christianity, W.E.H. LECKY, *op.cit.*, remains unsurpassed. D.J. O'CONNOR, *Aquinas and Natural Law* (1967), is a brief introduction to the most important of the Scholastic writers on ethics.

Ethics of the Renaissance and Reformation: Machiavelli's chief works are available in modern translations: NICCOLÒ MACHIAVELLI, *The Prince,* trans. and ed. by PETER BONDANELLA and MARK MUSA (1984), and *The Discourses,* trans. by LESLIE J. WALKER (1975). For Luther's writings, see the comprehensive edition MARTIN LUTHER, *Works,* 55 vol., ed. by JAROSLAV PELIKAN *et al.* (1955–76). Calvin's major work is available in JEAN CALVIN, *Institutes of the Christian Religion,* trans. by HENRY BEVERIDGE, 2 vol. (1979).

The British tradition from Hobbes to the Utilitarians: The key works of this period include THOMAS HOBBES, *Leviathan* (1651); RALPH CUDWORTH, *Eternal and Immutable Morality* (published posthumously, 1688); HENRY MORE, *Enchiridion Ethicum* (1662); SAMUEL CLARKE, Boyle lectures for 1705, published in his *Works,* 4 vol. (1738–42); 3RD EARL OF SHAFTESBURY, "Inquiry Concerning Virtue or Merit," published together with other essays in his *Characteristicks of Men, Manners, Opinions, Times* (1711); JOSEPH BUTLER, *Fifteen Sermons* (1726); FRANCIS HUTCHESON, *Inquiry into the Original of Our Ideas of Beauty and Virtue* (1725), and *A System of Moral Philosophy,* 2 vol. (1755); DAVID HUME, *A Treatise of Human Nature* (1739–40), and *An Enquiry Concerning the Principles of Morals* (1751); RICHARD PRICE, *A Review of the Principal Questions and Difficulties in Morals* (1758); THOMAS REID, *Essays on the Active Powers of the Human Mind* (1758); WILLIAM PALEY, *The Principles of Moral and Political Philosophy* (1785); JEREMY BENTHAM, *Introduction to the Principles of Morals and Legislation* (1789); JOHN STUART MILL, *Utilitarianism* (1863); and HENRY SIDGWICK, *The Methods of Ethics* (1874). Selections of the major texts of this period are brought together in D.D. RAPHAEL (ed.), *British Moralists, 1650–1800,* 2 vol. (1969); and in D.H. MONRO (ed.), *A Guide to the British Moralists* (1972). Useful introductions to separate writers include J. KEMP, *Ethical Naturalism* (1970), on Hobbes and Hume; W.D. HUDSON, *Ethical Intuitionism* (1967), on the intuitionists from Cudworth to Price and the debate with the moral sense school; and ANTHONY QUINTON, *Utilitarian Ethics* (1973). C.D. BROAD, *Five Types of Ethical Theory* (1930, reprinted 1971), includes clear accounts of the ethics of Butler, Hume, and Sidgwick. J.L. MACKIE, *Hume's Moral Theory* (1980), brilliantly traces the relevance of Hume's work to current disputes about the nature of ethics.

The continental tradition from Spinoza to Nietzsche: The major texts are available in many English translations. See BARUCH SPINOZA, *The Ethics and Selected Letters,* trans. by SAMUEL SHIRLEY, ed. by SEYMOUR FELDMAN (1982); JEAN-JACQUES ROUSSEAU, *A Discourse on Inequality,* trans. by MAURICE CRANSTON (1984), and *The Social Contract,* annotated ed., trans. by CHARLES M. SHEROVER (1974); IMMANUEL KANT, *Grounding for the Metaphysics of Morals,* trans. by JAMES W. ELLINGTON (1981), and *Critique of Practical Reason, and Other Writings in Moral Philosophy,* ed. and trans. by LEWIS WHITE BECK (1949, reprinted 1976); G.W.F. HEGEL, *Phenomenology of Spirit,* trans. by A.V. MILLER (1977), and *Hegel's Philosophy of Right,* trans. by T.M. KNOX (1967, reprinted 1980); KARL MARX, *Economic and Philosophic Manuscripts of 1844,* ed. by DIRK J. STRUIK (1964), *Capital: A Critique of Political Economy,* trans. by DAVID FERNBACH, 3 vol. (1981), and *The Communist Manifesto of Marx and Engels,* ed. by HAROLD J. LASKI (1967, reprinted 1975); FRIEDRICH NIETZSCHE, *Beyond Good and Evil: Prelude to a Philosophy of the Future,* trans. by R.J. HOLLINGDALE (1973), and *The Genealogy of Morals: A Polemic,* trans. by HORACE B. SAMUEL (1964). Among the easier introductory studies are H.B. ACTON, *Kant's Moral Philosophy* (1970); and PETER SINGER, *Hegel* (1983), and *Marx* (1980). C.D. BROAD, *op. cit.*, contains readable accounts of the ethics of both Spinoza and Kant.

20th-century Western ethics: The most influential writings in metaethics during the 20th century have been GEORGE EDWARD MOORE, *Principia Ethica* (1903, reprinted 1976); W.D. ROSS, *The Right and the Good* (1930, reprinted 1973); A.J. AYER, *Language, Truth, and Logic* (1936, reissued 1974); CHARLES L. STEVENSON, *Ethics and Language* (1944, reprinted 1979); R.M. HARE, *The Language of Morals* (1952, reprinted 1972), and *Freedom and Reason* (1963, reprinted 1977); and, in France, JEAN-PAUL SARTRE, *Being and Nothingness* (1956, reissued 1978; originally published in French, 1943), and *Existentialism and Humanism* (1948, reprinted 1977; originally published in French, 1946). RALPH BARTON PERRY, *General Theory of Value* (1926, reprinted 1967), was highly regarded in the United States but comparatively neglected elsewhere. WILFRID SELLARS and JOHN HOSPERS (eds.), *Readings in Ethical History,* 2nd ed. (1970), contains the most important pieces of writing on ethics from the first half of the 20th century. Widely discussed later works include THOMAS NAGEL, *The Possibility of Altruism* (1970, reissued 1978); G.J. WARNOCK, *The Object of Morality* (1971); J.L. MACKIE, *Ethics: Inventing Right and Wrong* (1977); RICHARD B. BRANDT, *A Theory of the Good and the Right* (1979); JOHN FINNIS, *Natural Law and Natural Rights* (1980); and R.M. HARE, *Moral Thinking: Its Levels, Method, and Point* (1981). A defense of naturalism can be found in two important articles by PHILIPPA FOOT, "Moral Beliefs" and "Moral Arguments," both originally published in 1958 and later reprinted in her *Virtues and Vices, and Other Essays in Moral Philosophy* (1978, reprinted 1981). DAVID WIGGINS, *Truth, Invention, and the Meaning of Life* (1976), is a statement of what has come to be known as "moral realism." MARY WARNOCK, *Ethics Since 1900,* 3rd ed. (1978); G.J. WARNOCK, *Contemporary Moral Philosophy* (1967); and W.D. HUDSON, *A Century of Moral Philosophy* (1980), provide guidance through 20th-century metaethical disputes.

Normative ethics: For Moore's ideal Utilitarianism, see G.E. MOORE, *Ethics,* 2nd ed. (1966). The best short statement of an act-Utilitarian position is J.J.C. Smart's contribution to J.J.C. SMART and BERNARD WILLIAMS, *Utilitarianism: For and Against* (1973). R.M. HARE, *op. cit.,* is an extended argument for a form of preference Utilitarianism that allows some scope to moral principles while not departing from act-Utilitarianism at the level of critical thought. DAVID LYONS, *Forms and Limits of Utilitarianism* (1965), probes the distinction between act- and rule-Utilitarianism. RICHARD B. BRANDT, *op. cit.,* includes a defense of a version of rule-Utilitarianism. DONALD REGAN, *Utilitarianism and Co-operation* (1980), is an ingenious discussion of how the need to cooperate can be incorporated into Utilitarian theory. AMARTYA SEN and BERNARD WILLIAMS (eds.), *Utilitarianism and Beyond* (1982), is a collection of essays on the difficulties of the Utilitarian position. A major contribution to consequentialist theory is DEREK PARFIT, *Reasons and Persons* (1984), which includes penetrating arguments on the nature of consequentialist reasoning in ethics. The standard defense of an ethic of prima facie duties remains W.D. ROSS, *op. cit.* H.J. MCCLOSKEY, *Meta-Ethics and Normative Ethics* (1969), is a restatement with some modifications. The most widely discussed alternative theory to Utilitarianism in recent years is set forth in JOHN RAWLS, *A Theory of Justice* (1971, reprinted 1981). ROBERT NOZICK, *Anarchy, State, and Utopia* (1974), criticizes Rawls and presents a rights-based theory. Another work giving prominence to rights is RONALD DWORKIN, *Taking Rights Seriously* (1977). Very different from the approach of both Nozick and Dworkin is the attempt to ground rights in natural law in JOHN FINNIS, *op. cit.,* and a shorter and more accessible introduction to natural law ethics is *Fundamentals of Ethics* (1983). Egoism as a theory of rationality is discussed by DEREK PARFIT, *op. cit.;* a useful collection of readings on this topic is DAVID P. GAUTHIER (ed.), *Morality and Rational Self-Interest* (1970); see also RONALD D. MILO (ed.), *Egoism and Altruism* (1973).

Applied ethics: Many of the best examples of applied ethics are to be found in journal articles, particularly in *Philosophy and Public Affairs* (quarterly). There are many anthologies of representative samples of such writings. Among the better ones are JAMES RACHELS (ed.), *Moral Problems,* 3rd ed. (1979); JAN NARVESON (ed.), *Moral Issues* (1983); and MANUEL VELASQUEZ and CYNTHIA ROSTANKOWSKI, *Ethics, Theory and Practice* (1985). There are also books and collections on specific topics. MARSHALL COHEN, THOMAS NAGEL, and THOMAS SCANLON (eds.), *Equality and Preferential Treatment* (1977), is a collection of some of the best articles on equality and reverse discrimination; while ALAN H. GOLDMAN, *Justice and Reverse Discrimination* (1979), is a book-length treatment of the issues. Some of the more philosophically probing discussions of feminism are JANET RADCLIFFE RICHARDS, *The Sceptical Feminist* (1980, reprinted with corrections, 1982); MARY MIDGLEY and JUDITH HUGHES, *Women's Choices: Philosophical Problems Facing Feminism* (1983); and ALISON M. JAGGAR, *Feminist Politics and Human Nature* (1983). The moral obligations of the wealthy toward the starving are discussed in the anthology *World Hunger and Moral Obligation,* ed. by WILLIAM AIKEN and HUGH LAFOLLETTE.

The ethics of the treatment of animals has given rise to much philosophical discussion. Books arguing for radical change include STANLEY GODLOVITCH, ROSLIND GODLOVITCH, and JOHN HARRIS (eds.), *Animals, Man, and Morals: An Enquiry into the Maltreatment of Non-Humans* (1971); PETER SINGER, *Animal Liberation: A New Ethics for Our Treatment of Animals* (1975); STEPHEN R.L. CLARK, *The Moral Status of Animals* (1977, reis-

sued 1984); and TOM REGAN, *The Case for Animal Rights* (1983). R.G. FREY, *Interests and Rights: The Case Against Animals* (1980), and *Rights, Killing, and Suffering: Moral Vegetarianism and Applied Ethics* (1983), resist some of these arguments. MARY MIDGLEY, *Animals and Why They Matter* (1983), takes a middle course.

Essays dealing with ethical issues raised by concern for the environment are collected in ROBERT ELLIOT and ARRAN GARE (eds.), *Environmental Philosophy* (1983); and K.S. SHRADER-FRECHETTE, *Environmental Ethics* (1981). Useful full-length studies include JOHN PASSMORE, *Man's Responsibility for Nature: Ecological Problems and Western Tradition,* 2nd ed. (1980); and H.J. MCCLOSKEY, *Ecological Ethics and Politics* (1983). For specific problems of future generations, see R. SIKORA and BRIAN BARRY (eds.), *Obligations to Future Generations* (1979). A difficult but fascinating discussion of the problem of optimum population size in an ideal world can be found in DEREK PARFIT, *op. cit.*

MICHAEL WALZER, *Just and Unjust Wars* (1977), is a fine study of the morality of war; RICHARD A. WASSERSTROM (ed.), *War and Morality* (1970), is a valuable collection of essays. NIGEL BLAKE and KAY POLE (eds.), *Objections to Nuclear Defence* (1984), and *Dangers of Deterrence* (1984), are collections of philosophical writings on nuclear war.

There is an immense amount of literature on abortion, though of various philosophical depth. MICHAEL TOOLEY, *Abortion and Infanticide* (1983), is a penetrating study. For contrasting views, see GERMAIN G. GRISEZ, *Abortion: The Myths, the Realities, and the Arguments* (1970); and BARUCH A. BRODY, *Abortion and the Sanctity of Human Life: A Philosophical View* (1975). Another notable treatment is L.W. SUMNER, *Abortion and Moral Theory* (1981). JOEL FEINBERG (ed.), *The Problem of Abortion,* 2nd ed. (1984), is a good collection of essays. For a discussion of sanctity of life issues in general, including both abortion and euthanasia, see JONATHAN GLOVER, *Causing Death and Saving Lives* (1977); and PETER SINGER, *Practical Ethics* (1979). The specific problem of the treatment of severely handicapped infants is discussed in HELGA KUHSE and PETER SINGER, *Should the Baby Live?* (1985).

For a comprehensive textbook on bioethics, see TOM. L. BEAUCHAMP and JAMES F. CHILDRESS, *Principles of Biomedical Ethics,* 2nd ed. (1983). Anthologies of essays on diverse topics in bioethics include SAMUEL GOROVITZ *et al.* (eds.), *Moral Problems in Medicine,* 2nd ed. (1983); and JOHN ARRAS and ROBERT HUNT (comp.), *Ethical Issues in Modern Medicine,* 2nd ed. (1983). JAMES F. CHILDRESS, *Who Should Decide?* (1982), deals with paternalism in medical care; while PETER SINGER and DEANE WELLS, *The Reproduction Revolution: New Ways of Making Babies* (1984), focusses on the new reproductive technology. For the philosophical issues underlying genetic engineering and other methods of altering the human organism, see JONATHAN GLOVER, *What Sort of People Should There Be?* (1984).

(P.Si.)

Europe

Among the continents, Europe is an anomaly. Larger only than Australia, it is a small appendage of the great landmass that it shares with an Asia more than four times its size. Yet the peninsular and insular western extremity of Eurasia, thrusting toward the North Atlantic Ocean, provides—thanks to its latitude and its physical geography—a relatively genial human habitat, and the long processes of human history came to mark off the region as the home of a distinctive civilization. In spite of its internal diversity, Europe has thus functioned, from the time it first emerged in the human consciousness, as a world apart, concentrating—to borrow a phrase from Christopher Marlowe—"infinite riches in a little room."

All the continents are conceptual constructs, but only Europe was not first perceived and named by outsiders. "Europa," as the more learned of the ancient Greeks first conceived it, stood in sharp contrast to both Asia and Libya, the name then applied to the known northern part of Africa. Literally, "Europa" is now thought to have meant "Mainland," rather than the earlier interpretation, "Sunset." It appears to have suggested itself to the Greeks, in their maritime world, as an appropriate designation of the broadening, extensive northerly lands that lay beyond, lands with characteristics but vaguely known; yet these characteristics were clearly different from those inherent in the concepts of Asia and Libya, both of which, relatively prosperous and civilized, were associated closely with the culture of the Greeks and their predecessors. Traders and travelers reported that Europe possessed distinctive physical units, with mountain systems and lowland river basins much larger than those familiar to inhabitants of the Mediterranean region. It was also clear that a succession of climates, markedly different from those of the Mediterranean borderlands, were to be experienced as Europe was penetrated from the south. The spacious eastern steppe and, to the west and north, primeval forests as yet only marginally touched by human occupancy further underlined environmental contrasts. Europe was culturally backward and scantily settled. It was a "barbarian"—that is, a non-Greek—world, its inhabitants making "bar-bar" noises in unintelligible tongues.

The Roman Empire, at its greatest extent in the 2nd century AD, revealed, and imprinted its culture on, much of the face of the continent, while trading relations beyond its frontiers also drew the remoter regions into its sphere. Yet it was not until the 19th and 20th centuries that modern science was able to draw with some precision the geologic and geographic lineaments of the European continent, the peoples of which had meanwhile achieved domination over—and set in motion vast countervailing movements among—the inhabitants of much of the rest of the globe.

As to the territorial limits of Europe, while these seem clear on its three seaward flanks, they have been uncertain and hence much debated on the east, where the continent merges, without sundering physical limits, with parts of western Asia. Even to the north and west, many island groups—Svalbard (Spitsbergen), the British Isles, the Faeroes, Iceland, and the Madeira and Canary islands—that are European by culture are included in the continent, although Greenland is conventionally allocated to North America. Further, the Mediterranean coastlands of North Africa and southwestern Asia also exhibit some European physical and cultural affinities, and Turkey and Cyprus, while geologically Asian, possess elements of European culture and may, perhaps, be regarded as parts of Europe. Eastward limits, now adopted by European (including Soviet) geographers, assign the Caucasus to Asia and are taken to run southward along the eastern foot of the Urals and then across the Mugodzhar Hills, along the Emba River, and along the northern shore of the Caspian Sea. West of the Caspian, the European limit follows the Kumo–Manych Depression and the Kerch Strait to the Black Sea.

This conventional eastern boundary, however, is not a cultural, political, or economic discontinuity on the land comparable, for example, to the insulating significance of the sparsely inhabited Himalayas, which clearly mark a northern limit to South Asian civilization. Inhabited plains, with only the minor interruption of the worn-down Ural Mountains, extend from central Europe to the Yenisey River in central Siberia. A homogeneous, highly centralized, Russian-based civilization dominates Soviet territory from the Baltic and Black seas to the Pacific Ocean. This civilization is distinguished from the rest of Europe by legacies of a medieval Mongol–Tatar domination that precluded sharing many of the innovations and developments of European "Western civilization." In partitioning the globe into meaningful large geographic units, therefore, modern geographers have been mindful of the distinctiveness of the Soviet Union. Most treat it as a distinct territorial entity, comparable to a continent, that is separate from Europe to the west and from the rest of Asia to the south and east. The ensuing discussion of Europe focuses primarily upon the territories and peoples lying west of the Soviet border, although note is taken, where appropriate, of physical and cultural features shared by the "European" Soviet Union with the rest of the continent. For a detailed discussion of the Soviet Union, see UNION OF SOVIET SOCIALIST REPUBLICS.

Europe occupies some four million square miles (10.4 million square kilometres) within the conventional borders assigned to it. Of this total, 2.1 million square miles are inside the Soviet Union. This broad territory reveals no simple unity of geologic structure, landform, relief, or climate. Rocks of all geologic periods are exposed, and the operation of geologic forces during an immense succession of eras has contributed to the molding of the landscapes of mountain, plateau, and lowland and has bequeathed a variety of mineral reserves. Glaciation, too, has left its mark over wide areas, and the processes of erosion and deposition have created a highly variegated and compartmentalized countryside. Climatically, Europe benefits by having only a small proportion of its surface either too cold or too hot and dry for effective settlement and use. Regional climatic contrasts nevertheless exist: oceanic, Mediterranean, and continental types occur widely, as do gradations from one to the other. Associated vegetation and soil forms also show continual variety, but little is left of the dominant woodland that clothed the continent when humans first appeared.

All in all, Europe enjoys a considerable and long-exploited resource base of soil, forest, sea, and minerals, notably coal, but population, considerable numerically, as well as technically highly qualified, is increasingly its principal resource. The continent contains a shrinking seventh portion of mankind, but this represents a population of high skill and initiative. Europe thus supports high densities of population, markedly concentrated in industrialized regions. In manufacture, commerce, and agriculture it still occupies an eminent, if no longer necessarily predominant, position, and, as agriculture increasingly rationalizes its structure, city life is, everywhere, becoming the norm.

Europe is preeminently the homeland of white peoples. Its early and continuing economic achievements, evidenced by a high standard of living, and its successes in science, technology, and the arts spring from the vigour of its peoples in developing a high civilization, the roots of which lie in ancient Greece and Rome, the Byzantine Empire, and Palestine. Whatever its indebtedness, Europe has always shown its own powers of creativity and leadership: although wracked and exhausted by continued

internal conflict, it has nevertheless advanced sufficiently to leave as its heritage the exploration, colonization, and development of other peoples and regions of the globe, if not always to the benefit of the other peoples and regions.

(W.G.E./T.M.P.)

This article treats the physical and human geography of Europe, followed by discussion of geographic features of special interest. For discussion of individual countries of the continent, see specific articles by name—*e.g.,* ITALY, POLAND, and UNITED KINGDOM. For discussion of major cities of the continent, see specific articles by name—*e.g.,* LONDON, ROME, and WARSAW. The principal articles discussing the historical and cultural development of the continent include EUROPEAN HISTORY AND CULTURE; GREEK AND ROMAN CIVILIZATIONS, ANCIENT; and HOLY ROMAN EMPIRE, THE HISTORY OF THE. Related topics are discussed in such articles as those on religion (*e.g.,* EUROPEAN RELIGIONS, ANCIENT; JUDAISM; and ROMAN CATHOLICISM) and literature (*e.g.,* DUTCH LITERATURE; HOMERIC EPICS, THE; and SPANISH LITERATURE). For further references, see the *Index.*

The article is divided into the following sections:

PHYSICAL AND HUMAN GEOGRAPHY

Geologic history

The geologic record of the continent of Europe started about three billion years ago and has continued intermittently to the present. It is a classic example of how a continent has grown through time. The Precambrian rocks in Europe range in age from about three billion to 570 million years and are succeeded by rocks of the Paleozoic era, which continued to 245 million years ago; the Mesozoic era, which lasted until 66.4 million years ago; and the Cenozoic era, which continues to today. The present shape of Europe did not finally emerge until the late Tertiary period, about five million years ago. The types of rocks, tectonic belts, and sedimentary basins that developed throughout the geologic history of Europe strongly influence human activities today.

GENERAL CONSIDERATIONS

Tectonic framework. The tectonic map of Europe shows the distribution of the main tectonic units. The largest area of oldest rocks is the Baltic Shield, which has been eroded down to a low relief; the youngest rocks occur in the Alpine system, which still survives as high mountains. Between these belts are basins of sedimentary rocks that form rolling hills, as in the Paris Basin and southeastern England, or an extensive plain, as in the Russian Platform. The North Sea is a submarine sedimentary basin on the shallow-water continental margin of the Atlantic Ocean. Iceland is a unique occurrence in Europe, because it is a volcanic island situated on the Mid-Atlantic Ridge within the still-opening Atlantic Ocean.

Precambrian rocks occur in three basic tectonic environments. The first is in shields, like the Baltic Shield, which are large areas of stable Precambrian rocks usually surrounded by later orogenic belts. The second is as the basement to a younger cover of Phanerozoic sediments (*i.e.,* deposits that have been laid down since the beginning of the Paleozoic). For example, the sediments of the Russian Platform are underlain by Precambrian basement, which extends from the Baltic Shield to the Ural Mountains, and

Structural features of Europe.

Precambrian rocks underlie the Phanerozoic sediments in southeastern England. The Ukrainian Massif is an uplifted block of Precambrian basement that rises above the surrounding plain of younger sediments. The third is as relicts in younger orogenic belts. For example, there are Precambrian rocks in the Bohemian Massif that are one billion years old and rocks in the Channel Islands in the English Channel that are 1.6 billion years old, both of which are remnants of the Middle Proterozoic era within the late Paleozoic Heryncian belt. In addition, the Precambrian Rhodope Mountains on the Balkan Peninsula are a relict block within the Alpine system.

Paleozoic sedimentary rocks either occur in sedimentary basins like the Russian Platform—which has never been affected by any periods of orogenesis and thus has sediments that are still flat-lying and fossiliferous—or occur within orogenic belts, such as the Caledonian and Hercynian, where they have commonly been deformed by folding and thrusting, partly recrystallized, and subjected to intrusion by granites.

Mesozoic–Cenozoic sediments occur either in a well-preserved state in sedimentary basins unaffected by orogenesis, as within the Russian Platform and under the North Sea, or in a highly deformed and metamorphosed state, as in the Alpine system.

Chronological summary. The geologic development of Europe may be summarized as follows. Archean rocks (those more than 2.5 billion years old) are the oldest of the Precambrian period and crop out in the northern Baltic Shield, the Ukraine, and northwestern Scotland. Two major Proterozoic orogenic belts (*i.e.,* between 2.5 billion and 570 million years old) also extend across the central and southern Baltic Shield. Thus, this shield has a composite origin, containing remnants of several Precambrian orogenic belts.

About 570 to 500 million years ago a series of new oceans opened, and their closure gave rise to the Caledonian, Hercynian, and Uralian orogenic belts. There is considerable evidence which suggests that these belts developed by plate-tectonic processes, and they each have a history that lasted several hundred million years. Formation of these belts gave rise to the supercontinent of Pangaea; its fragmentation at the beginning of the Middle Triassic epoch (about 240 million years ago) gave rise to a new ocean, the Tethys Sea. Closure of this ocean early in the Tertiary period, about 50 million years ago, by subduction and plate-tectonic processes led to formation of the Alpine orogenic system, which extends from the Atlantic to Turkey and contains many separate orogenic belts (which remain as mountain chains), including the Pyrenees, Betics, Atlas, Swiss-Austrian Alps, Apennines, Carpathians, Dinaric Alps, and Taurus and Pontic mountains. During the time that the Tethys was opening (about 180 million years ago), the Atlantic Ocean also began to open; the structure and age of the seafloor between Iceland and the continental margin of the British Isles and Norway are well known. The Atlantic is still opening along the Mid-Atlantic Ridge under the ocean, with Iceland constituting an area of the ridge that is raised above sea level. The youngest tectonic activity in Europe is represented by the present-day volcanic eruptions in Iceland; volcanoes, such as Etna and Vesuvius; and earthquakes, as in the Aegean and Turkey in the Alpine system, which result from current stresses between Europe and Africa.

Alpine orogenic system

STRATIGRAPHY AND STRUCTURE

The Precambrian. This major period of geologic time can be subdivided into the older Archean and the younger Proterozoic eons, the time boundary between them being 2.5 billion years ago. Compared with most of the other continents, Europe has few exposed Archean rocks. Some granitic gneisses, which are more than three billion years old, crop out in the northern Baltic Shield, the Ukrainian Massif, and northwestern Scotland. These rocks were recrystallized at a depth of about 12 miles (20 kilometres) in the Archean crust, but their tectonic environment is poorly understood. The Baltic Shield exhibits successively younger orogenic belts toward the south, from the Archean relicts in the north to the Late Proterozoic belt of the Sveconorwegian in southwestern Norway. A major orogenic belt, the Svecofennian, developed in the Early Proterozoic era (2.5 to 1.6 billion years ago); it now occupies the bulk of the Baltic Shield, especially in Finland and Sweden, where it extends from the Kola Peninsula to the Gulf of Finland near Helsinki. The Sveconorwegian is a north–south-trending orogenic belt that developed in the period between 1.2 billion and 850 million years ago. It occupies southern Norway and the adjacent area of southwestern Sweden between Oslo and Göteborg. On its northern side it has been reactivated almost beyond recognition within the Caledonian orogenic belt. The Ukrainian Massif and the small Laxfordian belt in northwestern Scotland consist mainly of granitic rocks and highly deformed and metamorphosed schists and gneisses that originally were sediments and volcanics, and their age is similar to that of the Svecofennian belt. In northwestern Scotland there is a north–south-trending belt of red sandstones and conglomerates belonging to the Torridonian group that is about one billion years old; these sediments may be the erosional products or molasse of a 1.2-billion-year-old orogenic belt, of which there are a few relicts within the Paleozoic Caledonian belt of Scotland. The Bohemian Massif is a diamond-shaped block in the heart of Europe, which has been heavily affected by the late Paleozoic Hercynian orogeny. Many of the rocks originally formed in the Archean (about 2.7 billion years ago), the Early Proterozoic (Svecofennian times), or later in the Proterozoic (about one billion years ago), however, were strongly deformed in several Precambrian orogenies and thus are now schists, gneisses, and amphibolites, accompanied by a variety of granites. Near the end of the Precambrian—about 800 to 570 million years ago—there was widespread deposition of conglomerates, sandstones, clays, and some volcanic sediments, which make up the Eocambrian (or Vendian) group; these were derived from the erosion of uplifted Precambrian mountains. They are well known for two features. First is their glacial sediments, which were deposited at a time of worldwide glaciation; they occur in northwestern Scotland (Islay Island), western Ireland, Norway (Finnmark and West Spitzbergen), Sweden, France (Normandy), and Czechoslovakia (Bohemian Massif). Second is the occurrence of impressions of soft-bodied organisms, such as seaweed, jellyfish, and worms, which represent the beginnings of Metazoan life before the explosion of life forms with hard parts for skeletons that became abundant in the Early

Cambrian. These impressions occur in Charnwood Forest in central England, southern Wales, northern Sweden, the Ukraine, and several localities in the Russian Platform.

Mineral deposits

The Precambrian rocks of Europe provide a rich source of economic minerals to sustain human activities, such as major iron ore deposits at Kiruna in northern Sweden and Krivoy Rog in the Ukraine; tin deposits associated with granites in Finland; extensive copper–nickel sulphide ores across Finland, especially at Outokumpu, and in Sweden; and magnetite ores containing vanadium and titanium in northern Finland.

The Paleozoic era. The Paleozoic (570 to 245 million years ago) tectonic geology of Europe can be divided into two parts: the major orogenic belts of the Caledonian (or Caledonides), the Hercynian (or Hercynides), and the Uralian (or Uralides); and the undisturbed, mostly subsurface (and thus poorly known) Paleozoic sediments in the triangular area between these belts in the Russian Platform.

Caledonian orogenic belt. The major factor that controlled the early mid-Paleozoic development of Europe was the opening and closing of the Iapetus Sea, which gave rise to the Caledonian orogenic belt that extends from Ireland and Wales through northern England and Scotland to western Norway and northward to Finnmark in northern Norway. The belt is confined between the stable blocks of the Baltic Shield and the Precambrian belt of northwestern Scotland. Remnants of the Iapetus seafloor are seen in ophiolites at Ballantrae in Strathclyde region, Scot., and near Bergen, Nor. During the Cambrian period (570 to 505 million years ago) widening of the Iapetus gave rise to extensive shelf seas on the bordering continents, which deposited a thin cover of limestone and shale with a remarkable diversity of fossils of numerous marine invertebrates. The presence of this sea can be demonstrated by the fact that trilobites and graptolites in northern Scotland, which was on one side, are significantly different from those in central England and southern Norway, which were on the other. In the Ordovician period (505 to 438 million years ago) the sea began to close by subduction, giving rise to major magmatic belts with lavas and tuffs in the Lake District of northern England and Snowdonia National Park in Wales—where there is associated gold and copper mineralization—and to many granites in the highlands of Scotland. In the Silurian period (438 to 408 million years ago) the Iapetus Sea closed, with the result that the bordering continental blocks collided, giving rise to deformation, metamorphism, and the orogeny of the Caledonian belt. In the Late Silurian, early land plants and the first freshwater fish appeared in lakes on the belt. The rifts of the Orkney Basin developed in the Devonian period (408 to 360 million years ago) on top of the thickened and unstable crust of the Caledonian orogenic belt in a manner comparable to the Quaternary rifts of Tibet (*i.e.,* those that have appeared in the last 1.6 million years) that has a crust thickened by the Himalayan orogeny of the Tertiary period (66.4 to 1.6 million years ago). Erosion of the uplifted mountain belt in the Devonian led to deposition of sandstones and conglomerates in basins over a wide region from the British Isles to the western Russian Platform, often called the Old Red Sandstone continent.

Hercynian orogenic belt. The Hercynian, or Variscan, orogenic belt evolved during Devonian and Carboniferous times, from about 408 to 286 million years ago. The belt extends form Portugal and western Spain, southwestern Ireland, and southwestern England in the west; through the Ardennes, France (Brittany, Massif Central, Vosges, and Corsica), Sardinia, West and East Germany (Odenwald, Black Forest, and Harz mountains); to Czechoslovakia (Bohemian Massif). The orogeny was formed by plate-tectonic processes that included sea-floor spreading, continental drift, and the collision of plates. Remnants of the original ocean floor are preserved as ophiolites in the Harz Mountains and in the Lizard Peninsula of southwestern England. In the Devonian a continental margin ran along the north side of the belt in Devon and Cornwall (England) on which extensive sandstones derived from the continent were deposited. In the Carboniferous period, shallow-water limestones were laid down in the area of the Pennines of England on a shelf or carbonate bank; this formation passes southward into deeper-water shales of the Culm Trench of southwestern England, within which are found the pillow lavas, gabbros, and serpentinites of the Lizard ophiolite. In Brittany there is an island arc with lavas and granites that resulted from subduction of the ocean floor. The main Hercynian suture zone of the collided plates extends from the south side of Brittany to the Massif Central. Throughout much of Europe there is evidence of extensive thrusting, implying that there was appreciable thickening of the continental crust and the formation of a Tibetan-style plateau across the Hercynian orogeny. The thickening led to melting of the lower crust and the formation of large numbers of Late Carboniferous granites, especially in the Massif Central. The plateau became overly thick and unstable, and this caused the formation of rifts that developed into coal-bearing basins—as in Silesia (Poland) and the Massif Central—in the Late Carboniferous and Permian periods (*i.e.,* between about 320 and 245 million years ago). The varied tectonic development of the Hercynian orogeny gave rise to widespread mineral deposits in many environments, which have been exploited in the economic development of many countries. Lead and zinc deposits occur in shelf carbonate sediments in Ireland and the Pennines of England; there are deposits of copper, lead, and zinc sulfides that formed in rifts in Silesia (Poland and East Germany) and at the Riotinto Mines in southwestern Spain; and important mineral deposits of tin, tungsten, and uranium are associated with crustal melt granites in Cornwall, the Massif Central, and Spain and Portugal.

Uralian orogenic belt. The Uralian orogenic belt extends for about 1,550 miles (2,500 kilometres) from the Arctic Ocean to the Aral Sea and forms the traditional eastern boundary of Europe. This is a late Paleozoic belt that developed as a result of collision between Asia and Europe. The earliest rifts in old Precambrian basement rocks began in the Late Cambrian–Early Ordovician, about 500 million years ago, and these developed into the floor of a new ocean. Island arcs formed in the Silurian period and countless ophiolitic slabs of ocean floor were thrust onto the continental margins. In Devonian times a considerable amount of thrusting and metamorphism occurred, and the final parts of the ocean floor were subducted (*i.e.,* thrust under continental masses); the result of this activity was that in the Carboniferous there was a final collision between the continents of Europe and Asia that gave rise to the Uralian orogenic belt. In the Permian there was widespread deposition of limestones followed by red sandstones, which were derived by erosion of the mountains. In the 1840s the British geologist Sir Roderick Murchison coined the term Permian System for the city of Perm. The Ural Mountains are very rich in mineral deposits—especially chromite, platinum, nickel, copper, and gold—which are associated with the major ophiolitic slabs of ocean floor distributed along the mountain chain.

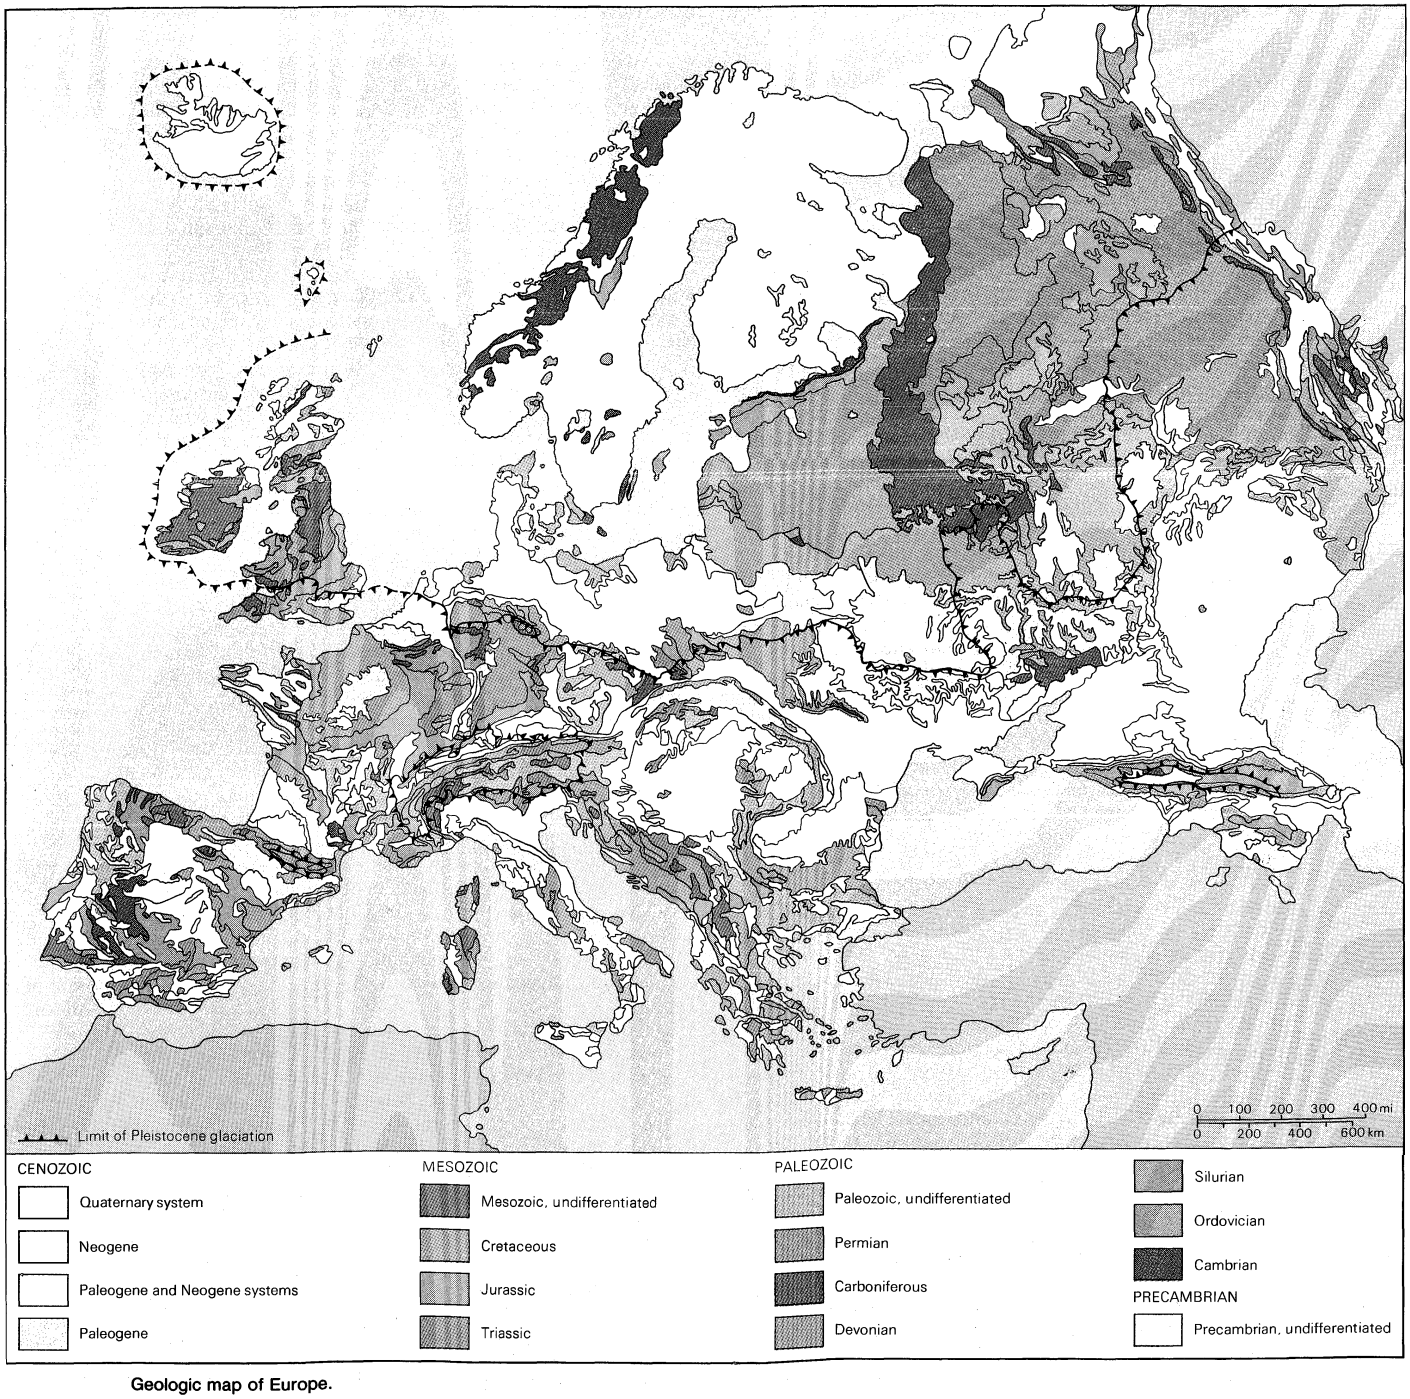
The Mesozoic and Cenozoic eras. During the Mesozoic era a new ocean, the Tethys, evolved in what is now southern Europe, and during the Cenozoic era this ocean was destroyed by subduction with the result that many small plates collided. These events gave rise to the present-day tectonic mosaic that extends eastward from the Atlas Mountains of North Africa, the Betic Cordillera of southern Spain, and the Pyrenees; via the Alps of maritime France, Switzerland, and Austria; to the Carpathians, the Apennines, the Dinaric Alps, the Alpine belt of Bulgaria, the Taurus and Pontic mountains of Turkey, and finally to the Caucasus. Within these belts must also be included the Pannonian Basin of Romania and the Balearic, Alboran, Tyrrhenian, and Adriatic basins of the Mediterranean Sea. The main cause of this Alpine orogeny during the Cenozoic was the northward compression of Africa into Europe.

Tectonic mosaic of southern Europe

The first rifting of the older continent began with salt and evaporite deposition in lakes in rift valleys in the Early Triassic (245 to 240 million years ago). By 220 million years ago, in the Late Triassic, the continental margins of the new, narrow Tethys were commonly covered by shallow water over fossiliferous, carbonate shelf sediments.

During the Middle Jurassic, about 180 million years ago, these carbonate shelves began to fragment, and in the Cretaceous (144 to 66.4 million years ago) the ocean floor was subducted in many places. This gave rise to volcanic island arcs, such as those of present-day Indonesia, and slabs of the Tethys ocean floor were thrusted as ophiolites onto the continental margins. Extensive remnants of these ophiolites can be seen today, especially in the northern Apennines and in Yugoslavia, Greece, Turkey, and Cyprus. Collisions between many of the continental microplates took place in the Eocene–Oligocene (about 58 to 24 million years ago) epochs. For example, the Iberian Peninsula rotated to give rise to the Pyrenees, the Italian Peninsula drove northward and compressed into Europe, causing growth of the Swiss-Austrian Alps, and Anatolia moved westward and gave rise to the Aegean arc and the mountains of Greece. It is interesting to consider that it was the opening of the Red Sea that caused the Arabian Peninsula to slide northward along the fault defined by the Dead Sea and the Jordan Valley and in so doing to form at its front the Zagros Mountains of Iran, which, in turn, pushed Anatolia westward and caused the deformation in Greece. This scenario illustrates the interlinking and interdependence of all these movements and structures in Europe with those outside the continent. In the Late Miocene (11.2 to 5.3 million years ago) many of the early Mediterranean basins (*e.g.*, Balearic, Tyrrhenian, Ionian, and Levantine) became isolated from the main Atlantic and Indo-Pacific oceans, and in these basins were laid down huge deposits of salt and gypsum in evaporites up to more than a mile thick. There are several important economic mineral deposits in the European Alpine system that can be related to the several stages of geologic evolution described above. Lead and zinc deposits occur in Triassic shelf limestones at Blei-berg, W.Ger. There are many chromite ores in the ophiolites of Yugoslavia, Greece, and Turkey. Copper ores formed in pillow-bearing basaltic lavas of the Tethyan ocean floor; copper mines

Mineral deposits in the Alps



Geologic map of Europe.

have been worked since antiquity in Cyprus, which lent its name to this element. The Tethys, however, was a relatively narrow ocean, and thus its limited subduction was not able to give rise, for example, to many granites and volcanic rocks, which might have contained useful mineral deposits. Active seismic disturbances expressed as earthquakes are a reflection of the continuing compression between several of the European microplates; they are common in the Atlas Mountains, the island arc of the South Aegean, Greece, the island arc of the Tyrrhenian Sea in southern Italy, Turkey, and the Caucasus Mountains.

The North European and Russian platforms. An approximately triangular area is described between the Caledonian orogeny in the west, the Hercynian orogeny and the Alps in the south, and the Urals in the east. This area includes the Russian and North European platforms and the North Sea. Within this area the Phanerozoic sedimentary rocks are either undeformed or only weakly deformed, and thus this area contrasts with the surrounding orogenic belts described above where such sediments are strongly deformed. Thus, throughout much of the extensive Russian Platform the Paleozoic, Mesozoic, and Cenozoic sediments have escaped the effects of the surrounding orogenies, and they are almost as horizontal as when they were laid down. Farther west in the portion of the North European Platform that includes southeastern England and northern France, Mesozoic and early Cenozoic sediments have been weakly deformed into anticlines and synclines by the Tertiary deformation of the Alpine orogenic belt to the south. This took place at a shallow level of the crust, and the sediments are still unmetamorphosed. Thus, the best place to find beautifully preserved Phanerozoic fossils is in this central triangular area of Europe. Under the North Sea there are gas reserves in Permian and Triassic sediments, and there are major oil reservoirs in Jurassic sediments. This is a subsided fragment of the continental margin of Europe flooded with water from the melted glaciers of the last Ice Age.

The Tertiary igneous province of northwestern Britain. From about 61 to 52 million years ago (early in the Tertiary) there were important igneous extrusions and intrusions in northwestern Britain. In Northern Ireland and northwestern Scotland, basaltic lava flows (*e.g.,* the Giant's Causeway and the northern part of the isle of Skye) are associated with northwest–southeast-trending basaltic dikes and many plutonic complexes, which are probably the roots of volcanoes. The dikes extend southeastward across northern England and continue under the North Sea. Related lavas occur in the Faeroe Islands, belonging to Denmark. These igneous rocks formed in the faulted and thinned continental margin of northwestern Europe contemporaneously with the rifting and seafloor spreading that gave rise to the Atlantic Ocean.

Basaltic lava flows and dikes

Iceland. The Mid-Atlantic Ridge is a major plate boundary separating the North American and the Eurasian plates, and it extends through the centre of Iceland. Along this ridge the Atlantic Ocean is still growing, and on Iceland this activity is expressed as major rifts, volcanoes, and steam geysers. The entire island is made of lavas, the oldest of which on the northwestern coast came from eruptions about 16 million years ago. Iceland thus preserves a unique record of the last stages of development of one of the world's major accreting plate boundaries, most of which is elsewhere submarine. (B.F.W.)

The Quaternary period. The Pleistocene epoch occupies the Quaternary period (the last 1.6 million years), with the exception of the last 10,000 years, which are called the Holocene epoch. Although the precise causes of the Ice Ages that mark the Pleistocene are controversial, it is known that prior to this glaciation northern Europe had risen to a much higher elevation than now and that ice formed to great depths there, as in the rest of the Atlantic landmass and the Alpine areas. The Pleistocene was punctuated by warm interglacial periods separating glacial advances; during its latter part, humans occupied niches in the more southerly parts of the continent.

Glaciers are the most powerful engines provided by nature for the transport—by plucking or quarrying—of large masses of rock, and certainly the European glaciers transformed the physique both of their source areas and of the lands to which they moved. Many physical forms of northern and Alpine Europe resulted from glacial erosion, supplemented by weathering, and the surfaces of areas where the glaciers eventually withered away consisted of masses of transported material. Southern Scandinavia, southern Finland, the Swiss Plateau, and the North European Plain were thickly plastered with a variety of forms, including boulder-studded clay, gravels, sands, and the windblown deposits known as loess. New drainage patterns were formed. The melting of so much ice raised the level of the oceans by an estimated 320 or more feet, while former ice-clad lands, including the North Sea area, began to rise isostatically. It was not until quite late in the Holocene that the northern seas of Europe—the Irish, North, and Baltic—took, by stages, their present shape.

The modern geologic framework. Although the exposed rocks of Europe are obscured increasingly by the works of humans, and while detailed understanding of rock patterns present challenges even to the expert, the major formations of the continent are clear. In the north lie wide areas of ancient worn-down rocks, stripped of soil by the glaciers but compensated in some measure by the coastal plains created by uplift. In contrast, southern Europe, although incorporating such relicts as massifs of Paleozoic rocks, is essentially a youthful world, not yet fully fashioned, as evidenced by continuing seismic disturbances. Eastern Europe, based on the vast Russian Platform, is a stable world still young in surface, since the floor of its shield rocks is deeply concealed beneath Mesozoic and Tertiary deposits, above which glacial material covers the northern half and loess deposits enrich the south. Although in scale this platform is a continental area, river development facilitates access to inland seas in both the north and the south. Ancient rocks, lying near the surface, offer mineral wealth, and the former Volga–Ural seas have left a residue of petroleum and mineral salts. For the rest, western and central Europe show great diversity of landforms and landscape as well as varied soil and mineral resources. Alpine ranges in the south and southeast combine high altitude and relief with scenic attractions and—more importantly—with high precipitation and water dispersion. Highland areas, remnants of faulted Hercynian belts surrounded by younger strata, provide another type of wooded landscape, with their contained coalfields. Iceland has the youngest landscape of Europe, with its spectacular semiactive volcanoes, high waterfalls, extensive glaciers, and steam geysers. Lastly, lowlands, of great human value, recall their varied origins—former sea and lake basins; lowlands of glacial deposition; parts of eroded synclinal structures; and alluvial and marine plains won from the sea by isostasy or, as exemplified by the Dutch polders, by the work of humans. (W.G.E./B.F.W.)

Differences between northern and southern Europe

The land

A contrast exists between the configuration of peninsular (or western) Europe, and eastern Europe, which is a much larger and more continental area. A convenient division is made by a line linking the base of the Jutland Peninsula with the head of the Adriatic Sea. The western part of the continent clearly has a high proportion of coastline with good maritime access and often with inland penetration by means of navigable rivers. Continental shelves—former land surfaces that have been covered by shallow seas—are a feature of peninsular Europe, while the coasts themselves are both submerged or drowned, as in southwestern Ireland and northwestern Spain, and emergent, as in western Scotland and southern Wales where raised former beaches are in evidence. East of the Vistula River, Europe's expansive lowlands have something of the scale and character of those of northern Asia, but the continent also comprises numerous islands, some—notably the Faeroes and Iceland—located at a distance from the mainland. Fortuitously, Europe has no continuous mountain obstacle aligned north–south, corresponding, for example, to the Western Cordillera of North America and the Andes of South America, that would limit access into western Europe from the ocean.

Peninsular and eastern Europe

RELIEF

Elevations. Lands lying at high altitude can, of course, be lands of low relief, but on the European continent relief tends to become more rugged as altitude increases. The greater part of Europe, however, combines low altitude with low relief. Only hill masses less than 800 feet (240 metres) in height rise gently within the Russian (or East European) Plain, which continues northward into Finland, westward into the North European Plain, and southward in the Romanian, Bulgarian, and Hungarian plains. The North European Plain, common to much of Poland, northern Germany, and Denmark, broadens in western France and continues, across the narrow seas, in southeastern Great Britain and Ireland. The major peninsula of Scandinavia is mostly upland and highland, with its relief greatest at the descent to the Norwegian fjords and the sea; eastward and southward the seas are approached more gently. The highest points reached in Norway and Sweden are, respectively, Galdhø Peak (8,100 feet) and Mount Kebne (6,926 feet). Iceland's highest peak is Mount Hvannadals, at 6,952 feet, while Ben Nevis, the highest summit in Great Britain, stands at a height of only 4,406 feet. Greater relief is found in those areas in the heart of western and central Europe where uplifted and faulted massifs survive from the Hercynian orogeny. The worn-down Ural Mountains also belong in this category, and their highest point, Mount Narodnaya (6,217 feet), corresponds approximately to that of the Massif Central in south central France. Altitudes in these areas are mainly between about 500 and 2,000 feet, and many steep slopes are to be seen.

The highest altitudes and the most rugged relief of the European continent are found farther south, where the structures of the Cenozoic orogeny provide mountain scenery. In the Alps, Mont Blanc rises to a height of 15,771 feet (4,807 metres), which is the highest point on the continent. In the Pyrenees and the Sierra Nevada of Spain, the highest of the peaks exceed 11,000 feet. The Apennines, Dinaric Alps, and Balkan Mountains, as well as the arc-shaped Carpathians and their southern portion, the Transylvanian Alps, also exhibit high altitudes. The highest peaks in these ranges are Mount Corno (9,554 feet) in the Abruzzi Apennines, Bobotov Kuk (8,274 feet) in the Dinaric Alps, Mount Botev (7,795 feet) in the Balkan Mountains, Gerlachovský Štít (Gerlach; 8,711 feet) in the Western Carpathians, and Mount Moldoveanu (8,347 feet) in the Transylvanian Alps. Above all, in southern Europe—Austria and Switzerland included—level, low-lying land is scarce, and mountain, plateau, and hill landforms dominate. The lowest terrain in Europe, virtually lacking relief, stands at the head of the Caspian Sea; there the Caspian Depression reaches some 95 feet (29 metres) below sea level.

Physiographic units. Four broad topographic units can be simply, yet usefully, distinguished in the continent of Europe: coastal and interior lowlands, central uplands and plateaus, the northwestern highlands, and southern Europe.

Lowlands. More than half of Europe consists of lowlands, standing mostly below 600 feet but, infrequently, rising to 1,000 feet. Most extensive between the Baltic and White seas in the north and the Black, Azov, and Caspian seas in the south, the lowland narrows westward, lying to the south of the northwestern highlands; it is divided also by the English Channel and the mountains and plateaus of central Europe. The Danubian and northern Italian lowlands are thus mountain-ringed islands. The northern lowlands are areas of glacial deposition and, accordingly, their surface is diversified by such hills as the Valdai and the North German Heights; by deposits of boulder clay, sands, and gravels; by glacial lakes; and by the Pripet Marshes, a large ill-drained area of the western Soviet Union. Another important physical feature is the southeast–northwest zone of windblown loess deposits that have accumulated from eastern Britain to the Ukraine. This *Börde* (German: "edge") belt lies at the northern foot of the Central European Uplands and the Carpathians. Southward of the limits of the northern ice sheets are vales and hills, with the Paris and London basins typical examples. Superficial rock cover, altitude, drainage, and

Scenic fjord, or sea inlet, winding deep into the mountainous coast of western Norway.
Bob and Ira Spring

soil have sharply differentiated these lowlands—which are of prime importance to human settlement—into areas of marsh or fen, clay vales, sand and gravel heaths, or river terraces and fertile plains.

Central uplands and plateaus. The central uplands and plateaus present distinctive landscapes of rounded summits, steep slopes, valleys, and depressions. Examples of such physiographic features can be found in the Southern Uplands of Scotland, the Massif Central of France, the Meseta Central of Spain, and the Bohemian Massif. Routes detour around, or seek gaps through, these uplands—whose German appellation, *Horst* ("thicket"), recalls their still wooded character, while their coal basins give them great economic importance. The well-watered plateaus give rise to many rivers and are well adapted to pastoral farming. Volcanic rocks add to the diversity of these regions.

Northwestern highlands. The ancient, often mineral-laden rocks of the northwestern highlands, their contours softened by prolonged erosion and glaciation, are found throughout much of Iceland, Ireland, and in northern and western Britain and Scandinavia. These highland areas include lands of abundant rainfall—which supplies hydroelectricity and water to industrial cities—and provide summer pastures for cattle. The land in these areas, however, is of little use for crops. The coasts of the northwestern highlands—and in particular the fjords of Norway—invite maritime enterprise.

Southern Europe. A world of peninsulas and islands, southern Europe is subject to its own climatic regime, with fragmented but predominantly mountain and plateau landscapes. Iberia and Anatolia (Turkey) are extensive peninsulas with interior tablelands of Paleozoic rocks that are flanked by mountain ranges of Alpine type. The restricted lowlands lie within interior basins or fringe the coasts; those of Portugal, Macedonia, Thrace, and northern Italy are relatively large. Runoff from the Alps furnishes much water for electricity-generating stations, as well as for the flow regimes of major rivers.

Peninsulas and islands of the south

Detailed discussion of the Alps, Apennines, Carpathian Mountains, European Plain, Pyrenees, and Ural Mountains can be found in *European geographic features of special interest* at the end of this article.

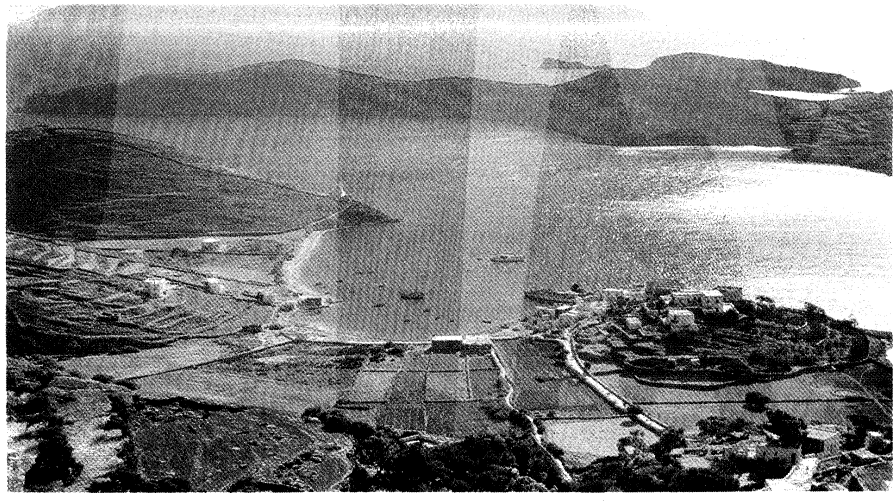
DRAINAGE

Topographic influences. The drainage basins of most European rivers lie in areas originally uplifted by the Caledonian, Hercynian, and Alpine mountain-building periods that receive heavy precipitation, including snow. Some streams, notably in the European Soviet Union, Finland, and Poland, have their sources in hills of Tertiary rocks, while others, including the Thames and Seine rivers, derive from hill country of Mesozoic rocks. Drainage is directly, or via the Baltic and the Mediterranean seas, to the Atlantic and the Arctic oceans and to the enclosed Caspian Sea.

Drainage basins

The present courses and valley forms of the major rivers result from an intricate history involving such processes as erosion by the headstream, downcutting, capture of other rivers, faulting, and isostatic changes of land and sea levels. The Rhine, for example, once drained to the Mediterranean before being diverted to its present

Josef Muench



Coastal landscape of submerged mountains and resulting islands and bays characteristic of Greece along the Aegean Sea.

northerly course. The courses of many rivers—notably those of Scandinavia and the North European Plain—have been shaped since the Pleistocene epoch. While the Alps, Apennines, and Carpathians provide watersheds, other mountain ranges have been cut through by rivers, as by the Danube at Vienna, Budapest, and the Iron Gate and by the Olt (in Romania). In the Russian Plain the rivers are long and flow sluggishly to five seas. In western, central, and eastern Europe, rivers are largely "mature"; *i.e.,* their valleys are graded, and their streams are navigable. Northern and southern Europe, in contrast, present still "youthful" rivers, as yet ill-graded and thus more useful for hydroelectricity than for waterways. The Atlantic rivers have scoured estuaries widening seaward, while, in the Baltic, Mediterranean, and Black seas, with minimum tidal influences, deltas and spits have been created. The upper Dnepr, since post-Pleistocene times, has failed to drain effectively the low area of minimal relief known as the Pripet Marshes.

Hydrography. The water volume of, and discharge from, the rivers of Europe are governed by factors that include local conditions of rainfall, snowmelt, and rock porosity. In consequence, the rivers in the western area have more volume and higher discharges in the winter season and are at their lowest in summer. In areas of mountainous and continental climate, thanks to the runoff of snowmelt, the rivers are highest in spring and early summer. The longer rivers of the continent, notably the Rhine and the Danube, have complex regimes, since their basins extend into areas of contrasting climate. Although embanking measures have reduced the problem, flooding is a continued threat. Thus, rivers in the Soviet Union are liable to flood with the spring thaw; oceanic rivers, after heavy or prolonged rain over the whole basin; and Alpine rivers, when the warm foehn wind rapidly melts the snow. In the Mediterranean region some rivers—as in peninsular Greece—tend to dry up in summer through a combination of scant rainfall, evaporation, and porous limestone beds. In the Abruzzi region of central Italy, however, heavy rainfall, mainly in winter, permeable and porous rocks within the basin, and abundant snow combine to regulate the river regimes.

Flood danger

The Rhône achieves a steady flow throughout the year, deriving a high input from the Cévennes Mountains—which experience heavy winter rain—plus abundant spring and summer snowmelt from the Alps via Lake Geneva. The Rhine and Danube tap supplies from the Alps in spring and summer, and the Rhine, especially, taps areas of winter rainfall maximum. The Volga has its highest water in spring and early summer, thanks to snowmelt, and falls to a summer low. The Saône, lying within the oceanic climatic area, tends to have a good flow year-round. The winter freeze of the east only rarely seriously affects the Danube and western European rivers.

Lake systems and marshes. Lakes cover less than 2 percent of Europe's surface and occur mostly in areas subjected to Pleistocene glaciation. The Scandinavian Peninsula and the North European Plain account for four-fifths of the area of lakes; and in Finland lakes cover one-fifth of the surface. The other major zones of lakes lie marginal to the Alpine system, while Scotland, too, has its many "lochs" and Ireland its "loughs." Lakes survive where the inflow of water exceeds loss from evaporation and outflow and should eventually disappear through alluvial accumulation. Their origins lie in the glacial excavation of softer rocks, in the building of dams by morainic material, and in tectonic, or deforming, forces, which may create depressions. This second explanation clearly applies to Alpine lakes; to many of those in the British Isles, including the small but scenic ones of the Lake District of England; and also to those of central Sweden. Volcanic crater lakes are found in central Italy, and small lakes of the lagoon type are found along the Baltic and Mediterranean, where spits have lengthened parallel to the coast and hence cut off sea access.

A well-developed zone (the *Marschen*) has formed along the low-lying and reclaimed marshes along the North Sea in West Germany and The Netherlands, and characteristically the estuaries of Europe's tidal rivers are edged by flat alluvial marshes. Fens, as exemplified by the polders in The Netherlands and the lowlands in eastern England, are made up of either alluvium or peat and stand too low to be drained effectively, except by continuous pumping. The continent's largest marshland is the Pripet Marshes of the Belorussian and Ukrainian Soviet Socialist republics.

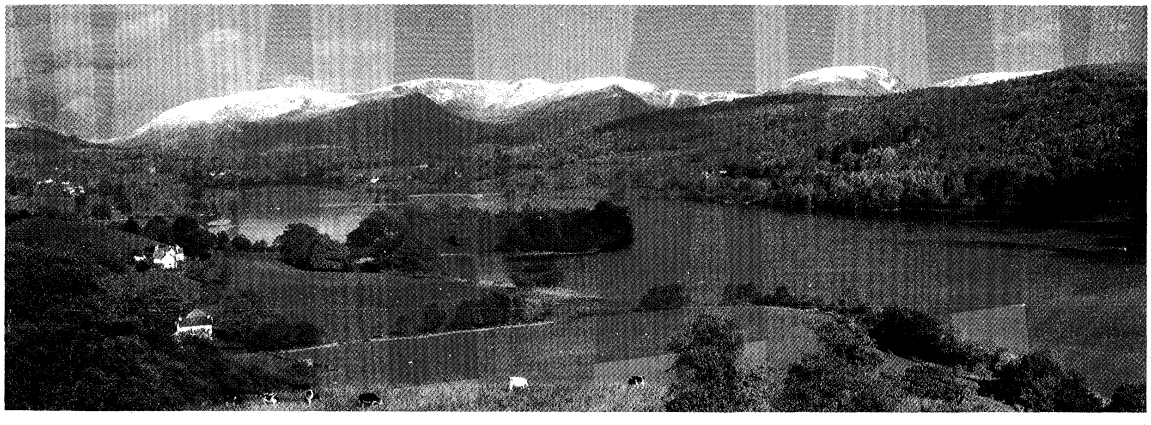
The *Marschen* zone

Detailed discussion of Europe's drainage systems can be found in *European geographic features of special interest* at the end of this article. The discussion for western Europe includes the Rhine, Rhône, and Seine rivers. The discussion for central Europe includes the Danube, Elbe, Oder, and Vistula rivers. The discussion for eastern Europe includes the Dnepr, Don, and Volga rivers.

SOILS

Regional divisions. The soil patterns of Europe are clearly and zonally arranged in the Russian Plain but are much more complicated in the rest of the continent, which exhibits a more varied geology and relief. Tundra soils occur only in Iceland, the most northerly parts of the Soviet Union and Finland, and in high areas of Sweden and Norway; they tend to be acidic, waterlogged, and poor in plant nutrients. South of this zone, and extending around the Gulf of Bothnia and across Finland and the Soviet Union north of the upper Volga, cool-climate podzols are characteristic. These soils, formed in a coniferous woodland setting, suffer from acidity, the leaching of minerals, hardpan formation and permafrost beneath the topsoil, and excess of moisture; given the climate, they are virtually useless for crops. The larger zone to the south stretches from the central Soviet Union westward to Great Britain and Ireland and southward from central Sweden, southern Norway, and Finland to the Pyrenees, Alps, and Balkan Mountains. In this region temperate-climate podzols and brown forest soils have developed in a mixed-forest environment, and these soils, which are highly varied, usually have a good humus content. Locally, the farmer recognizes soils of heavy to light texture, their different water-holding capacities, depth, alkalinity

FPG, Tom Wright



Mountain-encircled Esthwaite Water in the Lake District of northwestern England.

or acidity, and their suitability for specific crops. The soils, rich in humus, within this zone that cover loess are excellent loams; lowland clays, when broken down, also exhibit high quality, as do alluvial soils; in contrast, areas covered with dry, sandy, or gravelly soils are more useful for residential and amenity purposes than for farming. In the southwestern European Soviet Union, notably in the Ukraine, some soils that have been formed in areas of grass steppe are chernozems (black earths)—deep, friable, humus-rich, and renowned for their fertility. In the formerly wooded steppe lying to the north of the grass steppe in both the south central Soviet Union and the lower Danubian lowlands, soils of somewhat less value are known as degraded chernozems and gray forest soils. At best, chestnut soils—some needing only water to be productive—and, at worst, solonetzic (highly saline) soils cover areas of increasing aridity eastward of the Ukraine to the Ural River. Lastly, in southern Europe, where the countryside is fragmented by mountains, plateaus, and hills, much soil has been lost from sloping ground through forest destruction and erosion, and a bright red soil (terra rossa), heavy and clay-rich, is found in many valleys and depressions.

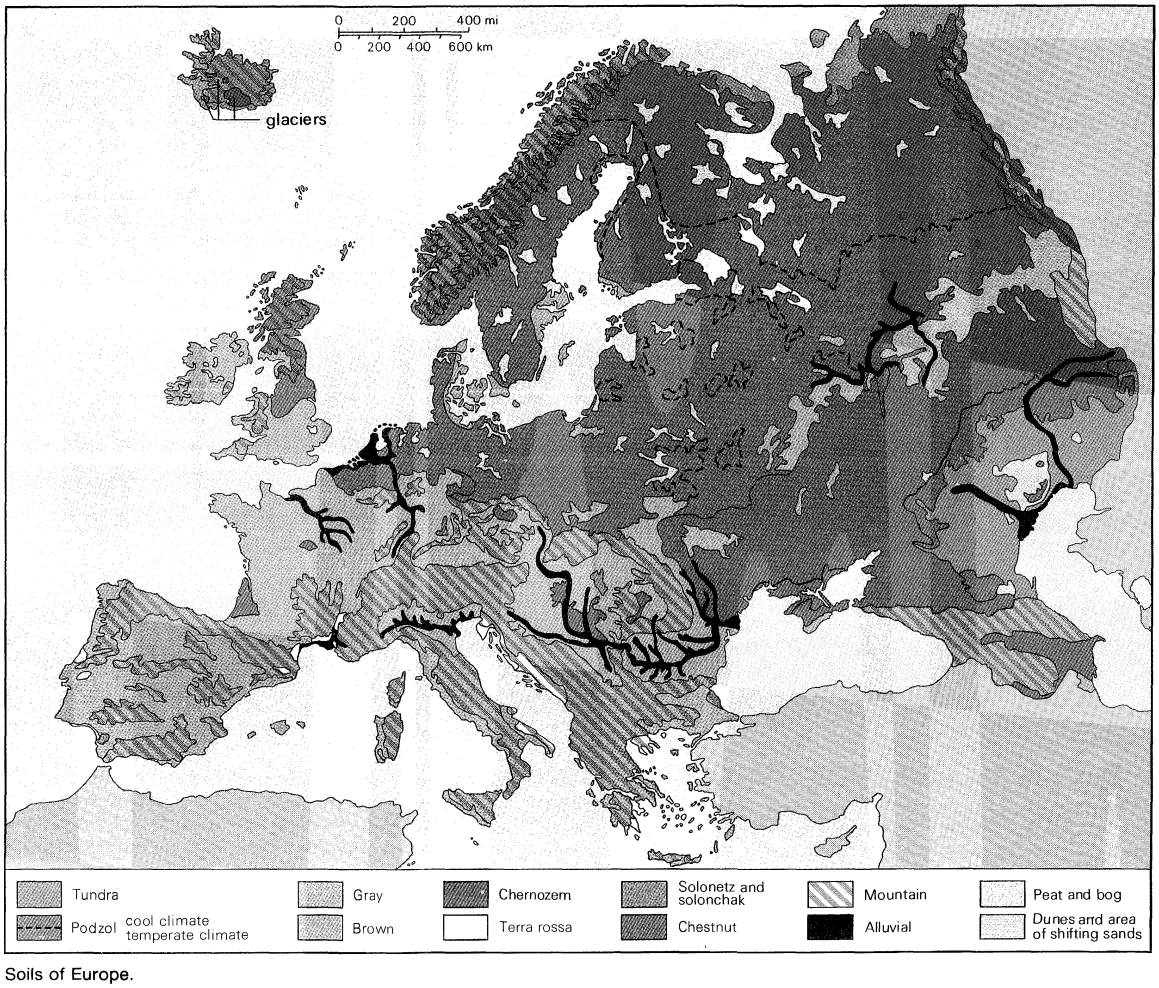
Soil fertility

Problems of classification. The origin, nature, variety, and classification of Europe's soils raise highly complex problems: so much is involved—bedrock, drainage, plant decomposition, biological action, climate, and the time factor. Humans, moreover, have done much to modify soils and, with increasing scientific knowledge, to render soils of greater and continuing value by drainage, crop rotation, and the input of suitable combinations of chemicals. In such ways, naturally poor soils can—as has been shown in Denmark—be made productive. The practice of an enforced "resting" of soils, by leaving fields fallow to recuperate, began to disappear with the agricultural revolution of the 18th century, and agronomic science continues to show how the best results can be achieved from specific soils and also how to check soil erosion. Europe's arable land lies mainly in the lowlands, which have podzols, brown, chernozem, and chestnut soils, although the upper elevation level of cultivation, as of animal husbandry, rises southward. New land is won from the sea, and this more than offsets coastal losses through erosion, but the continued losses to urban expansion and to such competitors for level land as airfields, on the other hand, have become increasingly serious.

CLIMATE

As Francis Bacon, the great English Renaissance man of letters, aptly observed, "Every wind has its weather." It is air-mass circulation that provides the main key to Europe's climate, the more so since masses of Atlantic Ocean origin can pass freely through the lowlands, except in the case of the Caledonian mountains of Norway. Polar air masses derived from areas close to Iceland and tropical masses from the Azores bring, respectively, very different conditions of temperature and humidity and produce different climatic effects as they move eastward. Continental air masses from eastern Europe have equally easy access westward. The almost continuous belt of mountains trending west–east across Europe also impedes the interchange of tropical and polar air masses.

Air-pressure belts. Patterns of some permanence controlling air-mass circulation are created by belts of air pressure over five areas. They are: the Icelandic Low, over the North Atlantic; the Azores High, a high-pressure ridge; the (winter) Mediterranean Low; the Russian High, centred over Central Asia in winter but extending westward; and the Monsoon Low, a low-pressure system over southwestern Asia. Given these pressure conditions, westerly winds prevail in northwestern Europe during the year, becoming especially strong in winter. The winter westerlies, often from the southwest, bring in warm tropical air; in summer, by contrast, they veer to the northwest



Soils of Europe.

Westerlies and the Russian High

and bring in cooler Arctic or subarctic air. In Mediterranean Europe the rain-bearing westerlies chiefly affect the western areas, but only in winter. In winter the eastern Mediterranean Basin experiences bitter easterly and northeasterly winds derived from the Russian High, and their occasional projection westward explains unusually cold winters in western and central Europe, the exceptionally warm winters of which, on the other hand, result from the sustained flow of tropical maritime air masses. In summer the Azores High moves 5°–10° of latitude northward and extends farther eastward, preventing the entry of cyclonic storms into the resultantly dry Mediterranean region. The eastern basin, however, experiences the hot and dry north and northeast summer winds called etesian by the ancient Greeks. In summer, too, the Russian High gives place to a low-pressure system extending westward, so that westerly air masses can penetrate deeply through the continent, making summer a wet season.

It is because of the interplay of so many different air masses that Europe experiences very changeable weather. Winters get sharply colder eastward, but summer temperatures relate fairly closely to latitude. Northwestern Europe, including Iceland, enjoys some amelioration due to warm Gulf Stream waters, which keep the Soviet port of Murmansk open all the year.

Climatic regions. Four regional European climatic types can be loosely distinguished, each characterized by much local topographically related variation. Further, the great cities of Europe, because of the scale and grouping of their buildings, their industrial activities, and the layout of their roads, create distinct local climates—including a central "heat island" and pollution problems.

Maritime climate. Characterizing western areas heavily exposed to Atlantic air masses, the maritime type of climate—given the latitudinal stretch of these lands—exhibits sharp temperature ranges. Thus, the January and July annual averages of Reykjavík (Iceland) and Coruña (Spain) are, respectively, 32° F (0° C) and 53° F (12° C), and 50° F (10° C) and 64° F (18° C). Precipitation is always adequate—indeed, abundant on high ground—falling the year round. The greatest amount of precipitation occurs in autumn or early winter. Summers range from warm to hot depending on the latitude and altitude, and the weather is everywhere changeable. The maritime climate extends across Svalbard, Iceland, the Faeroes, Great Britain and Ireland, Norway, southern Sweden, western France, the Low Countries, northern Germany, and northwestern Spain.

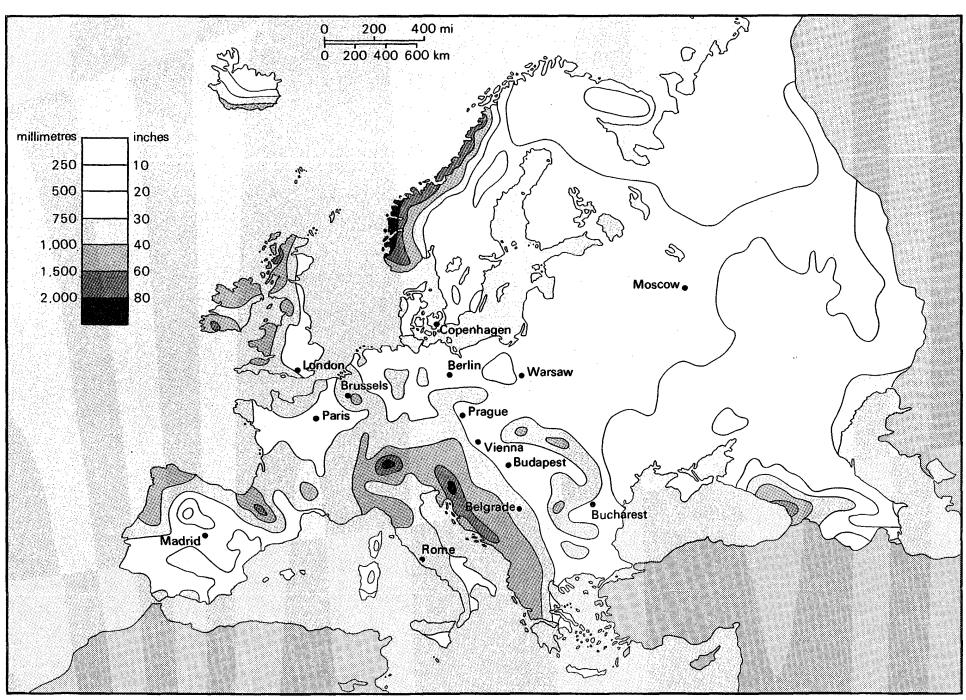
Interaction of air masses

Central European (transitional) climate. The central European, or transitional, type of climate results from the interaction of both maritime and continental air masses and is found at the core of Europe, south and east of the maritime type, west of the much larger continental type, and north of the Mediterranean type. This rugged region has colder winters, with substantial mountain snowfalls, and warmer summers, especially in the lowlands. Precipitation is adequate to abundant, with a summer maximum. The region embraces central Sweden, southern Finland, the Oslo Basin of Norway, eastern France, southwestern Germany, and much of central and southeastern Europe. The range between winter and summer temperatures increases eastward, while the rainfall can exceed 80 inches (2,000 millimetres) in the mountains, with snow often lying permanently around high peaks. The Danubian region has only modest rainfall (24 inches per year at Budapest), but the Dinaric Alps experience heavy cyclonic winter, as well as summer, rain.

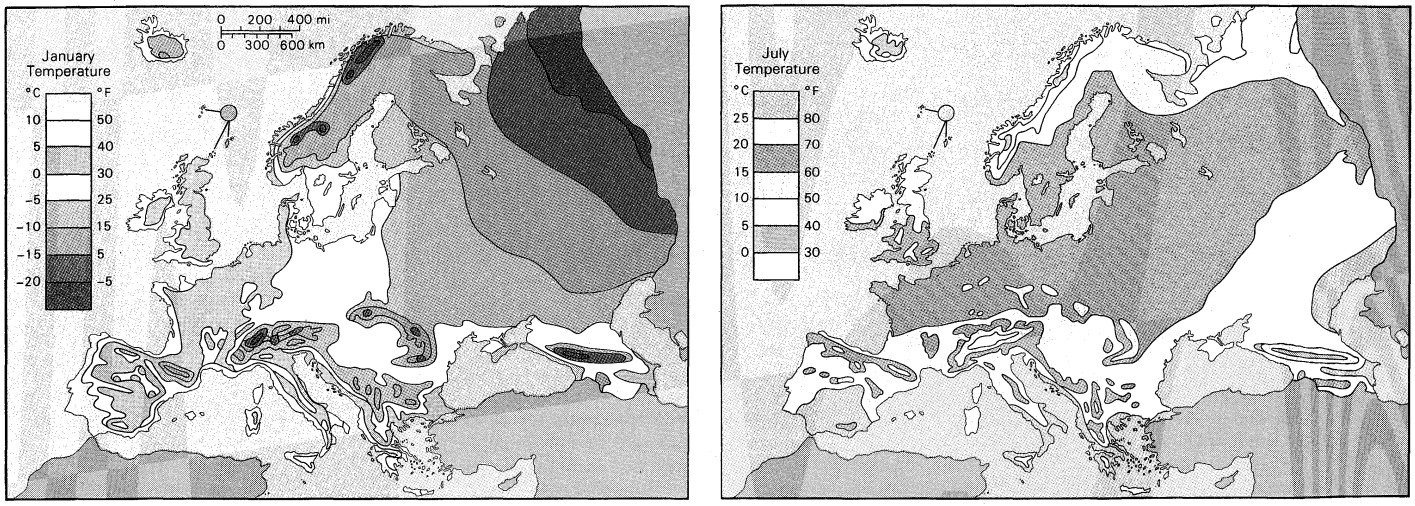
Continental climate. The continental type of climate dominates a giant share of Europe, covering the European Soviet Union (except the Baltic areas), most of Finland, and northern Sweden. Winters—much colder and longer, with greater snow cover than in western Europe—are coldest in the northeast, and summers are hottest in the southeast; the January to July mean temperatures range from 50° to 70° F (10° to 21° C). Summer is the period of maximum rain, which is less abundant than in the west: Moscow's annual average is 25 inches, while, in both the north and southeast of the Russian Plain, precipitation reaches only between 10 and 20 inches annually. In parts of the south, the unreliability of rainfall combines with its relative scarcity to raise a serious aridity problem.

Mediterranean climate. The subtropical Mediterranean climate characterizes the coastlands of southern Europe, being modified inland (for example in the Meseta Central, the Apennines, and the North Italian Plain) in response to altitude and aspect. The main features of this climatic region are mild and wet winters, hot and dry summers, and clear skies, but marked regional variations occur between the lands of the western and the more southerly lying eastern basins of the Mediterranean; the former are affected more strongly by maritime-air-mass intrusions. Rainfall in southern Europe is markedly reduced in areas lying in the lee of rain-bearing westerlies: Rome has an annual mean of 26 inches, but Athens has only 16 inches.

The effects of climate. The local and regional effects of climate on the weathering, erosion, and transport of rocks



Average annual precipitation for Europe.



Average temperatures for January (left) and July (right) in Europe.

clearly contribute much to the European landscape, and the length and warmth of the growing season, the amount and seasonal range of rainfall, and the incidence of frost affect the distribution of vegetation. Wild vegetation in its turn provides different habitats for animal life. Climate is also an important factor in the making of soils, while modern European industry and urban life depend increasingly on water supplies, with rivers and lakes continuing to provide important commercial waterways in some areas. The winter freeze in northern and eastern Europe is another effect of climate, and the spring thaw, by creating floods, impedes transport and harasses farmers. The snow cover of the more continental regions is useful to people, however, for it stores water for the fields and provides snow for sled users.

Regional variations of climate also help determine where crops are grown commercially. In southern Europe the climate supports specially adapted wild vegetation and precludes all-year grass in coastal lowlands, while the practice of moving flocks and herds to pastures seasonally available at different altitudes is clearly adapted to other conditions set by climate. In sum, in only a modest proportion of Europe does climate somewhat restrict human occupation and land use. These areas include regions of high altitude and relief, such as the subarctic highlands of the Scandinavian Peninsula and Iceland, the Arctic areas along the White Sea of the northern Soviet Union, and the arid areas of interior Spain.

PLANT LIFE

Major vegetation zones. The terms "natural," "original," and "primitive," as epithets applied to the vegetation of Europe, have no precise meaning unless they are related to a specific time in geologic history. It is, nevertheless, possible to envisage continental vegetation zones as they formed and acquired some stability during postglacial times, although such zones are only rarely recalled by present-day remnants.

The tundra. Tundra vegetation, made up of lichens and mosses, occupies a relatively narrow zone in Iceland and the extreme north of the European Soviet Union and Scandinavia, although this zone is continued southward in the mountains of Norway. Vegetation of a similar kind occurs at altitudes of 5,000–6,000 feet in the Alps and the northern Urals.

The boreal forest. Southward, the virtually treeless tundra merges into the boreal (northern) forest. The more northerly zone is "open," with stands of conifers and with willows and birch thickets rising above a lichen carpet. It is most extensive in the northern European Soviet Union but continues, narrowing westward, across Sweden. South of this zone, and with no abrupt transition, the "closed" boreal forest occupies a large fraction—mainly north of the upper Volga—of the Soviet Union proper and Scandinavia. Conifers, thin-leaved and resistant to cold, together with the birch and larch, predominate.

The mixed forest. The northern vegetation may superficially suggest its primeval character, but the zone of mixed forest that once stretched across the continent from Great Britain and Ireland to the central Soviet Union has been changed extensively by humans. Only surviving patches of woodland—associations of summer-leaf trees and some conifers, summarily described as Atlantic, central, and eastern—hint at the formerly extensive cover.

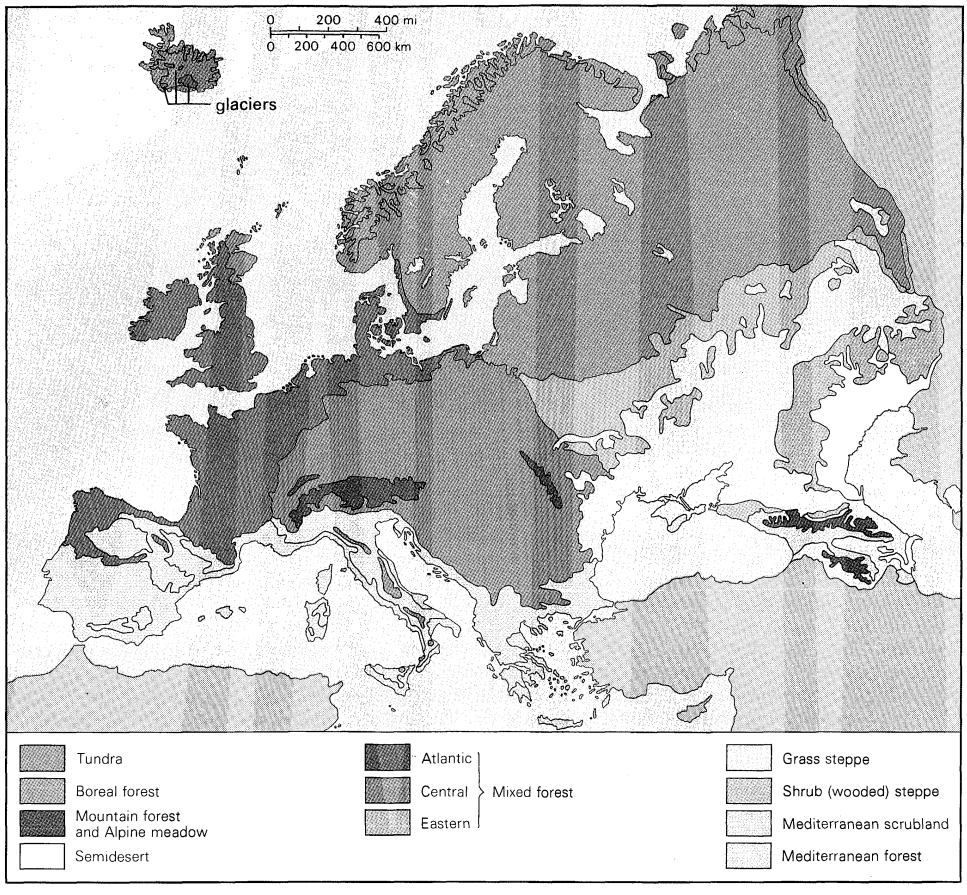
The Mediterranean complex. In southern Europe, Mediterranean vegetation has a distinctive character, containing hard-leaf forests and secondary areas of scrub, especially maquis (macchie), which is made up of trees, shrubs, and aromatic plants. Such scrub is scattered because of summer drought, particularly in areas where the soil is underlain by limestone or where there is little, if any, soil.

Steppe and semidesert. Three further vegetation zones are confined to the southeastern European Soviet Union, although the first two—the wooded steppe and the grass steppe—extend into the Danubian lowlands. Finally, semidesert vegetation characterizes the dry lowland around the northern shores of the Caspian Sea.

The shaping of vegetation zones. *Climatic change.* The primeval vegetation of Europe began to take shape as the climate ameliorated following the retreat of the Pleistocene ice sheets. The microscopic study of pollen grains preserved in datable layers of peat and sediments has made it possible to trace the continental spread, in response to

H. Fristedt—Carl E. Ostman ab

Coniferous forests and lakes on the ancient Baltic Shield of Finland.



Vegetation zones of Europe.

The Alpine barrier

climatic improvement, of forest-forming trees. The double barrier of the Alps and the Mediterranean Sea had checked the retreat of trees at the onset of the Great Ice Age, and there were relatively few indigenous species to return northward from unglaciated refuges. In the first postglacial climatic phase (the boreal), spruce, fir, pine, birch, and hazel nevertheless established themselves as far north as central Sweden and Finland. During the succeeding climatic optimum (the Atlantic phase), which was probably wetter and certainly somewhat warmer, mixed forests of oak, elm, common lime (linden), and elder spread northward. Only in the late Atlantic period did the beech and hornbeam spread into western and central Europe from the southeast.

During postglacial times, therefore, when small numbers of humans were living within Europe, the continental surface was thickly clad with trees and undergrowth, except where tree growth was precluded by extreme cold, high altitude, bad drainage, or exposure to persistent gales. Even those relatively attractive areas where windblown loess had been deeply deposited are now known to have had woods of beech, hawthorn, juniper, box, and ash, as did also limestone plateaus. The Mediterranean peninsulas also had evergreen and mixed forests rooted in an ample soil.

The role of humans. From prehistoric times onward, with ever-increasing force, humans, seeking optimum economic use of available resources, have acted as a vigorous agent of vegetation change. The effects of grazing animals may well explain why some heathlands (*e.g.*, the Lüneburg Heath in northeastern West Germany) replaced primeval forest. By fire and later by ax, forest clearance met demands for homes and ships, for fuel, for charcoal for iron smelting, and, not least, for more cultivation and pasture. The mixed boreal forests suffered most because their relatively rich soils and long and warm growing season promised good returns from cultivation. The destruction of woodlands was markedly strong when population was growing (as between about AD 800 and 1300). It was later intensified by German colonization east of the Rhine and reached maximum scale in the 19th century. In southern Europe—where naval demands were continuous and sources of suitable timber sharply localized—tree cutting entailed, from classical antiquity onward, serious soil loss through erosion, increased aridity, floods, and marsh formation. Farther north throughout the continent, as present distribution of arable land shows, former forests were reduced to remnants; only in the north and below the snow line of Alpine mountains have forests of large and continuing commercial value survived. These coniferous forests of Sweden, Finland, and the northern Soviet Union are "cropped" annually to preserve their capital value. On the more positive side may be noted the reclamation of marshlands and the soil improvement of hill grasslands and heaths, their wild vegetation being replaced by pasture and crops; in timber-deficient countries the afforestation of hillslopes, chiefly with quickly growing conifers, belatedly attempts to restore some of the former forests. Another drastic vegetation change brought about by humans has been the virtual elimination of the wooded and grass steppes, which have become vast granaries.

Afforestation in Scandinavia and the Soviet Union

Exterior influences and European survivals. To a surprising degree, European vegetation stemmed from the importation of plants from other continents, although some imported crops—notably citrus fruits, sugarcane, and rice—can only grow marginally in Europe, and then by irrigation. From an original home of wild grasses in Ethiopia, cultivated varieties of wheat and barley reached Europe early, via the Middle East and Egypt, as did also the olive, the vine, figs, flax, and some varieties of vegetables. Rice, sugarcane, and cotton, of tropical Indian origin, were introduced by the Arabs and Moors, especially into Spain. The citrus fruits, peaches, mulberries, oats, and millet reached Europe from original Chinese habitats, and Europe owes corn (maize), tobacco, squashes, tomatoes, red peppers, prickly pears, agave (sisal), and the potato—first grown for fodder but destined to become the cheap staple food for the large families of low-paid workers of the 19th century—to the Americas. Europe has drawn greatly

Deciduous forest of beech in autumn, New Forest, southern England, U.K.
Heather Angel—Biofotos

on East Asia and North America for trees, especially ornamental trees, while some acacias and the eucalyptus derive from Australia. The sugar beet, however, was a European discovery, first grown when much of Napoleonic Europe was subjected to maritime blockade.

The forests of northern Europe and the Alpine ranges, although in no sense primeval, represent unchanging land use during the postglacial period. The "closed boreal forest" occupies some one million square miles (2.6 million square kilometres), made up of a spruce–fir association (but with stands of pine, birch, and larch) above an undergrowth of mosses and herbs. This large and valuable reserve of timber is of world importance; forests once covered 80 percent of Europe's surface, and they still occupy about 30 percent.

Human adaptations. Clearly, animal life, wild and domesticated, has been adjusted to fit largely man-made patterns of vegetation, which, in turn, reflect agelong attempts to achieve chiefly economic ends. With such endeavours are associated varieties of *modes de vie,* or "modes of livelihood." In the mountains as in the boreal forests, the environment is exploited by winter lumbering and by the transport of felled trees by river after the spring thaw. So, too, agriculture in its many forms—in part for subsistence but commonly for urban markets—is a basic occupation of the lowlands, long cleared of extensive forests or steppe vegetation. In Mediterranean Europe, rural life, based on horticulture and arboriculture rather than on large-scale cultivation, as well as on the rearing of sheep and goats and wheat cultivation, continues, little changed in many areas. For such deeply rooted fruit-bearing trees as the olive and vine, use is made of sloping, broken, and terraced land. Farming also extends to specialized forms with respect to the subtropical crops that climate, sometimes supplemented by irrigation, permits.

Modes de vie

ANIMAL LIFE

Patterns of distribution. With animals as with plants, the earlier Pleistocene range and variety has been much reduced since man disposed of what nature provided. Wild fauna has been long in retreat since Upper Paleolithic times, when, as cave drawings portray, small human groups held their own against such big game as aurochs and mammoths, now extinct, and also against such survivors as the elephant, bison, horse, and boar. Hares, swans, and geese were also hunted, and salmon, trout, and pike were fished. Humans were, inevitably, the successful competitor for land use. By prolonged effort settlers won the land for crops and for domesticated animals, and they hunted animals, especially for furs. As population mounted in industrializing Europe, humans no less inevitably destroyed, or changed drastically, the wild vegetation cover and the animal life. With difficulty, and largely on human sufferance, animals have nevertheless survived in association with contemporary vegetation zones.

The tundra. In the tundra some reindeer (caribou), both wild and domesticated, are well equipped to withstand the cold. Their spoon-shaped hooves are useful in finding food in rough ground. Their herds migrate southward in winter and eat lichens and other plants, as well as flesh, notably that of lemmings and voles. Dogs, too, are reared for traction but yield less than reindeer, which also provide meat, milk, pelts, wool, and bone. The Arctic fox, bear, ermine, partridge, and snowy owl may appear in the

tundra, where, in the short summer, seabirds, river fish, and immigrant birds (swans, ducks, and snipes) vitalize a harsh environment then made almost intolerable by the swarms of biting midges.

The thinning out of animal species in boreal forests

Boreal associations. In the boreal forests the richness of animal and bird life, which had persisted throughout historical times, has now been greatly reduced. Among large surviving ungulates are the elk (moose), reindeer, and roebuck, and, among big beasts of prey, the large brown bear. The lynx has been exterminated by humans, but not the wolf, fox, marten, badger, polecat, and white weasel. The sable, which is much hunted for its fur, only just survives in the northeastern forests of the European Soviet Union. Rodents in the forests include squirrels, the white Arctic hare, and (in the mixed forests) the gray hare and the beaver. Among birds are the black game, snipe, hazel hen, white partridge, woodpecker, and crossbill, all of which assume protective colouring and are specially adapted to be able to find their food in a woodland environment. Owls, blackbirds, tomtits, and bullfinches may be seen in the forests, and, in meadow areas, geese, ducks, and lapwings may be seen.

The steppes. The fauna of the steppe zones now lacks large animals, and the saiga antelope has disappeared. Numerous rodents, including the marmot, jerboa, hamster, and field mouse, have increased in numbers to become pests, now that nearly all the steppe is under cultivation. Equally plentiful birds include the bustard—who can fly as well as run—quail, gray partridge, and lark. These take on yellowish gray or brown protective colouring to match the dried-up grass. Eagles, falcons, hawks, and kites comprise the birds of prey; water and marsh birds—especially the crane, bittern, and heron—also make their homes in the steppes. Different kinds of grasshopper (locusts) and beetles are insect pests.

Mediterranean and semidesert associations. In Mediterranean Europe, remnants of mountain woodland harbour wild goats, wild sheep—such as the small mouflon of Corsica and Sardinia—the wildcat, and wild boar. Snakes, including vipers, and lizards and turtles are familiar reptiles, but birds are few. The faunas of the semidesert areas of the southeastern European Soviet Union also show affiliations with the grass steppe and the desert between which they lie. Two types of antelope (saiga and jaran) survive there, as do rodent sand marmots and desert jerboa and, as a beast of prey, the sand badger. There are many reptiles—lizards, snakes (cobras and steppe boas)—and tortoises. The saksaul jay and the saksaul sparrow, named after the desert tree, also live there, while scorpions, the karakurt spiders, and the palangid are insects dangerous to humans and camels.

Conservation problems. Pressure on space, hunting, either for sport or to protect crops, the pollution of seawaters and fresh waters, and the contamination of cropland have so reduced many animal species that strong efforts are now being made to preserve those threatened with extinction, in such refuges where they still, precariously, live.

Nature reserves

Nature reserves have been set up in many European countries, with international support from the International Union for Conservation of Nature and Natural Resources and the World Wildlife Fund. Seabirds find safe homes, for example, in the Lofoten Islands of Norway and the Farne Islands of northeastern England. The snowy owl, which feeds on lemmings, is seen in Lapland, the rare great bustard in the Austrian Burgenland, and the musk-ox in Svalbard. Père David's deer, which had become extinct in China, its native home, was introduced in 1898 at Woburn Abbey, Eng., where it now flourishes. Nearly half the bird species of Europe, including the egret and the imperial eagle, are represented in the Doñana National Park, within a setting of wild vegetation in the Las Marismas region of the Guadalquivir estuary in southwestern Spain; there too the Spanish lynx survives. In Poland the extensive Białowieza National Park, a wild forest once hunted yearly by the tsars, contains deer, wild boar, elk (moose), bears, lynx, wolves, eagle owls, black storks, the European bison (wisent), and the tarpan, a gray-coloured horse and a survivor from remote days. Contiguous with the forest, in Belorussia, is the Belovezhskaya Pushcha, where European bison are preserved. Italy has its famous Gran Paradiso National Park in the Aosta Valley, which preserved from extinction the Alpine ibex; Austria has a bird refuge in Neusiedler Lake, which is the only breeding site of white egrets in western Europe; and the huge and magnificent delta of the Danube is largely left to wildlife. The golden eagle, Alpine marmots, and chamois are to be seen in the German Alps near Berchtesgaden.

Other rare birds are the sandwich tern, at Norderoog Island, W.Ger., and the spoonbill and cormorant, found, respectively, at Texel Island and Norderoog Island, the former in The Netherlands. For ornithologists (as for botanists) Iceland has abounding interest, notably at Slúttnes, an island in the shallow Lake Mývatn. The beautiful wild horses of Camargue Nature Reserve (Rhône delta), the wild ponies of the New Forest (England), and the Barbary apes, maintaining a politically disinterested foothold on the Rock of Gibraltar, continue undiminished in popular interest.

Thus, the European environment, once not so unequally shared by plants, animals, and people, has, with the march of civilization, been subjected to the attempt at mastery by humans. Favoured by their proximity to the Middle East, where crop cultivation and animal domestication first began, Europeans have fashioned cultural landscapes, at the expense of wild nature, to serve their economic and social ends. Only with difficulty—and sporadically—has wild nature survived, and only just in time has awareness of the cultural losses from the impoverishment of natural vegetation and its animal associates underlined the urgent need for careful protection and preservation of nonhuman nature for communal enjoyment and scientific research.

Against certain pests, notably the anopheles mosquito and the rabbit, war has been waged with good effect, for malaria no longer afflicts Mediterranean Europe, and rabbits, competitors for grass, have been greatly reduced. On the credit side, too, should be listed the full use made of domesticated animals for pastoral husbandry—on high and rough ground, as well as on farms. The familiar farm animals are selectively bred and reared with some regard to the physical character of their environment as also to market demands and government decisions. In the far north, herds of reindeer are adapted to withstand cold and to find their food in snow-covered ground. In the rough, hilly, scrubland of Mediterranean Europe, the sheep, goat, donkey, mule, and ass have adapted well. The horse, which, in its long history, has drawn chariots, carried mounted knights, and hauled the plow, wagons, artillery, stagecoaches, canalboats, and urban trams, is now largely replaced by the tractor, truck, and jeep. The horse is now raised more for racing, riding, ceremonials, and the hunting of fox and stag but is still used for farm work, especially in eastern Europe. Distribution maps of animals kept on farms show how widely they enter into farming: sheep have a special concentration in Great Britain and the Balkan countries, cattle have a small place in southern Europe, while pigs are relatively numerous in the north, especially in the highly populated areas of West Germany, Denmark, and the Low Countries.

The people

The vast majority of Europe's inhabitants are of the European (or Caucasoid) geographic race, characterized by white or lightly pigmented skins and variability in eye and hair colour and by a number of biochemical similarities; there is also an increasing number of people of African and Asian ancestry, although their proportion of the population is still small.

Origins of the Europeans

The origins of the Europeans as a distinct group may never be learned. It is known, however, that the continent had a scanty population of now-extinct hominid species before modern humans appeared some 40,000 years ago and that throughout its prehistoric period it received continual waves of immigrants from Asia. The legacy of these immigrants can be seen in the variety of physical types and cultural features that are found throughout Europe.

CULTURAL PATTERNS

Culture groups. Efforts have been made to characterize different "ethnic types" among European peoples, but these are merely selectively defined physical traits that, at best, have only a certain descriptive and statistical value. On the other hand, territorial differences in language and culture are well known; these have been of immense social and political import in Europe.

These differences stand in sharp contrast to such relatively recently settled lands as the United States, Canada, and Australia. Given the agelong occupation of its soil and minimal mobility for the peasantry—long the bulk of the population—Europe became the home of many linguistic and national "core areas," separated by mountains, forests, and marshlands. Its many states, some long-established, introduce another divisive element that was augmented by modern nationalistic sentiments. Efforts to associate groups of states for specific defense and trade functions appear, slowly, to point toward wider unitary associations, with fundamental East–West differences. Europe thus presents two clear-cut, opposing units, open to trade and cultural exchanges, and a number of such relatively neutral states as Ireland, Sweden, Austria, Switzerland, Yugoslavia, Finland, and Spain.

"Core areas"

The map showing the distribution of European ethnic culture areas identifies a total of about 160 different groups. Of these, about three-fifths are found principally west of the Soviet Union, and about two-fifths are situated mainly within Soviet Europe or the Transcaucasus region. Each of these large groups exhibits two significant features. First, each is characterized by a degree of self-recognition by its members, although the basis for such collective identity varies from group to group. Second, each group—except the Jews and Gypsies—tends to be concentrated and numerically dominant within a distinctive territorial homeland.

For a majority of groups the basis for collective identity is possession of a distinctive language or dialect. The Catalans and Galicians of Spain, for example, have languages notably different from the Castilian of the majority of Spaniards. On the other hand, some peoples may share a common language yet set each other apart because of differences in religion. In Yugoslavia, for instance, the Eastern Orthodox Serbs, Muslim Bosnians, and Roman Catholic Croats all speak the Serbo-Croatian language, but the members of each group generally have antagonistic views toward the others. Some groups may share a common language but remain separate from each other because of differing historic paths. Thus, the Walloons of southern Belgium and the Jurassians of Switzerland both speak French, yet they see themselves as quite different from the French because their groups have developed almost completely outside the boundaries of France. Even when coexisting within the same state, some groups may have similar languages and common religions but remain distinctive from each other because of separate past associations. In Czechoslovakia the historic linkages of Slovaks with the Hungarian kingdom and Czechs with the Austrian state have kept the two groups apart despite more than seven decades of coexistence within a single country.

The primary groups of the map have been associated by ethnographers into some 21 culture areas, 15 of which lie west of the Soviet border. The grouping is based primarily on similarities of language and territorial proximity. Although individuals within a primary group generally are aware of their cultural bonds, the various groups within an ethnographic culture area do not necessarily share any self-recognition of their affinities to one another. This is particularly true in the Balkan culture area. Peoples in the Scandinavian and German culture areas, by contrast, are much more aware of belonging to broader regional civilizations.

Languages. *Romance, Germanic, and Slavic languages.* Within the complex of European languages, three major divisions stand out: Romance, Germanic, and Slavic. All three are derived from a parent Indo-European language of the early migrants coming to Europe from southwestern Asia.

The Romance languages dominate western and Mediterranean Europe and include French, Spanish, Portuguese, Italian, and Romanian, plus such lesser-known languages as Occitan (Provençal) in southern France, Catalan in northeastern Spain and Andorra, and Romansh in southern Switzerland. All are derived from the Latin language of the Roman Empire.

The Germanic languages are found in central, northern, and northwestern Europe. They are derived from a common tribal language that originated in southern Scandinavia and Denmark, and they include German, Dutch, Danish, Norwegian, Swedish, and Icelandic, as well as the minor Germanic tongues of Frisian in the northern Netherlands and northwestern West Germany and Flemish in the Flanders provinces of northern Belgium and adjacent parts of northern France. English is a Romance-Germanic hybrid with extensive vocabularies from both linguistic strains.

The Slavic languages are characteristic of eastern and southeastern Europe, including the Soviet Union. These languages are usually divided into three branches: West,

Distribution of European ethnic culture areas.

East, and South. Among the West Slavic languages are Polish, Czech and Slovak, the Wendish language of East Germany, and the Kashubian language of northern Poland. The East Slavic languages are Russian, Ukrainian, and Belorussian. The South Slavic languages include Slovene, Serbo-Croatian, Macedonian, and Bulgarian.

Other languages. In addition to the three major divisions of the Indo-European languages, three minor groups are also noteworthy. Modern Greek is the mother tongue of Greece and of the Greeks in Cypress, as well as the people of other eastern Mediterranean islands. Older forms of the language were once widespread along the eastern and southern shores of the Mediterranean and in southern peninsular Italy and Sicily. The Baltic language family includes modern Latvian and Lithuanian. The Old Prussian language also belonged to the Baltic group but was supplanted by German through conquest and immigration. Europe's Gypsies speak the distinctive Romany language, which has its origins in the Indic branch of the Indo-European languages.

Two other Indo-European language divisions were formerly widespread but now are spoken only by a few groups. Celtic languages at one time dominated central and western Europe from a core in the German Rhineland. Cultural pressures from adjacent Germanic- and Romance-speaking civilizations eliminated the Celtic culture area, save for a few remnants, including the Welsh, the Gaelic-speakers of the Scottish Highlands and western Ireland, and the Celtic-speaking Bretons of the northwestern Brittany Peninsula of France. The Thraco-Illyrian branch of the Indo-European languages formerly was spoken throughout the Balkan Peninsula north of Greece. Its cultural survival is now to be found only in Albanian.

Non-Indo-European languages are also spoken on the continent. The sole example in western Europe is the Basque language of the western Pyrenees Mountains; its origins are obscure. In northeastern Europe the Finnish, Lapp, Estonian, and Hungarian languages belong to a family of the Finno-Ugric language group that has other representatives in the middle Volga River region. Turkic languages are spoken in parts of Bulgaria and Yugoslavia and in the Azerbaijan S.S.R. and adjacent regions of the Soviet Caucasus area.

Religions. Most primary culture groups in Europe have a single dominant religion, although the English, German, and Hungarian groups are noteworthy for the coexistence of Roman Catholicism and Protestantism. Like its languages, Europe's religious divisions fall into three broad variants of a common ancestor, plus distinctive faiths adhered to by smaller groups.

Christianity. The majority of Europeans adhere to one of three broad divisions of Christianity: Roman Catholicism in the west and southwest, Protestantism in the north, and Eastern Orthodoxy in the east. The divisions of Christianity are the result of historic schisms that followed its period of unity as the adopted state religion in the late stages of the Roman Empire. The first major religious split began in the 4th century, when pressure from "barbarian" tribes led to the division of the empire into western and eastern parts. The bishop of Rome became spiritual leader of the West, while the patriarch of Constantinople led the faith in the East; the final break occurred in 1054. The line adopted to divide the two parts of the empire remains very much a cultural discontinuity in the Balkan Peninsula today, separating Roman Catholic Croats, Slovenes, and Hungarians from Eastern Orthodox Montenegrins, Serbs, Bulgarians, and Romanians. The second schism occurred in the 16th century within the western branch of the religion, when Martin Luther inaugurated the Protestant Reformation. Although rebellion took place in many parts of western Europe against the central church authority vested in Rome, it was successful principally in the Germanic-speaking areas of Britain, northern Germany, and Scandinavia, the latter including the adjacent regions of Finland, Estonia, and Latvia.

Judaism and Islām. Judaism has been practiced in Europe since Roman times. Jews undertook continued migrations into and throughout Europe, in the process dividing into two distinct branches, the Ashkenazi and Sephardi. Although through persecution and emigration their numbers are much reduced in Europe—particularly in eastern Europe, where Jews once made up a large minority population—Jews are still found in urban areas throughout the continent.

Islām also has a long history in Europe. Islāmic incursions into the Iberian and Balkan peninsulas have been influential in the cultures of those regions. Muslim communities still exist in several parts of the Balkans, including European Turkey, Albania, central Yugoslavia, and northeastern Bulgaria. Muslims are more numerous in the European Soviet Union, including the Kazan Tatars and Bashkirs in the Volga-Ural region and the Azerbaijani and lesser groups in the Caucasus region.

DEMOGRAPHIC PATTERNS

Europe has always been one of the most populous parts of the world. Although its estimated population numbered only one-third of Asia's in 1650, 1700, and 1800, this nevertheless accounted for one-fifth of humanity. Despite large-scale emigration, this proportion increased to one-quarter by 1900, when Europe's total just exceeded 400 million. Such high numbers, achieved by high birth rates and falling death rates, were sustained by expanding economies. As numbers have grown proportionately faster in the Americas, Asia, and Africa, Europe's population has fallen to less than one-seventh of the world total.

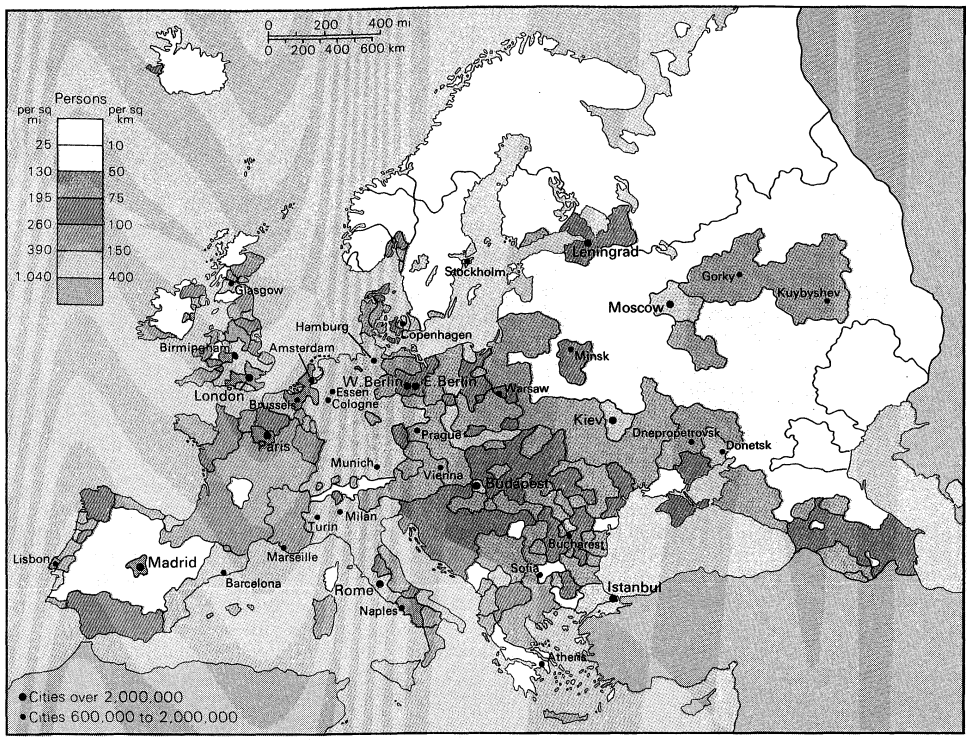
Overall densities. In antiquity the focus of settlement was in southern Europe; but the south lost its numerical domination as, from medieval times onward, settlement developed vigorously in western and central Europe and as, later still, the steppelands of the Ukraine and Hungary were settled for crop farming. While northern Europe, from Iceland and the Scottish Highlands to the northern European Soviet Union, is only scantily settled, the population reaches high densities in a more southerly belt, stretching from England across northern France and industrial Germany to the Moscow region. A second major population strip extends southward from the Ruhr valley through Italy. High populations are often associated with coalfields that, in the past more than today, strongly attracted industry, although giant cities like London, Paris, and Leningrad, offering large markets and labour forces, have created regions of high density. Other populous areas are sustained by mining, industry, commerce, and productive agriculture. The Netherlands is the most densely populated country; Iceland and Norway are the least dense. Population is scantiest in mountain regions, some highlands, arid parts of Spain, and the Arctic regions of the Soviet Union.

High-density areas

Urban and rural settlement. With easier travel and the lure of developing industrial areas, many culturally rich, high-altitude areas have suffered severe depopulation. Urbanization—offering varied employment, better social services, and, apparently, a fuller life—has further reduced the rural population, a drift aided by the mechanization of agriculture. City life has, from classical antiquity, nurtured European culture, although tributary rural life was for centuries the common lot. During the 19th and 20th centuries, however, there has been a revolutionary urbanization that embraces the majority of contemporary Europeans. Some towns are old, containing architectural survivals from their historic past; many more are creatures of the Industrial Revolution.

Nearly three out of four Europeans west of the Soviet border now live in cities. In most of the highly industrialized countries the proportion of urban dwellers is high: more than 90 percent in the United Kingdom, almost 90 percent in The Netherlands, and more than 80 percent in West Germany, Denmark, and Sweden. Others with figures greater than 70 percent include East Germany, Czechoslovakia, France, and Belgium. Only Portugal, Albania, and Yugoslavia have urban populations that number less than half of their national totals. Towns of different scale and varying function continue to grow rapidly, usually in concentric rings outward from the original core. Europe contains many cities of more than one million population, more than one-fifth of the world total, and many of the more highly industrialized parts of the

Conurbations



Population density of Europe.

continent are marked by giant, sprawling metropolitan areas. One distinct type is represented by the conurbation resulting from outgrowth from London; another, as in the Ruhr, by the fusing together of separate cities. Both areas stem from an unchecked industrial expansion associated with population growth—including immigration from rural areas. As elsewhere in the world, these giant agglomerations pose difficult social and aesthetic problems; but by concentrating population they help to preserve the countryside from becoming too built-up.

Population trends. Western and northern Europe took the lead in the medical and social "death controls" that since the mid-19th century have sharply reduced infant mortality and lengthened life expectancy. Although infant mortality rates remain relatively high in Yugoslavia, Romania, Hungary, and Poland, low mortality rates have been achieved virtually everywhere else in Europe.

Birth rates and death rates, as they vary in time and place, necessarily affect the proportion of manpower available to the different European countries for the economy and the armed forces. In most countries, increased longevity and lowered birth rates have generated a rising proportion of retired citizens. Also, the trend toward education over longer periods draws more young people from the economy. The labour force thus shrinks somewhat, although it is everywhere (except in Spain, Malta, Ireland, and Greece) more than 40 percent of the population, and in Denmark, Bulgaria, Finland, Sweden, the Soviet Union, and East Germany it exceeds 50 percent. In many European countries labour force totals have remained high, but this is primarily because of greater employment of women.

Emigration and immigration. Despite heavy mortality resulting from continual wars, Europe has always been in modern times a generous source of emigrants. Since the geographic discoveries of the late 15th century, both "push" and "pull" factors explain an exodus greatly accelerated by modern transportation. The push factors were often sheer poverty, the desire to escape from persecution, or loss of jobs through economic change. The pull factors included new opportunities for better living, often at the expense of original inhabitants elsewhere. All of Europe shared in this huge transfer of population, which affected the settlement and economic development of the Americas, Australia, southern Africa, and New Zealand. Through their involvement in the horrors of the African slave trade, Europeans also produced forced migrations of nonwhite peoples that were to have immense consequences in the Old and New Worlds. Since the early 19th century an estimated 60 million people left Europe for overseas; more than half settled in the United States. Ireland lost much of its population following the potato famine of the 1840s. Northwestern Europe—Great Britain, Scandinavia, and the Low Countries—contributed the largest share of emigrants, who settled, above all, where English was spoken. Emigrants from central, eastern, and southern Europe moved later, many in the early decades of the 20th century. Affinities of languages, religion, and culture clearly explain migration patterns; South American countries, for example, had more appeal to Spanish, Portuguese, and Italians. It has been estimated that emigration from 1846 to 1932 reduced the growth rate of Europe's population by three per 1,000 per annum. The year 1913 marked a peak, with at least 1.5 million—one-third Italian and more than a quarter British—migrating overseas. Subsequent entry restrictions in the United States reduced this flood. During the late 20th century, European migrants sought new homes mainly in Australia, Canada, South America, Turkey, and the United States.

Despite high population densities, some European countries still attract settlers from other continents, mainly because their expanding economies involve labour shortages. Thus France, to increase a manpower depleted by war losses and low 1930s birth rates, has received numerous French-Algerians (as well as other Europeans, including Turks) to supplement its labour force. The United Kingdom, which steadily supplies immigrants to Australia and Canada and specialist workers to the United States, has also attracted immigrants, notably Commonwealth citizens. These immigrants, who largely provide workers for the construction industries, transport, hospitals, and domestic service, include also doctors, scholars, and businesspeople. Some, having established themselves, are able to provide homes for their immigrant relatives. There is also a continued and significant migration of Russians and Ukrainians from the European to the Asian Soviet Union.

Intra-continental migrations

Within the continent there always has been some mobility of population, high during prehistoric times and well marked during the period of decline and fall of the Roman Empire in the West, when many tribal groups—especially of Germans and Slavs—settled in specific regions where they grew into distinctive nations. During and after World War II many Germans from outlying settlements

in central and east central Europe returned to western Germany, some as forced migrants. Many eastern Europeans, too, made their way to the West until the sealing of the East–West border curtailed this flow. Migrants are chiefly workers, seeking temporary work and, often with less success, new homes. The countries of the European Economic Community (EEC, or Common Market) draw workers from southern Europe, as does Switzerland. Two other conspicuous forms of mobility in Europe are the daily commuting of city workers and the increasing movements of tourists.

The economy

Europe was the first of the major world regions to develop a modern economy based on commercial agriculture and industrial development. Its successful modernization can be traced to the continent's rich endowment of economic resources, its history of innovations, the evolution of a skilled and educated labour force, and the interconnectedness of all its parts—both naturally existing and man-made—which facilitated the easy movement of massive quantities of raw materials and finished goods and the communication of ideas.

Europe's economic modernization began with a marked improvement in agricultural output in the 17th century, particularly in England. The traditional method of cultivation involved periodically allowing land to remain fallow; this gave way to continuous cropping on fields that were fertilized with manure from animals raised as food for rapidly expanding urban markets. Greater wealth was accumulated by landowners at the same time that fewer farmhands were needed to work the land. The accumulated capital and abundant cheap labour created by this revolution in agriculture fueled the development of the Industrial Revolution in the 18th century.

The revolution began in northern England in the 1730s with the development of water-driven machinery to spin and weave wool and cotton. By mid-century James Watt had developed a practical steam engine that emancipated machinery from sites adjacent to waterfalls and rapids. Britain had been practically deforested by this time, and the incessant demand for more fuel to run the engines led to the exploitation of coal as a major industry. Industries were built on the coalfields to minimize the cost of transporting coal over long distances. The increasingly surplus rural population flocked to the new manufacturing areas. Canals and other improvements in the transportation infrastructure were made in these regions, which made them attractive to other industries that were not necessarily dependent on coal and thus prompted development in adjacent regions.

Industrialization outside of England began in the mid-19th century in Belgium and northeastern France and spread to Germany, The Netherlands, southern Scandinavia, and other areas in conjunction with the construction of railways. By the 1870s the governments of the European nations had recognized the vital importance of factory production and had taken steps to encourage local development through subsidies and tariff protection against foreign competition. Large areas, however, remained virtually untouched by modern industrial development, including most of the Iberian Peninsula, southern Italy, and a broad belt of eastern Europe extending from the Balkans on the south to Finland and northern Scandinavia.

During the 20th century Europe has experienced periods of considerable economic growth and prosperity, and industrial development has proliferated much more widely throughout the continent; but continued economic development in Europe has been handicapped to a large degree by its multinational character—which has spawned economic rivalries among states and two devastating world wars—as well as by the exhaustion of many of its resources and by increased economic competition from overseas. Many industrial concerns have been deprived of the efficiencies of large-scale production serving a mass market (such as is found in the United States) by governmental protectionism, since this has tended to restrict the potential market for a product to a single country. In addition, enterprise efficiency has suffered from government support and from a lack of competition within a national market area. Within individual countries there have been growing tensions between regions that have prospered and those that have not. This "core–periphery" problem has been particularly acute in situations where the contrasting regions are inhabited by different ethnic groups.

RESOURCES

Mineral resources. With rocks and structures of virtually all geologic periods, Europe possesses a wide variety of useful minerals. Some, exploited since the Bronze Age, are depleted; others have been greatly consumed since the Industrial Revolution. Useful minerals include those that provide energy, ferrous and nonferrous metals and ferroalloys, and those that furnish materials to the chemical and building industries. Europe has a long and commendable prospecting tradition, but, as in the case of North Sea gas and oil, some surprises are still encountered. In relation to the ever-mounting requirements of its economy, however, Europe—the Soviet Union apart—is heavily dependent on mineral imports.

Coal. Europe commands abundant resources of hard and soft coal, which remains of considerable, if declining, importance as a source of power, in smelting minerals, and for its many by-products. Only exceptionally does northern Europe have coal measures of commercial scale, but coal seams are preserved in Hercynian basins throughout the continent, lying diagonally across Britain, Belgium, The Netherlands, France (especially Lorraine), North Rhine-Westphalia and Saarland (West Germany), Upper Silesia (mainly in Poland but also in Czechoslovakia), to the Donets Basin and Urals. There are numerous fields, small but often—as at Komló (near Pécs in Hungary) and in the Arctic fields of Soviet Vorkuta and Norwegian Svalbard—of great locational value. Some, as in southwestern Scotland and southern Belgium, have been worked out or have become uneconomic. Deeper workable seams are sought, in the Ruhr (West Germany), for example, and undersea off Yorkshire (England). Major reserves, encompassing mostly hard deposits of coking, anthracite, and steam coal, lie in the Ruhr, the Pennine fields of England, Upper Silesia, and the Donets Basin. Softer brown coal, or lignite, occurs in the two Germanies, the Chomutov fields of Bohemia, and the Moscow–Tula field.

Petroleum and natural gas. Known petroleum and natural gas reserves are, except in the Soviet Union, wholly disproportionate to Europe's requirements. The Volga-Ural field is the largest in the Soviet Union; Romania's reserves from the Carpathian and sub-Carpathian zones, once the largest in Europe, no longer meet its needs. Many western European countries have located and exploited reserves of petroleum, particularly Norway and the United Kingdom, which have tapped gas and oil from beneath the North Sea bed. In the late 1980s Romania became a leader in extracting oil from the Black Sea.

Uranium. Sources of uranium for use in nuclear reactors have been discovered in many European countries, including France (centred on the Massif Central), Spain, Hungary (the Mecsek Mountains), the Soviet Union (in the Ukraine and Estonia), and, in lesser amounts, in parts of central and eastern Europe.

Iron ores. The largest known iron reserves are the Soviet deposits at Krivoy Rog in the Ukraine, Magnitogorsk, and near Kursk. High-quality ores (of 60 percent iron) from the first two sources have become expensive to mine, but Soviet reserves are more than sufficient for the country and its European associates: the Kursk Magnetic Anomaly, located in the south of the country, has iron-rich quartzites. Deposits in other European countries are small and, except in France and Sweden, inadequate for large-scale heavy industry.

The Kursk Magnetic Anomaly

Ferroalloy metals. The richest ferroalloy deposits occur in the Soviet Union in the emerged shield rocks of the Kola Peninsula (titanium and molybdenum), the Urals, and the Ukraine. Nickel is also mined at Pechenga, in Kola, and at several Ural sites. The southern Urals have also deposits of manganese, required for basic steel manufacture, but these are dwarfed by that at Nikopol, near the Krivoy

Rog iron field, which is the largest and best-located in the world. Other countries have virtually no significant nickel or tin reserves and only small manganese resources. There are chromium deposits of some scale in the Soviet Orsk–Khalilovo region and in Macedonian Yugoslavia, which also contains antimony and molybdenum. Wolframite (for tungsten) is mined from Iberian Hercynian rocks. Norway has molybdenum and titanium workings, and Finland has deposits of titanium, vanadium, and cobalt—valuable and scarce alloys for special steels; the Soviet Union is also an important producer of vanadium.

Nonferrous base metals. With notable exceptions, known European reserves are small, partly as a result of the depletion, for example, of Cornish tin and Swedish copper. Deposits yielding copper, often from copper pyrites, are found in Scandinavia, the southern Urals, and Mediterranean lands. At Bor, Yugoslavia has the largest reserve of copper (low-grade) in Europe; its reserves in lead and, especially, zinc are also high. Mercury is obtained near Krivoy Rog, in Yugoslavia, and in southern Spain. Europe has much bauxite, the principal ore of aluminum, with Greece, Yugoslavia, and Hungary having the largest reserves. Nepheline, an alternative raw material for aluminum, is worked in Kola.

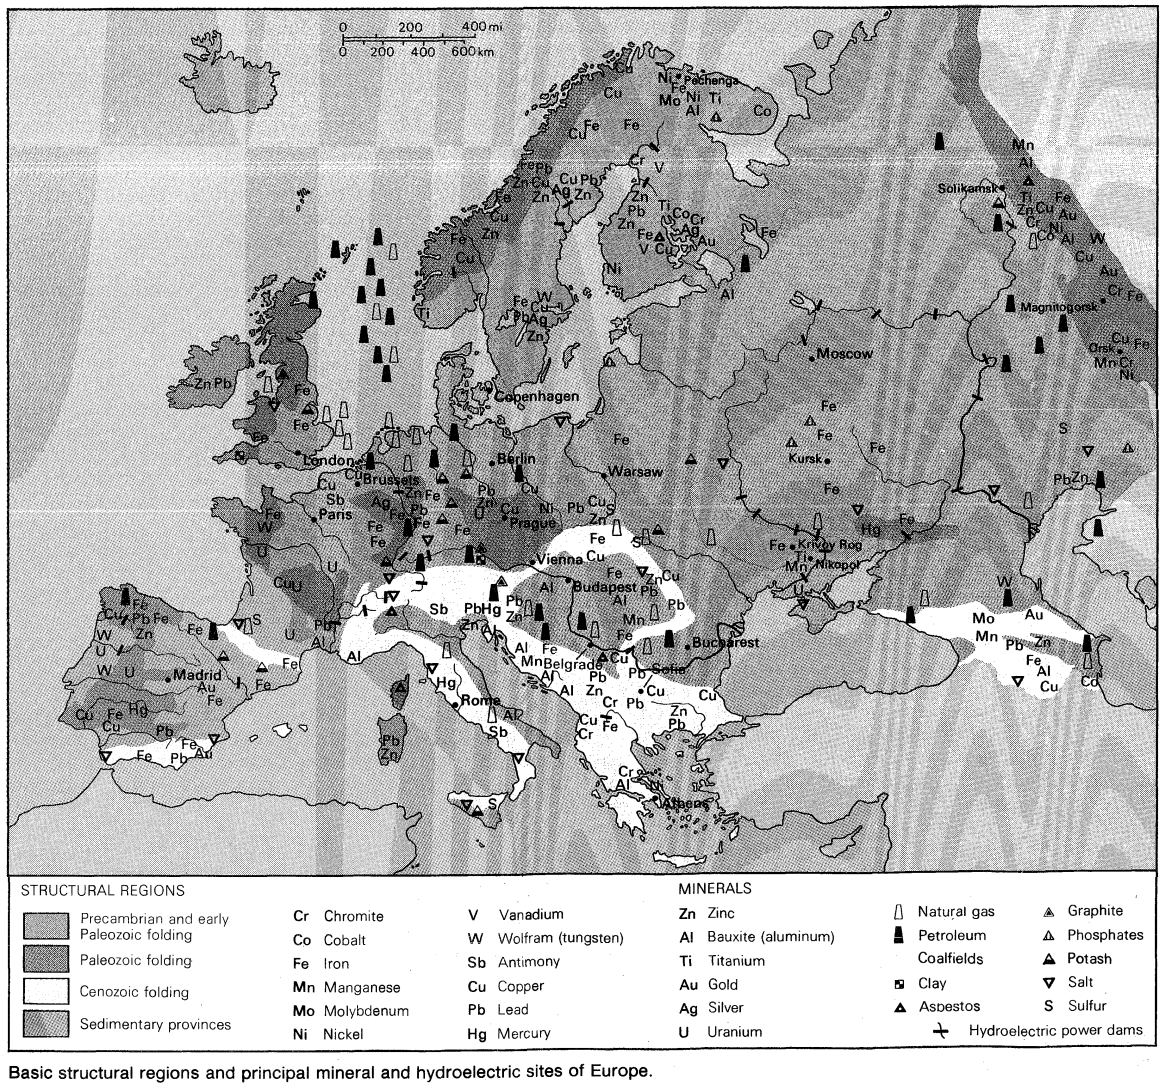
Bauxite reserves

Precious metals. Europe's once widely available reserves of gold appear largely exhausted. Some gold and silver are still produced, mainly in Yugoslavia, Spain, and Sweden.

Nonmetallic deposits. Minerals within this large category are widely available. Clay minerals include fuller's earth—used to cleanse wool and to finish cloth—derived from the decomposition of feldspar; kaolinite, of similar origin, and valuable as china clay, occurs in a pure form in southwestern England: it surpasses coal as a British export; rock salt, important in the chemical industry, occurs widely, much of it being precipitated in such geologically ancient salt lakes as the Soviet Lake Baskunchak (lower Volga), which contains strata 130 feet thick. Europe also has substantial sulfur deposits, and the mining of sulfur in Miocene beds in Sicily gave Italy a virtual monopoly before the opening up of New World deposits in Texas. The carbonate rock, dolomite, like talc, is used as a refractory material, as in lining metal furnaces, and is widespread. Graphite, a crystalline form of carbon used as a lubricant and the basis (with clay) of the "lead" in pencils, is worked in Austria, Czechoslovakia, and England. Nitrates, for fertilizers and explosives, are made from the air electrolytically in England, Norway, and the Soviet Union, and deposits generating potash and phosphate fertilizers are relatively abundant. The Soviet apatite (calcium phosphate) deposits of the Kola Peninsula are the world's largest, as are its potash deposits at Solikamsk, in the Urals. Corundum, a hard abrasive, occurs widely. Building materials for cement and bricks, as well as stone, are abundant, although only regionally available, depending on geologic structure. Particular building stones—marble from central Italy, granite from Norway and Scotland—have localized sources. Except in the Urals, precious stones are rare: these mountains also contain the chief European deposit of asbestos.

Building materials

Water resources. The mountainous and upland areas of Europe collect great amounts of surface water, which supply the rivers and lakes; the lowlands, with lower rainfall, thus receive much of their water from the higher portions of their river basins. In the Mediterranean lands, surface



Basic structural regions and principal mineral and hydroelectric sites of Europe.

water is minimal in summer, exceptions being northern and northwestern Iberia, which gets ample rain; the North Italian Plain, which has Alpine rivers, lakes, springs, and summer rain; and the Apennine zone of Italy. In the European Soviet Union, surface water is relatively abundant in the centre and north but decreases south and southeastward; in the drier regions, however, rivers, collecting water from extensive basins, bring in supplies, and dams on the Volga and Dnepr have created enormous reservoirs.

The increasing water requirements of thermal power stations and industry and, to a lesser extent, domestic needs make the little-populated and industrialized European highlands, which offer surplus water, indispensable to the lowlands. The pollution of water by effluents containing nonoxidizable detergents from urban areas and by those from oil refineries and chemical and metallurgical plants has reached such proportions in, for example, the section of the Rhine below Basel, the Ruhr region, and Lakes Geneva and Garda as to present serious problems and to incur high reclamation costs. In reaction to water shortages, water is, as in the Thames, recycled many times, a practice that leads to the improvement of river water quality.

Europe is relatively well supplied with water, for the water table is normally not far below the surface in the lowlands, and wells and springs are widely available there; underground water supplies (groundwater) that are held particularly in porous rocks are sporadically utilized through the process of pumping. A trend that appears to be growing is to artificially add to supplies of groundwater and thus integrate surface and underground water; nearly half of Sweden's urban water requirements are thus supplied. High capital costs, rather than an actual lack of water, leave some areas of the continent—notably the southeastern European Soviet Union and parts of interior Spain and Turkey—in an arid state. The needs of the major European cities and of the industrial regions involve continuing efforts to collect enough water by impounding surface water, by pumping groundwater, and by encouraging the economy, reuse, and reclamation of water.

Recycling of water

Biological resources. Some reference to plant, animal, and human resources is needed to complement any discussion of European resources. Reference has already been made above to what remains of Europe's plant and animal heritage, supplemented as this is by such vigorous developments as the breeding of livestock to specific purposes and the acclimatization of trees and plants of economic value, which have taken place throughout its history.

The human resources of Europe, since they result from the efforts applied at an ever-rising technical level, are in some respects inexhaustible. Although the cultivation of soil and mining and quarrying for metallic minerals were initiated in prehistoric times, the winning of some resources began only in relatively recent times, in response to new needs and technology. The clearing of woodlands for the plow has continued since the early Middle Ages; the cultivation of the steppe lowlands of the Ukraine and the lower Danube basin commenced only in the late 18th century. Effective drainage, in which the Dutch have excelled, especially during and following the 17th century, has made use of former marshlands. The large-scale mining of coal and iron ore date from the Industrial Revolution. Some industries—many of them concerned with the products of the chemical industry and the refining of aluminum—belong to the 20th century, during which electricity was developed as a form of energy and the internal-combustion engine was developed for use on land, sea, and in the air.

Economic growth stages

The concept of stage, too, helps an understanding of Europe's economic development, for the application to industry and agriculture of modern technology and scientific research has reached different parts of the continent successively. Great Britain, as the home of the Industrial Revolution, stimulated economic change in western, central, and northern Europe. The Soviet Union and the countries of eastern Europe were mostly late starters, and the pace and scale of their industrialization quickened markedly after 1945. The countries of southern Europe, notably northern Italy, also advanced economically following World War II. Europe is thus a highly developed part of the world, although economic development is uneven regionally.

AGRICULTURE

Distribution. Arable land in Europe covers almost 30 percent of the total area, a favourable comparison with both the United States (20 percent) and the Soviet Union (10 percent). Figures for individual countries vary sharply, from about three-fifths of the land in Denmark to less than 3 percent in Norway. Europe's industrialization and urbanization tend to conceal the fact that it is a great producer of cereals, roots, edible oils, fibres, fruit, and livestock and livestock products, accounting for more than 90 percent of the world's rye output, two-thirds of the potato and oats output, and two-fifths of the wheat total.

Europe's climatic range has helped to delineate production areas; thus the vine is commercially grown south of about latitude 50° N, and the olive is restricted to Mediterranean climatic regions. Corn, grown mainly for silage, is an important crop in the lower Danubian lowlands and southern Soviet Union; it appears also in France and Italy. Rice (in northern Italy) and citrus fruits (in Spain, Sicily, and Cyprus) depend on irrigation. The northern countries grow few cereals (mainly oats) and concentrate on animal husbandry, especially cattle and dairying. Grain cultivation is found in the lowland belt that stretches from eastern Great Britain to the Urals. Wheat, in rotation, seeks the better soils, oats and rye the poorer soils and moister lands. Mixed farming—*i.e.*, crop and animal farming—and the use of well-tried crop rotations have become the best economic practice. Viticulture, although widely distributed, is most important in Italy, France, and West Germany, where it is as remunerative as grain cultivation. As to industrial crops, the Soviet Union is the largest producer of flax and hemp, sugar beets (which are also grown widely elsewhere as a rotation crop in the better soils), and sunflower seeds (for edible oil). It is the fifth largest producer of tobacco, which figures importantly also in Bulgaria, Italy, and Macedonian Greece.

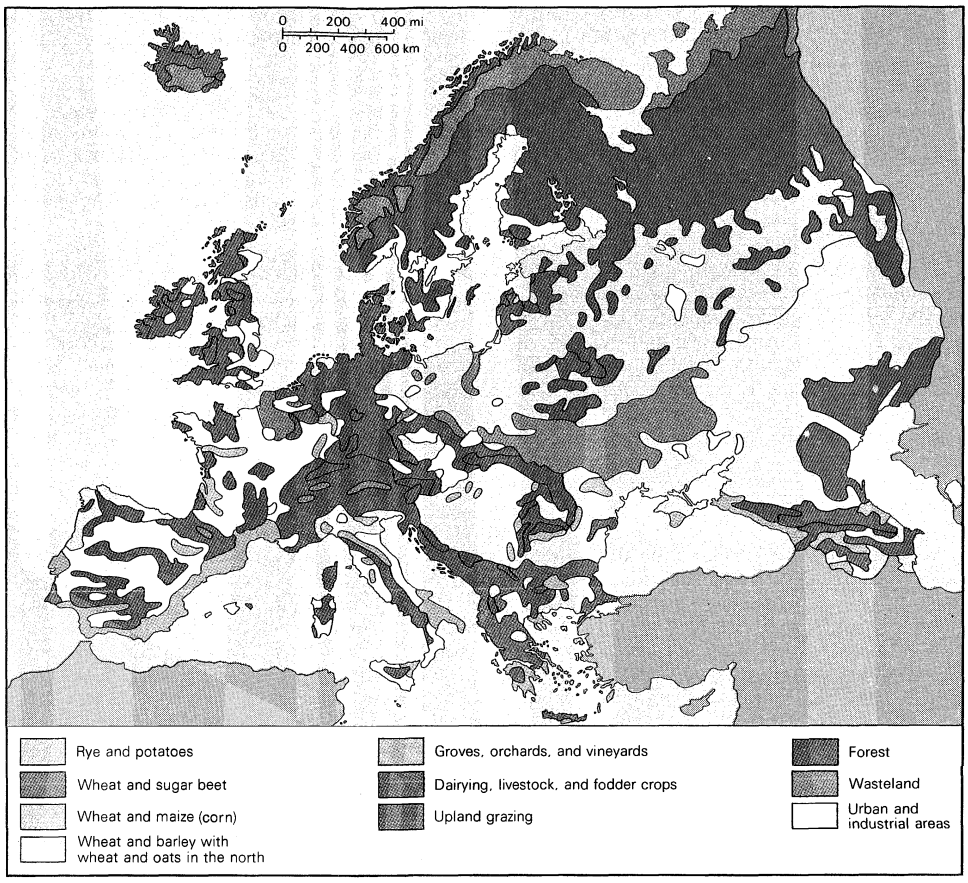
Agricultural organization. There are sharp differences in the way that European agriculture is organized and in its regional efficiency. Collective and state farming is the pattern in the Soviet Union and in most countries of the socialist bloc, but cooperative systems, with or without individual landownership, prevail elsewhere on the continent, with the consolidation of smaller holdings progressing steadily in western Europe. The capital-intensive agriculture of The Netherlands and Great Britain, where yields per acre and per person are high, differs from the extensive Soviet system, where, despite the benefits—notably mechanization—brought by collectivization, labour costs are high and yields low. Less than 3 percent of the working population of the United Kingdom is engaged in agriculture, but one-fourth are so engaged in Yugoslavia. The higher figures indicate high densities of rural population, a shortage of investment capital, and persistent underemployment.

The relative use of fertilizers—very high in The Netherlands and relatively low in Spain and Portugal—hints also at the range of crop productivity.

Irrigated areas, lying mainly in southeastern Spain, the North Italian Plain, and Mediterranean France, are small but disproportionately productive. Long-term prospects for using the irrigation capacity of the lower Danube and Volga are good.

Livestock farming and dairying associated with pigs and poultry is characteristic of European farms, except in the Mediterranean lands, which are better adapted to sheep and goats. Europe produces more than a third of the world's meat, chiefly beef, pork, and bacon, but this is insufficient to meet rising living standards. Domestic production of wool, hides, and leather is also insufficient, except in the Soviet Union, which derives much wool and cotton from its Asian territories. Special features of western European farming include market gardens and the greenhouse production of tomatoes, cucumbers, green vegetables, and flowers for the urban markets. Still another feature is the production of *primeurs:* table fruit, new

Specialty crops of western Europe



Agricultural regions of Europe.

potatoes, vegetables, salad crops, and flowers, produced when prices are high, due to the early spring that visits coastal Brittany, Cornwall, and southern France.

Despite great advances in agronomic science, the hazards of harvest shortfalls due to climate have not been eliminated, and intermittent emergency, as well as regular, claims have to be made on grain-surplus areas overseas. During the late 20th century, harvest shortfalls and increased feed requirements impelled the Soviet Union to import large amounts of grain, especially from the United States and Canada.

INDUSTRY

Mining. Mining provides employment in all countries, although for smaller numbers as mechanization is applied. High-grade iron ores are mined in the Soviet Union at Krivoy Rog and near Kursk and Magnitogorsk and in Arctic Sweden and Norway; these are supplemented by the low-grade minette ores of Lorraine (France) and Luxembourg, low-grade (quarried) Jurassic ores of England, and low-grade Spanish ores. Europe, including the Soviet Union, accounts for about one-third of the world's coal production and nearly four-fifths of its lignite. There was very little increase in coal production during the late 20th century, because European countries have made greater use of other forms of energy, especially oil, nuclear power, natural gas, and hydroelectricity. The chief coal producers are Poland (Upper Silesia), Great Britain, West Germany (the Ruhr and Saarland), and the Soviet Union, where the Donets Basin yields a third of the national output. East Germany is the world's chief source of lignite, mined also in West Germany, Czechoslovakia, and the central European Soviet Union. Many mineral deposits are of only local interest but, as a whole, Europe produces a fair proportion of the world's bauxite, copper, lead, and zinc. Minerals of more than domestic importance are natural gas in The Netherlands; bauxite in Greece, Yugoslavia, and Hungary; petroleum, apatites, and manganese from the Volga-Ural region, Kola, and the Ukraine respectively; and china clay from England.

Heavy industry and engineering. The change from charcoal to coke as fuel in blast furnaces led to the localization of Europe's iron and steel industries on its coalfields to economize transport costs, although imported iron ore, cheap American coal, electric furnaces, and technological efficiency have loosened this tie. Thus, Northumberland and Durham in England, North Rhine-Westphalia, Upper Silesia, and the Donets Basin have their coalfield furnaces and mills, while others are grouped near sources of the ore, as at Krivoy Rog and in Lorraine, or such convenient estuary or port sites as Port Talbot (southern Wales), Genoa, and Dunkirk (France). Europe produces one-half of the world's steel, with the countries of the European Community (EC) and the Soviet Union accounting for about one-third and two-fifths, respectively, of the European output. Europe also produces almost one-third of the world's iron ore. Steel-using industries that make heavy machine tools and mining, smelting, construction, and electrical equipment favour coalfield locations, while shipbuilding and motor-vehicle and aircraft construction show a wider distribution, including new sites.

Coalfield-based industry

Chemical industries. Covering many products, chemical industries have expanded greatly since 1945, partly in relation to hydroelectricity generation and partly as a result of the market-oriented use of refinery by-products. Many heavy chemicals are produced on the coalfields, notably in the Ruhr, where by-products of coke ovens and metallurgical plants are available. Other chemical industries make use of Europe's deposits of salt, potash, phosphates, and sulfur; and the industry has been revolutionized by the increasing production of synthetic rubber, plastics, synthetic fibres, detergents, insecticides, and fertilizers, particularly from petrochemicals.

Manufacturing, lumbering, and fisheries. A wide range of light consumer industries is found throughout Europe, but some countries have acquired reputations for specialty goods, as in the case of English and Dutch bicycles, Swedish and Finnish glass, Parisian perfumes and fashion goods, and Swiss precision instruments and chocolate. The United Kingdom's once-leading textile industry now con-

Specialty goods

centrates on high-quality goods, including many synthetic fibres, of which, together with West Germany, France, and Italy, it is a large producer.

The timber and fisheries extractive industries, now mechanized, are of considerable scale. The Soviet Union, Sweden, and Finland are major producers of softwood and hardwood and exporters of timber, wood pulp, and newsprint. Fishing is a large industry for Norway, Iceland, and the Soviet Union; catches yield not only human food but materials for many subsidiary industries. Fishing is also important in the United Kingdom and France.

Handicrafts and other industries. Of small importance in a continent where the economies of mass production involve standardized production, handicrafts nevertheless survive to serve a wide market, including that of tourists who seek specialty goods. Knitwear and Harris tweed are produced by crofters in the Scottish islands; traditional costumes are made and displayed in many eastern European countries; and custom-made tailoring for men, like dressmaking for women, survives as a supplement to ready-made clothing. Artistic pottery making is another active craft.

Some other European industries fall but uneasily into the preceding categories. Printing and publishing, especially in English, French, German, and Russian, are substantial industries that have worldwide effects, notably in the educational field. Europe is a large producer of pharmaceutical drugs and produces such world-famous beverages as the wines of the west and south, the northern beers, and, not least, whiskey, the status drink from Scotland. Technological and scientific researches are advanced, particularly at such facilities as the European Organization for Nuclear Research (CERN) near Geneva. The outstanding growth industry of tourism—supplementing business, professional, and student travel—brings employment and foreign exchange to many Europeans, especially in the Mediterranean countries, with their combination of sunshine, beaches, scenery, and historical monuments. Europe, with nearly 60 percent of international tourism receipts, is the tourist Mecca of the world.

Growth of tourism

POWER

The message of the Industrial Revolution was that mechanical energy, when it is harnessed to machines, could so supplement human muscle and animal power as to produce revolutionary changes in the scale and pace of factory production. Contemporary Europe, covering less than one-tenth of the inhabited earth, and with only one-seventh its population, uses about one-fourth of the world's energy.

Coal and hydroelectric power. Coal, used to drive steam engines and, as coke, in the smelting of metals, long held the predominant position. During the late 20th century, coal continued to provide energy to coalfield-based industries and was still important for the production of electricity.

Hydroelectricity has been markedly developed where precipitation and landforms provide good opportunities to dam rivers, as in northern and Alpine Europe and the Soviet Union. Norway, for example, derives almost all its electric power from this source; Spain, Portugal, Switzerland, Austria, Sweden, and Yugoslavia derive a large fraction. France has developed power-consuming industries, such as aluminum refining, close to the Alpine and Pyrenean generating sites.

Other power sources. In other countries, hydroelectricity contributes very little, and petroleum and natural gas claim a large share of the energy consumed. By the late 20th century petroleum and natural gas together accounted for one-seventh of the world energy consumption. Natural gas has replaced coal gas in the Soviet Union and Romania and supplements it in Great Britain. Fuel oil is widely used by diesel locomotives and electricity-generating stations and for space heating. Geothermal heat—using underground waters heated by volcanic action—is available in Italy and Iceland, while Ireland, which also lacks both coal and oil, makes efficient use of abundant peat resources. Nuclear-reactor electricity generation, promoted by the European Atomic Energy Community (Euratom) in the EC countries, provides, as in the Soviet Union and eastern European countries, a significant source of electrical energy.

Nuclear-reactor electricity generation

TRADE

Internal and external trade, both by land and by sea, has always been a vigorous part of Europe's economy, and no less so in the late 20th century when Europe faced such strong competitors as the United States and Japan. Trade is made necessary by the regional specialization of production, largely initiated by capitalist enterprise in the past and now predominantly guided by national or even supranational policy decisions. Economic geology partially explains, for example, the localization of Swedish iron and Soviet petroleum production, while climate localizes the production of olive oil and citrus fruits. Europe acquired a central position in modern times in the well-settled Northern Hemisphere, which oceanic and air transport systems still exploit. Simultaneously providing large managerial, market, and labour-force attractions, Europe inevitably attracts extra-European traders, with its ever more sophisticated industry producing outstanding exports and its large importation of petroleum products, metals, raw materials, and foodstuffs.

Within the continent, there has been a distinction between the general trade policy of western Europe and that of the socialist bloc. Prior to the late 1960s the Soviet Union and the eastern European countries adhered to the doctrine of economic self-sufficiency with more interregional than international trade. In the late 1960s and the '70s these trading patterns began to change. Improved relations between the East and the West enabled the socialist countries to meet an increased amount of their technological and agricultural needs with imports from Western countries. The nations of western Europe, on the other hand, have always relied heavily on international trade.

Europe plays the leading role in world commerce, making up more than one-half the total of world exports and imports. The bulk of this trade is carried on by the Western countries, which own almost one-fourth of the world's oceangoing tonnage. Most of the European countries long held political dependencies overseas where they created captive markets, and this imperialist trading momentum persists. Common Market countries have former colonial territories as associate members, and, similarly, the Commonwealth nations engage in much trade, now strictly competitive, with the United Kingdom, although the latter's accession to the Common Market in 1973 resulted in a decline in the proportion of British trade with the Commonwealth.

The international financial crisis

One of the continuing international difficulties that Europe has faced concerns currency and fluctuating exchange rates, as the currencies of Britain, France, and the United States have come under strain, while those of West Germany, The Netherlands, and Switzerland have grown harder, or relatively more valuable. European financiers play an important world role, as do a variety of such finance-related industries as banking, insurance, and shipping.

Internal trade. Within each European country a wide variety of goods is moved continually from ports and production centres to urban markets. Miscellaneous home-produced goods are also traded to consumer centres. Imported goods include fuels, tropical foodstuffs and drinks, raw materials, textile fibres, metals and metallic ores, and a wide range of manufactured goods.

Trading blocs. Active trading within groups of countries that have associated primarily for this purpose and to rationalize and so increase the profitability of their national economies has advanced. The policies of the EC and the Council for Mutual Economic Assistance (CMEA, or Comecon) have been directed toward economic specialization in increasingly interdependent member countries. West Germany supplies coking coal and chemicals to France, which provides Belgium with iron ore from Lorraine. Steel is moved to extranational markets, and Dutch natural gas is piped to France, Belgium, and West Germany. Specialty foodstuffs—wines, cheeses, spring vegetables, and fruit—find an enlarged market far beyond

their production centres, as do such manufactured items as fashion goods, automobiles, and major household appliances. Comecon countries direct their trade largely to each other, with the Soviet Union preeminent as a producer and a major market. The Soviet Union supplies petroleum, manganese, iron, and chrome ores, as well as cotton and other textile fibres; it receives machinery, textiles, and consumer goods.

The European Free Trade Association (EFTA) has also encouraged trade between its members, who exchange such complementary, rather than similar, products as Swedish and Finnish timber and Swiss watches and food products. In 1977 a free-trade agreement went into effect between the Common Market and the EFTA. The agreement eliminated tariffs on most industrial goods originating in the member countries, thereby increasing trade between the countries in the two blocs.

Trade between the West and the socialist bloc increased markedly during the late 20th century. Soviet natural gas was sold to Italy, France, and West Germany, and Western markets were also used for the sale of gold and diamonds in exchange for ships, machinery, and chemicals. European socialist countries supplied Soviet automobiles, canned salmon and caviar, vodka, Polish bacon, Czech glass, and Hungarian and Yugoslav wines.

Intra-Soviet trade. Given its continental scale, the regional trade of the Soviet Union, carried largely by a heavily worked railway system, supplemented by pipelines and an elaborate waterway system, deserves special notice. From the south, grain, meat, vegetable oils, sugar, tobacco, wine, and fruits are moved to the central and northern Soviet Union, where the consumption of such items exceeds local production; dried fish and salt are carried up the Volga. Timber is moved from northern, including Ural, areas to largely unforested southern regions, and Donets Basin coal is shipped by canal to Volgograd.

External trade. A major part of the external trade of European countries is with each other since, with regional specialization, dense populations, and relatively high standards of living, they provide strong markets. For the Common Market countries, as well as for those of northern Europe (EFTA), this trade proportion is very high. In the socialist bloc about three-fourths of the foreign trade is intra-Comecon. There is, nevertheless, a substantial amount of trading among EC, EFTA, and Comecon members, and, especially in the United Kingdom and West Germany, a vigorous two-way trade with the United States is conducted. European trade also extends to all other parts of the world, including the developing countries, where—in exchange for manufactured products—vital supplies of energy, raw materials, metals, ores, and foodstuffs are obtained.

North American trade links

The extracontinental exports of Europe include machine tools, automobiles, aircraft, chemicals (including pharmaceutical drugs), and such consumer items as clothing, textiles, books, expert services, and works of art. Western Europe depends heavily on imported petroleum from the Middle East, Algeria, and Libya and on many raw materials and metals. Europe imports much natural rubber, tea, coffee, cacao, cane sugar, vegetable oilseeds, tobacco, and fruit—fresh, canned, and dried—although it has attempted to lessen its dependence on imported agricultural products with greater domestic production and the manufacture of synthetic substitutes for vegetable fibres.

TRANSPORTATION

Roads. The European Soviet Union is, compared with western Europe—where motorways provide fast movement for commerce and travel—relatively deficient in engineered motor roads. Motorable roads have become more widely available; those of Spain and Ireland have particularly improved, and road tunnels now supplement railway tunnels beneath the Alpine passes. Animal transport has minimal importance yet survives locally: the horse-drawn cart may still be seen in east central Europe; and the ox-drawn plow and the loaded ass, mule, and donkey—surefooted in rough, hilly country—are still used in parts of southern Europe. In such regions with long, snowy winters as the Soviet North, the dog- or reindeer-drawn sled is used.

The role of animals in transport

Railways. Railways link European ports with their hinterlands and fan out from capitals and major cities to points on the international frontiers where they meet the railway system of their neighbours. In some cases—notably from France to Spain, and the Soviet Union to Poland—this involves a change of gauge. Underground and suburban railways also play an indispensable role for metropolitan commuters. Railways permit passage between the western and eastern European extremities but not quite to the extreme north; they have lost some of their passengers and freight to the automobile, coach, and truck, and many uneconomic local lines have been closed. Even so, rail services have notably improved with the use of electrified track or diesel locomotives, faster intercity passenger trains, and container freight trains. Railways remain all-important in the Soviet Union.

Waterways and pipelines. Seaports have been modernized and enlarged to deal more efficiently with the increasing size of ships and volume of oceanic trade. Even landlocked Switzerland has seagoing ships that use Dutch port facilities. The United Kingdom, Norway, and Greece also hold large freighter tonnages for hire.

Inland waterway transport, slow but cheap, is regionally important for the carriage of heavy and bulky commodities. The best waterways—the Rhine below Rheinfelden and the Danube below Belgrade—can carry 1,500-ton barges. The navigable Rhine has the legal status of an international waterway open to all users. Other rivers and canals are usable by smaller vessels. The Volga, however, is a valuable waterway linking Moscow with Caspian ports and, via the Volga–Don Shipping Canal, gives water access to the Donets Basin.

Barge carriers

Giant tankers, up to and beyond 300,000 gross registered tonnage and too deep in draught for most seaports, deliver their cargoes by pipelines that—for petroleum, natural gas, and water—provide the cheapest overland form of transport. They have been built in the United Kingdom for North Sea gas and oil; in France, Spain, and Italy for North African oil; and within and beyond the Soviet Union, whose Friendship Pipeline carries crude oil from the Volga-Ural field to eastern European refineries.

Airways. Air services between principal European cities and to all parts of the world are extensively organized. Airports at London, Frankfurt am Main, Paris, Stockholm, Amsterdam, and Moscow stand out as those of first importance. Passengers, mail, and commodities of high value in relation to their weight—such as gold and early spring flowers—make use of air transport.

(W.G.E./T.M.P.)

EUROPEAN GEOGRAPHIC FEATURES OF SPECIAL INTEREST

Landforms

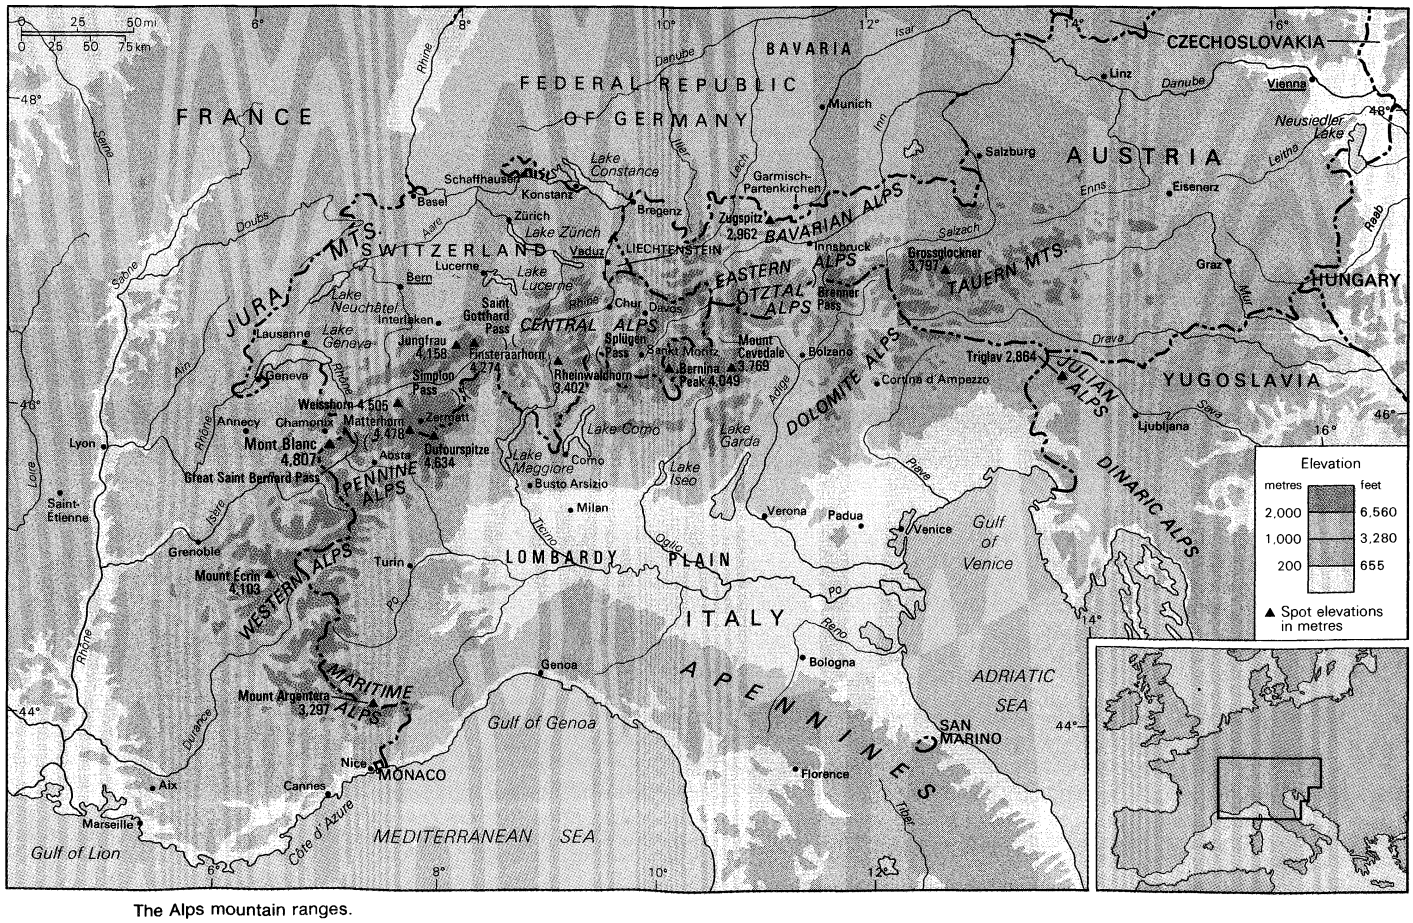
THE ALPS

The Alps are a small segment of a discontinuous mountain chain that stretches from the Atlas Mountains of North Africa across southern Europe and Asia to beyond the Himalayas. They extend north from the subtropical Mediterranean coast near Nice, Fr., to Lake Geneva before trending east-northeast to Vienna (at the Vienna Woods). There they touch the Danube River and meld with the adjacent plain. The Alps form part of six nations: France, Italy, Switzerland, West Germany, Austria, and Yugoslavia; only Switzerland and Austria can be considered true Alpine nations. Some 750 miles (1,200 kilometres) long and more than 125 miles wide at their broadest point between Garmisch-Partenkirchen, W.Ger., and Verona, Italy, the Alps are the most prominent of western Europe's physiographic regions.

Though they are not as high and extensive as other mountain systems uplifted during the Tertiary period—such as the Himalayas and the Andes and Rocky mountains—they are responsible for major geographic phenomena. The Alpine crests isolate one European region from another and are the source of many of Europe's major rivers, such as the Rhône, Rhine, Po, and numerous tributaries of the Danube. Thus, waters from the Alps ultimately reach the North, Mediterranean, Adriatic, and Black seas. Because of their arclike shape, the Alps separate the marine west-coast climates of Europe from the Mediterranean areas of France, Italy, and Yugoslavia. Moreover, they create their own unique climate based on both the local differences in elevation and relief and the location of the mountains in relation to the frontal systems that cross Europe from west to east. Apart from tropical conditions, most of the other climates found on the Earth may be identified somewhere in the Alps, and contrasts are sharp.

A distinctive Alpine pastoral economy that evolved through the centuries has been modified since the 19th century by industry based on indigenous raw materials, such as the industries in the Mur and Mürz valleys of southern Austria that used iron ore from deposits near Eisenerz. Hydroelectric power development at the end of the 19th and beginning of the 20th centuries, often involving many different watersheds, led to the establishment in the lower valleys of electricity-dependent industries, manufacturing such products as aluminum, chemicals, and specialty steels. Tourism, which began in the 19th century in a modest way, has become, since the end of World War II, a mass phenomenon. Thus, the Alps have become a summer and winter playground for millions of European urban dwellers and annually attract tourists from around the world. Because of this enormous human impact on a fragile physical and ecological environment, the Alps are the most threatened mountain system in the world.

Physical features. *Geology.* The Alps emerged during the Alpine orogeny, an event that began about 70 million years ago as the Mesozoic era was drawing to a close. A broad outline helps to clarify the main episodes of a complicated process. At the end of the Paleozoic era, about 245 million years ago, eroded Hercynian mountains, similar to the present Massif Central in France and Bohemian Massif embracing parts of West and East Germany, Austria, Poland, and Czechoslovakia, stood where the Alps are now located. A large landmass, formed of crystalline rocks and known as Tyrrhenia, occupied what is today the western Mediterranean basin, whereas much of the



The Alps mountain ranges.

rest of Europe was inundated by a vast sea. During the Mesozoic (245 to 66.4 million years ago) Tyrrhenia was slowly leveled by the forces of erosion. The eroded materials were carried southward by river action and deposited at the bottom of a vast ocean known as the Tethys Sea, where they were slowly transformed into horizontal layers of rock composed of limestone, clay, shale, and sandstone.

During the middle Tertiary period, about 44 million years ago, relentless and powerful pressures from the south first formed the Pyrenees and then the Alps, as the deep layers of rock that had settled into the Tethys Sea were folded around and against the crystalline bedrock and raised with the bedrock to heights approaching the present-day Himalayas. These tectonic movements lasted until nine million years ago. Tyrrhenia sank at the beginning of the Quaternary period, about 1.6 million years ago, but remnants of its mass, such as the rugged Estéral region west of Cannes, are still found in the western Mediterranean. Throughout the Quaternary period, erosive forces gnawed steadily at the enormous block of newly folded and upthrust mountains, forming the general outlines of the present-day landscape.

Glaciation

The landscape was further modeled during the Quaternary by Alpine glaciation and by expanding ice tongues, some reaching depths of nearly one mile (1.6 kilometres), that filled in the valleys and overflowed onto the plains. Amphitheatre-like cirques, arête ridges, and majestic peaks such as the Matterhorn and Grossglockner were shaped from the mountaintops; the valleys were widened and deepened into general U-shapes, and immense waterfalls, like the Staubbach and Trümmelbach falls in the Lauterbrunnen Valley of the Bernese Alps, poured forth from hanging valleys hundreds of feet above the main valley floors; elongated lakes of great depth such as Lake Annecy in France, Lake Constance bordering Switzerland, West Germany, and Austria, and the lakes of the Salzkammergut in Austria filled in many of the ice-scoured valleys; and enormous quantities of sands and gravels were deposited by the melting glaciers, and landslides—following the melting of much of the ice—filled in sections of the valley floors. The hills east of Sierre in the Rhône valley are an example of this last phenomenon, and they mark the French–German language divide in this area.

When the ice left the main valleys, there was renewed river downcutting, both in the lateral and transverse valleys. The river valleys have been eroded to relatively low elevations that are well below those of the surrounding mountains. Thus, Aosta, Italy, in the Pennine Alps and Sierre, Switz., look up to peaks that tower a mile and a half above them. In the valley of the Arve River near Mont Blanc, the difference in relief is more than 13,100 feet.

Glaciation therefore modified what otherwise would have been a harsher physical environment: the climate was much milder in the valleys than on the surrounding heights, settlement could be established deeper into the mountains, communication was facilitated, and soils were inherently more fertile because of morainic deposits. Vigorous glacial erosion continues in modern times. Many hundreds of square miles of Alpine glaciers, such as those in the Ortles and Adamello ranges and such deep-valley glaciers as the Aletsch Glacier near Brig, Switz., are still found in the Alps. The summer runoff from these ice masses is instrumental in filling the deep reservoirs used to generate hydroelectricity.

Physiography. The Alps present a great variety of elevations and shapes, ranging from the folded sediments forming the low-lying pre-Alps that border the main range everywhere except in northwestern Italy to the crystalline massifs of the inner Alps that include the Belledonne and Mont Blanc in France, the Aare and Gotthard in Switzerland, and the Tauern in Austria. From the Mediterranean to Vienna, the Alps are divided into Western, Central, and Eastern segments, each of which consists of several distinct ranges.

Divisions of the Alps

The Western Alps trend north from the coast through southeastern France and northwestern Italy to Lake Geneva and the Rhône valley in Switzerland. Their forms include the low-lying arid limestones of the Maritime Alps near the Mediterranean, the deep cleft of the Verdon Canyon in France, the crystalline peaks of the Mercantour Massif, and the glacier-covered dome of Mont Blanc, which at 15,771 feet (4,807 metres) is the highest peak in the Alps. Rivers from these ranges flow west into the Rhône and east into the Po.

The Central Alps occupy an area from the Great St. Bernard Pass east of Mont Blanc on the Swiss-Italian border to the region of the Splügen Pass north of Lake Como. Within this territory are such distinctive peaks as the Dufourspitze, Weisshorn, Matterhorn, and Finsteraarhorn, all 14,000 feet high. In addition, the great glacial lakes—Como and Maggiore in the south, part of the drainage system of the Po; and Thun, Brienz, and Lucerne (Vierwaldstättersee) in the north—fall within this zone.

The Eastern Alps, consisting in part of the Rätische range in Switzerland, the Dolomite Alps in Italy, the Bavarian Alps of West Germany and Austria, the Tauern Mountains in Austria, and the Julian Alps in Yugoslavia, are synonymous with a northerly and southeasterly drainage pattern. The Inn, Lech, and Isar rivers in West Germany and the Salzach and Enns in Austria flow into the Danube north of the Alps, while the Mur and Drau (Austria) and Sava (Yugoslavia) rivers discharge into the Danube east and southeast of the Alps. Within the Eastern Alps in Italy, Lake Garda drains into the Po, whereas the fast-flowing Adige, Piave, Tagliamento, and Isonzo pour into the Gulf of Venice.

Differences in relief within the Alps are considerable. The highest mountains, composed of autochthonous crystalline rocks, are found in the west in the Mont Blanc massif and also in the massif centring on Finsteraarhorn (14,022 feet) that divides the cantons of Valais and Bern. Other high chains include the crystalline rocks of the Mount Blanche nappe—which includes the Weisshorn (14,780 feet)—and the nappe of Monte Rosa Massif, sections of which mark the frontier between Switzerland and Italy. Farther to the east, Bernina Peak is the last of the giants over 13,120 feet (4,000 metres). In Austria the highest peak, the Grossglockner, reaches only 12,457 feet; West Germany's highest point, the Zugspitze in the Bavarian Alps, only 9,718 feet; and the highest point of Yugoslavia and the Julian Alps, Triglav, only 9,396 feet. Some of the lowest areas within the Western Alps are found at the delta of the Rhône River where the river enters Lake Geneva, 1,220 feet. In the valleys of the Eastern Alps north of Venice, elevations of only about 300 feet are common.

Climate. The location of the Alps, as well as the great variations in their elevations and exposure, give rise to extreme differences in climate, not only among separate ranges but also within a particular range itself. Because of their central location in Europe, the Alps are affected by four main climatic influences: from the west flows the relatively mild, moist air of the Atlantic; cool or cold polar air descends from northern Europe; continental air masses, cold and dry in winter and hot in summer, dominate in the east; and, to the south, warm Mediterranean air flows northward. Daily weather is influenced by the location and passage of cyclonic storms and the direction of the accompanying winds as they pass over the mountains.

Temperature extremes and annual precipitation are related to the physiography of the Alps. The valley bottoms clearly stand out because generally they are warmer and drier than the surrounding heights. In winter, nearly all precipitation above 5,000 feet is in the form of snow, and depths from 10 to 33 feet or more are common. Snow cover lasts from approximately mid-November to the end of May at the 6,600-foot level, blocking the high mountain passes; nevertheless, relatively snowless winters can occur. Mean January temperatures on the valley floors range from 23° to 39° F (−5° to 4° C) to as high as 46° F (8° C) in the mountains bordering the Mediterranean, whereas mean July temperatures range between 59° and 75° F (15° and 24° C). Temperature inversions are frequent, especially during autumn and winter, and the valleys often fill with fog and stagnant air for days at a time. At those times the levels above 3,300 feet can be warmer and sunnier than the low-lying valley bottoms. Winds can play a prominent role in daily weather and microclimatic conditions.

The foehn

A foehn wind can last from two to three days and blows either south–north or north–south, depending on the tracking of cyclonic storms. The air mass of such a wind is cooled adiabatically as it passes upward to the mountain crests, which precipitates either rain or snow and retards the rate of cooling. When this drier air descends on the lee side, it is adiabatically warmed by compression at a constant rate and therefore has a higher temperature at the same altitude than when it began its upward flow. Snow in the affected areas disappears rapidly.

Avalanches, one of the great destructive forces of nature, are an ever-present danger during the period from late November to early June. Though occurring wherever there are high mountains, open slopes, and heavy snowfalls, avalanches are a greater hazard in the Alps than in other mountain ranges because of the relatively high population density and the expansion of winter tourism. Avalanches not only cause widespread damage but, by carrying down large quantities of rock from the mountain slopes to the valley floors, also are significant agents of erosion. Most avalanches follow well-defined paths, but much of the fear of avalanches is related to the difficulty of predicting where and when they will strike.

Plant and animal life. Several vegetation zones that occur in the Alps reflect differences in elevation and climate. A variety of species of deciduous trees grow on the valley floors and lower slopes; these include linden, oak, beech, poplar, elm, chestnut, mountain ash, birch, and Norway maple. At higher elevations, however, the largest extent of forest is coniferous; spruce, larch, and a variety of pine are the main species. For the most part, spruce dominance reaches its upper limit at approximately 7,200 feet in the Western Alps. Better able to resist conditions of cold, lack of moisture, and high winds, larch can grow as high as 8,200 feet and are found interspersed with spruce at lower elevations. At the upper limits of the forests are hardy species such as the Arolla pine that generally do not grow below the 5,000-foot level; this slow-growing tree can live for 350–400 years and in exceptional cases up to 800 years. Its wood, strongly impregnated with resin, decays very slowly and was formerly prized for use in the construction of chalets. The areas of Arolla pine have been so reduced that cutting the trees is strictly controlled. Above the tree line and below the permanent snow line, a distance of about 3,000 feet, are areas eroded by glaciation that in places are covered with lush Alpine meadows. There sheep and cows are grazed during the short summer, a factor that has helped lower the upper limits of the natural forest. These distinctive mountain pastures—called *alpages,* from which both the names of the mountain system and the vegetational zone are derived—are found above the main and lateral valleys; the spread of invasive weeds, pollution from animal wastes, and erosion from ski-related development limit their carrying capacity. In the southern reaches of the Maritime Alps and the southern Italian Alps, Mediterranean vegetation dominates, with maritime pine, palm, sparse woodland, and agave and prickly pear evident.

The *alpages*

A few species of animals have adapted well to the higher mountains. Bears have vanished, but the ibex, which like the chamois is endowed with extraordinary nimbleness, was saved by Italian royal game preserves. Marmots hibernate in underground galleries. The mountain hare and the ptarmigan—a grouse—assume a white coat for winter. Several national parks amid the ranges ensure preservation of the native fauna.

Human impact on the Alpine environment. The early travelers to the Alps were greatly inspired by the pristine beauty of what they saw, and from their inspiration sprang the modern popularity of the Alpine region. With popularity, however, came growth; and the impact of so many people has caused a steady degradation of the Alpine environment since the mid-20th century. This has resulted in air of poorer quality; water pollution in rivers and lakes; a rise in noise pollution; slope erosion caused by the construction of ski slopes and roads; dumping, often indiscriminately, of solid and organic waste; erosion from the quarrying of rock, sand, and gravel for construction; and forests weakened by acid rain. Slowly, the unique landscape and flora of the Alps that so inspired the early travelers is being irrevocably altered.

Most conspicuous, perhaps, is the obvious transformation of the landscape. The main river valleys have been converted into linear conurbations of concrete and asphalt; and, in order to accommodate the expanding tourist trade, many villages in the higher lateral valleys have taken on the character of lowland suburbs. A highly visible result of this growth is the serious decline in air quality. Pollution from factories adds to that from home heating and motor vehicle exhausts, the situation aggravated by temperature inversions and weather conditions that often produce little wind. Many of the larger Alpine cities experience severe local air pollution, and some of the valleys can be filled with impure air for weeks at a time.

Pollution

The people. *Settlement.* Humans have been living in the Alps since Paleolithic times, 60,000 to 50,000 years ago. They hunted game and left their artifacts in various sites from the Vercors near the Isère valley in France to the Lieglhohle above Taupliz in Austria. After the retreat of the Alpine glaciers, 4,000 to 3,000 years ago, the valleys were inhabited by Neolithic peoples who lived in caves and small settlements, some of which were built on the shores of the Alpine lakes. Sites have been discovered near Lake Annecy, along the shores of Lake Geneva, in the Totes Mountains in Austria, and in the Aosta and Camonica Valleys in Italy. The latter valley is noted for some 20,000 rock engravings that leave an invaluable picture of more than 2,000 years of habitation.

From 800 to 600 BC Celtic tribes attacked the Neolithic encampments and forced their inhabitants into the remote valleys of the Alps. In the west the area around the juncture of France, Switzerland, and Italy was occupied by the Celts; the modern urban centres of the region, including Martigny, Switz., Aosta, Italy, and Grenoble, Fr., owe their origin to these people. The Celts also penetrated the valleys of Graubünden canton in eastern Switzerland, but the great centre of Celtic culture was found at Hallstatt, the site of a small settlement in Upper Austria. Because of rich archaeological finds there the name Hallstatt has become synonymous with the late Bronze and early Iron ages in Europe, a period dating from about 1000 to 500 BC. The Celts began to open the high Alpine passes for trade routes.

The Romans enlarged the old Celtic villages and built many new towns both in the valleys leading up to the Alps and within the Alps themselves. Villa Aniciaca (modern Annecy, Fr.), Octodurus (Martigny), Augusta Praetoria (Aosta), and Virunum (Zollfeld, Austria) flourished under Roman rule. The Romans improved water supplies and constructed arenas and theatres, the best preserved of which is in Aosta. Control of the Alpine passes was the key to Roman expansion, and they were enlarged from trails to narrow roads. The passes that linked the Roman outposts (*e.g.,* Great St. Bernard, Splügen, Brenner, and Plöcken) were particularly important. The first of the "barbaric" incursions took place in AD 259, and by 400 Roman control of the Alps had disintegrated.

The lands of the Romanized Celts were occupied by Germanic tribes that included the Burgundians, Alemanni, and Lombards. During the 8th and 9th centuries the Alpine lands became part of Charlemagne's Holy Roman Empire. The Treaty of Verdun (843) divided the empire among Charlemagne's grandsons, and in 888 further partition resulted in the basic linguistic differences that have endured until the present. The unity that was imposed on the Alps by the Celts, Romans, and barbarians disappeared during the Middle Ages. For the most part, each valley lived apart and isolated from its neighbours. Much of the history of Alpine peoples after the Roman domination, mirroring that of Europe as a whole, was characterized by an expedient and continuous shifting of religious and political alliances. The isolation of the Alpine peoples was broken by the Industrial Revolution and the coming of the railways that penetrated the Alps via great tunnels.

Partitions of Alpine lands

Languages. French is spoken in the Western Alps, including the Swiss cantons of Vaud and Valais, and in the northwestern Italian region of the Valle d'Aosta. Ostensibly bilingual, the Valle d'Aosta has not been able to resist

the impact of Italianization, and the use of French in daily affairs is confined to certain of the lateral valleys. Italian is spoken in the Central and Eastern Alps of Italy and in the Swiss canton of Ticino. The German language is used throughout the Central and Eastern Alps of Switzerland, Germany, and Austria, as well as in the Alto Adige region of Italy (before World War I the Südtirol area of Austria). There are pockets of Ladin and Friulian peoples in the Eastern Alps of northeastern Italy, and Slovenian is spoken in Yugoslavia and the adjacent Alpine border regions with Italy and Austria. Roman Catholicism is the main religion throughout the Alps, although there are regions that are predominantly Protestant, such as the Swiss cantons of Vaud and Bern. The Swiss canton of Graubünden reflects the diversity of languages and religion in the Alps, where some 45 percent of its population is Protestant and 50 percent Catholic; 60 percent speak German, about 15 percent Italian, and 20 percent Romansh. Added to the mixture of indigenous languages is the babel created by the variety of foreign seasonal workers, without whom the tourist industry, especially in Switzerland, would collapse.

The economy. *Agriculture.* Before the mid-19th century the economic basis of the Alps was predominantly agricultural and pastoral. Though since then there has been widespread abandonment of farms, especially in the high valleys of France and Italy and in western Austria, agriculture still survives in favoured locations both in the main and lateral valleys. The hot and dry Rhône valley in Switzerland, between Sierre and Martigny, is an intensive area of irrigated fruit and vegetable cultivation, and both the valley floor and slopes of the mountains have extensive vineyards from which excellent wines are made. Above Visp are some of the highest vineyards in the world, reaching more than 4,250 feet. Other regions of viticulture include the Alto Adige region in northern Italy, Ticino, and the southern regions of the Alps. Villagers in such locations as Chandolin in the Swiss Anniviers Valley—which at 6,561 feet is the highest settlement inhabited year-round in the Alps—cut grass for feeding dairy cows, but most of the agriculture and pastoralism in the high valleys exists as hobby farming or second-income enterprises.

Viticulture

Mining and manufacturing. The mainstay of the modern Alpine economy is a combination of mining and quarrying, manufacturing, industries, and tourism. Mining has been carried out since Neolithic times and is still significant in the Erzberg of Austria, where iron has been extracted from the mountain since the Middle Ages. Near Cluse, in the pre-Alps of Haute-Savoie not far from Geneva, a region of watch making, screw cutting, component manufacturing, and related industries emerged in the first quarter of the 19th century and evolved into one of the most concentrated industrial locations of its type in the world. Large steel mills were located in Aosta and in the Mur and Mürz valleys because of local supplies of iron and coal. In addition, pulp and paper plants that utilized the Alpine forests were established in the Eastern Alps of Austria. With the development of hydroelectricity in the late 19th and 20th centuries, heavy metallurgical and chemical industries were attracted to the major transverse valleys of France, southern Switzerland, and western Austria. Later, factories producing such consumer products as textiles (in the Rhine valley of Austria) and sporting goods (the Annecy area in France) were established. One result of this industrialization was the depopulation of the small villages in the lateral valleys, an occurrence that was partially stemmed by the emergence of the tourism boom after 1960. Many of the early industrial enterprises are no longer viable because of obsolescence, foreign competition, the high cost of transporting raw materials from coastal ports to interior valley locations, or—as is the case with the steel plant in Aosta—because indigenous raw materials have been exhausted. The remaining plants have had to modernize, rationalize, restructure, and develop new products in order to remain competitive in world markets.

Tourism. The most significant economic change for the Alps has been the development of mass tourism since World War II. Tourism in the Alps is a risky business: capital investment can be considerable, whereas the season in which to recoup expenditure is short and can be disrupted by economic difficulties in neighbouring countries or by a lack of snow in winter and cool, rainy weather in summer. Furthermore, there is fierce competition to attract tourists, not only among the different Alpine countries but also among the resorts within each country. There are some 600 ski resorts in the Alps, with more than 270 in Austria alone. Nevertheless, winter and summer tourism have injected enormous sums of money into the economies of the Alpine nations, a development that has been especially beneficial to the remote villages of the high lateral valleys. Employment opportunities in the service sector have increased substantially, taking up the slack caused by a decline in agricultural and industrial employment.

Transportation. The rugged and steep terrain of the Alps long was a barrier to transportation. Beginning in Celtic times, however, and continuing into the present, mountain passes have served as communication links between otherwise isolated valleys; the passes have evolved from simple paths to paved, multilane highways. Such settlements as Chur in eastern Switzerland, a focal point for the numerous passes in the region, have been inhabited for more than 5,000 years. Andermatt, in south central Switzerland, grew in a similar manner.

Role of mountain passes

The advent of rail and later road transportation and the accompanying improvements in road-building techniques have ended the isolation of most areas of the Alps. Tunnels—and road tunnels in particular—which allow huge numbers of people to pass under the great Alpine massifs at all times of the year, have had the greatest impact: by facilitating such a steady onslaught of motor vehicles and people, they not only have made possible the tremendous growth in tourism in the 20th century but also have become a major contributing factor in the degradation of the Alpine environment.

Study and exploration. Records of ascents of various peaks in the Alps date from at least as early as the 14th century, and, in the late 18th and the 19th centuries, the interest in this activity created a vogue for serious mountaineering that began in the Alps and spread throughout the world. Horace Bénédict de Saussure, a professor at the University of Geneva, made ascents of the peaks and

Aubrey Diem

The Apennines mountain range.

encouraged others to do so in the 1780s, when he made the earliest scientific observations of the mountains. With the systematization of geology as a science in the second half of the 19th century, Alpine investigation made great advances. The first geologic maps indicated the main structural outlines of the mountain system, which revealed unusually complicated geologic phenomena that seemed to be the result of something more than a massive upheaval within the Earth. One explanation was the theory of nappes—enormous masses of rock apparently squeezed and thrust across long distances by internal pressures in the Earth, eventually overlying strata of more recent age and different origin. This theory has been reinforced by the hypothesis of continental drift, which posited the realignment of entire land and water areas during vast geologic eras. Today, however, the tendency is to suppose a vertical uplift of the crystalline rock and a sliding down (under the effects of both gravity and the relatively plastic nature of the layers of schists and marls) of the sedimentary cover, and a somewhat more complicated origin for the nappes.

Simultaneous with this conjecture on geologic regions, the subjects of Alpine relief, climatology, and vegetable, animal, and human geography also came in for observation and analysis. The Alps are probably the most thoroughly studied mountain system on Earth, particularly at such institutions as the Universities of Grenoble, Fr., and Innsbruck, Austria, and the Swiss Federal Institute of Snow and Avalanche Research near Davos; yet they continue to present hosts of complex and evolving scientific problems. (P.V./A.Di.)

APENNINES

The Apennines (Italian: Appennino), a series of mountain ranges bordered by narrow coastlands, form the physical backbone of peninsular Italy and have had considerable influence on the human geography of that nation. From Cadibona Pass in the northwest, close to the Maritime Alps, they form a great arc, which extends as far as the Egadi Islands to the west of Sicily. Their total length is approximately 870 miles (1,400 kilometres), and their width ranges from 25 to 125 miles. Mount Corno, 9,554 feet (2,912 metres), is the highest point of the Apennines proper on the peninsula. The range follows a northwest–southeast orientation as far as Calabria, at the southern tip of Italy; the regional trend then changes direction, first toward the south and finally westward.

The Apennines are among the younger ranges of the Alpine system and, geologically speaking, are related to the coastal range of the Atlas Mountains of North Africa. Similarities have also been observed with the Dinaric Alps, which extend through Yugoslavia and Greece. The nearby islands of Sardinia and Corsica, on the other hand, are dissimilar to the Apennines, their granitic rock masses being linked to outcroppings along the Spanish and French coast, from which they parted some 20 million years ago.

Physical features. *Geology.* The majority of geologic units of the Apennines are made up of marine sedimentary rocks that were deposited over the southern margin of the Tethys Sea, the large ocean that spread out between the Paleo-European and the Paleo-African plates during their separation in the Mesozoic era (about 245 to 66 million years ago). These rocks are mostly shales, sandstones, and limestones, while igneous rocks (such as the ophiolites of the northern Apennines, the remains of an older oceanic crust) are scarce. The oldest rocks—metamorphic units of the late Paleozoic era (about 300 to 245 million years ago), with their continental sedimentary cover containing plant remains—represent the relicts of the ancient continental crust of Gondwanaland and are found in small outcroppings. The granitic intrusions and metamorphic units of the Calabrian and Sicilian ranges are also Paleozoic (Hercynian orogeny), but they are believed to be Alpine in origin and only became part of the Apennine chain through subsequent major tectonic movements.

Apennine orogeny

The Apennine orogeny developed through several tectonic phases, mostly during the Cenozoic era (*i.e.,* since about 66 million years ago), and came to a climax in the Miocene and Pliocene epochs (23.7 to 1.6 million years ago). The Apennines consist of a thrust-belt structure with three basic trending motions: toward the Adriatic Sea (the northern and central ranges), the Ionian Sea (Calabrian Apennines), and Africa (Sicilian Range). During Plio-Pleistocene times, ingression and regression of the sea caused the formation of large marine and continental sedimentary belts (sands, clays, and conglomerates) along the slopes of the new chain. In the past million years numerous large faults have developed along the western side of the Apennines, which may be connected to the crustal thinning that began about 10 million years ago and resulted in the formation of a new sea, the Tyrrhenian. Most of these faults have also facilitated strong volcanic activity, and a volcanic chain has formed along them from Mount Amiata in Tuscany to Mount Etna in Sicily; most of these volcanoes—including Mount Amiata, Mount Cimino, the Alban Hills near Rome, and the Ponza Islands—are extinct, but, to the south, Mount Vesuvius, the Eolie Islands, and Mount Etna are all still active. Seismic activity is common along the entire length of the chain (including Sicily), with more than 40,000 recorded events since AD 1000. Mostly earthquakes are shallow (three to 19 miles deep), and their occurrence is probably connected to the settlement of the chain in the complicated interaction between the African and European tectonic plates.

The geologic youth of the Apennines, and a great variety of rock types, are responsible for the rugged appearance of the range today. In the north, in Liguria, sandstones, marls, and greenstones occur. Landslides often occur in these brittle rocks. In Tuscany, Emilia, Marche, and Umbria, clay, sand and limestones are common. In Lazio, Campania, Puglia, Calabria, and northern and eastern Sicily, there are large calcareous rock outcrops, separated by lowland areas of shale and sandstone. In Molise, Basilicata, and Sicily, extensive argillaceous (clayey) rock types occur. Here, the landscape has a thirsty and desolate appearance, with frequent erosion of the *calanchi,* or badlands, type.

Physiography. Starting from the north, the main subdivisions of the Apennines are the Tuscan-Emilian Apennines, with a maximum height of 7,103 feet at Mount Cimone; the Umbrian-Marchigian Apennines, with their maximum elevation (8,130 feet) at Mount Vettore; the Abruzzi Apennines, 9,554 feet at Mount Corno; the Campanian Apennines, 7,352 feet at Mount Meta; the Lucanian Apennines, 7,438 feet at Mount Pollino; the Calabrian Apennines, 6,414 feet at Mount Alto; and, finally, the Sicilian Range, 10,902 feet at Mount Etna. The ranges in Puglia (the "bootheel" of the peninsula) and southeastern Sicily are formed by low, horizontal limestone plateaus, which remained less affected by the Alpine orogeny.

The rivers of the Apennines have short courses. The two principal rivers are the Tiber (252 miles long), which follows a southerly course along the western base of the Umbrian-Marchigian range before flowing through Rome to the Tyrrhenian Sea, and the Arno (155 miles), which flows westerly from the Tuscan-Emilian range through Florence to the Ligurian Sea. In spite of the limited length of the rivers, the action of running water is the chief agent of erosion responsible for molding the contemporary Apennine landscape. The character of the physical geography depends on the varying nature of the rocks in each region and their resistance to water action. The overall aspect of relief, however, exhibits characteristics of an early, or juvenile, stage in the cycle of erosion. In limestone areas, karst erosion, with crevasses worn by water action, predominates. In the highest part of the Apennines there are traces of the erosive action of the glaciers of the last Ice Age, although, unlike the Alps, contemporary glaciers are lacking.

Landscape formed by erosion

Lakes—which today are small and scattered in distribution—were also much more abundant in earlier Quaternary times. The alluvial Lake Trasimeno (49 square miles [128 square kilometres]) in the Umbrian-Marchigian Apennines is the largest lake of the present range. Other natural lakes, of varying origin, are scattered throughout the range. There are more than 200 artificial lakes created for purposes of power and irrigation.

Climate. The climate of the highest section of the Apennines is continental (as found in the interior of Europe) but ameliorated by Mediterranean influences. Snowfalls are frequent, with cold winters and hot summers (average July temperature 75°–95° F [24°–35° C]). Average rainfall—at between 40 and 80 inches (1,000 and 2,000 millimetres) per year—is higher on the Tyrrhenian slopes than on the eastern, or Adriatic, side of the Apennines.

Plant and animal life. The flora of the Apennines is Mediterranean in type and varies with both latitude and altitude. In the north, woodlands with oak, beech, chestnut, and pine predominate. To the south, ilexes, bays, lentisks, myrtles, and oleander (a flowery evergreen herb) abound. Prevailing crops are represented by the olive trees, growing to a height of about 1,300 feet above sea level; citrus fruits, which are well developed in Calabria and Sicily; and grapes, which are found in abundance in Tuscany, Lazio, and Puglia. Other products of the range include sugar beets (in the plain of Emilia), potatoes, vegetables, and fruit. The importance of corn (maize) diminished with the depopulation of hill farms. In the highland areas, pasturing remains the main form of land utilization.

Trucks carrying high-grade marble quarried in the Apennines near Carrara, Italy.

Apennine fauna has been little studied. In addition to typical Mediterranean fauna, many of the indigenous Apennine species (with several species found exclusively within the range, including some insects, the brown "marsicano" bear, the chamois, the wolf, and the wild boar) are now preserved in two natural reserves (Abruzzo National Park and Sila Park) and several regional parks.

Settlement patterns

The people and economy. Since prehistoric times the Apennines have been the home of Italic peoples. Today, the highest village settlement is found at about 4,500 to 5,000 feet above sea level, at the upper limit of cultivated land. More densely populated areas are found in the wide river valleys, which are rich in alluvial and cultivated land (*e.g.*, the valleys of Lunigiana in Liguria, Garfagnana in Tuscany, and those of the upper Arno and Tiber rivers). Internal basins (Foligno, Terni, Rieti, l'Aquila, Sulmona, Avezzano) are also well populated. Rural depopulation, resulting from the lack of development of the Italian south and the attraction of industrial areas in northern Italy and elsewhere in Europe, has reached major proportions. This emigration has nevertheless slackened, mainly as a result of attempts to develop the local economy.

In the foothills of the Apennines, manufacturing industries are widespread, while extraction industries have been developed in the adjacent coastal plain, often in association with important discoveries of natural gas. Such minerals as mercury, sulfur, boron, and potassic salts are also of significance, while the marble quarries—particularly those near Carrara—of the Apennines have been famous for centuries.

The Apennines are crossed by several railway lines, some of them double-tracked. There are numerous roads providing access to the range, although the rugged terrain makes for difficulties. Among the highways that have overcome the barriers of relief with imposing series of tunnels and embankments is the Autostrada del Sole ("Highway of the Sun"), which is the main artery of peninsular Italy and one of the great scenic routes of Europe.

Study and exploration. Various aspects of the Apennines—their geology, hydrography, zoology, and botany—have been studied by the leading Italian universities, the Italian Geological Survey, and such bodies as the National Research Council of Italy and the Hydrographic Service of the Ministry of Public Works. Since the late 1970s many scientists have organized several national research projects concerning the geologic evolution and hazards of the Apennines and have also conducted environmental evaluations and petroleum surveys. (B.A./Ma.P.)

CARPATHIAN MOUNTAINS

The Carpathian Mountains are a geologically young European mountain chain forming the eastward continuation of the Alps. From the Danube Gap, near Bratislava, Czech., they swing in a wide arc some 900 miles (1,450 kilometres) long to near Orşova, Rom., at the portion of the Danube River valley called the Iron Gate. These are the conventional boundaries of these arcuate ranges, although, in fact, certain structural units of the Carpathians extend southward across the Danube at both sites mentioned. The true geologic limits of the Carpathians are, in the west, the Vienna Basin and the structural hollow of the Leitha Gate in Austria and, to the south, the structural depression of the Timok River in Yugoslavia. To the northwest, north, northeast, and south the geologic structures of the Carpathians are surrounded by the sub-Carpathian structural depression separating the range from other basic geologic elements of Europe, such as the old Bohemian Massif and the Russian, or East European, Platform. Within the arc formed by the Carpathians are found the depressed Pannonian Basin, composed of the Little and the Great Alfolds of Hungary, and also the relatively lower mountain-and-hill zone of Transdanubia, which separates these two plains. Thus defined, the Carpathians cover some 80,000 square miles (200,000 square kilometres).

Although a counterpart of the Alps, the Carpathians differ considerably from them. Their structure is less compact, and they are split up into a number of mountain blocks separated by basins. The highest peaks, Gerlachovský Štít (Gerlach) in the Carpathians (8,711 feet [2,655 metres]) and Mont Blanc in the Alps (15,771 feet), differ greatly in altitude, and in average elevation the Carpathian mountain chains are also very much lower than those of the Alps. Structural elements also differ. The sandstone–shale band known as flysch, which flanks the northern margin of the Alps in a narrow strip, widens considerably in the Carpathians, forming the main component of their outer zone, whereas the limestone rocks that form a wide band in the Alps are of secondary importance in the Carpathians. On the other hand, crystalline and metamorphic (heat-altered) rocks, which represent powerfully developed chains in the central part of the Alps, appear in the Carpathians as isolated blocks of smaller size surrounded by depressed areas. In addition to these features, the Carpathians contain a rugged chain of volcanic rocks.

Similar differences can be observed in the relief of these two mountain systems, notably in the way that the processes of erosion have occurred. The relief forms of the Alps today result for the most part from the glaciations of the last Ice Age. These affected practically all mountain valleys and gave them their specific relief character. In the Carpathians, glaciation affected only the highest peaks, and the relief forms of today have been shaped by the action of running water.

Physical features. *Geology.* The Carpathians extend in a geologic system of parallel structural ranges. The Outer Carpathians—whose rocks are composed of flysch—run from near Vienna, through Moravia, along the Polish-Czechoslovak frontier, and through the western Ukraine into Romania, ending in an abrupt bend of the Carpathian arc north of Bucharest. In this segment of the mountains, a number of large structural units of nappe character (vast masses of rock thrust and folded over each other) may be distinguished. In the eastern part of the Outer Carpathians this fringe is formed by the Skole Nappe, and in the western part it is formed by the Silesian Nappe, both of which are split by the longitudinal central Carpathian depression. Overthrust on the Silesian Nappe is the Magura Nappe, the counterparts of which in the east are the Chernogora (Chornohora) and the Tarcău nappes.

Parallel structural ranges

The Inner Carpathians consist of a number of separate blocks. In the west lies the Central Slovakian Block; in the southeast lie the East Carpathian Block and the South Carpathian Block, including the Banat and the East Serbian Block. The isolated Bihor Massif, in the Apuseni Mountains of Romania, occupies the centre of the Carpathian arc. Among the formations building these blocks are ancient crystalline and metamorphic cores onto which younger sedimentary rocks—for the most part limestones and dolomites of the Mesozoic era (245 to 66.4 million years ago)—have been overthrust.

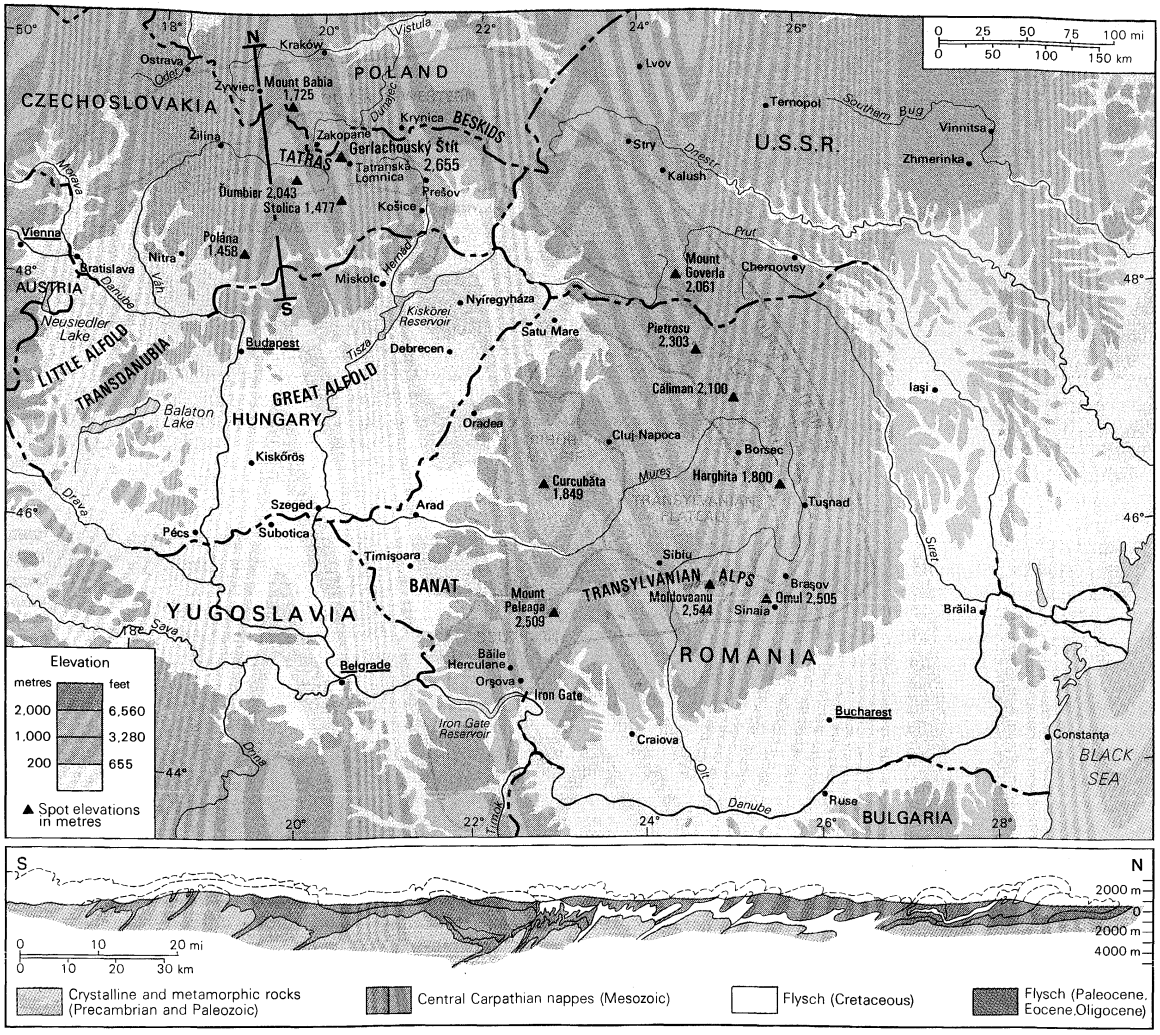
The third and innermost range is built of young Tertiary volcanic rocks formed less than 50 million years ago, differing in extent in the western and eastern sections of the Carpathians. In the former they extend in the shape of an arc enclosing, to the south and east, the Central Slovakian Block; in the latter they run in a practically straight line from northwest to southeast, following the line of a tectonic dislocation, or zone of shattering in the Earth's crust, parallel with this part of the mountains. Between this volcanic range and the South Carpathian Block, the Transylvanian Plateau spreads out, filled with loose rock formations of young Tertiary age.

The Central Slovakian Block is dismembered by a number of minor basins into separate mountain groups built of older rocks, whereas the basins have been filled with younger Tertiary rocks.

In Romania, orogenic, or mountain-building, movements took place along the outer flank of the Carpathians until late in the Tertiary period (less than 10 million years ago), producing foldings and upheaval of the sedimentary rocks of the sub-Carpathian depression; the result was the formation of a relatively lower range called the sub-Carpathians adjoining the true Carpathians.

Relief forms

The relief forms of the Carpathians have, in the main, developed during young Tertiary times. In the Inner Carpathians, where the folding movements ended in the Late Cretaceous epoch (97.5 to 66.4 million years ago),

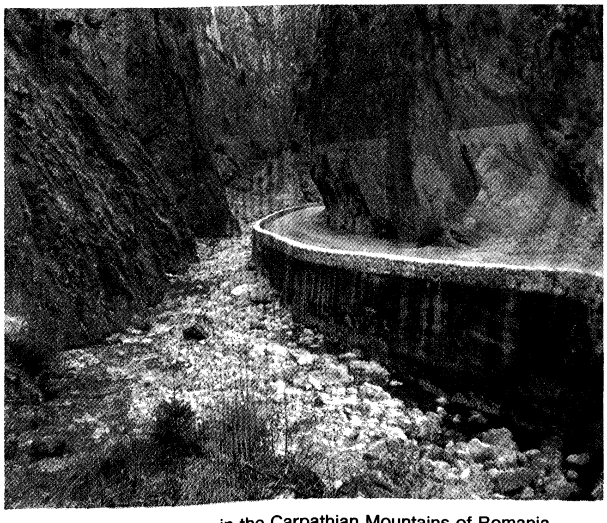


Regional division of the Carpathian Mountains and a geologic cross section of the Western Carpathians. The location of the cross section is shown by the line N–S on the map.

local traces of older Tertiary landforms have survived. Later orogenic movements repeatedly heaved up this folded mountain chain, leaving a legacy of fragmentary flat-topped relief forms situated at different altitudes and deeply incised gap valleys, which often dissect the mountain ranges. In this way, for example, the gap sections of the Danube and of some of its tributaries—the Váh, the Hernád, and the Olt—developed.

The last Ice Age affected only the highest parts of the Carpathians, and glaciers were never more than about 10 miles long, even in the Tatras, where the line of permanent snow ran at 5,500 feet above sea level.

Harrison Forman



Deep river-cut gorge in the Carpathian Mountains of Romania.

Physiography. Generally speaking, the Carpathians have been divided into the Western and the Eastern Carpathians, the latter also called—probably more accurately—the Southeastern Carpathians. The extent of these two regions and their subdivisions is given in Table 1. There are marked differences between these parts. The Western Carpathians show a clearly marked zoning in geologic structure and relief forms, and the highest elevations occur in the central part of this province, in the Tatras and the Lower Tatras ranges. The geologic structure of the inner part of the Western Carpathians is marked by a break running from the east and the south along a line of dislocation in the Earth's crust. Along this line, masses of volcanic rocks have been piled up surrounding the Central Western Carpathian Block in a wide arc, with its convex side turned eastward. The boundary between the Western and the Southeastern Carpathians occurs at the narrowest part of the mountain range, marked by the valley of the San River to the north and the Łupków Pass (2,100 feet) and the Laborec Valley to the south. There the Carpathians are only some 75–80 miles wide, while in the west they are 170 miles and in the east as much as 220–250 miles across.

The Southeastern Carpathians are formed by a triangular block of mountains surrounding a basin. The three mountain formations concerned differ in origin and structure. The Eastern Carpathians, running in a northwest–southeast direction, include the flysch band, which represents the continuation of the Outer Western Carpathians, and also an inner band of crystalline and volcanic rocks. In

Table 1: Subdivisions of the Carpathians

	approximate area	
	sq km	sq mi
Western Carpathians	68,000	26,000
Outer Western Carpathians	27,500	10,500
Central Western Carpathians	15,500	6,000
Inner Western Carpathians	25,000	9,500
Southern Carpathians	131,000	50,500
Outer Eastern Carpathians	35,500	13,500
Inner Eastern Carpathians	21,250	8,000
Southern Carpathians	28,250	11,000
Transylvanian Plateau	28,500	11,000
Bihor Massif (Apuseni Mountains)	17,500	7,000

contrast, the Southern Carpathians, running east-northeast to west-southwest, consist, in the main, of metamorphic rocks. The Bihor Massif is also of metamorphic rock but is covered with younger sediments.

The Outer Western Carpathians are generally of low altitude; the highest elevation is Mount Babia (5,659 feet) in the Beskid Range, straddling the borders of Poland and Czechoslovakia. On the Polish side, a national park has been established. A considerable part of the Outer Western Carpathians lacks a truly mountainous landscape and rather resembles a hilly plateau elevated to 1,300–1,600 feet above sea level.

The Tatras

The Central Western Carpathians consist of a series of isolated mountain ranges separated by structural depressions. Highest among them are the Tatras (Gerlachovský Štít, 8,711 feet), exhibiting a typical high-mountain glacial relief with ice-scoured (cirque) lakes and waterfalls. This highest Carpathian massif is built of crystalline (granite) and metamorphic rocks, but the northern part contains, upthrust from the south, several series of limestone rocks with associated karst, or water-incised, relief forms. On both the Polish and Slovakian sides, national parks have been established. South of the Tatras, separated by the Liptov and Spiš basins, run the parallel Lower Tatras, similar in geologic structure but lower (Ďumbier Peak, 6,703 feet) and with a less conspicuous glacial relief. Along the boundary line between the Outer and the Central Western Carpathians extends a narrow strip of klippen (limestone) rocks, which, north of the Tatras, has developed into the small but picturesque Pieniny mountain group. A narrow and sharply winding gap valley has been incised there by the Dunajec River, a tributary of the Vistula.

The Inner Western Carpathians are lower and more broken. The principal mountain groups are the Slovak Ore Mountains (Slovenské Rudohorie), with Stolica (4,846 feet) as the highest peak; they are built of metamorphic rocks and of sedimentaries of the Paleozoic era more than 250 million years old. Also found there are tableland areas of Mesozoic limestones, about 150 million years old, containing such large caves as the Domica-Aggtelek Cave on the Slovak-Hungarian boundary, which is 13 miles long. Mountain groups of volcanic origin are important in this part of the Carpathians; the largest among them is Pol'ana (4,784 feet).

Compared with the Outer Western Carpathians, the Outer Eastern Carpathians, which are their continuation, are higher and show a more compact banded structure. The highest mountain group is the Chernogora on the Ukrainian side, with Goverla (Hoverla; 6,762 feet) as the highest peak. The Inner Eastern Carpathians attain their highest altitude in the Rodna (Rodnei) Massif in Romania; they are built of crystalline rocks and reach a peak in Pietrosu (7,556 feet). To the south, extinct volcanoes in the Căliman and Harghita ranges have, to some extent, kept their original conical shape; the highest peaks of these ranges are 6,890 feet and 5,906 feet, respectively. Fringing the true Eastern Carpathians runs a narrow zone called the sub-Carpathians, which is made up of folded young Tertiary rocks superimposed on the sub-Carpathian structural depression.

The Southern Carpathians culminate in the Făgăraş Mountains (highest point Moldoveanu, 8,347 feet), which show Alpine-type relief forms. The western part of the Southern Carpathians—that is, the Banat Mountains and the mountains of eastern Serbia (which, at the Iron Gate, are split apart by the gap valley of the Danube)—do not exceed an altitude of 5,000 feet.

The Bihor Massif, which occupies an isolated position inside the Carpathian arc, features widespread flat summit plains bordered by narrow, deep-cut valleys. The highest peak is Curcubăta (6,067 feet).

Finally, mention should be made of the Transylvanian Plateau. This is made up of poorly resistant young Tertiary rocks and characterized by a forestless hilly landscape with elevations of 1,500 to 2,300 feet above sea level; the valleys are cut to depths of 325 and 650 feet.

Drainage. The water runoff from the Carpathians escapes for the most part (about 90 percent) into the Black Sea. The great curve of the mountain chain abuts in the south upon the Danube; in the east it is flanked by a tributary of the Danube, the Prut River, and farther on by the Dnestr River, which flows to the Black Sea. Only the northern slope of the Carpathians, mostly in Poland but partly in Czechoslovakia, is linked to the Baltic Sea by the drainage basins of the Vistula and (in part) Oder rivers. Larger rivers originating in the Carpathians include the Vistula and the Dnestr and the following Danube tributaries: Váh, Tisza, Olt, Siret, Prut. The Carpathian rivers are characterized by a rain–snow regime; high-water periods occur in the spring (March–April) and in summer (June–July), with the latter usually more powerful. Often these floods assume catastrophic dimensions caused by the poor ground retention of the rainfall. There has long been an urgent need for the construction of storage basins, work on which was initiated on a large scale in the decades following World War II. The largest storage basin is in the Danube River valley on the frontier between Romania and Yugoslavia. Other large basins include one in the Bistriţa valley in Romania, one in the San valley in Poland, and one in the Orava valley in Czechoslovakia. Altogether there are some 50 storage basins in the Carpathians. Natural mountain lakes are relatively rare, and all of them are small. Although there are some 450 lakes, their total surface is barely 1.5 square miles. The high-mountain lakes are mainly of glacial origin.

Flood peril

Climate. The situation of the Carpathians, on the boundary line between western and eastern Europe, is reflected in the features of their climate, which in winter is governed by the inflow of polar-continental air masses arriving from the east and northeast, while during other seasons oceanic air masses from the west predominate. The distance from the Atlantic Ocean (from 620 to 1,240 miles) and the influence of the intervening masses of the Alps and the Bohemian Massif cause diminished precipitation in the Carpathians. The Carpathians thus possess certain features of a continental climate, although from the viewpoint of relief they constitute a sort of island amid the surrounding plains, where the climate is much drier. The continentality of the climate is clearly seen in the intermontane depressions, however, as well as on the lower parts of the southern mountain slopes. In winter, temperature inversion, in which the low depressions retain very cold air while the mountaintops show relatively high temperatures, is a common occurrence throughout the Carpathians. In some depressed areas, notably the Transylvanian Plateau, the total annual precipitation is less than 24 inches (600 millimetres), while precipitation in the mountains at 2,600 feet (800 metres) above sea

Table 2: Climatic Stages of the Western Carpathians

type	stage	mean annual temperature		average altitude limits (above sea level)*	
		degrees Fahrenheit	degrees Celsius	feet	metres
Nival	cold	25	−4	8,710	2,655
Nival-pluvial	temperate cold	28	−2	6,070	1,850 (1,670)
	very cool	32	0	5,080	1,550 (1,400)
	cool	36	2	3,600	1,100
Pluvial-nival	temperate cool	39	4	2,300	700

	mountain foreland	46	8	under 820	under 250

*The figures in parentheses refer to the Outer Carpathians.

Table 3: Vegetation Stages of the Carpathians
(feet [metres])

stages	Western Carpathians		Eastern Carpathians	Southern Carpathians
	Outer	Inner		
Nival	—	up to 8,710 (2,655)	—	—
Alpine	up to 5,660 (1,725)	up to 7,200 (2,200)	up to 6,600 (2,000)	up to 8,344 (2,544)
Subalpine	up to 5,480 (1,670)	up to 5,900 (1,800)	up to 6,070 (1,850)	up to 7,200 (2,200)
Upper forest	up to 4,600 (1,400)	up to 5,080 (1,550)	up to 5,080 (1,550)	up to 5,900 (1,800)
Lower forest	up to 3,770 (1,150)	up to 4,100 (1,250)	up to 4,100 (1,250)	up to 4,900 (1,500)
Foreland	up to 1,800 (550)	up to 2,300 (700)	up to 2,000 (600)	up to 2,800 (850)

level is about 45 inches, and on the highest massifs it reaches 65 to 70 inches. The mean annual and monthly air temperatures vary according to altitude above sea level but by no means at constant rates.

For the Polish part of the Carpathians, a series of climatic types and stages has been distinguished; and with slight modification these may be applied to the whole Carpathian mountain range.

Plant and animal life. Different vegetation stages may also be distinguished for the various altitudinal zones of the Carpathians. The alpine stage is characterized by high mountain pastures, the subalpine stage by dwarf pine growth, the upper forest stage by spruce, and the lower forest stage by beech. The foreland stage is noted for oaks and elms. The natural vegetation stages are matched by stages of economic land use: the foreland by wheat and potato growing, the lower forest stage by oats and potato growing (up to 3,280 feet), and the upper forest stage and the subalpine stages by pastoral use.

The plant life of the Carpathians contains many unique species, especially in the southeastern part of the mountains where the effect of Quaternary climatic cooling was less marked. Forests have been best preserved in the eastern part of the Carpathians, and there the animal life includes bears, wolves, lynx, deer, boars, and, in the highest parts (in the Tatras), chamois and marmots.

The people. The distribution of the population in the Carpathians depends on natural land features and on socioeconomic conditions; hence it is very much diversified. In the valleys between the mountains and again on the northern slopes of the Western Carpathians, the population density is heavy, whereas close by practically uninhabited mountain massifs are to be found. On the whole, the Southeastern Carpathians are less densely settled than the Western Carpathians, but there also marked aggregations of people occur in the valleys.

Nationalities

The western slope of the Western Carpathians is inhabited by Czechs, the northern slope by Poles, the entire central part of the Western Carpathians by Slovaks, and the southern portion by Hungarians. The northern part of the Eastern Carpathians, both its outer and inner sectors, is occupied by Ukrainians; but south of latitude 47° a Romanian population predominates. Inside the arc of the Eastern Carpathians, and also partly on the Transylvanian Plateau, lives a compact island of Hungarian population and some remnants of German colonists dating from the Middle Ages. Finally, the southwestern margin of the Carpathians, beyond the Danube gap, is occupied by Serbs. Generally speaking, the greater part of the Western Carpathians and the northern part of the Eastern Carpathians is inhabited by a Slav population, and the southern part of both these Carpathian provinces, with the exception of the mountains of east Serbia, by Romanians and Hungarians.

In the 13th and 14th centuries Romanian shepherds, wandering with their flocks, moved along the Carpathians into what is today Ukrainian, Slovakian, and Polish territory, and traces of this penetration have survived in geographic nomenclature and in economic methods and also in types of buildings, garments, and customs, although by the second half of the 20th century many of the latter were gradually disappearing. In general outlines, but by no means in detail, the diversity in nationality coincides with today's pattern of the political boundaries.

The economy. *Agriculture and industry.* The Carpathians are a region of agriculture and forestry, with industry in an early stage of development. Agriculture flourishes on the Transylvanian Plateau, in intramontane basins, and on lower parts of the mountains, up to some 3,000 feet elevation. On the northern slopes wheat, rye, oats, and potatoes predominate; on the southern slopes corn (maize), sugar beets, grapes, and tobacco are grown. Above 3,000 feet elevation forestry and pastoral life are the rule. Natural gas, found mainly on the Transylvanian Plateau, is important among natural resources. Oil is also significant; the richest deposits lie in the Romanian sub-Carpathians. Brown coal is found in low-lying areas of the Western Carpathians in Czechoslovakia and Hungary, and some bituminous coal is mined in the Romanian Southern Carpathians. Also noteworthy are the rock salt beds of the Transylvanian Plateau, the Romanian sub-Carpathians, and the base of the Polish Carpathians, and the potassium salts found at the base of the Ukrainian Carpathians. Iron ores, ores of noniron metals, and gold and silver ores were intensively mined in the Middle Ages in the Bihor Massif and in the Slovakian Western Carpathians, but today all these deposits are of minor importance.

Economic development

Larger industrial centres are Bratislava, the capital of the Slovak Republic, with a thriving machinery and a petrochemical industry; and Košice, the principal town of eastern Slovakia, with a modern steel mill. Prominent in Romania are Cluj-Napoca, which is the principal town of the Transylvanian Plateau, concentrating on machinery making and chemical and food products; Braşov, situated in a basin near the boundary between the Western and Southern Carpathians, a town where machine production predominates; and Sibiu, lying between the Transylvanian Plateau and the Southern Carpathians.

Tourism. The Carpathians are a popular tourist and recreation venue, especially for the people of Poland, Czechoslovakia, Hungary, and Romania. Tourist travel from other countries is less developed, although a number of areas attract visitors from abroad. Most important among these are Zakopane, a centre of sports activities, tourism, and recreation, situated in Poland north of the Tatras. On the Slovak side of the Tatras, a similar role is played by a number of localities, notably Tatranská Lomnica, Smokovec, and Štrbské Pleso. In Romania the outstanding centre for winter sports and tourism is Sinaia, situated in the Prahova valley. The Carpathians are noted for their abundance of mineral springs. Among the best-known Carpathian health spas are Krynica in Poland, Piešťany in Czechoslovakia, and Borsec, Băile Herculane, and Tuşnad in Romania.

Transportation. The railway network of the Carpathians came into existence in the latter half of the 19th century and the beginning of the 20th, at a time when most of the mountains were in Austria-Hungary. In this period the nodal point was Budapest, situated in the centre of the Carpathian arc. The principal railway lines were laid out radially from Budapest across the various mountain passes and were tied in with the main longitudinal west–east trunk line running in an arc along the northern flank of the Carpathians between Vienna and Chernovtsy, Ukrainian S.S.R. (then situated in Austria-Hungary). This northern trunk continued in the sub-Carpathian Romanian railway line running toward Bucharest and, farther on, to Orşova, which, in turn, was linked by a Hungarian railway section with Budapest and thus with Vienna. After the Austro-Hungarian Empire had collapsed, this system lost much of its economic and strategic importance. Within its boundaries the new state of Czechoslovakia started to build

The historical legacy

longitudinal west–east railway lines. For Romania, which had been allotted Carpathian Transylvania, the previously neglected lines became highly important. To some extent, a change in this pattern came about after World War II, when the northern part of the Eastern Carpathians and Trans-Carpathian Ukraine became part of the Soviet Union. The railway lines crossing this part of the Carpathians became arteries linking the Soviet Union, Czechoslovakia, and Hungary. Although the lines between Poland and Slovakia lost most of their importance in passenger and freight transport, truck routes utilizing the Dukla (1,640 feet), Jablonkov, and other passes became significant in freight traffic between Poland and the countries south of the Carpathians. The most important Carpathian railway lines have been electrified, although the Budapest–Vienna line was electrified before World War II.

Study and exploration. Many nationalities are in contact with one another in the Carpathians, and this diversity has had its effect on the development of scientific research in the region. From the end of the 18th century until World War I, most of the Carpathians were within the boundaries of Austria-Hungary, and throughout this period the Carpathians were readily accessible to all scientists of this multinational empire; the work of Polish scientists, together with that of Germans and Hungarians, is considered most noteworthy. In the late 19th century the

Mapping

Austrian general staff published the first comprehensive topographic map of the region. A century later, each of the countries whose territory covered part of the Carpathians—Czechoslovakia, Poland, Romania, Hungary, and the Soviet Union—had at hand topographic maps drawn to a scale of 1:50,000 and 1:200,000—compiled on the basis of a coordinated geodetic system and in a mutually correlated sheet pattern.

As for geologic maps, the first paper dealing with the geology of the Carpathians as a whole was published in 1815. Today, each of the Carpathian countries has its own general geologic maps, and there is also abundant regional geologic literature. In 1922 the International Geological Congress created an association of Carpathian geologists, which met every three years thereafter. Regional research in physical geography is also well advanced, and in 1963 a geomorphologic committee for the Carpathians and the Balkans was established.

Research is somewhat less advanced in climatology and biogeography, although a number of papers began to appear in the second half of the 20th century. In human geography much attention has been given to the problems of pastoral life and associated population movements. No synthetic survey of the economic geography of the whole Carpathians has appeared as economic problems have been studied separately in each of the countries involved. Indeed, the first comprehensive geographic account of the Carpathians as a whole, by the Polish geographer Antoni Rehman, was not published until 1895.

Since World War II the Carpathians have become the object of research by a number of scientific centres in the countries involved, with the geographic institutes of the several national academies of sciences and the geographic and natural history institutes of various universities playing a leading role. National geologic institutes and institutes of hydrology and meteorology have also amassed a considerable body of information. (J.A.K.)

EUROPEAN PLAIN

One of the greatest uninterrupted expanses of plain on the Earth's surface sweeps from the Pyrenees Mountains on the French-Spanish border across northern Europe to the Ural Mountains in the Soviet Union. In western Europe the plain is comparatively narrow, rarely exceeding 200 miles (320 kilometres) in width, but as it stretches eastward it broadens steadily until it reaches its greatest width in the Soviet Union, where it extends more than 2,000 miles.

Because it covers so much territory, the plain gives Europe the lowest average elevation of any continent. The flatness of this enormous lowland, however, is broken by hills, particularly in the west.

Physical features. *Physiography.* The western and central European section of the plain covers all of western and northern France, Belgium, The Netherlands, southern Scandinavia, northern Germany, and nearly all of Poland. From northern France and Belgium eastward it is commonly called the North European Plain.

The North European Plain

Conditions in the North European Plain are complex in detail. The terrain is flat or gently undulating. Most of the area was glaciated several times during the Pleistocene epoch (1.6 million to 10,000 years ago), and the landscape is typically postglacial. Drainage is poorly developed, glacial deposits called moraine blanket much of the area, and large sections are underlain by glacial outwash plains. Hilly terminal moraines, marking the stationary edges of the Pleistocene ice sheets, are strewn in great arcs across northern Germany, Poland, and the European sections of the Soviet Union. Interspersed with these moraines are long parallel spillways where glacial meltwaters flowed to the sea parallel to the ice front. These spillways were covered with sand and gravel by the rushing glacial streams. Today they are occupied by flat, poorly drained wetlands that are relatively unproductive. Sandy duneland borders the North and Baltic seas, and extensive windblown loess deposits, resulting from the intense wind erosion of the barren interglacial and postglacial landscapes, stretch across the North European Plain from France to the Soviet Union.

Other landforms in the North European Plain include the extensive delta plain of The Netherlands that is formed by the deposits of the Rhine River as it enters the North Sea. Like many other delta plains, this area has rich and fertile soils and a flat terrain that is favourable for agriculture where it has been properly drained. The Rhine has historically provided excellent transportation, and the region is one of the most densely populated areas in the world.

The East European Plain

In the east the plain is called the East European Plain (Russian: Vostochno-Yevropeyskaya Ravnina). Finland in the northwest is underlain by ancient, resistant, crystalline rocks, part of the Precambrian Scandinavian Shield. Because it was near the origin of the Pleistocene ice sheets that advanced southward over continental Europe, Finland's landscape is characterized more by glacial erosion than by glacial deposition. With its numerous lakes and swamps caused by the disarranged and immature drainage pattern, together with its thin soils and coniferous forests, the Finnish plain is similar in character and appearance to northern and eastern Canada, another heavily glaciated Precambrian Shield area. The continental glaciers that planed, eroded, and polished the rock surfaces in Finland deposited part of the material over the plains to the south.

The European section of the Soviet Union is deeply underlain by a relatively rigid platform of ancient rocks. At various times in its history, however, this area has slipped beneath the sea and been covered with sedimentary rocks. These rocks have been mildly bent and warped, but nowhere have they been sharply deformed. Consequently, the whole area from the Black Sea to the Arctic is one uninterrupted plain, everywhere below 1,500 feet (450 metres) in elevation.

Climate. The climate on the whole is characterized by marked seasonal changes, with cold winters and warm summers. The west has a maritime climate very favourable to agriculture. It has enough rain in all seasons to keep fields green. Summers are warm but not hot, and winters are cold but not freezing. As one moves eastward, the ameliorating maritime influence diminishes, and the character of the climate becomes more continental: rainfall is concentrated in the warmer months, summers are hotter, and winters become extremely cold. Spring and fall nearly disappear as separate seasons, and the greenness of the summer gives place abruptly each year to the gray drabness of a frozen winter. Agriculture in eastern Europe tends to be more difficult and less productive than in the west.

Drainage. The Garonne and the Loire rivers, with their numerous tributaries, drain much of western France before they enter the Bay of Biscay, and the Seine crosses the broad synclinal lowland of the Paris Basin on its way to the English Channel. The Scheldt and its affluents (Lys, Scarpe, Dender, Demer) drain the Plain of Flanders and the low plateaus of central Belgium. The Meuse pursues a

Rolling expanse of the East European Plain, consisting of glacial deposits, in southern Poland.
D.C. Williamson

varied course through the scarplands of Lorraine, crosses the Ardennes in a valley cut transversely to the structure, turns at right angles along the coal furrow of southern Belgium, and then in a sweeping curve flows across the plain of the southern Netherlands to form a joint floodplain with the lower Rhine.

The Rhine is the main river of west central Europe, 865 miles in length, crossing the various structural and relief zones from its Alpine sources and entering its plain course in the North Sea lowlands. Farther east the several broadly parallel systems include the Weser, the Elbe, the Oder, and the Vistula, which rise in the uplands of central Europe and flow in a general northwesterly direction across the lowlands to the North or Baltic Sea. Each of these rivers reveals distinct right-angle bends, the result of the Pleistocene ice sheets, the margins and terminal moraines of which lay along an east–west line so that meltwaters escaping to the sea had to flow in a westerly direction, eroding broad intermorainal channels (*Urstromtäler*). When the ice sheets withdrew, the rivers occupied some sections of the east–west meltwater channels between their northerly courses. During the 19th and early 20th centuries several of these channels were used as routes to construct canals linking the north-flowing rivers. The Mittelland Canal between East and West Germany is the most prominent of these.

Plant and animal life. Deciduous and coniferous forests diversify the landscape of the North European Plain, although present forests are no more than remnants of a thick mixed forest of oak, elm, ash, linden, and maple, which, since the Middle Ages, has given way to villages and fields in most places. The East European Plain, despite its great uniformity in terrain, exhibits strong regional contrasts in vegetation. Climatic differences produce great belts of characteristic plant life extending approximately east–west across the country. The southern part of the plain is an area of semiarid grasslands, which grade toward the north into more humid lands with taller grasses and rich, fertile soils. North of the grasslands lies a belt of hardwood forests; in the severely cold north lies a belt of coniferous forests and, bordering the Arctic Ocean, a belt of tundra.

Forest remnants

The wild animals of the plain are those characteristic of the whole of Europe, but their numbers have been considerably reduced and their habitats modified by intense human settlement of most areas of the plain.

The people. A variety of languages is spoken on the plain. As in the rest of Europe, almost all belong to the Indo-European family. The primary exceptions are the Finno-Ugric languages Hungarian and Finnish. Three major branches of Indo-European speech are represented. The Germanic branch is represented by Dutch, Flemish (in part of Belgium), German (including the dialect of Austria), Danish, and Swedish. The major representative of the Romance branch is French, along with some inhabitants of the East European Plain who speak Romanian. In most of the east, however, people speak languages of the Slavic branch, of which Polish, Russian, Belorussian (White Russian), and Ukrainian are the most widespread, but also including Czech, Slovak, Slovene, Serbo-Croatian, and Bulgarian.

The European Plain includes people as diverse in culture as the French, Russians, Hungarians, and Swedes. In spite of cultural differences, many of these peoples traditionally shared underlying similarities that derived in part from a common pattern of village life and agricultural routine. Although the eastern part of the plain has remained traditional in many ways, the western part has been transformed as urban centres and industrialization have expanded into the surrounding countryside. Modern transportation has made it easy for farmers to get regularly to town. In many places, members of farming families, released from working on the land by the efficiency of modern machinery, find jobs in town but without moving from the farm. Conversely, urbanites find that they can live in villages and work in town. Where this has occurred, the centuries-old distinction between urban and rural cultures (or subcultures) has been obliterated; even where developments have not gone that far, to the extent that the farmer is no longer parochial, the old distinction has been broken down. (R.T.A./Ed.)

The economy. The European Plain has long been a region of major agricultural importance, and, apart from the relatively small area occupied by its cities and towns today, the landscape—especially in the east—remains predominantly agricultural. Since the mid-19th century, however, the plain has also been one of the world's major heavy industrial regions. This has been especially true in the west, where the industrial concentration extending from West Germany's Ruhr valley north along the Rhine River and west into The Netherlands, Belgium, and northern France has become Europe's most important centre of coal, steel, and chemical production. Similar industrial concentrations have grown up around smaller coalfields farther east, notably in East Germany's Westphalia and Poland's Upper Silesia regions and in the Donets coalfield of the Soviet Ukraine. The increasing importance of bulky imported raw materials to Europe's economy since the end of World War II has made large seaports such as Hamburg and Rotterdam major centres of industry and commerce as well.

Heavy industry

History. Parts of the European Plain harboured hunter-gatherer groups through much of the late Pleistocene, but significant settlement on the plain did not begin until postglacial times. Immigrants from the south moved north after the glaciers retreated and settled in widely scattered areas along the seacoasts, rivers, and lakeshores of the then heavily wooded plain. Until about 3000 BC—when agriculture became widespread in northern Europe—hunting, fishing, and foraging with stone and bone tools was the characteristic mode of life on the plain.

The first agricultural settlements were made primarily on lightly wooded sites with porous, easily worked, and well-drained soils—*i.e.*, those most suited to the fragile wooden

tools of the time. Such areas were found on the loess belt of the northern plain, which became the principal region of prehistoric settlement north of the Alps. Settlement on the thickly forested clay soils of the lowlands did not become feasible until the 8th century AD, with the invention of the heavy-wheeled plow. One of the most significant technological inventions of the Middle Ages, the heavy-wheeled plow opened the European Plain to settlement as never before and was soon followed by other improvements in agrarian technology.

The traditional two-field system of crop rotation, in which half the agricultural land was left fallow each year to maintain soil fertility, gave way to the more sophisticated three-field system: in addition to the usual sowing of wheat, barley, or rye in the autumn, another part of the land was planted in oats or nitrogen-fixing legumes (peas and beans) in the spring, and only the remaining third of the land was left fallow. The cultivation of a surplus of oats from the spring planting, moreover, provided feed that made possible the substitution of the swifter-gaited horse for plowing in place of the oxen. The ever-larger agricultural surpluses resulting from these advances led to the establishment of towns—and eventually cities—on the European Plain.

The character of the European Plain, however, remained primarily rural and agricultural until the 19th century, when the Industrial Revolution spread from England onto the Continent. Major coalfields stretching along the North European Plain from the Franco-Belgian border to the Donets Basin in the Soviet Union became focal points for the development of heavy industry. The plain's excellent system of rivers and canals furnished a network for the transport of such bulk cargo as coal and iron ore, and, when faster bulk transport later became necessary, its flat terrain enabled the unhindered construction of an extensive rail system. (Ed.)

The Industrial Revolution

PYRENEES

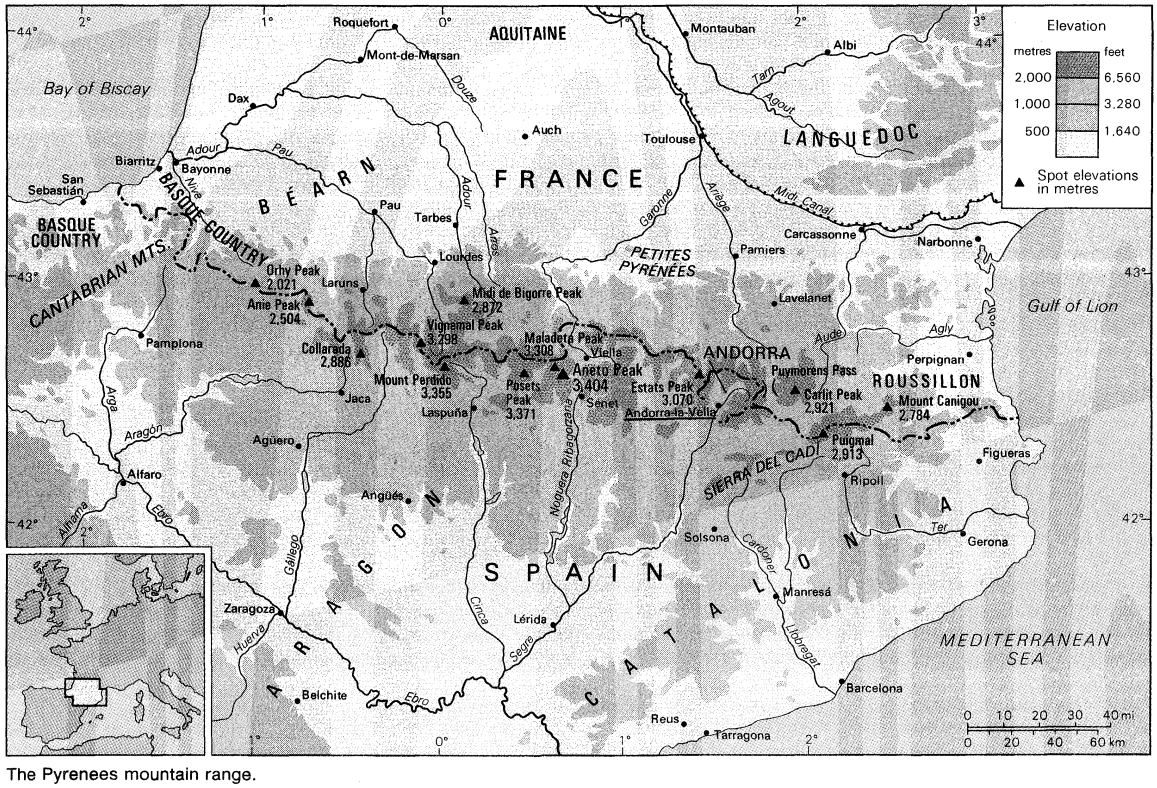
A mountain chain stretching from the shores of the Mediterranean Sea on the east to the Bay of Biscay on the Atlantic Ocean on the west, the Pyrenees (French: Pyrénées; Spanish: Pirineos) form a high wall between France and Spain that has played a significant role in the history of both countries and of Europe as a whole. The range is some 270 miles (430 kilometres) long; it is barely six miles wide at its eastern end, but at its centre it reaches some 80 miles in width. At its western end it blends imperceptibly into the Cantabrian Mountains along the northern coast of the Iberian Peninsula. Except in a few places, where Spanish territory juts northward or French southward, the crest of the chain marks the boundary between the two countries, though the tiny, autonomous principality of Andorra lies among its peaks. The highest point is Aneto Peak, at 11,169 feet (3,404 metres), in the Maladeta ("Accursed") massif of the Central Pyrenees.

The Pyrenees long have been a formidable land barrier between Spain and Portugal on the Iberian Peninsula and the rest of Europe; as a consequence, these two countries traditionally have developed stronger associations with Africa than with the rest of Europe, and they have become tied to the sea. From Carlit Peak (9,584 feet) near the eastern limit of the Pyrenees to the peaks of Orhy and Anie, a succession of mountains rise nearly 9,800 feet; at only a few places, all well to the west, can the chain be crossed through passes lower than 6,500 feet. In both the lower eastern and northwestern sectors, rivers dissect the landscape into numerous small basins. The range is flanked on both sides by broad depressions—the Aquitaine and Languedoc to the north and the Ebro to the south—both receiving waters from the major rivers flowing out of the mountains, the Garonne of France and the major tributaries of the Ebro of Spain.

Cultural barrier

Physical features. *Geology.* The Pyrenees represent the geologic renewal of an old mountain chain rather than a more recent and vigorous mountain-building process that characterizes the Alps. Some 500 million years ago the region now occupied by the Pyrenees was covered with the folded mountains created during the Paleozoic era, called the Hercynian, of which the Massif Central in France and the Meseta Central in Spain are but two remnants. Although these other massifs have had a comparatively quiet history of internal deformation, or tectonism, since their emergence, the Pyrenean block was submerged in a relatively unstable area of the Earth's crust that became active about 225 million years ago.

The earliest formations, which were sediments severely folded over a granitic base, were submerged and covered by secondary sediments. They later were lifted once again into two parallel chains running to the north and south of the original Hercynian massif. These became the two



The Pyrenees mountain range.

zones of pre-Pyrenean ridges—of which the Spanish is the more fully developed—that are now great spurs of the main chain of the Pyrenees.

Under the forces of folding, the more recent and comparatively more plastic layers folded without breaking, but the original rigid base fractured and became dislocated. In the vicinity of the breaks, hot springs appeared and some metal-containing deposits formed. This upheaval affected chiefly the central and eastern regions. During this era, erosion continued incessantly, and, in the most exposed of the raised areas, weathering wore away the softer terrain and uncovered the old Hercynian sedimentary formations, occasionally reaching the deeper granitic bedrock.

Even today the old rocks, slates, schists, limestones transformed into marble (all of which come from old sediments transformed by great pressures and enormous heat), and granites of various kinds make up the spine, or axial zone, of the chain. The geologic phases of this zone, which rises and widens from west to east and ends by sinking, with a steep drop of nearly 9,800 feet, into the depths of the Mediterranean, have determined the evolution of the massif as a whole.

Physiography. The structure of the Pyrenees is characterized by patterns of relief and of underlying structure running in a north–south sequence (like the base rock); these alternate with depressions, some of which are the result of internal deformations, others of erosion of less resistant overlying deposits. In a cross section directly through the central area, where the tectonic activity reached its fullest width and development, it is possible to distinguish, from north to south, two strips of the comparatively recent pre-Pyrenean fold, one Spanish and one French, in juxtaposition with the axial massifs. An outer strip to the north consists of folds constituting the Petites Pyrénées. Cut into channels, they permit the passage of rivers. Nearer the middle of the range rise the Inner Ridges, represented by the mighty cliffs of the Ariège, which contain the primary, or granitic, axial zones. On the Spanish side the series is repeated in the opposite direction, but it is more highly developed and thicker. Thus the Interior Ridges—*e.g.*, Mount Perdido and the massif of Collarada—are sometimes higher than the neighbouring primary axial peaks. They are followed, to the south, by a broad, pre-Pyrenean, middle depression, with a succession of marine and continental deposits of varying hardness that constitute the valleys of such tributaries of the Ebro as the Aragón. This depression continues across the rest of the pre-Pyrenean ridges, among which are new secondary outcrops that form the fringe of Exterior Ridges and the northern rim of the depression of the Ebro; they are not, however, as thick or as important as the Interior Ridges.

North–south sequences of topography

From the structure of their relief and from the climatic conditions (especially on the south) that derive from the geographic situation of the chain, the Pyrenees have been divided into three natural regions: the Eastern (or Mediterranean), Pyrenees, the Central Pyrenees, and the Western Pyrenees. The different vegetation, the linguistic divisions of the people, and—to a point—certain ethnic and cultural distinctions appear to confirm this classification.

Drainage. The hydrographic system consists basically of series of parallel valleys that descend from the high peaks and from the passes. They are bordered by high, dividing ridges in a north–south direction, perpendicular to the axis of the chain. This type of valley produces short, torrential rivers that drop precipitously over short stretches; only seldom do these rivers flow, like the Aragón, through valleys that, as in the Alps, have both gentle slope and greater length. Their flow, extremely variable, especially on the southern side, is heavily influenced by the climate, as well as by the relief. Different maximum low waters occur in summer and winter; the spring, with maximum rain and melting snow, usually sees the greatest flows. In the Western Pyrenees and the northern zone, the rainfall pattern helps produce greater regularity; hence, flow is only slightly lower in summer. On the south a few torrential rivers are fed principally by melting snows, a few largely by rain, but most from a combination of sources.

The river patterns and flow have been important since antiquity in human use of both the land and the rivers—from the floating of timber rafts downstream, which can be done only in the spring, to harnessing waterpower for industry and irrigation on the southern side by means of dams. The torrential flow of many of the rivers is the cause both of the purity of the Pyrenean waters and of their excellence and richness as fishing streams.

The present Pyrenean glaciers, perhaps more frequent on the northern than on the southern slopes, have been reduced to high basins—cirques or hanging valleys—at elevations over 9,800 feet. During and after the great Ice Ages (*i.e.*, within the past 2.5 million years), however, especially in the Central and much of the Eastern Pyrenees, glaciers left widespread erosion and various important sediments. The present-day lower lakes and idyllic meadows with their winding rivulets are among their marks. Glacier tongues were also the main causes of the deep valleys containing the river system.

The fractured areas have many hot springs, both sulfurous and saline. The former are found throughout the axial massif, while the latter occur at the edges. These springs were popular in Roman times and reorganized and modernized toward the end of the 19th century. There are more than 20 famous spas on the French side; those in Spain are as numerous but are less fully exploited.

Climate. Major factors in the climate are the two abutting bodies of water and the extensive continental areas to the north and south. The Atlantic influence penetrates southward across the low peaks of the Western Pyrenees, as far south as Pamplona, Spain, tempering somewhat the differences of climate between the northern and southern slopes. This is not the case in the rest of the chain, especially the Central Pyrenees. The contrast in humidity between the French and Spanish sides is remarkable. To the north the oceanic influence, meeting no obstacles on the French plains of the Aquitaine, penetrates eastward and goes a little beyond the north–south watershed of the French rivers flowing into the Mediterranean. To the east the levanters, winds from the east and southeast, carry damp air from the Mediterranean, some of which falls as precipitation over the southeastern part of the eastern spurs. As a result, these regions are humid, while to the northeast the French depression of the Roussillon acquires Mediterranean characteristics.

Marine and terrestrial influences on climate

South of the Central Pyrenees the valley of the Ebro—which runs in a general northwest–southeast direction and is blocked by the southwest–northeast-trending Catalonian ranges near the eastern coast of Spain—acts as a "little continent." Hence, its climate is one of great thermal contrasts that are exaggerated by the generally high altitude of the Iberian Peninsula, but it is Mediterranean and unlike anything known in other European countries. Thus, the variegated climatic pattern of the Pyrenees ranges from the limpid, sunny atmosphere of the continental zone to the mild mists of the northwest and includes all transition stages in between.

Plant and animal life. Forms of life in the Pyrenees have some remarkable characteristics that cannot be explained merely by the influences of climate and soil. The historical vicissitudes of the chain and its isolation at the southwestern limit of the main European peninsula, far from the centres of dispersion and variation of the various species (including humans), have influenced the structure and character of its population.

In the northwest–southeast direction, the vegetation shows a marked and gradually decreasing oceanic influence; the contrary is the case with the Mediterranean influence from southeast to northwest. The exposure of the mountain surfaces and the conditions of local climate caused by mountain relief create special localized enclaves of all kinds. The most characteristic feature of the oceanic influence is the predominance of broad-leaved deciduous trees in the forests of the lower levels and the medium-height mountains, while the Mediterranean influence, represented by evergreen broad-leaved trees, not only is dominant in hot surroundings but also bears drought conditions better.

The variety of altitudinal vegetation shows itself in levels. From the medium-height mountain upward, the broad-leaved woods at about 5,200 feet are replaced by nee-

Vegetation zones

dled conifers that require less water. The subalpine level, sometimes as low as 6,500 feet but usually above 7,800 feet, gives way to the more sparsely covered pastures of the alpine level. This altitudinal scheme pertains in the vegetation east of the Orhy and Anie peaks. The oceanic influence, however, with its greater rainfall gives the west of the chain a different pattern. Broad-leaved deciduous beeches may be found as high as 5,850 feet, with some mix of the subalpine conifers, and there the high pastures are more resistant to damp and permanent snow. Overall the landscape is more like that of the high mountains of western Europe.

The Mediterranean influence expands through the entire valley of the Ebro, but it acquires marked signs of a more variable continental climate in the Central Pyrenees. There, great quantities of mountain pines, which are more drought-resistant, take the place of deciduous trees in the higher, colder, and drier parts of the medium and higher levels of the southern slopes.

Some groups among the fauna, such as the cave-dwelling animals and frogs and toads, represent a migratory wave that came from ancient Tyrrhenia—associated with Corsica and Sardinia—and displaced certain native European species, relegating them to the Cantabrian Mountains. The Pyrenean fauna is rich today, in larger herbivores as well as in the variety and abundance of predators. Some species, such as the wolf, lynx, and brown bear, have disappeared or had their numbers severely reduced in the northern Pyrenees, although the marmot has been successfully reintroduced. The southern Pyrenees, however, represent one of the last important reserves for wild European fauna driven out of sectors more heavily populated by humans. The present distribution and differentiation of large, warm-blooded animals is undoubtedly connected with the climate and the landscape, but the central-European origin of Pyrenean fauna is clear; for example, of the two species of desman (a semiaquatic member of the mole family), one inhabits the Pyrenees and the other the south central Soviet Union.

Similar comments may be made as to the origin of all cold-blooded animals as well as of the vegetation. Basic differentiations exist among the latter. Pyrenean flora of tropical origin differentiated without any ancient European competition as the new chain replaced the old Hercynian; flora of Arctic origin, brought southward during relatively recent ice ages, are represented by two different branches of orophiles, or plants adapted to mountain life, from central Europe and from Siberia. Other orophiles have long been differentiated, but they are of Mediterranean origin and are dominant in the drier, sunnier parts of the southern slopes. An Atlantic group of flora predominates in the Western Pyrenees.

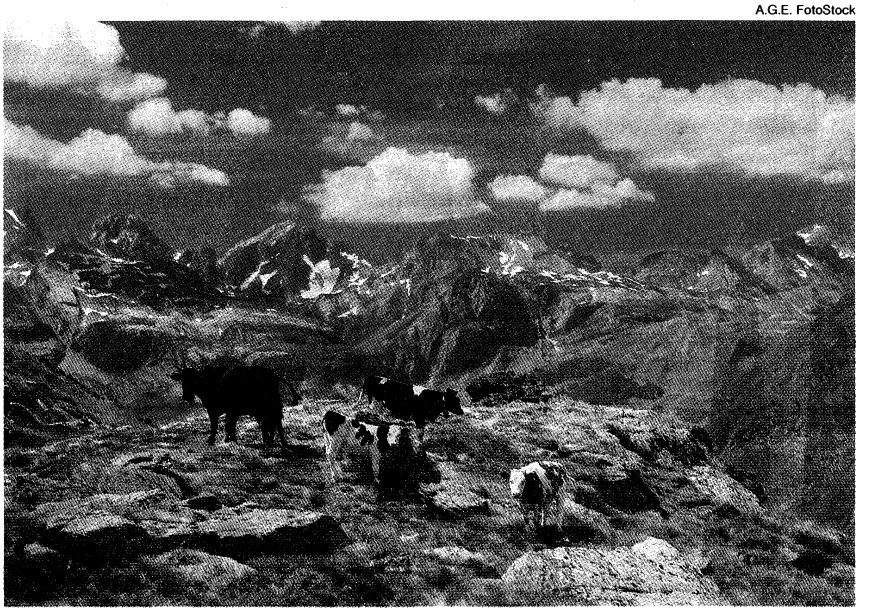
The people and economy. The Pyrenees are the home of a variety of peoples, including the Andorrans, Catalans, Béarnais, and Basques. Each speaks its own dialect or language, and each desires to maintain and even augment its own autonomy while at the same time acknowledging a general unity among Pyrenean peoples. Of these groups, only the Andorrans have anything approaching a sovereign state, and even then Andorra is an autonomous principality with close ties with both Spain and France. The Basques, perhaps the best-known Pyrenean people, speak a language that is non-Indo-European and have a long tradition of fiercely defending their autonomy. The Basques

The people of the Pyrenees traditionally have depended on agriculture and livestock raising for their livelihood. The factors that influenced the development of Pyrenean flora also influenced traditional land usage, the kind of crops raised, and the farming system of each district. Typical Mediterranean products such as wines, vegetables, and fruits predominate in the Eastern Pyrenees and at the foot of the chain's southern slope, while in the Western and Central Pyrenees, with their abundant rainfall, potatoes, sweet corn, and forage crops are grown. Livestock breeding, the other essential element of the traditional economy, consists of a seasonal process of moving flocks of sheep and cows up and down the mountains and also using as well as possible the meadows of the valley bottoms and the pastures of the higher altitudes, depending on the snow cover. Frequently in winter, the livestock herds travel far from the Pyrenees, moving to the plains of the Ebro, near the Mediterranean Sea in Languedoc, or on the moors of Aquitaine.

This traditional organization—in which the common exploitation of forest areas for timber also played a large part—has been disappearing slowly. Most farmers are now elderly, and few young people have been willing to settle into the old ways. Gradually, the less fertile plots have been deserted, and the landscape has become dotted by patches of brooms and brackens and plantings of resinous trees. Even local breeds of sheep or cows have been superseded by imported breeds, which perhaps are more profitable but are less adapted to the climate and the relief. Except for such areas as the Basque Country of Spain and the Roussillon region of France, the agriculture of the Pyrenees is in serious decline.

The growing weakness of the Pyrenean agriculture has not been matched by growth in industry. Although the Pyrenees offer considerable hydroelectric potential, the mining of some resources, and an appreciable and diverse supply of wood, most of the mills (steel and paper) and factories (textiles, chemicals, and shoes) established in the 19th and 20th centuries have faced the threat of closing. Except in the two extremities of the chain, most of the

A.G.E. FotoStock



Cows grazing high in the Central Pyrenees, Huesca province, Spain.

industries are far from any major transportation routes. Scarcely any railroads and no major highways traverse the region, although an express highway is slowly being built between Toulouse, Fr., and Barcelona, Spain. Financed by foreign capital and dependent on the aid of the Spanish and French governments, the remaining factories face an uncertain future.

Perhaps the policies that have been formulated since 1980 by the two Pyrenean countries to develop and protect the mountains may slow down the exile of Pyrenean peoples, who have seen their massif transformed by the tremendous increase in tourism. Although a boon to the local economy, the crowds of people seeking winter sports, summer sojourns, hunting and fishing, and visits to the national parks of the Central Pyrenees have also contributed to the abandonment of traditional ways of life.

Tourism

Study and exploration. For centuries a general lack of knowledge about the Pyrenees permitted repetition of the errors and misconceptions about the mountains that had been propounded by such authors of antiquity as Diodorus Siculus of Sicily and the Greek geographer-historian Strabo (both 1st century BC). In 1582 the first explorations were made, followed by botanical works from the academies at Montpellier-de-Médillan, Fr., and by other studies, including those of the 18th-century Swiss pioneer alpinist Horace Bénédict de Saussure. The earliest military map of the region dates from 1719, while early topographical studies were the bases of frontier treaties.

In the 19th century the first topographical and geologic maps were made of the mountains, the latter beginning a series of geologic interpretations and controversies among French and Spanish scientists. German studies added to the interpretive geology, but only in 1933 was the first study made that was based on modern research methods. Since World War II, scientists and scholars from universities, technical institutes, and national councils for research in France and Spain have thoroughly explored the Pyrenees and have produced a wealth of knowledge about the massif. (F.O./Ed.)

URAL MOUNTAINS

The major part of the traditional boundary between Europe and Asia, the Ural Mountains are a rugged spine across the middle of the Soviet Union, running more than 1,300 miles (2,100 kilometres) from the fringe of the Arctic in the north to the bend of the Ural River in the south. The low, severely eroded Pay-Khoy Ridge forms a fingerlike extension to the northern tip of the Urals proper, with the long curve of Novaya Zemlya forming an insular extension separating the Barents and Kara seas. The Mugodzhar Hills, a broad, arrowhead-shaped southerly extension, form the divide between the Caspian and Aral basins. The north–south course of the Urals is relatively narrow, varying from about 20 to 90 miles in width, but it cuts across the vast latitudinal landscape regions of the Eurasian landmass, from Arctic waste to semidesert; the Urals also are part of the Ural Economic Region, a highly developed industrial complex closely tied to the mineral-rich Siberian region, and are the home of peoples with roots reaching deep into history.

Physical features. *Physiography.* The Urals divide into five sections. The northernmost Polar Urals extend some 240 miles from Mount Konstantinov Kamen in the northeast to the Khulga River in the southeast; most mountains rise to 3,300–3,600 feet (1,000–1,100 metres) above sea level, although the highest peak, Mount Payer, reaches 4,829 feet. The next stretch, the Nether-Polar Urals, extends for more than 140 miles south to the Shchugor River. This section contains the highest peaks of the entire range, including Mount Narodnaya (6,217 feet [1,895 metres]) and Mount Karpinsk (6,161 feet). These first two sections are typically Alpine and are strewn with glaciers and heavily marked by permafrost. Farther south come the Northern Urals, which stretch for more than 340 miles to the Usa River in the south; most mountains top 3,300 feet, and the highest peak, Mount Telpos-Iz, rises to 5,305 feet. Many of the summits are flattened, the remnants of ancient peneplains (eroded surfaces of large area and slight relief) uplifted by geologically recent tectonic movements. In the north, intensive weathering has resulted in vast "seas of stone" on mountain slopes and summits. The lower Central Urals, extending more than 200 miles to the Ufa River, rarely exceed 1,600 feet, though the highest peak, Mount Sredny Baseg, rises to 3,261 feet. The summits are smooth, with isolated residual outcrops. The last portion, the Southern Urals, extends some 340 miles to the westward bend of the Ural River and consists of several parallel ridges rising to 3,900 feet and culminating in Mount Yamantau, 5,380 feet; the section terminates in the wide uplands (less than 2,000 feet) of the Mugodzhar Hills.

The Urals' five sections

Tass/Sovfoto

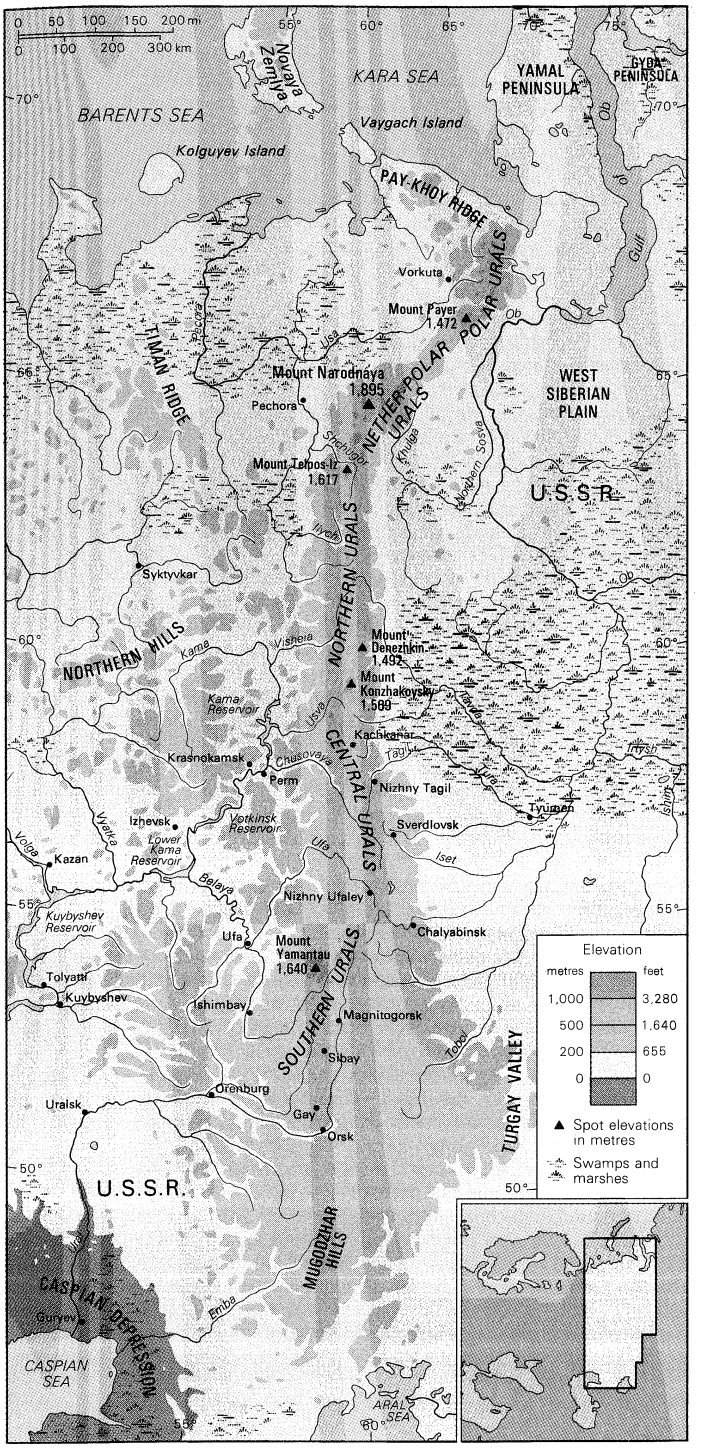
Nurgush Range, Southern Ural Mountains, Russian S.F.S.R.

The rock composition helps shape the topography: the high ranges and low, broad-topped ridges consist of quartzites, schists, and gabbro, all weather-resistant. Buttes are frequent, and there are north–south troughs of limestone, nearly all containing river valleys. Karst topography is highly developed on the western slopes of the Urals, with many caves, basins, and underground streams. The eastern slopes, on the other hand, have fewer karst formations; instead, rocky outliers rise above the flattened surfaces. Broad foothills, reduced to peneplain, adjoin the Central and Southern Urals on the east.

Geology. The Urals date from the structural upheavals of the Hercynian orogeny (about 250 million years ago). About 280 million years ago there arose a high mountainous region, which was eroded to a peneplain. Alpine folding resulted in new mountains, the most marked upheaval being that of the Nether-Polar Urals. In the watershed region lies the Ural-Tau Anticlinorium (a rock formation of arches and troughs, itself forming an arch), the largest in the Urals, and in the Southern Urals, west of it, is the Bashkir Anticlinorium. Both are composed of layers (sometimes four miles thick) of ancient metamorphic (heat-altered) rocks—gneisses (metamorphic rocks separable into thin plates), quartzites, and schists—that are between 570 and 395 million years old.

The western slope of the Urals is composed of middle Paleozoic sedimentary rocks (sandstones and limestones) that are about 350 million years old. In many places it descends in terraces to the Cis-Ural depression (west of the Urals), to which much of the eroded matter was carried during the late Paleozoic (about 300 million years ago). Here there are widespread karst (a starkly eroded limestone region) and gypsum, with large caverns and subterranean streams. On the eastern slope, volcanic layers alternate with sedimentary strata, all dating from middle Paleozoic times. These rocks compose the Tagil-Magnitogorsk Synclinorium (a group of rock arches and troughs, itself forming a trough), the largest in the Urals. In the Central and Southern Urals the eastern slope blends into

Sedimentary rocks of the western slope



The Ural Mountains.

broad peneplained foothills, where there are frequent outcrops of granite and often fantastically shaped buttes. To the north the peneplain is buried under the loose, easily pulverized deposits of the West Siberian Plain.

Drainage. The rivers flowing down from the Urals drain into either the Arctic Ocean or the Caspian Sea. The Pechora River, which drains the western slope of the Polar, Nether-Polar, and part of the Northern Urals, empties into the Barents Sea. Its largest tributaries are the Ilych, Shchugor, and Usa. Almost all the rivers of the eastern slope belong to the Ob River system, emptying into the Kara Sea. The largest are the Tobol, the Iset, the Tura, the Tavda, the Severnaya Sosva (Northern Sosva), and the Lyapin. The Kama (a tributary of the Volga) and the Ural rivers belong to the drainage basin of the Caspian Sea. The Kama collects water from a large area of the western slope: the Vishera, Chusovaya, and Belaya all empty into it. The Ural River, with its tributary the Sakmara, flows along the Southern Urals.

The location and character of the Urals' rivers and lakes are closely connected with the topography and climate. In their upper reaches many rivers flow slowly through the mountains in wide, longitudinal troughs. Later they change to a latitudinal direction, cut through the ridges in narrow valleys, and descend to the plains, particularly in the Northern and Southern Urals. The main watershed does not correspond with the highest ridges everywhere. The Chusovaya and Ufa rivers of the Central and Southern Urals, which later join the Volga drainage basin, have their sources on the eastern slope.

The rivers on the western slope carry more water than those of the east, particularly in the Northern and Nether-Polar Urals; the slowest rate of flow is on the eastern slope of the Southern Urals, reflecting intense evaporation as well as low precipitation. In winter the rivers freeze for five months in the south and for seven months in the north.

There are many lakes, especially on the eastern slope of the Southern and Central Urals. The largest are Uvildy, Itkul, Turgoyak, and Tavatuy. On the western slope are many small karst lakes. In the Polar Urals, lakes occur in glacial valleys, the deepest of them being Lake Bolshoye Shchuchye, at 446 feet deep. Medicinal muds are common in a number of the lakes, such as Moltayevo, and spas and sanatoriums have been established.

Climate. The climate is of the continental type, marked by temperature extremes that become increasingly evident both from north to south and from west to east. The Pay-Khoy Range and the Polar Urals enjoy the moderating influence of the Arctic and the North Atlantic oceans, particularly in winter. In the Mugodzhar Hills and the Southern Urals there are summer winds of hot, dry air from Central Asia. Winds are for the most part westerly and bring precipitation from the Atlantic Ocean. In spite of their low elevation, the mountains exert a considerable influence on the moisture distribution, and the western slope receives more moisture than the eastern. Precipitation is particularly heavy on the western slope of the Nether-Polar and Northern Urals, as high as 40 inches (1,000 millimetres). Northward and southward precipitation diminishes to about 18 inches. On the eastern slope there is less moisture (about 12 inches) and snow. Annual snow depth on the western slope averages 35 inches and on the eastern, 18 inches. Maximum precipitation occurs in the summer, for the cold, dry air of the Siberian anticyclone is powerful in winter. The eastern slope is particularly chilled, and winter lasts longer than summer throughout the Urals. In January the average temperature in the north is −6° F (−21° C), and in the south the average is 5° F (−15° C). Average temperatures in July vary more, between 50° F (10° C) in the north and 72° F (22° C) in the south.

Precipitation

Plant life. The Urals pass through several vegetation zones, with the northern tundra giving way to vast mixed forests, while still farther south is the steppe, culminating in semidesert around the Mugodzhar Hills. Feather grass and meadows predominate on the chernozems (black earth) and dark chestnut soils (a characteristic steppe soil). Other characteristic growths are clover, fescue (a pasture grass), and timothy (a grass grown for hay). South of the Ural River the steppes give way to wormwood and semidesert growths on light chestnut soils (again typical steppe soil), which are highly saline in places.

The forest landscapes of the Urals are varied. The more humid western foothills of the Southern Urals are covered mostly by mixed forests growing on a gray mountain-forest type of soil. There, such broad-leaved species as oak, small-leaf linden, and elm are mixed with Siberian fir and Siberian spruce. The broad-leaved forests extend to 2,100 feet, above which conifers appear. On the eastern slope there are no broad-leaved trees except the linden, and magnificent pine forests with some larches are widespread.

Farther to the north, in the Central Urals, taiga forests of spruce, fir, pine, and larch grow on the mountain, podsolic soils. In the more northerly regions, dark coniferous species are common, and, in the Northern Urals,

the Siberian cedar is widespread. There forests climb to 2,800 feet or so, above which is a narrow belt of larch and birch, trailing off to mountain tundra. In the Nether-Polar and Polar Urals the forest yields to mountain tundra at elevations as low as 1,300 feet. Whereas moss tundra is generally found on the more humid western slope, lichen tundra is common on the eastern. There are numerous sphagnum moss marshes on both slopes. Only brushwood and moss–lichen tundra grows on the Pay-Khoy Ridge.

Animal life. There are no specifically mountain animals in the Urals, primarily because of the low elevations and easy accessibility, and fauna differs little from that of the adjacent areas of eastern Europe and western Siberia. The most valuable animal of the tundra is the Arctic fox. Ob lemmings, snowy owls, tundra partridge, and reindeer are other inhabitants, though the latter are few. Many wild ducks, geese, and swans breed there in summer. But the richest and most varied fauna in the Urals, such as the brown bear, lynx, wolverine, and elk, are found in the forested zones. Some have valuable furs: the sable (in the Northern Urals), ermine, fox, marten (in the Southern Urals), Siberian weasel, and squirrel. In the taiga forests there are such birds as the wood grouse, black grouse, capercaillie (another member of the grouse family), cuckoo, and hazel hen (a woodland grouse). In the mixed, broad-leaved forests of the Southern Urals' western slopes live roe deer, badgers, and polecats, as well as many birds typical of the European part of the Soviet Union, such as the nightingale and oriole. The commonest animals of the steppes and semideserts are rodents, including susliks (a type of ground squirrel), jerboas (a social, nocturnal, jumping rodent), and other agricultural pests. Reptiles include the common adder and grass snake. The rivers and lakes of the Northern Urals abound in fish, the most valuable being the nelma (related to the whitefish), common salmon, grayling, and sea trout. Farther south, in the densely populated and industrial regions, animal life is less abundant.

Similarity of fauna in adjacent regions

The vigorous economic development and growth in population that have occurred in the Urals in the 20th century have altered considerably the chain's landscape and the abundance of wildlife. Conservation measures during the Soviet period have included establishing national nature preserves such as Pechoro-Ilych in the Northern Urals, Basegi and Visim in the Central Urals, and Ilmen and Bashkir in the Southern Urals.

The people. Human habitation of the Urals dates to the distant past. The Nenets (Nentsy) are a Samoyed people of the Pay-Khoy region, and their language belongs to the Samoyedic group of languages, which is widespread throughout northern Siberia. Farther south live the Komi, Mansi (Voguls), and Khants (Ostyaks), who speak a tongue belonging to the Ugric group of the Finno-Ugric languages. The most numerous indigenous group, the Bashkirs, long settled in the Southern Urals, speak a tongue related to the Turkic group. Some Kazakhs live in the Mugodzhar Hills. Most of these formerly nomadic peoples are now settled. The Nenets, Komi, Mansi, and Khants are virtually the only inhabitants in the highest parts of the Urals, especially in the north, where they have preserved their traditional ways of life, raising reindeer, hunting, and fishing. The Bashkirs are excellent horse breeders. The indigenous peoples, however, now constitute only about one-fifth of the total population of the Urals; the great majority are Russians. The Russian population is concentrated primarily in the Central and Southern Urals, and most people live in cities (notably Sverdlovsk, Chelyabinsk, Perm, and Ufa) and work in industries. Agricultural populations predominate in the steppe region of the Southern Urals, where conditions are favourable for wheat, potatoes, and other crops.

The economy. The Urals are extremely rich in mineral resources, with variations on the eastern and western slopes according to geologic structure. Ore deposits, for example, notably magnetite, predominate on the eastern slope, where contact (the surface where two different rock types join) deposits are found, as at Vysokogorsk and Mount Blagodat, as well as magmatic deposits (formed from liquid rock), as at Kachkanar. Some of the ore deposits, such as the magnetite ores at Magnitogorsk, are exhausted or nearly depleted. Sedimentary deposits are of less importance. Some ores contain alloying metals—vanadium, a gray-white, resistant element, and titanium—as impurities. The largest copper ore deposits are at Gay and Sibay, and nickel ores are found at Ufaley. There are also large deposits of bauxite, chromite, gold, and platinum.

Mineral resources

Among the nonmetallic mineral resources of the eastern slope are asbestos, talc, fireclay, and abrasives. Gems and semiprecious stones have long been known: they include amethyst, topaz, and emerald. Among the western deposits are beds of potassium salts on the upper Kama River and petroleum and natural gas deposits in the Ishimbay and Krasnokamsk areas. Bituminous coal and lignite are mined on both slopes. The largest deposit is the Pechora bituminous coalfield in the north.

The vast forests of the Urals are also of great economic importance: not only do they yield valuable wood, but they also regulate the flow of the rivers and shelter many of the valuable fur animals. Agriculture is significant mainly in the eastern steppe region of the Southern Urals. Much of the land there has been plowed up and converted to arable lands, and in large areas wheat, buckwheat, millet, potatoes, and vegetables are grown.

Because of its wealth of mineral resources, the leading industries in the Urals are mining, metallurgy, machine building, and chemicals. Of national importance are the metallurgical plants at Magnitogorsk, Chelyabinsk, and Nizhny Tagil; chemical plants at Perm, Ufa, and Orenburg; and large-scale engineering at Sverdlovsk.

Study and exploration. The existence of the Riphean and Hyperborean mountains at the eastern fringe of Europe in antiquity was regarded as being more mythical than real. Not until the 10th century AD does the first mention of the Urals occur, in Arabic sources. At the end of the 11th century the Russians discovered the northernmost part of the Urals, but they did not complete the discovery of the entire range until the beginning of the 17th century, when the mineral wealth of the Urals was discovered. The first geographic survey of the chain was made in the early 18th century by the Russian historian and geographer Vasily N. Tatishchev, who undertook the survey for Peter I the Great. Systematic extraction of iron and copper ore also began at that time, and the Urals rapidly became one of the largest industrial regions of Russia.

Scientific studies of the Urals

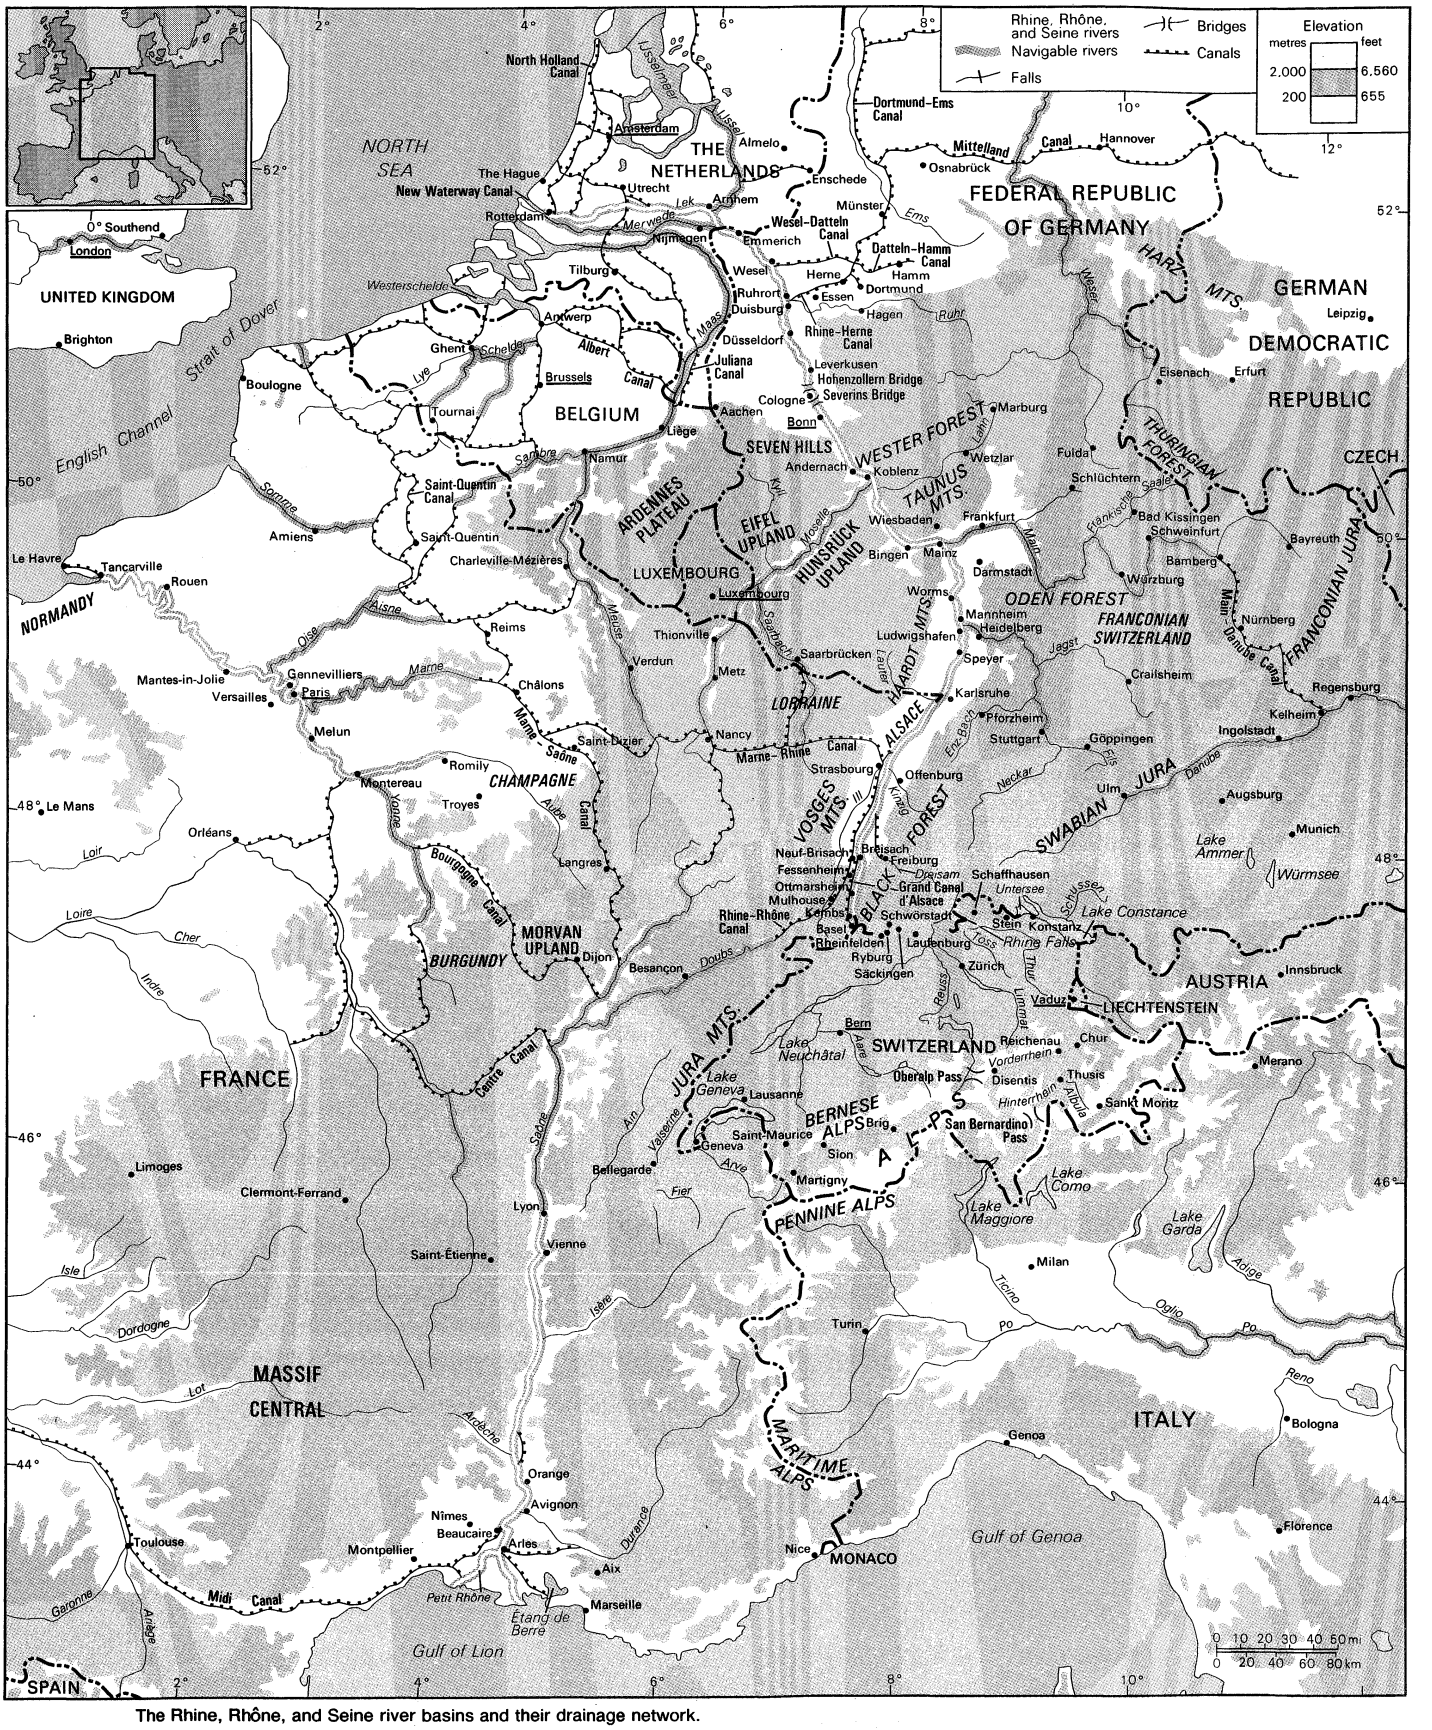
The first serious scientific study of the Urals was made in 1770–71. Scholars studying the Urals during the 19th century included several Russian scientists, such as the geologist A.D. Karpinsky, the botanist P.N. Krylov, and the zoologist L.P. Sabaneev, and also such prominent foreign scholars as the German naturalist Alexander von Humboldt and the English geologist Sir Roderick Murchison, who compiled the first geologic map of the Urals in 1841. Much work has been done in the Soviet period on geologic structure and associated mineral resources. (Y.V.Y.)

Western European drainage systems

RHINE RIVER

Culturally and historically one of the great rivers of Europe and among the most important arteries of industrial transport in the world, the Rhine River flows 865 miles (1,390 kilometres) from east central Switzerland north and west to the North Sea, into which it drains through The Netherlands. The German spelling is Rhein; Dutch, Rijn; French, Rhin—all derived from the Latin, Rhenus. An international waterway since the Treaty of Vienna in 1815, it is navigable overall for some 540 miles, as far as Rheinfelden on the Swiss-West German border. Its catchment area, including the delta area, exceeds 85,000 square miles (220,000 square kilometres).

The Rhine has been a classic example of the alternating roles of great rivers as arteries of political and cultural unification and as political and cultural boundary lines. The river has also been enshrined in the literature of its lands, especially of Germany, as in the famous epic *Nibelungenlied.* Since the time when the Rhine valley became incorporated into the Roman Empire, the river has been one of Europe's leading transport routes. Until the



The Rhine, Rhône, and Seine river basins and their drainage network.

19th century the goods transported were of high value but relatively small in volume, but since the second half of the 19th century the volume of goods conveyed on the river has increased greatly. The fact that cheap water transport on the Rhine helped to keep prices of raw materials down was the main reason the river became a major axis of industrial production: one-fifth of the world's chemical industries are now manufactured along the Rhine. The river was long a source of political dissension in Europe, but this has given way to international concern for ecological safeguards as pollution levels have risen; some 6,000 toxic substances have been identified in Rhine waters.

No other river in the world has so many old and famous cities on its banks—Basel, Switz.; Strasbourg, Fr.; and Worms, Mainz, and Cologne, W.Ger., to name a few—but there are also such industrial cities as Ludwigshafen and Leverkusen in West Germany, which pollute the waters and mar the scenic attraction of the riverbanks. Nonetheless, the middle Rhine (the section between the West German cities of Bingen and Bonn), with such steep rock precipices as the Lorelei crag and numerous castles, still presents breathtaking vistas and attracts tourists. This is the Rhine of legend and myth, where the medieval Mouse Tower (Mausturm) lies at water level near Bingen, and the castle of Kaub stands on an island in the river. The Alpine section of the Rhine lies in Switzerland, and below Basel the river forms the boundary between West Germany and France, as far downstream as the Lauter River. It then flows through West German territory as far as Emmerich, below which its many-branched delta section epitomizes the landscapes characteristic of The Netherlands.

Source

Physical features. *Physiography.* The Rhine rises in two headstreams high in the Swiss Alps. The Vorderrhein emerges from Lake Toma at 7,690 feet, near the Oberalp Pass in the Central Alps, and then flows eastward past Disentis to be joined by the Hinterrhein from the south at Reichenau above Chur. (The Hinterrhein rises about five miles west of San Bernardino Pass, near the Swiss-Italian border, and is joined by the Albula River below Thusis.) Below Chur, the Rhine leaves the Alps to form the boundary first between Switzerland and the principality of Liechtenstein and then between Switzerland and Austria, before forming a delta as the current slackens at the entrance to Lake Constance. In this flat-floored section the Rhine has been straightened and the banks reinforced to prevent flooding. The Rhine leaves the lake via its Untersee arm. From there to its bend at Basel, the river is called the Hochrhein ("High Rhine") and defines the Swiss-German frontier, except for the area below Stein am Rhein, where the frontier deviates so that the Rhine Falls at Schaffhausen are entirely within Switzerland. Downstream, the Rhine flows swiftly between the Alpine foreland and the Black Forest region, its course interrupted by rapids, where—as at Laufenburg, Säckingen, and Schwörstadt—barrages (dams) have been built. In this stretch the Rhine is joined by its Alpine tributaries, the Thur, Töss, Glatt, and Aare, and by the Wutach from the north. The Rhine has been navigable between Basel and Rheinfelden since 1934.

Below Basel the Rhine turns northward to flow across a broad, flat-floored valley, some 20 miles wide, held between, respectively, the ancient massifs of the Vosges–Black Forest and the Haardt–Oden Mountains. The main tributary from Alsace is the Ill, which joins the Rhine at Strasbourg, and various shorter rivers, such as the Dreisam and the Kinzig, drain from the Black Forest. Downstream, the regulated Neckar, after crossing the Oden Mountains in a spectacular gorge as far as Heidelberg, enters the Rhine at Mannheim; and the Main leaves the plain of lower Franconian Switzerland for the Rhine opposite Mainz. Until the straightening of the upper Rhine, which began in the early 19th century, the river described a series of great loops, or meanders, over its floodplain, and today their remnants, the old backwaters and cutoffs near Breisach and Karlsruhe, serve to mark the former course of the river.

The middle Rhine

The middle Rhine is the most spectacular and romantic reach of the river. In this 90-mile stretch the Rhine has cut a deep and winding gorge between the steep, slate-covered slopes of the Hunsrück Mountains to the west and the Taunus Mountains to the east. Vineyards mantle the slopes as far as Koblenz, where the Moselle River joins the Rhine at the site the Romans called Confluentes. On the right bank, the fortress of Ehrenbreitstein dominates the Rhine where the Lahn tributary enters. Downstream the hills recede, the foothills of the volcanic Eifel region lying to the west and those of the Wester Forest to the east. At Andernach, where the ancient Roman frontier left the Rhine, the basaltic Seven Hills rise steeply to the east of the river, where, as the English poet Lord Byron put it, "the castle crag of Dachenfels frowns o'er the wide and winding Rhine."

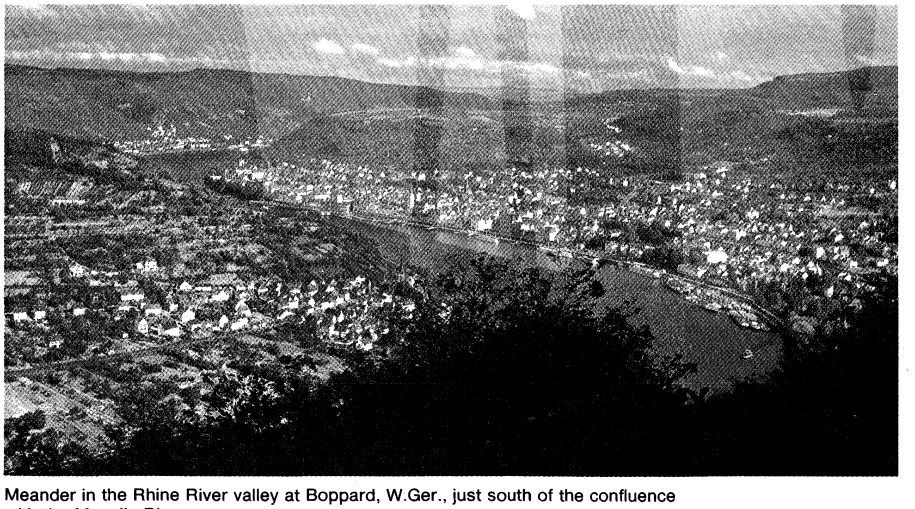
Below Bonn the valley opens out into a broad plain, where the old city of Cologne lies on the left bank of the Rhine. There the river is spanned by the modern Severin Bridge and by the rebuilt Hohenzollern railway bridge, which carries the line from Aachen to Düsseldorf and the Ruhr industrial region. Düsseldorf, on the right bank of the Rhine, is the dominant business centre of the North Rhine–Westphalia coalfield. Duisburg, which lies at the mouth of the Ruhr River, handles the bulk of the waterborne coal and coke from the Ruhr as well as imports of iron ore and oil.

The delta region

The last section of the Rhine lies below the frontier town of Emmerich in the delta region of The Netherlands. There the Rhine breaks up into a number of wide branches, such as the Lek and Waal, farther downstream called the Merwede. With the completion of the huge Delta Project in 1986—constructed to prevent flooding in the southwestern coastal area of The Netherlands—all main branches of the Rhine were closed off; sluices and lateral channels now allow river water to reach the sea. Since 1872, however, the New Waterway Canal, constructed to improve access from the North Sea to Rotterdam, has been the main navigation link between the Rhine and the sea; along this canal was built Europoort, one of the world's largest ports. (A.F.A.M./K.A.Si.)

Hydrology. The Alpine Rhine—with its steep gradient, high runoff coefficient (80 percent of the precipitation in its catchment area), pronounced winter minimum, high water in spring from snowmelt, and high early summer maximum resulting from heavy summer rains—has a

J. Allan Cash



Meander in the Rhine River valley at Boppard, W.Ger., just south of the confluence with the Moselle River.

characteristic Alpine regime. Although variations in flow are evened out by Lake Constance, which is fed by upland streams as well as by the Rhine (and which also acts as a filter), they are increased again by the confluence with the Aare, which on an average carries more water than the Rhine. Below Basel, however, the tributaries from the uplands, with their spring maximums at higher and winter maximums at lower elevations, increasingly moderate the unbalance. Thus, at Cologne the average deviations from mean flow are slight, and the regime is favourable to navigation. Winters in the navigable regions of the river, moreover, are generally mild, and the Rhine freezes only in exceptional winters.

The economy. As a commercial artery, the Rhine is unrivaled among the world's rivers, historically as well as in the amount of traffic carried. The Romans maintained a Rhine fleet, and the importance of the river increased enormously with the rise of medieval trade, which relied on water transport wherever possible because of the poor roads. The rock barrier of the gorge at Bingen divided navigation into two sections: predominantly upstream traffic by seagoing vessels to Cologne and predominantly downstream movement of commodities—brought first across the Alpine passes—from Basel to Mainz and Frankfurt am Main. After about 1500, navigation declined because of reorientation of trade toward the Atlantic and political disintegration of the Rhineland. The rise of modern navigation began in the 19th century, and its present magnitude is attributable largely to four factors: removal of political restrictions on navigation, physical improvements to the navigation channel, canalization of the Rhine's hinterland, and increasing industrialization of the riparian countries.

Navigation agreements

The principle of free navigation on the Rhine was agreed upon by the Congress of Vienna in 1815 and was put into effect by the Mainz Convention of 1831, which also established the Central Commission of the Rhine. This first treaty was simplified and revised in the Mannheim Convention of 1868, which, with the extension in 1918 of all privileges to ships of all countries and not merely the riverine states, remains (broadly speaking) in force.

Navigational improvements. Historically, two sections presented serious handicaps to navigation: the rock barrier at Bingen and the southern upper Rhine. At Bingen two navigation channels were blasted out in 1830–32; canalization of the upper Rhine by confining it within an artificial bed and straightening its course was undertaken in 1817–74. In neither case were the resulting improvements entirely satisfactory, but the channels at Bingen were doubled in width and deepened, thus eliminating the need for a pilot. Navigation on the upper Rhine, despite the further improvements made after 1907, suffers from seasonal variations of flow and the swift current.

To improve navigation and to procure hydroelectric power, France (by the Treaty of Versailles) obtained the right to divert Rhine water below Basel into a canal that was to rejoin the Rhine at Strasbourg. Construction of the first section of this Grand Canal d'Alsace, designed to take vessels of 1,500 tons, was completed with the building of a dam at Kembs in 1932 and greatly improved navigation. Construction was resumed after World War II, but in a treaty (1956) France, in return for West German agreement to the canalization of the Moselle, consented to terminate the canal at Neu Breisach. The remaining four of a total of eight dams utilize Rhine water by the construction of canal loops only.

Below Basel the Huningue branch of the Rhine–Rhône Canal leads to Mulhouse, where it meets the main arm of that waterway, which joins the Rhine at Strasbourg. The Rhine–Rhône Canal (1810–33) is navigable by 300-ton craft and carries only moderate traffic. More important, although no larger, is the Rhine–Marne Canal (1838–53), which also joins the Rhine at Strasbourg.

The Neckar is canalized through Stuttgart as far as Plochingen and the Main as far as Bamberg. There, the completed northern portion of the Main–Danube Canal leads south to Nürnberg, which has become an important port. A treaty signed in 1956 between West Germany, France, and Luxembourg provided for canalization of the Moselle from Koblenz to Thionville (170 miles), which was completed in 1964. The Lahn also is canalized for small (200-ton) craft for 42 miles.

In the Ruhr region the Ruhr itself (except for the last seven miles) and the Lippe are not used as waterways. Their place is taken by the Rhine–Herne Canal, completed in 1916 between Duisburg and Herne and linking the Rhine through the Dortmund–Ems Canal with the German North Sea coast and through the Mittelland Canal with the waterways of central and eastern Germany and eastern Europe; and by the less important Wesel–Datteln–Hamm Canal (1930), which runs parallel to the lower course of the Lippe. The Rhine–Herne Canal's capacity for craft of 1,350 tons became the standard both for the minimum capacity of canals built since World War II and for barges. Nearer the Rhine's mouth, the Merwede Canal (enlarged 1952) south of Amsterdam provides another route to the sea for ships displacing as much as 4,300 tons.

Growth of the Rhine as a waterway

Traffic. Three factors were important in the rise of traffic on the Rhine. First, the political impediments to free navigation—particularly the approximately 200 toll stations along the course of the river—were removed by the Congress of Vienna of 1815. Second, the means of transport were improved by the introduction of steam-powered, and later diesel-powered, tugs; prior to the mid-19th century, barges moving upstream were towed either by teams of horses or gangs of men. Third, the waterway itself was improved, the stages of which are discussed above.

The first steamship voyage on the Rhine was made from London to Koblenz in 1817, but this was a solitary event. The harbour installations of Mannheim were opened in 1840, and for almost a century this was the effective head of navigation. Although Basel had been reached by a steamship by 1832, its development as a Rhine port started a century later. Despite the improvement of the navigation and means of transport, there was at first little growth in the volume of transport. Increase came with the rise of modern industry in the 19th century, which necessitated the bulk movement of coal, ore, building materials, raw material for the chemical industry, and (since about 1950) oil. Although coal and ore transport declined, there was an overall increase in the volume of transport until the mid-1960s; since then, however, freight tonnage has decreased to about a third of its former level.

The mode of transport from 1840 onward was by tugs towing a number of barges. Development after 1945 involved initially the introduction of self-propelled barges and subsequently the introduction of push tugs, whereby one tug can propel four-barge units and thus save labour costs. An increase in the traffic volume was also effected by the introduction of radar navigation in the 1950s, which made round-the-clock operation possible. There is also regular passenger service on the Rhine during summer, especially the middle Rhine section and from Rotterdam to Basel, but this is almost exclusively for tourists.

History. The effects of rivers on the regions through which they flow tend to alternate between trends toward unifying the regions culturally and politically and making a political boundary of the river. Of this phenomenon the Rhine is a classic example. During prehistoric times the same culture groups existed on both banks; similarly, in early historic times Germanic tribes settled on either side of its lower and Celts alongside its upper course. Although bridged and crossed by Julius Caesar in 55 and 53 BC, the Rhine became for the first time, along its course from Lake Constance to its mouth at Lugdunum Batavorum (Leiden, Neth.), a political boundary—that of Roman Gaul. This division did not endure for long, because under the emperor Augustus the provinces of Germania Superior and Germania Inferior were established on the other side of the Rhine, and south of Bonna (Bonn) the boundary of the Roman Empire was marked by the limes (Roman fortified frontier) well east of the river. Nevertheless, because the Rhine had been the boundary of Gaul for a time, it resulted in later claims by France, esteeming itself the successor to Gaul, to the Rhine as its natural boundary. When the Western Roman Empire disintegrated, the Rhine was crossed along its entire length by Germanic tribes (AD 406), and the river formed the central backbone first of the kingdom of the Franks and then of the Car-

Boundary of Roman Gaul

olingian empire. When in 843 that empire was divided, stretches of the Rhine formed the eastern boundary of the central part, Lotharingia, until 870 when the Rhine again became the central axis of a political unit, the Holy Roman Empire. Subsequent events shifted the axis of this empire eastward and caused political disintegration along the Rhine. The Thirty Years' War (1618–48) ended with the final separation of the Rhine headwaters and delta area from Germany and a gradual advance of France toward the Rhine, which it reached under Louis XIV through his acquisition of Alsace.

The French Revolutionary Wars included further French advances, and the Treaty of Lunéville (1801) made the Rhine, along most of its course, France's eastern boundary. But France advanced beyond the Rhine and included northwestern Germany within its borders, and the Confederation of the Rhine, created by Napoleon, extended French control as far as the Elbe and Neisse rivers. The resultant upsurge of German nationalism was expressed by E.M. Arndt, who in 1813 wrote, "The Rhine is Germany's river, not its boundary." The Congress of Vienna, nevertheless, left France in possession of Alsace and thus with a Rhine frontier. Ambitions of Napoleon III to acquire further Rhenish territory strongly aroused German feelings. In 1840 Max Schneckenburger wrote his patriotic poem "Die Wacht am Rhein" ("The Watch on the Rhine"), which was set to music by Karl Wilhelm in 1854 and became the rousing tune of the Prussian armies in the Franco-German War of 1870–71. One result of this war was that France lost Alsace and thus its Rhine frontier, which it regained after World War I.

The fortified defensive system of the Maginot Line (built in 1927–36) adjoined the French bank of the upper Rhine from the Swiss frontier to near Lauterbourg. The opposing *Westwall,* or Siegfried Line (1936–39), adjoined the German bank from the Swiss frontier to near Karlsruhe.

Events after World War II suggested that the struggle for possession of the Rhine had been superseded by a trend toward economic and even political union of the riparian states. In addition, the increased pollution of the Rhine has resulted in growing international cooperation to combat the threat. (K.A.Si.)

RHÔNE RIVER

The Rhône, a historic river of Switzerland and France and one of the most significant waterways of Europe—it is the only major river flowing directly to the Mediterranean Sea—is thoroughly Alpine in character. In this respect it differs markedly from its northern neighbour, the Rhine, which leaves all of its Alpine characteristics behind when it leaves Switzerland. The scenic and often wild course of the Rhône, the characteristics of the water flowing in it, and the way it has been used by humans have all been shaped by the influences of the mountains, right down to the river mouth, where sediments marking the Rhône's birth in an Alpine glacier are carried into the warmer waters of the Mediterranean.

The Rhône is 505 miles (813 kilometres) long and has a drainage basin of some 37,750 square miles (97,775 square kilometres). The course of the river can be divided into three sectors lying, respectively, in the Alps, between the Alps and the Jura Mountains and through the latter, and finally in the topographical furrow of Alpine origin running from the city of Lyon to the sea.

Physical features. *Physiography.* The Rhône originates in the Swiss Alps, upstream from Lake Geneva. It comes into being at an altitude of about 6,000 feet (1,830 metres), emerging from the Rhône Glacier, which descends the south flank of the Dammastock, a nearly 12,000-foot peak. The river then traverses the Gletsch Basin, from which it escapes through a gorge, and flows along the floor of the Goms Valley at an altitude between 4,000 and 4,600 feet. It next enters another gorge before reaching the plain of the Valais, which extends between the towns of Brig and Martigny, and descends in altitude 2,300 to 1,600 feet. In crossing this high and rugged mountain area, the river makes successive use of two structural troughs. The first runs between the ancient crystalline rock massifs of the Aare and of the Gotthard; farther downstream the second runs between the arched rock mass of the Bernese Oberland and, on the south, the massive rock face of the Pennine Alps. From Brig onward, the landscape changes. During the last Ice Age a large glacier, fed by several small ones, plowed down the valley floor of the Valais, and, except for some harder rock obstacles found near the town of Sion, succeeded in widening and deepening the narrow valley floor. As it did so, it held back both the upper Rhône and those of its tributaries that come down from the Pennine Alps. When the ice sheets retreated, both the tributaries—the Vispa, Navigenze, Borgne, and Drance—and the Rhône cut new, deep gorges to connect their lower courses to the new valley floor. These gorges have created considerable difficulty for modern transportation, necessitating a series of hairpin-bend road links.

The Alpine sector

After Martigny, where the valley floor is wider, the youthful Rhône thrusts northward at a right angle, cutting across the Alps through a transverse valley. At first, near the town of Saint-Maurice, this is no more than a small gorge, but it soon becomes wider and flatter. There, too, the river route has been assisted by structural factors, specifically by a dip in the crystalline rock massifs running from Mont Blanc to the Aare and by the discontinuity between the limestone masses of the Dents du Midi and of the Dent de Morcles. Across the mountain barrier the muddy waters of the Rhône enter another wide plain surrounded by high mountains and then plunge into the clearer, stiller waters of Lake Geneva, forming an enlarging delta.

The second sector of the Rhône's course commences with Lake Geneva, large (224 square miles) and deep (1,000 feet) and lying between Switzerland and France in a basin hollowed out of the less resistant terrain by the former Rhône Glacier. Upon leaving Lake Geneva, which has turned the course of the river to the southwest and decanted the sediment from its waters, the Rhône very quickly regains in full the milky colour so characteristic of Alpine rivers. Just below the city of Geneva, it receives its powerful tributary the Arve, which rushes down from the glaciers of Mont Blanc.

The middle course

From its juncture with the Arve to the French city of Lyon, the Rhône has to cross a difficult obstacle, the undulating series of ridges forming the Jura Mountains. It does this by cutting through deep longitudinal valleys called *vaux* and transverse valleys called *cluses,* which were formed when the Jura Mountains were uplifted during the Alpine orogeny. As a result, the river follows a complicated zigzag course. At the town of Bellegarde the river is joined from the north by the Valserine and, swinging south, plunges into a deep gorge now submerged in the 14-mile-long Génissiat Reservoir. In the wider sections of its course in this region, the Rhône runs through glacier-excavated basins that its own deposits have barely filled, causing intermittent marshy areas. It is also joined by the Ain, from the north, and, on the left bank, by the Fier and Guiers. The river next widens, and the terrain becomes less hilly and, at Le Parc (some 95 miles above Lyon), becomes officially navigable, although the average depth is no more than three feet.

The lower sector

At Lyon the Rhône enters its third sector as it heads south toward the Mediterranean, which is characterized by the great north–south Alpine furrow that is also drained by its principal tributary, the Saône. The latter lies in the basins that the Ice Age glaciers hollowed out between the Jura Mountains to the east and, farther west, the eastern edge of the Paris Basin and the uplands of the Massif Central. It forms an important commercial link to the industrialized regions of northern France. From the city of Lyon onward, the river occupies the trough lying between the Massif Central and the Alps, a channel up which the sea of the Tertiary period (66.4 to 1.6 million years ago) ascended covering the present Rhône valley. A body of water, Lake Bresse, spread over the Saône basin. Into this lake drained a river—the present Rhine—which then flowed south through the valley and into the Saône basin; later tectonic movements caused the Rhine to reverse its flow, and the Doubs, a tributary of the Saône, now partly follows the former Rhine drainage pattern. In the late Tertiary the gulf of the sea was uplifted to expose the lower Rhône valley, and Lake Bresse drained out to the

south through the Saône River. Though the Rhône–Saône corridor is underlain by sediments laid down during the Tertiary period, much of its present surface is formed by debris deposited by valley glaciers that extended from the Alps during the Pleistocene epoch (1.6 million to 10,000 years ago). These sediments were instrumental in cutting deep channels through the edge of the crystalline Massif Central, as evidenced at Vienne and Tain. The valley consequently takes the form of a series of gorges and basins, the latter often having a series of terraces corresponding to variations in the levels of ice and of river. Although the tributaries—notably the Ardèche—rushing down into the Rhône from the Massif Central are formidable when in flood, the great Alpine rivers, the Isère, and the Durance, joining the left bank, are most important in their effect on riverbed deposits and on the volume of water. Below Mondragon the Rhône valley becomes wider, and what was once a marshy landscape open to flooding has been regulated by a series of dams and canals.

The river's delta begins near Arles and extends about 25 miles to the sea. Twin channels of the river, the Grand and Petit Rhône, enclose the Camargue region. This region, formed by alluvium, is continuously extending into the Mediterranean. The finer materials are carried by onshore currents to form the barrier beaches of the coast and the sandbars closing off the Étang de Berre. One part of the delta has been set aside for a nature reserve, thereby protecting the feeding and nesting grounds of flamingos, egrets, ibis, and other rare species. Since 1962 the left bank of Fos has been transformed into a vast industrial complex consisting of port facilities, refineries, oil-storage tanks, and steel mills.

Hydrology. The flow regime of the Rhône owes its remarkable mean volume to the influence of the Alps. At Lyon the flow amounts to 22,600 cubic feet (640 cubic metres) per second; there, the Saône alone contributes 14,100 cubic feet per second. The Isère adds another 12,400 cubic feet per second. The melting of the Alpine snows gives the highest mean flows in May, while the Saône attains its maximum in January. The flood volumes of spring and autumn are formidable, reaching 460,000 cubic feet per second for the Rhône at Beaucaire, just above the delta. Thus, the Rhône has an abundant flow but maintains a strong gradient almost to its mouth. At Lyon, for example, its altitude is 560 feet at 205 miles from the sea. As the size of the delta region testifies, the river transports enormous amounts of alluvial deposits and is also powerful enough to cut through a variety of rock masses. As a result, the Rhône of today is well adapted to the production of electricity and, though difficult to navigate in the past, is now an important waterway from the Mediterranean to Lyon.

Flood volumes

The economy. The Rhône basin constitutes one of the great economic regions of Switzerland and of France, draining rich plains as well as an important part of the Alps. The utilization of the region by humans, however, has required a long historical struggle, which entered a decisive phase only in the second half of the 20th century. The economy of the Rhône region consists of five major elements: agriculture, industry, energy, tourism, and transportation.

Agriculture in the Rhône valley largely covers the low areas, plains, and islands. In the canton of Valais, the Rhône has been diked and narrowed, and the surrounding plain has been drained. Comparable works have been carried out in France, notably on the Isère, at Combe de Savoie and Grésivaudan, and on the upper Durance. River waters are used extensively for irrigation. Forage crops and livestock raising coexist with vineyards, fruit orchards, and vegetable farming; the Camargue region is noted for its rice fields.

Industries, both large and small, have been established throughout the region. Notable concentrations include the aluminum and chemical plants in Valais, the oil refineries at Lyon, and the refineries and steel mills at Fos. The production of hydroelectricity is evident throughout the length of the Rhône and particularly so in its lower reaches, where a series of dam projects have harnessed more than half of the entire potential hydroelectric power of the river. In France several nuclear generating stations utilize river waters for cooling purposes.

The course of the Rhône has long attracted tourists, and tourism has played an increasingly key role in the regional economy since the mid-20th century. The great variety of recreational activities offered—from skiing and climbing in the Alps, to visiting the historic cities of Provence, to horseback riding in the Camargue—have been key to the river's popularity.

Navigation has always been carried on, particularly between Lyon and the sea, and the Rhône traditionally has been the transportation funnel between northern and southern France; the Rhône valley in Valais served a similar function in Switzerland, particularly with the construction of a number of rail and road tunnels under some of the mountain barriers. The most extensive improvements to the river itself have taken place between Lyon and the Mediterranean: shoals have been submerged under the reservoirs created by dams or bypassed by canals, and the original gradient has been replaced by a succession of level reaches and locks.

Transportation

The Rhône River at Avignon, Fr., with the Saint-Bénézet Bridge in the foreground and the Papal Palace in the background.

History. Great cities attest the antiquity and the strength of people's interest in the region, which long ago was influenced by Celtic settlement and then by Roman domination. Brig, Sion, and Martigny in the Alpine section; Lausanne and Nyon on Lake Geneva; Lyon, at one of the major European crossways; and the Provençal cities of Nîmes, Arles, and Orange all contain evidence of their Roman past. From AD 1033 much of the region was controlled by the house of Savoy; ultimately, Valais, Geneva, and Vaud joined the Swiss Confederation, while Savoy itself became part of France. During the 14th and early 15th centuries, Avignon (located just north of the Rhône delta) was the residence of the popes of the Avignon papacy and antipopes of the Western Schism. The river, once a spearhead for the penetration of Mediterranean cultures and peoples into northern Europe, again became a routeway for invasion, when Allied armies followed it north after landing in southern France during World War II. (P.V./A.Di.)

SEINE RIVER

The Seine River, 485 miles (780 kilometres) long, with its tributaries drains an area of about 30,400 square miles (78,700 square kilometres) in northern France; it is one of Europe's great historic rivers, and its drainage network carries most of the French inland waterway traffic. Since the early Middle Ages it has been above all the river of Paris, and the mutual interdependence of the river and the city that was established at its major crossing points has been indissolubly forged. The fertile centre of its basin in the Île-de-France was the cradle of the French monarchy and the nucleus of the expanding nation-state and is still its heartland and metropolitan region.

Physical features. *Physiography.* The Seine rises at 1,545 feet (471 metres) above sea level on the Mont Tasselot in the Côte d'Or region of Burgundy but is still only a small stream when it traverses porous limestone country beyond Châtillon. Flowing northwest from Burgundy, it enters Champagne above Troyes and traverses the dry chalk plateau of Champagne in a well-defined trench. Joined by the Aube near Romilly, the river bears west to skirt the Île-de-France in a wide valley to Montereau, where it receives the Yonne on its left bank. This tributary is exceptional in rising beyond the sedimentary rocks of the Paris Basin on the impermeable crystalline highland of the Morvan, a northward extension of the Massif Central. Turning northwest again, the Seine passes Melun and Corbeil as its trenched valley crosses the Île-de-France toward Paris. As it enters Paris, it is joined by its great tributary the Marne on the right, and, after traversing the metropolis, it receives the Oise, also on the right. In its passage through Paris, the river has been trained and narrowed between riverside quays. Flowing sluggishly in sweeping loops, the Seine passes below Mantes-la-Jolie across Normandy toward its estuary in the English Channel. The broad estuary opens rapidly and extends for 16 miles below Tancarville to Le Havre; it experiences the phenomenon of the tidal bore, which is known as the *mascaret,* although continued dredging since 1867 has deepened the river so that the *mascaret* has gradually diminished.

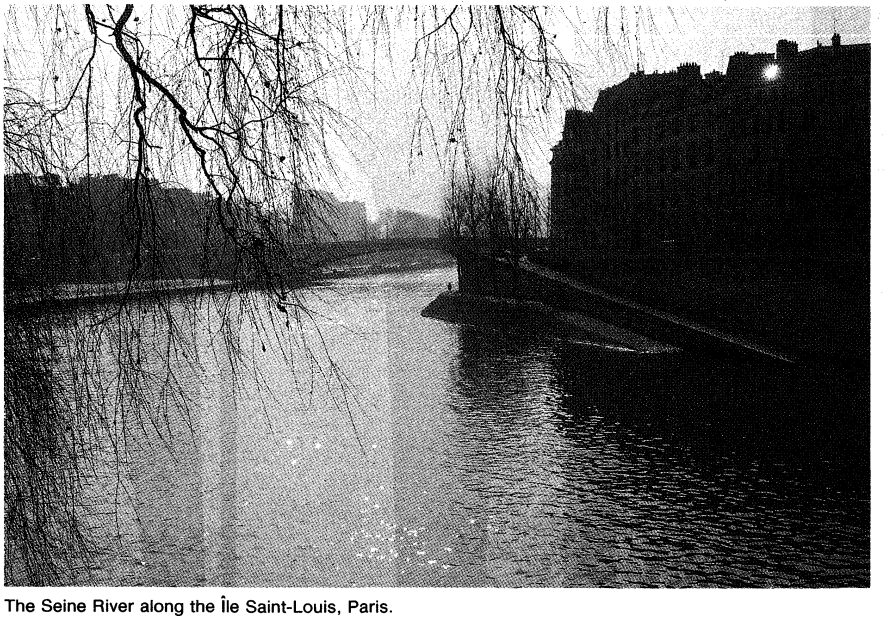
From its source to Paris, the Seine traverses concentric belts of successively younger sedimentary rocks, infilling a structural basin, the centre of which is occupied by the limestone platforms of the Île-de-France immediately surrounding Paris. The rocks of this basin are inclined gently toward Paris at the centre and present a series of outward-facing limestone (including chalk) escarpments (*côtes*) alternating with narrower clay vales. The *côtes* are breached by the Seine and its tributaries, which have made prominent gaps. As they converge upon Paris, the trenchlike river valleys separate a number of islandlike limestone platforms covered with fertile, easily worked windblown soil (*limon*). These platforms have provided rich cereal-growing land from time immemorial and constitute the Île-de-France. The lower course of the Seine, below Paris, is directed in a general northwesterly direction toward the sea, in conformity with the trend of the lines of structural weakness affecting the northern part of the basin. The English Channel breaches the symmetry of the basin on its northern side, interrupting the completeness of the concentric zones. Still in the chalk belt, the river enters the sea.

The geologic background

The basin of the Seine presents no striking relief contrasts. Within 30 miles of its source the river is already below 800 feet, and at Paris, 227 miles from its mouth, it is only 80 feet above sea level. It is thus slow flowing and eminently navigable, the more so because its regime is generally so regular.

Hydrology. Most of the river basin is formed of permeable rocks, the absorptive capacity of which mitigates the risk of river floods. Precipitation throughout the basin is modest, generally 25 to 30 inches (650 to 750 millimetres), and is evenly distributed over the year as rain, with snow infrequent except on the higher southern and eastern margins. The Yonne—unique among the tributaries in being derived from impermeable, crystalline highlands, where there is also considerable winter snow—also has the greatest influence on the Seine's regime (flow) because of the great variability of its flow; but the Seine is the most regular of the major rivers of France and the most naturally navigable. Occasionally the summer level is considerably reduced (such as in the summers of 1947 and 1949), but the sandbanks that are so typical of the

© Dana Hyde—Photo Researchers



The Seine River along the Île Saint-Louis, Paris.

Loire do not appear. Low water is further masked by the regularization of the river that has been carried out to improve its navigability. Winter floods are rarely dangerous, but in January 1910 exceptionally heavy rainfall caused the river to rise above 28 feet at Paris, flooding the extensive low-lying quarters along its ancient meander loop (the Marais). To match this high level it is necessary to go back to February 1658; but in January 1924 and also in January 1955 the river again rose to more than 23 feet in Paris. The average flow at Paris is about 10,000 cubic feet (280 cubic metres) per second, as compared with the 1910 flood rate of about 83,000 and the 1947 and 1949 minimums of about 700.

Economic aspects of the river

The economy. The Seine, especially below Paris, is a great traffic highway. It links Paris with the sea and the huge maritime port of Le Havre. Rouen, although some 75 miles from the sea, was France's main seaport in the 16th century, but it was surpassed by Le Havre in the 19th century. Vessels drawing up to 10 feet (3.2 metres) can reach the quays of Paris. Most of the traffic, which chiefly consists of heavy petroleum products and building materials, passes upstream to the main facilities of the port of Paris at Gennevilliers. The lower Seine system is connected with that of the Rhine by way of the Marne, and the Oise links it with the waterways of Belgium. The links with the Loire waterway and with the Saône-Rhône, dating from the 17th and 18th centuries when connecting canals were built, are now of minor importance. The water of the Seine is an important resource for the riverine population. Large electric power stations, both thermal and nuclear, draw their cooling water from the river. In addition, half of the water used in the region around Paris, both for industry and for human consumption, and three-fourths of the water used in the region between Rouen and Le Havre, is taken from the river.

Development of the river. Although the regime of the Seine is relatively moderate, improvements have been considered necessary since the beginning of the 19th century. To improve navigation, the water level was raised by means of dams and by storage reservoirs in the basin of the Yonne River. Lake Settons (1858), originally designed for the flotation of wood, and Crescent (1932) and Chaumeçon (1934) reservoirs have proved useful in reducing floods as well as in ensuring a constant water supply in summer. Upstream from the basin four large storage reservoirs have been built since 1950 on the Yonne, Marne, and Aube, as well as on the Seine itself. These relatively shallow impoundments (averaging about 25 feet in depth) cover large areas. The Seine Reservoir, for example, covers some 6,175 acres (2,500 hectares), while the Marne Reservoir, with an area of about 11,900 acres, is the largest artificial lake in western Europe. Surrounded by woodland and countryside, these reservoirs have become bird sanctuaries and tourist attractions in a new nature reserve.

Central European drainage systems

DANUBE RIVER

The Danube is the second longest river of Europe after the Volga. It rises in the Black Forest mountains of West Germany and flows for approximately 1,770 miles (2,850 kilometres) to its mouth on the Black Sea. Along its course, it passes through eight countries under six variations of its name. In West Germany and Austria it is known as the Donau, in Czechoslovakia as the Dunaj, in Hungary as the Duna, in Yugoslavia and Bulgaria as the Dunav, in Romania as the Dunărea, and in the Soviet Union as the Dunay.

The Danube played a vital role in the settlement and political evolution of central and southeastern Europe. Its banks, lined with castles and fortresses, formed the boundary between great empires, and its waters served as a vital commercial highway between nations. The river's majesty has long been celebrated in music. The famous waltz *An der schönen, blauen Donau* (1867; *The Blue Danube*), by Johann Strauss the Younger, became the symbol of imperial Vienna. In the 20th century the river has continued its role as an important trade artery. It has been harnessed for hydroelectric power, particularly along the upper courses, and the cities along its banks—including the national capitals of Vienna, Budapest, and Belgrade—have depended upon it for their economic growth.

Physical features. *Physiography.* The Danube's vast drainage of some 315,000 square miles (817,000 square kilometres) includes a variety of natural conditions that affect the origins and the regimes of its watercourses. They favour the formation of a branching, dense, deepwater river network that includes some 300 tributaries, more than 30 of which are navigable. The river basin expands unevenly along its length. It covers about 18,000 square miles at the Inn confluence, 81,000 square miles after joining with the Drava, and 228,000 square miles below the confluences of its most affluent tributaries, the Sava and the Tisza. In the lower course the basin's rate of growth decreases. More than half of the entire Danube basin is drained by its right-bank tributaries, which collect their waters from the Alps and other mountain areas and contribute up to two-thirds of the total river runoff or outfall.

Three sections of the Danube

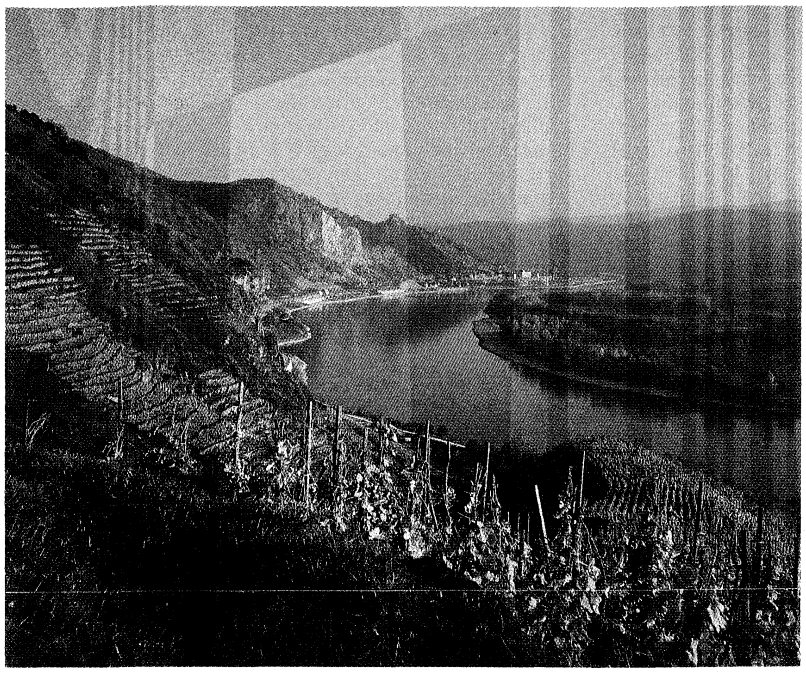
Three sections are discernible in the river's basin. The upper course stretches from its source to the gorge, called the Hungarian Gates, in the Austrian Alps and the Western Carpathian Mountains. The middle course runs from the Hungarian Gates to the Iron Gate Gorge in the Southern Romanian Carpathians. The lower course flows from the Iron Gate to the deltalike estuary at the Black Sea.

The upper Danube springs as two small streams—the Breg and Brigach—from the eastern slopes of the Black Forest mountains of West Germany, which partially consist of limestone. From Donaueschingen, where the headstreams unite, the Danube flows northeastward in a narrow, rocky bed. To the north rise the wooded slopes of the Swabian and the Franconian mountains; between Ingolstadt and Regensburg the river forms a scenic canyonlike valley. To the south of the river course stretches the large Bavarian Plateau, covered with thick layers of river deposits from the numerous Alpine tributaries. The bank is low and uniform, composed mainly of fields, peat, and marshland.

At Regensburg the Danube reaches its northernmost point, from which it veers south and crosses wide, fertile, and level country. Shortly before it reaches Passau on the Austrian border, the river narrows and its bottom abounds with reefs and shoals. The Danube then flows through Austrian territory, where it cuts into the slopes of the Bohemian Forest and forms a narrow valley. In order to improve navigation, dams and protecting dikes have been built near Passau, Linz, and Ardagger. The upper Danube, some 600 miles long, has a considerable average inclination of the riverbed (0.93 percent) and a rapid current of two to five miles per hour. Depths vary from three to 26 feet (one to eight metres). The Danube swells substantially at Passau where the Inn River, its largest upstream tributary, carries more water than the main river. Other major tributaries in the upper Danube course include the Iller, Lech, Isar, Traun, Enns, and Morava rivers.

In its middle course the Danube looks more like a flatland river, with low banks and a bed that reaches a width of more than one mile. Only in two sectors—at Visegrád (Hungary) and the Iron Gate—does the river flow through narrow, canyonlike gorges. The basin of the middle Danube exhibits two main features—the flatland of the Little Alfold and the Great Alfold plains, and the low peaks of the Western Carpathians and the Transdanubian Mountains.

The Danube enters the Little Alfold plain immediately after emerging from the Hungarian Gates Gorge near Bratislava, Czech. There the river stream slows down abruptly and loses its transporting capacity, so that enormous quantities of gravel and sand settle on the bottom. A principal result of this deposition has been the formation of two islands, one on the Czech side of the river and the other on the Hungarian side, which combined have an area of about 730 square miles that support some 190,000 inhabitants in more than 100 settlements. The silting hampers navigation and occasionally divides the river into two or more channels. East of Komárno the Danube enters the Visegrád Gorge, squeezed between the foothills of the Western Carpathian and the Hungarian Transdanu-



Vineyards along the Danube River in the Wachau region, Austria.
G. Hofmann—Superstock

bian Mountains. The steep right bank is crowned with fortresses, castles, and cathedrals of the Hungarian Árpád dynasty of the 10th to 15th century.

The Danube then flows past Budapest and across the vast Great Alfold plain until it reaches the Iron Gate gorge. The riverbed is shallow and marshy, and low terraces stretch along both banks. River accumulation has built a large number of islands, including Csepels Island near Budapest. In this long stretch the river takes on the waters of its major tributaries—the Drava, the Tisza, and the Sava—which create substantial changes in the river's regime. The average runoff increases from about 83,000 cubic feet (2,400 cubic metres) per second north of Budapest to 200,000 cubic feet at the Iron Gate. The river valley looks most imposing there, and the river's depth and current velocity fluctuate widely. The rapids and reefs of the Iron Gate once made the river unnavigable until a lateral navigation channel and a parallel railway allowed rivercraft to be towed upstream against the strong current.

The Iron Gate

Beyond the Iron Gate the lower Danube flows across a wide plain; the river becomes shallower and broader, and its current slows down. To the right, above steep banks, stretches the tableland of the Danubian Plain of Bulgaria. To the left lies the low Romanian Plain, which is separated from the main stream by a strip of lakes and swamps. The tributaries in this section are comparatively

The Danube River basin and its drainage network.

small and account for only a modest increase in the total runoff. They include the Olt, the Siret, and the Prut. The river is again obstructed by a number of islands. Just south of Cernavodă, the Danube heads northward until it reaches Galaţi, where it veers abruptly eastward. Near Tulcea, some 50 miles from the sea, the river begins to spread out into its delta.

The river splits into three channels—the Chilia, which carries 63 percent of the total runoff; the Sulina, which accounts for 16 percent; and the Sfîntu Gheorghe (St. George), which carries the remainder. Navigation is possible only by way of the Sulina Channel, which has been straightened and dredged along its 39-mile length. Between the channels, a maze of smaller creeks and lakes are separated by oblong strips of land called *grinduri*. Most *grinduri* are arable and cultivated, and some are overgrown with tall oak forests. A large quantity of reeds that grow in the shallow-water tracts are used in the manufacture of paper and textile fibres. The Danube delta covers an area of some 1,660 square miles and is a comparatively young formation. About 6,500 years ago the delta site was a shallow cove of the Black Sea coast, but it was gradually filled by river-borne silt; the delta continues to grow seaward at the rate of 80 to 100 feet annually.

Hydrology. The different physical features of the river basin affect the amount of water runoff in its three sections. In the upper Danube the runoff corresponds to that of the Alpine tributaries, where the maximum occurs in June when melting of snow and ice in the Alps is the most intensive. Runoff drops to its lowest point during the winter months.

In the middle basin the phases last up to four months, with two runoff peaks in June and April. The June peak stems from that of the upper course, reaching its maximum 10 to 15 days later. The April peak is local. It is caused by the addition of waters from the melting snow in the plains and from the early spring rains of the lowland and the low mountains of the area. Rainfall is important; the period of low water begins in October and reflects the dry spells of summer and autumn that are characteristic of the low plains. In the lower basin all Alpine traits disappear completely from the river regime. The runoff maximum occurs in April, and the low point extends to September and October.

The river carries considerable quantities of solid particles, nearly all of which consist of quartz grains. The constant shift of deposits in different parts of the riverbed forms shoals. In the stretches between Bratislava and Komárno and in the Sulina Channel, draglines are constantly at work to maintain the depth needed for navigation. The damming of the river has also changed the way in which sediments are transported and deposited. Water impounded by reservoirs generally loses its silt load, and the water flowing out of the dam—which is relatively silt-free—erodes banks farther downstream.

The temperature of the river waters depends on the climate of the various parts of the basin. In the upper course, where the summer waters derive from the Alpine snow and glaciers, the water temperature is low. In the middle and lower reaches summer temperatures vary between 71° and 75° F (22° and 24° C), while winter temperatures near the banks and on the surface drop below freezing. Upstream from Linz the Danube never freezes entirely because the current is turbulent. The middle and lower courses, however, become icebound during severe winters. Between December and March, periods of ice drift combine with the spring thaw, causing floating ice blocks to accumulate at the river islands, jamming the river's course, and often creating major floods.

The winter freeze

The natural regime of river runoff changes constantly as a result of the introduction of stream-regulating equipment, including dams and dikes. The mineral content of the river is greater during the winter than the summer. The content of organic matter is relatively low, but pollution increases as the waters flow past industrial areas. The river's chemistry also changes as city sewerage and agricultural runoff find their way into the river.

The economy. The Danube is of great economic importance to the eight countries that border it—the Soviet Union, Romania, Yugoslavia, Hungary, Bulgaria, Czechoslovakia, Austria, and West Germany—all of which variously use the river for freight transport, the generation of hydroelectricity, industrial and residential water supplies, irrigation, and fishing. The movement of freight is the most important economic use of the Danube, and such cities as Izmail, Ukranian S.S.R.; Galaţi and Brăila, Rom.; Ruse, Bulg.; Belgrade, Serbia; Budapest; Bratislava, Czech.; Vienna; and Regensburg, W. Ger., are among the major ports. Since World War II, navigation has been improved by dredging and by the construction of a series of canals, and river traffic has increased considerably. The most important canals—all elements in a continentwide scheme of connecting waterways—include the Danube–Black Sea Canal, which runs from Cernovadă, Rom., to the Black Sea and provides a more direct and easily navigable link, and the Main–Danube Canal, being built to link the Danube to the Rhine and thus to the North Sea.

The Danube has been tapped for power, mainly in its upper course. The process, however, has spread downstream. One of the largest hydroelectric projects—the Djerdap High Dam and the Iron Gate power station—was built jointly by Yugoslavia and Romania. Not only does the project produce hydroelectricity but it also makes navigable what was once one of the most difficult stretches on the river.

Dams and irrigation

Industrial use of Danube waters is made at Vienna, Budapest, Belgrade, and Ruse. The main irrigated areas are along the river in Czechoslovakia, Hungary, Yugoslavia, and Bulgaria. The river, however, has nearly become unfit for irrigation as well as for drinking water because of the tremendous increase in pollutants; pollution has also diminished the once-rich fishing grounds, although some of the fish have moved to side lakes and swamps.

History. During the 7th century BC, Greek sailors reached the lower Danube and sailed upstream, conducting a brisk trade. They were familiar with the whole of the river's lower course and named it the Ister. The Danube later served as the northern boundary of the vast Roman Empire and was called the Danuvius. A Roman fleet patrolled its waters, and the strongholds along its shores were the centres of settlements, among them Vindobona (later Vienna), Aquincum (later Budapest), Singidunum (later Belgrade), and Sexantaprista (later Ruse).

During the Middle Ages the old fortresses continued to play an important role, and new castles such as Werfenstein, built by Charlemagne in the 9th century, were erected. When the Ottoman Empire spread from southeastern to central Europe in the 15th century, the Turks relied upon the string of fortresses along the Danube for defense. The Habsburg dynasty recognized the navigational potential of the Danube. Maria Theresa, queen of Hungary and Bohemia from 1740 to 1780, founded a department to oversee river navigation, and in 1830 a riverboat made a first trip from Vienna to Budapest, possibly for trading purposes. This trip marked the end of the river's importance as a line of defense and the beginning of its use as a channel of trade.

Regulated navigation on the Danube has been the subject of a number of international agreements. In 1616 an Austro-Turkish treaty was signed in Belgrade under which the Austrians were granted the right to navigate the middle and lower Danube. In 1774, under the Treaty of Küçük Kaynarca, Russia was allowed to use the lower Danube. The Anglo-Austrian and the Russo-Austrian conventions of 1838 and 1840, respectively, promoted free navigation along the entire river, a principle that was more precisely formulated in the Treaty of Paris of 1856, which also set up the first Danubian Commission with the aim of supervising the river as an international waterway. In 1921 and 1923 final approval of the Danube River Statute was granted by Austria, Germany, Yugoslavia, Bulgaria, Romania, Great Britain, Italy, Belgium, Czechoslovakia, Hungary, and Greece. The international Danube Commission was thus established as an authoritative institution with wide powers, including its own flag, the right to levy taxes, and diplomatic immunity for its members. It controlled navigation from the town of Ulm to the Black Sea and kept navigational equipment in good repair.

International control

During World War II, free international navigation along the course of the river was interrupted by the hostilities, and a consensus concerning the resumption of navigation was not reached until the Danubian Convention of 1948. The new convention provided for the Danubian countries alone to participate in a reconstituted Danube Commission; of these countries, only West Germany did not join the convention. (P.G.P.)

ELBE RIVER

The Elbe (Czech: Labe), one of the major waterways of central Europe, runs from Czechoslovakia through East and West Germany to the North Sea, flowing generally to the northwest. It rises on the southern side of the Krkonoše (Giant) Mountains near the border of Czechoslovakia and Poland. The river makes a wide arc across Bohemia (northwestern Czechoslovakia) and enters East Germany near Dresden. Between Wittenberge, E.Ger., and Lauenburg, W.Ger., it forms the boundary between the two German states. Above Hamburg the Elbe (now wholly in West Germany) splits into two branches; these rejoin farther downstream and the river then broadens into its estuary, the mouth of which is at Cuxhaven, where it flows into the North Sea.

The total length of the Elbe is 724 miles (1,165 kilometres), of which 352 miles are in East Germany. Its total drainage area is 55,620 square miles (144,060 square kilometres). Major tributaries are the Vltava (Moldau), Ohře (Eger), Mulde, and Saale, all of which join it from the left; and the Iser, Schwarze ("Black") Elster, Havel, and Alster from the right.

Physical features. *Physiography.* The Elbe is formed by the confluence of numerous headwater streams in the Krkonoše Mountains a few miles from the Polish-Czechoslovak frontier. It flows south and west, forming a wide arc for about 225 miles in Czechoslovakia to its confluence with the Vltava at Mělník and is joined 18 miles downstream by the Ohře. It then cuts to the northwest through the picturesque Elbe Sandstone Mountains, and, in a gorge four miles long, it enters East Germany. Between Dresden and Magdeburg the Elbe receives many long tributaries, of which all except the Schwarze Elster are left-bank streams. These are the Mulde and the Saale and its tributaries—including the Weisse ("White") Elster, the Unstrut, and the Ilm. These left-bank tributaries rise in the Ore Mountains or the Thuringian Forest and form the drainage basin of the middle Elbe with its geographic foci in Halle and Leipzig. Halle is on the Saale, just below the confluence of the Weisse Elster; Leipzig lies at the confluence of the Pleisse and the Weisse Elster. Below Magdeburg the Elbe receives most of its water from its right bank. Most of these tributaries rise in the uplands of Mecklenburg.

The middle Elbe

The river enters the North German Plain at Riesa, 25 miles below Dresden; below Riesa it meanders in a wide floodplain and has some abandoned loops. Dikes begin there and continue as far as the confluence of the Mulde. Between Wittenberg and Dessau the east–west valley floor narrows to five miles in width, and hilly land rises to the north (the Fläming Heath) and south. From Dessau to Magdeburg the floodplain widens, and dikes have been constructed continuously down to the sea. In its course below Magdeburg the floodplain is two miles wide down to the confluence with the Havel. The river keeps to the left of its floodplain and sometimes cuts into the low hills on its banks. Below the confluence with the Havel the river flows southeast–northwest; the floodplain widens and has distributaries and backwaters often flanked by low sandy hills (geest). Reclaimed salt marshes begin at Lauenburg. Above Hamburg—which the Elbe transverses in two arms, the Norder Elbe and the Süder Elbe—the floodplain is eight miles wide but narrows to four miles between the sandy geest of Schleswig-Holstein and the Lüneburg Heath.

The estuary proper of the Elbe (Unterelbe) extends from Hamburg to Cuxhaven, a distance of about 55 miles. It varies in width from one to two miles, but much of it is occupied by mud flats and sandbanks. The main channel is buoyed and dredged. At high tide the channel has a depth of some 53 feet (16 metres). The south or left bank is low and marshy and the river has sandbanks; the right bank is steep below Hamburg, but farther downstream there are marshes, diked and drained, that are intensively cultivated. The great port city of Hamburg grew up on the Alster River on low sandy hills above the marshes. The modern port facilities have spread to the low-lying south bank of the Elbe.

Hydrology. The flow of water in the Elbe varies considerably with the amount of precipitation and thawing in its drainage basin. At Dresden the discharge rate averaged 11,200 cubic feet (317 cubic metres) per second in the period 1931–75, but the rate varied from a minimum of 800 cubic feet to a maximum of 118,700. At Neu-Darchau, about 140 miles above the mouth, the discharge rate was 24,700 cubic feet per second in the period 1926–65, with extremes of 5,100 and 127,700. These great variations sometimes hinder navigation. Although there are dams on the upper Elbe in Czechoslovakia and at Geesthacht,

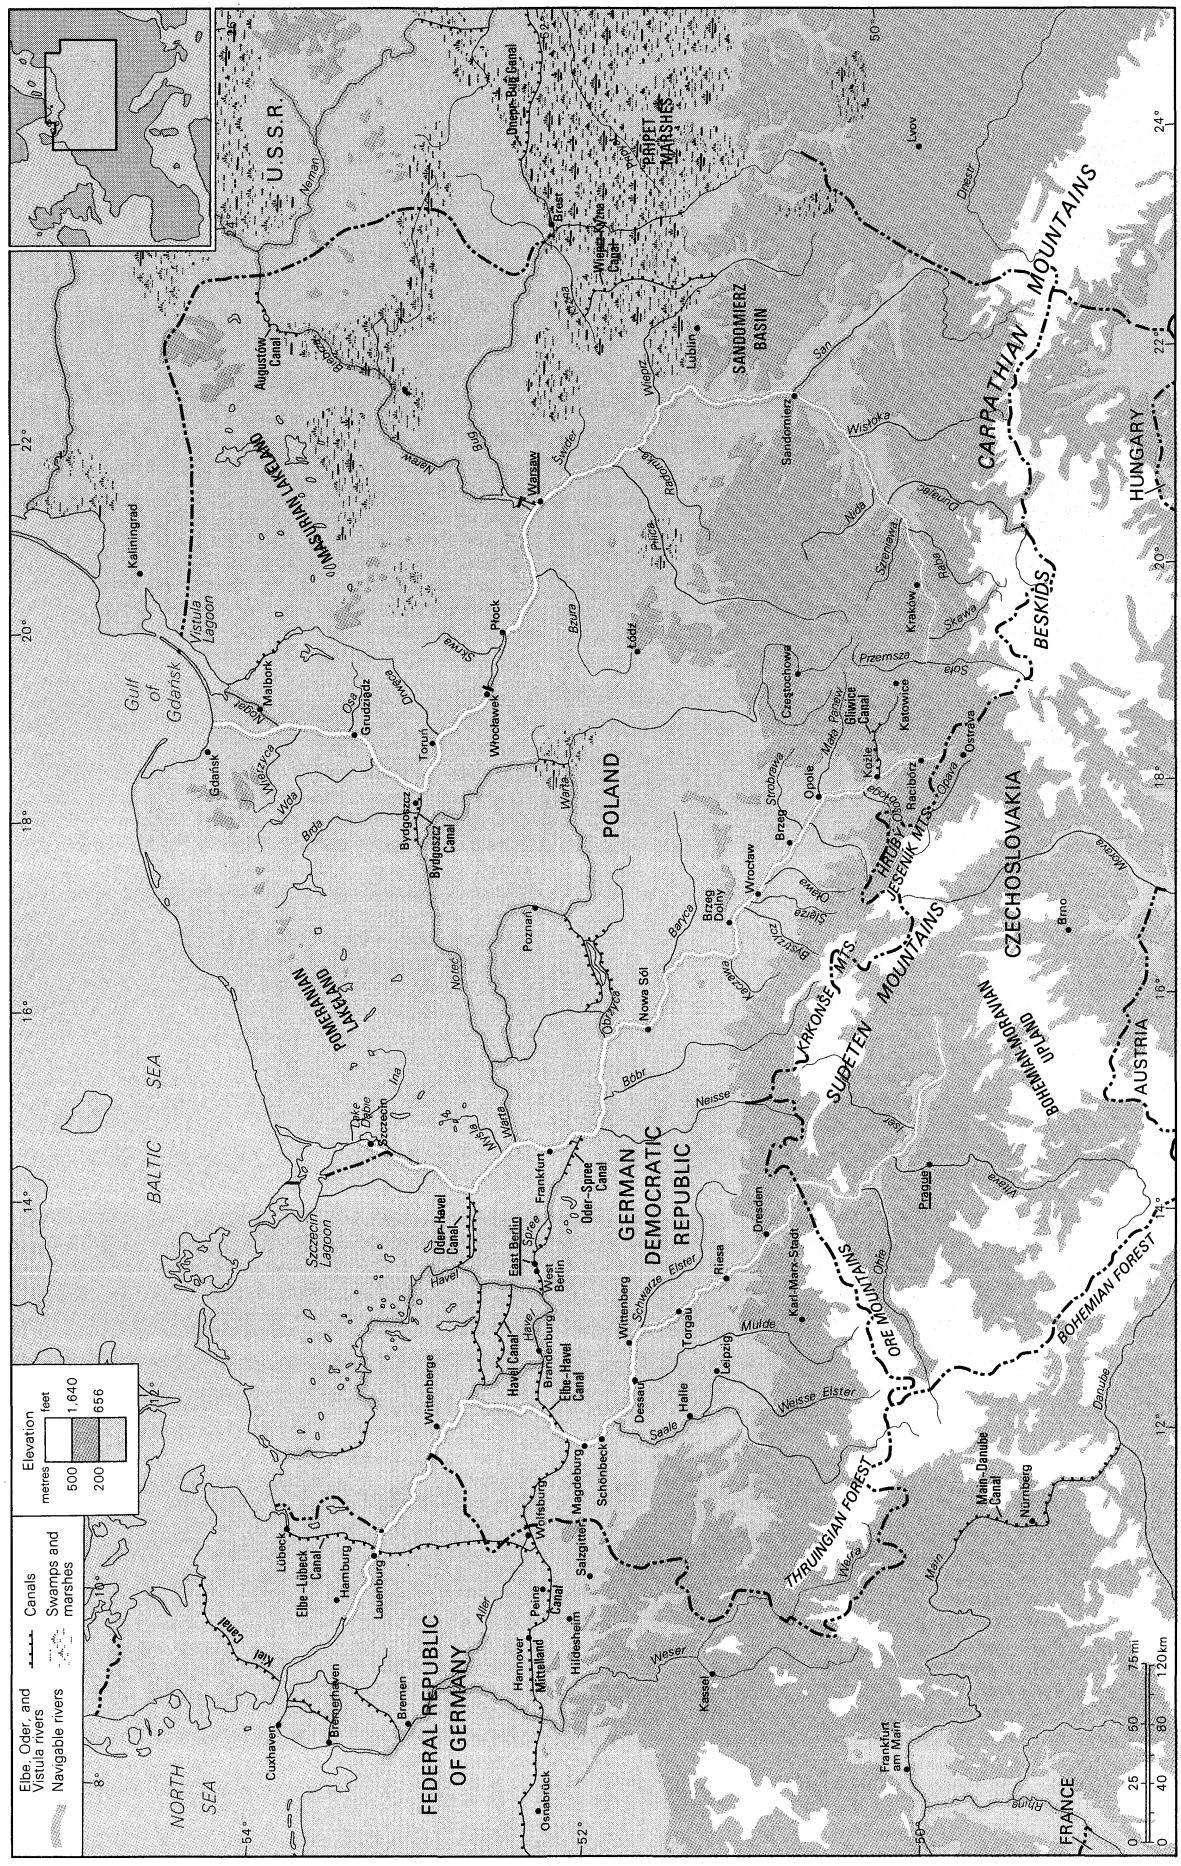
The Kiel Canal, which runs from the mouth of the Elbe River to the Baltic Sea, at Kiel, W.Ger.



The Elbe, Oder, and Vistula river basins and their drainage network.

W.Ger., and large dams have been built on the Vltava and on the Saale in the Thuringian Forest, these are not sufficient to control the water level of the Elbe.

The lower course of the Elbe is tidal as far as the dam at Geesthacht, above Hamburg, where the river flow periodically reverses its direction. The average tide at Hamburg is about eight feet, and during storms the water may rise much higher, occasionally even flooding parts of the city.

Traffic on the Elbe

The economy. By means of the Elbe and its connecting waterways, vessels from Hamburg can navigate to Berlin, the central and southern sections of East Germany, and Czechoslovakia. The Mittelland Canal, a short distance below Magdeburg, runs westward about 200 miles to the Dortmund–Ems Canal, carrying barges of up to 1,000 tons to the West German industrial cities of Osnabrück, Hannover, Salzgitter, Hildesheim, Peine, and Wolfsburg and connecting with the Weser and Rhine rivers. The Elbe–Havel Canal carries traffic from Magdeburg eastward to the network of waterways around Berlin and farther on to Poland. The Kiel Canal runs from the mouth of the Elbe to the Baltic Sea, and the Elbe–Lübeck Canal, starting at Lauenburg, also runs to the Baltic, following an older (14th-century) canal. Another canal connects the lower Elbe with Bremerhaven on the Weser River. The Elbe itself is navigable for 1,000-ton barges as far as Prague through the Vltava. In East Germany it serves the river ports of Magdeburg, Schönebeck, Aken, Dessau, Torgau, Riesa, and Dresden, carrying bituminous coal, lignite, coke, metal, potash, grain, and piece goods. Although Hamburg lies far upstream from the mouth of the Elbe, it is one of the largest seaports in Europe; a six-line railway tunnel and a multilane road tunnel under the Elbe there are important links in trans-European traffic flows.

History. The basin of the Elbe has been settled since prehistoric times. Until the Middle Ages the river was the western boundary of the area inhabited by the northern Slavs. In the 12th century the Germans began to colonize the lands east of the Elbe and along the Baltic Sea. In World War II a point on the Elbe, near Torgau, was the meeting place of the U.S. and Soviet armies. Later the river formed part of the demarcation between East and West Germany.

Hamburg

The city of Hamburg dates from the early 9th century AD. Together with Lübeck, Hamburg established the Hanseatic League in 1241. Today it is West Germany's largest city, excluding West Berlin. Another ancient city on the Elbe is Magdeburg, which in the early 9th century was a trading post on the border between the Germans and the Slavs. In the 13th century it was a flourishing commercial city and an important member of the Hanseatic League. Today it is the largest inland harbour of East Germany. The other chief city of the Elbe is Dresden, founded about 1200. During the 18th century Dresden developed into a great centre of the fine arts, known as "Florence on the Elbe." Its beautiful architecture, almost completely destroyed during World War II, has been partially rebuilt. Other towns of historical interest along the Elbe include Wittenberg, the birthplace of the Protestant Reformation, and Meissen, which became famous for the manufacture of porcelain. (H.F./F.G.)

ODER RIVER

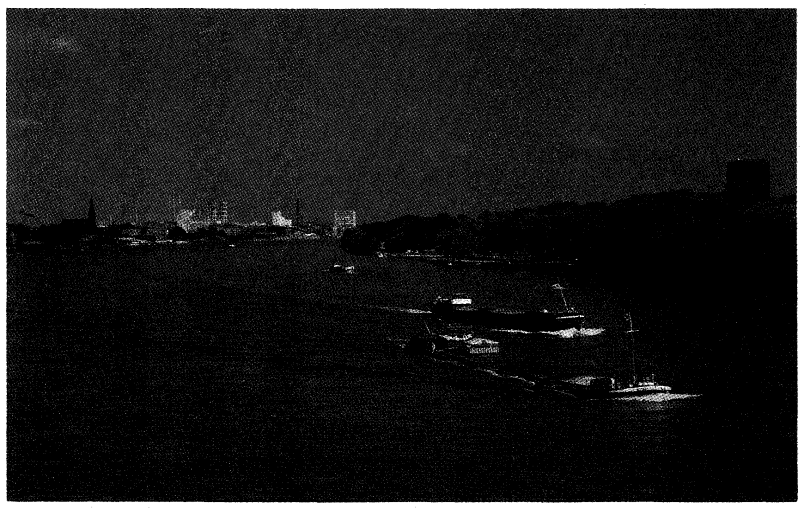
The Oder River, a vital economic artery in east central Europe, runs through the western portions of Poland and has considerable contemporary regional importance. It is one of the most significant rivers in the catchment basin of the Baltic Sea, second only to the Vistula in discharge and length. For the first 70 miles (112 kilometres) from its source, it passes through Czechoslovakia. For a distance of 116 miles in its middle reach, it constitutes the boundary between Poland and East Germany before reaching the Baltic Sea via a lagoon north of the Polish city of Szczecin. Called the Odra in Polish and Czech and the Oder in German, the river is an important waterway, navigable throughout most of its length. It forms a link, by way of the Gliwice Canal, between the great industrialized areas of Silesia (Śląsk), in southwestern Poland, and the trade routes of the Baltic Sea and beyond. The Oder is connected with the Vistula, Poland's largest river, by means of a water route utilizing the Warta and Noteć rivers, together with the Bydgoszcz Canal, and is tied in with the waterway system of western Europe by way of the Oder–Spree and Oder–Havel canals in East Germany.

The total length of the Oder River is 531 miles (854 kilometres), 461 miles of which lie in Poland. The total watershed area has been calculated at 46,000 square miles (119,000 square kilometres), of which about 90 percent is in Polish territory. The mean elevation of the Oder basin is 535 feet (163 metres) above sea level. From the river's source and over the greater part of its course, the Oder flows in a generally southeast–northwest direction; only from the junction with the Neisse (Polish: Nysa Łużycka) River does the northward trend toward the Baltic commence. The principal left-bank tributaries are the Opava of Czechoslovakia and the Osobłoga, Nysa Kłodzka, Oława, Ślęza, Bystrzyca, Kaczawa, Bóbr, and Neisse of Poland; from the east the main tributaries are the Olše of Czechoslovakia and the Kłodnica, Mała Panew, Strobrawa, Widawa, Barycz, Obrzyca, Warta, Myśla, and Ina of Poland. From the junction with the Opava the Oder is navigable for a distance of some 475 miles for 220 to 230 days of the year. Towns of particular importance along the Oder are Ostrava in Czechoslovakia, Frankfurt in East Germany, and Racibórz, Opole, Brzeg, Wrocław, Nowa Sól, and Szczecin in Poland.

Source

Physical features. *Physiography.* The Oder starts its course in Czechoslovakia, at an altitude of nearly 2,100 feet in the Hrubý Jeseník Mountains. Initially it runs as a mountain stream with a steep gradient that progressively lessens until the river reaches the floor of the structural depression called the Moravian Gate; from there the Oder continues its course in a wide valley. After receiving the Olše River, the Oder enters Poland and makes its way as a river that in a characteristic manner alternates between following ancient east–west stream valleys of glacial origin and crossing gaps cut in the intervening uplands. Where the Oder takes advantage of these preexisting valleys, it reaches widths as great as six miles or more, while in gaps it narrows to about a mile. Near Koźle the Gliwice Canal enters the Oder; and from there as far as Brzeg Dolny, a short way downstream from Wrocław, the river has a navigable channel controlled by locks. From Brzeg Dolny downstream until the final outflow into the Szczecin Lagoon, the river channel is fully improved. Beginning with the confluence with the Neisse River and continuing to just above Szczecin, the Oder becomes the borderline between Poland and East Germany. In this part of the valley the Oder–Spree and the Oder–Havel canals branch off to the west. Farther downstream the Oder valley contains numerous cross branches and parallel channels. About 50 miles from its outflow into the Baltic, the Oder splits into two main branches; the left canalized branch, called the Western Oder, passes through Szczecin and enters the Szczecin Lagoon directly, while the right branch, the Eastern Oder (in its final section called the Regalica), passes east of Szczecin via the large Lake Dąbie and then also enters the Szczecin Lagoon.

Hydrology. The Oder has a limited flow volume; its mean ratio of outflow to precipitation is the lowest among the rivers flowing into the Baltic. During low-water periods, in summer and autumn, the river is fed from storage reservoirs built in the upper tributaries. The mean water depth in the Oder Channel is three feet, and the mean velocity is three feet per second. In summer the upper reaches of the Oder system are flooded by heavy precipitation, while in spring the middle and lower reaches suffer from meltwater floods. Flow volume varies with the amount of precipitation. In the period 1951–80, for example, the discharge rate of the Oder's upper course averaged 1,560 cubic feet (145 cubic metres) per second, with extremes of 150 and 31,430; during that same period in the middle course the average was 18,820 cubic feet per second, with extremes of 5,510 and 76,630. The ice cover on the river lasts up to 40 days per year. As is the case with many of the world's great rivers flowing through heavily industrialized regions, the Oder's waters have become heavily polluted; of the fish that are still found in the river, the most common are bream and eel.



Barge traffic on the Oder River at Wrocław, Pol.
Ginette Laborde, Paris Charenton, Fr.

Improvements

The first hydraulic works—embankments and other structures for flood prevention—were started in the Oder valley as early as the 12th century; spillway dams built in the 13th century were in operation until the 18th century, when work was initiated on channel straightening by means of excavated cuts. Improvement of the straightened part of the Oder Channel was for the most part completed around 1900 (although final improvements were not made until after World War II), while control works in the middle and lower reaches were carried out in the interwar period.

The economy. The Oder River is an important element in the Polish economy, serving as a supplement to the heavily overburdened railway and highway systems linking the highly industrialized regions of the south with the largest Polish seaport, Szczecin, at the Oder's Baltic mouth. The river carries about 10 percent of the total tonnage handled by the port. The Oder is also used by the barges of East Germany, which travel over a system of navigable canals that connect the Oder with the central European waterway network. A system of navigable canals connects the Oder with the Vistula, Poland's largest river, and also with the rivers of the eastern portion of the country and the waterway system of the Soviet Union. This creates the possibility that the entire system may evolve into an all-water commercial route, transporting commodities from west to east and from east to west.

History. Because of its geographic situation, the Oder was, in ancient times, of major importance as the zone where people inhabiting southern and northern Europe came into contact with each other and exchanged cultural values. The first agricultural population arrived from the south after passing the Moravian Gate, which separates the Sudeten ranges from the Carpathian Mountains. Along the middle reach of the Oder there developed the pre-Lusatian and the Lusatian cultures (of the Bronze Age), which greatly affected the later evolution of the Slav population. In the area surrounding the Oder estuary, there was a mutual interpenetration by Scandinavian, Germanic, and Slav cultures. Finally, in the 9th and 10th centuries, the Polish state developed between the Oder and the Vistula. In the 13th century the German expansion dislodged Poland eastward, away from the Oder basin. But, on the basis of the 1945 Potsdam Conference between the Soviet Union, the United States, and Great Britain, the Polish nation returned to its former lands bordering the Oder River.

VISTULA RIVER

The Vistula (Polish: Wisła) is the largest river of Poland and of the drainage basin of the Baltic Sea. With a length of 651 miles (1,047 kilometres) and a drainage basin of some 75,100 square miles (194,500 square kilometres), it is a waterway of great importance to the nations of eastern Europe; more than 85 percent of the river's drainage basin, however, lies in Polish territory. The Vistula is connected with the Oder drainage area by the Bydgoszcz Canal. Eastward the Narew and Bug rivers and the Dnepr–Bug Canal link it with the vast inland waterway system of the Soviet Union.

Source

The source of the Vistula is found about 15 miles south of Bielsko-Biała on the northern slopes of the western Beskid range, in southern Poland, at an altitude of 3,629 feet (1,106 metres). It flows generally from south to north, through the mountains and foothills of southern Poland, across the lowland areas of the great North European Plain, ending in a delta estuary that enters the Baltic Sea near the port of Gdańsk. The average elevation of the Vistula basin is 590 feet above sea level; the mean river gradient is 0.10 percent, and the mean velocity in the river channel amounts to 2.6 feet per second. In addition to Poland's capital city, Warsaw, a number of large towns and industrial centres lie on the banks of the Vistula. These include Kraków, which was Poland's capital from the 11th century to the close of the 16th, Nowa Huta, Sandomierz, Płock, Toruń, Malbork, and Gdańsk. Numerous centres of tourism and recreation as well as many health resorts flank the Vistula valley. Here and there along the river rise the ruins of medieval strongholds, some of which have been restored.

Physical features. *Geology.* The present spatial pattern of the Vistula's tributary system and delta is the result of the changes in relief that occurred during the second half of the Tertiary and the Quaternary periods—*i.e.,* since about 30 million years ago. In the mountains the Vistula valley assumed its present shape much earlier and still reveals the way in which it has adapted itself to the geologic structure; in the lowland, on the other hand, the valley evolution was contingent on the history of the successive glaciations and, in particular, on changes during the interglacial period in which the Vistula abandoned its previous west–east valley and established its present northward course. The terminal part of the lower Vistula was finally stabilized in postglacial times, after the formation of the Baltic Sea.

A characteristic feature of the Vistula drainage basin is its asymmetry, with a predominance of right-bank over left-bank tributaries. This is the result of the general slant of the North European Plain in a northwesterly direction, which enabled the more powerful rivers of the Baltic drainage area to intercept the glacial streams flowing farther east.

Physiography. The course of the Vistula consists of three principal sections delineated by the San and Narew rivers, the two most prominent tributaries. The upper reach extends from the source to where the San joins its parent river near Sandomierz; its length is about 240 miles. The middle reach, from the mouth of the San to that of the Narew, below Warsaw, is about 170 miles long. Finally, the lower reach, extending to the Baltic, covers 240 miles from the mouth of the Narew to the mouth of the estuary into the Gulf of Gdańsk.

The upper course

In its upper course the Vistula is a mountain stream with a steep gradient of up to 5 percent. Its main sources are the Czarna Wisełka and the Biała Wisełka, two brooks that meet to form the Mała Wisła ("Small Vistula"), which then flows northward. Some 25 miles farther on, the river gradient decreases suddenly to some 0.04 percent; from there, after turning eastward, the Vistula enters Lake Goczałkowice, an artificial storage basin built in 1955. Upon exiting the lake, the Vistula assumes the character of a lowland stream, with its gradient decreasing to 0.03–0.02 percent in the middle reaches and to 0.02–0.002 percent in its final stages. At a distance of 65 miles from the source, the Vistula is joined by the Przemsza River, a left-bank tributary, after which—for 585 miles—it is navigable. After the Soła and Skawa—two right-bank tributaries—join the river, the Volga forces its way through a gap curved through a range of hills just before the city of Kraków. Channel improvements to this section have deprived the Vistula of much of its original character: several spillway steps have been constructed, creating a channel navigable by 300-ton barges. After passing through Kraków the Vistula turns to the east and, later, northeastward, crossing the wide Sandomierz Basin, where the valley is entered successively by the left-bank tributaries Szreniawa, Nida, Czarna, and Koprzywianka and from the right by the rivers Raba, Dunajec, Wisłoka, and San.

The inflow of the San River marks the beginning of the middle reaches of the Vistula, which then turns northward, breaching another gap through an upland area. In the course of its middle reaches the Vistula absorbs, from the left, the Radomka and Pilica and, from the right, the rivers Wieprz, Wilga, Świder, and Narew. Below the confluence with the Narew, where the lower reach of the river starts, the Vistula turns first to the west, and then after receiving the Bzura, a left-bank tributary, in a northwesterly direction; meanwhile from the right, the Skrwa and Drwęca join the river. In part of the valley, from the mouth of the Wieprz River to Toruń, the natural, untamed character of the Vistula predominates.

There the river runs in a channel 2,000 to 4,000 feet wide, practically devoid of controlling structures; in parts, the valley reaches widths up to six to nine miles, with the banks often 200 to 330 feet high. The low gradient of the river channel and abundant sandbanks render navigation difficult; in spring, when the ice cover breaks up and floats downstream, dangerous ice dams may form, causing the flooding of surrounding areas and often destroying embankments and bridges. A spillway step constructed at Włoclawek in 1968 initiated a series of improvements that continued through the 1980s.

From Toruń to its entry into the Baltic, the Vistula has been turned into a fully improved waterway. The 19th-century Bydgoszcz Canal, following an ancient glacial valley, links the Vistula with the Oder, the second largest of Polish rivers. Also near Bydgoszcz, the Vistula, having received a left-bank tributary in the Brda, turns northeastward in its third gap section cut through the Pomeranian highlands. Above Grudziądz the river finally turns northward to approach the Baltic. After receiving three further tributaries—the Osa from the right and the Wda and the Wierzyca from the left—the Vistula enters Żuławy Wiślane, its delta area, renowned for its splendidly fertile soils. Żuławy is a forestless plain, partly below sea level, threaded by the Vistula and its branches, together with a great number of canals and drainage ditches. Some of the local embankments and dikes date to the 13th century. During World War II a great part of Żuławy was flooded, but improvements were made in the postwar years.

The delta region

In the past the Vistula crossed its delta and entered the sea by two or more branch channels, notably the Nogat, which issued into the Vistula Lagoon, and the Leniwka (now called the Martwa Vistula), which followed the true Vistula Channel to the Gulf of Gdańsk. Improvements, the ultimate aim of which was to control the Vistula's outlet to the sea and make the entire delta region economically productive, were initiated at the end of the 19th century: first, a cut toward the open sea was excavated near Świbno to facilitate floodwater runoff and the removal of debris and ice carried by the river; later, all lateral watercourses were separated by locks, rendering them navigable, with controlled flows; the Świbno cut was extended into the open sea by lengthening the controlling embankments. This last change was intended to prevent the accumulation, at the river mouth, of the more than two million tons of sediment carried down annually by the Vistula.

The water level

Hydrology. Climatic variations in the Vistula basin cause a diversity in runoff and hence marked oscillations in the water level of the river, which averages 12 feet in the upper, 25 feet in the middle, and up to 33 feet in the lower reaches. Protracted low-water periods, lasting from late summer well into spring, are frequent. These hamper or entirely interrupt navigation. Spring floods caused by melting snow and ice in the whole drainage basin and summer floods resulting from heavy rains in the foothill and mountain regions are a common feature. During the period 1951–80 the mean flow of the upper course of the Vistula averaged about 2,200 cubic feet (62 cubic metres) per second, with extremes of 410 and 52,620 feet per second; the average for the middle course was about 20,900 feet per second, with extremes of 3,810 and 199,530; and the average for the lower course was 38,500 feet per second, with extremes of 8,940 and 276,870. Exceptionally heavy floods occurred in 1924, 1934, 1947, 1960, 1962, and 1970. There are a number of storage reservoirs in

D.C. Williamson, London

The Vistula River at Warsaw. In the background is the Old Town.

the valleys of the mountain tributaries that are intended to counteract excessive floods. Some newer, larger storage basins have been built.

Usually ice forms on the surface of the Vistula in the first half of January, breaking up toward the end of February. In the upper and lower reaches the duration of the ice sheet is from 20 to 40 days, in the middle reach it is 40 to 60 days, and in the estuary section, up to 20 days.

The quality of the Vistula's waters is affected by water-management structures such as dams and hydroelectric plants, by the discharge of municipal and industrial wastewater, and by agricultural and storm runoff. Although the upper reaches of the river remain relatively pure, the lower portions of the Vistula, in common with similar stretches of many of the great rivers of the world, exhibit a high degree of pollution.

Temperature regime

The mean annual temperature of the Vistula water is 46° F (8° C) in the upper reaches and 49° F (9° C) in the middle and lower reaches; in the middle and lower parts of the river the water is some 4° F (2° C) warmer than the mean annual air temperature of Poland. In winter the water temperature is 36° to 37° F (2° to 3° C); in summer it varies from 54° to 59° F (12° to 15° C). In river sections that are thermally affected by nearby industries, however, as in the regions of Kraków, Warsaw, and Włocławek, the water temperature is apt to be as much as 11° to 18° F (6° to 10° C) or even higher.

Plant and animal life. Higher-growth aquatic plant species most often encountered in the Vistula valley are, among plants submerged in the water, arrowhead (*Sagittaria sagittifolia,* variety *vallisinfolia*); among plants with floating leaves, the water lily (*Nuphar luteum*); and, among air-growing plants, sweet flag (*Acorus calamus*).

More than 40 kinds of fish exist in the Vistula. In the upper reach, turbot is the most common, with bream in the middle and lower reaches, and, in the waters of the estuary, salmon trout and vimba vimba. Species penetrating the river from the Baltic are found only sporadically.

The economy. The Vistula is connected with the Oder River by the Brda River, the Bydgoszcz Canal, and the Notec and Warta rivers; and in 1960 the Soviet Union, East Germany, and Poland agreed to establish permanent shipping lines along this route. In 1963 a canal was opened to avoid the natural hazards at the confluence of the Vistula and the Narew, improving the links between the Vistula and the Soviet waterways system.

Despite the Vistula's potential role as a transport link between the heavy industrial centres of southern Poland and the Baltic ports, navigational hazards have restricted its traffic. Nevertheless, attracted by water supply and by the possibilities of cheap transport rates for bulk materials, a number of large industrial projects have sprung up along the Vistula.

History. The Vistula played a prominent part in the ancient history of Poland. Since early Stone Age times the river served both as a trade route and as a means of expansion, from both north and south, for various peoples and cultures. Initially, raw materials and flint tools journeyed northward, while amber was sent to the south. By the time of the Roman Empire, the Vistula was one of the principal trade routes leading into central Europe; and from this period date the first historical references—by the classical geographers Pliny, Tacitus, and Ptolemy—to the Vistula and the Slav tribes living along its banks.

Medieval trade

Much later, in the early period of the Polish state (10th–13th century), the most important goods shipped over the Vistula route were salt, timber, grain, and building stone. The most intensive development of the Vistula as a trade route came from the 15th to 18th century, during which period a variety of hydraulic structures were put up, as well as embankments to provide flood protection. Many granaries and storehouses, built in the 14th century, line the banks of the Vistula. At the end of the 18th century, the partition of Poland between Prussia, Austria, and Russia put an end to the economic importance of the Vistula. Minor navigation improvements were undertaken only locally, in Prussia and in Austria. The major 19th-century improvements in the region of the delta and the construction of the Bydgoszcz Canal have been mentioned above. From 1920 to 1939 very little was done to improve the river channel. It was only after World War II that concerted efforts were undertaken to restore the Vistula to its historic function as a navigable waterway. This was done by the construction of a number of storage reservoirs and spillway dams in the river and its tributaries: the purpose was to take advantage of the river's hydroelectric potential and, at the same time, to adapt the channel to the travel of freight barges of 600- to 1,000-ton capacity.

A number of institutions are concerned with research on the Vistula and with keeping the waterway in operation. The highest authority coordinating activities in the field of research and deciding on technical expenditures and on navigational improvements is the Ministry of Environment Protection and Natural Resources. In addition, hydrologic measurements and investigations as well as engineering studies are carried out by the Institute for Meteorology and Water Management. (W.Pa./Je.P.)

Eastern European drainage systems

DNEPR RIVER

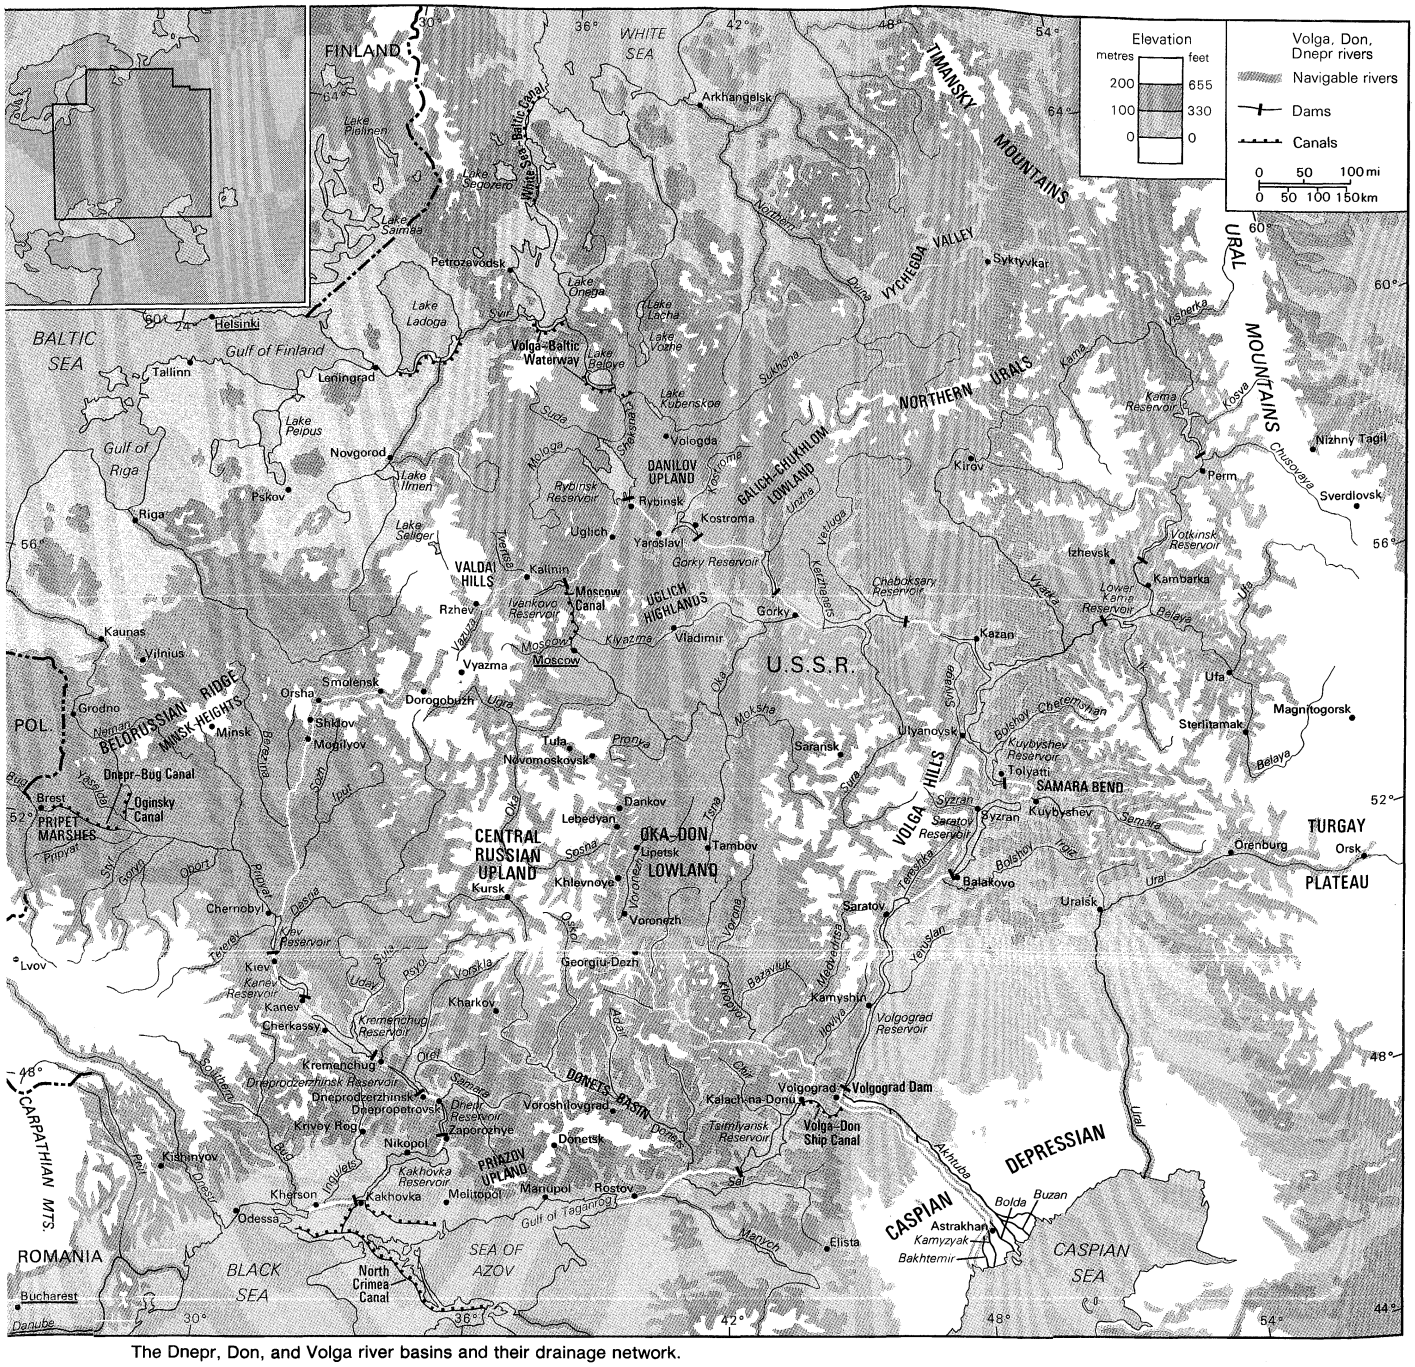
The Dnepr (conventional English: Dnieper; Ukrainian: Dnipro; Belorussian: Dnepro; the Borysthenes of ancient Greek authors) is the third river in length in the European part of the Soviet Union and the fourth longest in Europe, after the Volga, Danube, and Ural rivers. It is 1,367 miles (2,200 kilometres) long and drains an area of about 195,000 square miles (505,000 square kilometres).

The Dnepr rises at an altitude of about 720 feet (220 metres) in a small peat bog on the southern slope of the Valdai Hills, about 150 miles west of Moscow, and flows in a generally southerly direction to the Black Sea. For the first 300 miles, it passes through the Smolensk oblast of the Russian S.F.S.R., first to the south and then to the west; near Orsha it turns south once more and for the next 370 miles flows through the Belorussian S.S.R. Next, it flows through Ukrainian territory: south to Kiev, southeast from Kiev to Dnepropetrovsk, and then south-southwest to the Black Sea.

The Dnepr watershed includes the Volyno-Podolsk Upland, the Belorussian Ridge, the Valdai Hills, the Central Russian Upland, and the Priazov Upland. The centre of the basin consists of broad lowlands. Within the forest area and to some extent within the forest steppe area, the basin is covered with morainic and fluvioglacial deposits; on the steppe it is covered with loess. In some places, where the basin borders upon the basins of the Bug and the Western Dvina rivers, there is a flat swampy area. This facilitated the cutting of connecting water routes from the Dnepr to neighbouring rivers even in ancient times. At the end of the 18th century and the beginning of the 19th, the Dnepr was connected to the Baltic Sea by several canals; the Dnepr–Bug Canal running by way of the Pripyat, Bug, and Vistula rivers; the Oginsky Canal by way of the Pripyat and the Neman; and the Berezina water system by way of the Berezina and the Western Dvina. These canals later became obsolete.

Three sections

Physical features. *Physiography.* The Dnepr is customarily divided into three parts: the upper Dnepr as far as Kiev, the middle Dnepr from Kiev to Zaporozhye (Ukrainian S.S.R.), and the lower Dnepr from Zaporozhye to the mouth. The basin of the upper Dnepr is mainly within a forest area where peat-podzolic soils predominate (replaced in the southern portion of the upper course by podzolized, gray forest soils). The upper Dnepr is characterized by excessive moisture and great swampiness. The river network is well developed in this area, where about four-fifths of the basin's annual runoff forms and the longest tributaries with the greatest runoff (the Berezina, Sozh, Pripyat, Teterev, and Desna) flow. The basin of the middle Dnepr is in a forest steppe area with black earth. Forests stand in the watersheds and along the river valleys. The river network is less dense there, and the rivers carry comparatively less water. The principal tributaries of the middle Dnepr are the Ross, Sula, Psyol, Vorskla, and Samara. The lower Dnepr basin lies within the Black Sea Lowland, in the black-soil steppe area, which has now been completely plowed up. The grassy steppe vegetation



The Dnepr, Don, and Volga river basins and their drainage network.

has been preserved only in the nature reserves and preserves and in old ravines and gullies. Near the Black Sea there is wormwood–fescue vegetation of the semiarid type in chestnut brown soil mixed with saline solonetz and solonchak soils. The lower Dnepr passes through a region of insufficient moisture, where irrigation is employed. The river network there consists for the most part of intermittent streams, the beds of which are ravines that fill with water in the spring and after torrential rains. The largest tributary of this section is the Ingulets.

From its source to Dorogobuzh, Russian S.F.S.R., the Dnepr is a small river flowing past low wooded and, in some places, swampy banks. Downstream the banks rise, and the width of the valley to Orsha varies for the most part from two to six miles, narrowing to less than half a mile in places. Its bed, from 130 to 400 feet wide, is sinuous, with numerous sandbanks. Above Orsha the Dnepr crosses a layer of Devonian limestone, forming the so-called Kobelyaki Rapids, which hamper navigation. From Orsha to Shklov the Dnepr flows between raised, sometimes steep banks overgrown with woods; the left bank becomes lower, whereas the right remains high as far as the confluence with the Sozh River (where the Dnepr enters the Ukrainian S.S.R.). The valley is wide on this stretch, reaching six to nine miles in places. The riverbed from Orsha to Mogilyov is relatively straight; below Mogilyov the Dnepr splits into several channels, producing many islands and sandbanks. The width of the river from Orsha to the confluence with the Sozh ranges from 260 to 1,300 feet, and from the mouth of the Sozh to the mouth of the Pripyat it is from 1,600 to 2,000 feet. The vegetation along the banks of the upper Dnepr consists mainly of wide floodplain meadows, thickets of willows and alders, and old lowland marshes.

Marked asymmetry of the river valley is characteristic of the middle Dnepr. The steep, high right bank (up to 260 feet above the river) forms the escarpment of the Volyno-Podolsk Upland, which stretches along the whole middle course of the river. The low and sloping left bank is formed by broad, ancient terraces. Isolated hills, rising over 300 feet, appear on the low-lying left bank. On the southern portion of the middle Dnepr, the river cuts through the

Ukrainian crystalline masiff and flows for 56 miles in a narrow, almost unterraced valley bounded by high, rocky banks. The Dnepr Rapids, which for centuries prevented continuous navigation, were once located there. The rapids were flooded by the backwaters of the Dnepr hydroelectric power station dam, above Zaporozhye, which raised the level of the river by 130 feet and backed its waters up to Dnepropetrovsk.

The lower river

Below Zaporozhye the Dnepr again passes into a wide valley with a high right bank (130 feet near Nikopol, 260 feet near Kherson). The slopes of the river there are very slight. Before the development of the Kakhovka Reservoir, the waters of which inundated a vast territory, the Dnepr split into a multitude of streams; flat swampy islands, overgrown with floodplain vegetation and reeds, lay among the channels. Today, much of this is hidden under the waters of the reservoir.

Below Kherson the Dnepr forms a delta, the numerous streams of which flow into the Dnepr estuary. Some have been deepened for navigational purposes.

Hydrology. The flow characteristics of the Dnepr have been thoroughly studied. Data on the river's annual runoff date to 1818, while estimates of the maximum discharges—computed from the old high-water marks—extend back more than 250 years. Hundreds of hydrometric stations and posts operate in the Dnepr basin. Under natural conditions the Dnepr had high flows during the spring and fall and low flows during the summer and winter; but dams have altered this regime, so that the river now has pronounced high flows in spring, diminishing flows in summer, and low flows from September to March. Spring snowmelt in the river's upper basin provides the majority of the annual discharge. About 60 percent of the annual runoff occurs from March to May. The period of stable ice on open water in the upper Dnepr sets in at the beginning of December, and in the lower Dnepr at the end of December. Thaw starts at the beginning of April in the upper course and in early March in the lower course. The average annual flow of the river at its mouth is some 59,000 cubic feet (about 1,670 cubic metres) per second; for individual years, the variations in runoff can be considerable. The water of the Dnepr is low in minerals and is soft. In a year the river carries an average of 8.6 million tons of dissolved matter to the sea.

Climate. The climate of the Dnepr basin is, on the whole, temperate and is much milder and damper than that of more eastern regions of the Russian S.F.S.R. located at the same latitude. The continental nature of the climate increases from northwest to southeast. The mean annual air temperature in the upper part of the basin is 41° F (5° C); in the middle (near Kiev), 45° F (7° C); and in the lower reaches of the Dnepr, 50° F (10° C). Winters in the northeast of the basin are long and persistent, whereas in the south they are shorter and milder with frequent thaws; in the north the mean temperature in January is 16° F (−9° C) and in the south 27° F (−3° C). The amount of precipitation decreases from north to south. On the slopes of the Valdai Hills and the Minsk Heights, annual precipitation is about 30–32 inches (760–810 millimetres), while in the lower Dnepr region it is about 18 inches. The mean annual precipitation for the upper Dnepr basin (above Kiev) is about 28 inches. The precipitation average for the entire basin is about 27 inches, with about half falling as rain during the summer and fall.

Temperatures

Plant and animal life. The Dnepr has diverse aquatic flora and fauna. In its upper course the plankton consist mainly of diatom and protococcal algae, rotifers, and *Bosmina.* Blue-green algae come from the mouth of the Pripyat. In its lower course the amount of plankton decreases sharply under the influence of the reservoirs. More than 60 species of fish live in the Dnepr. Commercially important species include pike, roach, chub, ide, rudd, rapfen, tench, barbel, alburnum, golden shiner, goldfish, carp, catfish, burbot, pike perch, perch, and ruff. In the spring the lower Dnepr serves as a habitat for migratory and semimigratory fish (sturgeon, herring, roach, and others). The reservoirs have been stocked artificially with fish of commercial importance, including whitefish, pike perch, golden shiner, and carp.

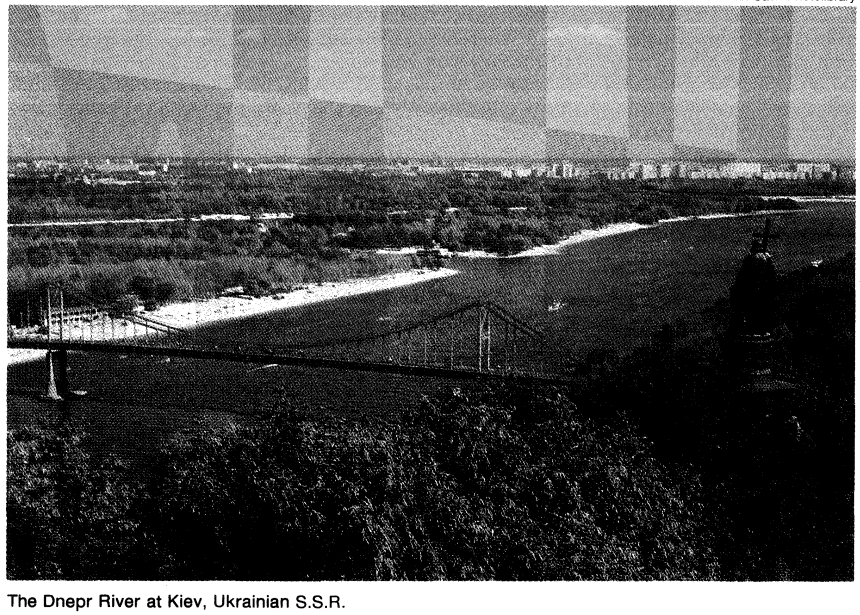
History and economy. The Dnepr basin has been populated since ancient times. It was of central importance in the history of the peoples of eastern Europe, particularly in the founding of the ancient Kievan state. Along this waterway a system of river routes developed in the 4th to 6th century AD a "route from the Varangians to the Greeks," connecting the Black Sea with the Baltic and linking the Slavs with both the Mediterranean and the Baltic peoples. Half of the Dnepr (about 700 miles) borders or passes through territory of the Ukrainian S.S.R., and the river is for the Ukrainians the same kind of national symbol that the Volga River is for the Russians.

The first historical information about the Dnepr is recorded by the Greek historian Herodotus (5th century BC); the river is also mentioned later by the ancient writers Strabo and Pliny the Younger. It was first depicted on a map drawn by Ptolemy in the 2nd century AD. Instrument surveys of the Dnepr were begun early in the 18th century.

River development

Under the Soviets, in line with the general plan for water management, much work has been undertaken for the multipurpose exploitation of the Dnepr's water resources. In 1932, in accordance with the Soviet Union's electrification plan, the river's first hydroelectric power station was completed at Zaporozhye in the region of the rapids. It was the largest power station in Europe until the construc-

J. Allan Cash Photolibrary



The Dnepr River at Kiev, Ukrainian S.S.R.

tion of the huge power stations on the Volga in the 1950s. Completely destroyed by the German army during World War II, the dam was rebuilt in 1947, and its capacity increased. Hydroelectric power stations and reservoirs have also been built on the Dnepr at Kiev (completed 1966), Kanev (1973), Kremenchug (1961), Dneprodzerzhinsk (1965), and Kakhovka (1958). As a result of their construction, many problems have been solved: a continuous deepwater route from the mouth of the Pripyat to the Black Sea has been created; the chronic water shortages in the Donbass and Krivoy Rog industrial regions has been solved; and irrigation of arid lands in the southern Ukraine and the Crimea has been made possible.

Regular navigation on the Dnepr extends as far upstream as Orsha, and, when the water is high, to Dorogobuzh. On the upper Dnepr the required depths are maintained by straightening and by dredging. Below the confluence with the Pripyat, navigable locks make the passage of modern vessels possible. The principal cargoes are coal, ore, mineral building materials, lumber, and grain. The chief ports are Dorogobuzh, Smolensk, Orsha, Mogilyov, Rechitsa, Loyev, Kiev, Cherkassy, Kremenchug, Dnepropetrovsk, Zaporozhye, Nikopol, Kakhovka, and Kherson.

The Krivoy Rog region is supplied with water from the Kakhovka Reservoir by means of the Dnepr–Krivoy Rog Canal. The North Crimea Canal, which was completed in 1971, originates in the reservoir; the canal, 250 miles long, is designed for irrigation of the steppes of the Black Sea Lowland and the northern Crimea and for the creation of a water route from the Dnepr to the Sea of Azov.

Damming the Dnepr and diverting its waters, however, have radically altered its natural hydrology and ecology. Seasonal flow variations have been reduced, upstream access for anadromous fish has been reduced, effluents from cities and industry (as well as from increased agricultural runoff) have caused pollution, and diversion of water for irrigation and evaporation from reservoirs have lowered the annual outflow of the river by some 20 percent. In addition, the wetlands around the river's estuary have been seriously damaged by pollution and reduced discharge.

(A.P.D./P.P.M.)

DON RIVER

One of the great rivers of the European portion of the Soviet Union, the Don has been a vital artery in Russian and Soviet history since the days of Peter I the Great, who initiated a hydrographic survey of its course. Throughout the world the river is associated with images of the turbulent and colourful Don Cossacks—romanticized in a famous series of novels by the 20th century Russian writer Mikhail Sholokhov—and with a series of large-scale engineering projects that have enhanced the waterway's economic importance. The Don rises in the small reservoir of Shat, located in the Central Russian Upland near the city of Novomoskovsk. It flows generally in a southerly direction for 1,162 miles (1,870 kilometres), draining a basin of some 163,000 square miles (422,000 square kilometres), before it enters the Gulf of Taganrog in the Sea of Azov. It is one of the major rivers of the European portion of the Soviet Union, lying between the Volga River to the east and the Dnepr River to the west. In its middle and lower courses, from the confluence with the Chyonaya Kalitva to its mouth, the Don forms an enormous eastward-bulging arc as far as its junction with the Ilovlya. Near the top of the arc, the vast Tsimlyansk Reservoir begins. The Volga–Don Ship Canal stretches from the upper part of the reservoir to the Volga, which at that point is a mere 50 miles distant. From its source in the Tula oblast, the Don crosses the Lipetsk, Voronezh, Volgograd, and Rostov oblasts, through the forest steppe and renowned steppe zones of the Soviet Union. Along the way it collects the waters of numerous tributaries, the most important of which are the Krasivaya Mecha, Sosna, Chyornaya Kalitva, Chir, and Donets (right bank), and the Voronezh, Khopyor, Medveditsa, Ilovlya, Sal, and Manych (left bank). The river winds throughout its course, and the drop along its length is about 620 feet (190 metres).

Important tributaries

Physical features. *Physiography.* In the upper portion of the Don—that is, as far downstream as the southeastward bend—the river flows along the eastern edge of the Central Russian Upland through a generally narrow valley. The right bank is pronounced, reaching heights of 160 feet above the river at the cities of Dankov and Lebedyan, and its limestone and chalk rocks are cut into by ravines and gullies. The left bank borders a flatter floodplain, and the river itself widens intermittently into small lakes; depths range from a few feet in the shoals to 33 feet, with a maximum width of 1,300 feet.

In the middle course, to the beginning of the Tsimlyansk Reservoir, the valley widens to about four miles, and its path is marked by floodplains, more small lakes, and relict channels; the banks, especially the right bank, become steeper, with chalk, limestone, and sandstone predominating. The river narrows to 330–1,300 feet.

The lower course is dominated by the nearly 190 miles of the Tsimlyansk Reservoir, completed in 1953. With an area of some 1,050 square miles and a maximum width of nearly 25 miles, the reservoir has an average depth of about 30 feet. Finally, the lower section of the Don has a valley width of 12–19 miles, with a huge floodplain and a braided river channel as much as 66 feet deep.

The landscape of the upper and middle Don basin is characterized on the right bank by undulating plains cut into by jagged gorges and on the left bank by the smoother, pond-dotted topography of the Oka–Don Lowland. Farther downriver the vast open landscapes of the steppes predominate. Rich, black chernozem soils fill almost the entire basin, though there are patches of gray forest soil in the north, where forests cover up to 12 percent of the area.

Hydrology. The long-term fluctuations in the water level of the Don reach about 40 feet in the upper course, 25 feet in the middle course, and 20 feet in the lower course. The highest levels are in the spring, the lowest in autumn and winter. At the mouth of the Don strong winds from the sea cause increases in the water level (wind surges). The average rate of discharge at the mouth of the Don is about 31,800 cubic feet (900 cubic metres) per second, but the river experiences great variation in its flow during the year. For example, at the city of Georgy-Dezh, in the river's upper course, the average flow is about 8,900 cubic feet per second, but flows range from 1,500 to approximately 395,000 cubic feet per second. There are corresponding variations as the annual flow increases downstream. At the city of Kalach-na-Donu about 65 percent of the annual flow occurs during April and May, compared with about 7 percent in March before the snowmelt begins. Below the Tsimlyansk Reservoir the flow has been partially regulated. At Nikolayevskaya, for example, 34 percent of the annual volume occurs in spring, 33 percent in summer, 22 percent in autumn, and 11 percent in winter.

Fluctuating water levels

The northern portion of the Don begins to freeze by about mid-November and is clear of ice by mid-April. In the lower course the river is frozen from the end of November to the end of March at Kalach-na-Donu and from mid-December to the beginning of April at Rostov-na-Donu.

Climate. The climate of the basin is moderately continental, with average January temperatures ranging from 12° F to 18° F (−11° C to −8° C), while July readings reach 66° F to 72° F (19° C to 22° C). Annual precipitation diminishes from 23 inches (584 millimetres) in the north to 14–15 inches in the south.

History and economy. Archaeological evidence of early settlement of the Don River basin dates from the Upper Paleolithic (40,000–13,000 years ago). At the beginning of the 2nd century BC, tribes of herdsmen occupied the valley of the Don and developed livestock raising and crop agriculture there. The Tatars conquered the region during the first half of the 13th century AD. The Russian state, expanding southward from the Grand Principality of Moscow, incorporated the Don River basin between the middle of the 15th and 16th centuries. The famed Don Cossacks established themselves in independent military settlements along the middle and lower Don by the 16th century but subsequently came under tsarist control.

Since the early 1950s the Don has undergone intensive

Quays along the Don River at Rostov-na-Donu, Russian S.F.S.R.
M. Koene—H. Armstrong Roberts

Construction of reservoirs

economic development. The key to this was the creation of the huge Tsimlyansk Reservoir along its lower course. The project included a hydroelectric station, a fish elevator, two navigation locks, an irrigation canal, a 1,580-foot concrete dam, and an eight-mile earthen dam. By 1975 an additional 116 reservoirs, with volumes exceeding 35 million cubic feet each, existed in the basin.

The Tsimlyansk Reservoir contributed to a rapid expansion of irrigation in the Don River basin, which grew from about 124,000 acres (50,000 hectares) in 1950 to nearly 2.5 million acres by 1980. In the upper basin an extensive network of ponds aids irrigation; these ponds are also used for raising fish.

The significance of the Don as a navigable waterway greatly increased with the construction of the Volga–Don Ship Canal. The river itself is navigable from the mouth to the city of Georgy-Dezh (a distance of 842 miles) and in the spring for another 150 miles upstream. Navigation in the lower course has been facilitated greatly by the Tsimlyansk project. Navigation at the mouth of the Don is occasionally hindered by the declines in water level induced by strong, persistent offshore winds, while dredging operations are necessary to maintain and improve navigation in the upper reaches. The largest ports are Kalach-na-Donu, Tsimlyansk, and Rostov-na-Donu.

The development of the Don has provided substantial economic benefits to the riverine populations as well as to the nation, but these alterations have reduced substantially the amount of water discharged at the river's mouth. This decrease—estimated in 1975 to be 20 percent of the 1950 level and still rising—has come chiefly from water diversion for irrigation and through evaporation from the artificial reservoirs; and, as a result of it, the salinity of the Sea of Azov has risen considerably, diminishing the sea's biological productivity and lowering fish catches.

(A.M.Ga./P.P.M.)

VOLGA RIVER

The significance of the river

Europe's longest river, the Volga (ancient Ra, medieval Itil or Etil) is the historic cradle of the Russian state. Its basin, sprawling across a third of what is now the European part of the Soviet Union, contains a quarter of the entire Soviet population. The Volga's immense economic, cultural, and historic importance—along with the sheer size of the river and its basin—ranks it among the world's great rivers. Rising in the Valdai Hills northwest of Moscow, the Volga discharges into the Caspian Sea, some 2,193 miles (3,530 kilometres) to the south. It drops slowly and majestically from its source 748 feet (228 metres) above sea level to its mouth 92 feet below sea level. In the process the Volga receives the water of some 200 tributaries, the majority of which join the river on its left bank. Its river system, comprising 151,000 rivers and permanent and intermittent streams, has a total length of 357,000 miles.

Physical features. The river basin—533,000 square miles (1,380,000 square kilometres) in area—drains one-third of the Soviet Union's European territory, stretching from the Valdai Hills and Central Russian Upland in the west to the Ural Mountains in the east, and narrowing sharply at Saratov in the south. From Kamyshin the river flows to its mouth uninterrupted by tributaries for some 400 miles.

Four geographic zones lie within the Volga basin: the dense, marshy forest, which extends from the river's upper reaches to Gorky and Kazan; the forest steppe extending from there to Kuybyshev and Saratov; the steppe from there to Volgograd; and semidesert lowlands southeast to the Caspian Sea.

Physiography. The course of the Volga is divided into three parts: the upper Volga (from its source to the confluence of the Oka); the middle Volga (from the confluence of the Oka to that of the Kama); and the lower Volga (from the confluence of the Kama to the mouth of the Volga itself). The Volga is a small stream in its upper course through the Valdai Hills, becoming a true river only after the entrance of several of its tributaries. It then passes through a chain of small lakes, receives the waters of the Selizharovka River, and then flows southeast through a terraced trench. Past the town of Rzhev, the Volga turns northeastward, is swelled by the inflow of the Vazuza and Tvertsa rivers at Kalinin, and then continues to flow northeastward through the Rybinsk Reservoir, into which other rivers, such as the Mologa and the Sheksna, flow. From the reservoir the river proceeds southeastward through a narrow, tree-lined valley between the Uglich Highlands to the south and the Danilov Upland and the Galich-Chukhlom Lowland to the north, continuing its course along the Unzha and the Balakhna lowlands to Gorky. (Within this stretch the Kostroma, Unzha, and Oka rivers enter the Volga.) On its east-southeastward course from the confluence of the Oka to Kazan, the Volga doubles in size, receiving waters from the Sura and Sviyaga on its right bank and the Kerzhenets and Vetluga on its left. At Kazan the river turns south into the Kuybyshev Reservoir, where it is joined from the left by its major tributary, the Kama. From this point the Volga becomes a mighty river, which, save for a sharp loop at the Samara Bend, flows southwestward along the foot of the Volga Hills in the direction of Volgograd. (Between the Samara Bend and Volgograd it receives only the relatively small left-bank tributaries of the Samara, Bolshoy Irgiz, and Yeruslan.) Above Volgograd the Volga's main distributary, the Akhtuba, branches southeastward to the Caspian Sea, running parallel to the main course of the

river, which also turns southeast. A floodplain, characterized by numerous interconnecting channels and old cutoff courses and loops, lies between the Volga and the Akhtuba. Above Astrakhan a second distributary, the Buzan, marks the beginning of the Volga delta, which, with an area of more than 7,330 square miles, is the largest in the Soviet Union. Other main branches of the Volga delta are the Bakhtemir, Kamyzyak, Staraya (Old) Volga, and Bolda.

Hydrology. The Volga is fed by snow (which accounts for 60 percent of its annual discharge), underground water (30 percent), and rainwater (10 percent). The natural, untamed regime of the river was characterized by high spring floods (*polovodye*). Before it was regulated by reservoirs, annual fluctuations in level ranged from 23 to 36 feet on the upper Volga; from 39 to 46 feet on the middle Volga; and from 10 to 49 feet on the lower Volga. At Kalinin the average annual rate of river flow is about 6,400 cubic feet (180 cubic metres) per second, at Yaroslavl 39,000 cubic feet per second, at Kuybyshev 272,500 cubic feet per second, and at the river's mouth 284,500 cubic feet per second. Below Volgograd the river loses about 2 percent of its waters in evaporation. More than 90 percent of annual runoff occurs above the confluence of the Kama. Increased flow below the Kama is only about 7 percent.

Former fluctuations in water level

Climate. The climate of the Volga basin changes significantly from north to south. From its source to the Kama confluence, it lies within a temperate climatic zone characterized by a cold, snowy winter and a warm, rather humid summer. From the Kama to below the Volga Hills, hot, dry summers and cold winters with little snow prevail. Temperatures and evaporation increase, and precipitation decreases, toward the south and east: the average January temperatures in the river's upper reaches range from 19° F (−7° C) to 6° F (−14° C) and those of July from 62° F (17° C) to 68° F (20° C), while on its lower reaches at Astrakhan corresponding temperatures are 19° F (−7° C) and 77° F (25° C). Annual rainfall ranges from 25 inches (635 millimetres) on the northwest to 12 inches on the southeast. Evaporation from land ranges from 20 inches in the northwest to eight inches in the southeast. The upper and middle courses of the Volga begin to freeze at the end of November, the lower reaches in December. At Astrakhan the ice breaks up in mid-March, at Kamyshin at the beginning of April, and everywhere else in mid-April. The Volga is generally free of ice for about 200 days each year and near Astrakhan for about 260 days. As great masses of water accumulated within the reservoirs constructed during the Soviet period, however, the temperature regime of the Volga was so changed that the duration of ice increased on the headwaters of the reservoirs and decreased on the stretches below the dams.

The changing river regime

The economy. *Dams and reservoirs.* A string of huge dams and reservoirs now line the Volga and its major tributary, the Kama River, converting them from free-flowing rivers to chains of man-made lakes. All of the reservoir complexes include hydroelectric power stations and navigation locks. The uppermost complex on the Volga, the Ivankovo , with a reservoir covering 126 square miles, was completed in 1937, and the next complex, at Uglich (96 square miles), was put into operation in 1939. The Rybinsk Reservoir, completed in 1941 and encompassing an area of about 1,750 square miles, was the first of the large reservoir projects. Following World War II, work continued below Rybinsk. The Gorky and Kuybyshev reservoirs were both completed in 1957, and the Cheboksary Reservoir, located between them, became operational in 1980. The huge Kuybyshev Reservoir, with an area of some 2,300 square miles, is the largest element of the Volga reservoir system; it not only impounds the waters of the Volga but also backs water up the Kama for some 375 miles. The Saratov and Volgograd reservoirs (completed in 1968 and 1962, respectively) are the last such bodies on the Volga itself. The chain on the Kama consists of three reservoirs, the newest of which—the Lower Kama Reservoir—became operational in 1979. There are a total of eight hydroelectric stations on the Volga and three on the Kama, which combined have an installed generating capacity of some 11 million kilowatts of power.

Navigation. The Volga, navigable for some 2,000 miles, and its more than 70 navigable tributaries carry more than half of all Soviet inland freight and nearly half of all the passengers who use Soviet inland waterways. Construction materials and raw materials account for about 80 percent of the total freight; other cargoes include petroleum and petroleum products, coal, foodstuffs, salt, tractors and agricultural machinery, automobiles, chemical apparatus, and fertilizers. The major ports on the Volga are Kalinin, Rybinsk, Yaroslavl, Gorky, Kazan, Ulyanovsk, Kuybyshev, Saratov, Kamyshin, Volgograd, and Astrakhan.

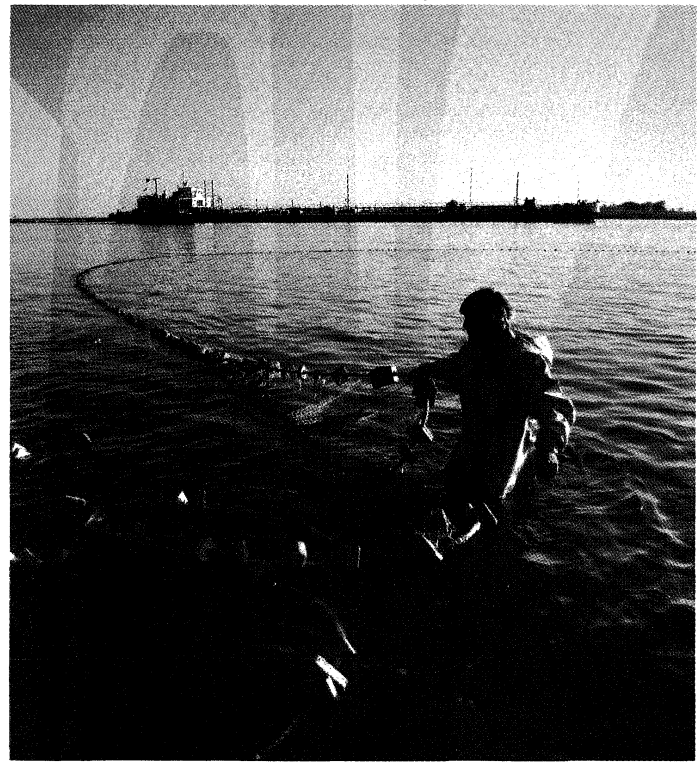
Freight patterns

The Volga is joined to the Baltic Sea by the Volga–Baltic Waterway, which, in turn, is joined to the White Sea (via Lake Onega) by the White Sea–Baltic Canal; to the Moscow River, and hence to Moscow, by the Moscow Canal; and to the Sea of Azov by the Volga–Don Ship Canal. The river has thus become integrated in a vital way with virtually the entire waterway system of the European Soviet Union.

Environmental changes. Although the extensive development of the Volga has made a major contribution to the Soviet economy, it also has had adverse ecological consequences. The system of dams and reservoirs has blocked or severely curtailed access for such anadromous species as the beluga sturgeon (famous for the caviar made from its roe) and whitefish (*belorybitsa*), which live in the Caspian Sea but spawn in the Volga and other inflowing rivers, and it has fundamentally altered the habitat of the nearly 70 species of fish native to the river. These changes—along with pollution by industrial and municipal effluents and by agricultural runoff—have led to deterioration of the major Volga fisheries. Water loss by impoundment and evaporation and by diversion (chiefly for irrigation) have diminished discharge at the mouth of the Volga compared with natural conditions, and this has contributed to an almost steady decline in the level of the Caspian Sea since 1930. Intensive efforts to alleviate these man-made influences, however, have been under way for a number of years. For example, some three-fifths of the Caspian sturgeon are now bred artificially rather than in their natural spawning grounds.

Study and exploration. The Volga was known to the Alexandrian geographer Ptolemy (2nd century AD), to the Slavs, and to the Arab geographers of the 10th and 11th

Jonathan Wright—Bruce Coleman Inc.



Fishing for beluga sturgeon in the Volga River, Volgograd, Russian S.F.S.R.

centuries. Information on it is contained in the *Kniga bolshomu chertyozhu* (1627; "Book of the Great Chart") and in a hydrographic description of 1636. Its flow was first measured below Kamyshin by the Englishman John Perry in 1700. Two pioneer Russian navigators, Makeyev and Gavril Andreyevich Sarychev, surveyed the stretch between Tver (now Kalinin) and Nizhny Novgorod (now Gorky) in 1782–83; in 1809–17 and 1829 the Maritime Bureau surveyed the delta and measured its depth; and from 1875 to 1894 the river was investigated from the Rybinsk to the Volga mouth. Investigations of the upper Volga were made from 1896 to 1901, and in 1894 the upper reaches of the Volga, Oka, Syzran, and other rivers were also examined. Many institutes have carried out hydrographic and hydrometric research during the Soviet period: by the late 20th century there were more than 500 points at which the water levels of the Volga had been observed. (P.S.K./P.P.M)

BIBLIOGRAPHY. *General:* Sources that provide brief but comprehensive information on European states include *Western Europe 1989: A Political and Economic Survey* (1988), from Europa Publications; and two surveys from "The World Today Series": WAYNE C. THOMPSON and MARK H. MULLIN, *Western Europe 1988,* 7th annual ed. (1988); and M. WESLEY SHOEMAKER, *The Soviet Union and Eastern Europe 1988,* 19th annual ed. (1988). RICHARD MAYNE (ed.), *Western Europe,* rev. ed. (1987); and GEORGE SCHÖPFLIN (ed.), *The Soviet Union and Eastern Europe,* rev. ed. (1986), both from the series "Handbooks to the Modern World," are more detailed analyses. DENYS HAY, *Europe: The Emergence of an Idea,* rev. ed. (1968), is a work of historical geography that explores the concept "Europe." Other historical works include GORDON EAST, *An Historical Geography of Europe,* 5th ed. (1966); and NORMAN J.G. POUNDS, *An Historical Geography of Europe, 450 B.C.–A.D. 1330* (1973), *An Historical Geography of Europe, 1500–1840* (1979), and *An Historical Geography of Europe, 1800–1914* (1985). Annuals include *The Statesman's Year-Book* and UNITED NATIONS, *Statistical Yearbook.* (T.M.P.)

Physical and human geography: (*Geologic history*): A survey of the geology of the continent is offered in DEREK V. AGER, *The Geology of Europe: A Regional Approach* (1980). ROLAND BRINKMANN, *Geologic Evolution of Europe,* 2nd rev. ed. (1969; originally published in German, 8th ed., 1959), is an introductory summary. DEREK V. AGER and M. BROOKS (eds.), *Europe from Crust to Core* (1977), collects papers on geologic events, from oldest to youngest, presented at a meeting of European geologic societies. M.G. RUTTEN, *The Geology of Western Europe* (1969), provides a general geologic background of part of the continent. Basic geologic elements are discussed in two articles published in *Geologie en mijnbouw,* vol. 57, no. 4 (1978): PETER A. ZIEGLER, "North-Western Europe: Tectonics and Basin Development," pp. 589–626; and H.J. ZWART and U.F. DORNSIEPEN, "The Tectonic Framework of Central and Western Europe," pp. 627–654. D.V. NALIVKIN, *Geology of the U.S.S.R.* (1973; originally published in Russian, 1962), includes substantial coverage of the European part of the country. Beautiful colour maps illustrating the evolution of Europe are found in PETER A. ZIEGLER, *Geological Atlas of Western and Central Europe* (1982). (B.F.W.)

(*The land*): General discussions of such topics as climate, topography, relief, vegetation zones, and animal distribution are found in GEORGE W. HOFFMAN (ed.), *A Geography of Europe,* 5th ed. (1983); TERRY G. JORDAN, *The European Culture Area,* 2nd ed. (1988); MARGARET REID SHACKLETON, *Europe, a Regional Geography,* 7th enlarged ed., rev. by GORDON EAST (1969); F.J. MONKHOUSE, *A Regional Geography of Western Europe,* 4th ed. (1974); and E.C. MARCHANT (comp.), *The Countries of Europe as Seen by Their Geographers* (1970). See also "Europe (Excluding Russia)," pp. 297–388 in W.G. KENDREW, *The Climate of the Continents,* 5th ed. (1961).

Works that focus on the geography of specific regions of Europe include BRIAN S. JOHN, *Scandinavia* (1984); ROY E.H. MELLOR, *The Two Germanies* (1978); D.S. WALKER, *The Mediterranean Lands,* 3rd ed. (1965); J.M. HOUSTON, *The Western Mediterranean World* (1964); NORMAN J.G. POUNDS, *Eastern Europe* (1969); DEAN S. RUGG, *Eastern Europe* (1985); PAUL E. LYDOLPH, *Geography of the U.S.S.R.* (1979); and LESLIE SYMONS *et al., The Soviet Union, a Systematic Geography* (1983).

(*People*): Historical development of anthropological and ethnological characteristics is outlined in TIMOTHY CHAMPION *et al., Prehistoric Europe* (1984); CARLETON STEVENS COON, *The Races of Europe* (1939, reprinted 1972); MICHAEL W. FLINN, *The European Demographic System, 1500–1820* (1981); and JOHN GEIPEL, *The Europeans: An Ethnohistorical Survey* (1969). BRIAN W. ILBERY, *Western Europe: A Systematic Human Geography,* 2nd ed. (1986), is a concise overview. Population trends of Europe in relation to those of the other continents are discussed in J. BEAUJEU-GARNIER, *Geography of Population,* 2nd ed. (1978; originally published in French, 2 vol., 1956–58). For statistical information, UNITED NATIONS, *Demographic Yearbook,* is useful. The growing minority nationalist movements are examined in CHARLES R. FOSTER (ed.), *Nations Without a State: Ethnic Minorities in Western Europe* (1980); HUGH SETON-WATSON, *Nations and States: An Enquiry into the Origins of Nations and the Politics of Nationalism* (1977); LOUIS L. SNYDER, *Global Mini-Nationalisms: Autonomy or Independence* (1982); GEORGE KLEIN and MILAN J. REBAN (eds.), *The Politics of Ethnicity in Eastern Europe* (1981); and STEPHEN CASTLES, *Here for Good: Western Europe's New Ethnic Minorities* (1984), which focuses on the problems of foreign labour forces. A broad range of other topics is treated in such special studies as STANLEY HOFFMANN and PASCHALIS KITROMILIDES (eds.), *Culture and Society in Contemporary Europe* (1981); JAN F. TRISKA and CHARLES GATI (eds.), *Blue-Collar Workers in Eastern Europe* (1981); S.H. FRANKLIN, *The European Peasantry: The Final Phase* (1969); DAVID LANE, *The End of Social Inequality?: Class, Status, and Power Under State Socialism* (1982); RICHARD T. DE GEORGE and JAMES P. SCANLAN (eds.), *Marxism and Religion in Eastern Europe* (1975); and VERNON MALLINSON, *The Western European Idea in Education* (1980).

(*Economy*): An introduction to European economic history is useful for understanding the modern European economy. The ongoing multivolume series "Cambridge Economic History of Europe," begun in the 1960s under the general editorship of M.M. POSTAN, provides comprehensive surveys. Important historical periods are explored in HARRY A. MISKIMIN, *The Economy of Early Renaissance Europe, 1300–1460* (1975), and *The Economy of Later Renaissance Europe, 1460–1600* (1977); CARLO M. CIPOLLA, *Before the Industrial Revolution: European Society and Economy, 1000–1700,* 2nd ed. (1980; originally published in Italian, 1974); A.G. KENWOOD and A.L. LOUGHEED, *The Growth of the International Economy, 1820–1980* (1983); and M.C. KASER (ed.), *The Economic History of Eastern Europe, 1919–1975,* 3 vol. (1986–87).

General analyses of the economic character of Europe include HUGH CLOUT, *Regional Development in Western Europe,* 3rd ed. (1987); WALTER LAQUEUR, *A Continent Astray: Europe, 1970–1978* (1979); ANDREA BOLTHO (ed.), *The European Economy* (1982); ANDREW J. PIERRE (ed.), *Unemployment and Growth in the Western Economies* (1984); JOZEF M. VAN BRABANT, *Socialist Economic Integration: Aspects of Contemporary Economic Problems in Eastern Europe* (1980); ALAN H. SMITH, *The Planned Economies of Eastern Europe* (1983); and PAUL STONHAM, *Major Stock Markets of Europe* (1982). For current information on a diversity of economic topics, UNITED NATIONS, *Economic Survey of Europe* (annual), is useful. European agriculture is discussed in MICHAEL TRACY, *Government and Agriculture in Western Europe, 1880–1988,* 3rd ed. (1989); RUTH ELLESON, *Performance and Structure of Agriculture in Western Europe* (1983); KARL-EUGEN WÄDEKIN, *Agrarian Policies in Communist Europe* (1982); and ORGANISATION FOR ECONOMIC CO-OPERATION AND DEVELOPMENT, *Prospects for Agricultural Production and Trade in Eastern Europe,* 2 vol. (1981–82). Industry, technology, and energy are the special focus of GEOFFREY SHEPHERD, FRANÇOIS DUCHÊNE, and CHRISTOPHER SAUNDERS (eds.), *Europe's Industries* (1983); and GEORGE W. HOFFMAN, *The European Energy Challenge* (1985).

WILLIAM ASHWORTH, *A Short History of the International Economy Since 1850,* 4th ed. (1987), provides an introduction to the idea of economic cooperation; and cooperation is further explored in JULIET LODGE (ed.), *Institutions and Policies of the European Community* (1983); PETER LUDLOW, *The Making of the European Monetary System* (1982); DENNIS SWANN, *Competition and Industrial Policy in the European Community* (1983); and VALERIE J. ASSETTO, *The Soviet Bloc in the IMF and the IBRD* (1988). (T.M.P.)

Special geographic features: Literature on the geographic features of Europe is often sketchy or technical. For general overviews of the features discussed in the article, the reader is advised to turn to books cited above in the *Physical and human geography* section of the bibliography.

(*Landforms*): General descriptive studies of the Alps include PAUL VEYRET and GERMAINE VEYRET, *Au Coeur de l'Europe, les Alpes* (1967), and PAUL VEYRET, *Les Alpes* (1972); GÜNTER GLAUERT, *Die Alpen, eine Einführung in die Landeskunde* (1975); and *The Alpes* (1984), an illustrated multilanguage work published under the auspices of the 25th International Geographical Congress. Works on physical geography include LÉON W. COLLET, *The Structure of the Alps,* 2nd ed. (1935, reprinted 1974), which sets forth the theory of the nappes; ERNST KRAUS, *Die Baugeschichte der Alpen,* 2 vol. (1951), which provides a geologic synthesis; and ALBRECHT PENCK and EDUARD BRÜCKNER, *Die Alpen im Eiszeitalter,* 3 vol. (1901–09), which traces

the history of glaciation. For human geography, see PIERRE GABERT, *Les Alpes et les états alpins* (1965); MICHEL CÉPÈDE and E.S. ABENSOUR, *Rural Problems in the Alpine Region, an International Study* (1961); and PIER PAOLO VIAZZO, *Upland Communities: Environment, Population, and Social Structure in the Alps Since the Sixteenth Century* (1989). PIERRE GEORGE and JEAN TRICART, *L'Europe centrale* (1954), includes information on economic development of the region in the first half of the 20th century; and LOUIS CHABERT, *Les Grandes Alpes industrielles de Savoie: évolution économique et humaine* (1978), is a regional socioeconomic analysis. Other regional economic studies include PAUL VEYRET and GERMAINE VEYRET, *Atlas et géographie des Alpes françaises* (1979); AUBREY DIEM (ed.), *The Mont Blanc-Pennine Region* (1984); ERNST A. BRUGGER *et al.* (eds.), *The Transformation of Swiss Mountain Regions* (1984), a detailed survey; AUBREY DIEM, *Switzerland, Land, People, Economy* (1986); BERNARD JANIN, *Une Région alpine originale, la Val d'Aoste,* 2nd rev. ed. (1976), a descriptive work with an economic focus; and ELISABETH LICHTENBERGER, *The Eastern Alps* (1975), a brief description in the series "Problem Regions of Europe"; and MARY L. BARKER, "Traditional Landscape and Mass Tourism in the Alps," *Geographical Review* 72(4):395–415 (October 1982). Specific features of the Alpine economy, especially agriculture, are addressed in JOHN FRÖDIN, *Zentraleuropas alpwirtschaft,* 2 vol. (1940–41); and H. AULITZKY, *Endangered Alpine Regions and Disaster Prevention Measures* (1974). The historical character of the region is explored in PAUL GUICHONNET (ed.), *Histoire et civilisations des Alpes,* 2 vol. (1980); and LUDWIG PAULI, *The Alps: Archaeology and Early History* (1984; originally published in German, 1980). (A.Di.)

Literature on the Apennines includes D. POSTPISCHL (ed.), *Catalogo dei terremoti italiani dall'anno 1000 al 1980* (1985), a scientific catalog of earthquakes, with an extended abstract in English that provides information on geologic characteristics of the range; CALVINO GASPARINI, ENRICO GIORGETTI, and MAURIZIO PAROTTO, *Il terremoto in Italia: cause, salvaguardia, interventi* (1984), a study of the seismic hazards in the region and of protective measures against them; SANDRO PIGNATTI, *Flora d'Italia,* 3 vol. (1982), a discussion of the major plants of the area; J.M. SCOTT, *A Walk Along the Apennines* (1973), which offers a description of views and localities; and ROLAND SARTI, *Long Live the Strong: A History of Rural Society in the Apennine Mountains* (1985). Works that contain detailed geologic information on the Apennines include L. OGNIBEN, M. PAROTTO, and A. PRATURLON (eds.), *Structural Model of Italy: Maps and Explanatory Notes* (1975), and *Cento anni di geologia italiana* (1981), a centennial publication of the Italian Geological Society. (Ma.P.)

Thorough, though sometimes brief, treatments of the Carpathians are found in regional geographies such as EMMANUEL DE MARTONNE, *Europe centrale,* 2 vol. (1930–31); MÁRTON PÉCSI and BÉLA SÁRFALVI, *The Geography of Hungary* (1964); TIBERIU MORARIU, VASILE CUCU, and ION VELCEA, *The Geography of Romania,* 2nd ed. (1969); JAROMÍR DEMEK *et al., Geography of Czechoslovakia,* trans. from Czech (1971); and IRENA KOSTROWICKA and JERZY KOSTROWICKI, *Poland: Landscape and Architecture* (1980; originally published in Polish, 1969). Specifically on the Carpathians, G.Z. FÖLDVARY, *Geology of the Carpathian Region* (1988), is informative and detailed, though technical. The Carpathian region is one of the three mountain regions discussed in P. SKALNIK, "Uneven and Combined Development in European Mountain Communities," pp. 123–154 in DAVID C. PITT (ed.), *Society and Environment, the Crisis in the Mountains* (1978). (J.A.K.)

Research articles on the Pyrenees appear in such journals as *Pyrénées* (quarterly), published by the Musée Pyrénéen du Château-Fort de Lourdes; *Revue géographique des Pyrénées et du Sud-Ouest* (quarterly); *Annales du Midi* (five times a year); and *Pirineos: publicación de la Estación de Estudios Pirenaicos* (annual). General surveys include HENRY MYHILL, *The Spanish Pyrenees* (1966); FRANÇOIS TAILLEFER (ed.), *Les Pyrénées: de la montagne à l'homme* (1974); GEORGES VIERS, *Les Pyrénées,* 3rd ed. (1973); and CLAUDE DENDALETCHE, *Pyrénées* (1982). ROGER HIGHAM, *Road to the Pyrenees* (1971); and J.M. SCOTT, *From Sea to Ocean: Walking Along the Pyrenees* (1969), are descriptive works based on travel experiences. PAUL G. BAHN, *Pyrenean Prehistory: A Palaeoeconomic Survey of the French Sites* (1983); and DANIEL ALEXANDER GÓMEZ-IBÁÑEZ, *The Western Pyrenees: Differential Evolution of the French and Spanish Borderland* (1975), are historical geographies. For human geography, see MICHEL CHEVALIER, *La Vie humaine dans les Pyrénées ariégeoises* (1956); LLUÍS SOLÉ I SABARÍS, *Los Pirineos: el medio y el hombre* (1951); and NEIL LANDS, *History, People, and Places in the French Pyrenees* (1980). (F.O.)

Sources on the Urals in Western languages are scarce. I.V. KOMAR and A.G. CHIKISHEV (eds.), *Урал и Приуралье* (1968), is a comprehensive survey of relief, geology, climate, drainage, soils, flora, and fauna of the region, with data on natural resources, economic development, and preservation of the environment. A.A. MAKUNINA, *Ландшафты Урала* (1974), deals specifically with the geomorphology of the region. N.P. ARKHIPOVA and E.V. YASTREBOV, *Как были открыты Уральские горы* (1971), is the history of the discovery and development of the Ural mountain region. B. RYABININ, *Across the Urals,* trans. from Russian (1973), is a descriptive work based on travels in the area. M.T. IOVCHUK and L.N. KOGAN (eds.), *The Cultural Life of the Soviet Worker: A Sociological Study* (1975), offers a glimpse of working-class life in this highly developed industrial region. (Y.V.Y.)

(*Western European drainage systems*): On the Rhine, see WILLIAM GRAVES, "The Rhine: Europe's River of Legend," *National Geographic* 131(4):449–499 (April 1967), based on a voyage aboard a Rhine tanker from Rotterdam to Karlsruhe. GORONWY REES, *The Rhine* (1967), is a longer description, which follows the Rhine from its source to its mouth and includes historical, political, cultural, and economic information. ROYAL INSTITUTE OF INTERNATIONAL AFFAIRS, *Regional Management of the Rhine* (1975), is a collection of scholarly but readable papers on the effects of human activity on the ecology of the river, with analyses of transport, navigation, flood control, pollution, generation of electricity, regional planning, and recreational use. H.J. MACKINDER, *The Rhine, Its Valley and History* (1908), is a classic study by one of the founders of modern academic geography, still worth reading. E.M. YATES, "The Development of the Rhine," *Transactions, Institute of British Geographers,* publication no. 32, pp. 65–81 (1963), examines the physical evolution of the Rhine and its valley from the Oligocene to the end of the Ice Age. ROY E.H. MELLOR, *The Rhine: A Study in the Geography of Water Transport* (1983), surveys the history of navigation on the river. Fuller systematic treatments, which include discussions of the history of economic activity of the region, population dynamics, and political and cultural developments, are ÉTIENNE JUILLARD, *L'Europe rhénane* (1968); and JEAN DOLLFUS, *L'Homme et le Rhin* (1960). (K.A.Si.)

Much of what has been written on the Rhône is included in general and regional geographies of Switzerland, France, and western Europe, such as AUBREY DIEM, *Western Europe, a Geographical Analysis* (1979). DANIEL FAUCHER, *L'Homme et le Rhône* (1968), provides a historical survey of water resources development and economic conditions. To supplement it, see the earlier exhaustive works by a hydrologist of world reputation, MAURICE PARDE, *Le Régime du Rhône: étude hydrologique* (1925), continued in his *Quelques Nouveautées sur le régime du Rhône* (1942). A short account that focuses on economic conditions, from the series "Problem Regions of Europe," is IAN B. THOMPSON, *The Lower Rhône and Marseille* (1975). (A.Di.)

The earliest scientific work on the Seine is EUGÈNE BELGRAND, *La Seine, études hydrologiques: régime de la pluie, des sources, des eaux courantes* (1872), with an accompanying *Atlas* (1873), which is still valuable despite its age. Development of navigation on the river is surveyed in AIMÉ V. PERPILLOU, "Un Exemple de canalisation de rivière: la Seine," pp. 37–49 in the author's *Géographie de la circulation: conditions générales de la navigation intérieure* (1950). JACQUES GRAS, *Le Bassin de Paris méridional* (1963), examines the morphology of the Paris and Loire basins, as well as of the Loing valley and part of the Yonne basin. Useful information on the Seine basin is found in *Les Bassins de la Seine et des cours d'eau Normands* (1975), published by Agence Financière de Bassin Seine-Normandie. Available English-language sources include such travel books as ANTHONY GLYN, *The Seine* (1966); and WILLIAM DAVENPORT, *The Seine: From Its Source, to Paris, to the Sea* (1968). EVELYN BERNETTE ACKERMAN, *Village on the Seine: Tradition and Change in Bonnières, 1815–1914* (1978), is a scholarly examination of history and socioeconomic conditions as influenced by the river. (M.Da.)

(*Central European drainage systems*): Useful works include JOSEF BREU, *Atlas of the Danubian Countries,* 11 issues in 2 vol. (1970–89), a comprehensive, multilingual source on the Danube region's geography; and ANTON SIKORA, LUDOVÍT ÜRGE, and DOMOKOS MIKLÓS, *Danube* (1988). Much of the literature in English on the Danube itself consists of descriptive works based on travel experiences, such as PATRICK LEIGH FERMOR, *Between the Woods and the Water: On Foot to Constantinople from the Hook of Holland: The Middle Danube to the Iron Gates* (1986); and CLAUDIO MAGRIS, *Danube* (1989; originally published in Italian, 1986). Navigation of the river and its influence on the economic development of the region are surveyed in J.P. CHAMBERLAIN, *The Regime of the International Rivers: Danube and Rhine* (1923, reprinted 1968); and STEPHEN GOROVE, *Law and Politics of the Danube* (1964), discusses the regulations of navigation and the river's international importance. A number of works survey the region's long historical significance, including EMIL LENGYEL, *The Danube* (1939); JOSEPH WECHSBERG, *The Danube: 2000 Years of History, Myth, and Legend*

(1979); and SPIRIDON G. FOCAS, *The Lower Danube River in the Southeastern European Political and Economic Complex from Antiquity to the Conference of Belgrade of 1948,* trans. from Romanian (1987). (P.G.P.)

Materials in English on the Elbe, Oder, and Vistula rivers are scarce. Two brief works on the Elbe are K. SCHMIDT, "Hydrological Structure of the Federal Republic of Germany," pp. 31–39 in HANS-JÜRGEN KLINK and HERBERT LIEDTKE (ed.), *Physical Geography in the Federal Republic of Germany* (1984); and G. LUTTIG and K.-D. MEYER, "Geological History of the River Elbe, Mainly of Its Lower Course," pp. 1–19 in P. MACAR (ed.), *L'Évolution Quaternaire des bassins fluviaux de la mer Nord méridionale* (1974). The Elbe's regime is discussed in FRANKDIETER GRIMM, "Das Abflussverhalten in Europa, Typen und regionale Gliederung," *Wissenschaftliche Veröffentlichungen des Deutschen Instituts für Länderkunde* 25/26: 18–180 (1968). A.C. SEMMLER (ed.), *Der Elbstrom, von seinem Ursprunge bis zu seiner Mündung in die Nordsee* (1845, reprinted 1984), is a comprehensive work. (F.G.)

The only substantial works providing comprehensive coverage of the Oder and Vistula are in Polish and include JULIUSZ STACHÝ (ed.), *Atlas Hydrologiczny Polski,* 2 vol. (1987), containing maps and tables; and ZDZISLAW MIKULSKI, *Zarys hydrografii Polski* (1965), which, though dated, is still considered the fundamental professional study. ANDRZEJ GRODEK *et al.* (eds.), *Monografia Odry* (1948), is the standard source for the Oder. Useful information is also found in DON E. BIERMAN, *The Oder River: Transport and Economic Development* (1973), focusing on shipping and navigation. Surveys of the Vistula include ANDRZEJ PISKOZUB (ed.), *Wisła, monografia rzeki* (1982); and ALEKSANDER TUSZKO, *Wisła przyszłości* (1977). LESZEK STARKEL (ed.), *Evolution of the Vistula River Valley During the Last 15000 Years,* trans. from Polish, 2 vol. (1982–87), explores the geomorphology of the area. JAN STYCZYŃSKI, *Vistula, The Story of a River* (1973; originally published in Polish, 1973), is a descriptive pictorial work. JAN CZARNECKI, *The Goths in Ancient Poland: A Study on the Historical Geography of the Oder–Vistula Region During the First Two Centuries of Our Era* (1975), is a concise examination of events in relation to the geographic setting. (Je.P.)

(*Eastern European drainage systems*): The Dnepr, Don, and Volga rivers are often treated together because of their physical and economic interaction. Survey information is found in such general sources as NATIONAL GEOGRAPHIC SOCIETY, *Great Rivers of the World* (1984); MICHAEL T. FLORINSKY (ed.), *McGraw-Hill Encyclopedia of Russia and the Soviet Union* (1961); S.V. KALESNIK and V.F. PAVLENKO (eds.), *Soviet Union: A Geographical Survey* (1976; originally published in Russian, 1972); and, in Russian, M.I. LVOVICH, *Реки СССР* (1971). The following works study the influence of civilization and human interference on riverine biology, ecology, and river flow: I.A. SHIKLOMANOV, *Антропогенные изменения водности рек* (1979); S.L. VENDROV, *Проблемы преобразования речных систем СССР,* 2nd rev. ed. (1979); A.B. AVAKYAN and V.A. SHARAPOV, *Водохранилища электростанций СССР* (1962), focusing on water reservoirs and hydroelectric power plants; F.D. MORDUKHAI-BOLTOVSKOI (ed.), *The River Volga and Its Life* (1979; originally published in Russian, 1978), on the flora and fauna of the Volga and their changes; PHILIP P. MICKLIN, "Environmental Costs of the Volga–Kama Cascade of Power Stations," *Water Resources Bulletin* 10(3):565–572 (1974), and a longer article by the same author, "International Environmental Implications of Soviet Development of the Volga River," *Human Ecology* 5(2):113–135 (June 1977); and S.L. VENDROV and A.B. AVAKYAN, "The Volga River," pp. 23–38 in GILBERT F. WHITE (ed.), *Environmental Effects of Complex River Development* (1977).

There are a number of writings describing travels along the Russian rivers and providing political and social insights: MARVIN KALB, *The Volga: A Political Journey Through Russia* (1967), originated as a television documentary; HOWARD SOCHUREK, "The Volga, Russia's Mighty River Road," *National Geographic* 143(5):579–613 (May 1973), reports a trip by an experienced journalist; and DANIEL R. SNYDER, "Notes of a Visit to the Middle Volga," *Soviet Geography* 21(3):180–183 (1980), describes a cruise on the Volga and Don and visits to the major cities of the area. The many relevant historical works include the following: RICHARD G. KLEIN, *Man and Culture in the Late Pleistocene* (1969), which deals with the Stone Age civilization of the Don River valley; BORIS A. RAEV, *Roman Imports in the Lower Don Basin,* trans. from Russian (1986), based on the result of the archaeological excavation in the Don River region; ROBERT PAUL JORDAN, "Viking Trail East," *National Geographic* 167(3):278–317 (March 1985), which explores the role of the Volga and Dnepr in the founding of the early Russian state; ELVAJEAN HALL, *The Volga: Lifeline of Russia* (1965), a concise historical work; WILLIAM T. ELLIS, "Voyaging on the Volga amid War and Revolution: War-Time Sketches on Russia's Great Waterway," *National Geographic* 33(3):245–265 (March 1918), which focuses on the events of the first two decades of the 20th century; MAYNARD OWEN WILLIAMS, "Mother Volga Defends Her Own," *National Geographic* 82(6):793–811 (December 1942), which explores life along the Volga in the period before World War II; ANNE D. RASSWEILER, *The Generation of Power: The History of Dneprostroi* (1988), which surveys the construction of the power plant on the Dnepr; and BORIS SHIROKOV (comp.), *The Undying Tradition: Folk Handicrafts in the Mid-Volga Region,* trans. from Russian (1988), which explores the cultural tradition influenced by the great Russian rivers. (P.P.M.)

European History and Culture

The history of Europe is the story of the growth, development, and spread of a distinctive culture from its origins within a small geographical area at the western end of the Eurasian landmass. Economic, political, and social events influenced the development of that culture, and periods of harmony alternated with periods of discord among the various European peoples. From very early times, however, Europeans showed the determination to spread their civilization beyond its geographic home.

The Hellenistic and Roman empires both influenced and were influenced by the peoples they conquered and ruled. Northern European tribes (the so-called barbarians) migrated across the continent in the early centuries AD, and the meeting of northern and Mediterranean peoples resulted in a new, distinctive culture. "Christendom" was born through the spread of a new religion, and the expansion of the Christian faith was accompanied by the spread of the new culture. Later explorations were undertaken for economic and political reasons as well as continuing missionary efforts, but these too resulted in the enrichment and increasing influence of European civilization (see also EUROPEAN OVERSEAS EXPLORATION AND EMPIRES, THE HISTORY OF).

Economic resources, favourable geographic and climatic conditions, and the size of the population were among the factors that allowed this civilization to flourish. (For a discussion of the physical and human geography of the continent, see EUROPE.) By the beginning of the modern period, Europeans had spread their society and institutions throughout the world, and North and South America, Australia, and New Zealand were largely European in cultural tradition. The successful spread of the culture led, however, to the development of societies that in the 20th century began to compete with Europe for economic power and political influence. (Ed.)

For coverage of related topics in the *Macropædia* and *Micropædia,* see the *Propædia,* sections 912, 921, 923, 961, 962, 963, 971, and 972.

This article is divided into the following sections:

Prehistory

SPREAD OF NEOLITHIC FARMING COMMUNITIES

Asian and indigenous influences

Agriculture and stock raising, the economic basis of peasant and ultimately of urban life, first appeared in the Aegean about the end of the 7th millennium BC but did not reach the more remote parts of temperate Europe for another 2,000 or in places even 3,000 years. Although settled life based on farming had been developed earlier in parts of southwestern Asia, Europe played a far from passive role. Horses, for instance, were almost certainly domesticated first in southern Russia and dogs in northern Europe; and it may even be that cattle were first tamed in southeastern Europe. Again, while it is true that many elements of material culture, notably pot making and the equipment used in harvesting agricultural crops, were invented earlier in southwest Asia, there was certainly no question of the spread of a single, uniform culture over the European continent. The development of Neolithic farming communities, which lay at the very basis of European civilization, was as complex as it was prolonged, and the diverse pattern to be found in the archaeological record reflects considerable variety in the culture of the indigenous Mesolithic population.

First phase. Communities of mixed farmers appeared in mainland Greece and on Crete about 8,000 years ago. Their most visible memorials are the mounds, or tells, formed, as in southwest Asia, by the disintegration of settlements of mudbuilt houses rebuilt generation by generation on permanently occupied village sites. The artifacts from such settlements—the handmade pots, clay figurines of women, stamps or seals, reaping knives, querns, and polished stone axes—resemble in their general form and character those from Syria, Iraq, and Iran. Yet the pots from Greece have their own idiosyncrasies of style. The vessels with simple, geometric, painted designs that accompany plain wares from this period in Thessaly or western Macedonia differ from comparable Asiatic wares and contrast even more strongly with the deeply incised wares from early levels at Knossus in Crete, whose affinities lie rather in Anatolia.

Second and third phases. By the middle of the 6th millennium permanent tell settlements had begun to grow up in the southern Balkans. Pottery and ancillary objects in the Starčevo-Körös style occur with minor local variations over a territory extending from the Adriatic coast of Yugoslavia, across to Bulgaria and Romania, and as far as the Prut River in present-day U.S.S.R. The main characteristics of this extensive culture are common to those earlier established in Greece, and it is significant that some of its distinctive features, such as the prevalence of surface roughening or rustication and the occasional use of naturalistic plastic ornamentation, appear on pottery from Greek Macedonia. The middle of the 5th millennium witnessed the expansion of farming economy over a territory centred on middle Europe, but extending to the Rhineland, the Low Countries and northern France in the west, to Hannover and Silesia in the north, and in the east outflanking the Carpathians as far as the western Ukraine. This culture, called Danubian, used pottery ornamented by pairs of parallel lines arranged in spiral or meander patterns. The Danubian peasants lived in communities very similar to large modern villages in the same territories. Their rectangular farmhouses, commonly up to 30 or even 40 metres long, were built on massive timber frames and apparently included storage space and possibly stalls. Their settlements were not marked by tells as those of the Starčevo-Körös and Aegean culture areas. This was due in part to the fact that it was no longer practicable in more temperate latitudes to build in sun-dried brick or *pisé* but in part also to the fact that the first peasants to occupy the loess of middle Europe appear to have practiced a form of shifting agriculture that involved frequent changes of settlement. In addition to practicing the same form of economy, living in the same sorts of houses, and making the same kind of pottery, the Danubians everywhere favoured polished stone adz blades for the working of timber, buried their dead in crouched positions in inhumation cemeteries and, at least in the later stages of their culture, were careful to provide them with ornaments that were made from the *Spondylus gaederopus* mussel.

Danubian culture

Fourth phase. The fourth phase in the expansion of farming economy in Europe can be studied in three main areas. In the eastern area a new peasant culture, the Boian, grew up in Romania beyond the limits of the Starčevo-Körös area; it used distinctive forms of pottery that were decorated by surface rippling, painting, and by excised or incised linear designs. To the north of the Boian culture, and owing something to its inspiration as well as to the inspiration of the Danubian, another one, called after Cucuteni and Tripolye, developed between the Seret and the Bug rivers with an extension to the Dnepr. The pottery of this culture was fired in well-controlled ovens to a red or orange colour after having been decorated in curvilinear designs that were painted onto or grooved into the surface. Its makers occupied rectangular houses that they grouped into substantial villages. In some of these villages the houses were arranged radially. Kolomiishchina, near Kiev, comprised a circular setting of about 39 houses with others in the middle; another at Vladimirovka, also near Kiev, had at least 162 houses in five concentric rings.

On the North European Plain during the 4th millennium, it appears that the hunter-fisher population was influenced by the Danubian peasants to the immediate south. The immediate outcome was the Ertebølle-Ellerbek culture, based on a mixed hunter-farmer economy and marked in the archaeological record by pointed based pottery and specific forms of flint and antler artifacts. The end of the

The Funnel-Neck Beaker industry

4th millennium saw the emergence of the Funnel-Neck Beaker industry, a farming economy extending from what is now The Netherlands across Poland and as far north as southern Norway and middle Sweden.

The Megalithic cult. At approximately the same time, a distinct cultural province developed in western Europe over a territory which included much of Switzerland, France, the British Isles, and Iberia. Excavation of the waterlogged deposits of the Swiss lakeside settlements belonging to the Cortaillod culture have yielded particularly full information about subsistence and crafts, such as weaving and embroidery, generally absent from the archaeological record. More significant is the region's contribution to the spiritual life of the time, as regards both funerary ritual and public ceremonial activities. The most numerous visible monuments dating from the 3rd millennium and the centuries either side of it are chamber tombs, sometimes cut out of the living rock, more usually built from megalithic blocks packed around with smaller stones, and held in place by overlying mounds. The construction of such tombs, designed as burial places for successive generations of families or clans, involved a physical and social effort comparable to that implied by the building of churches in early historic times and implies well-disciplined religious emotion. Some insight into the nature of the Megalithic cult is provided by the symbolic designs pecked, carved, or painted on stones incorporated into megalithic structures. The spread of this cult can hardly be accounted for in simple terms of diffusion, still less of wholesale ethnic movements. The variety of tomb forms and the varying form and incidence of symbolic art point to intense local and regional development and the transmission of ideas over a rather long time. It is significant that by and large the grave goods relate to the indigenous cultures.

In addition to funerary structures, these people erected single, standing stones, or menhirs, alignments and other elongated structures, and circular monuments, sometimes on a massive scale. The most impressive alignments are

Menhirs

those at Carnac, Brittany, comprising nearly 3,000 menhirs in parallel rows over a distance of between three and four miles. Smaller alignments occur in southwest England. The British Isles have many circular settings of menhirs or heavy timbers dating from this period; the best known example is Stonehenge.

The closing centuries of the 3rd and the opening ones of the 2nd millennium were marked by the widespread adoption over much of north, central, and eastern Europe of perforated stone battle-axes. This was during the time when farming economy spread in European Russia far beyond the forest steppe (to which the Tripolye peasants had been confined) over the southern Taiga up to the Oka-Volga basin, the homeland of the Fatyanovo culture. In northern Europe the Funnel-Neck Beaker culture gave place to a variety of local battle-ax-using groups all associated with single-grave burial, but in other respects showing many differences. Here, again, it seems that mixed farming continued to provide the basis of subsistence, and there is evidence that a light plow was already in active use as well as disk-wheeled wagons which likewise were drawn by yoked oxen. The construction of collective tombs was abandoned about the same time in western Europe. The

The Bell-Beaker culture

rapid and widespread occurrence over large parts of central and western Europe of pots of bell-shaped beaker form, decorated in horizontal zones by finely toothed stamps, suggests the movement of small mobile groups; and there is evidence that these actively sought out copper and gold.

The circumpolar culture. North of the farming zone, extensive parts of circumpolar Europe continued to support communities that lived by hunting, fishing, and gathering. Although there was some overlapping and contact, the culture of the circumpolar people was quite distinct from that of the peasant peoples of the rest of Europe. Even the art of potting, which they took over from their neighbours, was used to make distinctive ovoid pots reminiscent of basket forms; and the deep pits, which together with stamped comb imprints served to decorate these vessels, themselves stemmed, like much else in the culture, directly from Mesolithic antecedents. The widespread use of polishing was another archaic element originally developed in relation to bone but now applied to a variety of knives, projectile heads, and hollow-ground adzes of slate and stone. As hunters the people were accustomed to movement. During the extensive period of snow cover they used heavy sledges, presumably drawn by dogs, for shifting camp and skis for hunting and personal movement. Skin-covered boats represented on rock engravings were probably used for hunting seals and porpoises and for fishing. Dependence on hunting helps to account for the keen observation shown in the representation of animals that played a leading role in their graphic art. Engravings, sometimes life-size, of game animals and carvings of animal heads on a variety of artifacts, from perforated stone axes to the handles of wooden ladles, reveal a mentality totally opposed to that of the peasants to the south, whose art was mainly abstract and repetitive. Burial rites were also distinctive, taking the form of interment in cemeteries, the body fully clothed and in an extended position.

THE BRONZE AGE (C. 2500–C. 650 BC)

The beginnings of European metallurgy

While the peasants who pioneered farming economy in remote territories of the temperate zone were restricted to stone, metallurgy was already being practiced in parts of southeastern Europe and Iberia. The smelting of metallic copper from its ores was in itself a remarkable feat in the history of technology; it marked the first of what was to prove a long series of operations by which men were able to conjure up new materials, and it is worth emphasizing that to obtain ore, smelt it, and convert it into artifacts implied a more advanced degree of specialization of labour than was needed for a technology based on working flint or stone. It is no accident that in the Old World metallurgy should have been one of the features persistently found in the context of the earliest literate civilizations. Indeed, it has commonly been assumed that the appearance of metallurgy in prehistoric barbarian societies can only be explained in terms of their contacts with early centres of civilization. In the case of southern Iberia, eastern Mediterranean and specifically Cycladic (south Aegean) influence has been detected at copper-working settlements dating from the mid-3rd millennium; the defenses of Los Millares, for instance, display bastions identical in pattern with those of Chalandriani on Syros (Greece). Here it looks as though there were "factories" established for the prime purpose of securing supplies of copper for Aegean markets. The initial impetus for opening up the copper resources of Transylvania may also have come from the demands of Aegean and possibly even Asiatic markets. It is no less true that the exploitation of copper ores in southeastern and central Europe underwent its own development. Whereas in Iberia the initial impetus was soon lost, the opening up of ores in Transylvania led to the development of cuprous industries, first in Bohemia, central Germany, and the east Alps, and ultimately as far away as Ireland, where copper deposits were first sought out by the Bell-Beaker prospectors at about the end of the 2nd millennium. These copper resources catered wholly or in large measure to barbarian markets. Thus shafthole axes and ax-adzes of Transylvanian copper are found predominantly in Transylvania and the Danubian basin both above and below the Iron Gate, though a few reached the Elbe basin; spiral armbands and embossed disks reached as far north as Denmark, where they occur at the end of the local Early Neolithic. Again, flat axes of trapezoidal plan of the form made from east Alpine and central German copper found their way as far north as Scania (Scandinavia).

The earliest bronze industries

Central Europe was also the original focus of the local use of bronze alloys that not only resulted in tougher tools, but, by making it easier to use valve molds, made it possible to produce more complex forms. The new industries—those of Únětice on the Upper Elbe, of Tomaszów in Poland, of Kistapostag and Perjámos in Hungary, of Straubing on the Upper Danube, and of Adlerberg on the Middle Rhine—produced a variety of bronze items, including daggers, neck ornaments, and pins for securing garments. The occurrence of similar ornaments at Byblos in Lebanon and Ugarit in Syria dating from *c.* 2000–1800 BC suggests continued contact between middle Europe

and areas of higher culture to the southeast, but this does not mean that one must attribute the advanced bronze industries of middle Europe around the middle of the 2nd millennium to stimulus from this direction. The Únětice and allied metal industries rested on a middle European tradition already many hundreds of years old. Again, regional bronzeworking traditions were developing at this time in many parts of Europe as far apart as Spain, where metallurgy revived in the El Argar culture, and Britain and Ireland, which gave birth to a distinctive Hiberno-British style.

The use of tin as an alloy laid a great emphasis on organized systems of exchange, since this metal was one with a more restricted distribution than copper. These involved the movement not only of ingots but of finished artifacts, as may be seen in the importation of Hiberno-British and middle European forms of ax to Denmark during the final phase of its Stone Age, a period significantly marked above all by flint daggers based ultimately on metal ones too expensive to import in adequate numbers. It is interesting to note how the Aegean and by this time the specifically Mycenaean world became enmeshed in this wide-ranging system of exchange, due in all probability to their need for central European or Cornish tin. The occurrence of segmented faience beads, of a kind invented in Egypt but probably made also in the Aegean, in the territory of the Únětice and allied cultures, and also notably in Wessex, a territory that probably controlled supplies of Cornish tin, is suggestive of Mediterranean influence in the north. But the importance of the Mycenaeans in the European Bronze Age should not be overemphasized. The indirect effects of the play of the Mycenaean market may have been important—for instance, the Mycenaean demand for amber probably played its part in the rise of the Nordic Bronze Age by making it possible for the Danes to import central European bronzes and ingots—but metalsmiths in several parts of barbarian Europe were producing bronzes that compare favourably with anything produced in the Aegean at the time; and faience beads of local shapes were produced even in northern Britain.

The loss of Mycenaean markets was no longer enough to affect the prosperity of central Europe. Copper was mined on an increasing scale and, being cheaper, was used for tools, armour, and containers, as well as for weapons and ornaments. The later stages of the Bronze Age also were marked by a greater emphasis on cremation and the burial of ashes in urns. Urnfield burial, together with many innovations in industry and armament, was adopted over extensive tracts of Europe from Iberia to eastern Europe and from Italy to southern Scandinavia. How much this was due to the normal process of diffusion by which innovations spread over extensive territories in the course of time, and how much to ethnic movement, is still obscure. Yet it is hard not to believe that raids by armed marauders did not play a part more especially in relation to the rich territories of the Mycenaean world. Already in the 15th century BC heavy slashing swords, with flanged grips to secure the handle, were being made in east central Europe, and such swords were among the innovations that spread widely with the adoption of urnfield burial. The sudden appearance of these in mainland Greece, Crete, and Cyprus has been identified by some scholars with intrusion f the Dorians mentioned by Thucydides as entering the Peloponnesus at a time when archaeology speaks of the destruction of Mycenaean civilization. Egyptian records tell of raiders from the north as early as the 13th century BC and, in the ensuing centuries, the east Mediterranean region as a whole underwent a time of troubles, a period that witnessed the decline not only of the Mycenaean but also of the Hittite power. Other peoples were on the move at this time and may well have been more important, but it looks as though pressure may have come in part from the north. (J.G.D.C./Ed.)

Urnfield cultures

The expansion of Urnfield cultures in Europe.

The "barbarian" peoples

The interrelated cultures of ancient Europe that were fully established by about 1000 BC incorporated indigenous traditions and stocks, from region to region, but from this time the archaeological evidence in cultural zonation leads on ever more clearly to the appearance in history of the European barbarian peoples.

CELTS

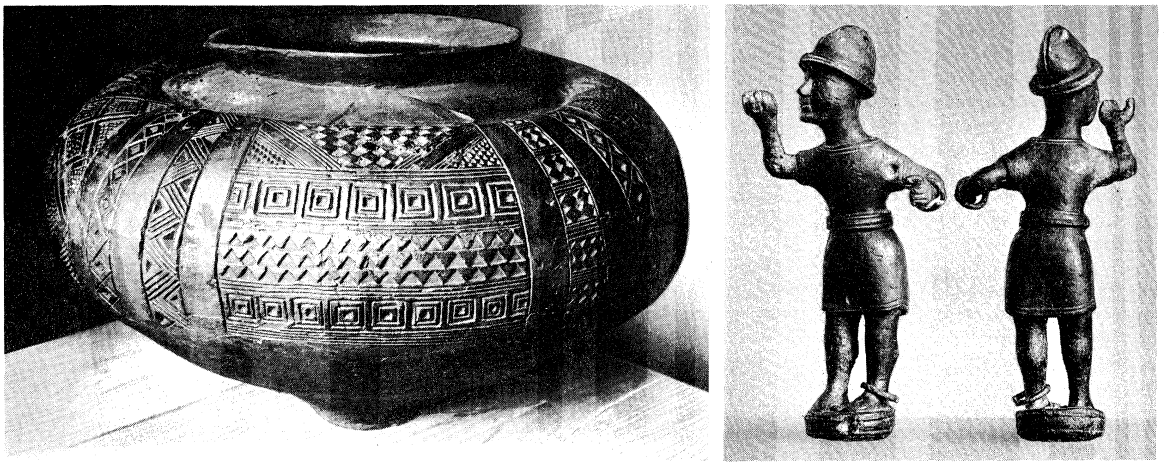
The Celts were the first prehistoric people to rise from anonymity in the European territories north of the Alps. Until the middle of the first millennium BC nothing was known of them by the civilized Mediterranean world. For the Greeks they were *Keltoi;* the Romans called them Gauls. At the time when these Celts had become the predominant people in the barbarian world they were settled throughout a great part of Europe, extending from Ireland and Britain to the Balkans, and even as far as Anatolia. They were a numerous people of considerable political and military significance. Their creative activity completed the prehistoric development of Europe; by the 4th century BC Greek writers ranked the Celts, together with the Scythians and the Persians, among the most numerous "barbarian" peoples of the then known world. Although they never formed a unified ethnic group or a great empire and were split into many tribes with different dialects, they became an important factor in the development of a specifically European civilization.

Early Celtic settlements. Archaeological investigation strongly suggests that the area in which the historical Celtic tribes developed comprised part of present-day France, southern Germany, and adjacent territory reaching as far as southern and central Bohemia. It is possible to trace their origins as far back as the Bronze Age Tumulus culture, which reached its high point about 1200 BC. Various cultural components were unified in the succeeding Urnfield culture (12th–8th centuries BC). This was followed by the Hallstatt period (7th–6th centuries; named after the burial ground near Hallstatt in the Salzkammergut in upper Austria). During that time other peoples known to history made their appearance in Europe: the Illyrians in the southeast and the Germans in the north.

From the Urnfield period on, archaeological evidence of the Celtic confederation northwest of the Alps is increasingly noteworthy, producing, in the later Urnfield stage, a fresh phase of Tumulus burials, some of these being located in areas where Celtic power later became predominant.

Burial finds

Burial grounds of the Hallstatt period comprise chamber graves containing four-wheeled wagons, splendidly decorative yokes and harness fittings, and a large amount of pottery and other artifacts, which indicate a complex burial ceremony. Such elaborate burials, found in Bohemia, throughout southern Germany, and in northeastern France, would appear to be those of chieftains or



Artifacts of Celtic cultures.

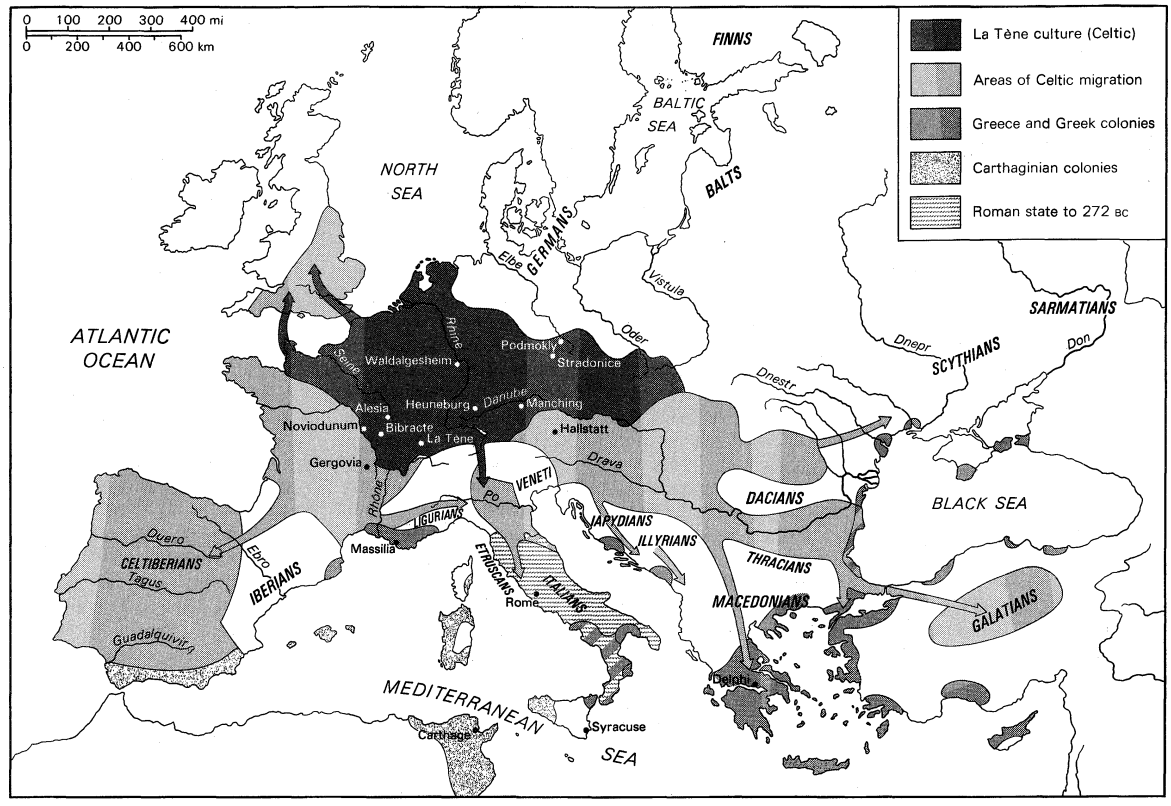
members of a leading oligarchy. To this period there may also be ascribed the first known fortified castles of western central Europe. The fortified hill residence at Heuneburg on the Danube, dating from the late Hallstatt period, was rebuilt at least five times. One phase shows a mature building technique including the use of brick masonry in towerlike bastions, a Mediterranean characteristic quite alien to the region. Adjacent to Heuneburg is a group of chieftains' barrows, one of which, Hohmichele, has wood-lined chambers and wall draperies and contains a four-wheeled wagon, gold decorations, and jewelry. It is clear that imports from the south, such as amphorae of wine or Greek Black Figure pottery, were common. A fortified hill site on Mt. Lassois near Châtillon-sur-Seine, France, in which Greek pottery was found, was built at the junction of long-distance trade routes. A bronze vessel, also of Greek manufacture, was found in the neighbouring grave of a Celtic princess.

Evidence of wealth

The wealth of the Celtic princes seems to have been very great, some of the barrows (mound graves) being particularly richly furnished for their size. That at Apremont (Haute-Saône), with an average diameter of 70 metres, contained a wagon, gold objects, a crown, brooches, and a vessel. The grave at Pflugfelden near Ludwigsburg (Württemberg) was the burial of a man in a splendid robe and a golden crown; the hilt of his dagger was inlaid with amber. By the 6th century the wealth of the ruling Celtic groups was well established and they were able to import Etruscan wares, the merchants of Massilia (Marseille) acting as distributing agents.

The unusual concentration of early Hallstatt chieftains' burials on the upper Danube and on the upper Rhine as far north as the Neckar River lasts only to the beginning of the 5th century. At that time the Celts were preparing armed raids into the remaining parts of Europe. Thereafter, rich burials are found farther northwest, on the middle Rhine or on the Saar and Moselle rivers. The number and the richness of the burials steadily increased, including two graves at Schwarzenbach that contain two beaked flagons, a vessel in a gold openwork casing, and various gold ornaments showing mask motifs.

The La Tène culture. Artifacts from the La Tène culture, which developed in the 5th century BC, are found in the barrows of the middle Rhine and of Champagne in France. From the second half of the century at the latest native Celtic craftsmen were adapting southern models and developing their own style with increasing confidence. The geometric patterns found in ornament of the Hallstatt period give place to zoomorphic and floral designs, supplemented by human-head motifs or masks.



The Celtic migrations.

From Grosser Historischer Weltatlas, vol. 1, *Vorgeschichte und Altertum* (1972); Bayerischer Schulbuch-Verlag, Munich

A remarkable genre of the style are the bronze-mask brooches, adorned with human and animal masks varying from lifelike to fantastic portrayal. Such brooches have been found at Panenský Týnec near Louny (animal mask) and near Manětín-Hrádek in the Plzeň region (imaginative human likeness) in Czechoslovakia and at Parsberg and Oberwittighausen in Germany.

These early La Tène pieces, typical of the second half of the 5th century BC, are still much influenced by southern models. The mature La Tène style, also called the Waldalgesheim style, dates from the second half of the 4th century, and its products are found in chieftains' graves throughout Europe. In the 3rd century the use of jewelry extended to all social classes, and craftsmen became more numerous, no longer working exclusively in the entourage of the rulers. While elaborately linked bracelets and brooches became common ornaments, the skill of leading craftsmen was adapted to ornamenting swords, scabbards, and helmets for the aristocracy.

The development of Celtic art in Britain was quite individual in character. Local workshops and "schools" were established, in which the native craftsmen combined technical skill with a freshness of conception. When the Celtic art of the Continent had passed its zenith, that of Britain continued to flourish, producing a variety of beautiful artifacts, such as gold and silver jewelry, swords and scabbards, shields inlaid with enamel, and bronze mirrors.

Celtic expansion. During the Hallstatt period, the Celts expanded through France to the Iberian Peninsula, to the British Isles, and also to some extent eastward into central Europe. Military expansion was probably due to overpopulation and social tensions. Celtic bands also entered Italy, groups such as the Boii, the Insubres, the Lingones, and the Senones first attacking Etruria, while later groups reached the Adriatic coast and about the year 387 BC (the conventional date is 390) raided and plundered Rome, also penetrating into southern Italy. The Romans later recovered and drove the Celts back to the Alpine foothills, whence some of them withdrew, probably into central Europe.

In the second stream of expansion their raids reached central Europe, the Carpathians, and the Balkans. This expansion was later described by the Roman historian Livy, who recounts how two branches of the Bituriges settled near the Hercynian Forest, a range of mountains of southern and central Germany (under their ruler Sigovesus) and in Italy (under Bellovesus). Literary sources suggest that the Celts reached the Carpathians in the 4th century, later moving into present-day Bulgaria, Romania, Thrace, and Macedonia; they raided the shrine at Delphi, Greece, in 279. One group reached Anatolia, where they settled and gave their name to Galatia. In the 3rd century Celts were serving as mercenaries in Greece, Anatolia, and Egypt.

Incursion of the Cimbri

An important dividing line in the history of the Celts was the incursion of the Germanic Cimbri. Their assault was repulsed by the Boii about 113 BC, somewhere in the neighbourhood of Bohemia. The Cimbri then attacked the Scordisci near Belgrade and later, in association with the Teutoni, attacked several Celtic tribes in the west, penetrating as far as Aquitania in Gaul. Although the Cimbri were defeated by the Romans in the Po Valley at the end of the 2nd century, their incursion into Celtic territory foreshadowed later invasions.

Gaul and Britain. In the 1st century BC Gaius Julius Caesar described Gaul as having three regions, inhabited respectively by the Galli (Gauls, present Central France), the Aquitani (southwestern France), and the Belgae in the north. The Gauls comprised many tribes: the Helvetii in present-day Switzerland, the Sequani and Lingones farther west, the Arverni in Auvergne, the powerful Aedui between the Saône and Loire rivers, and the Bituriges along the Loire Valley. The Celts reached the shores of the Mediterranean later than other parts of Gaul; the Carthaginian commander Hannibal made contact with them there late in the 3rd century BC. In the 1st century, Caesar subdued the Helvetii and other tribes, pressed the Germans back beyond the Rhine, and made two expeditions to Britain. Finally, he suppressed a revolt of Gallic tribes under Vercingetorix. From that time, Gaul was subject to Rome and increasingly open to Romanization. Britain was subjugated in the 1st century AD.

In the 2nd century BC the Romans reached southern Gaul and founded their province Gallia Narbonensis (Provence).

The names of many tribes in the British Isles are known: the Dumnonii in Cornwall, the Dobuni on the upper Thames, and the Ordovices in Wales. About the middle of the 3rd century BC a new wave of immigrants from Gaul introduced the La Tène culture into Britain. Some Belgic tribes (the Cantae, Catuvellauni, Atrebates, Durotriges) settled in Britain in the 1st century BC.

The final phases. From the middle of the 1st century BC the Celtic world was caught in the press of two dangerous forces: the Roman Empire was extending its frontiers to the Rhine and the Danube, while the Germanic tribes were thrusting southward. Even before this time a strong settlement of the Celtic Boii existed in Pannonia, where they had apparently taken refuge after being driven out of Bohemia. After Burebistas, king of Dacia, destroyed the Boii (*c.* 50 BC), the Celts withdrew across modern Switzerland into Gaul. By the end of the century the Celts on the Continent had lost their commanding position and the Rhine and the Danube and were confined to the frontier between the Roman and Germanic worlds.

The Celtic tradition survived most strongly in Britain and Ireland, where its art was still flourishing at the beginning of the Christian Era. Several of its elements were revived in the neo-Celtic art forms of the 7th to 9th centuries AD.

Celtic society. In the eyes of Greeks and Romans, the Celts were remarkable for their height, muscularity, and fair colouring. These were characteristics of the warrior class rather than of the whole population, and skeletal remains point to considerable variations in stature and head form. The 1st-century-BC Greek geographer and historian Strabo describes them as a people who love war and adventure, pleasure and feasts. Information on Celtic institutions is available from various classical authors and from ancient Irish literature. A striking feature, even as early as the La Tène period, is the large number of tribes competing for dominance. Kingship was common among some tribes in the La Tène period. Some kings, however, were elected, and the power of the aristocracy tended to increase, their rule predominating in Gaul in Caesar's time. In Ireland, by customary law, the social system was threefold; king, warrior aristocracy, and freemen farmers. In the later period in the western Celtic world, the strength of the aristocracy was increased and the freedom of common people was diminished by the widespread introduction of clientism, a system by which lesser men placed themselves under obligation to a powerful lord from whom they received protection. As in other Indo-European systems, the family was patriarchal and kingship was recognized by agnatic descent (from a common male ancestor). Landownership was vested in the family, which was also responsible for many social obligations. The household was of the "archaic-joint" type, consisting of a man with his wives, children, and grandchildren. The status of women seems to have varied considerably according to rank and the prosperity of the community.

Druids

The Druids, who were occupied with religious and legal duties, were recruited from families of the warrior class but ranked higher. They offered sacrifices and were responsible for the education of the young nobles, and the sacred oak groves were under their protection. Druidism, still flourishing at the beginning of the Roman occupation of Celtic areas, strongly resisted Romanization and was thus particularly marked out for deliberate suppression. It survived longest in Ireland, where the Romans did not penetrate. Caesar describes the Celtic sacred sites, woods with sacred trees and groves (*loci consecrati*). There is no evidence that they had temples in his time, but these were built later, in the Gallo-Roman period. Cult sites have been found, however, in several places in central and western Europe. An example is at Libenice near Kolīn in Bohemia, excavated in 1959, which had a stone slab for sacrifices. In the centre of the cult area a woman was found buried, with typical La Tène ornaments. Caldrons connected with the cults spread as far as northern Europe, and splendid examples have been found in silver at Gundestrup and at Brå in East Jutland. It is difficult to generalize about Celtic religion and mythology, because each tribe seems to have had its own cults and local deities. There is no firm distinction between gods and heroes; the names of some deities (*e.g.*, Taranis, Teutates, Esus, Lug) antedate the Romanization of Gaul, but later they sometimes became associated with Roman gods. Divine or semidivine pairs and trinities also occurred.

Celtic economy

The basic economy of the Celts was mixed farming, and, except in times of unrest, single farmsteads were usual. All kinds of grain were cultivated, also flax, hemp, beetroot, and several other kinds of vegetables. The grain was stored in special pits or silos deep in the ground or in large jars. Owing to the wide variations in terrain and climate, cattle raising was more important than cereal cultivation in some regions. The prevalence of oak forests encouraged the breeding of pigs, and boar hunts were a popular sport. The wool of Celtic sheep was well known in Rome. Later, Gaul supplied the Roman armies on the Rhine with horses.

Trousers, perhaps an Eastern innovation, were worn by men of the Cisalpine Gaulish tribes from at least the 3rd century BC and are attested in the 1st century BC in Transalpine Gaul, but a belted tunic, or shirt, with a cloak seems to have been the most widespread form of male dress. Women wore a single long garment with a cloak. Coarse linen as well as wool was employed, and bright colours were popular. According to Poseidonius the food of the Celts consisted of bread and meat, either boiled or roasted. Beer, home brewed from barley, was the most common drink; the upper classes also used wine imported from the south. The Celts were hospitable, fond of feasting, drinking, and quarrelling, and incapable of prolonged concerted action. At feasts bards sang the praises of those present, accompanying the song with a lyrelike instrument. The Celts greatly prized music and many forms of oral literary composition.

The earliest Celts had fortified strongholds or chieftains' residences; hill forts (*oppida*), with a considerable concentration of population and production, were constructed from the second half of the 2nd century BC, partly as a result of Germanic pressures. A belt of flourishing hill forts existed in Caesar's time, but his victory led to their decline in Gaul, although many in central Europe were occupied until the end of the last century BC. (J.F./Ed.)

GERMANIC PEOPLES

The origin of the Germanic, or Teutonic, peoples is a problem of profound obscurity. A major cause of the difficulty is the paucity of archaeological finds relating to them in northern Germany and southern Sweden between the end of the Bronze Age (*c.* 500–400 BC) and the 2nd century BC. It may be supposed, however, that in the Late Bronze Age Germanic peoples inhabited southern Sweden, the Danish peninsula, and northern Germany between the Ems and Oder rivers and the Harz Mountains. The Vandals, Gepidae, and Goths migrated from southern Sweden in the closing centuries BC and occupied the area of the southern Baltic coast between the Oder and the Vistula and even beyond to the Passarge (Pasłęka) River. At an early date there was also a migration of Germanic peoples toward the south and west at the expense of the Celtic peoples who then inhabited much of western Germany; the Helvetii, for example, who were confined to Switzerland in the 1st century BC, had once settled areas extending as far as the Main River.

By the time of Julius Caesar, Germans were established west of the Rhine and had reached the Danube in the south. Their first great clash with Romans came at the end of the 2nd century BC, when the Cimbri and Teutoni (Teutones) invaded southern Gaul and northern Italy and were annihilated by Marius in 102 and 101. Although individual travellers from the time of Pytheas onward had visited Teutonic countries in the north, it was not until the middle of the 1st century BC that the Romans learned to distinguish precisely between the Germans and the Celts, a distinction that is made with great clarity by Julius Caesar. It was Caesar who incorporated within the frontiers of the Roman Empire those Germans who had penetrated west of the Rhine, and it is he who provides the earliest extant description of Germanic culture. In 9 BC the Romans pushed their frontier eastward from the Rhine to the Elbe, but in AD 9 a revolt of their subject

Germans headed by Arminius ended in the destruction of the occupying army of P. Quinctilius Varus in the Teutoburg Forest and in the withdrawal of the Roman frontier to the Rhine. In this period of occupation and during the numerous wars fought between Rome and the Germans in the 1st century AD, enormous quantities of information about the Germans reached Rome. When Tacitus published in AD 98 the book now known as the *Germania,* he had reliable sources of information on which to draw.

Distribution of Germans. The principal Germanic peoples were distributed as follows in the time of Tacitus. The Chatti lived in what is now Hesse. The Frisii inhabited the coastlands between the Rhine and the Ems. The Chauci were at the mouth of the Weser, and south of them lived the Cherusci, the people of Arminius. The Suebi, who have given their name to Schwaben, were a group of peoples inhabiting Mecklenburg, Brandenburg, Saxony, and Thuringia; the Semnones, living around the Havel and the Spree rivers, were a Suebic people, as were the Langobardi (Lombards) who lived northwest of the Semnones. Among the seven peoples who worshipped the goddess Nerthus were the Angli (Angles), centred on the peninsula of Angeln in eastern Schleswig. As for the Danubian frontier of the Roman Empire, the Hermunduri extended from the neighbourhood of Regensburg northward through Franconia to Thuringia. The Marcomanni, who had previously lived in the Main Valley, migrated during the last decade BC to Bohemia (which had hitherto been occupied by a Celtic people called the Boii). To the east were the Quadi in Moravia. On the lower Danube were a people called the Bastarnae, who are usually thought to have been Germans. The Goths, Gepidae, and Vandals on the Baltic coast have already been mentioned. Tacitus mentions the Suiones and the Sitones as living in Sweden. He also speaks of several other peoples of less historical importance than those listed here but he knew nothing of the Saxons, the Burgundians, the Franks, and others who became prominent after his time.

New tribes

By the end of the 3rd century AD important changes had taken place. East of the Rhine lived three great confederacies of peoples unknown to Tacitus. The Roman frontier on the lower Rhine now faced the Franks. The Main Valley was occupied from *c.* 260 by the Burgundians, while the *agri decumates* (the area south of the Main River and immediately east of the Rhine) were held by the Alemanni. The Burgundians appear to have been immigrants from eastern Germany. The Franks and the Alemanni may have been confederacies of peoples who had lived in these respective areas in Tacitus' day, though perhaps with an admixture of immigrants from the east. The peoples whom Tacitus mentions as living on the Baltic coast had moved southeastward in the second half of the 2nd century. The Goths now controlled the Ukraine and a large section of the present-day country of Romania; the Gepidae were in the mountains north of Transylvania with the Vandals as their neighbours on the west.

By the year 500 further striking changes had taken place. The Angles and Saxons were in England and the Franks controlled northeastern Gaul. The Burgundians were in the Rhône Valley with the Visigoths as their western neighbours. The Ostrogoths were established in Italy and the Vandals in Africa. In 507 the Franks expelled the Visigoths from most of their Gallic possessions, which had stretched from the Pyrenees to the Loire River, and the Visigoths thereafter lived in Spain until their extinction by the Muslims in 711. In 568 the Lombards entered Italy and lived there in an independent kingdom until they were overthrown by Charlemagne (774). The areas of eastern Germany vacated by the Goths and others were filled up by the Slavs, who extended westward as far as Bohemia and the basin of the Elbe. After the 8th century the Germans recovered eastern Germany, lower Austria, and much of Styria and Carinthia from the Slavs.

Material culture. According to Julius Caesar the Germans were not primarily agriculturists; they were pastoralists, and the bulk of their foodstuffs—milk, cheese, and meat—came from their flocks and herds. But agriculture was not unknown. Grain and a great variety of root crops and vegetables were known to them, though of fruits only the apple was cultivated by them in the Roman period. As for the techniques of agriculture, Caesar and Tacitus are silent on these, but even the Bronze Age rock carvings at Bohuslän in southern Sweden include a picture of an ox-drawn plow.

It must be stressed, however, that cattle were the main source of food for the Germans. There is no reason to think that in the historical period cattle were owned by the clan collectively; they were the private property of individuals, and a man's status was reckoned on the basis of the number of cattle he owned. Both the cattle and the horses of the Germans were of poor quality by Roman standards.

The Iron Age had begun in Germany about four centuries before the days of Caesar, but even in his time metal appears to have been a luxury material for domestic utensils, most of which were made of wood, leather, or clay. Of the larger metal objects used by them, most were still made of bronze, though this was not the case with weapons. Pottery was for the most part still made by hand and pots turned on the wheel were distinctly unusual.

Trade

The degree to which trade was developed in early Germany is very obscure. There was certainly a slave trade and many slaves were sold to the Romans. Such potters as used the wheel—and these were relatively few—and smiths and miners no doubt sold their products. But in general the average Germanic village is unlikely to have used many objects that had not been made at home. Foreign merchants dealing in Italian as well as Celtic wares were active in Germany in Caesar's time and supplied prosperous warriors with wine, bronze vessels, and so on. But from the reign of Augustus onward there was a huge increase in German imports from the Roman Empire. The German leaders were now able to buy whole categories of goods—glass vessels, red tableware, Roman weapons, brooches, statuettes, ornaments of various kinds, and other objects—that had not reached them before. These Roman products brought their owners much prestige, but how the Germans paid for them is not fully known. The amber trade, however, became important after the middle of the 1st century BC, though for the most part it affected eastern Germany alone.

Growth of the *comitatus*

Form of government. The German polity had developed considerably by the time of Tacitus. The rudiments of the state had made their appearance. Power, insofar as it existed at all, was tending to become concentrated and wealth to accumulate in private hands. Perhaps the most remarkable development concerns the "retinue" (*comitatus*). In Caesar's day one of the leading men would announce in the assembly that he proposed to undertake a foray and would call for followers. Whoever was attracted by the proposal would volunteer his services, and when he had done so public opinion would not allow him to withdraw. The relationship between the leader and his followers was a purely temporary one, lasting only for the duration of the raid, and the followers could not be described as dependents of the leader. But in the time of which Tacitus speaks the relationship between the leader and his "companions" (*comites*) had become a permanent one. The leader fed them and kept them about him in peacetime as well as in war. He supplied them with their weapons and horses and with a share in the booty taken during their raids, though in these early times he could not supply them with land, for full private ownership of land hardly existed as yet. The retinue leader thus acquired a military force over which the other warriors had little or no control, and his followers were prepared to fight for him to the death—it was a disgrace for them to survive their leader. The members of the retinues seem nearly always to have been drawn from among the more well-to-do warriors, so that in Tacitus' time the tribal aristocracy appeared to be well on the way to overthrowing the earlier primitive democracy of councils of warriors and to establishing something like state power among the various peoples. But in fact only one Germanic chieftain is known who was able before AD 100 to set up a personal tyranny over his people. This was Maroboduus, who led the Marcomanni from their homes in the Main Valley *c.* 9 BC and settled them in Bohemia. From there he conquered a con-

Maroboduus' kingdom

siderable number of other Germanic peoples between the Elbe and the Vistula, including the Semnones, the Lombards, and the Lugii. But the Cherusci, joined by some of the king's subjects, attacked him in AD 17, overthrew him, and drove him into Roman territory. All other chiefs who attempted in this period to establish monarchies were, so far as is known, defeated.

Many of the peoples who had been prominent in western Germany in the days of Tacitus disappeared from history during the 2nd century and their place was taken by the Franks, Burgundians, Alemanni, and others. Sources for their internal and social history during the 3rd and later centuries are very fragmentary. In general it is not easy to detect any substantial difference in their material civilization or social organization from what Tacitus had described, except that there is little or no evidence for the existence of the general assembly of the warriors among any of the great peoples living along the Rhine and the Danube. Information about the Visigoths is more abundant than information about any of the other peoples and yet nothing is said by the ancient authorities about the Visigothic warriors having the right to assemble together in order to approve or veto the recommendations of their leaders. This suggests that in the 4th century the rank and file of the population had less control over their own affairs than they had had 300 years earlier. Even so, there are few reports in this period of the overthrow of such democratic institutions as still existed or of the establishment of monarchies. The only certain example is that of Ermanaric who ruled the Ostrogoths in the Ukraine as a king in the middle of the 4th century. The monarchy did not become fully established in the Germanic world until German peoples had settled as federates inside the Roman Empire, after which the leaders of the Ostrogoths in Italy, the Visigoths in Gaul and Spain, and the Vandals in Africa became the first Germanic kings. Other famous German chieftains in this period, such as Athanaric and Alaric who lived outside the Roman frontier or whose peoples were not federates settled in the provinces under a treaty (*foedus*) to defend the frontier, seem to have had little more personal authority than the war leaders described by Tacitus. (E.A.T./Ed.)

The absence of monarchies

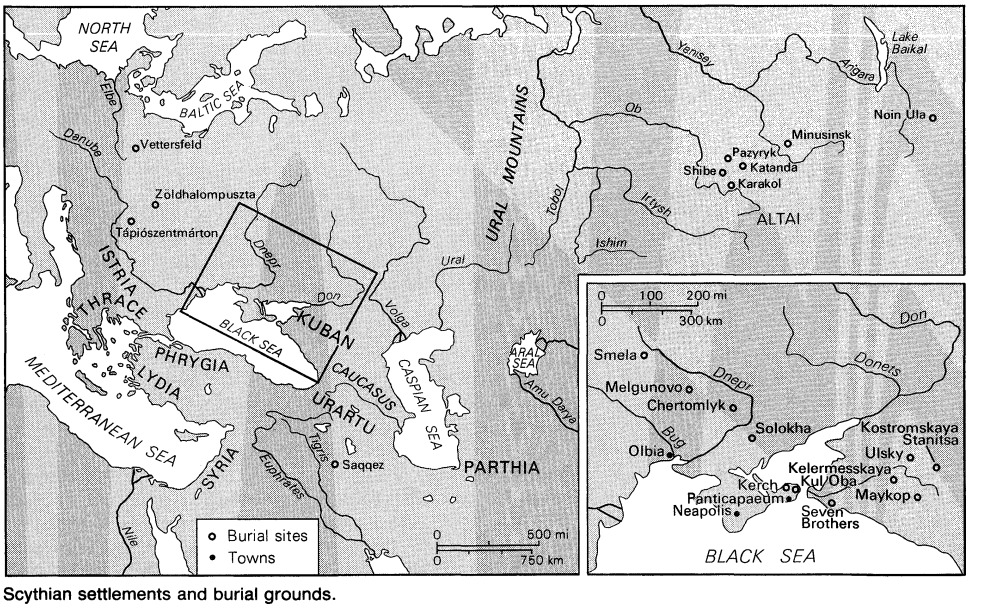
EASTERN PEOPLES

The grasslands that extended from the Black Sea northwestward outside the Carpathian Mountains as far as the Baltic Sea provided at the beginning of the 2nd millennium BC not only suitable habitation for pastoralists and mixed-farming communities but also means of long-distance intercommunication. Here Corded Ware people had first intruded on older communities. From the middle of the 2nd millennium BC various regional cultures have been distinguished, evidently representing continuity in settlement but showing varying degrees of influence from both the Bronze Age cultures of middle Europe and the steppeland. A phase of renewed activity over the steppe resulted in the appearance of the Cimmerians. Some burials and bronze horse trappings of the 9th century BC have been ascribed to them. Then, during the 8th and 7th centuries, followed the Scythians, whose warlike qualities and vivid animal art style had a profound influence even beyond the Carpathian Shield.

Scythians. *Migration and expansion.* During the 9th century BC the Scythian and kindred tribes were probably concentrated somewhat to the east of the Altai, but it was not until the Chinese ruler Hsüan Wang (827–781 BC) decided to send an armed force to curb the fierce Hsiung-nu, who had begun to make a practice of raiding China's western boundaries, that the Scythian nomads became restless. When the Hsiung-nu were forced back from the Chinese frontier and, in retreating, dislodged the Massagetai, who occupied the grazing grounds to the north of the Oxus (Amu Darya) River, and when the latter in their turn assaulted their immediate neighbours, the Scythians, a wide-scale nomadic migration was set in motion. There is reason for thinking that the struggle for grazing land was rendered more acute by a severe drought and that this factor may very well have convinced the Scythians to move westward rather than remaining to fight for their traditional rights. The Scythians were accomplished horsemen, among the earliest people to master the art of riding. Their mobility gave them a considerable advantage over their neighbours, so that when they eventually advanced westward across the Oxus they moved so rapidly that both Herodotus and contemporary Persian sources refer to the remarkable suddenness of their appearance on Iran's northeastern border. Their advance brought the Scythians into fierce conflict with the Cimmerians who had for centuries enjoyed possession of the Caucasus and the plain lying to the north of the Black Sea. The Cimmerians, however, still fought on foot and the Scythian cavalry quickly gained the upper hand. Some Cimmerians retreated through the Daryal (Dariel) Pass and were pursued across the Volga, where the Scythians were able to destroy and supplant them.

Destruction of the Cimmerians

Meanwhile another Scythian force chased the rest of the Cimmerian army across Urartu (Armenia), while a third entered the Derbent defile and reached Lake Urmia sometime during the reign of King Sargon of Assyria (722–705 BC), linking up there with the second contingent to continue the fight against the Cimmerians. Thus strengthened, the Scythian troops were able to force the Cimmerians into a steady retreat that lasted for about 30 years, ending only when both combatants had reached the borders of Assyria. Then the Scythians formed an alliance with King Esarhaddon of Assyria (reigned 680–669 BC), but they



Scythian settlements and burial grounds.

soon abandoned this and concentrated on destroying the Cimmerians, giving the latter no respite until they had forced them back across Phrygia into Lydia, where they were finally wiped out.

This astonishing series of victories brought great fame to the Scythians. Their chieftain Partatua (Bartatua) and his son Madyes were quick to take advantage of it by setting themselves up as rulers of west Persian lands stretching to the Halys (Kızıl Irmak) River, establishing their capital at Saqqez. They invaded Syria and Judaea *c.* 625 BC. Later they reached the borders of Egypt, but Psamtik I (663–610 BC) wisely decided to check any further advance by purchasing peace terms from them.

Meanwhile the Medes had become masters of Persia. They considered the Scythians' increasing might a real threat to their own security, and they decided to concentrate their efforts in launching a decisive attack against the tribesmen. Their better disciplined troops eventually contrived to push the Scythians northward, whence they had first appeared, some retreating through Urartu. Although the nomads thereby lost the control they had wielded during the previous 28 years over most of Anatolia, their lands still stretched from the Persian border through the Kuban into most of southern Russia. When forced by the Medes to retreat, some of them likewise settled between the Caspian and Aral seas, where they intermingled with their Dahae kinsmen to produce the people who, some three centuries later, were to become known as the Parthians, while others penetrated into India and established kingdoms there.

The Scythians in southern Russia

The Scythians who settled in the Kuban and southern Russia quickly attained a position of importance. Many of them became extremely prosperous. Graves of the 7th–6th centuries BC situated in the Kuban abound in objects of gold and other precious materials, and although a form of patriarchal rule remained in force, it is clear that a class of wealthy chieftains or nobles was beginning to come into being there. In the 6th–5th century BC the richest burials were in southern Russia and the Crimea. These are associated with a relatively small number of Scythians who, as the Royal Scyths, established themselves as rulers of the area. Isolated groups of their tribesmen penetrated as far as what became Hungary and East Prussia. The kingdom of the Royal Scyths developed into a community that was to enjoy considerable economic power until about the 1st century BC. Its political importance was established when it was able to resist Darius on his invasion of Scythian territory about 513 BC; the Scythians resorted to a scorched-earth policy, which enabled them to avoid a large-scale battle and obliged Darius to beat a hasty retreat in order to preserve his army. His consequent withdrawal from the plain lying to the northwest of the Black Sea left the Scythians in control of it; some of the Greek cities of the Pontus even had to pay the Scythians an annual tribute in order to preserve their security. Scythian power remained paramount there until the 4th century BC, when the Sarmatians appeared on the Don. Thenceforth the new invaders began steadily to increase their pressure on the Scythians until, in the 2nd century BC, they managed to confine them within the Crimean area, gradually supplanting them as rulers of the plain until, in the 2nd century AD, they finally succeeded in destroying the last remnants of this once powerful community.

Scythian society. For administrative purposes the Royal Scyths divided their kingdom into four districts, each of which was controlled by a governor provided with a paid military bodyguard. The governor dispensed justice and levied taxes from the settlers and tribute from certain of the Greek Pontic cities. The tribal way of life remained in force; communities were governed by their elders or chieftains, these dignitaries being periodically summoned to attend a general assembly held in the presence either of the governor or of the sovereign. These assemblies differed from the gatherings held by the sovereign in the spring of each year in order to inspect and feast his army. In times of war the country was divided for purposes of recruitment into three sections, the enrolled men being later grouped into units, each one of which was commanded by its own officer.

The army consisted entirely of freemen; *i.e.,* Scythian tribesmen; they were fed and clothed but paid no wage, though those of them who could produce the head of a soldier killed in battle were entitled to share in the day's booty. According to Herodotus, the Scythians scalped their victims, fashioning their skulls into cups that they wore attached to their belts, using them to pledge an oath in a mixture of blood and water. Such cups mounted in delicately worked gold have been found in several tombs.

Taking of scalps

Many Royal Scyths wore bronze helmets and chain-mail jerkins of the Greek type lined with red felt. Their shields were generally round and made of leather, wood, or iron and were often decorated with a central gold ornament in the form of an animal, but other tribesmen carried square or rectangular ones. All used a double-curved bow, shooting over the horse's left shoulder; arrows had trefoil-shaped heads made, according to date, of bronze, iron, or bone. Arrows and bow were carried in a *gōrytos* (bow case) slung from the left side of the belt. Their swords were generally of the Persian type, with a heart-shaped or triangular crosspiece intricately ornamented. According to date, the blades were of bronze or iron; in southern Russia, the sheaths were often encased in gold worked into embossed designs and offset with paste or ivory inlay and gems. Their knives were of various shapes and lengths, some being curved in the Chinese manner. They wore the dagger attached to the left leg by straps, and many carried spears or standards surmounted by bronze terminals depicting real or imaginary beasts.

Every Scythian owned at least one gelding to serve as a riding horse, but the wealthy possessed a great many mounts; most Scythians also owned oxen or rough ponies, which served as beasts of burden. The finest riding horses were of the Fergana breed, but the majority were Mongolian ponies. The Scythians devoted much time and

attention to their horses and ornamented all their trappings. Bridles were provided with metal cheekpieces in the shape of animals, and the leather straps were adorned with embossed, cutout, or appliqué designs, which also often represented animals. Saddles consisted of two felt cushions mounted on wooden frames bound with yellow or red and sometimes embellished with gold plaques; the felt saddle cloths were adorned, as were the seats of the saddles, with appliqué designs. Metal stirrups were not known to the Scythians, but there is reason to believe that they rested their feet in felt or leather supports. Women travelled with their children in covered wagons with solid wheels and a central shaft along which mules or oxen could be yoked in pairs.

The frozen tombs of Pazyryk contained many well-preserved articles of clothing, all of which were profusely trimmed with complicated embroidered and appliqué designs; the clothes of the wealthy in southern Russia were covered with tiny gold-embossed plaques, sewn to the garments. At Pazyryk, felt appliqué wall hangings were found, some displaying religious scenes featuring the Great Goddess or anthropomorphic beasts, others with geometric or animal motifs. Even the embalmed body of a man was covered with tattooed designs of real and mythical beasts executed with great spirit and delicacy. Felt rugs were found, as well as a knotted, woollen pile carpet of Persian origin, from the 5th century BC, displaying figures of riders, elks, and stars. Felt cushions and mattresses; wooden tables with carved or turned legs and detachable, slightly hollowed, traylike tops; and wooden blocks serving as stools or head rests were customary.

The tombs of the Eurasian plain as a whole produced a mass of tools and domestic utensils, many of them made of precious materials. Rich jewelry and arms of great value and beauty are frequently found in the burials belonging to the western section. In addition, each burial throughout the entire area contained a cast bronze caldron of the distinctive Scythian shape. These caldrons vary in size from quite small examples to others weighing as much as 75 pounds; an overwhelming majority have a solid base, shaped like a truncated cone, around which the fire was heaped. The upper section is a semispherical bowl provided not with a loop handle but with handles (shaped like animals) fixed to the rim opposite each other. The finest caldron, found at Chertomlyk in the Dnepr (Dnieper) district, has six handles. At Pazyryk, small caldrons filled with stones and hempseeds were found standing beneath leather or felt tentlets with three or six supports. Herodotus referred to what he termed a Scythian purification rite that, he noted, consisted in inhaling the fumes of hempseeds thrown onto hot stones; the passage was well-nigh incomprehensible until archaeologists discovered that a smoking outfit of this sort had been provided for each person buried at Pazyryk, making it clear that hemp fumes were inhaled for pleasure and not, as Herodotus assumed, as part of a religious observance.

Hemp smoking

Occupations and beliefs. The Scythians were keen huntsmen and fishermen; they were skilled at curing hides; they excelled at working metals; and the settlers were good agriculturalists. Though they had neither an alphabet nor, until later times, a coinage, they carried on a lively trade not only with the inhabitants of Central Asia but also with the Greeks of the Pontic cities, often exchanging surplus goods and furs for Greek luxuries such as fine ceramic wares.

The Scythians worshipped the elements but they were not a devout people and never felt the need for temples. Their deepest feelings were centred on the Great Goddess, Tabiti-Hestia, the patroness of the fire and beasts, and she alone of all their deities figures in art.

Sarmatians. *Migration and conquests.* It is evident now that the Sarmatians advanced from central Asia to invade and conquer the Scythians and did not, as earlier thought, rise against them from within their own territory. It has become possible to divide Sarmatian history into four periods. The first extends from the 6th to the 4th century BC, during which the Sarmatians migrated from Asia and penetrated to the western foothills of the Urals. Toward the end of this period the Roxolani pushed on toward the Volga River and the Alani settled in the Kuban Valley. For the most part they remained till they were dislodged in the period of the great migration, when some of the latter infiltrated into Ossetia, surviving there as a community until about the 9th century AD.

Invasion of Scythia

The Sarmatians followed closely in the steps of these tribes, and by the 5th century BC they had already made themselves masters of the plain that stretches between the Urals and the Don River. This success encouraged them to intensify their pressure on the Scythians, and in the 4th century BC they crossed the Don and entered Scythia proper. This rapid advance may well have coincided with a decline in Scythian might, resulting from the death of their aged king, Ateas, in battle against Philip II of Macedon in 339 BC; if so, this would help to account for its speed.

The incursion serves to herald the second (Early Sarmatian) period in Sarmatian history, from the 4th to the 2nd century BC, often called the Prokhorov Period after the important burials of that name with which it is associated. During this period the Sarmatians partially overcame the Scythians and gradually succeeded them as rulers over most of southern Russia. The Roxolani had begun by joining with the Sarmatians in attacking the Scythians, advancing upon them from the south. Toward the end of this period, when the Sarmatians had strengthened their hold over the territory of the Royal Scyths, the Roxolani changed their allegiance, joining forces with the Scythians to attack the Greek Black Sea cities.

In the third (Middle Sarmatian) period, between the 1st century BC and the 1st century AD, the Sarmatians conquered all but the Crimean Scythians, bringing the assaults on the Greek cities to an end. Having consolidated their hold over the captured areas, the Sarmatians did not attempt to annex any of these cities; instead, early in Nero's reign, they invaded the Roman province of Lower Moesia (Bulgaria). Although the Roman general Plautius Silvanus Aelianus ejected them in AD 62–63, the Sarmatians and some Germanic tribes they had joined were thenceforth a menace to the Romans in the west, as were the Alani in the Caucasian area. Vespasian, Trajan, and Marcus Aurelius were forced to adopt such defensive measures as to attempt to transform the vassal Bosporan kingdom into a buffer state. Hadrian had to build a network of fortresses manned with Roman troops along the borders of Lower Moesia and Cappadocia.

In the last phase of their history, spanning the 2nd to 4th centuries AD, the Sarmatians and their Germanic allies entered Dacia (Romania) and began raiding the lower reaches of the Danube, but in the 3rd century the Gothic invasion put an end to their independence. Many Sarmatians nevertheless retained their position and influence under the Goths; others joined them to sweep into western Europe, fighting at their sides. Soon after AD 370, however, waves of migrating Huns effectively ended the very existence of Sarmatia; the majority of the Sarmatians who remained in southern Russia perished at the hands of these Asian invaders. Some of the survivors were assimilated by their new masters and others by the Slavs of the lower Dnepr, but most fled westward to join their neighbours in harassing the Huns and the remaining Goths. Their descendants continued to do so until the 6th century, when they finally disappeared from history.

Sarmatian society. The social structure or way of life developed by the Sarmatians at first followed closely that established by the Scythians, largely as the result of a common Central Asian origin and heritage. Nevertheless, several fundamental differences serve to distinguish the two peoples. Scythians venerated nature deities, while the Sarmatians were fire worshippers who sacrificed horses to their god. Scythian women were relegated to a life of semiseclusion; Sarmatian women, at least in the earlier periods, however, were expected to fight in time of war, and could not marry until they had killed an enemy in battle. After marriage, however, women were obliged to abandon warfare and to devote themselves entirely to their homes and families. Greek tales about Amazons may have been based on exploits of early Sarmatian women, many of whom were buried with their weapons.

Amazons

When the Sarmatians penetrated into southeastern Europe, they were already accomplished horsemen. They followed a nomadic way of life, devoting themselves to hunting and to pastoral occupations; most of them adhered to this form of existence to the end. There is evidence that some of them practiced an elementary form of husbandry, but few settlements of Sarmatian origin have as yet been studied. In the earlier periods their customs, clothes, and many other possessions resembled those of the Scythians, but their society was matriarchal in character. Gradually, as a prosperous class began to form, the tribe entered a transitional phase during which tribal chieftains tended to replace women as rulers; eventually, kings seem to have predominated.

The rise of a male monarchy may have been stimulated by the formation of a male corps of heavy cavalry, facilitated by the probably Sarmatian invention of a metal stirrup, soon followed by that of the spur. The methods of warfare thus made possible were largely responsible for Sarmatia's military supremacy. The Romans noted and gradually adopted certain of their tactics. During the 3rd century they went so far as to incorporate Sarmatian units in some Roman regiments, equipping them with their traditional weapons and encouraging them to fight in their own manner. From early times onward Sarmatian military accoutrements included conically shaped helmets worn with scale, ring, or plate armour of iron that often protected horses as well as riders. Unlike the Scythians, the Sarmatians did not excel at archery; they relied on long lances or spears and long, sharply pointed swords.

The Sarmatians were excellent craftsmen. Perhaps artistically less inventive than the Scythians, they were nevertheless equally proficient metalworkers, better potters, and no less adept at curing hides; they were thus able to maintain the important trade in furs, grain (levied from local settlers), honey, fish, and metal that the Scythians had established with the Greek cities on the northern shores of the Black Sea. The Sarmatians also developed commercial contact with the Syr-Darya region, the borderlands of China, and the kingdom of Khwārezm (Chorasmia).

Until disrupted by the Huns, Sarmatian culture presented a uniform and all-embracing character, even though it altered with each period in its history. Its evolution is reflected in burials that distinguish each of the four periods. Thus, no large mounds are associated with the earliest phase when objects were seldom included in the graves, though the occasional presence of articles points to the beginnings of a class society. Burials of the second period often display considerable wealth; those of the third phase also reflect the growth of a more complex way of life, stemming in part from the Sarmatian subjugation of alien tribes and assimilation of many of their customs. It also was a result of the flourishing trade the Sarmatians had established. During these periods the truly typical Sarmatian culture evolved and was imposed on the entire region. In the last phase Germanic influence led to the introduction of fibulae (brooches or clasps like safety pins), with resulting changes in costume.

Other Eastern peoples. These westward-moving peoples from the steppes are considered to have spoken Indo-European languages, but they may be regarded more as having been transitory overlords rather than substantial settlers. It is impossible to point to any one of them alone as exclusively ancestral to the first historical peoples of eastern Europe. The Slavs, whose historical documentation is later and less informative than that of the Celts and Teutonic peoples, probably represent the ultimate fusion of all the Indo-European elements on the western fringes of the steppeland. The people of the Lausitz culture may also have contributed, but the sequence of events remains very obscure. For the east Baltic Indo-European-speaking peoples, as represented by the Letts and Lithuanians, the archaeological evidence appears to indicate an undisturbed continuity of settlement going back to the time of the intrusion of Corded Ware people into that region.

(T.T.R./Ed.)

Greeks, Romans, and barbarians

The main treatment of classical Greek and Roman history is given in the article GRECO-ROMAN CIVILIZATION. Only a brief cultural overview is offered here, outlining the influence of Greeks and Romans on European history.

GREEKS

The history of Europe was determined by the diffusion throughout the continent of Indo-European tribes of European origin, of whom the Greeks were foremost as regards both the period at which they developed an advanced culture and their importance in further evolution. The Greeks came into being in the course of the 2nd millennium BC through the superimposition of a branch of the Indo-Europeans on the population of the Mediterranean region in the course of the great migrations of nations that started in the region of the lower Danube. From 1800 BC

onward the first early Greeks reached their later areas of settlement between the Ionian and the Aegean seas. The fusion of these earliest Greek-speaking people with their predecessors produced the civilization known as Mycenaean. They penetrated to the sea into the Aegean region and via Crete (approximately 1400 BC) reached Rhodes and even Cyprus and the shores of Asia Minor. From 1200 BC onward the Dorians followed from Epirus. They occupied principally parts of the Peloponnese (Sparta and Argolis) and also Crete. Their migration was followed by a dark age—two centuries of chaotic movements of tribes in Greece—at the end of which (*c.* 900 BC) the distribution of the Greek mainland among the various tribes was on the whole completed.

Mycenaean civilization

From *c.* 800 BC there was a further remarkable Greek expansion through the founding of colonies overseas. The coasts and islands of Asia Minor were occupied, from south to north, by the Dorians, the Ionians, and Aeolians respectively. In addition, individual colonies were strung out around the shores of the Black Sea in the north and across the eastern Mediterranean to Naukratis on the Nile Delta and in Cyrenaica and also in the western Mediterranean in Sicily, lower Italy, and Massilia (Marseille). Thus, the Hellenes, as they called themselves thereafter, came into contact on all sides with the old, advanced cultures of the Middle East and ultimately transmitted many features of these cultures to western Europe. By their own genius, however, the Greeks accomplished much more, and their achievements laid the foundations of European civilization.

The position and nature of the country exercised a decisive influence in the evolution of Greek civilization. The proximity of the sea tempted the Greeks to range far and wide exploring it, but the fact of their living on islands or on peninsulas or in valleys separated by mountains on the mainland confined the formation of states to small areas not easily accessible from other parts. This fateful individualism in political development was also a reflection of the Hellenic temperament. Though it prevented Greece from becoming a single unified nation that could rival the strength of the Middle Eastern monarchies, it led to the evolution of the city-state. This was not merely a complex social and economic structure and a centre for crafts and for trade with distant regions; above all it was a tightly knit, self-governing political and religious community, whose citizens were prepared to make any sacrifice to maintain their freedom. Colonies, too, started from individual cities and took the form of independent city-states. Fusions of power occurred in the shape of leagues of cities, such as the Peloponnesian League, the Delian League, and the Boeotian League. The efficacy of these leagues depended chiefly upon the hegemony of a leading city (Sparta, Athens, or Thebes), but the desire for self-determination of the others could never be permanently suppressed and the leagues broke up again and again.

Leagues of cities

The Hellenes, however, always felt themselves to be one people. In relation to the barbarians they were conscious of a common character and a common language, and they practiced only one religion. Furthermore, the great athletic contests and artistic competitions had a continually renewed unifying effect. The Hellenes possessed a keen intellect, capable of abstraction, and at the same time a supple imagination. They developed, in the form of the belief in the unity of body and soul, a serene, sensuous conception of the world. Their gods were only loosely connected by a theogony that took shape gradually; in the Greek religion there was neither revelation nor dogma to oppose the spirit of inquiry.

The Hellenes benefitted greatly from the knowledge and achievement of other countries as regards astronomy, chronology, and mathematics, but it was through their own native abilities that they made their greatest achievements, in becoming the founders of European philosophy and science. Their achievement in representative art and in architecture was no less fundamental. Their striving for an ideal, naturalistic rendering of the third dimension found its fulfillment in the representation of the human body in sculpture in the round. Another considerable achievement was the development of the pillared temple to a greater degree of harmony. In poetry the genius of the Hellenes created both form and content, which have remained a constant source of inspiration in European literature.

The strong political sense of the Greeks produced a variety of systems of government, from which their theory of political science abstracted types of constitution that are still in use. On the whole, political development in Greece followed a pattern: first, the rule of kings, found as early as the period of Mycenaean civilization; then a feudal period, the oligarchy of noble landowners; and finally, varying degrees of democracy. Frequently there were periods when individuals seized power in the cities and ruled as tyrants. The tendency for ever-wider sections of the community to participate in the life of the state brought into being the free democratic citizens, but the institution of slavery, upon which Greek society and the Greek economy rested, was untouched by this.

In spite of continual internal disputes the Greeks succeeded in warding off the threat of Asian despotism. The advance of the Persians into Europe failed (490 and 480–79 BC) because of the resistance of the Greeks and in particular of the Athenians. The 5th century BC saw the highest development of Greek civilization. The classical period of Athens and its great accomplishments left a lasting impression, but the political cleavages, particularly the struggle between Athens and Sparta, increasingly reduced the political strength of the Greeks. Not until they were conquered by the Macedonians did the Greeks attain a new importance as the cultural leaven of the Hellenistic empires of Alexander the Great and his successors. A new system of colonization spread as far as the Indus city-communities fashioned after the Greek prototype, and Greek education and language came to be of consequence in the world at large.

Greece again asserted its independence through the formation of the Achaean League, which was finally defeated by the Romans in 146 BC. The spirit of Greek civilization subsequently exercised a great influence upon Rome. Greek culture became one of the principal components of Roman imperial culture, and together with it spread throughout Europe. When Christian teaching appeared in the Middle East, the Greek world of ideas exercised a decisive influence upon its spiritual evolution. From the time of the partition of the Roman Empire leadership in the Eastern Empire fell to the Greeks. Their language became the language of the state, and its usage spread to the Balkans. The Byzantine Empire, of which Greece was the core, protected Europe against potential invaders from Asia Minor until the fall of Constantinople in 1453.

ROMANS

The original Mediterranean population of Italy was completely altered by repeated superimpositions of peoples of Indo-European stock. The first Indo-European migrants, who belonged to the Italic tribes, moved across the eastern Alpine passes into the plain of the Po River about 1800 BC. Later they crossed the Apennines and eventually occupied the region of Latium, which included Rome. Before 1000 BC there followed related tribes, which later divided into various groups and gradually moved to central and southern Italy. In Tuscany they were repulsed by the Etruscans, who may have come originally from Asia Minor. The next to arrive were Illyrians from the Balkans, who occupied Venetia and Apulia. At the beginning of the historical period Greek colonists arrived in Italy, and after 400 BC the Celts, who settled in the plain of the Po.

The city of Rome, increasing gradually in power and influence, created through political rule and the spread of the Latin language something like a nation out of this abundance of nationalities. In this the Romans were favoured by their kinship with the other Italic tribes. The Roman and Italic elements in Italy, moreover, were reinforced in the beginning through the founding of colonies by Rome and by other towns in Latium. The Italic element in Roman towns decreased: a process—less racial than cultural—called the Romanization of the provinces. In the 3rd century BC central and southern Italy were dotted with Roman colonies, and the system was to be extended to ever more distant regions up to imperial times.

Romanization of the provinces

As its dominion spread throughout Italy and covered the entire Mediterranean basin, Rome received an influx of people of the most varied origins, including eventually vast numbers from Asia and Africa.

The building of an enormous empire was Rome's greatest achievement. Held together by the military power of one city, in the 2nd century AD the Roman Empire extended throughout northern Africa and western Asia; in Europe it covered all the Mediterranean countries, Spain, Gaul, and southern Britain. This vast region, united under a single authority and a single political and social organization, enjoyed a long period of peaceful development. In Asia, on a narrow front, it bordered the Parthian Empire, but elsewhere beyond its perimeter there were only barbarians. Rome brought to the conquered parts of Europe the civilization the Greeks had begun, to which it added its own important contributions in the form of state organization, military institutions, and law. Within the framework of the empire and under the protection of its chain of fortifications, extending, uninterrupted, the entire length of its frontiers (marked in Europe by the Rhine and the Danube), there began the assimilation of varying types of culture to the Hellenistic-Roman pattern. The army principally, but also Roman administration, the social order, and economic factors, encouraged Romanization. Except around the eastern Mediterranean, where Greek remained dominant, Latin became everywhere the language of commerce and eventually almost the universal language.

The empire formed an interconnected area of free trade, which was afforded a thriving existence by the *pax romana* ("Roman peace"). Products of rural districts found a market throughout the whole empire, and the advanced technical skills of the central region of the Mediterranean spread outward into the provinces. The most decisive step toward Romanization was the extension of the city system into these provinces. Rural and tribal institutions were replaced by the *civitas* form of government, according to which the elected city authority shared in the administration of the surrounding country region; and, as the old idea of the Greek city-state gained ground, a measure of local autonomy appeared. The Romanized upper classes of the provinces began supplying men to fill the higher offices of the state. Ever-larger numbers of people acquired the status of Roman citizens, until in AD 212 the emperor Caracalla bestowed it on all freeborn subjects. The institution of slavery, however, remained.

The enjoyment of equal rights by all Roman citizens did not last. The coercive measures by which alone the state could maintain itself divided the population anew into hereditary classes according to their work; and the barbarians, mainly Germanic, who were admitted into the empire in greater numbers, remained in their own tribal associations either as subjects or as allies. The state created a perfected administrative apparatus, which exercised a strongly unifying effect throughout the empire, but local self-government became less and less effective under pressure from the central authority.

The decline of the late empire was accompanied by a stagnation of spiritual forces, a paralysis of creative power, and a retrograde development in the economy. Much of the empire's work of civilization was lost in internal and external wars. Equally, barbarization began with the rise of unchecked pagan ways of life and the settlement of Germanic tribes long before the latter shattered the Western Empire and took possession of its parts. Though many features of Roman civilization disappeared, others survived in the customs of peoples in various parts of the empire. Moreover, something of the superstructure of the empire was taken over by the Germanic states, and much valuable literature was preserved in manuscript for later times.

The spread of Christianity

It was under the Roman Empire that the Christian religion penetrated into Europe. By winning recognition as the religion of the state, it added a new basic factor of equality and unification to the imperial civilization and at the same time reintroduced Middle Eastern and Hellenistic elements into the West. Organized within the framework of the empire, the church became a complementary body upholding the state. Moreover, during the period of the decline of secular culture, Christianity and the church were the sole forces to arouse fresh creative strength, by assimilating the civilization of the ancient world and transmitting it to the Middle Ages. At the same time the church in the West showed reserve toward the speculative dogma of the Middle Eastern and Hellenic worlds and directed its attention more toward questions of morality and order. When the Western Empire collapsed and the use of Greek had died there, the division between East and West became still sharper. The name Romaioi remained attached to the Greeks of the Eastern Empire, while in the West the word Roman developed a new meaning in connection with the church and the bishop of Rome. Christianity and a church of a Roman character, the most enduring legacy of the ancient world, became one of the most important features in western European civilization.

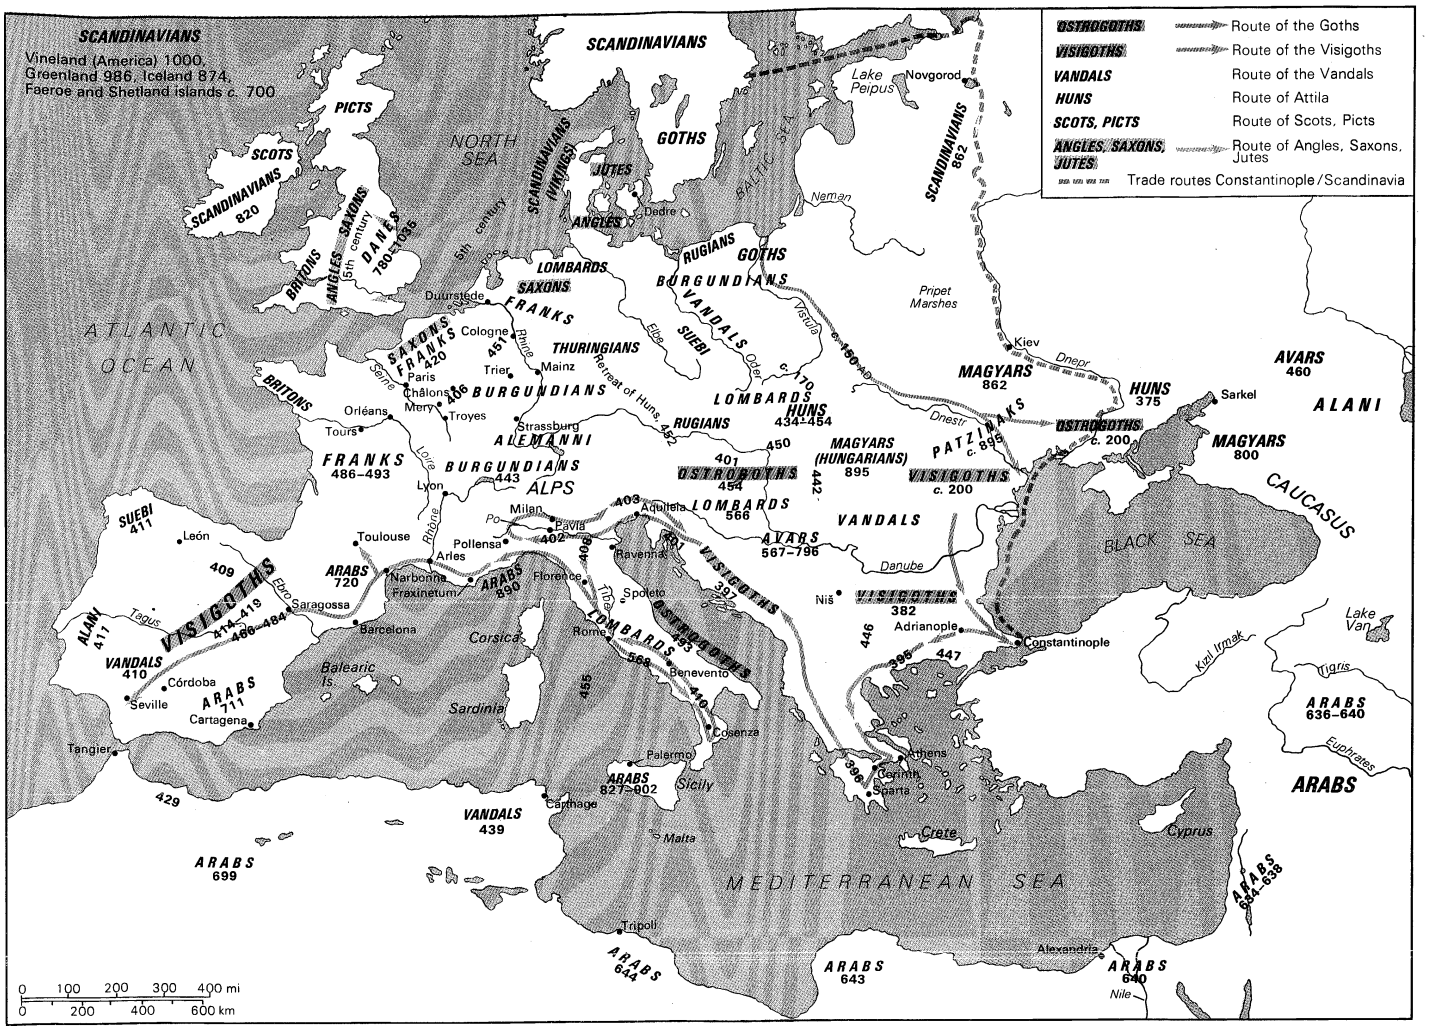
BARBARIAN MIGRATIONS AND INVASIONS

The Germans and Huns. The wanderings of the Germanic peoples, which lasted until the early Middle Ages and destroyed the Western Roman Empire, were, together with the migrations of the Slavs, formative elements of the distribution of peoples in modern Europe. The Germanic peoples originated about 1800 BC from the superimposition, on a population of megalithic culture on the eastern North Sea coast, of Battle-Ax people from the Corded Ware culture of middle Germany. During the Bronze Age the Germanic peoples spread over southern Scandinavia and penetrated more deeply into Germany between the Weser and Vistula rivers. Contact with the Mediterranean through the amber trade encouraged the development from a purely peasant culture, but during the Iron Age the Germanic peoples were at first cut off from the Mediterranean by the Celts and Illyrians. Their culture declined and an increasing population together with worsening climatic conditions drove them to seek new lands farther south. Thus the central European Celts and Illyrians found themselves under a growing pressure. Even before 200 BC the first Germanic tribes had reached the lower Danube, where their path was barred by the Macedonian kingdom. Driven by rising floodwaters, at the end of the 2nd century BC migratory hordes of Cimbri, Teutoni, and Ambrones from Jutland broke through the Celtic-Illyrian zone and reached the edge of the Roman sphere of influence, appearing first in Carinthia (113 BC), then in southern France, and finally in upper Italy. With the violent attacks of the Cimbri the Germans stepped onto the stage of history.

The nature of the Germanic migrations

These migrations were in no way nomadic; they were the gradual expansions of a land-hungry peasantry. Tribes did not always migrate en masse. Usually, because of the loose political structure, groups remained in the original homelands or settled down at points along the migration route. In course of time, many tribes were depleted and scattered. On the other hand, different tribal groups would sometimes unite before migrating or would take up other wanderers en route. The migrations required skilled leadership, and this promoted the social and political elevation of a noble and kingly class. In 102 BC the Teutoni were totally defeated by the Romans, who in the following year destroyed the army of the Cimbri. The Swabian tribes, however, moved steadily through central and southern Germany, and the Celts were compelled to retreat to Gaul. When the Germans under Ariovistus crossed the upper Rhine, Julius Caesar arrested their advance and initiated the Roman countermovement with his victory in the Sundgau (58 BC). Under the emperor Augustus, Roman rule was carried as far as the Rhine and the Danube. On the far side of these rivers the Germans were pushed back only in the small area contained within the Germano-Raetian limes (fortified frontier) from about AD 70.

The pressure of population was soon evident once more among the German peoples. Tribes that had left Scandinavia earlier (Rugii, Goths, Gepidae, Vandals, Burgundians, and others) pressed on from the lower Vistula and Oder rivers (AD 150 onward). The unrest spread to other tribes, and the resulting wars between the Romans and the Marcomanni (166–180) threatened Italy itself. The successful campaigns of Marcus Aurelius resulted in the ac-



Migrations and conquests, 2nd to 10th century.

quisition by Rome of the provinces of Marcomannia and Sarmatia, but after his death these had to be abandoned and the movement of the Germanic peoples continued. Soon the Alamanni, pushing up the Main River, reached the upper German limes.

To the east the Goths had reached the Black Sea about AD 200. Year after year Goths and others, either crossing the lower Danube or travelling by sea, penetrated into the Balkan Peninsula and Asia Minor as far as Cyprus on plundering expeditions. Only with the Roman victory at Nish (269) was their advance finally checked. Enriched with booty and constituted imperial mercenaries in return for a yearly tribute, they became a settled population. The Romans, however, surrendered Dacia beyond the Danube.

In 258 the Alamanni and the Franks broke through the lines and settled on the right bank of the Rhine, continuously infiltrating thereafter toward Gaul and Italy. Everywhere within the empire towns were fortified, even Rome itself. Franks and Saxons ravaged the coasts of northern Gaul and Britain, and for the next three centuries incursions by Germanic peoples were the scourge of the Western Empire. Nevertheless, it was only with German help that the empire was able to survive as long as it did. The Roman army received an ever-growing number of recruits from the German tribes, which also provided settlers for the land. The Germans soon proved themselves capable of holding the highest ranks in the army. Tribute money to the tribes, pay to individual soldiers, and booty all brought wealth to the Germans, which in turn gave warrior lords the means with which to maintain large followings of retainers. In the West, however, among the Alamanni and Franks, the beginnings of political union into larger groups did not go beyond loose associations. Only in the East did the Gothic kingdom gather many tribes under a single leadership. Above all, the development of the East Germans was stimulated by their undisturbed contact with the frontiers of the ancient world. Their economy, however, was still unable to support a steadily growing population, and pressure from overpopulation resulted in further incursions into the Roman Empire. The imperial reforms of Diocletian and Constantine the Great brought a period of improvement. The usurpation of the imperial title by a Frankish general in 356 let loose a storm along the whole Rhine and subsequently on the Danube, but the frontiers were restored by the emperors Julian and Valentinian I, who repelled attacks by both the Franks and the Alamanni.

The advent of the Huns

Now, however, a new force appeared. In 375 the Huns from Central Asia first attacked the Ostrogoths—an event that provoked serious disturbances among the East Germans. The Huns remained in the background, gradually subjugating many Germanic and other tribes. The terrified Goths and related tribes burst through the Danube frontier into the Roman Empire, and the Balkans became once again a battlefield for German armies. After the crushing defeat of the Romans at Adrianople (378), the empire was no longer in a position to drive all its enemies from its territories. Tribes that could no longer be expelled were settled within the empire as "allies" (*foederati*). They received subsidies and in return supplied troops. The Germanization of the empire progressed, that of the army being nearly completed. None of the tribes, however, that had broken into the Balkans settled there. After the division of the empire in 395, the emperors at Constantinople did all in their power to drive the Ger-

manic tribes away from the vicinity of the capital toward the Western Empire.

From the beginning of the 5th century the Western Empire was the scene of numerous further migrations. The Visigoths broke out of the Balkans into Italy and in 410 temporarily occupied Rome. In 406–407 Germanic and other tribes (Vandals, Alani, Suebi, and Burgundians) from Silesia and even farther east crossed the Rhine in their flight from the Huns and penetrated as far as Spain. The Vandals subsequently crossed to Africa and set up at Carthage the first independent German state on Roman soil. In the Battle of the Catalaunian Plains (451) the Roman commander Aëtius, with German support, defeated Attila, who had united his Huns with some other Germans in a vigorous westward push. The Balkans suffered a third period of terrible raids from the East Germans; and Jutes, Angles, and Saxons from the Jutland Peninsula crossed over to Britain. The Franks and the Alamanni finally established themselves on the far side of the Rhine, the Burgundians extended along the Rhône Valley, and the Visigoths took possession of nearly all Spain. In 476 the Germanic soldiery proclaimed Odoacer, a barbarian general, as king of Italy, and when Odoacer deposed the emperor Romulus Augustulus at Ravenna, the empire in the West was at an end.

The restoration of the imperial power in the West by Justinian I, who reconquered Africa, Italy, and parts of Spain, was of short duration. The Visigoths regained their position in Spain; Africa was lost to the Arabs; and in 568 the Lombards conquered upper and central Italy, Rome and Ravenna alone excepted. The Lombards had been driven from the plains of the Danube and Tisa by a new wave of mounted Asian nomads, the Avars. The Germanic migrations on the European mainland were finally at an end. All the Roman territories between the Danube and Rhine and the Atlantic had been penetrated by the Germans. In western Europe a new ethnic pattern was established, which subsequently was scarcely altered.

Three zones of Germanic influence

The Germanic tribes were roughly distributed into three zones. The central part of Germany was composed of peoples of purely Germanic stock. In the second zone a mixture of Germanic peoples ruled in Britain, in the country west of the Rhine as far as the Seine basin, and in the area south of the Danube toward the Alps. In the third zone (southern France, Italy, and Spain) the German element was much dispersed among the Romance peoples.

The migrations had meant that at first only the Germans' warlike qualities were revealed, and their manifold talents only gradually became apparent. But originating with the Goths, a characteristic decorative art developed which, though eclectic, gave expression to the spirit of the Germanic ruling class. Together with an epic poetry, purely Germanic in origin, it reached its highest point with the growth of independent Germanic states, and its influence was carried on into the Middle Ages. The Germanic states, with their simpler political systems, saved Western society from authoritarian oppression. Beginning with the great translation of the Bible by Ulfilas, the Goths created a religious literature, which, however, was soon destroyed because of its Arianism. Nevertheless, codes of law that, with the help of Roman jurists and the Latin language, were promulgated by the Visigoths (*c.* 450), by the Ostrogoths (508), and by the Franks (*lex salica,* 508–511) survived. To a certain extent the Germans were able to take over constituent parts of the Roman state. Through their conversion to Christianity they became members of the Roman Church, which had most fully inherited the culture of antiquity.

The Slavs, Bulgarians, and Hungarians. The Slavs were the last of the Indo-Europeans to settle in their present home. They originally occupied the area between the Vistula and Dnepr rivers, stretching northward from the Carpathian Mountains as far as the Narew River. The Slavs were first mentioned by name in 518, when they broke into the Roman Empire by way of the lower Danube. Their social structure was simple, consisting of small tribal units. Their further expansion was caused partly by the Avars, who from 568 were the sole rulers of the Hungarian plain, holding the surrounding Slavs in subjection. In 623–624 the Slavs overthrew the Avar lordship in Bohemia. Gradually they established frontiers with the German tribes in the Eastern Alps at the Bohemian Forest and along the Saale and Elbe rivers. By the end of the 8th century at the latest, Slav settlements stretched from the east coast of Holstein as far as the Vistula. The weakness of the Byzantine Empire made possible further attacks across the Danube. Even after the heavy defeat of the Avars before Constantinople in 626, the Slavs remained in the Balkan Peninsula under Byzantine lordship. The Balkans became a Slav territory, the Greeks fell back on the eastern and southern coasts, and the Romans fell back on the Adriatic or remained in isolation as "Balkan Romanians."

In 679 the Bulgarians, or Bulgars, a Turanian people from southern Russia, burst across the lower Danube and conquered the eastern part of the Balkan Peninsula. They were quickly assimilated to the Slavs, however, and with them were converted to Christianity by the end of the 9th century. A new invasion from the 9th century onward of Asian nomads, the Hungarians, or Magyars, divided the Slavs of the south from those of the west and the east. The West Slavs, moreover (Czechs, Slovaks, Elbe Slavs, Poles, and Pomeranians), received Christianity from the west, and this separated them from the East Slavs (White Russians, Ukrainians, and Great Russians), who adhered to the Greek Orthodox Church. After the Mongol invasions from 1223 onward the East Slavs withdrew from the Dnepr territories toward the wooded lands to the northwest, where they drove back the Finns and themselves developed as the Great Russians. (H.Au.)

The Middle Ages

The ancient world had unified around the Mediterranean—politically by the supremacy of Rome and culturally by a common Greco-Roman or Hellenistic literature, thought, and art. This unity was never complete, and signs of disintegration were clearly apparent during the 4th century; within another 250 years the unity of the Mediterranean was permanently broken. Thus antiquity was both more and less than the beginning of Western civilization—more because it was also the beginning of the Byzantine and the Islāmic civilizations, less because Western civilization included elements that were lacking or not fully assimilated in the Roman Empire at its height. Medieval Europe expanded far beyond the geographical limits of antiquity and included peoples who were never under Roman rule, and its culture was dominated by Christianity, which originated within the empire as an element alien to pagan and classical antiquity. The heritage of Rome was fused with the Germanic and Christian elements to provide the medieval foundations of Western civilization.

THE CHRONOLOGY OF THE MIDDLE AGES

Germanic kingdoms. The decline of Roman authority in the West, culminating in the deposition of Romulus Augustulus (476) and the establishment of Germanic kingdoms in its place is described above. The eastern provinces of the empire fared better during the period of invasions after 378: the emperors in Constantinople ensured their safety not only by arms but also by a diplomacy aimed at sending troublesome tribes westward to gain their fortunes. Thus in 489 Zeno granted the title of patrician to Theodoric, king of the Ostrogoths, and gave him permission to conquer Italy and rule there in the emperor's name.

The Ostrogoths under Theodoric

The kingdom of the Ostrogoths under Theodoric (493–526) was the most advanced of the barbarian kingdoms. Like the others, but far more successfully, the Ostrogothic kingdom strove to preserve as much of Roman institutions and culture as its more limited resources allowed.

The last great Germanic conquest and the most lasting was that of Clovis, who led his Franks into northern Gaul and by 507 had pushed the Visigoths south into Spain. Only the kingdom of Burgundy and the Mediterranean coastal strip (Septimania and Provence) lay outside the Frankish Merovingian kingdom. Perhaps the most important reason for Clovis' success, apart from his ability as a warrior, was his policy toward the church. Unlike

most of the other Germanic tribes, who were Christians of the heretical Arian sect, the Franks were still heathen when they crossed into Gaul. The conversion of Clovis to the Catholic faith was a decisive moment in the history of western Europe. He was now the only Catholic ruler among the Germanic kings and thus gained what no other ruler could: the support of the church and the Gallo-Roman subject population. His conquest of Gaul became a war of liberation from the yoke of the hated Arian heretics.

In the 6th century none of the Germanic kingdoms achieved political stability, except for brief periods under exceptionally strong rulers. In Gaul the Merovingian kingdom was divided among the sons after the death of the king, a provision that almost guaranteed continual war for supremacy. In Anglo-Saxon England, where partible inheritance was not the rule, there were yet so many original petty kingdoms (Bernicia, Deira, Lindsey, Mercia, East Anglia, Essex, Wessex, Kent, and several other regions whose tribal leaders briefly claimed royal status) that warfare there was also endemic, as each ruler strove to maintain and expand the political boundaries of his kingdom. On the continent, except in Merovingian Gaul, the barbarian kingdoms declined. Burgundy was conquered by the Merovingians; the Byzantine emperor Justinian destroyed the Vandal kingdom, reconquered Ostrogothic Italy, and temporarily reoccupied the southern part of Visigothic Spain in campaigns lasting from 533 to 556. But Italy was so ravaged that the real beneficiaries of Justinian's policy were the Lombards, the last of the Germanic peoples to settle within the limits of the Roman Empire. Beginning in 568, the Lombard conquest was rapid, and by about 600 only a few districts, such as Ravenna, Sicily, and Rome, remained nominally subject to the Byzantine Empire, organized as the exarchate of Ravenna.

Except in England, where the vestiges of late Roman civilization were almost wiped out, the barbarian conquerors did not purposefully destroy the Roman system that they took over; rather, they were unable to maintain it. The *civitas* (city with surrounding countryside) continued to be the unit of local government, but the local count had only loose ties to the central royal government, and it was so difficult to collect the old Roman taxes that they eventually disappeared. In the stagnant economy, however, this was not serious, for the barbarian government performed almost no service other than to maintain some semblance of law and order. The law was twofold, in accordance with the Germanic concept of "personality of law." The provincial Roman population lived under codes derived from the already simplified version of Roman law in the Theodosian Code (*c.* 438), while the various Germanic tribes lived under their *leges barbarorum* ("laws of the barbarians"). The latter, written in Latin, were also influenced by Roman-law concepts.

Genesis of Latin Christendom. Christianity originated as an offshoot from Judaism, in an eastern province of the Roman Empire. It began as a religion profoundly hostile to many of the values and vested interests of the ancient world. At first merely suspect and despised, later actively repressed by the Roman government, within three centuries it had spread throughout the empire, and the emperor was a Christian. Christianity had absorbed many of the best cultural and institutional elements of antiquity, which it was the historic role of the church to transmit to the Middle Ages. By the end of the 4th century, not only was Christianity the official religion of the empire but all other religions were proscribed.

The gradual division of Christianity into a Latin and a Greek communion was part of the breakdown of the cultural unity of the Mediterranean. By the end of the 3rd century there were few educated men who could read and speak both Greek and Latin. Equally important in the growth of a distinctly Latin church was the rise of the papacy between the 4th and 7th centuries. The popes were recognized as specially preeminent in the West by the emperors of the 4th century, and papal supremacy was recognized by the Council of Constantinople (381), though such recognition was not accepted in the Greek East. The absence of the imperial government, now in Constantinople, and the consistent record of the bishops of Rome for conservatism and orthodoxy during the early heresies also contributed to the rise of the papacy. At an early date the Petrine theory of the supremacy of the pope as St. Peter's successor was widely accepted, though the first pope to enunciate the doctrine formally was Leo I the Great, in the 5th century.

The rise of the papacy

With the decline of imperial authority in Italy the pope became practically an independent secular ruler of Rome, and with the disintegration of the empire into barbarian kingdoms, the church, with the pope at its head, became the most important element of unity in the west. Latin Christendom grew with the conversion of the barbarians to the Catholic faith (either from Arianism or from heathen religious beliefs). Conversion was actively promoted by missionaries of the monastic order founded by St. Benedict, about 520, and their work was often sponsored by the papacy. Especially notable was the conversion of the Anglo-Saxons in the 7th century and of the Germans in the 8th. In each case the papacy either initiated or supported a movement undertaken by monks.

The art, literature, and thought of the early Middle Ages were almost completely dominated by the interests of the church. The age of the Latin Fathers, whose greatest achievement in theology was reached in the works of Ambrose, Jerome, and Augustine, was followed by a long cultural decline. The three centuries from about 450 to around 750 were the Dark Ages of western Europe, but even in this period not all was darkness. The monks not only spread the faith but also, in their monasteries, preserved the literary remains of classical antiquity as well as the writings of the Fathers. Among the writers who had the greatest influence upon or interest for the future of medieval culture were Boëthius, Gregory of Tours, Pope Gregory the Great, Isidore of Seville, and the best scholar of the whole period from the decline of Rome to the high Middle Ages, the Northumbrian historian and theologian, Bede.

Final breakdown of Mediterranean unity. The Greek half of the Roman Empire did not suffer, relatively, much economic or political loss from the barbarian invasions that inaugurated the early Middle Ages in the West. In fact, the Byzantine Empire preserved much of the civilization of antiquity and added elements from the Hellenistic and Oriental world that further differentiate the Byzantine East from the Latin West (see BYZANTINE EMPIRE). Under Justinian I (527–565) the Byzantine Empire enjoyed a prosperity and a flourishing of the arts that made later generations think of that period as a golden age. But Justinian failed in his greatest ambition, to reconquer the lost western provinces and reunite the Mediterranean. His greatest monuments were not military and political, as he hoped, but cultural: the great church of Hagia Sophia and the codification of the Roman law in the *Corpus juris civilis.* Actually, the Byzantine Empire had weaknesses that neither Justinian nor his successors were able to overcome. Most notable was the bitter and sometimes violent religious dissension between the Greek and Orthodox people of Constantinople and the nearby provinces and the various Christian sects in the provinces of Egypt, Syria, and parts of Asia Minor. Also, for centuries, danger from Persia had drained Byzantine resources; finally, Heraclius (610–641) was triumphant in a great war against Persia, but the empire emerged almost wholly exhausted.

The rise of Islām

In the struggle between Persia and the Byzantine Empire the ultimate victor was Islām. The prophet Muḥammad in the 7th century united the Arabs under his religious and military leadership. In less than a hundred years his successors, the caliphs, conquered lands that stretched all the way from southern Gaul and Spain to western India. The Byzantine provinces of North Africa, Egypt, Syria, and Palestine (where religious antagonism toward Constantinople undermined resistance against the relatively tolerant Arabs) fell quickly; all of Persia was overrun in a few years. Christendom—both Greek Orthodox and Latin—was confronted with a successful and hostile Arab empire whose unity and strength derived from a common religion, Islām, and a common Arab culture and language.

The breakdown of Mediterranean unity was completed

by the middle of the 8th century. The Merovingian kings had degenerated in *rois fainéants,* and their power had passed to the Carolingian mayors of the palace. The popes, threatened by the Lombards who sought to conquer all territories still under Byzantine sovereignty, appealed in vain to Constantinople for help. The Byzantine emperors, hard pressed to defend their frontiers against the Muslims, could spare no troops to rescue Rome from Lombard conquest. Furthermore, the emperor Leo III the Isaurian (717–741) inaugurated a religious policy, iconoclasm, that Latin Christians considered heretical; Leo and his successors attempted to force iconoclasm on the pope. Confronted with this situation, the pope sought help from another quarter—the Carolingian mayor in Merovingian Gaul, Pepin III the Short, who was eager to win the pope's support for his desire to supplant the Merovingians and become king of the Franks. The alliance between papacy and Frankish monarchy was completed when Pepin was consecrated king in return for intervention in Italy to save Rome from the Lombards. By transferring to the pope the former Byzantine territory that he reconquered from the Lombards, Pepin established the Papal States under the pope as temporal ruler. The pope then conferred upon Pepin the title of *patricius Romanorum.* To justify these transactions (which, to be legal, should have been accomplished or at least approved by the Byzantine emperor), the papal chancery or someone familiar with its practice produced the Donation of Constantine, the most famous forgery of all time. It purported to be a grant of supreme authority in the West from the emperor Constantine to Pope Sylvester I and his successors.

Carolingian Empire. As king, Pepin extended his power over all of Gaul by reducing counts and dukes to obedience and pushing the Muslims back across the Pyrenees. His successor was Charlemagne (Charles I), who subdued all the hitherto independent German tribes, reduced the Slavonic peoples on the eastern border to a tributary status, conquered the Lombard kingdom in Italy (taking the title of king of the Lombards for himself), and established a Frankish county south of the Pyrenees in Spain. His kingdom now stretched from the Elbe-Saale line in the northeast to the Ebro in the southwest and from the North Sea to the marches of Benevento in southern Italy. Except in the British Isles, there was no territory inhabited by Christians in western Europe that did not owe allegiance to Charlemagne. He was acclaimed the "leader of the Christian people" and "defender of Christ's churches." Except for purely spiritual matters, Charlemagne considered himself ruler of both church and state. He used bishops and abbots as officials of the government; and his laws, the capitularies, regulated the affairs of both clergy and laity. His officials and advisers were already beginning to refer to his dominions as a "Christian empire" and to him as successor of Constantine when in the year 800 he went to Rome to put down a local uprising against Pope Leo III. On Christmas day, unexpectedly, Leo crowned him, and the assembled clergy and people acclaimed him Augustus and emperor. The actual power and nature of his authority were not changed by the act, which merely recognized and formalized the position he had attained.

Cultural revival under Charlemagne

The revival of cultural activities under Charlemagne and his successors was so impressive that the period from about 775 to about 875 has been called a renaissance. Charlemagne's immediate purpose was to provide a better educated clergy, as part of his concern for the general welfare of the church. He encouraged monasteries and cathedrals to maintain schools, and he made his court a centre of learning by inviting scholars and writers from Ireland, England, Spain, and Italy, as well as Gaul. The most important of these men was Alcuin of York, who later became abbot of St. Martin's of Tours, where he reformed the degenerated handwriting of the times. The new style, called Carolingian minuscule, was employed for the copying of most of the manuscripts of the classical works that have survived. It was also in this period that the seven liberal arts were organized into the formal curricula that remained until the 16th century. These were the *trivium* (grammar, rhetoric, and dialectic) and the *quadrivium* (arithmetic, geometry, astronomy, and music). Little that was original or profound was produced in the Carolingian Renaissance; in the cultural history of Europe it marks a stage in which preservation of the heritage of both pagan and Christian antiquity was the main achievement.

Collapse of the Carolingian Empire. Imposing as it was, Charlemagne's great empire had real weaknesses: geographically it was too large for the rudimentary governmental system; economically it was backward; in communications, transport, and military organization it was inferior to the Roman Empire. Also, among the nobility there were deep-rooted desires to control local affairs independently of the central government and the rest of the empire. A fatal flaw in the system was that it needed a Charlemagne to make it work. These were the underlying causes of the disintegration of the empire after Charlemagne's death. The direct causes were civil wars among his successors and a new wave of barbarian invasions.

The unity of the empire was formally preserved when Charlemagne was succeeded by his only surviving son, Louis I the Pious, but long before Louis died his sons were making war over their respective shares of the Frankish inheritance. The principle of unity of the empire, symbolized by the title and supremacy of the emperor and supported by the church, was in conflict with the traditional Frankish principle of equal division of the inheritance of the father among the surviving sons. Louis's eldest son was crowned emperor, but his brothers refused to be deprived of their equal share of territory, and they resisted any effort by their older brother to intervene in their kingdoms. On this basis the Wars of the Three Brothers were brought to an end by the Treaty of Verdun in 843. Three kingdoms, roughly equal in size and resources, were recognized and their boundaries defined. Louis the German, as king of the eastern Franks, received the area generally east of the Rhine and north of the Alps; Charles II the Bald, as king of the western Franks, received the western two-thirds of Gaul; and Lothair I, the eldest son, was recognized as emperor and assigned the narrow strip of territory in between, stretching all the way from the Low Countries through Burgundy and Provence and including the Carolingian kingdom of Italy. In 855 this middle kingdom was partitioned equally among the three sons of Lothair on the latter's death. His eldest son, Louis II, received the title of emperor and ruled Italy; Charles ruled in the kingdom of Provence; and Lothair II inherited the northern third, called Lotharingia (Lorraine), or "Lothair's kingdom." On the death of Lothair II in 870 his uncles, Louis the German and Charles II the Bald, partitioned Lorraine by the Treaty of Mersen. This partition, however, pleased neither side, and the successors of Louis and of Charles waged many wars in their efforts to reunite Lorraine to one or the other kingdom. The Carolingian kingdom of Provence was partitioned between two non-Carolingian claimants: Boso assumed the title of king in the southern part, while Rudolf was recognized as king of Trans-Jurane Burgundy in the north. The two kingdoms were later united as the kingdom of Burgundy under a descendant of Rudolf.

The later Carolingians were incapable of ruling over large territories. The medieval habit of dubbing rulers with brutally accurate nicknames suggests the level to which the line had fallen: whereas Charlemagne was "the Great," his descendants of the fourth and fifth generations were "the Simple," "the Stammerer," "the Fat," or "the Child." One cause of their downfall was the necessity of granting crown lands and privileges to nobles in return for their support in the endless wars of the period. The local nobility of a particular region were more obedient to their count or duke than to the ineffective ruler whose Carolingian descent gave him the title of king or emperor. (R.S.Ho.)

New barbarian invasions. *The Vikings.* Meanwhile, new barbarian invasions were ravaging western Europe, beginning in the second quarter of the 9th century. When the Viking Age began, Scandinavia was by no means an isolated, unknown corner of Europe. Trading contacts with other people had existed for centuries, and colonization abroad had been started by the Swedes in one of the directions the Vikings would later take. The cause of the explosion of the Vikings into the world is a matter of much controversy. Obviously, the urge for adventure and

Cause of Viking expansion

desire for loot motivated some of the Vikings, but deeper explanations vary. Some historians posit overpopulation in Scandinavia, while others point to a deteriorating climate that made agriculture less profitable and more difficult. On the other hand, new land was broken at home throughout the age, and a limit to new cultivation was apparently not reached. The deterioration of the Mediterranean trade, caused by conflicts between Muslims and Christians, undoubtedly played a role, with the northern route from east to west becoming an important alternative. Other factors were the lack of organized resistance to the Norse raiders and the superior shipbuilding techniques of the Scandinavians, which made possible the Viking ship, shallow, pointed at both ends, easily manoeuvrable in rivers and bays, and powered by sail and oars.

The Viking expeditions went in two general directions—west and east—with the Danes and Norwegians more prevalent in the former and the Swedes in the latter. The Scandinavian states were loose confederations at the beginning of the Viking Age, and the identity of the Vikings as Danes, Norwegians, and Swedes is only approximate. The Viking Age is generally accepted as having begun in 793 with the raid on the English cloister, at Lindisfarne (Holy Island, off northern Britain). Monasteries—isolated, wealthy, and inadequately defensed—provided an attractive target for these early Vikings, who were interested in easily won booty and travelled singly or in small groups of ships. After several decades, however, the raiders began to assemble large fleets and to winter abroad. They established camps at strategic places in the British Isles and, later, in France, from which they could make raids into the interior areas; settlements by the Norsemen followed soon after. By 842 half of Ireland was subject to the Vikings, and 11 years later, Olaf the White was the overking of the land where the kingdoms of Dublin and Waterford were established. The Vikings first wintered in England in 851, and in 865 their armies began the overthrow of the Anglo-Saxon kingdoms of Northumbria, Mercia, and East Anglia. In 878 Alfred the Great ceded the territory north and east of a line from London to the northern edge of Wales (about three-fourths of England) to the invaders. This area of Viking settlement was given the name Danelaw; the Danes were predominant in the southern and northeastern parts of the territory, and the Norwegians in the northwest. For more than a century, the Vikings apparently devoted themselves to peaceful settlement and trading in the areas they had won; but around 1000, a new series of raids began, led by the Danish king Sweyn Forkbeard (Svend Tveskæg), and the English were forced to pay tribute (Danegeld) in the hope of avoiding attacks and plundering. In 1013 the attacks reached a peak; all of England submitted, and Denmark and England were joined in one kingdom. But the distance between the two countries and the lack of unifying interests worked to prevent a real unification; when Sweyn died in 1014, it was only through the efforts of his son Canute (Knud) that England remained in the Danish sphere. Canute succeeded his older brother on the Danish throne in 1018, reuniting the kingdoms, and later efforts led to the inclusion of Norway and the Swedish territory of Västergötland in the Danish Empire. Canute devoted most of his attention to England but also sent English missionaries to Christianize Denmark. With the death of Canute's son and successor, Hardecanute (Hardeknud; ruled 1035–42), the Danish empire dissolved. An attempt by the Norwegian king Harald Hardraade (Norwegian Hårdråde; 1047–66)

The Danish Empire of Canute

to reconquer England in 1066 failed but facilitated the conquest of the island by William I the Conqueror, whose Norman duchy had been formed out of another wave of Nordic expansion.

While Vikings from Norway and Denmark were raiding and, later, settling the British Isles, where they soon became assimilated with the native population, the Norwegians were also travelling to the uninhabited or sparsely inhabited islands west of the Scandinavian peninsula: the Shetland, Hebrides, Orkney, and Faeroe islands; Iceland; Greenland; and, finally, North America. The Shetlands were visited quite early: with a favourable wind, the Vikings could reach them from the Norwegian coast in one day. With the Shetlands as a base, settlers moved on to the Hebrides, Orkneys, and Faeroes and to Iceland, where the few residents, Irish monks, were driven out beginning in 874. Expeditions proceeded to Greenland in *c.* 986, and around the year 1000, a few Vikings reached Vinland (Wineland) on the North American coast; no settlements were made there, however.

Of these settlements, Iceland is the best known because of medieval Icelandic documents and histories. A West Norwegian chieftain, Ingólfur Arnarson, moved to Iceland in 874 and was followed by settlers, mainly chieftains and their retinues. By 1100 the population was between 70,000 and 80,000. Early local government by the chieftains led to the establishment of the Icelandic commonwealth in 930, with a national parliament.

While some of the Vikings concentrated on the islands and England, others raided the Continent. By the end of the 9th century, Frisia was controlled by the invaders, mainly Danes, and there were attacks on Paris in 845 and 885–887. The lower Loire was also ravaged during the 9th century. Around 900 the Vikings attacked the northern coast of France, and in 911 the French king ceded land on both sides of the mouth of the Seine to the chieftain Rollo and his followers, who in turn promised to prevent attacks by other Norsemen. The territory ruled by the Danes received the name Normandy, and settlers moved in along with the warriors. The attacks, beginning in the 9th century, in Germany, northern Spain, the North African coast, and Italy were more sporadic, and their permanent effects were negligible.

Russian settlements

The primary attraction of the eastern route, followed primarily by Swedish Vikings, was the riches of the East, brought to Byzantium and Baghdad along the major East–West trade routes; and because these riches were found in well-established, well-defended states, the primary activity of the Vikings here was trade. Early in the 9th century the Swedes had begun to penetrate into Russia, via the Dnepr River to the Black Sea and Constantinople and via the Volga River to the Caspian Sea and Baghdad; and in the later part of the 9th century, kingdoms (most prominently Kiev and Novgorod) were established by the Swedes in Russia. The native Slavs and Finns in the area were easily conquered; the Swedish settlers were quickly assimilated. The export of Russian and Swedish products (furs, slaves, and weapons) and the import of metals and spices from the Orient brought great wealth to Sweden, and the town of Birka, on an island in Lake Mälaren, became an important trading centre during the 9th and 10th centuries; the town disappeared during the 11th century, when the Viking Age was waning. In an attempt to monopolize the northern trade route, the Swedes captured Hedeby (in southern Jutland) in *c.* 900, which remained in Swedish hands for about 30 years.

Decline of the northern route

By the mid-11th century, the Viking Age was over; the last eruption was Harald Hardraade's unsuccessful attempt to win back England in 1066. In the west, the weak states of the 9th century had been replaced by powers no longer defenseless; in the east, the entrance of the Turks produced unease, and the goods of the Orient no longer flowed into Russia as they had a century earlier. Around 1050 the political connections between Sweden and Russia ceased. At the end of the century, the Mediterranean was reopened to the Orient trade by the First Crusade, and the northern route was no longer necessary or attractive. At the same time, Christianity had been established in the Scandinavian countries, and its teachings were inimical to the bold Viking life-style and to the trade of slaves, a prime export. The rise of primitive national states in Scandinavia during the Viking Age also provided an outlet for talents formerly used in trading, settling abroad, or raiding. (H.En.)

Magyars. Another wave of invasions came not from the north but from the east toward the end of the 9th century. The invaders were the Magyars (Hungarians), who made their first authenticated raid into Moravia in 894. The early history of this people is a matter of dispute; but it is certain that they were in southeast Russia in the 9th century, if not before, and probably between the Don and the Kuban rivers; and they appear at one time to have been vassals of the Khazars. Driven westward by the Petchenegs, they arrived at the mouth of the Danube in 889; expelled by the Petchenegs and Bulgars, they entered Pannonia for final settlement in 895 or 896, under their leader, Árpád. They easily subdued the scattered population of the Central Plain, crushed the empire of Great Moravia in 906, and defeated the German forces gathered to meet them in 907. They were then firmly established in Hungary, although Transylvania was probably not truly conquered until at least a century later.

For the following 70 years little is known of the internal history of the Magyars. Árpád died in 907, and his immediate successors, Zsolt (907–947) and Taksony (947–972), are little more than chronological landmarks. During this period the Magyar horsemen ravaged Thuringia, Swabia, and Bavaria, and defeated the Germans on the Lechfeld in 924, whereupon the German king, Henry I, bought them off for nine years while reorganizing his army. In 933 the war was resumed, and Henry defeated the Magyars at Gotha and at Ried (933). The only effect of these reverses was to divert them elsewhere. In 934 and 942 they raided the Byzantine Empire and were bought off under the very walls of Constantinople. In 943 Taksony led them into Italy, and in 955 they ravaged Burgundy. The same year the emperor Otto I overwhelmed them at the famous Battle of the Lechfeld (August 10, 955). This catastrophe convinced the leading Magyars of the necessity of accommodating themselves as far as possible to the empire. They thus retreated into Hungary, accepted western Christianity, and were at last contained. (Ed.)

Foundation of the medieval states. Political recovery from the disintegration that characterized western Europe after the mid-9th century came slowly and took different forms. In England, as already noted, Alfred the Great organized a successful defense against further Viking invasions and won the allegiance of all Anglo-Saxons. His successors slowly reconquered the Danelaw (the areas under Viking rule) and unified all of England under the West Saxon (Wessex) royal house. The strength of the English monarchy was enhanced by the prestige of military conquest; it effectively controlled the local government of the shires under royally appointed sheriffs; and it enjoyed the loyal cooperation of the nobility. In France the monarchy after Charles II the Bald (died 877) declined in prestige as it proved incapable of defending the kingdom or maintaining order. In the 10th and early 11th centuries political stability was rebuilt on the local level by counts and dukes who ignored the king. The crown itself was contested between the later Carolingians and the rising House of Neustria, whose representative, Hugh Capet, finally, late in the 10th century, brought the crown permanently to his family and thus founded the Capetian dynasty. In contrast with the West Saxon kings of England, the Capetian kings in France had almost no influence over most of their kingdom beyond the small royal domain centred on Paris. They were so weak that they aroused no jealousy or resistance from their nominal vassals, the counts and dukes who willingly gave their allegiance.

The most impressive recovery of political stability occurred in Germany, where the last Carolingian, Louis the Child, died in 911 and the greater lords chose one of the powerful dukes, Conrad of Franconia, to be king, as Conrad I. When he died, the nobles again elected their new king, Henry I, duke of Saxony, who repulsed the Magyars and laid the foundations of the German monarchy. His son, Otto I the Great, succeeded by what was in fact a hereditary claim though the formalities of an election were

Europe and the Byzantine Empire *c.* 1000.

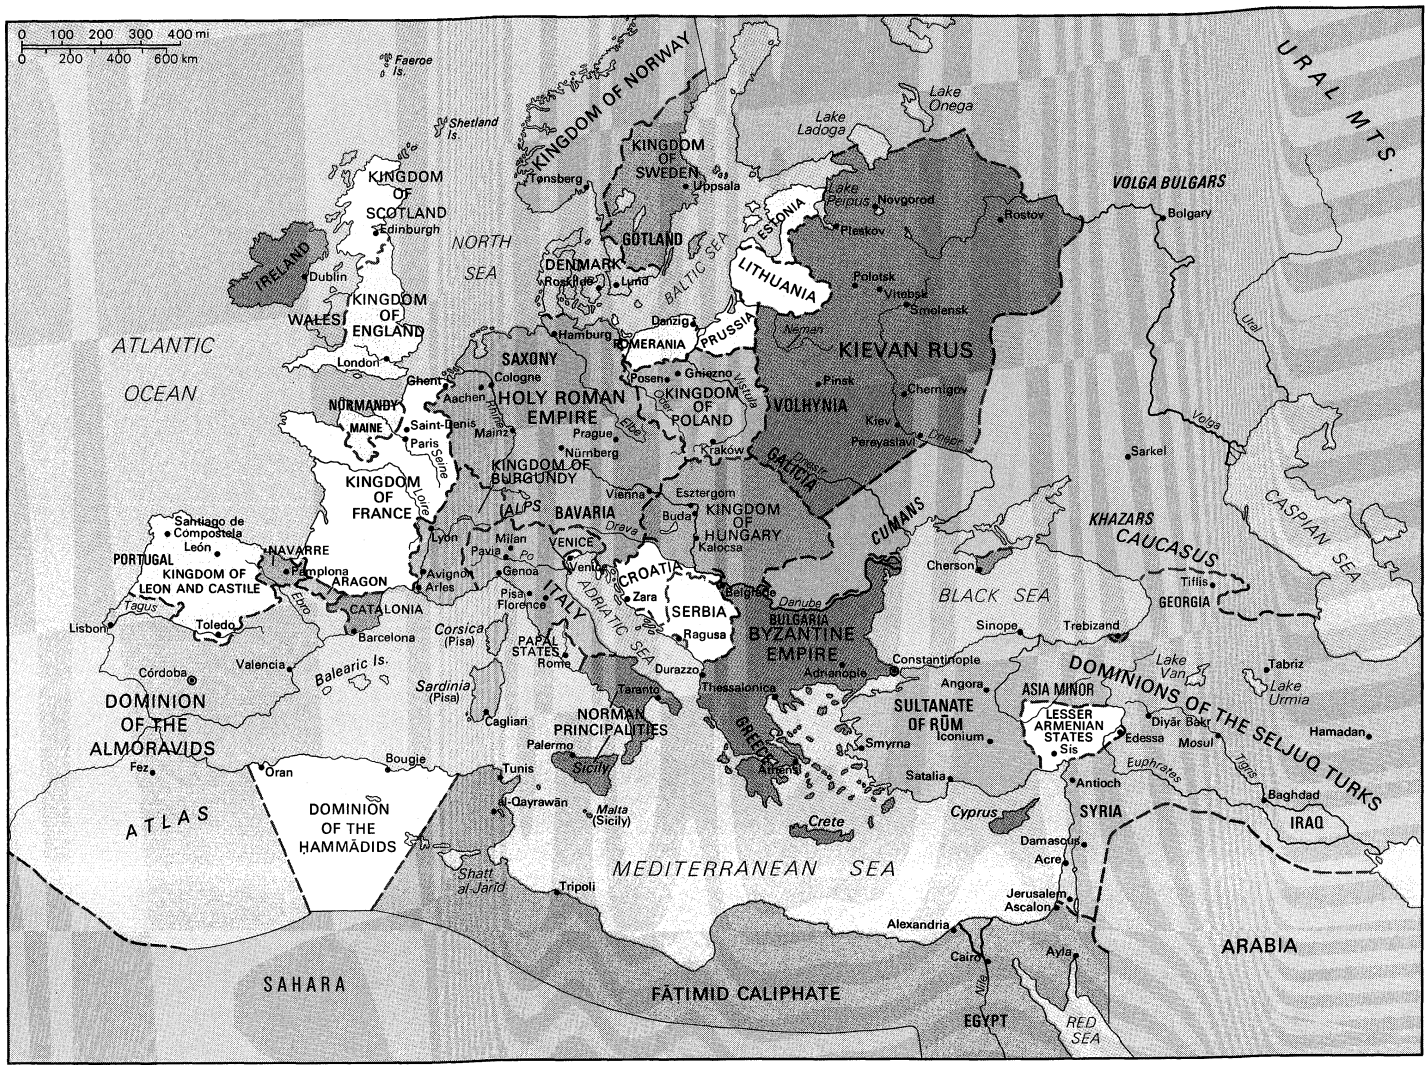
observed. In alliance with the church, Otto I stamped out rebellions and enforced his authority over the duchies and principalities that constituted Germany. In 955 he won a great victory over the Magyars, which permanently ended their raids, and in 962 he made good his claim to be king of Italy and was crowned emperor by the pope. The imperial title had been vacant since 924, and this coronation marks the real beginning of the medieval empire that in a later age was called the Holy Roman Empire.

Defeat of the Magyars

12th-century revival. *The empire and the papacy.* The medieval empire reached its height under Henry III (1039–56), the greatest emperor of the Salian dynasty. Bohemia, Poland, and Hungary acknowledged his suzerainty, and he made his direct rule effective in the kingdom of Burgundy, which his father had annexed to the empire. In Germany he based his power on extensive crown lands, on an imperial civil service recruited from the low-born instead of nobles, and on the church, which he firmly controlled while he promoted ecclesiastical reform. Within the church, reform was sponsored primarily by the monks of the monastery of Cluny and its daughter houses. The Cluniacs welcomed the cooperation of secular rulers, even when such help also entailed secular influence over the election of bishops and abbots. The papacy was untouched by the Cluniac reform and had fallen on evil days, when the throne of St. Peter was the prize of local Roman noble factions. In 1046 no fewer than three men claimed to be pope, against each of whom various charges ranging from simony to heresy had been brought. Henry III intervened: at the Synod of Sutri (1046) he deposed all three and later had his own nominee elected. Under Henry's patronage succeeding popes supported the Cluniacs both in Italy and northern Europe, thus making papal influence effective north of the Alps for the first time since the days of Pope Nicholas I (858–867).

A new phase of ecclesiastical reform was inaugurated by Hildebrand, who became Pope Gregory VII. The Gregorian Reform Party accepted the goals of the Cluniacs but added two more: independence from secular interference in the church and papal leadership of reform. Both issues crystallized in the Investiture Controversy carried on by Gregory and his successors against the new emperor, Henry IV (1056–1106), and his successors. A compromise settlement was finally worked out in the Concordat of Worms (1122), which limited the influence of lay rulers over episcopal elections and prohibited lay investiture of ecclesiastical office.

The feudal monarchies. In England the Norman Conquest of 1066 swept away the upper ranks of the Anglo-Saxon nobility and introduced a new feudal nobility from Normandy and northern France. Uniting the strength of the old English monarchy—the king's peace, an advanced system of local government, and the power to tax—with the powers that he held as feudal lord of the whole realm, William I the Conqueror was the most powerful ruler in western Europe in the most thoroughly feudalized kingdom. Although Normandy and England were divided between his two elder sons, his third son, Henry I, reunited the duchy and kingdom. Because constant warfare on the continent, to protect his duchy, necessitated his frequent absence from England, Henry developed an advanced government, including a specialized department devoted to finances (the Exchequer), which could operate under a viceroy, the chief justiciar.



Europe and the Mediterranean about 1097.

In France the earliest sign of an increase of royal authority appeared under Louis VI (1108–37), the first Capetian to exercise full control over the royal domain and to win the respect of his great vassals. Though unsuccessful in his attempt to wrest Normandy from Henry I of England, he achieved a greater triumph by marrying his heir to the heiress of the duchy of Aquitaine. When Louis VII succeeded to the throne he was the first Capetian king to rule directly a greater territory than any of his vassals.

The Crusades. In the two centuries after Charlemagne, when western Europe was disintegrating because of civil strife and barbarian invasions, civilization in the Muslim and Byzantine lands flourished. But at just the time when feudal Europe began to regain social and political stability, the once-brilliant caliphate of Córdoba, the ʿAbbāsid caliphate in the east, and the Byzantine Empire under the Macedonian dynasty were all declining.

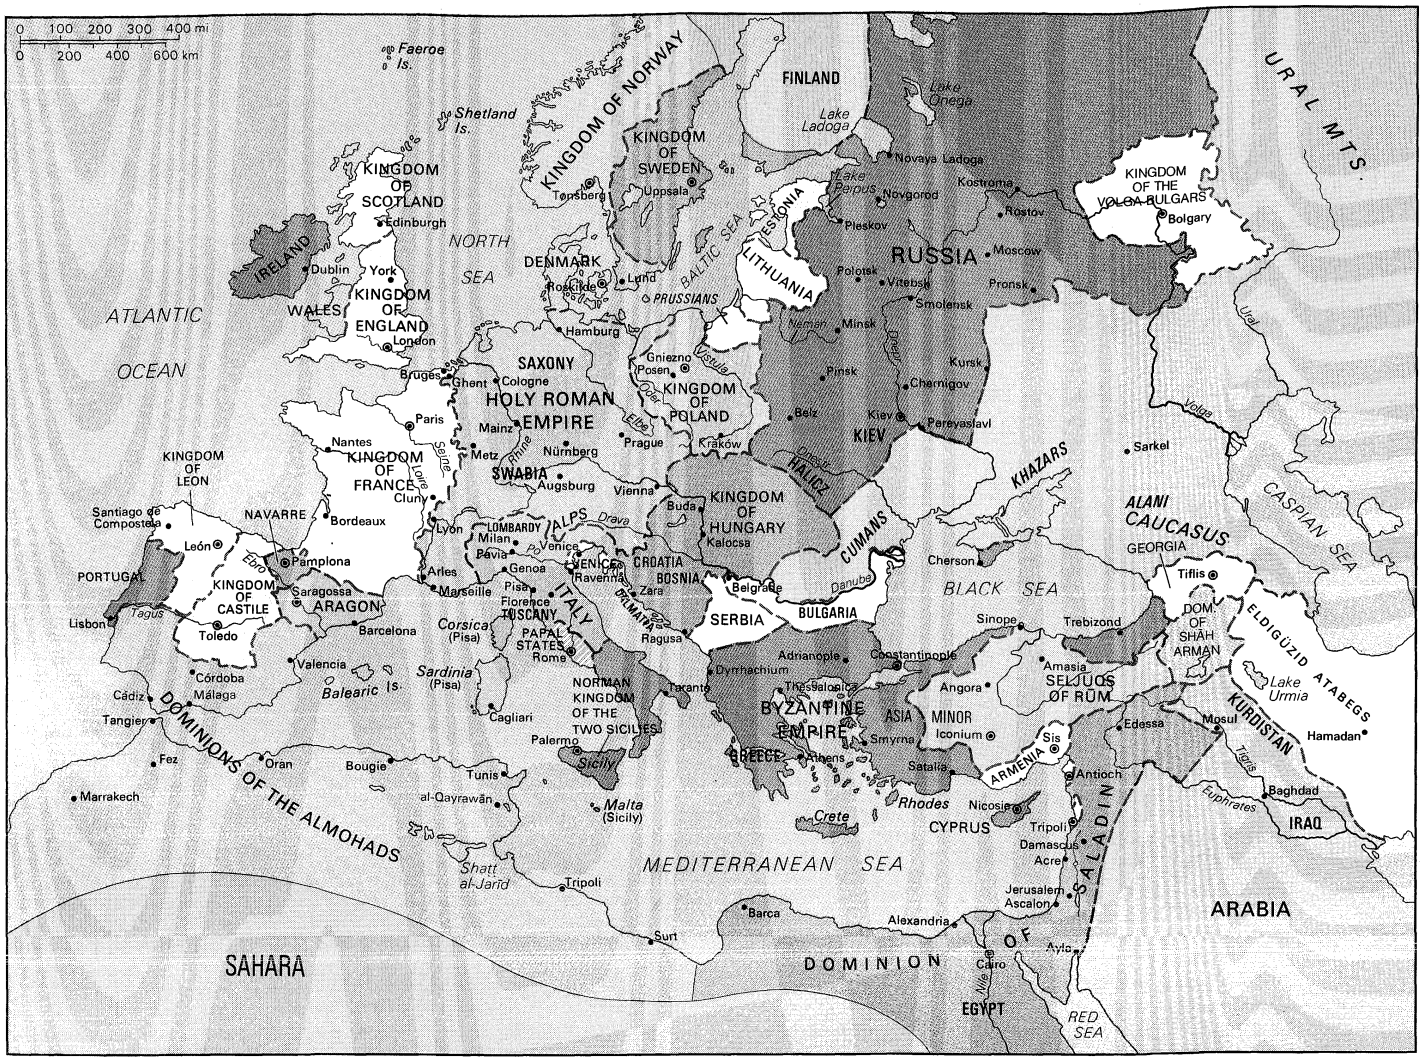
Under such circumstances the petty Christian rulers in northern Spain began to push back the Moors in a centuries-long struggle, the Reconquista, from which the kingdoms of Castile and Aragon emerged as the dominant powers. In southern Italy—an unstable patchwork of principalities under Muslim, Byzantine, and Lombard princes—adventurous and unruly knights from the duchy of Normandy sought their fortune and under the lead of Robert Guiscard won control of both the southern mainland and the island of Sicily, which became the Kingdom of Sicily in the 12th century. In the east Muslim weakness made possible the conquests of the Seljuqs, who first replaced the ʿAbbāsids and then crushed the Byzantine forces in the great Battle of Manzikert (1071). After this victory the Seljuqs swept over Asia Minor and reduced the Byzantine Empire to its European provinces.

The rise of the Seljuqs

To regain his lost provinces in Asia Minor the Byzantine emperor appealed to the West for help, first to secular rulers without success and then to the pope—promising the reunion of the Greek and Latin churches under papal supremacy as the *quid pro quo* by which the pope, Urban II, undertook to raise mercenary troops to reinforce the Byzantine army. At the Council of Clermont (1095) Urban II preached the Crusade. The Emperor and the kings held back, but the greater and lesser nobility of France and Germany enthusiastically responded to the appeal, some feeling a religious dedication to the liberation of the Holy Land from Muslim domination, others welcoming the opportunity to conquer lands for themselves. This First Crusade was successful: Jerusalem was delivered from the infidel, and the crusaders carved out feudal principalities from Muslim Syria and Palestine.

But the Byzantine emperor's hopes for reconquest of his lost provinces were dashed and the compact between the Emperor and the Pope was not fulfilled.

Holy Roman Empire and the apogee of the medieval papacy. After the death of Henry V in 1125, Germany suffered from a disputed succession and civil strife that weakened the monarchy. Peace was reestablished when Frederick I Barbarossa resolutely set out to restore his regalian rights over the lay nobility and the church in Germany and his imperial authority in Italy. Successful in Germany, his efforts south of the Alps led to stout resistance from the Lombard League of northern communes and a revival of the struggle against the papacy.



Europe and the Mediterranean about 1190.

From W. Shepherd, *Historical Atlas*, Harper & Row, Publishers (Barnes & Noble Books), New York; revision copyright © 1964 by Barnes & Noble, Inc.

After their victory at the Battle of Legnano (1176) the Lombard communes secured almost complete rights of self-government in return for recognition of the emperor's suzerainty. With the Pope, Barbarossa came to a compromise that settled none of their conflicts; on balance, it was a defeat of the Emperor's effort to control the papacy and church in Italy as he did in Germany. Papal independence of secular interference was further assured by a decree of the third Lateran Council (1179) that a two-thirds majority of the College of Cardinals sufficed in the election of a new pope, without confirmation by the emperor. Barbarossa's only success in Italy was the marriage of his son to the heiress of the Kingdom of Sicily.

Under Pope Innocent III (1198–1216) the papacy reached the height of its prestige, leadership, and power, and the ideal of the unity of Christendom came nearest to realization. To the papal curia appeal lay from all the ecclesiastical courts of Europe, and the courts of archdeacons, bishops, and archbishops, steadily enlarging their jurisdiction since the days of Gregory VII, entertained accusations or disputes involving not only all the clergy but all the laity who were *miserabiles personae* (widows, orphans, paupers, and others incapable of protecting themselves). The ecclesiastical courts also claimed jurisdiction over all disputes concerning the discipline or administration of the church, property claimed by clergy or ecclesiastical corporate bodies, and questions touching marriages, wills, vows and oaths, the sacraments, and heresy. Over all these matters the pope was supreme judge (*judex ordinarius*) and even claimed the right to interfere in temporal affairs where sin might be committed and the salvation of Christian souls endangered—as, for example, when war threatened between the kings of England and France, Innocent intervened as peacemaker in a wholly feudal quarrel. The fourth Lateran Council, summoned by Innocent III in 1215, legislated on matters of church reform; condemned the use of superstitious ordeals in all courts, both ecclesiastical and lay; proclaimed a Crusade; deposed the emperor Otto IV in favour of Frederick II; condemned the heresy of the Albigensians and excommunicated their lay protector, the Count of Toulouse; required all Christians to partake of the sacrament of the Eucharist at least once each year; and pronounced transubstantiation to be a dogma.

Heresy flourished mostly in towns, where ideas as well as commodities from far-off places were traded and where the growth of the population far outstripped the increase of churches and clergy. To minister to these needs and to meet the threat of heresy two new monastic orders were established: the Franciscans and the Dominicans, who, instead of retiring from the world, preached in the towns. Where heresy was so strongly entrenched that it had to be repressed, the special papal ecclesiastical court, the Inquisition, was employed. Dominicans staffed the court; lay rulers were obliged under pain of excommunication to carry out its sentences.

The Franciscan and Dominican orders

Frederick II (1215–50), who inherited the Kingdom of Sicily from his mother and the Holy Roman Empire from his father, renewed the struggle with the papacy. From the conflict both sides emerged exhausted. In Germany imperial authority almost lapsed; in Italy the Lombard towns staved off Frederick's efforts to unite all Italy under his autocratic rule, and the resources of Sicily were drained

off by war. The papacy lost prestige by proclaiming a Crusade against a Christian monarch and employing spiritual weapons (excommunication or interdict) for worldly ends. The 13th-century popes were able administrators and dedicated reformers, but they failed to preserve the spiritual leadership. After Frederick II's son Conrad IV there was a period of disputed succession and vacancy in the empire, the Great Interregnum (1254–73) that witnessed the collapse of central authority. Yet the greater prelates and princes of the empire maintained order within their archbishoprics and bishoprics or their duchies, counties, and other principalities.

Rise of the Western monarchies. In England, France, and Spain the medieval monarchs founded national states that were to survive—in contrast with the more universal and supreme claims of both papacy and empire, neither of which could preserve the spiritual and temporal authority exercised by earlier popes and emperors. In England the state-builders who accomplished most were Henry II and Edward I. In France, Philip II Augustus (1180–1223) by his conquest of Normandy from John of England not only initiated the growth of the royal domain, which finally included all the kingdom under the king's direct rule, but also precipitated the quarrels between John and his barons that led to the issue of Magna Carta (1215). If Philip II won the respect, Louis IX (1226–70) won the love of Frenchmen. St. Louis made the monarchy the focus of national aspiration and pride in France, and his successors made good use of the loyalties he had awakened.

In the 14th and 15th centuries England and France fought the Hundred Years' War, a conflict in which the English lost all their French possessions (except the port of Calais), and France was ravaged by the pillaging and dislocations of war. Yet each monarchy emerged stronger at the end. Emergency conditions in France allowed the kings to assume the power to tax all subjects without consent and to maintain a standing army of professional soldiers. The continual need for money to support the military effort had the opposite effect in England, where Parliament assumed more power because the kings had to gain its consent to taxation. The aftereffects of the war disrupted England and led to the dynastic Wars of the Roses, the only solution of which was acceptance of a strong monarchy. In Spain, the Reconquista was brought to a successful climax under the lead of the kings of Castile and Aragon. After 1270 only the little kingdom of Granada remained unconquered. The marriage of Isabella of Castile and Ferdinand of Aragon in 1469 was followed by the union of Castile and Aragon and the expulsion of the Moors from Granada (1492). Ferdinand and Isabella employed the Inquisition to drive out Moors and Jews and to eliminate political opponents by convicting them of heresy.

Eastern frontiers of medieval Europe. At the times of the great migrations (*Völkerwanderung*) the Slavs—referred to by Tacitus, Pliny, and Ptolemy under the name of Veneti or Venedi—lived between the middle Vistula River to the west, the Carpathian Mountains to the south and the Dnepr River to the east. In the north their neighbours were the Balts, ancestors of the Old Prussians, Lithuanians, and Letts, or Latvians. After the departure of the Goths and other Germanic tribes (who moved southward, entering the territories of the Roman Empire), the Slavs advanced westward, crossing the Elbe-Saale line in the 5th century, and southward, penetrating into the Danubian Basin and the Balkan Peninsula. Three centuries later, when Charlemagne conquered and evangelized the lands of the heathen Saxons, the western Slavs found themselves in danger. On the borders of a great empire with a superior culture, they led a pastoral life with a rudimentary social and political organization. A German *Drang nach Osten* (drive to the east) began. The idea of a universal Christian empire inspired it; demographic and economic conditions gave it force. The density of population was greater west of the Rhine than east of the Elbe, and by the end of the 8th century there was little unsettled agricultural land within the Frankish state. The Slavonic tribes living between the Elbe and Oder rivers—the Polabs (the Obodrites, or Bodrycy, and the Wilcy, or Lutycy) as well as the Lusatian Sorbs—were partly conquered during the 9th century, their conquerors being mainly the Saxons, who had become the outpost of German eastward expansion.

Poland. To protect them against the fate that had befallen the Polabs and to enable them to defend themselves against the German advance, the Piast dynasty during the 9th century grouped the Polish tribes—Polans, Mazovians, Vislans, and Silesians—into one state. The fifth prince of this house, Mieszko (or Mieczysław) I, received Christianity direct from Rome in 966, thus depriving the German emperors of a pretext for a missionary drive into Polish lands east of the Oder. His son, Bolesław I the Brave, in agreement with the emperor Otto III, secured the independence of the Polish church (1000) with an archbishop at Gniezno; in 1024 Bolesław was crowned king of Poland. But this did not stop the German pressure. More than a century later, in 1107, Archbishop Adelgot of Magdeburg appealed to his compatriots to carry the Christian faith to the Poles in these words:

The Polish church

> They are the worst of pagans, but their land so abounds in the best of meat, honey, corn, and all products of the earth that no other land may be compared with it. Wherefore, O Saxons, Franks, Lotharingians, and Flemings, you can there both save your souls and gain the best of land in which to live.

For two centuries the Oder River was the western frontier of Poland, but in 1135 King Bolesław III the Wrymouth had to acknowledge the emperor's suzerainty over western Pomerania. Bolesław died three years later. He divided his kingdom among his four sons, Władysław, the eldest, receiving Silesia. His position as suzerain was enhanced by his tenure of Kraków, the capital, and of Pomerania (Pomorze). By the beginning of the 13th century the Old Prussians and Lithuanians were the only heathen neighbours of Poland. The former resisted conversion by Polish missionaries and often raided Poland instead. Prince Conrad of Mazovia, whose lands suffered most, asked the Teutonic Order in 1225 to help in evangelizing Prussia. The offer was accepted, and a few decades later Poland had a powerful German state on its northern border. In 1308 the Teutonic Order conquered Pomerania and Danzig. Władysław I the Short reunited the kingdom in 1320 and was crowned king in Kraków but was unable to dislodge the order from eastern Pomerania. As the western part of this province was transferred in 1225 from the Polish archbishopric of Gniezno to that of Magdeburg, a German corridor separated Poland from the Baltic. This sea became a German lake for two main reasons: first, because by 1227 the present-day Latvia and Estonia had been conquered by the Order of the Knights of the Sword (which in 1237 joined the Teutonic Order); second, because the Hanseatic League, founded in the mid-13th century by the German maritime towns to control trade between eastern and western Europe, had become a power able to wage war against Denmark and dictate to King Valdemar IV the Treaty of Stralsund (1370). At that time more than 50 towns—from Brugge to Reval (Tallinn)—belonged to the league, and the Hanseatic settlements in the east helped the process of Germanization.

The Mongol–Tatar invaders who devastated southern Poland in 1241 were stopped and defeated at Legnica by the army of Prince Henry II the Pious of Silesia (of the House of Piast), who perished in the battle. To rehabilitate the country, his successors encouraged the immigration of German peasants and artisans, which helped the country's economic and cultural advance but also contributed to its Germanization. The growing German menace led to a Polish–Lithuanian union under the Jagiellon dynasty. Their combined forces defeated the Teutonic Order at Grunwald and secured the return of Pomerania and Danzig to Poland (1466). Poland became a great power in eastern Europe and the *Drang nach Osten* was brought to a halt.

Bohemia. Great Moravia, the first western Slavonic state, was founded at the beginning of the 9th century. It included not only the present Czech and Slovak lands but also Lusatia, the southern part of present-day Poland, and the western part of present-day Hungary. Great Moravia was weakened by German invasions from the west, and, at the beginning of the 10th century, it was destroyed by the Magyars.

In Bohemia proper the Czech Přemyslid dynasty founded in the first half of the 10th century a state the first historically known ruler of which was Wenceslas (Václav), assassinated by his brother in 929. In 1212 Bohemia became part of the Holy Roman Empire, and German colonization followed. The Přemyslid dynasty, extinguished in 1306, was succeeded by the House of Luxembourg. The second ruler of this dynasty—king of Bohemia as Charles I and emperor as Charles IV—resided in Prague, raised its bishops to the rank of archbishops (1344), and founded Prague University (1348). In 1356 he also fixed the attributions and the composition of the imperial college of electors, including the king of Bohemia as one of the four lay members. (The three others were the count palatine of the Rhine, the duke of Saxony, and the margrave of Brandenburg; the bishops of Mainz, Trier, and Cologne were the ecclesiastical electors.)

Before Charles I's reign the Catholic hierarchy of Bohemia and its bourgeoisie were German. A Czech bourgeoisie now appeared on the scene, and that marked the beginning of a struggle against German preponderance in the country's cultural and economic life. The movement for church reform headed by John Huss was to a great extent a national one. The burning of Huss (1415) was in the eyes of the Czech people an act of collusion between the Germans and the pope. A civil war started in Bohemia, and it ended with the election of George of Poděbrady (1457), a Czech nobleman, as the Hussite king of Bohemia.

John Huss

Hungary. The Magyars, after the destruction of Great Moravia, subjugated Slovakia and settled the Danubian Plain. Their raids against Germany ended after the defeat they suffered at Lechfeld (955). Géza, a ruler of the Árpád dynasty, was converted to Christianity in 975, but it was under the reign of his son, Stephen I, that Hungary, a multinational state, entered the European community, as a kingdom outside the Holy Roman Empire. In 1102 Hungary and Croatia were united under St. Stephen's crown. The Mongol invasion of 1241–42 left the country ravaged and depopulated. When the House of Árpád became extinct in 1301 it was succeeded by the Angevins (1308–82)—a period of power and prosperity for Hungary. In 1345, however, the Ottoman Turks had secured a bridgehead in Europe. In 1363 an allied army led by King Louis I of Hungary, was defeated by the Turks on the Maritsa River in Thrace. In 1389 the Serbian Empire founded by the Nemanja dynasty was destroyed by the Turks at Kosovo. Hungary itself was in danger.

After Louis I's death Hungary had as kings a Luxembourg (Sigismund) and a Habsburg (Albert), who, being elected Roman emperors in succession, were concerned more with the interests of the empire than with those of Hungary. In 1440 Władysław III Jagiełło, king of Poland, was crowned as King Ulászló I of Hungary, but in 1444 he fell at Varna, leading a Hungarian-Polish army against the Turks. János Hunyadi, the Hungarian commander who survived the Varna disaster, became regent of Hungary for Albert Habsburg's posthumous son, King Ladislas V. When Ladislas died in 1457 at age 18, Matthias Corvinus became the only Hungarian national king after the Árpáds.

Scandinavian kingdoms. The pagan Norsemen discovered toward the 8th century that plundering rich foreign lands was more profitable than extracting a living from the sea or the unfertile soil. While the Swedes turned their attention to the east of the Baltic and gave Russia its first dynasty, the Danes and Norwegians moved westward to Scotland, England, and Ireland and also southward to France, Spain, and Sicily. Under Canute the Great (*c.* 995–1035) Britain was part of a Scandinavian empire comprising Denmark, Norway, and part of Sweden. Canute became a Christian and supported the evangelization of Scandinavia. After his death his empire fell to pieces. Denmark, Norway, and Sweden became independent kingdoms warring among themselves. Between the 12th and 14th centuries Denmark was the leading Scandinavian power. For a time it annexed Estonia, the then Slavonic island of Rügen (Rugia), and part of Pomerania. Sweden undertook in the 12th century the evangelization and conquest of Finland and in 1323 concluded a peace treaty with the Russian duchy of Novgorod that fixed the first eastern frontier of Finland.

In 1397 a union between Denmark, Sweden, and Norway was concluded at Kalmar. It was ruled by Margaret I, daughter of a king of Denmark and widow of a king of Norway. The Swedish nobles banished their unpopular king, Albert of Mecklenburg, and elected Margaret as "sovereign lady and ruler." She died in 1412 and was succeeded by Erik of Pomerania. His plan to create a great Baltic empire did not materialize, and the Hanseatic League continued to control the Baltic trade. The Kalmar Union continued formally until 1523, although in Sweden there was strong opposition to it.

Russian duchies under Mongol domination. The invasion of Russia in 862 by Rurik (Hrörekr) and his Norsemen marks the beginning of Russian recorded history. The Norsemen followed the rivers and lakes from the Baltic to the Black Sea and established their capital in Kiev. Vladimir Svyatoslavich, grand duke of Kiev (978–1015), probably a direct descendant of Rurik in the third of fourth generation, accepted the Christian faith from Byzantium in 988. There were many Russian duchies and endless family wars waged with the purpose of deciding which among the large number of Rurikovichi was at the time the senior and thus entitled to rule in Kiev, the richest duchy. The Mongol-Tatar invasion of 1237–40 destroyed the Kievan power and subjected all Russian lands (except Novgorod) to the domination of the Golden Horde. In spite of Dmitry Donskoy's victory at Kulikovo (1380) it lasted until 1480.

The church in the later Middle Ages. The most extreme claims to papal power and ecclesiastical exemption from royal jurisdiction were made by Boniface VIII (1294–1303), who forbade taxation of the clergy without consent of the pope. This precipitated a contest between Boniface and the kings of England and France, each of whom claimed that he had to tax his clergy to defend his realm against attack from the other king. In a brief struggle, replete with vituperative propaganda against Boniface, the monarchs were triumphant, and the pope was reduced to claims he had no means of enforcing. His successors, French popes, resided at Avignon from 1309 until 1377, when Pope Gregory XI returned to Rome, where he died. The cardinals then elected an Italian as the new pope, Urban VI, but then—claiming that election to be invalid because it was made under duress from the Roman mob—elected a new French pope, Clement VII, who promptly returned to Avignon. Thus began the Great Schism (1378–1417) that divided the allegiance of Europe about equally, while each pope excommunicated the other and the other's supporters. This scandalous situation led to demands not only for reunion but for reform of the papacy as well. The great councils held at Pisa (1409), Constance (1414–18), and Basel (1431–37) restored unity by electing Martin V (1417–31) and deposing all other claimants, of whom there were then three. The conciliar movement failed to achieve significant reforms or to limit papal authority. The price paid for papal victory was high: to woo away the support of secular rulers the popes made concessions that amounted to sharing papal authority with them. But even more costly was the loss of prestige, which the Renaissance popes did nothing to make good.

The Avignon papacy

Fall of Constantinople. By the end of the 13th century the last of the Crusaders' principalities had fallen to Muslim reconquest, despite the efforts of such leaders as Frederick Barbarossa, Richard the Lion-Heart, Frederick II, and St. Louis, each of whom led a Crusade without lasting result. In 1291 Acre, the last city of the kingdom of Jerusalem, fell, and only the island of Cyprus remained in Christian hands. In the 14th century the Ottoman Turks swept westward, attacking Muslim, Byzantine, and independent territories in both Asia and Europe. They crushed the greatest Balkan power, Serbia, and overran the rest of the peninsula. They were then free to complete the conquest of the rest of Asia Minor and to lay siege to Constantinople. The great fortress city fell in 1453. This event hardly changed the situation in the Levant—Italian traders continued to enter the ports and markets, though Venetian trade suffered.

Italy and Germany in later Middle Ages. Both north and south of the Alps political disintegration of the Holy Roman Empire was accompanied by the growth of smaller states. In Italy these were the city-states, dominated by the wealthy merchants. Venice, Milan, Florence, and Rome were the most important, while the Kingdom of Naples was still a power. Though many of the city-states had republican forms of government, almost all were in fact governed either by a small oligarchy or by a single despot. The popes, in their policies and their plots and intrigues, were hardly distinguishable from other despots. In Germany the situation is summed up in the term particularism—*i.e.,* the division of the country into autonomous principalities and self-governing free cities. The emperor was elected by seven electoral princes, and after 1356 papal claims to adjudicate a disputed election were explicitly denied. After 1438 the Habsburg dynasty once more came to the imperial throne, this time to retain the title permanently. Socially and culturally Italy and Germany present a striking contrast at the end of the Middle Ages. In northern Europe society was still dominated by the rural nobility, in Italy by the urban bourgeoisie. In arts and letters, as in education, medieval styles, interests, and methods continued in the north, while in Italy the Renaissance brought a revival of the literature, artistic styles, and interests of classical antiquity.

(R.S.Ho./Ed.)

MEDIEVAL SOCIETY

For most of the medieval period in most of Europe, the structure of society was determined by the difficulties of providing an adequate and continuous supply of food and raw materials. The proportion of grain reaped to seed sown was generally low; acute difficulties of transport made agricultural specialization hazardous and prices local and unstable. Hence, particularly between the 8th and 11th centuries, the proportion of the population freed of all agricultural tasks was low, and the materials of luxury or warfare were rare and highly prized.

The aristocracy that could be supported by such a society was both in form and origin a blend of Roman and Germanic elements. Late Roman society was marked by the existence of an aristocracy of wealthy landowners whose estates were worked by slaves either maintained in the household or housed on small plots about the great house. Other dependents, of rather higher status, might be freedmen or formerly independent cultivators, such as the *coloni,* whom war or financial distress had brought under the landowner's protection. Well before the formal end of the empire in the West, such landowners had been accustomed to deal out a usurped justice even over their free clients and had maintained armies of *bucellarii* (bodyguards) in their own defense, though rarely placing a high value on military accomplishments. With difficulty they retained their contacts with the towns and with the traditional urban education of their class.

Decline of the towns

Earlier Roman government had depended upon these towns, which were almost universally in decline by the 5th century. Vandal and, later, Muslim piracy disrupted the vital sea routes to Africa and the East; on land the impotence of local government made communications dangerous; and ever heavier taxation crippled trade. Long-range commerce and the more local urban industries declined, until even wheel-turned pottery became scarce or vanished. The retreat toward economic self-sufficiency and a barter economy was reflected in the near collapse of Western coinage. Over this society, rapidly receding into a pre-Roman localism, there presided, with ever-feebler effect, an emperor or emperors who attained office at the head of an army and according to no settled principle of succession. Once in power the emperor exercised a nearabsolute authority over the army, the courts, and the administration, limited only by prudence and the likelihood of mutiny or assassination. Emperors were hailed as themselves divine before the conversion of Constantine early in the 4th century; thereafter, even a Christian emperor who enforced the precepts of the church readily took on a quasi-priestly character.

The Germanic invaders who settled in or along the frontiers of this empire lived very differently. Not all seem to have had kings, at least permanently, but the majority, whether as allies or invaders, entered the empire as warrior bands led by chiefs who depended for power on their continued capacity to win battles and to retain followers with gifts of present wealth and hope of more. Kings were ring givers, holders of great feasts, lords of men. Yet their authority rested on other grounds too—their descent from the gods and a belief sometimes current that divine favour was assured the people through the royal lineage. Some of the pagan kings (such as the Ynglings of Sweden) acted as priests, and a king's subjects usually followed him to the font for baptism as they followed him to war. Very special measures, including the earliest recorded Frankish consecration by a bishop, were required to legitimize the succession of a king from outside the ruling dynasty.

The politically active element in the people was represented by the warriors—the freemen—who formed the army; when this was gathered it represented the people for war or peace, and it was the army that acclaimed each new king by raising him upon their shields or enthroning him upon some sacred stone. Among these freemen there was a group of special importance and standing, set apart by their birth and their lord's favour—the *comitatus,* or *gasindi,* already known to the Roman historian Tacitus in the 1st century AD. For them, loyalty to their lord was the supreme virtue, celebrated in epic verse from *Beowulf* on. From their ranks were drawn the barbarian officers of post-Roman and Germanic society, though the highest such posts seem to have been monopolized by a restricted number of noble kin groups, distinguished by their descent and deeds rather than by any set title to property.

The rulers. *Kings.* In the societies in which these disparate patterns blended, beginning in the 8th century, the medieval kings were raised to office by a combination of ritual acts that revealed the elements of their power. Until the principle of male primogeniture became dominant in the late 12th century, the king would first be "chosen" in an assembly from among the kin of the last ruler, whose designation would carry great weight in cases of doubt; this choice was often not complete until the new king had travelled through his kingdom in what has been called a continuous election. After the consecration of Pepin the Short as king of the Franks by St. Boniface in 751, it became increasingly common for the king so acclaimed to be consecrated with a liturgy carefully modelled upon the Old Testament precedents of Saul and Solomon and to be invested with such insignia of kingship as crown, sword, helmet, or sceptre. Before or after this ceremony, the leading men of the kingdom came in to declare their allegiance, often performing symbolic acts of domestic service at the coronation feast. In these ceremonies the king secured both rights and duties. As the anointed of the Lord, he had a special claim on the obedience of the church and a measure of physical security; the murder of Canute II of Denmark in 1086 horrified Europe, and the violent deaths of kings continued to be regarded as striking at the whole fabric of the divine and human order. This process, whereby the church sharply distinguished the king from the chieftain, in part explains an important transition of the 9th and 10th centuries. Thenceforward, the multiplication of kings, common among the descendants of Clovis or Charlemagne, ceased; only a formal act of the papacy under rare conditions was thought capable of legitimizing such later kingdoms as Hungary (999), Sicily (1139), or Portugal (1143).

Medieval notions of kingship

The church, which played so large a part in creating such a king, was active in prescribing duties; the coronation oaths and prayers insisted upon his obligation to protect the church, the defenseless, and the poor, to make war upon the heathen in the service of Christ, and to ensure that justice was done. It was chiefly in church councils that the king's duty to the whole people was emphasized against his relations with his warriors.

Even where, as with the Capetian dynasty between 987 and 1316, son succeeded father in unbroken descent, it was conventional to refer to the king as chosen by his people, and this became an active principle when there was no obvious claimant, as at the end of the Saxon or Ho-

henstaufen dynasties in Germany or in such exceptional cases as the founding of the Latin kingdom of Jerusalem in 1099. Among the larger kingdoms of the 13th century, only Germany, beset by frequent changes of dynasty and by the papacy's hostility to a hereditary empire, was still in practice an electoral state. Charles IV's Golden Bull of 1356 formally defined the procedures of election that remained in force in the empire until 1806, although after 1437 the throne was monopolized by the family of Habsburg. In Denmark, Sweden, and Poland the kingship was also formally and often practically elective, though hereditary right became absolute in France, England, and Spain.

Emperors. Theoretically, after 800 the emperors—the heirs of Charlemagne—stood above the kings. The appearance of a second Christian empire caused endless difficulties with Byzantium, and the nature of its pre-eminence was always diffuse and uncertain. It could be considered a recognition of facts—the attribution of a supreme title to the most powerful of the Latin kings—and many saw Charlemagne or Otto I in this light; but none of their successors enjoyed the same authority as did these founders of empire. The more general view, dominant by the end of the 10th century, was that the empire was specifically Roman, but in several possible senses. Because it was Pope Leo III who had taken the lead in recognizing Charlemagne as the first emperor in the West in 300 years, and, because Leo's successors had the undoubted right to consecrate later emperors at Rome, it could be claimed that the empire was an office within the Christian community, or *ecclesia.* The chief duty of such an emperor would then be the protection of the church and the enforcement of ecclesiastical discipline. When the emperor Henry III summoned the synod of Sutri of 1046, which ratified the withdrawal of three rival popes, he fulfilled one interpretation of this role; when Pope Gregory VII declared Henry IV deprived of his kingship in Italy and Germany for offenses against the church in 1076, he was employing another. Rome was, however, the city of the Caesars as well as of St. Peter, and some claimed that the emperors were the heirs of Augustus and the pagan emperors as well as of Charlemagne, with a universal authority that owed nothing to the church. This view was asserted notably by the apologists of Frederick I Barbarossa (reigned 1152–90), supporting their claims upon the revived study of the Roman civil law; modified by the doctrines of Aristotle, it survived in the writings of Dante and among the courtiers of the emperor Henry VII (reigned 1308–13).

Chief duty of the emperor

Without effective control in Rome, all of these views lacked substance, and such control was made impossible because of political stress in Germany under Henry IV and, later, the rise of the Lombard towns (which inflicted a serious defeat on Frederick I at Legnano in 1176) and the papacy's determination to establish an independent state in central Italy under Innocent III and his successors. After the death of the emperor Frederick II (reigned 1215–50), who had united the crowns of Germany, Italy, and Sicily in his own person, prolonged succession disputes on both sides of the Alps ruined the foundations of central authority in Italy and Germany. After the reign of Otto I (German king, 936–973; emperor from 962), the king of Germany had an exclusive title to the empire, though he could only secure it through coronation at Rome. The universal and ecclesiastical pretensions enshrined in this act had become a fiction long before the last imperial coronation in Rome, that of Frederick III in 1452, the bulk of whose reign was spent trying to maintain a foothold even in his own duchy of Austria.

Popes. If the imperial authority became progressively more confined, that of the popes made great advances, partly at the empire's expense. The foundation of papal authority lay, first, in the claim to inherit all the powers conveyed to St. Peter by Christ and, second, in the special position of the bishop of Rome. Until the 8th century, papal pre-eminence was complicated by the existence of jealous patriarchates of the East, not least the new Rome at Constantinople, whose emperor remained the nominal and sometimes the effective overlord of the city of Rome. By 700, however, most of the other patriarchs were subject to Muslim rulers, and Byzantine military weakness had forced such popes as Gregory I to take on most civil responsibility for the city of Rome. Dogmatic disputes in the Byzantine Empire over the veneration of icons (725–843) hastened a process of estrangement between the Greek Eastern and Latin Western churches that was to deepen eventually into near permanent schism. Rome then was left in solitary eminence in the West. Missionaries from Anglo-Saxon England, which had been converted by Roman agents, came to exercise a dominant influence upon the Frankish kings of the early 8th century; under Pepin the Short, Charlemagne, and the latter's son Louis the Pious, strenuous efforts were made to enforce a single liturgy, canon law, and monastic observance, the authenticity of which was guaranteed by its use at Rome.

Until the 11th century this confirming and legitimizing of action begun elsewhere was the predominant if not exclusive role of a papacy largely under the control of a series of such local Roman noble houses as the Crescentii and counts of Tusculum. The papacy favoured rather than led movements of active reform in the monastic and secular church. With the accession of Gregory VII, however, the papacy assumed the leadership of a movement that saw the inertia of the bishops and archbishops as the chief obstacle to ecclesiastical reform and viewed this situation as a consequence of excessive lay influence on their appointment and conduct. Accordingly, Gregory and his successors pursued a policy aimed at reducing the authority of the secular princes over the church (so provoking the long and bitter Investiture Controversy with the emperors Henry IV and Henry V) and at replacing secular authority with an ecclesiastical government based upon the written canon law and directed from Rome. By the pontificate of Innocent III (reigned 1198–1216) substantial successes had been achieved. The Fourth Lateran Council of 1215, attended by more than 400 bishops and 800 abbots from the whole of the Latin obedience and by representatives of all the greater princes, disposed of secular and ecclesiastical business on the widest scale. The difficulties that beset a full realization of the papal vision of a Christian and priestly monarchy were both internal and external. Internally, the process of centralization of authority made for slow and expensive decisions and was thought to demand a political independence in Italy that, in turn, involved long and costly wars with the Hohenstaufen and their successors north and south of the Papal States. Both centralization and the need to levy taxes on the church at large aroused the distrust and resentment of the local hierarchy, which could be exploited by kings (such as Philip IV of France in his contest with Boniface VIII) who were determined to secure their own right to tax their clergy and to submit them to the royal law.

Papal leadership

The rise of national consciousness that accompanied this resistance as well as the exile of the popes at Avignon made the pope's universal role as arbitrator in secular or ecclesiastical affairs harder to sustain. The double election of 1378 created a schism and weakened the position of the papacy. Because neither contestant would give way, the schism could only be ended by an external agency—a general council of the church held at Constance in the presence of the emperor Sigismund between 1414 and 1418. The energies of the abler reformers of the next 30 years or so were largely diverted to disputing the rival claims to authority of a monarchical papacy and a general council. With the failure of the most ambitious of these at Basel, the papacy emerged from the struggle again in Rome and again enjoying the plenitude of power; but the chief beneficiaries of the struggle were the secular princes, who had secured valuable concessions of control over their clergy as the price of their support.

The aristocracy. *The greater aristocracy.* By 1100 a greater aristocracy had evolved over almost all the Latin West, marked by a combination of three elements. First, its members were normally the lords of a number of men bound to them by an oath of fealty and an act of homage, while they were themselves so bound to a king, a prelate, or the pope; the obligations such bonds involved were various, but the performance of military service was the most widespread and characteristic. Second, this aristocracy commonly exercised a large measure of judicial,

Elements of aristocracy

financial, and administrative authority over its own men as lords and often over others as royal officers. Third, this was a landowning aristocracy that rewarded its dependents with grants of lands (fiefs), much as its own wealth had been enhanced by grants from kings, and maintained large households from the proceeds of the estates retained in the lord's own hand—the domain.

To this combination, or some elements of it, the term feudalism is commonly though inconsistently applied; Marxists sometimes further apply it to a particular form of agricultural exploitation, the manorial system. But none of these elements necessarily supposes the others: in England it could be said that all land was received from the king, yet public authority remained unusually concentrated in his hands; in Germany the greatest princes came to hold rights of jurisdiction from the emperor rather than land, and their reciprocal duties were very slight; in southern France and Italy tenure for homage and service was rare but political authority was exceptionally fragmented.

Within the ranks of the greater aristocracy, certain distinctions came to exist. Originally, there seem to have been a limited number of very great families in Germanic society, defined by birth and sometimes uniquely described as free, but this division slowly gave way to others whose titles derived from functions rather than social rank. The term duke was widely applied to the lords of certain areas, which were incorporated in the Frankish empire without wholly losing their identity—*e.g.,* Bavaria, Burgundy, Brittany, Aquitaine, Saxony—and also to the lesser lords of the loosely constructed kingdom of the Lombards; the Scandinavian jarls or Anglo-Saxon earls after the reign of Canute (died 1035) were similar. In origin the word duke (*dux*) meant military commander, and it was on the basis of military need that the majority of 10th-century duchies emerged; for similar reasons, there appeared the margraves of Italy and Germany, lords of border land with a wider military authority. In Germany duchies multiplied in the 12th century, as in the creation of Austria in 1156, when the title implied membership of the highest rank in the social and tenurial scale; in 13th-century France and 14th-century England the term was only revived for great lordships (appanages) created for the cadets of the royal family.

The most widespread of such titles originally denoting public office and only later social rank or landed wealth was the Latin *comes* (German *Graf,* Anglo-Saxon *ealdorman*), or "count." *Comes* originally meant companion or member of the king's household of specially trained warriors; the appointment of members of the Frankish king's inner circle to the earlier administrative districts of *gau* or *pagus* caused the word to be applied to an officer of Carolingian government, then to a hereditary holder of office and rights, and finally to the head of a noble landed family. The terms duke, marquis, and count were themselves no necessary guide to relative wealth or prestige because some duchies were almost empty titles while the powerful lords of Flanders or Champagne were only counts. The institution of the *Reichsfürstenstand,* the class of imperial princes in late 12th-century Germany, was conceived as defining the highest rank of lay and church princes standing immediately about the throne. While the French institution was to become essentially an empty honour under the monarchical government of later kings, the German class was buttressed with important privileges that gave it enduring importance.

Recognition of rank

The origins of this greater aristocracy and its privileges were diverse. Some Roman senatorial families survived or absorbed their invaders; some descendants of independent chieftains of war bands that did not secure lasting kingdoms entered the Frankish, Anglo-Saxon, or Scandinavian nobility; the descendants of some specially favoured royal companions were able to hold onto the gains of their ancestors. Birth was from the outset probably an essential element of both exalted rank and access to royal favour, but important modifications to this took place between the 9th and the 12th centuries; slowly, the emphasis upon patrilineal descent and primogeniture became ever more absolute, and the extended kin group gave way to the dynasty. The passing of public offices into hereditary possession, the growing importance of military considerations, and a concentration of wealth and influence upon a limited number of indivisible castles all contributed to this effect. Whereas the great Carolingian families of the 9th century derived their names from an ancestor, their successors named themselves after the area of their rule or their principal stronghold.

Entry into this later aristocracy was possible by a variety of routes. Throughout this period the enduring hazard of central authority was that those appointed to maintain its interest would succeed in converting this representation into a right. In Germany even the unfree class of *ministeriales* sometimes succeeded in establishing such claims to the imperial fiefs and castles entrusted to their care and thus forced their way into the aristocracy. In France and England in the later Middle Ages, royal servants were commonly enriched by the opportunity to deprive or buy out those outside the circle of royal favour. There, too, in the 14th century a certain number of great merchants in the service of the crown were able to enter the ranks of the nobility; in Italy, however, the incompatibility of merchant adventure with noble birth had broken down much earlier. In later medieval Europe the emergence of more professional armies (especially in Italy and France during the widespread disorders of the 14th century) provided opportunities for successful soldiers of modest birth to rise into the ranks of an aristocracy coloured by ideals of an elaborate knightly code.

Lesser nobility. It was of the essence of high social rank that the aristocrat should have a large following of men who were themselves of free birth. Every great man, like every king, was made great by his capacity to maintain a retinue and reward his followers. An estate was valuable less for its revenues in money and goods than for the men whose services could be secured from it. The noble retinue was held together by gifts of gold, horses, weapons, or hawks, while those who served their lord well might hope for a gift of land. The numbers of such followers, or knights, were swollen by freemen who were driven by need to surrender their own land to the lord and to receive it back as a conditional grant by him; in return they received a protection modelled upon that extended to the lord's own blood kin. With increasing specialization of warfare, free birth tended to give way to the skills of cavalry warfare as the essential qualification for noble service; these knights (French *chevalier,* German *Ritter*) might live as retainers in the lord's household or hold land from him—a knight's fee, or fief—coming only at an exceptional summons to his feasts, courts, or wars. Many enjoyed a large freedom in the government of their estates and came to form a lesser nobility, bearing arms, using their own seals, and living in more or less fortified manor houses. As the apparatus and conventions of knightly warfare became more elaborate and the influence of the courtly romances more pervasive, membership in the nobility came to depend on knighthood.

Knights

The rise of the knight to this more exalted status was in part a function of the dissolution of the tight bonds of dependence his land tenure would once have imposed. This was a general phenomenon of the later Middle Ages, for the complexity of tenurial obligations made them increasingly inadequate either for defining status or for providing the lord with his honorable retinue. The later medieval principalities therefore owed their legal constitution to the powers of the lord in the exercise of his sovereign rights rather than to his personal claims on the services of his vassals; by a parallel development, the lord's household and following were commonly then paid for their services. Even at the lower levels of society, the same movement can be seen at work. In the 9th century a great estate would normally have a proportion of household slave labour; by the 13th century almost all the household servants would receive some wages, though food, lodging, and security still formed the bulk of their payment.

The church hierarchy. The greater aristocracy throughout Europe included a number of churchmen, for the sees of bishops and many monasteries had received wide grants of land, over which they often exercised more extensive rights than did their lay fellows, both as lords

of tenants and as royal officers. Under Charlemagne and later princes, the state intervened to enforce universal acquiescence in the form of spiritual government over the whole body of the laity, and this could be burdensome or even oppressive. Set aside from their fellows to a different and a higher calling, this aristocracy and its subordinate officers were also, in theory, recruited on quite different principles. In practice, however, high office in the church remained almost wholly the prerogative of the aristocracy and later of the kinghtly classes. Between the 8th and the 15th centuries it has been calculated that not much more than one-third of the 2,000 bishops appointed to German bishoprics came from non-noble families, and only five are known to have come from the dependent peasantry that formed the great bulk of the population. Certain monasteries and colleges of cathedral canons were explicitly reserved to those of the most carefully authenticated noble birth. Yet access to the highest church offices was in part dictated by other considerations; from the 11th century onward, royal or papal service and mastery of the disciplines of theology and canon law provided the means for men to rise on their ability alone. Suger—abbot of Saint-Denis, a monk of modest origins who became chief adviser to Louis VI of France, and regent for Louis VII—and died one of the most powerful men of Europe, or Thomas Wolsey, a butcher's son who rose to be cardinal and archbishop of York and chief minister to Henry VIII of England, illustrate the advancement that the church could provide, however rarely. Opportunities for this upward mobility were closely related to the existence of an effective royal administration capable of excluding the local magnates from a monopoly of patronage; the hope of modest advances provided many obscure but devoted clerical servants for the infant bureaucracies of 12th-century kings.

Bishops

The original nucleus of church organization had lain in the bishoprics, groups of which, from the end of the 8th century at least, formed provinces normally presided over by an archbishop or metropolitan. The special interest of the church in political concord, which derived not merely from its dedication to charity but also from the vulnerability and wide extent of its property, made it for long the natural ally of kings and emperors; the anathemas of the bishops were regularly employed to reinforce the sword of the Lord's anointed. Being, if aristocratic, at least not hereditary magnates, the bishops were the allies upon whom the Saxon and Salian emperors of Germany and the early Capetian kings of France largely depended as a counterpoise to their greater secular subjects. Episcopal estates were treated as royal estates whenever the king journeyed about his kingdom, and the burdens of military service on German ecclesiastical estates were often unusually heavy; the royal administration was staffed and directed by the clergy, and the church's endowments were used to reward them. In return the bishops secured great privileges; the archbishops on either side of the Rhine—at Reims, Sens, Mainz, Trier, or Cologne—were at once powerful landowners and retainers of a wide measure of delegated royal authority, and these were only among the more visible examples of a movement in progress throughout Europe. Theoretically, the success of the Gregorian reform movement in the 11th and 12th centuries had stemmed from the distinction it drew between the bishop's absolute obedience to canon law and his subordinate obligation to the prince. But in practice, the bishops continued to depend on royal authority for defense against grasping lay neighbours, for the enforcement of ecclesiastical discipline (particularly in matters of heresy), and, in the later Middle Ages, for protection against the growing anti-clericalism of some of the educated laity and even the financial demands of the papacy.

Secular clergy

From the 5th century onward, the original constitution of the diocese, which rested upon the bishop and a small group of clergy living with him at a central point, altered substantially. Subordinate centres grew up within the diocese, some large and early ones served by groups of resident clergy but the great majority caring for only a small parish and served by a single priest. Recruitment to these was wide; some houses of canons and wealthy parishes provided revenues for men of high birth or influence, while others were served by men drawn from the peasant population, who were little more than domestic servants of the landowner who had built the church. The widespread grant of parish churches to monasteries and religious communities (as many as one-third of the parishes of a diocese could be so granted) and the prevalence of absentee clergy, such as pluralists holding several benefices or scholars engaged in study at the universities, meant that many churches were served by substitutes—vicars, who enjoyed only a proportion of the revenues of their office, often a quite inadequate one. Besides these, most parishes also provided some employment for a floating population of clerks in minor orders. With a rapid decline in the creation of new parishes in western Europe after the 12th century, it was the endowment of chantries, the setting aside of money and buildings exclusively for the saying of mass for the soul of the founder, that provided the greater number of new, if modest, benefices, though these were often attached to other parochial or charitable obligations.

The determined efforts made first by the early Carolingians and then by the reformers of the 12th and 13th centuries to provide an efficient system of supervision and control over the local pastoral work of the diocese ultimately produced an administrative hierarchy parallel to, though partly distinct from, the pastoral one. The rise of the bishop's formal jurisdiction saw the appearance of a host of legal and financial agents, ranging from the powerful archdeacon to the humble summoner, whose task was to enforce attendance at the church courts. The increasing centralization of church government at Rome in the 13th and 14th centuries required the appearance of other officers, proctors of bishops and abbots at Rome, collectors of papal taxes, and, later, such disreputable figures as the itinerant peddlers in papal indulgences and dubious relics—the pardoners.

Administrative hierarchy

Regular clergy

By the mid-13th century there existed beside this hierarchy another one, the regular clergy, living under a formal and corporate rule more demanding than the minimum canonical requirements of the seculars. Between the 5th and the 11th centuries this sector had been overwhelmingly monastic, composed of autonomous houses ruled over by an abbot with near absolute powers and devoted to the maintenance of the regular liturgical cycle; there was one pre-eminent rule, that of St. Benedict, which envisaged a life of corporate self-sufficiency as the norm. In the 11th and 12th centuries a number of variations on this rule appeared, designed to heighten the emphasis upon manual labour, corporate poverty, or solitary contemplation; in a more striking departure, some houses of canons under the flexible rule of St. Augustine were, it was hoped, to combine monastic rigour of life with active parochial work, while military orders founded in the course of the Crusades in the Holy Land and Spain and on Germany's eastern frontier combined the yet more disparate profession of war with monastic ideals. All these were property-owning corporations, as were the houses of nuns and canonesses that lived under similar conditions; their presidents, especially the abbots of the more well-to-do Benedictine abbeys, were often wealthier than many bishops and were drawn from a similar social background. Only among the Cistercian lay brothers was entry into the monastic life readily open to men of humble origin. The original followers of St. Francis (died 1226) were often drawn from a much wider variety of classes, but by the end of the 13th century both they and the followers of St. Dominic, originally intended to be educated preachers trained to combat heresy, had become orders of friars with a strong academic tradition, excluding all but the most talented of the very poor. These men renounced all property (even corporate), were especially engaged in the work of preaching (notably in the towns), and travelled constantly. By 1300 the multiplication of religious orders had come to a virtual standstill.

Other social groups. *Townspeople.* The urban society of the Roman Empire in the West was breaking down long before the deposition of the last emperor in the late 5th century, and it continued to fade with few interruptions until the 10th century. The estimated population of

Rome fell from more than 1,000,000 in the 1st century AD to 40,000 in the 7th; nevertheless, it long remained the largest city of the Christian West, although tiny compared to the greater Muslim cities or Constantinople. Many Roman towns continued to be occupied, often because they remained, or became, the seats of bishoprics or abbeys and so centres at least of consumption, or because their walls offered some shelter from a long series of invaders. Commercial activity continued in those ports of Italy still in touch with Byzantium and perhaps on a modest scale in some of the Lombard towns. It even increased in such northern ports as Duurstede in the Rhine Delta, the Viking entrepôt at Hedeby (in Schleswig), and the Russian cities trading through the Black Sea. By the end of the 11th century the recovery of urban life was more general. Merchants trading over long distances began to appear as an urban aristocracy, wealthy men anxious to secure a larger measure of control in the government of their towns. In Venice this development was already clearly visible, and the fleets and trade of this port stimulated a revival of town life throughout northern Italy. The origins of these early capitalists are much disputed: some may well have been fortunate peddlers, but more can be shown to have been members of the lesser aristocracy, or tenants or officers of great churches, with capital to invest in goods and transport. In Italy the participation of the landed aristocracy in the life and trade of the towns was shown by the presence of clusters of their tall stone towers within the city walls rather than on outlying hill tops.

Recovery of urban life

Increasing political stability on land and contact with the Levant by sea saw the rapid increase of such trading communities in size and influence. The Italian cities of Genoa, Pisa, Lucca, and Siena rose to challenge the earlier dominance of Venice and Milan. In Germany the Rhineland towns were already a political force to be reckoned with in the civil wars at the beginning of the 12th century, but they came to be overshadowed by the great prosperity and activity of the Baltic towns of the Hanseatic League, such as Lübeck, Hamburg, and later Danzig (Gdańsk), and later by the prosperity of such South German towns as Augsburg and Nürnberg. In Flanders textile manufacture, based in part on imported wool, produced in the 12th century a precocious industrial community with a large unstable proletariat concentrated in such towns as Ypres, Ghent, Bruges, and Arras; alone of the northern cities these could compete in influence with the greater Italian centres such as the manufacturing town of Florence (with a population of perhaps as high as 200,000 in the 13th century, largely supported by its textile industry) or the equally large Milan, celebrated for its metalwork and, most notably, its armories. Paris by the end of the 12th century was already acquiring most of the qualities of a capital city for the fast-growing area of Capetian power, with a population estimated at 80,000.

By the 13th century the Italian towns commonly contained a group of aristocrats by birth or by wealth long possessed whose political dominance was challenged by the more substantial of the merchants. Below these were the retailers and masters of the smaller crafts and then the wage labourers, apprentices, and beggars, who were normally without a political voice but whose grievances sometimes broke out in violence and even bloodshed. The urban nobility of Italy was without true parallels north of the Alps and it was the greater merchants, or merchant adventurers of the later phrase, who formed the directing elite in most towns. Although even at the end of the medieval period the towns' share in the wealth and population of Europe was still very limited (over most of the Continent perhaps not above one-tenth of the total), their influence was much greater. Since the 14th century, access to the towns had been an important agent in social change, and the continuing or growing prosperity of some 15th-century towns was in marked contrast to the widespread decline of agricultural production and profit. Politically, the merchant interests of the towns were of the first importance, for it was only they who could provide the large sums of ready cash with which the kings of the later 15th century established royal authority over the magnates. To the degree that the king could continue to enjoy the taxes of the burgesses of his towns, he could maintain or extend his authority; without them he was reduced to competing with his own magnates on little better than equal terms.

Agricultural society. The countryside during the Roman period was chiefly cultivated either by the slaves of the great *villa* estates or by more or less free cultivators, sometimes bound by the government to remain on their land in order to maintain a tax-paying population but otherwise not labouring under grave personal disabilities before the law. In the Germanic societies of the invasion period, a threefold division of the agricultural population was common—the people *par excellence* (the *karl, ceorl,* or *bôndhi*), free peasants cultivating their own land, bearing arms, and so participating in the public assemblies of *gau* or hundred; a more obscure group often described as freedmen (*aldiones* for the Lombards and Bavarians, *Leti* among the Germans, Franks, Frisians, and also perhaps in Kent), possibly freed slaves, possibly the survivors of an earlier conquered population who enjoyed limited rights but did not usually play an active part in the courts; and the thralls, slaves either captured in war, condemned to their state by the law, or reduced to it by penury. Such bondsmen might sometimes have their own huts, plots of land, and houses and therefore enjoy a minimal independence.

Germanic division of agricultural society

These forms tended to merge so that over much of western Europe by AD 1000 the characteristic villager (villein) held a substantial plot in the village fields but equally was expected to perform such onerous services on a lord's domain as ploughing, reaping, and carting and was subject to his lord's will in much the same fashion as the earlier landless slave. In addition, the village community would usually contain other men with smaller plots of land (cottagers), whose rents in labour and goods were correspondingly lighter, and also a small number of slaves, in the old sense of the word. All these unfree cultivators could be described as serfs, however diverse their economic conditions. In parts of Europe, notably in northern Germany and eastern England, the earlier free peasantry still formed an important element in the population, and by the 14th century their ranks were swollen by numbers of villeins whom changing economic conditions had allowed to commute their servile obligations for fixed rents in money. The settlers who had been persuaded to take up holdings in the planned land clearances of the 12th and 13th centuries by offers of considerable freedom of tenure had reached the same goal by different means. At the other end of the social scale, the landless wage labourer was now much more common.

The timing of this process, whereby many of the earlier free peasants were first assimilated to the legal if not the economic conditions of Roman slaves and then increasingly recovered their personal liberty to become rent-paying tenants, was extremely uneven. The cycle was complete for much of Italy by 1200 and for most of France and England by 1400, but the free peasantry of Scandinavia, parts of eastern Europe, and Castile was only beginning to feel the presence of a serf-owning class of landlords in the 14th and 15th centuries, at a time when it was fast becoming obsolete elsewhere.

Beggars and outlaws. A society that was at best only just above subsistence level maintained a large body of vagrants. Economic disasters such as plague or famine forced a desperate population to attack the crops of more fortunate neighbours; in the late 12th century, freelance mercenaries roamed Europe in search of employers and booty, while the 14th and 15th centuries saw more organized (and so more formidable) free companies of professional troops whose favoured fields of operation were France and Italy, where their captains traded their services like sovereign princes. All large towns either generated or attracted their share of beggars and petty thieves; in François Villon, 15th-century Paris produced a universal poet to express the pleasures and much more frequent miseries of this vagrant life. Town and country alike lacked any effective police force, and therefore, although the majority of known or suspected criminals could be dispossessed of land and property, even murderers were rarely apprehended. At times in 13th-century England only one in

The vagrant life

100 murderers was ever brought to trial and convicted. The rest fled, many apparently into the forest to live like beasts or find an organized band of outlaws, idealized tales of which became widely current in the later Middle Ages in the legends of Robin Hood. The local community protected itself as best it could against such bands, but the assistance of a local knight at the head of his retainers could rarely be distinguished from the nuisance it was supposed to abate. The fate of these outlaws was bound up with that of the forests, and both were in decline by 1500. But with the first signs of a recovery of population, vagrancy and unemployment were probably increasing.

Women. A society directed by warriors and celibate clergy was not one in which women would exercise extended rights very often. After *c.* 1100 patrilineal descent was almost exclusively the test of nobility, while matrilineal descent was often the test of serfdom. The property rights of women, though protected by canon and secular law, were confined; it was a cherished freedom for widows to be allowed to refuse a second match proposed by lord or kin. Practice, however, did not altogether conform to this appearance. In barbarian society in the period after the invasions, and sometimes long after, matrilineal descent was often important—the house of Charlemagne traced its origins back to a daughter of Arnulf, bishop of Metz. Although few queens ruled in their own right, many exercised great political authority, as in the minority of their sons; the regency of Blanche of Castile for St. Louis in France was a notable and successful example. The remarkable Queen Margaret succeeded in uniting the three kingdoms of Sweden, Denmark, and Norway under her regency in the Union of Kalmar of 1397, an act that influenced the future of all Scandinavia. Similarly, although debarred from the priesthood by their sex, a number of women played a leading role in ecclesiastical affairs. St. Catherine of Siena and St. Bridget of Sweden played a major role in achieving the return of the papacy from Avignon to Rome in 1377; both were celebrated adepts of the spiritual life, the female contribution to which is also attested by the works of Margery Kempe in England. The influence of women was also felt in their role as patrons, sometimes of Christianity itself, as when a number of the invading chieftains of the 5th and 6th centuries were first married to Christian princesses and then converted. Queen Margaret of Scotland (died 1093) was responsible for the thoroughgoing reform of the church in her kingdom, which brought it rapidly into the mainstream of the Latin Church; another notable lady, Matilda of Tuscany (died 1115), had been the last refuge of the reforming papacy for almost a generation.

As patrons of the arts, and above all of poetry, Eleanor, duchess of Aquitaine and wife first of Louis VII of France and then of Henry II of England, and her daughter Marie, countess of Champagne, were the leading figures of their century. At Marie's request, Chrétien de Troyes translated Ovid's *Art of Love* and also wrote one of the first courtly romances to be based on Geoffrey of Monmouth's Arthurian history. In Marie de France the courtly romance found a skillful female writer—appropriately, because these tales, which evolved from the masculine world of the chanson de geste, reveal the growth of a new social convention in which women had a larger part and a higher function. Foreshadowed in the diffusion of the cult of the Virgin Mary in the 11th century, this new convention was developed in the Italy of Petrarch and Dante.

Medieval economic patterns. Latin Europe by 1500 covered a great diversity of lands and climates. A first division was that between the heavy soils of Germany, northern France, and Britain and the predominantly lighter soils of the Mediterranean lands of Spain, Languedoc, and Italy, in which vines and olives formed an important adjunct to grain.

Medieval communities. Both main types of agriculture were conducted by cultivators who lived, where possible, in large settlements, with their churches, mills, and barns, the whole settlement often walled, as in the *bastides* of southern France, or at least hedged against animal and human marauders. Both economies contrast with those that existed on their perimeters and in the less fertile or more broken country of the interior. In the Celtic lands of Ireland, Scotland, and Wales, in Spain and the foothills of the Alps, as well as in Hungary and the Latin Balkans, a largely pastoral economy flourished, depending on flocks of cattle, sheep, or goats and producing a quite different pattern of living. As oxen provided the essential power for the cereal farmer's plough, and milk, cheese, salt, and meat were as important to his diet as a minimum of crops were to the most pastoral of societies, so most medieval communities represented a precarious balance of forces between the needs of crops and beasts. Beyond these types of communities there existed various types of highly specialized settlements, such as the fishing communities of the North Sea coast, the salt evaporators of southwestern France, the fenmen and the miners, sometimes solitary and sometimes organized in tightly knit communities, as were the tin miners of Cornwall and Bohemia. With few technological resources and poor communications, all medieval communities were largely conditioned by their environment.

Some of the Mediterranean communities of Italian cultivators had been organized as great estates (*latifundia*) in the late and post-imperial period; each tenant held only as much land as could support him and his family while he worked on the lord's estate. Very early, however, the comparatively widespread use of coinage allowed landowners to abandon such direct exploitation, which was clumsy and time consuming, in favour of a variety of leases for terms of years or lives. By such means the community became one of independent cultivators, each with his own field. Similar tenancies prevailed over much of southern France, where a Roman Law much modified by custom and the decay of the judicature continued to regulate contracts and the functions of the market.

The triangle formed by the rivers Loire and Rhine contained the chief area of nucleated cereal-growing settlements, though there were notable extensions of this into Britain to the west and into Franconia, Swabia, Bavaria, and the German east. In the Loire–Rhine region, with its heavy soils and wet climate, the earlier small enclosed fields of the Iron Age gave way widely to the characteristic open fields of the medieval vill, where the arable land of the community lay in large blocks cultivated by heavy, ox-drawn ploughs. The mechanical difficulties of turning such an implement and the need for effective drainage produced a characteristic effect of long narrow parallel strips running down contours of the hills. Such cultivation required a regular alternation of crops because there were few means available for restoring the fertility of the soil except allowing either half or one-third of the land to lie fallow each year. Similarly, the other resources of the land in pasture, woodland, water, and common grazing needed careful annual regulation because there was constant tension between the needs of men, crops, and beasts. This required an organism whose common life maintained some continuity regardless of the divisions that accidents of lordship might impose; later, the village was often a legislative body, enacting its own bylaws.

Open fields of the medieval vill

Until the 13th century this open-field cultivation continued to support the classical manorial organization. The lord drew his profit partly from his possession of a share of the vill's arable land, which was exploited for him by his tenants for some of the week, and partly from the exercise of his right to compel his tenants to use his ovens and mills, at a price, and to control and exploit the use of the surrounding waste land. In practice such communities had always maintained a population of landless men—slaves earlier and labourers later—and there usually were tenants who owed rent or personal services of a less strictly economic variety. (Such free tenancy became widespread with the clearing of outlying lands in the 12th and 13th centuries, especially in the planned colonies along the frontiers.) Again, principally under the impact of increasing internal trade and a greater circulation of money, cumbrous forms of exploitation tended to break down in the later Middle Ages as the domain was leased out and the lord allowed his tenants to commute their labour dues into cash rents. When, in the late 14th and 15th centuries, the relation between land and labour shifted

drastically in favour of the tenant over most of western Europe, the economic centralization of the local community focussed on the lord's estate almost vanished, though the need for common action in the agricultural cycle did not. In contrast to these tightly knit, often productive and vulnerable agricultural communities stood the much looser society of the higher lands, where settlement was necessarily dispersed and where social bonds rested much more exclusively upon the ties of the kin or clan than they did in the nucleated villages. Even the arable farmers in a scattered community had more independence than did their lowland fellows. The Icelandic sagas written down in the 13th century, in manuscripts typically preserved in farmhouses rather than in monastic libraries, provide a vivid picture of such communities.

Increasing volume of economic exchange

The increasing economic specialization of the period between 1100 and 1500, which saw vine growing and sheep rearing rise to the status of basic rather than supplementary occupations for whole communities, was made possible by a great increase in the volume of exchanges, itself a function of greater political stability. These exchanges took place pre-eminently in three settings: the markets, chiefly for local produce, held at short and regular intervals; the trading communities of the towns; and the occasional great fairs, annual events to which merchants travelled from the ends of Europe and the proceeds of which enriched such fortunate princes as the count of Champagne, lord of the fair towns of Provins, Troyes, Lagny, and Bar-sur-Aube.

Urban growth. Early concentrations of population in settlements occurred for political, ecclesiastical, or defensive reasons as often as for commercial ones; but the period from the 11th century onward saw the widespread rise of classes of men engaged in the commerce of exchange or manufacture and settled for that purpose in urban groups. Many of these were originally only merchants in a subsidiary sense; and many towns were barely distinct from large villages, being surrounded by the town fields cultivated by the citizens and containing within their boundaries numerous livestock and small patches of cultivated ground. Yet, a common interest among merchants or craftsmen produced associations of considerable importance. Merchant guilds developed—groups of men whose interests extended far beyond the political horizons of the lords of most towns, anxious for the reduction of tolls and in need of their own courts of justice appropriate to the urgent demands of itinerant commerce. It was these who led the struggle for urban autonomy in Europe north of the Alps—a movement which almost always involved conflict with the local lords, especially bishops and abbots, but was often favoured by princes such as the counts of Flanders or Henry the Lion, duke of Saxony, in the German east—and thus the juridical phenomenon of the town as a corporate person emerged, created within a pattern of territorial lordships. Similarly, such towns acted corporately, much like their contemporary landed magnates, seeking to subordinate neighbouring communities to the authority of the city magistrates, to compel the man of the countryside to acknowledge the legal and economic primacy of the urban centre, and to divert profitable trade routes to their own advantage. The 12th-century crusading movement reflected such local hostilities—the Byzantine monopoly enjoyed by Venice was challenged by the direct access to the trade of the East offered by the crusader states, often maintained by the rival fleets of Pisa, Genoa, or Lucca. Long intercommunal wars, such as those between Pisa and Genoa or between Venice and Ravenna and Pola (now in Yugoslavia), saw the rise of a small number of city republics governed by elected consuls combining birth and commercial substance in a unique blend. Within such towns there existed other interests also driven by their common economic interests into corporate action.

In some towns, such as London or Bologna, a civil organization based on a geographical division into wards or quarters existed in potential conflict with the alternative divisions by occupation or wealth. Associations of craftsmen and retailers formed themselves in guilds that had many objects beyond the commercial. Among the earliest known forms of such guilds were those of prayer; and many guilds had their own chaplains, churches, and such distinctive religious pageants as the cycles of plays performed by the various mysteries (or crafts) at Wakefield in England. Many also maintained a form of insurance for their members, for the old, and for the widows. But all came to be devoted largely to the regulation of their crafts—especially entry to them—and to the struggle for their interests against the competing ones of their suppliers or of related trades. The interests of the masters of these crafts were often opposed to those of the greater merchants, thus producing a struggle for control of the machinery of town government. Equally, however, other divisions cut across this classification by trades. Within the guilds there was a struggle between masters and men, between those anxious to reduce competition and those bent on a larger independence. Occasionally, and most strikingly in the industrial towns of Flanders in the 13th and 14th centuries, this produced proletarian risings of wide impact; at Courtrai in 1302 an army largely drawn from the Blue-Nails, the hired dye workers, inflicted a defeat upon the forces of the King of France and the Count of Flanders; frequently, the larger Flemish towns acted to free themselves from the power of the count or to maintain their communications with the English wool trade against the pressures of France.

Struggles for the control of town government

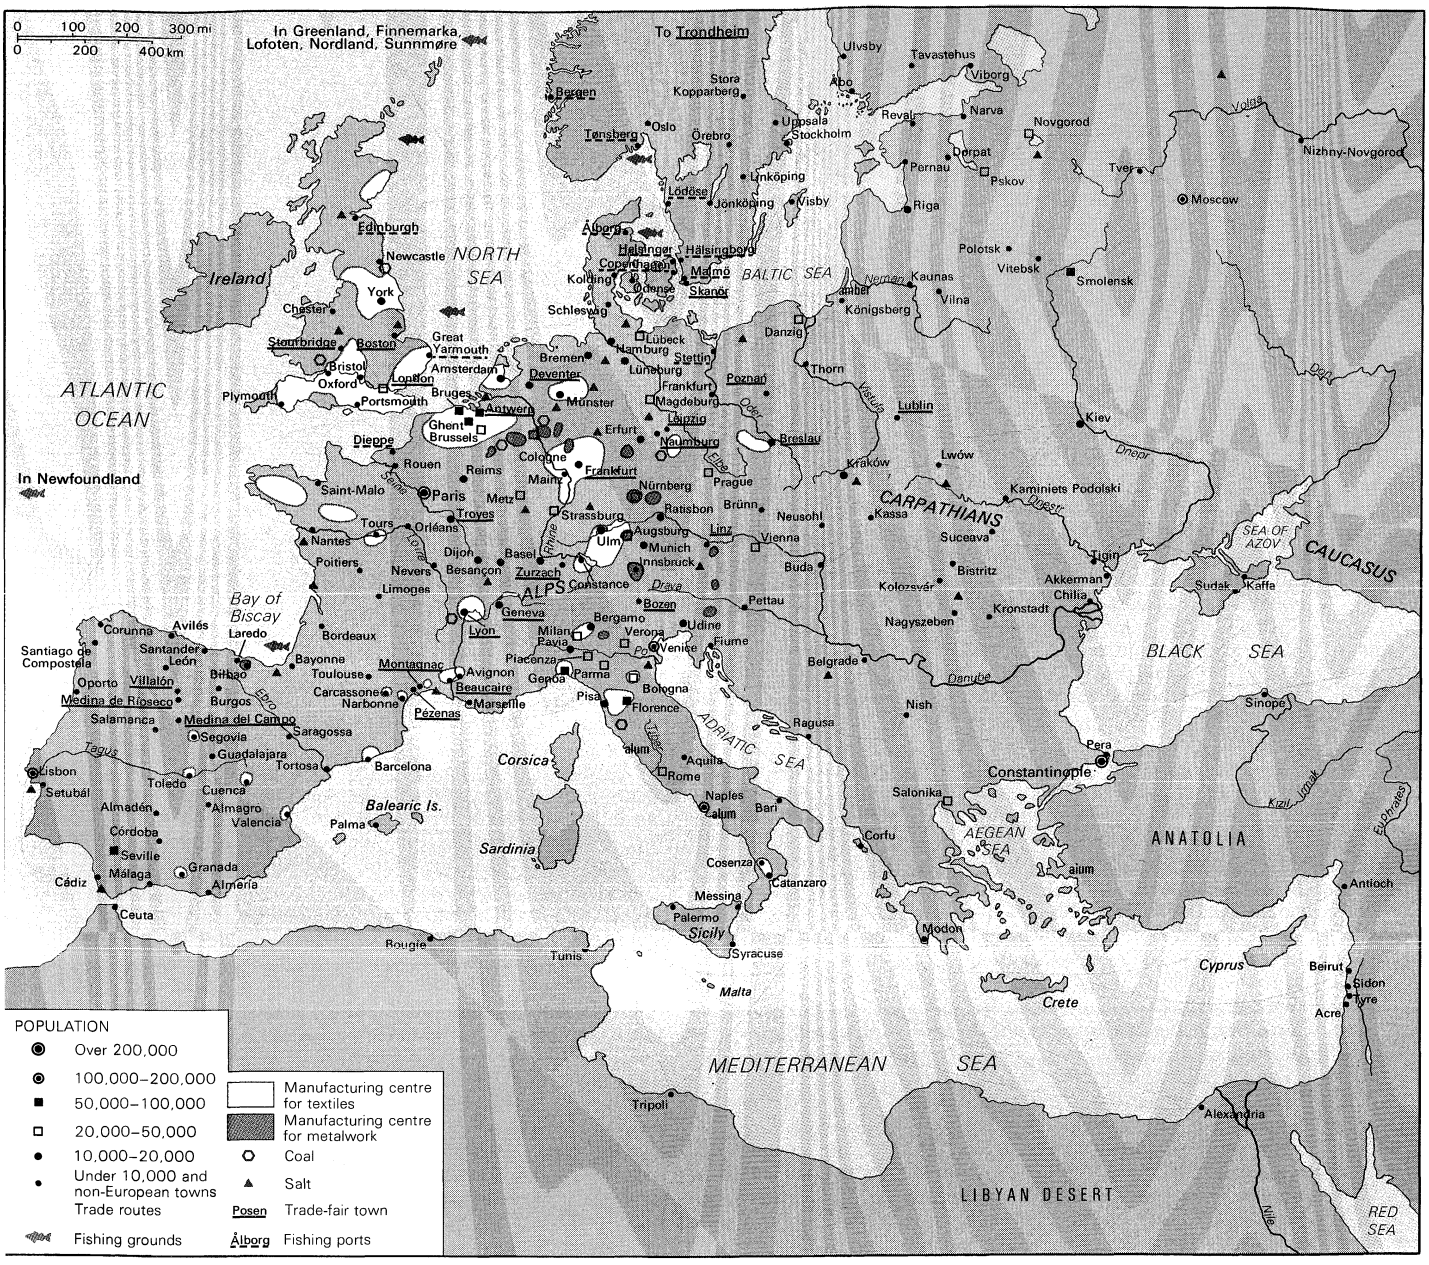
Though an urban proletariat of this kind was rare in medieval Europe, conflict between an urban oligarchy of landowners or great merchants (the *popolo grasso* of Italy) and the lesser craftsmen and labourers (the *popolo minuto*) was extremely common; it was at its fiercest where the cities enjoyed great autonomy, especially in Italy, where there was no effective or extensive central authority to maintain order. Hence, there were frequent civil wars in the Lombard towns, complicated by their external relations with each other, with the papacy, and with the empire; and there was a wide variety of forms of communal government, ranging from such attempts at radical democracy as the rising of the Ciompi of Florence in 1378 to an increasingly dominant model of dictatorship, such as that exercised by the Malatesta of Rimini, the Visconti of Milan, or even the Medici of Florence.

The independence of the Italian city-states, which was complete by the end of the 14th century, had rested in part upon the successes of the Lombard League against the empire in the late 12th century. North of the Alps, particularly in Germany and the German-settled lands of the east, towns established similar but rather more restricted liberties against the greater princes and formed into leagues of economic communal interest, of which the most notable was the Hanseatic League of Baltic towns, which secured a near monopoly of the profitable northern trade in timber, furs, wax, and amber. First clearly organized in the late 13th century, by the 14th the league was the dominant commercial force in northern Europe. In alliance with the Teutonic Knights and by an aggressive policy of embargo and blockade, it secured privileges superior even to those of the native merchants in Russia, Sweden, Norway, England, and Flanders. Only in the later 15th century did the league begin to decline, with the failure of the Knights, the increasing commercial activity of the western kingdoms, and the decline of the Baltic herring fisheries.

Urban independence on the Lombard or Hanseatic model was exceptional, however; in France, Spain, parts of Germany, and England the towns remained firmly within the framework of royal or princely government, not least because only the king could be relied upon to maintain political and fiscal stability at home and to negotiate commercial privileges abroad. Contingents from the towns formed a numerically formidable element in the royal army at Bouvines (1214), when Philip Augustus defeated a combination of Norman, Flemish, and imperial forces aiming to restore the earlier independence of some of the greater vassals. The protection of merchants had been a duty to which 11th-century popes had recalled kings; it was the financial support of the towns that was of importance in the triumph of the "new monarchies" of 15th-century France, Spain, and Tudor England.

Protection of merchants

Forms of lordship. Upon these economic structures there rested a variety of structures of lordship. The earliest



Medieval industry and trade *c.* 1500.

that can be discerned in the centuries after the migrations were extremely complex, being functions of a power that was at once one of property, of kinship, of public function, and even sometimes of priesthood; only in the course of the later medieval period did these elements of authority come to be distinguished and sometimes divided.

Serfs. The economic bases of lordship in its least complex form lay in the ownership of men: the large household of slaves was the lord's property, and they worked his land. They enjoyed no rights against their lord, and he was responsible for maintaining peace and regulating their duties; such households of slaves became rare quite early over most of Europe. Domestic slavery was still an active force in the Iberian peninsula and Southern Italy at the end of the Middle Ages, though only in Sicily and the Balearic Islands were slaves widely engaged in large-scale agriculture. The responsibility of the lord for his own domestic servants remained near absolute, the successors of many household slaves were the serfs who settled on small plots of land; the descendants of other freer men were reduced to a similar status by poverty, war, the burdens of public taxation or even by the justice of the church. Like the Roman slave, the medieval serf had no public rights against his lord; he was *adscriptus glebae*—so bound to his land that he could not leave it, and a part of its stock to be sold with it. The lord, by virtue of holding the land, was responsible for all police jurisdiction over his unfree men in his own court. His serfs were unable to marry without the lord's consent; in theory, their goods were his to tax at will during their lifetime and to confiscate at their death; their children were born into serfdom; and in all disputes there was no appeal from the lord to any higher tribunal.

Practice diverged at least in part from this grim theory. The agricultural cycle in which these serfs lived was conservative and complex, and custom operated powerfully to maintain it. Correspondingly, the disputes of tenants with each other and with the lord were regulated essentially by local custom, which was proclaimed by the body of the tenants in the lord's court. The rights of the lord to the labour of his serfs through the year and at the chief seasons of ploughing and harvest were also fixed by custom and were rarely (and slowly) altered except at times of sudden crisis. The rights of the lord to the property of the serf were equally confined, so that the serfs' duties were expressed as the obligation to render produce for the great

feasts of the year or to take their grain to the lord's mill, their flour to his ovens, or their grapes to his wine press or to make fixed payments at the marriage of a daughter, a father's death, or entry into a peasant holding, whether by inheritance, marriage, or purchase. Any or all of the other services could be commuted for money payments also, and, in western Europe at least, the function of the lord's court in regulating serf labour on his demesne was becoming obsolete by 1500, though its other functions still had a long future.

The bond between serf and lord

In some parts of Europe the duties of the serfs included services that are less comprehensible; and the very intimate bond between serf and lord might contain elements more accessible to an anthropologist than to an economist or historian. In many cases the autocratic power of the lord was mitigated not merely by force of custom but also by close and frequent personal contact. The plans of early manor houses and castles show no extensive private rooms for the lord's use: he dined with his servants in his great hall, where he meted out justice. There was, until the later Middle Ages, little provision for private gardens for the lord's use; all but very great men could be found working at their own harvest. And feasts in the hall brought together the whole village community.

The lord had need of other services beyond those of his house and arable land; the greater Carolingian estates had even carried their complement of carpenters, smiths, potters, and weavers, free or unfree, as well as the usual haywards, shepherds, and beekeepers. Men personally as unfree as the serf might also undertake more responsible tasks; the *ministeriales,* pre-eminently of Germany, acted not only as bailiffs but even bore arms as knights, though in such cases the dignity of the occupation came ultimately to cancel the defect of birth.

Feudal bonds. Men of free birth were found over all Europe, though in varying numbers, who recognized the authority of a lord for some purposes—holding his land in return for rent or services less servile than those of the villein. Most areas of Scandinavian settlement, much of Saxony, and the Low Countries were marked by numbers of such men, who often pronounced judgments in their lord's court or escorted him through his estates, providing a contingent of men-at-arms in war and rent-paying tenants in peace. Lordship of this kind stemmed directly from the ownership both of land and of some of its tenants; the profits of lordship were, however, drawn from much wider sources than the labour of serfs or the rents of free tenants. Either by grant or by usurpation, a great variety of forms of indirect taxation were open to the lord. The levy of tolls on rivers, bridges, or roads was perhaps the easiest source of revenue open to any man; a license to hold a market in a vill would not be sufficient in itself but also involved payments for the holding of stalls and even a tax on individual transactions. Very great men might even mint their own coinage; consequently, the currencies of France, Germany, and Italy were extremely fragmented and often unstable.

The most distinctive form of medieval lordship, however, was that which is often called feudal, from the Latin *feudum,* meaning "fief," which was its central feature. In essence this was a fusion of the earlier *precaria,* a grant of land made for a fixed term in exchange for services or rents, with the very general commendation by which a man placed himself under a lord's protection by becoming his man or vassal. Some of those who had served their lord well would receive from him a benefice of land or revenue as a reward; others in dire need of protection would surrender their own land to the lord to receive it back as a benefice from him. When the tenant's right to his land became hereditary and his tenancy, or fief, ceased to be a reward for past services and became the reason for services to be performed in the future, feudal tenure was fully developed. These processes can already be traced before the end of the 9th century in the Carolingian Empire.

Creation of feudal bond

By the 12th century such tenure was to be found throughout Latin Europe. It was characterized by a number of symbolic acts. The first was homage, the process by which the man knelt and placed his hands between those of his lord, so putting himself at the lord's disposal and under his protection. The next was the oath of fidelity, sworn by the man to his lord, sometimes sealed with a kiss. Then came investiture, by which the lord handed over some token of the fief to his new man. This sequence was first fully described in the year 1127, but its various elements can be traced or inferred very much earlier, though they were not all necessarily found together. The bond so created was much more than a form of land tenure; it was first a human relationship, in which the lord assumed many of the rights and duties of a father and from which the man could escape only if the lord directly attacked his life or family. If the lord died leaving a child as heir, it was the duty of the tenants to maintain the heir's rights until he came of age; similarly, if a tenant died leaving children under age, their wardship was the lord's. Not the least of the man's obligations might be that of attending the lord at the great feasts of the year, which were at once parties, parliaments, and law courts.

The duties of the lord to the tenant were usually only generally stated; he was bound to protect his man in war and peace, in the field, and in the law court. Carolingian legislation sought to ensure that every man had a lord to answer for him; a lordless man was a man in danger himself and a danger to others. The duties of the man to his lord varied enormously. Sometimes, even very early, the terms of his tenure were minutely defined. More often the general phrases of aid and counsel were called on to cover every possibility. As in the case of the servile tenant of the vill however, a general subordination to the lord first became fixed by custom and then often commuted into a money rent. The aid the man owed was primarily military aid, essentially service with the full equipment of a knight—lance, sword, helmet, mail hauberk, and powerful horse. A great man's household usually contained a permanent body of these knights, who were often landless young men of good birth but no fortune; but the obligations of the enfeoffed knights living in the estates they held of their lords were early restrained, by custom at least, to a period of service in the field of 40–60 days and sometimes a limited period of garrison duty or castle guard at the lord's fortress. Not all personal aid, however, was military: there were also the sergeanties—fiefs held on condition of performing other services. These ranged from fulfilling the highest offices in the lord's household, such as steward, constable, or marshal (or even jester), to picturesque or purely honorific obligations, such as providing the lord with an annual goshawk, a leash of hounds, or a pair of gloves. All such services might come to be commuted for money payments; by 1200 it was common for the bulk of the knights liable for royal and even magnate service to settle their obligations by the payment of sums of scutage (literally shield money). Because, by then, service was seen as a burden on land and because this land might be in the hands of a church, a minor, or a woman or might be divided up among many heirs, such payments were a convenience to the tenant. The campaigning season and the high costs of a changing pattern of warfare often made money payment just as attractive to the lord.

Payment of scutage

Sometimes the lord might need financial aid for less strictly military reasons; again, custom came to distinguish the aids that he could levy from his tenants by right from those extraordinary ones for which the tenant's consent had to be sought. Practice varied, but the four most frequent were the knighting of his eldest son, the marriage of his eldest daughter, his setting out on crusade, or the ransom of his body.

Although in all these cases custom tended to establish the tenants' right in their land, there were three important traces of the lord's continued interest in what his ancestors had once granted: the relief, payable by an heir on entering into his inheritance; escheat, by which the lord recovered control of a tenure for which no direct heir could be found; and forfeit in the case of a tenant's treason or failure to perform his duties. The financial exploitation of these incidents of tenure and of the rights of wardship and marriage was among the most widespread of grievances against kings and great magnates in the 13th and 14th centuries.

The counsel that a tenant owed his lord also acquired a

formal sense. By virtue of having tenants, a lord had an honour court, where disputes between tenants or between lord and tenant were heard. The tenant's duty to attend (to perform his suit of court) was of the greatest importance to the lord: it was the number and dignity of the suitors to his court that gave its judgments authority and stability. Around this central institution of the lord's court grew up in the greater honours much of the apparatus of a sovereign state. The greater officers of the lord's household, most notably the steward, or seneschal, played an active part in overseeing the lord's estates, and in the later Middle Ages they often formed a council with regular sessions to audit the accounts of their lord's estates and developed their own code of legal precedents. In the 13th century, treatises upon the customs of such tenurial courts appeared in considerable numbers side by side with studies in Roman or royal government (the *Sachsenspiegel* in Germany or the work of Beaumanoir in France may serve as examples). Only their homage to the king or emperor, with a variable liability to be summoned to his court, distinguished the greater magnates of France or Germany from sovereign princes.

Hierarchy of lordships

Theoretically, society could be conceived as a hierarchy of such lordships, with the sovereign at its head; but the practice was usually very different. In Germany the obligations of vassalage long retained traces of their servile origins, so that great men assumed them only with reluctance. It was correspondingly rare for a man to be the vassal of more than one lord; hence, a hierarchy of homages could appear in the late 12th-century *Heerschild* (a formal definition of social standing according to the number of intermediate lords between a man and the emperor) with the emperor at its head, the greater churches beneath him, then the imperial princes, who had done homage only to the emperor or the church, then counts, then noblemen, and so on. Even here, however, the consent of the other princes (the *Reichsfürstenstand*) was necessary for admission to the highest ranks, and the obligations such homage entailed were relatively very slight. Elsewhere—in France particularly—homage to more than one lord was frequent (the county of Champagne was held of 10 different lords), so that no such organizing principle could operate. What determined the permanence and vitality of tenurial networks was in part political and military circumstance, in part the extent to which some higher authority was able to intervene between lord and vassal, and in part the extent to which this lordship over men or tenants was able to absorb earlier administrative or public authority.

Royal government. The growth of the centralized institutions of predominantly royal government is a phenomenon that was involved with the rise of certain technical skills in the collecting and organizing of information. Until the 13th century there were no maps of great practical value; the statistics occasionally collected by medieval governments were often inconsistent and made according to erratic principles. Until near the end of the period, the usual methods of accounting and bookkeeping precluded most calculations performed by a modern government. It is a notorious defect of medieval chroniclers that the numbers they attribute to populations or even comparatively small armies are almost invariably the purest fantasy. The technology of transport was equally primitive; the best roads in the 15th century were still the Roman imperial streets, for all their thousand years of neglect, and winter flooding still affected most river systems in spite of some large-scale drainage works that had been undertaken in the Netherlands, Italy, and elsewhere. Under such conditions a central government wholly free of "constitutional" restraints would still be obliged to leave its local agents a large measure of independence, and the custom of the neighbourhood was necessarily the chief regulator of political as well as social and economic relations.

The royal household. The seed from which all medieval institutions of central administration were to grow was the immediate personal household of the king; its members were the only permanent staff he had, and only their intimate personal association with their lord was a guarantee to others that they did indeed represent his views and bear his authority. The essential elements of the early royal household therefore provided the framework of the first departments of state.

Officers of the hall

The chief elements of the royal household were four—the hall, the chamber, the chapel, and the courtyard, with its horses and stables. The whole household, but in particular the hall, which was at once palace, law court, and dining room, was directly governed by the steward (*dapifer, seneschal,* or *drost*), under whose direction the guests were seated and the feasting conducted, while the wine was under the charge of a butler (*pincerna, Oberschenk*). Under the later Merovingians in Gaul, the mayor of the palace (literally chief of the house) became a figure so powerful as first to overshadow and then replace his king; elsewhere, though less powerful, the steward was the usual chief deputy of the king. Under the Capetians of France he was charged with the annual scrutiny of the accounts tendered by the king's local bailiffs, the provosts; in Normandy, Jerusalem, and elsewhere he was the natural choice as regent in his lord's absence; the butler shared some of the prestige of the steward but had yet few defined functions.

The chamber

The chamber, the room in which the king slept or took private counsel, was also the natural place to store his treasure; hence, the chamberlains were often specially charged with the collection of revenue and handing it out as the king had need. The papal treasury was known as the Apostolic Chamber, and the papal chamberlains were widely entrusted with financial missions.

The chapel, containing the royal altar and relics (the term chapel derives from the *capella,* the short cloak of Saint Martin preserved among the chief relics of the Carolingian royal treasury), was served by chaplains, to say the daily mass, assisted by a body of clerical assistants. As the chief and sometimes only literate members of the household, these men were responsible for drawing up such documents as the earlier kings required; among their number and often at the head stood the chancellor, whose special task was the authentication of royal acts, usually with the seal, which he kept.

This royal household was constantly on the move, carried on carts or packhorses, and hence the great importance of the last two major household offices, those of the constable and marshal. The duty of the count of the stable (constable) was closely associated with the organization of the army, and hence the term came to be used of commanders of garrisons as well as the central household officer. The office of the marshal was originally more humble but shared the military fortunes of that of constable. In the 14th and 15th centuries constable and marshal came to a new importance as military commanders and correspondingly acquired judicial competence as presidents of the courts of chivalry, which dealt especially with military discipline, the division of ransoms, and the right to bear a coat of arms.

The growth of a permanent bureaucracy. These early household offices, with characteristically unspecialized duties, changed greatly under the impact of two forces. First, these central offices had a tendency to become hereditary, much as the local offices of count or duke had done; since the domestic service of the king, at least on public occasions, was itself a very great dignity, the most powerful families claimed the right to perform it, so that the office came to be the prerogative of great magnates who were too preoccupied elsewhere to perform their duties in person. Even the chancellorship sometimes became attached to certain archbishoprics—Reims or Mainz, for instance; since the king's domestic needs continued, a distinction evolved between the hereditary dignitaries such as high steward or archchancellor and the men of much humbler rank who actually performed the routine duties of the household. Second, the increasing volume of business done in the king's name—judicial, administrative, or financial—demanded ever more elaborate records and a more extensive staff; therefore, the offices of government were less mobile, and a physical distinction became common between the constantly itinerant household about the king's person and the more cumbrous (though rarely wholly static) departments of permanent officials. Furthermore, the processes of government, especially in the

chancery or (particularly well documented) the English exchequer, became arts or mysteries that demanded a staff of financial or legal experts with a specialized training. Thus were born the chief departments of state; well beyond the end of the medieval period, however, their principal officers were still considered the king's servants in a literal sense. This household character of public office made the distinction between loyalty to the king's person and loyalty to the office extremely hard to draw and frustrated many early efforts at "constitutionalism."

The chancery

Of these departments of state, the chancery was perhaps the most essential, for without a means of transmitting a number of recognizably authentic commands or recording the business already done, no large measure of centralized activity was possible. The first sign of the emergence of a chancery proper is the appearance of stereotyped formulas for the drafting of documents, classified according to their purpose. The papal chancery was the earliest office to develop this skill on a large scale; the rhythm of the text and the forms of authentication for papal bulls were already formalized before the mid-12th century. Similar tendencies are found in England in the reign of Henry II, and in France only a little later. (The urban notaries of Italy and parts of southern France were already using formalized business documents, though for a much more restricted area.) The second sign is the appearance of a substantial collection of records; apart from the financial records, dealt with below though often compiled by chancery clerks, the essential element was the keeping of copies of documents issuing from the chancery, distinguished according to their character. Papal registers had probably been kept from a very early date, and a later copy of the Register of Gregory I still survives; an imposing and ever more complex consecutive series of original registers survives from the early 13th century. These were in the form of books. In England, where the great period of initial expansion lay in the period between 1190 and 1216, and in France, where the early royal archives have suffered much graver losses at the hands of time, the characteristic record was a series of parchment membranes stitched together to form long rolls. These archives evolved rapidly through the 13th, 14th, and 15th centuries, with the preservation of many more classes of document, including informal memoranda. Such records served the purposes of both governor and governed, for they provided precedents and the material for the reform and improvement of administration for the king's servants. They also provided authentic copies of title deeds or privileges for a subject at odds with his fellow or even the king himself. The conventions of the chancery had a marked tendency toward autonomy; efforts at magnate control in England or extensive reform of papal administration in Rome were partly frustrated by the elaboration and conservatism of chancery procedures that might at other times offer a useful defense against arbitrary government.

Among the most immobile elements of medieval government were those connected with the collecting and checking of the royal revenue. Until the 13th century, the only coinage current was the silver penny (or denier), so that large sums could only be transported packed in barrels of great weight. It was therefore natural for royal treasuries to appear as places of permanent deposit, from which the itinerant court or army could be supplied at need. Often the treasury would also be the first site of any permanent archives. The rendering of accounts by the sheriffs, provosts, bailiffs, or seneschals who were local collectors of royal revenue was a matter that could not be performed at a wholly itinerant court. Not only was it necessary for auditors and agents to have a known place and time at which to meet, but all except the least sophisticated forms of accounting required the keeping of records of former debts and present liabilities. Under Charlemagne, a *Capitulare de villis* envisaged a wide enquiry into the estates of the emperor, though only fragments of the returns survive; similar surveys were being made in 11th-century France and Germany on a small scale, but no early text can rival the record of Domesday Book (compiled in 1086/87), a survey of almost all of England, shire by shire and fief by fief, drawn up by the clerks of William the Conqueror. It is still preserved among the English public records.

The growth of permanent records

The rise of the exchequer as a semipermanent office and court for the hearing of accounts and the adjudication of financial claims was an early and striking feature of Anglo-Norman government on either side of the Channel. The exchequer took its name from the checkered cloth used by the royal officials as an accounting device. The cloth was used as a kind of abacus and may have owed something to Arabic skill in mathematics transmitted by the Norman settlements of Sicily. Certainly in existence soon after 1100, its first surviving pipe roll of 1130 is the earliest record of receipts of its kind for all of medieval Europe. In France the Capetian kings for more than a century used the Knights Templar as their bankers, so that it was not until after the withdrawal of his treasure from their hands by Philip the Fair in 1295 that a fully independent Chambre des Comptes emerged, with a comprehensive staff of financial experts.

The cumbersome machinery of such financial bodies was a grave impediment in times of political, financial, or military crisis, although as in the case of the chanceries, due process offered some protection against arbitrary government. The frequent wars of the English kings and their long absences in France, as well as their desire to escape the oversight of great officers approved by their magnates, encouraged the appearance of various financial systems within the household to compete with that of the Exchequer; the wardrobe under Edward I, for example, expanded from its original function as the king's domestic treasury to become the organ responsible for the payment of his whole army or, under his descendants, of the chamber itself.

The king's council

As these departments of state became more fixed, professional, and independent, royal councillors who gave a political direction to the government acquired a distinct existence. From the beginning, the king's household had been of shifting composition, and a number of men enjoying his special confidence were often to be found there even if they were not holding household office. In the early 13th century the king's more or less permanent advisers began to take on a more formal character as the king's council. This council, often given definition by the taking of a common oath, was as omnicompetent as the king it served, and correspondingly, in times of political crisis, magnates or great assemblies sought to impose their nominees—as in England in the crisis of 1258–65 or France in 1356–57 or Aragon under Alfonso III. The direct and personal nature of the council's functions made such efforts almost always abortive. Only in Scandinavia, where the union of the three crowns involved prolonged regencies and uncertainties of succession, did the Råd enjoy a large independence from its king, though many German princes of the 14th and 15th centuries were compelled by their estates to accept a nominated council. In the 15th century the powers of last resort possessed by the king and exercised in consultation with his council allowed the formation of offshoots of this council as prerogative courts of justice, administration, and finance.

Birth of parliamentary bodies. Over the same period, the larger assemblies in which some royal action had long taken place were also taking on a clearer form and defined functions, issuing in the assemblies of estates to be found over most of Europe in the 15th century. Three distinct influences lay at the origin of this development—ancient custom, feudal law, and administrative convenience. The Germanic tribes described by the Roman historian Tacitus in the 1st century AD gathered regularly in arms to determine matters of general importance. In some respects it was the size of such gatherings that decided the size of the kingdoms to which they elected chieftains; such gatherings of the warriors continued well into the period of Frankish rule, even in those areas where the powers of the king were very great. In Scandinavia meetings of the *thing* never wholly passed into the power of magnates or royal officials, though elsewhere they changed radically.

As the old *mallus* or *thing,* with its lawgivers and its president, had become the court of an hereditary count and his vassals, so the assembly of freemen was widely altered

in the same way. To the king's great courts his chief tenants were summoned by virtue of their obligation to give their lord counsel; the number of those who came was the critical test of the king's authority. The decline of French royal power in the 10th and 11th centuries or of German kingship in the 11th and 12th centuries can be plotted on maps by examining the composition of their great courts, especially at the chief feasts of the Christian year (or at principal landmarks in the life of the royal family, such as marriages and the knighting of the eldest son).

Since these large sessions of the tenants were also the most solemn courts a king could hold, great issues would be brought to it; since they were usually held at known times and places, those who desired the king's help in securing justice would seek them out. There were, however, further reasons why the king should try to enlarge the attendance at his courts or councils; the bonds of land tenure in most of Europe before 1300 had long ceased to articulate all the elements of society. To regulate the affairs of merchants, for instance, the feudal bond was worthless to secure counsel or consent. More important still, the obligations of feudal tenure no longer provided the forms of taxation needed for the defense of the state, and whatever methods of raising money supplemented them required the consent of the community in a new sense. The princes of the late 13th century claimed to be lords of states, not merely of associations of men; in their conflicts with the papacy, in their assertion of legislative authority, in their claims to the financial support of the whole community, kings required a very general assent. Unless qualified representatives could be gathered, the king's will could not be known or the justification of changes publicized; the rise of the representative assembly is parallel to the rise of royal propaganda.

Representative institutions

In the 13th and 14th centuries these considerations produced a variety of experiments. In France after 1300, two meetings of the estates of magnates, churchmen, and burgesses were held often: one for the provinces of northern France (Languedoïl), another for culturally different provinces of the south (Languedoc). Provincial gatherings of this kind were naturally prevalent in the states of Germany, where the dynastic disputes and poverty of many of the princes made them peculiarly subject to the pressures of their estates of knights, burgesses, and clergy; the imperial Reichstag, attended theoretically by the tenants in chief (chief vassals) of the emperor and representatives of the imperial towns, was intended to cover the whole of Germany but was as powerless as its central authority. In the kingdoms of Spain, signs of development appeared very early, representatives of the towns being summoned in 1188 in Leon; by the mid-13th century, the presence of townsmen in representative assemblies was customary throughout the country. In Aragon magnates and knights were separate elements, but elsewhere the more usual pattern of the three estates of nobles, churchmen, and burgesses prevailed. The English gatherings to which the term parliament came increasingly to be applied differed in important respects. From early in the 13th century, the king had summoned his tenants in chief to meet at the same time the central courts of justice and finance were in session; thus, royal officers, innumerable representatives of the shires and boroughs, and the magnates were gathering at one time. By the end of the 13th century, it was becoming common for special representatives to be summoned from the shires and the boroughs to attend these parliaments; by the mid-14th century, their attendance had become the rule, but the clergy had largely withdrawn, except for the great ecclesiastical magnates who sat with the temporal lords, while the knights of the shire and the burgesses of the towns met together as a single body. Hence, there emerged a quite exceptional body with two chambers and a permanent representation of the non-noble landowners to contrast with the much more widespread model of the three estates.

English Parliament

The business undertaken by these gatherings was extremely various. For reasons essentially of convenience, it was customary to publish legislation at such assemblies, as church councils had done for centuries. In Aragon and Catalonia, Scandinavia and much of Germany, the consent of the assembly was required to legitimize such enactments; custom produced much the same effect in England, and the Aragonese kings of Sicily (who replaced the Angevins there during the War of the Sicilian Vespers, 1282–1302) proclaimed the same principle. Yet more frequently they were assembled to assent to taxation, sometimes, though never wholly, saving the prince the difficulty of negotiating with each town or community for a contribution to the common need; they continued to constitute also the most weighty public court for the hearing of great causes. Though summoned essentially to consent to decisions made by the king and his inner council, such assemblies necessarily possessed a potential power to refuse or demand a precedent redress of grievances; and as the powers of central government became greater, efforts to impose restraints on the prince in the name of the community became more widespread. Such restraints had long been recognized in theory, but the rise of these larger assemblies provided a focus for such claims that was more effective than the earlier courts of feudal tenants. Precocious efforts to subordinate royal government to the scrutiny of the magnates in Parliament, and even to require general assent to the appointment of officers of state, occurred in England between 1258 and 1265 and continued with some formal success in the 14th and 15th centuries. It was a successful struggle in the 14th century to require parliamentary consent to all extraordinary taxation that ensured the regular summons of such gatherings and made possible their use as an occasional forum of political discontent or even revolution, as in the reign of Richard II.

The States General in France made similar efforts at political control of the kingship in the crises associated with the capture of King John, between 1356 and 1358 and again in 1413. The Cortes of Spain secured an even larger measure of success; in 1287 the magnates extracted from Alfonso III of Aragon the Privilegio de la Unión, which conferred upon the Cortes even the power to depose an unjust king; here, too, assent to taxation was a prerogative of the assembly, though grants were made only by the burgesses. The weakness of these estates were very like those of the 15th-century councils of the church in their conflicts with the pope. Essentially they were occasions, rather than permanent bodies, which were either summoned by the king or—if gathered by any other means—were unrepresentative. Their control over the monarchy lasted only so long as they were in session, and exhaustion or particularism frustrated their long continuance. The kings could normally exploit either the localism or the diverging class interests of their estates to prevent any continuous supervision. In Catalonia in the 15th century, the Cortes possessed a Diputaçio del General, a standing committee to watch over the government, which not only granted but collected and spent any extraordinary taxation; but the forms of taxation divided the burgesses from the knights and nobles. In England there was less division of class interest but no effective or continuous supervision. In all cases, the resistance of the magnates was a precondition of large claims on behalf of the estates; yet a prolonged and successful magnate resistance destroyed that fusion of local and class interests upon which the estates depended for their vitality.

Cultural life. The communities of the early Middle Ages lived on intimate terms with a largely hostile environment. Storms on sea and land, floods, pestilences, and famine were constant hazards. Even in the more densely settled parts of Europe, impenetrable forest and trackless fen covered large areas. These areas were often believed to be the haunts of demons and, in fact, provided refuge for brigands and outlaws as well as wolves and wild beasts. The uncultivated moorlands and mountain passes were safely crossed only in haste and with company.

Pagan religious survivals

The religious beliefs of the pagan tribes were appropriate to this environment of apparently random disaster. The gods of the Germanic tribes were wanton and crafty, and fertility cults were probably widespread though intensely local. Formal belief in Odin, Thor, or Freyja gave way rapidly before the missionary fervour of Arian and Roman missionaries, but many pagan elements passed into

the superficial Christianity of the first converts. Devotion to local saints was often (even deliberately) based upon earlier pagan cults, while churches were built on the sites of temples or sacred groves. Early miracle stories often attribute markedly pagan qualities of willful jealousy or capricious good will to the saints. The mere possession of such wonder-working relics as the Holy Lance of the empire was supposed to confer a title to the crown and a formidable military authority to its holder. There was a brisk traffic in such objects among princes, while the sacred groves and wells of the earlier religion rapidly took on the name of some local saint for the peasant population. Augury, the sacrifice of cattle, and a host of other pagan rites continued throughout the period, though the ecclesiastical police system was more and more successful in sharpening the distinction between acceptable devotion and witchcraft.

Christian life at the parish level necessarily reflected such conditions. In a literate society it was the ceremonial performance of the sacraments that was of paramount importance; indeed, preaching was a late and occasional addition to the duties of the parish clergy. The blessing of harvests and houses, the averting of plague, fire, and invasion by regular formal intercession were the essential functions of the parish clergy. Correspondingly, communal disaster and outbreaks of anti-clericalism were closely connected. For the salvation of the individual the church required annual confession and very occasional taking of the sacrament. Private confession and private penance became the rule by 1100, but penance might be done by extensive travelling. By the 12th century, pilgrimages were made to the great international shrines of Jerusalem, Rome, Santiago de Compostela, or even St. Thomas of Canterbury, as well as to a host of lesser local shrines, insuring against the future or expiating past crimes. The Crusades, in part intended to restore the pilgrim road to Jerusalem, were themselves a means of securing full remission of sins for the participants. Their frequent failure or diversion to trivial or political ends made them a dying force after 1300, but the need for such concrete means of salvation continued (see CRUSADES). Papal jubilees and the organization of a system of indulgences secured by generous alms met this need, though offering many opportunities for abuse.

Until the 12th century, when Manichaeism spread through Italy and southern France, the orthodox church in the West was notably free of the doctrinal divisions that rent the Eastern Church. Eradicated by prolonged and bloody war, this heretical view had little later influence, but the source of its success—the wealth and pastoral inertia of the secular church—was to produce a multitude of dissident movements that laid stress either upon the defects of the propertied clergy or upon the direct illumination of the individual, notably by the reading of the Scriptures; already in the 12th century the Waldenses had adopted such views. In the late 14th century, John Wycliffe in England preached individual salvation and criticized the whole fabric of the church, sacramental and hierarchic. Wycliffe's doctrines met with little response in England but provided the starting point for the Hussite movement in Bohemia, where economic, political, and doctrinal revolution united to threaten the whole social and ecclesiastical order of eastern Europe.

In part this multiplication of dissent drew on the anticlericalism of the more educated laity and on wider knowledge of the Scriptures in vernacular versions, but it also coincided with the end of the period of monastic reform and development; while the fervour of St. Francis produced a new order to perform a vital function within the church, the devotional tendencies of the 14th and 15th centuries associated with the names of Meister Eckehart or Thomas à Kempis were largely devoid of institutional consequences. At the opposite extreme of this interior devotion was the proliferation of extravagant sects such as the recurring appearance of the flagellants in the years after the Black Death and its successors ravaged Europe. The prophetic form of much of the Scriptures, the frequency of disasters that appeared, at least locally, to portend the collapse of human society, and the general belief that the centuries after Christ's coming represented the last age of mankind produced a steady trickle of sects believing in the imminence of judgment or the new Jerusalem, encouraged by an easy distortion of the view of such academic prophets as Joachim of Fiore.

Communal organization

Against the hostility of their world, seen or unseen, medieval societies also fell back upon a wide variety of communities vowed to mutual support. The minimal privacy of the characteristic medieval household gave all houses a communal quality. It was common for several generations to live, eat, and sleep under one roof, which often enough covered the livestock too. The earliest forms of Germanic settlement and organization rested upon the kin group, the early codes all supposing that the kin had absolute responsibility for its members. In the unstable society of the early Middle Ages, the bonds of commendation by which men bound themselves to a protector provided a substitute for the security and social cohesiveness of the earlier kin group. The medieval impulse toward the formation of communities bound together by oaths may be seen also in the trading guilds of the communes, in the councils of kings and princes, and even in the societies of rebels or robber bands.

The tightly knit character of most medieval communities was a result of the relative immobility of the population. While the church and warfare were international occupations, in which a man might serve from one end of Europe to the other, and though merchants travelled with their wares across a multitude of frontiers, the bulk of the agricultural population rarely journeyed more than a few miles from their village, and many townsmen were equally confined. News travelled slowly and inaccurately, borne by pilgrims, peddlers, bailiffs, and beggars; marriage outside the village was unusual; and local dialects sharply contrasted. On the edge of this society, however, some adventurous travellers were covering huge distances. The Vikings sailed south to the Mediterranean, east and south to the Black Sea, and west to Iceland, Greenland, and the coast of North America. In the 13th century, the Venetian traveller Marco Polo crossed the breadth of Asia to China, where several Franciscan missionaries were to follow. In the 15th century, Portuguese seamen groped their way south along the African coast in pursuit of gold and a sea route to the Indies, rounding the Cape of Good Hope in 1488. In 1492 a Genoese seaman, in the service of Ferdinand and Isabella of Spain, crossed the Atlantic and returned; remarkable though Columbus' voyage was, the rapidity with which its significance was assessed and exploited provided proof of how much the European view of the world was changing.

Technological advances

Primitive though the vessels and instruments of these navigators were, they showed a marked advance over the equipment of their predecessors, an advance that was widespread and accelerating in the 14th and 15th centuries. From the 9th century on, water power was extensively harnessed to mill flour, replacing the infinitely laborious querns of past millennia; it was also at work driving the hammers of the ironworkers and the first fulling mills, which revolutionized the social patterns of cloth working. In the late 12th century, windmills also began to be used widely, while at about the same time changes in the forms of harness allowed horses to take over some of the ploughing and carting formerly performed by oxen. In the 13th century, mining techniques for the first time allowed the driving of deep but drained shafts beneath the surface to the richer iron, copper, tin, and lead of Bohemia, Sweden, or Cornwall. By 1500 the demand for charcoal for smelting and timber for shipbuilding was already pressing hard upon the once inexhaustible forest of an older Europe.

As a consequence of these changes, the use of iron became common, even in the implements and houses of the poor. Metal cooking pots, glass bottles, and glazed wheel-turned pottery came into widespread use. Houses of stone or even brick often now had the chimneys and glass windows formerly found only in palaces. Domestic furniture of these centuries survives to show that it was no longer confined to crude benches, tables, and chests but was more carefully fitted and elaborately decorated. In the 15th century the former cloth-working town of

Arras expanded its manufacture of the tapestry hangings for which it would be long famous, while silk, linen, and cotton came into wider use. Sumptuary laws showed how much wider a range of society was able to dress in the materials and fashions that had once been the hallmark of the highest rank.

Architecture

The earliest surviving medieval architecture is ecclesiastical; outside the area of continuing Byzantine occupation, these are small churches sometimes built out of the fragments of former Roman buildings and always derivative in style. Some of the greater Carolingian churches, however, were more ambitious in scale and conception, and the surviving 11th- and 12th-century Romanesque churches show the emergence of a wholly distinctive architectural convention in enormous and complex buildings. Gothic emerged in early 12th-century France and became the dominant style of the Latin West. In Italy the success of this style came late and was short-lived, for it was overtaken by the revived classical models before it had long taken root; but over much of northern Europe the Gothic survived into the 20th century.

The earliest surviving medieval domestic architecture is found in a few stone houses of the towns and in the modifications of fortresses to serve more domestic purposes. By the 13th century the stone palaces of princes were constructed with the skills first practiced in churches. Such planned towns as Aigues-Mortes foreshadowed the elaborate fortifications of many towns of the 15th century, within which numerous multistoried houses of wealthier merchants survive to the present. The single chamber of the lord's hall or the peasant's hut was increasingly giving way to the house divided into rooms, though in much of rural Europe there was little to distinguish the cabins of the poor of 1500 from those of a millennium earlier.

Recreation

The recreations of most ranks of society are poorly attested before the later Middle Ages. Among great men and warriors, the life of the hall and forest was pre-eminent. In the hall the long eating and heavy drinking of the lord's followers were favourite motifs of the heroic poetry once sung by household or itinerant poets, and feasts were an essential focus of social life. Coronations, weddings, and funerals were all celebrated with banquets. Pagan customs of punctuating the year with such events were either contested or taken over by the church; the gathering of the harvest and the celebration of Christmas were regular occasions of the kind, and from time to time the enthronement of a bishop produced a banquet of extraordinary splendour. The earliest texts stress the quantity (rather than the quality) of food and drink, but the more detailed later medieval records show that scarce or exotic foods and an extreme elaboration in their preparation were becoming the marks of ceremonial extravagance, the highest achievement of the pastrycook being such "subtleties" as the Holy Trinity surrounded by choirs of angels. Eating, drinking, and singing were supplemented by various forms of gambling, to which the Germanic peoples were so addicted that men were known to stake their own liberty on the fall of the dice and so condemn their descendants to slavery. Backgammon, chess, and (late in the period) card games were played by those with leisure and means.

The principal recreations of the nobility in the countryside were hunting and fighting, both of which were originally conducted in an extremely dangerous way. The main beasts chased were the deer, boar, wolf, and bear, with rabbits, hares, and foxes serving as a lesser challenge; all were usually pursued on horses with packs of hounds, the variety and qualities of which were discussed in numerous later medieval treatises. The support of the chase was an important economic and legal institution. The rearing of the lord's dogs and other services for his hunting were conditions of some tenures, and the preservation of hunting rights was a source of revenue and a cause of oppression. Another honourable sport was falconry. There was an appropriate bird for each rank of society, and in this sport women might participate more often than in the hunt.

The holding of sham battles for enjoyment and exercise became general in the 12th century, when the ransom of prisoners was an accepted means of support for skilled but landless knights. By the end of the century, the practice was so widespread as to attract the condemnation of the church and to represent, it was supposed, a threat to the stability of the state, since gatherings of armed men could readily become rebellions. In later centuries, this generalized melee gave way increasingly to highly formalized jousting between individual knights wearing armour especially adapted for a variety of possible rules of combat. In the 14th century this was still a possible means of capture, ransom, or death; by the end of the 15th it was almost entirely a sport.

For the less wealthy, the available entertainments were rarer and less elaborate but not perhaps much safer. Football, wrestling, or fighting with staves, regulated by few conventions, produced a heavy casualty rate, as did brawling in innumerable unregulated alehouses. Brewing was a cottage industry frequently engaged in by women, who sold their product subject to a seignorial right to examine the quality of the drink. In a society in which sugar was expensive even for kings and in which honey was prized but scarce, the thick beer and mead of the north was not only a focus of recreation but also an essential element of diet, as was the wine of the south.

Medieval music

Among the earliest of recorded arts was that of song, and a substantial body of medieval music has survived. The best known is the ecclesiastical plainsong, whose origins are attributed to the liturgical reforms of Pope Gregory I, which was elaborated into the complex polyphony of the 14th and 15th centuries, when for the first time the names of individual composers are recorded. The songs of troubadours and minnesingers of the 11th and 12th century show the rise of a sophisticated secular music that was increasingly accompanied by a variety of musical instruments. Well before 1500 the playing of music as an autonomous and often purely secular art was already established.

The decorative arts of painting and sculpture had undergone a similar progress, but here the revived interest in the secular products of classical antiquity and extensive lay patronage may have hastened the emergence of such arts from a wholly ecclesiastical setting to produce the flourishing schools of Italian and Flemish painting and the extensive sculpture of 15th-century Italy. In both cases the remarkable triumphs of the earlier period, the mosaics of Ravenna or Norman Sicily, for instance, or the sequences of sculpture across the west face of Autun or Laon were subordinate to a larger ecclesiastical unity—the liturgical drama of the church; the sculpture of Donatello and the painting of Botticelli were not, whatever the piety of their creators.

The rise of printing

The rise of the professional painter of pictures to be considered as a creator in his own right is largely matched by the decline of the illumination of manuscripts, which reached a peak of elaboration in the mid-15th century just as the earliest printed books were heralding the end of the role of the hand-copied manuscript. Printing on wooden blocks spread rapidly in the second half of the 15th century, and by 1500 presses were at work in every major country in Europe. Though the earliest printed books were extremely expensive and their purpose frequently liturgical, their potential importance was great because they could cater to the new market of the educated laity. These now included far more than the circle of great men who commissioned the splendid psalters and books of hours of the 14th and 15th centuries, which had overthrown a monastic monopoly of lavish manuscripts that had prevailed since the time of Cassiodorus and his copyists at Vivarium in the 6th century.

Education

The institutions and the subject matter of education had already proceeded according to a similar rhythm. The only schools of Europe in the 8th century, except perhaps in parts of northern Italy, were those attached often to monasteries and more rarely to bishoprics. Independent thought, even in theology, was extremely rare; theology remained under the long shadow of St. Augustine of Hippo, and the Greek learning and originality of John Scotus Erigena in the 9th century was little pursued. The rise of the new skills in dialectic in the 11th and 12th centuries produced two phenomena: first, a confidence in rational thought as a means of solving problems, especially those

raised by the conflict of authorities; and, second, a number of teachers whose exceptional talents attracted scholars from the farthest ends of Europe. The self-confidence and European reputation of Abelard reveal this movement at its most distinctive. Around such teachers grew up either religious communities such as that of Saint-Victor of Paris or the earliest universities. In the 12th century the lawyers of Bologna, the doctors of Salerno, and, above all, the theologians of Paris were becoming organized bodies governed by a chancellor; by the 13th century the universities possessed their own statutes regulating the arduous courses of study toward recognized degrees. The crown of studies was the pursuit of the highest knowledge, theology. The forms of 13th-century university study gave rise to the characteristic theological achievements of the period, the *summae* of the Dominican St. Thomas Aquinas and the Franciscan St. Bonaventure. The founding of universities received a new impetus at the end of the 14th and 15th centuries, when they spread into Scandinavia, Scotland, and eastern Europe. It was in these years that most secured a large independence from external ecclesiastical government, and in the councils of Constance and Basel the universities claimed a position of the highest authority.

Much of the earlier confidence in the capacity of intellectual endeavour according to the established forms of enquiry drained away in the 15th century. Logicians in the tradition of Duns Scotus and William of Ockham asserted the essential disparity of faith and reason; the canon law proved incapable of resolving the most pressing problems of ecclesiastical authority or of securing effective reforms; and the only literary forms that offered novelty and room for growth were the vernacular literature of the court and the classical poetry of the Humanists. Whatever changes occurred in education were generated not in the universities but in the schools of such Italians as Vittorino da Feltre near Mantua or of the Brethren of the Common Life in the Netherlands. These first insisted upon the effects of education, on the whole personality, where the numerous grammar, guild, and charitable schools had provided only a grounding in the mechanics of literacy. The retreat of the monopoly of the church in education stands beside the work of the explorers and the rise of the absolute monarchies as an important mark of the ending of medieval society.

(Ma.Br.)

The emergence of modern Europe, 1492–1648

THE CHRONOLOGY OF RENAISSANCE EUROPE

In the 15th century changes in the structure of European polity, accompanied by a new intellectual temper, suggested to such men as the philosopher and clerical statesman Nicholas of Cusa that the "Middle Age" had attained its conclusion and a new era had begun. The papacy, the symbol of the spiritual unity of Christendom, lost much of its prestige in the schism and the conciliar movement and became infected with the lay ideals prevailing in the Italian peninsula. In the 16th century the Protestant Reformation reacted against the worldliness and corruption of the Holy See, and the Catholic Church responded in its turn by a revival of piety known as the Counter-Reformation. While the forces that were to erupt in the Protestant movement were gathering strength, the narrow horizons of the Old World were widened by the expansion of Europe to America and the East.

In western Europe nation-states emerged under the aegis of strong monarchical governments, breaking down local immunities and destroying the unity of the European *Respublica Christiana.* Centralized bureaucracy came to replace medieval government. Underlying economic changes affected social stability. Secular values prevailed in politics, and the concept of a balance of power came to dominate international relations. Diplomacy and warfare were conducted by new methods. Permanent embassies were accredited between sovereigns, and on the battlefield standing armies of professional and mercenary soldiers took the place of the feudal array that had reflected the social structure of the past. At the same time scientific discoveries cast doubt on the traditional cosmology. The systems of Aristotle and Ptolemy, which had long been sanctified by clerical approval, were undermined by Copernicus, Mercator, Galileo, and Kepler.

The movement termed the Renaissance (see below) substituted new standards of culture and methods of thought for the Gothic styles and scholastic exercises of the past. The harmony of classical models was preferred to the disordered grandeur of medieval architecture, while in art pagan realism and the worship of the human form replaced religious symbolism, even in the representation of Biblical subjects. The revival of interest in ancient Greece and Rome was stimulated by an influx of Byzantine scholars, even before the conquest of the Constantinople by the Ottomans in 1453. The subsequent invention of the printing press popularized the rebirth of classical ideals and heightened the effect of scholarly criticism of religious and pseudohistorical dogmas. In both its rational, humanist aspect and its mystic, neoplatonic guise, the Renaissance expanded from its centre in the petty despotisms of Italy to all the confines of Europe.

Discovery of the New World. In the Iberian Peninsula the impetus of the counteroffensive against the Moors carried the Portuguese to probe the West African coastline and the Spanish to attempt the expulsion of Islām from the western Mediterranean. In the last years of the 15th century Portuguese navigators established the sea route to India, and within a decade had secured control of the trade routes in the Indian ocean and its approaches. Mercantile interests, crusading and missionary zeal, and scientific curiosity were intermingled as the motives for this epic achievement. Similar hopes inspired Spanish exploitation of the discovery by Christopher Columbus of the Caribbean outposts of the American continent in 1492. The Treaties of Tordesillas and Saragossa in 1494 and 1529 defined the limits of westward Spanish exploration and the eastern ventures of Portugal. The two states acting as the vanguard of the expansion of Europe had thus divided the newly discovered sea lanes of the world between them.

By the time of the Treaty of Saragossa, when Portugal secured the exclusion of Spain from the East Indies, Spain had begun the conquest of Central and South America. In 1519, the year in which Ferdinand Magellan embarked on the westward circumnavigation of the globe, Hernán Cortés launched his expedition against Mexico. The seizure of Peru by Francisco Pizarro and the enforcement of Portuguese claims to Brazil completed the major steps in the Iberian occupation of the continent. By the middle of the century the age of the conquistadores was replaced by an era of colonization, based both on the procurement of precious metal by Indian labour and on pastoral and plantation economies using imported African slaves. The influx of bullion into Europe became significant in the late 1520s, and from about 1550 it began to produce a profound effect upon the economy of the Old World.

Nation-states and dynastic rivalries. The organization of expansion overseas reflected in economic terms the political nationalism of the European states. This political development took place through processes of internal unification and the abolition of local privileges by the centralizing force of dynastic monarchies. In Spain the union of Aragon, Valencia, and Catalonia under John II of Aragon was extended to association with Castile through the marriage of his son Ferdinand with the Castilian heiress Isabella. The alliance grew toward union after the accession of the two sovereigns to their thrones in 1479 and 1474 respectively and with joint action against the Moors of Granada, the French in Italy, and the independent kingdom of Navarre. Yet at the same time provincial institutions long survived the dynastic union, and the representative assembly (Cortes) of Aragon continued to cling to its privileges when its Castilian counterpart had ceased to play any effective part. Castilian interest in the New World and Aragonese ties in Italy, moreover, resulted in the ambivalent nature of Spanish 16th-century policy, with its uneasy alternation between the Mediterranean and the Atlantic. The monarchy increased the central power by the absorption of military orders and the adaptation of the Hermandad, or police organization, and the Inquisition

for political purposes. During the reign of Charles I (the emperor Charles V) centralization was quickened by the importation of Burgundian conciliar methods of government, and in the reign of his son Philip II Spain was in practice an autocracy.

Other European monarchies imitated the system devised by Roman-law jurists and administrators in the Burgundian dominions along the eastern borders of France. In England and France the Hundred Years' War had reduced the strength of the aristocracies, the principal opponents of monarchical authority. The pursuit of strong, efficient government by the Tudors in England, following the example of their Yorkist predecessors, found a parallel in France under Louis XI and Francis I. In both countries revision of the administrative and judicial system proceeded through conciliar institutions, although in neither case did it result in the unification of different systems of law. A rising class of professional administrators came to fulfill the role of the king's executive. The creation of a central treasury under Francis I brought an order into French finances already achieved in England through Henry VII's adaptation of the machinery of the royal household. Henry VIII's minister, Thomas Cromwell, introduced an aspect of modernity into English fiscal administration by the creation of courts of revenue on bureaucratic lines. In both countries the monarchy extended its influence over the government of the church. The unrestricted ability to make law was established by the English crown in partnership with Parliament; in France the representative States General lost its authority and sovereignty reposed in the king in council. Supreme courts (*parlements*) possessing the right to register royal edicts, imposed a slight and ineffective limitation on the absolutism of the Valois kings. The most able exponent of the reform of the judicial machinery of the French monarch was Charles IX's chancellor, Michel de L'Hôpital, but his reforms in the 1560s were frustrated by the anarchy of the religious wars. In France the middle class aspired to ennoblement in the royal administration and mortgaged their future to the monarchy by investment in office and the royal finances. In England, on the other hand, a greater flexibility in social relations was preserved, and the middle class engaged in bolder commercial and industrial ventures.

Territorial unity under the French crown was attained through the recovery of feudal appanages (alienated to cadet branches of the royal dynasty) and, as in Spain, through marriage alliances. Brittany was regained in this way, although the first of the three Valois marriages with Breton heiresses also set in train the dynastic rivalry of Valois and Habsburg. When Charles VIII of France married Anne of Brittany he stole the bride of the Austrian archduke and future emperor Maximilian I and also broke his own engagement to Margaret of Austria, Maximilian's daughter by Mary of Burgundy. Margaret's brother Philip, however, married Joan, heiress of Castile and Aragon, so that their son eventually inherited not only Habsburg Germany and the Burgundian Netherlands but also Spain, Spanish Italy, and America. The dominions of Charles V thus encircled France and incorporated the wealth of Spain overseas. Even after the division of this vast inheritance between his son, Philip II of Spain, and his brother, the emperor Ferdinand I, the conflict between the Habsburgs and the French crown dominated the diplomacy of Europe for over a century.

The principal dynastic conflict of the age was less unequal than it seemed, for the greater resources of Charles V were offset by their cumbrous disunity and by local independence. In the Low Countries he was able to complete the Seventeen Provinces by new acquisitions, but, although the coordinating machinery of the Burgundian dukes remained in formal existence, Charles's regents were obliged to respect local privileges and to act through constitutional forms. In Germany, where his grandfather Maximilian I had unsuccessfully tried to reform the constitution of the Holy Roman Empire, Charles V could do little to overcome the independence of the lay and ecclesiastical princes, the imperial knights, and the free cities. The revolts of the knights (1522) and the peasantry (1525), together with the political disaggregation imposed by the Reformation, rendered the empire a source of weakness. Even in Spain, where the rebellion of the *comuneros* took place in 1520–21, his authority was sometimes flouted. His allies, England and the papacy, at times supported France to procure their own profit. France, for its part, possessed the advantages of internal lines of communication and a relatively compact territory, while its alliance with the Turk maintained pressure on the Habsburg defenses in southeast Europe and the Mediterranean. Francis I, however, like his predecessors Charles VIII and Louis XII, made the strategic error of wasting his strength in Italy, where the major campaigns were fought in the first half of the century. Only under Henry II was it appreciated that the most suitable area for French expansion lay toward the Rhine.

Turkey and eastern Europe. A contemporary who rivalled the power and prestige of Francis I and Charles V was the ruler of the Ottoman Empire, the sultan Süleyman I the Magnificent (1520–66). With their infantry *corps d'élite* (the janissaries), their artillery, and their cavalry, or *sipahis,* the Ottomans were the foremost military power in Europe, and it was fortunate for their Christian adversaries that Eastern preoccupations prevented them from taking full advantage of Western disunity. A counterpoise was provided by the rise of the powerful military order of the Ṣafavids in Persia—hostile to the orthodox Ottomans through their acceptance of the heretical Islāmic cult of the Shī'ah. Ottoman strength was further dissipated by the need to enforce the allegiance of Turkmen begs in Anatolia and of the chieftains of the Caucasus and Kurdistan and to maintain the conquest of the sultanate of Syria and Egypt by Süleyman's predecessor, Selim I. Süleyman himself overran Iraq and even challenged Portuguese dominion of the Indian Ocean from his bases in Suez and Basra. The Crimean Tatars acknowledged his suzerainty, as did the corsair powers of Algiers, Tunis, and Tripoli. His armies conquered Hungary in 1526 and threatened Vienna in 1529. With the expansion of his authority along the North African coast and the Adriatic littoral, it seemed for a time as if the Mediterranean, like the Black Sea and the Aegean, might become an Ottoman lake.

Though it observed the forms of an Islāmic legal code, Turkish rule was an unlimited despotism, suffering from none of the financial and constitutional weaknesses of Western states. With its disciplined standing army and its tributary populations, the Ottoman Empire feared no internal threat except the periods of disputed succession, which continued to occur despite a law empowering the reigning sultan to put to death collateral heirs. It was not unusual for the sultan to content himself with the overlordship of frontier provinces. Moldavia and Walachia were for a time held in this fashion, and in Transylvania the *voivode* John Zápolya gladly accepted Süleyman as his master in return for support against Ferdinand of Austria.

Despite the expeditions of Charles V against Algiers and Tunis, and the inspired resistance of Venice and Genoa in the war of 1537–40, the Ottomans retained the intiative in the Mediterranean until several years after the death of Süleyman. The Knights of St. John were driven from Rhodes and Tripoli and barely succeeded in retaining Malta. Even after the combined fleet of Spain, the papacy, Venice, and Genoa had crushed the Turkish armament in 1571 in the Battle of Lepanto, the Ottomans took Cyprus and recovered Tunis from the garrison installed by the allied commander, Don John of Austria. North Africa remained an outpost of Islām and its corsairs continued to harry Christian shipping, but the Ottoman Empire did not again threaten Europe by land and sea until late in the 17th century.

In eastern Europe the states of Poland, Lithuania, Bohemia, and Hungary were all loosely associated at the close of the 15th century under rulers of the Jagiellon dynasty. In 1569, three years before the death of the last Jagiellon king of Lithuania–Poland, these two countries merged their separate institutions by the Union of Lublin. Thereafter the Polish nobility and the Roman Catholic faith dominated the Orthodox lands of Lithuania and held the frontiers against Muscovy, the Cossacks, and the Tatars. Bohemia and the vestiges of independent Hungary

were regained by the Habsburgs as a result of dynastic marriages, which the emperor Maximilian I planned as successfully in the East as he did in the West. When Louis II of Hungary died fighting the Ottomans at Mohács in 1526, the Archduke Ferdinand of Austria obtained both crowns and endeavoured to affirm the hereditary authority of his dynasty against aristocratic insistence on the principle of election. In 1619 Habsburg claims in Bohemia became the ostensible cause of the Thirty Years' War, when the Diet of Prague momentarily succeeded in deposing Ferdinand II.

In the 16th century eastern Europe displayed the opposite tendency to the advance of princely absolutism in the West. West of the Carpathians, and in the lands drained by the Vistula and the Dnestr, the landowning class achieved a political independence that weakened the power of monarchy. The towns entered a period of decline, and the propertied class, though divided by rivalry between the magnates and the lesser gentry, everywhere reduced their peasantry to servitude. In Poland and Bohemia the peasants were reduced to serfdom in 1493 and 1497 respectively, and in free Hungary the last peasant rights were suppressed after the rising of 1514. The gentry, or *szlachta,* controlled Polish policy in the Sejm (parliament), and when the first Vasa king, Sigismund III, tried to reassert the authority of the crown after his election in 1587, the opportunity had passed. Yet despite the anarchic quality of Polish politics, the aristocracy maintained and even extended the boundaries of the state. In 1525 they compelled the submission of the secularized Teutonic Order in East Prussia, resisted the pressure of Muscovy, and pressed to the southeast, where communications with the Black Sea had been closed by the Ottomans and their tributaries.

Farther to the east the grand duchy of Muscovy emerged as a new and powerful despotism. Muscovy, and not Poland, became the heir to Kiev during the reign of Ivan III the Great in the second half of the 15th century. By his marriage with the Byzantine princess Sofia (Zoë) Palaeologus, Ivan also laid claim to the traditions of Constantinople. His capture of Novgorod and repudiation of Tatar overlordship began a movement of Muscovite expansion, which was continued by the seizure of Smolensk by his son Vasily (Basil) III and by the campaigns of his grandson Ivan IV the Terrible (1533–84). The latter destroyed the khanates of Kazan and Astrakhan and reached the Baltic by his conquest of Livonia from Poland and the Knights of the Sword. He was the first to use the title of tsar, and his arbitrary exercise of power was more ruthless and less predictable than that of the Ottoman sultan. After his death Muscovy was engulfed in the Time of Troubles, when Polish, Swedish, and Cossack armies devastated the land. The accession of the Romanov dynasty in 1613 heralded a period of gradual recovery. Except for occasional embassies, the importation of a few Western artisans, and the reception of Tudor trading missions, Muscovy remained isolated from the West. Despite its relationship with Greek civilization, it knew nothing of the Renaissance. Though it experienced a schism within its own Orthodox faith, it was equally untouched by Reformation and Counter-Reformation, the political consequences of which convulsed western Europe in the second half of the 16th century.

Reformation and Counter-Reformation. In a sense the Reformation was a protest against the secular values of the Renaissance. No Italian despots better represented the profligacy, the materialism, and the intellectual hedonism that accompanied these values than did the three Renaissance popes, Alexander VI, Julius II, and Leo X. Among those precursors of the reformers who were conscious of the betrayal of Christian ideals were figures so diverse as the fiery Ferraran monk Savonarola, the Spanish statesman Cardinal Jiménez, and the Humanist scholar Erasmus.

The corruption of the religious orders and the cynical abuse of the fiscal machinery of the church provoked a movement that at first demanded reform from within and ultimately chose the path of separation. When the Augustinian monk Martin Luther protested against the sale of indulgences in 1517, he found himself obliged to extend his doctrinal arguments until his stand led him to deny the authority of the pope. In the past, as in the controversies between pope and emperor, such challenges had resulted in mere temporary disunity. In the age of nation-states the political implications of the dispute resulted in the irreparable fragmentation of clerical authority.

Luther had chosen to attack a lucrative source of papal revenue, and his intractable spirit obliged Leo X to excommunicate him. The problem became of as much concern to the emperor as it was to the pope, for Luther's eloquent writings evoked a wave of enthusiasm throughout Germany. The reformer was by instinct a social conservative and supported existing secular authority against the upthrust of the lower orders. Although the Diet of Worms accepted the excommunication in 1521, Luther found protection among the princes. In 1529 the rulers of electoral Saxony, Brandenburg, Hesses, Lüneberg, and Anhalt signed the "protest" against an attempt to enforce obedience. By this time Charles V had resolved to suppress Protestantism and to abandon conciliation. In 1527 his mutinous troops had sacked Rome and secured the person of Pope Clement VII, who had deserted the imperial cause in favour of Francis I after the latter's defeat at the Battle of Pavia. The sack of Rome proved a turning point both for the emperor and the Humanist movement that he had patronized. The Humanist scholars were dispersed, and the initiative for reform then lay in the hands of the more violent and uncompromising party. Charles V himself experienced a revulsion of conscience that placed him at the head of the Catholic reaction. The empire he ruled in name was now divided into hostile camps. The Catholic princes of Germany had discussed measures for joint action at Regensburg in 1524; in 1530 the Protestants formed a defensive league at Schmalkalden. Reconciliation was attempted in 1541 and 1548, but the German rift could no longer be healed.

Lutheranism laid its emphasis doctrinally on justification by faith and politically on the God-given powers of the secular ruler. Other Protestants reached different conclusions and diverged widely from one another in their interpretation of the sacraments. In Geneva, Calvinism enforced a stern moral code and preached the mystery of grace with predestinarian conviction. It proclaimed the separation of church and state, but in practice its organization tended to produce a type of theocracy. Huldreich Zwingli and Heinrich Bullinger in Zürich taught a theology not unlike Calvin's but preferred to see government in terms of the godly magistrate. On the left wing of these movements were the Anabaptists whose pacifism and mystic detachment were paradoxically associated with violent upheavals.

Lutheranism established itself in north Germany and Scandinavia and for a time exercised a wide influence both in eastern Europe and in the west. Where it was not officially adopted by the ruling prince, however, the more militant Calvinist faith tended to take its place. Calvinism spread northward from the upper Rhine and established itself firmly in Scotland and in southern and western France. Friction between Rome and nationalist tendencies within the Catholic Church facilitated the spread of Protestantism. In France the Gallican Church was traditionally nationalist and anti-papal in outlook, while in England the Reformation in its early stages took the form of the preservation of Catholic doctrine and the denial of papal jurisdiction. After periods of Calvinist and then of Catholic reaction, the Church of England achieved a measure of stability with the Elizabethan religious settlement.

In the years between the papal confirmation of the Jesuit order in 1540 and the formal dissolution of the Council of Trent in 1563, the Catholic Church responded to the Protestant challenge by purging itself of the abuses and ambiguities that had opened the way to revolt. Thus prepared, the Counter-Reformation embarked upon recovery of the schismatic branches of Western Christianity. Foremost in this crusade were the Jesuits, established as a well-educated and disciplined arm of the papacy by Ignatius Loyola. Their work was made easier by the Council of Trent, which did not, like earlier councils, result in the diminution of papal authority. The council condemned such abuses as pluralism, affirmed the traditional practice

in questions of clerical marriage and the use of the Bible, and clarified doctrine on controversial issues such as the nature of the Eucharist, divine grace, and justification by faith. The church in this way made it clear that it was not prepared to compromise; and with the aid of the Inquisition and the material resources of the Habsburgs, it set out to reestablish its universal authority. It was of vital importance to this task that the popes of the Counter-Reformation were men of sincere conviction and initiative, who skilfully employed diplomacy, persuasion, and force in the offensive against heresy. In Italy, Spain, Bavaria, Austria, Bohemia, Poland, and the southern Netherlands (the future Belgium), Protestant influence was destroyed. As the movement gathered strength in the age of religious warfare, its course became confused with the national ambitions of Philip II of Spain.

The Wars of Religion. Germany, France, and the Netherlands each achieved a settlement of the religious problem by means of war, and in each case the solution contained original aspects. In Germany the territorial formula of *cuius regio, eius religio* applied—that is to say, in each petty state the population had to conform to the religion of the ruler. In France, the Edict of Nantes in 1598 embraced the provisions of previous treaties and accorded the Protestant Huguenots toleration within the state, together with the political and military means of defending the privileges that they had exacted. The southern Netherlands remained Catholic and Spanish, but the Dutch provinces formed an independent Protestant federation in which republican and dynastic influences were nicely balanced. Nowhere was toleration accepted as a positive moral principle, and seldom was it granted except through political necessity.

There were occasions when the Wars of Religion assumed the guise of a supranational conflict between Reformation and Counter-Reformation. Spanish, Savoyard, and papal troops supported the Catholic cause in France against Huguenots aided by Protestant princes in England and Germany. In the Low Countries, English, French, and German armies intervened; and at sea Dutch, Huguenot, and English corsairs fought the Battle of the Atlantic against the Spanish champion of the Counter-Reformation. In 1588 the destruction of the Spanish Armada against England was intimately connected with the progress of the struggles in France and the Netherlands.

Behind this ideological grouping of the powers, national, dynastic, and mercenary interests generally prevailed. The Lutheran duke Maurice of Saxony assisted Charles V in the first Schmalkaldic War in 1547 in order to win the Saxon electoral dignity from his Protestant cousin, John Frederick; while the Catholic Henry II of France supported the Lutheran cause in the second Schmalkaldic War in 1552 to secure French bases in Alsace. John Casimir of the Palatinate, the Calvinist champion of Protestantism in France and the Low Countries, maintained an understanding with the neighbouring princes of Lorraine, who led the ultra-Catholic Holy League in France. In the French conflicts Lutheran German princes served against the Huguenots, and mercenary armies on either side often fought against the defenders of their own religion. On the one hand, deep divisions separated Calvinist from Lutheran; and, on the other hand, political considerations persuaded the moderate Catholic faction, the Politiques, to oppose the Holy League. The national and religious aspects of the foreign policy of Philip II of Spain were not always in accord. Mutual distrust existed between him and his French allies, the family of Guise, because of their ambitions for their niece Mary Stuart. His desire to perpetuate French weakness through civil war led him at one point to negotiate with the Huguenot leader, Henry of Navarre (afterward Henry IV of France). His policy of religious uniformity in the Netherlands alienated the most wealthy and prosperous part of his dominions. Finally, his ambition to make England and France the satellites of Spain weakened his ability to suppress Protestantism in both countries.

In 1562, seven years after the Peace of Augsburg had established a truce in Germany on the basis of territorialism, France became the centre of religious wars which endured, with brief intermissions, for 36 years. The political interests of the aristocracy and the vacillating policy of balance pursued by Henry II's widow, Catherine de Médicis, prolonged these conflicts. After a period of warfare and massacre, in which the atrocities of St. Bartholomew's Day (1572) were symptomatic of the fanaticism of the age, Huguenot resistance to the crown was replaced by Catholic opposition to the monarchy's policy of conciliation to Protestants at home and anti-Spanish alliances abroad. The revolt of the Holy League against the prospect of a Protestant king in the person of Henry of Navarre released new forces among the Catholic lower classes, which the aristocratic leadership was unable to control. Eventually Henry won his way to the throne after the extinction of the Valois line, overcame separatist tendencies in the provinces, and secured peace by accepting Catholicism. The policy of the Bourbon dynasty resumed the tradition of Francis I, and under the later guidance of Cardinal Richelieu the potential authority of the monarchy was realized.

In the Netherlands the wise Burgundian policies of Charles V were largely abandoned by Philip II and his lieutenants. Taxation, the Inquisition, and the suppression of privilieges for a time provoked the combined resistance of Catholic and Protestant. The House of Orange, represented by William I the Silent and Louis of Nassau, acted as the focus of the revolt; and in the undogmatic and flexible personality of William, the rebels found leadership in many ways similar to that of Henry of Navarre. The sack of the city of Antwerp by mutinous Spanish soldiery in 1576 (three years after the dismissal of Philip II's autocratic and capable governor, the Duque de Alba) completed the commercial decline of Spain's greatest economic asset. In 1579 Alessandro Farnese, duke of Parma, succeeded in recovering the allegiance of the Catholic provinces, while the Protestant north declared its independence. French and English intervention failed to secure the defeat of Spain, but the dispersal of the Armada and the diversion of Parma's resources to aid the Holy League in France enabled the United Provinces of the Netherlands to survive. A 12-year truce was negotiated in 1609, and when the campaign began again it merged into the general conflict of the Thirty Years' War. It was during this last phase of the struggle that Amsterdam came to replace Antwerp as the trading centre of Europe.

(J.H.McM.S.)

Thirty Year's War. *Western Europe.* The later wars of aggression, waged by Louis XIV of France and by Napoleon I, tend to obscure the fact that from the middle of the 16th to the middle of the 17th century France was the victim of a deliberate policy of encirclement by the Habsburg powers. In the south, possession of Roussillon gave Spain a firm foothold north of the Pyrenees. In the southeast, the Republic of Genoa was a Spanish satellite and the Duchy of Milan was Spanish territory. Genoa and Milan guaranteed a short and safe line of communication from Spain to Austria proper as well as to the Spanish possessions along the eastern borders of France, namely, Franche-Comté (contiguous with Austrian Alsace) and the Low Countries (Luxembourg Hainaut, and Artois on the French frontier, with Flanders, Brabant, and the rest of the Netherlands in their immediate hinterland). After the successes of the Dutch rebellion, from 1572, the overland route from Genoa to Brussels was the more important because the final link of the chain around France had snapped after the death of Mary I of England (1558): the fate of the Armada in 1588 had demonstrated the insecurity of the northern sea route from Spain to the Netherlands.

Habsburg encirclement of France

The breaking of this Habsburg stranglehold was the foremost task of French statesmanship. It was first undertaken when Henry IV of France resisted the attempt by the Habsburgs, in 1609, to acquire Jülich-Cleves-Mark-Berg, as this attempt threatened to deal the deathblow to the independence of the United Provinces of the Netherlands and to lay open France's northern frontier. Henry's policy, interrupted by his assassination (1610) and by the pro-Spanish appeasement of the French regency under Marie de Médicis, was resumed by Cardinal de Richelieu,

in power from 1624 until his death in 1642, and was continued by his successor, Cardinal Mazarin. France, at first too weak to wage open war against the Habsburgs, began by making treaties with powers hostile to them (or to their satellites in Germany or in eastern Europe), namely, with the United Provinces (1624), with Sweden (1631), and with Russia (1632); but the defeat of the United Provinces' ally Denmark (Peace of Lübeck, 1629) the withdrawal of Russia (Peace of Polyanov, 1634), the defeat of the Swedes (Battle of Nördlingen, 1634), and the defection of Sweden's German allies (Peace of Prague, 1635) forced Richelieu to declare open war on Spain (1635), after which Catalonia and Portugal (1640) and later Great Britain (1657) also joined the French camp. The modest French military successes were surpassed at the conference table: the Peace of Westphalia (1648) established the preponderance of France and France's allies throughout central and northern Europe; the formation of the League of the Rhine (1658) gave France a decisive voice in the affairs of the empire; and the Peace of the Pyrenees (1659) enlarged and secured France's frontiers and marked the end of Spain as a great power.

Twelve years' Truce of Antwerp

For the Dutch, the period of the Thirty Years' War forms part of their Eighty Years' War against Spain (1568–1648). The 12 years' Truce of Antwerp (April 9, 1609) can now be seen as the de facto recognition of the independence of the United Provinces; but contemporary Dutch statesmen foresaw that the Spanish crown would not easily abandon the hope of reducing the rebellious heretics and recovering its richest European province. In fact, Philip IV of Spain, whose accession in 1621 coincided with the expiry of the truce, immediately renewed the war. But whereas at the outbreak of the rebellion Spain had been the leading maritime, commercial, and colonial power, superiority in all these spheres had passed to the Netherlands. The only weakness of the maritime republic was its lack of land forces; but the States-General had no difficulty in enlisting foreign mercenaries or paying subsidies to foreign princes. Whereas the interest of Spain demanded the localization of every conflict so that resources might be concentrated against the Dutch, the interest of the Dutch was served best by extending the war so as to engage Spain's power away from their borders. Religious and constitutional affinities gave the Calvinist Dutch republicans additional zest in their support (1) of the Calvinist elector John Sigismund of Brandenburg in his struggle for Jülich; (2) of the semirepublican nobles of Bohemia in their fight against Austrian absolutism; and (3) of the generals who, from 1621, continued the Bohemian War, nominally on behalf of the Calvinist elector Frederick V of the Palatinate. But practical political considerations made the United Provinces the focal point of every anti-Habsburg coalition: the Franco-Dutch Treaty of Compiègne (June 20, 1624) was the prelude of the Treaty of The Hague (1625), which effectively brought Denmark into the war against the emperor Ferdinand II; and, after Denmark's defeat, Dutch diplomacy and subsidies aided Richelieu in enlisting Gustavus II Adolphus of Sweden as the military champion of the anti-Habsburg cause (1630–32).

From the middle of the 1630s, the French superseded the Dutch as leaders of the anti-Habsburg struggle. The conquest of Alsace and of Breisach by France's protégé Bernhard of Saxe-Weimar in 1638 and the secession of Portugal in 1640 shook Spain into preferring to come to an arrangement with the Dutch; and the latter, having smashed the Spanish Navy in the English Channel (1639) and off Pernambuco (1640), thereby putting an end to Spanish overseas expansion, now considered France and the Portuguese colonial empire greater rivals to their mercantile interests than Spain. Disregarding the alliance with France, which they had made in 1635, the Dutch on January 30, 1648, signed a separate peace with Spain.

Struggle for Baltic supremacy

Northern Europe. Viewed from northern Europe, the first half of the 17th century comprises the attempts of the two Scandinavian kingdoms, Denmark and Sweden, to obtain what the diplomatic language of the time called the *dominium maris Baltici* ("lordship of the Baltic Sea"); *i.e.*, the possession of the leading Baltic ports through whose customs sheds the raw materials of the North German, Polish, and Russian hinterlands found their way into the West.

Denmark's repeated attempts to overpower Sweden failed, and the Danish outposts in the eastern Baltic were lost. King Christian IV's attempt to make himself supreme in Lower Saxony by acquiring the German bishoprics of Bremen, Verden, Minden, and Hildesheim led to the Danish War (1625–29), in which the superior generalship of his adversaries outweighed the subsidies granted to him by the Dutch and the British. The Peace of Lübeck (1629) finished Denmark as a European power of consequence.

Denmark's decline was emphasized by the simultaneous rise of Sweden. The Peace of Knäred (1613) made only transitory concessions to Christian IV of Denmark, who had attacked Sweden in 1611. Thenceforward, King Gustavus II Adolphus systematically began to close the ring of Swedish possessions around the Baltic. After preliminary gains at the expense of Muscovite Russia, whose access to the Baltic he closed (1617), he successfully attacked the Baltic provinces of Poland and of Poland's vassal, Prussia (1621–29). Besides pursuing this Baltic ambition, he may also have been aspiring to supplant his Catholic cousin, Sigismund III Vasa, on the Polish throne. Any such design, however, had to be abandoned: on the one hand the Swedish nobility objected to it; on the other, the king's Baltic policy was challenged by the advance of imperial armies along the southern shore from the west, which drew him into intervening in German affairs. The Swedish-Polish Truce of Altmark (1629) was followed by alliance with France (Treaty of Bärwalde, January 23, 1631).

The alliance with France survived the death of Gustavus Adolphus and remained the sheet anchor of his successors' position until Sweden's collapse as a great power (1721). Sweden reaped the fruits of this policy; first in the Peace of Brömsebro at the end of the Swedish-Danish War of 1643–45; then in the Peace of Westphalia (1648); and finally in the Peace of Roskilde (1658), with Denmark in the course of the First Northern War. By the end of this period Sweden had achieved dominance in the Baltic area.

Eastern Europe. The first half of the 17th century also embraces the first attempt by Poland to force Orthodox Muscovy (Russia) into the orbit of Latin Christianity as well as the first attempt on the part of the House of Romanov to enter the comity of western Europe. Poland, tied to the Habsburgs by religion and tradition, hostile to Sweden by religion and dynastic rivalry, and implacably hostile to Muscovy by history and religion, exploited the "troubles" that convulsed Russia after the death of Boris Godunov (1605). The experiment of ruling Russia through a Polish puppet, the first False Dmitry, failed in 1606 when the usurper succumbed in an outbreak of Russian nationalism and Orthodox fanaticism. But Poland came nearest to making Russia a satellite when in 1610 Sigismund III had his son, the future Wladyslaw IV of Poland, elected as tsar: the Polish dictatorship in Moscow lasted two years.

Russia's "Time of Troubles"

In 1609, the first Russo-Swedish alliance had been concluded by the tsar Vasily III Shuysky; and, despite Sweden's later aggressions, the new Romanov dynasty (from 1613) continued to regard Sweden as Russia's natural ally against Poland. England and the United Provinces acted as intermediaries at the Russo-Swedish Peace of Stolbova (1617), and 13 years later French envoys brought about Muscovy's indirect support of Gustavus Adolphus' war in Germany. Russia, however, did not want to be involved directly in Germany, and the Russo-Polish War of Smolensk (1632–34) remained a sideshow. After Gustavus Adolphus died, Swedish-Russian relations cooled, as the Swedish chancellor Axel Oxenstierna correctly assessed Russia as potentially more dangerous than Poland.

The Russo-Polish Treaty of Polyanov (1634), which included Wladyslaw IV's final resignation of his claim to the Russian throne, freed Poland to resume hostilities against Sweden and, by thus tying down Swedish troops, contributed to the Swedish disaster at Nördlingen.

Germany. All these European conflicts affected Germany more often and more deeply than any of the other contestants. Germany was the only country where the Reformation had resulted in a permanent split into three

Dynastic rivalry

religious factions—Catholic, Lutheran, and Calvinist. As these religious divisions largely marched with political frontiers, they were sustained and aggravated by dynastic rivalries, such as that between the Catholic Wittelsbachs in Munich (Bavaria) and the Calvinist Wittelsbachs in Heidelberg (the Palatinate) or that between the Calvinist Kassel branch and the Lutheran Darmstadt branch of the House of Hesse. In turn, these political and religious dissensions were partly exacerbated and partly overlaid by constitutional problems: the Holy Roman emperor, a Habsburg and a Catholic, wanted to establish monarchical absolutism in the empire; the electors, Catholics and Protestants alike, wanted to maintain what they called the "electoral preeminence" in the empire's affairs; and lastly, the other princes wanted to overthrow the ascendancy of both the emperor and the electors, so as to obtain complete freedom of action for themselves.

Each of the rivals found it easy and profitable to call in some foreign power. On the whole, the emperor relied on his Spanish cousins; the Protestant towns and smaller princes relied on Sweden, on France, and on the Dutch; Catholic Bavaria, with its satellites Cologne, Liège, Münster, Paderborn, and Hildesheim, usually blackmailed the emperor, while inclining to France and opposed to Spain; Lutheran Saxony disliked all foreign entanglements, but regarded the Calvinists as worse than the Catholics and generally found it most profitable to side with the emperor (since repeated endeavours to rally a neutralist "third force" never succeeded); and Protestant Brandenburg was weak and irresolute until 1640, when Frederick William, "the Great Elector," began to play off emperor, Swedes, Dutch, Poles, and French with such skill that by 1660 he had raised Brandenburg-Prussia to the rank of a great German and minor European power.

Great Britain. From the death of Queen Elizabeth I (1603) to the passing of the first Navigation Act by Cromwell's Parliament (1651), Great Britain's influence upon European affairs was negligible. The European policy of the government was vacillating between Spain, France, and the United Provinces, while Parliament and public opinion were enthusiastically anti-Spanish but unwilling to transform brave words into hard cash.

James I originally wanted to continue Elizabeth's pro-French and pro-Dutch policy, but assented to peace with Spain (1604). In 1613 he gave his daughter Elizabeth in marriage to Frederick V of the Palatinate, leader of the Protestant anti-Habsburg faction in Germany; but twice, in 1617 and in 1623, he tried to obtain a Catholic Spanish Habsburg princess for his son Charles before betrothing him, in 1624, to a Catholic French Bourbon.

James had at least not dissuaded his son-in-law from accepting the Bohemian crown (1619), but his dislike of the Czech nobility's republican sympathies and religious radicalism, combined with his desire to appease the Spaniards, prevented him from giving tangible support to Frederick during the war in Bohemia. It was only when Frederick had lost the Palatinate and when the Spanish marriage project had collapsed that a cautious parliamentary grant for the preparation of war against Spain gave expression to the English public's lively sympathy for the Protestant cause. An expedition to the Palatinate was hopelessly bungled.

Charles I, on succeeding his father, undertook the war against Spain and also associated himself with the Dutch in the Treaty of The Hague (December 9, 1625) for the support of Christian of Denmark against the emperor and the Catholic League in Germany. But the naval expedition against Cádiz (1625) was a failure; and Charles failed to pay Denmark the promised £360,000 per annum, after the first installment of £46,000. Soon afterward, he squandered ships, troops, and money on the disastrous expedition of 1627 to help the Huguenot rebels of La Rochelle against his brother-in-law, Louis XIII of France. Thereafter Charles's devious foreign policy was hampered by lack of funds, which forced him to conclude peace both with France (1629) and with Spain (1630), and by lack of interest in foreign affairs on the part of his most capable adviser, Strafford. In 1636 and again in 1641, Charles offered to the Habsburgs an alliance against the Dutch in return for the restoration of the Palatinate to his nephew Charles Louis; but the Habsburgs declined this offer because Bavaria objected to it. Richelieu likewise in the same years preferred for France an understanding with Bavaria to a possible rapprochement with England.

Religious aspects. Religious issues were insolubly interwoven with political and constitutional problems. For Germany the whole question stemmed from the Peace of Augsburg of 1555, a compromise between the Catholic and Lutheran Estates (members) of the empire. Neither party was satisfied, neither meant to abide by it. It fixed the religious frontiers as they had existed in 1552; *i.e.*, at the lowest ebb of Protestant fortunes. It gave the sovereign lay princes the right to change with their own religion that of their subjects; but it prohibited any Catholic bishopric or free city from adhering in future to the Lutheran creed. It expressly excluded Calvinists from the toleration granted to Lutherans. Above all, it failed to lay down any criteria by which the many doubtful points might be interpreted or to create any machinery to enforce its observance.

Peace of Augsburg

One of the many points left in suspense by the Peace of Augsburg concerned the right of the Protestant gentry in town and country under Catholic sovereigns to keep Protestant pastors and hold Protestant services. This issue played a part in the revolts of the Austrian and Bohemian nobility against their Habsburg overlords, which began in 1609 and ended with the Bohemian War in 1620. The ecclesiastical reservation that forbade the "reform" of Catholic bishoprics prevented Cologne from turning Protestant together with its archbishop, Gebhard, in 1583. Gebhard's deposition was the basis of the greatness of the House of Wittelsbach: Bavarian princes held the archbishopric of Cologne continuously from 1583 to 1761, the bishoprics of Hildesheim and of Liège almost uninterruptedly throughout the same period, and the bishoprics of Paderborn and of Münster with but few more interruptions. Thus the undisputed leadership of Catholic Germany by the Wittelsbach Maximilian I of Bavaria was grounded on the pre-eminence of his house not only in the south but also in the northwest of Germany, where Jülich and Berg in the hands of his brother-in-law fortified his house.

The distribution of the religious parties in the empire during the first half of the 17th century, according, be it understood, to the sovereign's choice of religion, was approximately as follows: the whole of northern, northeastern, and central Germany, with the exception of the bishopric of Hildesheim and the abbey of Fulda, was Protestant; northwestern, western, and southeastern Germany, with the exception of the Rhenish Palatinate in the west, was Catholic, as were all the Habsburg dominions (Austria and Tirol, Bohemia-Moravia and Silesia, a portion of Swabia). Württemberg in Swabia, Ansbach and Bayreuth in Franconia, and nearly all the free cities, even those in otherwise Catholic districts, adhered to the Protestant faith. The nobility and townspeople in Bavaria and the Habsburg countries, nearly all of whom had been Protestants, had been recatholicized or expelled by about 1625.

The historian must not doubt the strength and sincerity with which the champions of the contesting factions and their humblest followers believed in the exclusive truth of their church: the emperor Ferdinand II, Maximilian of Bavaria, Tilly, and Richelieu were devout Catholics; Gustavus Adolphus, Bernhard of Weimar, the electors of Brandenburg, Saxony, and the Palatinate were unswerving Protestants; Wallenstein is perhaps the only personality of note who seems to have been entirely indifferent to religious distinctions, astrology having largely supplanted Christianity as his creed. Motives other than religious zeal, however, were the factors determining political allegiance.

The subordination of religion to politics

Pope Urban VIII and the cardinals Richelieu and Mazarin were unbending in their opposition to Catholic Spain and to the Catholic emperor. The Lutheran elector of Saxony and the Lutheran landgrave of Hesse-Darmstadt were firm adherents of the emperor so long as circumstances permitted. Lutheran Saxony and Catholic Bavaria were consistently anti-Spanish and anti-Swedish. Calvinist Hesse-Kassel was Lutheran Sweden's most reliable ally and, together with Bavaria, mostly pro-French. The struggle for

the Baltic brought the Lutheran Gustavus Adolphus into conflict with Orthodox Russia, with Catholic Poland, and with Lutheran Denmark; but his fight in Germany made him the ally of Catholic France and of Orthodox Russia. Maximilian of Bavaria extended his power at the expense alike of the Lutheran cities in Swabia and in Franconia, of the Calvinist elector Palatine, and of the Habsburg emperor and did so mostly in conjunction with Lutheran Saxony and Catholic France. The bishops of Würzburg and of Bamberg were the first to abandon the Catholic interest at the peace congress of Münster. Protestant as well as Catholic princes, prelates, and cities were susceptible to French subsidies. Of none of the belligerents can it be said that religious motives were responsible for any major decision. The secret debates (1629–30) in the Swedish council about entry into the war are revealing: the security and defense of Sweden and the conquest of Germany were declared the war aims; the king was expressly warned against speaking of a war of religion since France might take umbrage.

Success of monarchy

The suppression of Protestantism by Ferdinand II in Austria and in Bohemia and by Richelieu in France was undertaken mainly on political considerations. The Protestants not only infringed the spiritual unit of the country (a tenet still held by every government) but also were the chief opponents of royal absolutism and, not without cause, were suspected of republican tendencies on Dutch and Swiss models. Their defeat therefore paved the way for that spiritual and administrative uniformity that became the hallmark of 17th- and 18th-century monarchy.

Similarly, the contest of the emperor against the Protestant princes and cities was to a large extent a contest to decide whether the empire was to be a monarchy, with the emperor at its head and the princes as his vassals, or a federation of more or less independent princes, with the emperor as its titular president. So long as Ferdinand II was willing to concede to the six electoral princes their traditional prerogatives in the government of the empire, these electors (including Lutheran Saxony and Calvinist Brandenburg) sided with him against the lesser princes. When Ferdinand in 1629 unmasked his real intentions by the Edict of Restitution, the electors, led by Catholic Bavaria, turned against him. The Peace of Westphalia brought about the triumph of the lesser princes, with whom the electors now identified themselves against any recurrence of imperial centralism.

In fact, the Peace of Westphalia proved the interdependence of the problems, religious and constitutional, political and economic, that again and again were used as interchangeable counters. The recognition of the adherents of the Reformed (Calvinist) religion as being of equal right with those of the Lutheran faith was largely a byproduct of the dispute over Pomerania between Brandenburg and Sweden. The emperor sacrificed the north German bishoprics to the Protestant claimants (Sweden, Brandenburg, Saxony, Mecklenburg, and Brunswick) and Alsace and the bishoprics of Metz, Toul, and Verdun to France; and in return Sweden and France renounced their claims to Austrian territory in Silesia and in Swabia respectively and assented to the exclusion of the Austrian Protestants from the treaty's clauses on restitution and toleration. The attitude of the Catholic princes to Pope Innocent X's protest against any formal agreement with the Protestants is characteristic of the trend toward excluding denominational considerations from political decisions: the first secret intimation that the nuncio gave to the emperor and to the

Sites associated with the Thirty Years' War.

Catholic princes in November 1647 was answered with evasive excuses; and the formal protocol handed over on Christmas Eve did not even receive an answer from any prince, temporal or ecclesiastical. A special "anti-protest clause" in the peace treaty was signed by all parties: it declared Innocent's condemnation of the peace invalid and ineffective and thus demonstrated the complete emancipation of secular politics from ecclesiastical tutelage. The religious questions left unanswered by the Peace of Augsburg in 1555 were solved in 1648 in the modern spirit of the "reason of state."

Catholic League and Protestant Union

War of the Jülich Succession (1609–14). The settlement that the Peace of Augsburg had formulated for Germany was shaken in 1607–08 when Maximilian I of Bavaria annexed and recatholicized the Lutheran city of Donauwörth. Some of the German Protestant states concluded a military alliance, the Union, on May 14, 1608. The death of Duke John William of Jülich on March 25, 1609, opened a crucial question of succession over which war broke out. On July 10, 1609, a Catholic military alliance, the League, was formed.

The wealth of John William's lands—Cleves, Jülich, Mark, and Berg—and their strategic position attracted not only the powerless legitimate heirs, namely, John Sigismund of Brandenburg and Wolfgang Wilhelm of Palatinate-Neuburg but also every powerful neighbour. The Habsburgs wished to install an Austrian prince who would have placed the lands at the disposal of the Spaniards in their struggle with the Dutch and would incidentally have counteracted the predominance of Bavaria in northwestern Germany. France, the United Provinces, and England naturally objected to any strengthening of the Spaniards in that region. The assassination of Henry IV of France (May 14, 1610) prevented the war from becoming a European contest, though Spanish, Austrian, and Dutch troops repeatedly invaded the duchy in pretended support of one or the other of the heirs. The Protestant Union, which John Sigismund had joined by turning Calvinist, and the Catholic League, of which Wolfgang Wilhelm had become a member by entering the Roman Church and marrying a sister of Maximilian, brought about a compromise that excluded all foreign claims (October 24, 1610) and led to the partition of the inheritance between Brandenburg and Neuburg (Treaty of Xanten, 1614).

Bohemian and Palatine War (1618–23). This war began with the insurrection, in 1618, of the Bohemian and Austrian Estates against the future emperor Ferdinand II, whose intention was to impose absolutist rule and to enforce the Catholic Counter-Reformation. The Bohemian nobles toyed with the idea of setting up a republic in order to secure the support of the Dutch but eventually, in August 1619, elected as their king the elector Frederick V of the Palatinate in the hope of obtaining the aid of the Protestant Union and Great Britain. Their expectations proved fallacious. Frederick failed to discipline the haughty Bohemian nobles or to rally the Bohemian townsmen and peasants (whom he did nothing to relieve from harsh oppression by their feudal lords) and was abandoned by his German allies as well as by his father-in-law, James I of Great Britain. Ferdinand, although in a very weak position, succeeded in buying the support of Maximilian of Bavaria and the Catholic League at a heavy price in money and land. In a campaign of a few months, the League's troops under Johann Tserclaes von Tilly crushed the Austrian Estates and broke the rule of Frederick in the

Battle of the White Mountain

Battle of the White Mountain, near Prague (November 8, 1620). The conquest of Glatz (Klodzko) on October 25, 1622, completed the subjugation of the lands of the Bohemian crown.

In the meantime, the Spaniards from their bastions in Luxembourg and in Franche-Comté had since 1620 been overrunning the Rhenish Palatinate, where Tilly joined them in 1662, after he and Maximilian had in 1621 subdued the Upper Palatinate (north of Bavaria and west of Bohemia). Tilly also overcame the badly coordinated actions of several German princelings and generals who, in the pay of the United Provinces, Denmark, and England, still upheld Frederick's cause, notably, Ernst von Mansfeld and Christian of Brunswick. Whereas the Protestant Union had dissolved itself (May 1621), Lutheran Saxony, which had never adhered to the Union, was won over to the emperor by the offer of Lusatia. The defeat of Christian of Brunswick by Tilly at Stadtlohn (August 6, 1623) left the situation as follows: the emperor was in undisputed control of his Austrian and Bohemian territories; Maximilian of Bavaria, who was created elector, had become the leading power in southern and northwestern Germany; the Spaniards were in possession of the Rhenish Palatinate; and Frederick was a landless exile, living on the bounty of the Dutch.

The Valtellina

Struggle for Graubünden (1620–39). The Valtellina, leading from the northern frontier of the Duchy of Milan through the Alps toward Tirol, opened the shortest and safest land route between Spanish Italy and the Austrian territories in Germany, whence the Spaniards could reinforce their troops in the Netherlands and in the Palatinate. It belonged to Graubünden, or the Grisons, a union of leagues in loose relations with the Swiss. Spain and Austria obviously wanted to bring the Union's lands under their own control; France and Venice naturally opposed the forging of this link, which would have completed encirclement of both of them by the Habsburg powers. The political and military issues were here poisoned by religious, personal, local, and clannish rivalries, of which Georg Jenatsch was the stormy centre. A Spanish occupation of the Valtellina (1620), reinforced by an Austrian incursion into the other territories of Graubünden (1621), provoked French and Venetian protests, which led to the nominal "deposit" of the Valtellina in the hands of the papacy (1623)—in fact a veiled means of prolonging Spanish control there. Then Richelieu ventured on the first French occupation of Graubünden (1624–26); but the internal weakness of France, where Richelieu's regime was challenged on the one hand by the pro-Spanish faction of Catholic zealots (the Parti Dévot) and on the other by the Huguenots, made it impossible to maintain this indirect attack on Spain. The Treaty of Monzón (1626) made Graubünden into a sort of Franco-Spanish protectorate, with papal troops in occupation. During the War of the Mantuan Succession, the Habsburgs again overran the country (1629–31). A final French occupation (from 1635) was ended in 1639 by a reaction of Graubünden against the French. Eventually the Peace of Milan (September 3, 1639), between Spain and Graubünden, brought the country into virtually complete dependence on Spain.

Swedish–Polish War (1621–29). From 1611, Gustavus Adolphus had taken advantage of the "Time of Troubles" and its aftermath in Muscovite Russia; and by the Peace of Stolbova (1617) he had acquired Karelia and Ingria, which together constituted the land bridge between Swedish Finland and Swedish Estonia, so that the Gulf of Finland was converted into a Swedish lake. He then turned against Poland (1621). His conquest of Livonia gave him Riga, the chief Baltic port (though the Swedish nobles possessed themselves of the largest land properties in the country, to the detriment of the Swedish crown); and from the Duchy of Prussia, Poland's vassal, he took the ports of Memel and Pillau, the latter commanding the approach to Königsberg. Sweden's position in the Baltic, however, was eventually endangered by the course of the Danish War, as the imperial general Wallenstein conquered Mecklenburg (with the ports of Wismar and Rostock) and threatened moreover to conquer Pomerania; and in summer 1628 Swedish forces were sent to help the port of Stralsund, which Wallenstein was besieging. Finally, the Truce of Altmark (September 25, 1629) was concluded between Sweden and Poland, largely thanks to French mediation. Livonia and the Prussian ports were left in Sweden's possession.

Protestant coalition

Danish War (1625–29) and the Edict of Restitution. Christian IV of Denmark had observed strict neutrality during the Bohemian War despite repeated Dutch attempts to enlist his help on behalf of Frederick of the Palatinate. In 1624, however, he began to contemplate offensive action. His motives were rivalry of Sweden in the Baltic regions and the wish for Danish supremacy in the estuaries of the Elbe and Weser. The king's election, in spring 1625, as director of the Lower Saxon Circle of the empire

furnished him with the legal pretext for interference in Germany. The Treaty of The Hague (December 9, 1625), in the negotiation of which the British statesman George Villiers, 1st duke of Buckingham, played a major part, promised British and Dutch subsidies for a military effort by Denmark on Frederick's behalf, in cooperation with the German generals who had already tried to uphold the latter's cause; and this Protestant coalition could expect the sympathy of the Habsburgs' other enemies—prince Gábor Bethlen of Transylvania, the Ottoman Turks, and also Catholic France.

The coalition's plan seems to have envisaged a fourfold advance: Christian of Brunswick was to overpower the Wittelsbach bishoprics and duchies in Westphalia and in the lower Rhineland; Christian IV of Denmark was to make himself master of Lower Saxony; Ernst von Mansfeld, generalissimo of the coalition, was to press forward into Bohemia, Silesia, and Moravia; and Bethlen was to sally forth from Hungary and join forces with Mansfeld.

On the opposite side were ranged the veteran troops of the Catholic League under Tilly, who was to deal with Christian of Brunswick and with Christian IV of Denmark, and the imperial army of Wallenstein, who was to repel Mansfeld and Bethlen.

On both sides the generals were on bad terms with one another and never effectively coordinated their efforts. But Tilly and Wallenstein had the advantage of fighting on interior lines and could therefore tackle their adversaries in turn. The coalition, on the other hand, was weakened by the faithless policy of Charles I of Great Britain, who failed to honour his financial obligations and let Buckingham embark on a foolish expedition against France in aid of the Huguenots of La Rochelle (June–November 1627). Wallenstein forced Mansfeld out of northern Germany (Battle of Dessau, April 25, 1626); and Mansfeld, though he held a strong position in Silesia, neither made full use of anti-Habsburg movements (apart from discontent in the Bohemian lands, a peasants' revolt broke out in Austria in May) nor effected a junction with Bethlen and the latter's Turkish auxiliaries. Wallenstein outmanoeuvred Bethlen, and Mansfeld died on his way to Venice (November 29, 1626), whence he hoped to receive fresh subsidies. Isolated Danish troops maintained themselves in Silesia until the autumn of 1627, when Wallenstein overwhelmed them.

Meanwhile, Tilly was favoured by the untimely death of Christian of Brunswick (June 16, 1626) and by the military incompetence of Christian IV of Denmark. The Danish Army suffered a crushing defeat in the Battle of Lutter (August 27, 1626). In 1627 Tilly pursued the beaten Danes into Holstein; and Wallenstein, who joined him, continued the pursuit into Jutland. Mecklenburg, whose dukes had sided with Christian, was given by the emperor to Wallenstein, who immediately set about obtaining bases on the Baltic for an imperial navy. His attempt to add the Pomeranian port of Stralsund to his Mecklenburg ports of Wismar and Rostock led to the intervention of Gustavus Adolphus.

Wallenstein's contact with maritime affairs changed his whole outlook. His first sight of large river barges on the Oder had made him believe that they were oceangoing capital ships; but he now realized the importance of sea power and overseas trade and reassessed the political position that the emperor might take up with regard to the Hanse towns, Denmark, the Netherlands, England, and Spain. Denmark, which he wished to draw into the emperor's interest, profited by his mediation: at the Peace of Lübeck (May 22, 1629) Christian IV had only to renounce further participation in the affairs of the empire.

The defeat of the anti-Habsburg coalition raised the position of the emperor to its greatest height since Charles V's victory over the League of Schmalkalden in 1547.

Edict of Restitution

Ferdinand II's Edict of Restitution (March 6, 1629), prescribing the recovery by the Catholics of all ecclesiastical lands in which Protestantism had been established since 1552, was more than an act of reparation of the damage suffered by the Catholic Church since Luther's time: it was an unambiguous assertion of the imperial prerogative in all matters pertaining to the constitutional structure of the empire. At the Electoral Diet of Regensburg (1630) the opposition, led by Lutheran Saxony (anxious to retain its threatened acquisitions) and by Catholic Bavaria (determined to counteract the emperor's aggrandizement) forced Ferdinand to dismiss Wallenstein and so to make himself defenseless at the very moment when Gustavus Adolphus had landed on German soil.

War of the Mantuan Succession (1628–31). The death of Vincenzo II Gonzaga, duke of Mantua and Montferrat, on December 26, 1627, led to the first direct clash between the Habsburgs and France, albeit on a secondary theatre of war. The claims of the legitimate Gonzaga heir, Charles, duc de Nevers, whom France supported, were overridden by Ferdinand II, supreme lord of the imperial fiefs in Italy; and Spain lent military aid to Ferdinand so as to keep a French vassal away from the approaches to Milan. Richelieu, however, was soon stronger. The Huguenot rebels of La Rochelle capitulated to Louis XIII (autumn 1628); Savoyard forces, which attempted to block the French king's way into Piedmont, were defeated at Susa (March 6, 1629); and the Peace of Susa with England (April 14), followed by the submission of the Huguenot rebels in Languedoc to the Peace of Alais (June 28), secured the French rear. The Habsburg forces withdrew from Casale in October 1630; and Richelieu, who in November triumphed over the pro-Spanish faction in France (the so-called Day of Dupes), achieved full success. By the Treaty of Cherasco (1631), the French candidate was installed in Mantua. Meanwhile, Savoy had ceded the fortress of Pinerolo to France; and Pope Urban VIII, determined opponent of the Habsburgs, annexed Urbino, another vacant imperial fief. The Austro-Spanish monopoly in Italy was broken.

Swedish War (1630–35) and the Peace of Prague. The suspension of hostilities between Sweden and Poland freed Gustavus Adolphus to intervene in Germany. After landing at Usedom (July 6, 1630), he quickly occupied the whole duchy of Pomerania and restored Wallenstein's duchy of Mecklenburg to its hereditary dukes. He concluded the Treaty of Bärwalde (January 23, 1631) with France, whereby he was to receive annual subsidies of 1,000,000 livres to enable him to campaign for the restoration of the "liberty" of the German princes "oppressed" by the emperor. In these circumstances an immediate objective for Gustavus was to stop the enforcement of the Edict of Restitution on Magdeburg, which commanded a strategic crossing point on the Elbe; but his advance into central Germany was impeded by the hardly veiled hostility of the electors George William of Brandenburg and John George I of Saxony. Saxony tried at the Convent, or Conference, of Leipzig (February 1631) to establish a neutral party between the emperor and Sweden, which proved unacceptable to either. Though Gustavus stormed the Brandenburg fortress of Frankfurt an der Oder (April 13), thereby both securing his left flank against the Poles and intimidating the two electors, the delay led to the fall of Magdeburg to Tilly (May 20). Brandenburg and Saxony now yielded to the Swedish threats, especially as Tilly imprudently invaded Saxony and treated it as enemy country. Alliances with Brandenburg (June 20) and with Saxony (September 11) protected Gustavus' rear and virtually rendered the electorates Swedish satellites. The defeat of Tilly at Breitenfeld (September 17) and the conquest of Prague (November 15) by the Saxons under Hans Georg von Arnim opened southern Germany to the Swedes.

Battle of Breitenfeld

The smaller German Protestant princes, such as Bernhard of Saxe-Weimar, flocked to Gustavus' standards; by April 1632 Gustavus had advanced as far as Munich, and his armies had reached Lake Constance to the south and Mainz to the west. The archbishopric of Mainz and the Rhenish Palatinate were placed under Swedish administration; the bishoprics of Würzburg and Bamberg were given to Bernhard as a Swedish fief under the name of Duchy of Franconia. The king's war aims gradually widened: his agreements with the German princes became more onerous, and the stipulations that the Treaty of Bärwalde had made for the protection of France's friends and of the Catholic religion were treated lightly. Gustavus did not aim at the imperial crown, but his secret negotiations with Wallenstein show that he thought

of placing the Habsburg dominions under the rule of Swedish puppets.

The recall of Wallenstein to the leadership of the imperial army completely changed the situation: Gustavus was manoeuvred out of southern Germany and shortly afterward was killed in the Battle of Lützen (November 16, 1632). While the conduct of Swedish military operations then fell to Johan Banér and subsequently Lennart Torstenson, the direction of policy was undertaken by the chancellor, Axel Oxenstierna, who, by the Treaty of Heilbronn (April 23, 1633), consolidated the Swedish alliance with the German princes, albeit without Brandenburg and Saxony. Wallenstein's victory at Steinau in Silesia (October 11) and Bernhard's capture of Regensburg (November 14) cancelled each other out, and Wallenstein's machinations to make himself the arbiter of affairs caused the emperor to have him murdered (February 25, 1634); but the Swedish defeat at Nördlingen (September 5–6, 1634) led to the dissolution of the League of Heilbronn and to the open defection of most German princes, led by Saxony, from the Swedish cause.

The Peace of Prague (May 30, 1635) reconciled the emperor and nearly all the German opponents of the Edict of Restitution, which it modified by making the year 1627 the criterion of rightful possession of ecclesiastical lands (instead of 1552). Thenceforth, Sweden played only a subordinate part in the war. The leading role fell to France.

War of Smolenski (1632–34). From *c.* 1628, Gustavus Adolphus and Richelieu had been trying to bring about alliances with Russia, Turkey, Transylvania, the Crimean Tatars, and the Ukrainian Cossacks, who were to engage the emperor and Poland on their eastern frontiers. Concerted action, however, proved difficult to achieve. But Moscow gave Gustavus considerable indirect aid by selling to Sweden, on a cash-and-carry basis at an artificially low price, cereals that the Swedes resold in Amsterdam at considerable profit: between 1628 and 1633 the Swedes bought Russian grain at a cost of 100,000 talers per annum and sold it at 400,000 talers per annum (the latter sum being equal in amount to the direct subsidy received annually from France). Russo-Swedish military cooperation was eventually achieved, largely through the efforts of Sweden's envoy Alexander Leslie (later earl of Leven in the peerage of Scotland): the Russians invaded Poland in autumn 1632 and besieged Smolensk, while Gustavus Adolphus moved eastward and ordered his general Carl Gustav von Wrangel to prepare an offensive from his bases in Prussia.

Swedish-Russian cooperation

The great scheme came to nought. The deaths of Gustavus Adolphus and of the Moscow patriarch Philaret (October 1633), who had been the two chief architects of Swedish-Russian cooperation, removed the mutual goodwill as the basis for a real alliance. Turkey, moreover, was committed in a war with Persia; the Tatars of the Crimea turned against Muscovy instead of Poland; and the revolt of the Ukrainian Cossacks against their Polish overlords was delayed. Finally, an insurrection of the peasants in central Russia forced Tsar Michael's government to conclude the Peace of Polyanow with Poland (June 14, 1634).

French and Swedish War (1635–48). The near-collapse of the Swedish system in Germany in 1634–35 forced Richelieu to abandon his cautious policy of nonintervention. He concluded offensive and defensive alliances with the United Provinces (February 8, 1635) and with Sweden (Treaty of Compiègne, April 28), sent a French army to the Valtellina (March–April), and declared war on Spain (May 19). He then secured an alliance with Savoy and Parma (League of Rivoli, July 11); mediated the 20-year Truce of Stuhmsdorf between Sweden and Poland (September 12); and took the best of the German generals still serving Sweden, Bernhard of Saxe-Weimar, into French pay (October 27).

In 1636 the invasion of northern France from the Spanish Netherlands by Ottavio Piccolomini, whose capture of Corbie (August 15) threatened to expose Paris, was outweighed by a series of Swedish victories over Saxon and imperial forces, culminating in Banér's defeat of Melchior von Hatzfeldt at Wittstock (October 4), which reestablished Swedish supremacy in northern and central Germany. A careless northward movement of the imperial commander in chief, Matthias Gallas, in 1637, laid southern Germany open to the French; and Bernhard of Saxe-Weimar, having overrun Alsace, in 1638 conducted a brilliant campaign in the course of which he took the key fortresses of Rheinfelden (March 23), Freiburg (April 6), and Breisach (December 17). Before Bernhard's death, the incompetence of the French led to Piccolomini's great victory of Thionville (June 7, 1639), which, however, was to be the last success of the Austro-Spanish armies. The outbreak, in 1640, of revolution both in Catalonia and in Portugal compelled the Spaniards to limit their commitments outside the Iberian Peninsula. The capitulation of the great stronghold of Arras to the French (August 9, 1640) endangered the Spanish position in the Netherlands, and a Spanish counteroffensive into Champagne ended with the French victory at Rocroi (May 19, 1643), won by the young duc d'Enghien (Prince de Condé).

In Germany the various commanders—French, Swedish, Bavarian, and imperial—waged war almost on each one's own responsibility: no coherent pattern can be found in those campaigns, which were nearly always small-scale raids with limited objectives. The Swedish victory over Saxon and imperial forces at Breitenfeld (November 2, 1642) and the capture of the Little Town quarter of Prague by the Swedes (July 26, 1648) are—besides the Swedish campaign against Denmark—the most notable military events of these years. They were overshadowed by the diplomatic activity that began in 1640 and ended in 1648 with the Peace of Westphalia.

During the French and Swedish War, death had removed three great figures from the international scene: the emperor Ferdinand II on February 15, 1637, leaving the succession to his son Ferdinand III; Richelieu on December 4, 1642; and Louis XIII of France on May 14, 1643. Richelieu's place was taken by Cardinal Mazarin during the regency for Louis XIV.

Swedish–Danish War (1643–45). The precarious situation of the imperial cause after Breitenfeld and the Danish jealousy and fear of Sweden brought about an understanding between Ferdinand III and Christian IV; and Sweden's decision to wage a preventive war against Denmark gave the emperor a respite, since the Swedish army under Torstenson had to abandon its march on Vienna (September 1643) and to turn northward instead. In a lightning campaign (December 1643–January 1644) Torstenson conquered Schleswig-Holstein and Jutland. When an imperial army under Gallas came to the succour of the Danes, Torstenson at once marched against him, destroyed his army at Jüterbog (November 23, 1644), and invaded Bohemia, where another imperial army was wiped out at Jankov (March 6, 1645). By the Peace of Brömsebro, signed on August 23, 1645, Denmark ceded Jämtland and Härjedalen on the Norwegian frontier, Halland on the Kattegat, and the Baltic islands of Gotland and Ösel to Sweden.

Peace of Westphalia (1648). Treaties signed in the Westphalian towns of Münster and Osnabrück terminated both the Eighty Years' War between Spain and the United Provinces of the Netherlands (January 30, 1648) and the war between France, Sweden, and the German Protestants on the one side and the emperor and the German princes on the other (October 24). The Peace of Prague (1635) between the emperor Ferdinand II and the majority of the German princes had proved abortive: it expressed too much the temporary ascendancy of the emperor, took little account of Sweden, and completely disregarded France, which at that very moment openly took up arms against Spain and the emperor. No general peace was possible without the participation of Sweden, France, and Spain; and in 1640 the parties began in earnest to prepare the summoning of a peace congress. The emperor Ferdinand III entered into secret negotiations with Sweden in Hamburg; the Imperial Diet demanded a universal congress instead of bilateral transactions. The renewal of the Franco-Swedish alliance on June 30, 1641, included the stipulation that two congresses be held simultaneously in neighbouring Westphalian towns: the Catholic envoys were to meet in Münster, the Protestant envoys, in Osnabrück.

In 1643–44 Sweden and France sent out the first invitations, and the congress began to take shape. The slow and tortuous negotiations about procedure and substance, protocol and ceremonial, the admission or rejection of envoys and mediators—all these fumblings, which went on right to the actual signing of the treaties—were mostly due not to obstruction but to inexperience. By trial and error the congress had to explore and define the methods of modern international diplomacy. The 150 representatives (about 110 Germans and 40 foreigners) lacked any precedent for their tasks, starting, as it were, from scratch every time a fresh topic turned up. They gradually developed a kind of esprit de corps, which cut across political and religious frontiers and contributed not a little to the realistic settlement, which was satisfactory to all but a few diehards.

The negotiators

Though the plenipotentiaries were bound fairly narrowly by instructions from their governments, a few figures stand out to whom the successful outcome was largely due. The imperial ambassador, Maximilian Graf von Trauttmansdorff, outshone the rest; he had been the architect of the Peace of Prague and became the main author of the Peace of Westphalia. He and his chief secretary, Isaac Volmar, were converts to the Roman faith and therefore understood the opposing positions and did their best to check the firebrands in the Catholic camp. France was brillantly represented by the duc de Longueville (Henry d'Orléans) and his duchesse (Anne Geneviève de Bourbon-Condé), but as members of the princely faction they were suspect to Mazarin. Mazarin also mistrusted France's principal actual negotiator, Claude de Mesmes, comte d'Avaux, whereas the latter's equally skillful but more ruthless colleague, Abel Servien, enjoyed the cardinal's confidence; their mutual antagonism, however, in no way impaired their efficiency as representatives of the French crown. Similar dissensions rent the Swedish mission: Johan Oxenstierna, the chancellor's son, stood for the policy of conquest sponsored by the Swedish nobility, whereas Johan Adler Salvius, a gifted and experienced diplomat of humble birth, sided with the young queen Christina in wishing for peace at almost any price. The Spanish ambassadors, the conde de Peñaranda (Gaspar de Bracamonte) and Antonius Brun, succeeded in terminating the war with the Dutch (January 30, 1648) with great sacrifice to Spanish power but without loss to Spanish honour.

The Brunswick counsellor, Jacob Lampadius, stands out as the expert in all legal problems and the Lübeck envoy, David Gloxin, as the champion of the mercantile interest. Johann Rudolf Wettstein, of Basel, was accredited only as a representative of the Swiss Protestant cantons but acted on behalf of the whole Swiss Confederation. Lastly, the two unofficial mediators must be mentioned—the papal nuncio Fabio Chigi (later Pope Alexander VII) and, especially, the Venetian diplomat Alvise Contarini: they employed their good offices for smoothing out factional divisions and keeping alive the mutual interests of the European comity of nations.

The territorial clauses of the peace treaty all favoured France, Sweden, and their allies.

Sweden obtained the largest share: Hither Pomerania (Vorpommern), with Stettin and sole control over the Oder estuary; the Mecklenburg port of Wismar; and the archbishopric (but not the city) of Bremen and the bishopric of Verden, with control over the Elbe and Weser estuaries. In addition, there was the "satisfaction" of the Swedish Army, amounting to 5,000,000 talers guaranteed collectively by the members of the empire.

French gains

France incorporated the cities and bishoprics of Metz, Toul, and Verdun in Lorraine (French protectorates since 1552) and added to them the suzerainty over the secular vassals of the three bishops. France also obtained the ill-defined feudal rights exercised by the emperor over various towns, villages, and districts in Alsace (excluding Strassburg but including the bridgehead of Breisach), and the permanent right to garrison Philippsburg, on the right bank of the Rhine south of Speyer. These gains appeared modest. The possession of Breisach and Philippsburg, however, laid all southern Germany open to French arms; and the deliberate vagueness of the clauses relating to the cessions in Lorraine and Alsace later provided the legal or casuistical pretexts for the wars of aggression waged by Louis XIV.

The only major setback that France suffered was the conclusion of the separate peace between Spain and the United Provinces. This deprived France of an ally in the rear of the Spanish Netherlands and prolonged the Franco-Spanish War by a decade.

The gains and losses of the German princes were determined by the convenience of the principal powers: France, Sweden, and Austria. These used the claims of their lesser partners as pawns mainly for adjusting differences among themselves at somebody else's expense.

Brandenburg obtained Farther Pomerania (Hinterpommern); the bishoprics of Kammin, Halberstadt, and Minden; the county of Hohnstein; and the reversion of the archbishop of Magdeburg on the death of the existing administrator, Augustus of Saxony (which occurred in 1680). Bavaria was to keep the Upper Palatinate and the electoral dignity, but the Rhenish Palatinate was restored to Frederick V's heir, Charles Louis, for whom a new electorate was created. Saxony retained what had been secured at the Peace of Prague, namely, Lusatia and Magdeburg, but the latter only for the lifetime of the present administrator. Hesse-Kassel ousted Hesse-Darmstadt from the district of Marburg and incorporated the abbey of Hersfeld and the county of Schaumburg. The Welfs of Brunswick obtained the right to have one of their princes elected as Protestant administrator of Osnabrück in alternation with a Catholic bishop. Mecklenburg was compensated for the loss of Wismar by the bishoprics of Schwerin and Ratzeburg.

Finally, the United Provinces of the Netherlands and the Swiss Confederation were released from their legal obligations toward the empire and so recognized as independent republics.

For Germany, the Peace of Westphalia brought to a conclusion the century-old struggle between the monarchical tendencies of the emperor and the federalistic aspirations of the princes. In the course of this contest Ferdinand II had made considerable progress in revitalizing the imperial power: without consulting the electors or princes, he had arrogated to himself the outlawry of Frederick V of the Palatinate and the transfer of the latter's electoral dignity to Maximilian of Bavaria (1623) and the deposition of the dukes of Mecklenburg (1628); on his own authority, he had interpreted, that is, in fact, rescinded, the Peace of Augsburg by the Edict of Restitution (1629), thereby superseding the legislative authority of the Imperial Diet; and by the Peace of Prague (1635), he had transformed all princely troops into contingents of an army under his supreme command and abolished the princes' traditional right to conclude alliances among themselves or with foreign powers.

The Peace of Westphalia completely reversed this trend. It confirmed the full sovereignty of the members of the empire, including their right to form alliances, restricted only by the meaningless proviso "except against the emperor and *Reich*." It bound the emperor to the decisions of the Imperial Diet in all matters concerning war and peace. The Diet, which during the past 40 years had met only three times (1608, 1613, 1640–41), increased its sphere of competence at the expense of the emperor as well as the electors; the Protestant administrators of the secularized bishoprics were admitted with full voting rights. From 1663 the Diet remained in permanent session at Regensburg.

The peace established equality of rights between Catholics, Lutherans, and Calvinists: the supreme court of the empire was to be staffed by 26 Catholics and 24 Protestants, and Protestants were admitted to the Aulic Council in Vienna. The Edict of Restitution was repealed, and 1624 was declared the "standard year" according to which territories should be deemed to be in Catholic or Protestant possession. Except in the Habsburg dominions, where toleration was not granted to non-Catholics, dissidents were allowed private worship, liberty of conscience, and the right of emigration. Religious disputes were not to be decided by majority vote of the Imperial Diet but to be solved amicably between the Corpus Evangelicorum (the Protestant states collectively) and the Corpus Catholicorum, orga-

nized under the directorate of Saxony and of Mainz respectively.

Aftermath. The conclusion of a separate peace with the United Provinces helped Spain to continue the struggle against France; and Condé's victory over the Spaniards at Lens (August 20, 1648) was offset by the outbreak of the Fronde. During these civil wars in France (1649–53), the rebel leaders, including Condé, even made treaties of their own with Spain. Success came to the French from 1655, especially after the outbreak of hostilities between Spain and England and the conclusion of Anglo-French treaties of friendship (September 5, 1656) and of alliance (March 23 and May 9, 1657). Robert Blake's exploits in the Mediterranean and in the Caribbean (1655–57), followed on land with the Battle of the Dunes (June 14, 1658) and the capture of Dunkerque (June 25) and Gravelines (August 24, 1658), broke Spain's resistance. In the Franco-Spanish Treaty of the Pyrenees (November 7, 1659), France obtained Roussillon and northern Cerdagne (thus establishing the frontier along the line of the Pyrenees), Artois, and a number of frontier fortresses in the Netherlands and Luxembourg. Spain had ceded to France the first place among the great powers of Europe.

Treaty of the Pyrenees

The last decade of the 50-year period here surveyed witnessed another conflict in northern Europe. It arose, however, from the start of the Thirteen Years' War between Russia and Poland (1654–67), which is best considered as belonging to a later historical period, characterized by the decline of Poland and by the rise of Russia and of Brandenburg-Prussia. Insofar as it reaffirmed certain tendencies of the earlier period, it may be briefly summarized here.

The question of the Ukraine led to war between Russia and Poland in 1654. Charles X of Sweden took advantage of this war to attack Poland in July 1655. The elector Frederick William of Brandenburg took the Swedish side from 1656 to 1657 but changed to the Polish in 1658. Russia began war against the Swedes in June 1656 but concluded the Truce of Valiesari in December 1658. In 1657 the emperor Ferdinand III's heir, Leopold I, allied Austria with Poland. Frederick III of Denmark attacked Sweden in June 1657.

Baltic settlement

By the Peace of Roskilde (February 26, 1658), Denmark was forced to cede to Sweden not only Trondheim on the North Sea coast of Norway but also Bohuslän on the Swedish coast at the end of the Skagerrak, Skåne on the eastern side of the Sound, with adjacent Blekinge, and the island of Bornholm, thus forfeiting all hope of the "lordship of the Baltic." Denmark, however, subsequently refused to close the Baltic to Western shipping and was attacked by Sweden again in summer 1658. The Dutch, in their own commercial interests, came to Denmark's support, and the Treaty of Copenhagen (June 6, 1660) restored Bornholm and also Trondheim to Denmark, but otherwise confirmed the settlement of Roskilde.

The Peace of Oliva (May 3, 1660), between Sweden on the one hand and Poland, Austria, and Brandenburg on the other, assigned Livonia to Sweden and recognized Brandenburg's full sovereignty over ducal Prussia, both these stipulations being made at Poland's expense. The Russo-Swedish Peace of Kardis (July 1, 1661) reestablished the terms of the Peace of Stolbova (1617).

France had played an active role in mediating the Baltic settlement. Habsburg Austria had gained nothing from the conflict and was meanwhile confronted by the League of the Rhine (August 14, 1658), organized by Mazarin, whereby France, Sweden, the electoral archbishoprics (Mainz, Cologne, and Trier), Münster, Brunswick-Lüneburg, Palatinate-Neuburg, and Hesse-Kassel guaranteed the Peace of Westphalia against Habsburg revisionism.

(S.H.St./Ed.)

ECONOMIC DEVELOPMENT OF THE EARLY MODERN WORLD

The decline of the feudal system and the growth of commerce. No sharp divide separates the economic life of the Middle Ages from that of the early modern world. But, in retrospect, much of the 15th century in Europe displayed the symptoms of the decay of an old order. Population in many places was smaller than a century and a half earlier, and prices had generally declined. These changes were reflected in both the rural and the urban economies.

In those areas of Europe where a manorial type of agrarian economy existed, the links between lord and peasant were becoming either looser or tighter. The customary tenant, who held his land in return for services performed on the lord's demesne (estate), was in some places becoming a rent-paying tenant, even (in England, for example) turning into a tenant-farmer exploiting the disintegrating demesne land. In eastern Europe, beyond the Elbe River, however, the reverse was happening. There the great lords were tightening their hold on the peasants' lands. Peasant was becoming serf and serf becoming slave. Thus, the old balance within feudalism was being tipped one way or the other.

Trade and industry were similarly changing in character. The traditional organization of the city crafts into guilds was breaking up, and companies of merchants, on the one hand, and of journeymen, on the other, began to assume responsibility for the specialized functions of their members. Germany in the 15th century suffered continual urban conflicts as the guilds struggled among themselves for power and privilege, and everywhere in Europe guild control over industry receded in the face of an almost universal tendency for individual urban capitalists, or groups of capitalists, to assume control, through mercantile capital, over the entire process of manufacture in textiles, leatherworking, mining, and the metallurgical industry.

The structure and direction of international trade was also changing. The cities of the Hanseatic League (a league of towns in northern Germany that banded together in the latter part of the Middle Ages to protect and develop their foreign trade), which had long been dominant economically and politically in northeast Europe, had fallen into fratricidal war. Their conflict with the Scandinavian powers in the 16th century virtually brought about their final collapse, and this, in turn, had a depressing effect on those important sectors of economic life in such cities as Bruges, in Flanders, and London, which had been closely dependent upon the League. North Italy, which had long been the most advanced economic area, was also under severe pressure. The four great cities of Venice, Milan, Genoa, and Florence, which had dominated the life of the Po Valley, the Tuscan Plain, and large areas of the Mediterranean, were now faced with new competition and problems. The great voyages of discovery had opened up by 1500 an alternative route to the Orient around the southern tip of Africa, thus threatening the overland spice trade of Venice, although the effects of this were slow to be felt and their incidence was only intermittent until well into the 17th century. More serious was a slow but steady shift of the centre of European economic activity away from the Mediterranean toward the Low Countries. North Italy still remained an advanced area of wool and silk production and glass and porcelain manufacture and a centre for the great merchants in spices, grain, alum, wine, sugar, and other exotic products. Venice and Genoa also showed a sinuous flexibility in meeting the competition of the Portuguese spice traders. But the 16th century was to be the age of Antwerp, in the Netherlands, rather than of Venice, and its successor in the 17th century was a north Netherlands economy dominating the world from the great entrepôt of Amsterdam.

The Hanseatic League

The influence of population on economic growth. Modern research has established almost beyond doubt that behind the new impetus stimulating the developments of the 16th century lies the reversal of the population decline of the 15th century. In its last decades there began the steady growth that may be detected everywhere in Europe throughout the 16th century and seems to level off only by the middle of the 17th century. By 1600 Europe had a population approaching about 100,000,000. Of these, perhaps one-half lived in countries bordering the Mediterranean. This probably represented between 20 and 30 percent more than in 1450 and was to increase by another 30 or 40 percent by the middle of the 18th century. Most countries shared in the 16th-century increase, especially

Italy, England, the Low Countries, and France. By 1700 it was apparent that the increase was slowing down and even declining in some countries. The population of Germany was severely cut by the disease and poverty that followed the Thirty Years' War, and the population of Spain may have dropped from 8,000,000 to 6,000,000 in the 17th century. But, in general, the European economy reflected the buoyant increases in areas such as England and the Low Countries, especially in the area that today constitutes The Netherlands, where the population virtually doubled between 1500 and 1650.

The reasons for this increase have been much debated. Population movement must depend upon the balance between the birth rate and the death rate. Mortality, especially through the bubonic plague, which attacked everywhere sporadically, was extraordinarily high, but the incidence of plague seems to have slackened in the 16th century, and it finally disappeared from western Europe by the beginning of the 18th century. The declining virulence of the plague, coupled with the removal or relaxation of restraints on early marriage, thereby facilitated a rise in the birth rate. This, in turn, was followed by urban growth, the decline of guild and apprenticeship laws, and the increase of individual farm holdings.

Bubonic plague

If the origins of this demographic revolution are obscure, its consequences, on the contrary, are quite clear. Everywhere it generated an increased demand for food and the necessities of life. This increase, in turn, not only became a major factor in the great inflation of the 16th century but also brought into being a new class of entrepreneurs, or middlemen, who seized the opportunities for trade and profit that it offered.

The rise of Antwerp and Amsterdam. The rise of Antwerp in the first half of the 16th century to the position of the leading entrepôt in the world vividly reflected this new movement. From about 15,000 in the mid-15th century, its population had passed the 100,000 mark by the middle of the 16th century. Antwerp was supreme during the half century from 1520 to 1576 as the warehouse and market of world trade. It not only absorbed the industrial production of its own textile centres, such as Ghent, Lille, and Ypres, but it also formed a sophisticated centre for merchant adventurers, bankers, and speculators from all over Europe. The merchant adventurers from England concentrated the largest part of the export trade in English cloth in Antwerp. The south German bankers (Fuggers, Welsers, Paumgartners) traded in cloth, spices, and metals with Germany and Italy. Italian merchants sold the produce of north Italy into northern Europe through the Antwerp market, while agents for the kings of Portugal sold great cargoes of Indian pepper, nutmeg, cinnamon, and cloves. Ships from Cádiz brought in cargoes of Spanish wool and wine and, later, of silver, to pay for purchases of cloth, iron, coal, and glass or to repay the financiers who fed, armed, and clothed the Spanish and Imperial armies.

Antwerp was not only a centre of trade but also of finance, where the European governments borrowed on a vast scale, especially for war purposes. In England the Tudor financial agent Sir Thomas Gresham acted as royal factor from 1551 to 1574, with the duties of raising long- and short-term loans for the crown on the Antwerp money market. Most other kings and princes did the same. Among the great banking houses were those originating from south Germany, of whom the Fuggers were the greatest. Starting as weavers and manufacturers of cheap textiles in Augsburg in the late 14th century, the Fuggers had risen to be a world trading and banking house. They were now among the leading exponents of the arts of public finance, farming the revenues of the emperor and advancing capital against concessions of silver, copper, and iron mines in the Habsburg territories. They were thus the greatest subsidizers of European war and dynasticism, lending 500,000 florins to secure the election of Charles V as Holy Roman Emperor in 1519.

The Fugger banking houses

The sack of Antwerp in 1576 by Spanish troops added severely to the economic problems that beset Antwerp increasingly after the 1550s. Its capture by Alessandro Farnese, duke of Parma, in 1585 sealed its fate, for the Dutch blocked the approaches of the Scheldt River and virtually ended Antwerp's career as a world market for two and a half centuries.

The stream of refugees from the southern Netherlands began in the 1550s and continued for half a century but was at its peak in the 1570s and 1580s. Up to this time the northern Netherlands were much poorer than their southern neighbour, but, with the aid of the migrants, much wealth, enterprise, and skill was transferred across the great rivers from the vulnerable south to the more defensible north. Amsterdam, seceding from Spanish loyalty to the rebels in 1578, swiftly succeeded to the position lost by Antwerp. At Leiden immigrant merchants and textile workers from the area around Ypres launched a variety of woollen industries making the "new draperies." At Haarlem others set up bleaching centres that attracted great quantities of coarse linens from Germany. Other southern industries, such as silk weaving, glass blowing, paper making, sugar boiling, distilling, and printing, also moved to Amsterdam.

The growth of international trade. The great migration out of the southern Netherlands exported much talent and wealth also to London, Norwich, Colchester, and other English towns and cities, bringing the new textile skills and much mercantile and financial technique to England. But at this stage the Dutch republic was the greatest gainer, and between 1585 and 1620 Amsterdam became the centre of a world network of trade. This network was extended until it reached from the Baltic to the Mediterranean, from the British Isles deep into Germany, and throughout the 17th century it was increasingly linked to India and the East by the operations of the new Dutch East India Company (1602) and to America, the West Indies, and Brazil through the Dutch West India Company (1621). As a victualling station, the southern tip of Africa was settled with Dutch farmers, while Dutch slave traders built castles on the coast of West Africa. As merchants, financiers, shippers, and drainage engineers, the Dutch were as ubiquitous in the 17th century as were the Scots in the 19th.

Dutch East India Company

The Bank of Amsterdam (1609), the Loan Bank (1614), the Bourse (1609), the Marine Assurance Chamber (1598), and the Grain Bourse (1616) collectively formed the central machinery of an economy through which a large proportion of world trade passed. Except for the great herring fishery and the cloth industry of Leiden (the largest in the world), the Dutch were middlemen, carriers, and brokers rather than industrial producers, but their commercial skill, advanced financial techniques (including a fully developed stock exchange and company-share system), together with a low rate of interest, abundant capital, and a willingness to put it at risk overseas as well as at home, gave them a commanding position in the 17th-century world economy. The silver that represented the profit won in their trade with Spain was not hoarded but used to purchase goods from areas such as the East Indies and the Baltic, and these, in turn, were resold to the European nations, including Spain itself. Above all, the Dutch were the first to develop a purpose-built, oceangoing boat (the "flyboat"), which was unarmed and cheap to build and operate. With the cheap freight rates provided by the flyboat, the Dutch captured such great bulk trades as corn, timber, salt, and sugar.

Repression in the agricultural sector. The demand for Baltic grain, arising from the general increase in European population, which had everywhere turned food surpluses into deficits, was the greatest commercial opportunity seized by the Dutch. Throughout the 17th century a procession of Dutch flyboats passed through the Danish Sound carrying cargoes of grain from the southern shores of the Baltic Sea. To supply this demand, the large-scale farming system, based everywhere on the process that came to be known as *Bauernlegen* ("repressing the peasants"), spread throughout central and eastern Europe. Throughout eastern Germany, Austria, Hungary, Bohemia, Poland, and Russia, a process of increasing serfdom set in, culminating by the mid-18th century in Russia, where peasants were bought and sold like cattle. The rural population repressed thus had actually enjoyed more freedom than their counterparts in medieval western Europe, but now

Increase in serfdom

the great demesnes grew as prices rose and corn exports increased. Germans and Slavs were lumped together in virtual slavery in Mecklenburg and Pomerania. In Bohemia the German Catholic conquerors imposed brutal terms on the Czech heretic population. Conditions did not improve until the early 18th century in central Europe, and in Russia serfdom survived until the 19th century. Everywhere, the system produced economic stagnation, depriving trade and industry of capital and labour.

The agrarian system around the Mediterranean was less harsh, but, even there, the scarcity of fertile land, such as the Po Valley, the Roman Campagna, and the Tuscan Plain, gave rise to severe social problems. In Italy the limited areas of cultivable land demanded heavy capital investment, either for irrigation or drainage. The nobility or the municipality that provided the capital and carried out such works naturally demanded the lion's share of the profit. Hence the bitter comment of a 16th-century writer: "The plains belong to the lord, the mountains belong to the peasant."

Yet, sun, bread, and wine were not lacking. Rice and corn were among the crops that the enterprise of Venetian and Milanese landowners added to the Mediterranean scene. Italy therefore stood halfway between the stagnation of the East and the modest progress of the West, where some increase in productivity was discernible. England, northern France, and western Germany formed an area quite different from that in the East. In the West lords tended to become *rentiers*. Peasants redeemed their quitrents; in France many gained the status of something like owner-occupiers, and in England many became tenant farmers. Others declined into landless labourers. Providence offered a variety of fates; but all were free men, and the society of which they were a part could move on to a commercial or industrial future, exchanging feudalism for a reformed monarchy or constitutionalism.

The consequences of the different agrarian economic systems and social structures adopted east and west of the Elbe were very marked. The social organization and capital investment in Western countries, together with modest improvements in plows, implements, drainage, manure, and enclosure, resulted in higher yields and a perceptible increase in productivity, especially by the second half of the 18th century. In east Europe, serfdom and stagnation produced an actual decline in productivity from 1650 onward.

The rise of the entrepreneur and the labour market. The 16th century was an age of industrial expansion that in some places, such as Britain, continued into the second half of the 17th century. Elsewhere, it levelled off by the middle of the 17th century, as, for example, in Holland. In Germany, progress was halted by the Thirty Years' War. This age of expansion resulted from many related causes: price inflation, population growth, the demands of governments in the new centralized states for war and court luxury (France, Spain, Sweden, and Britain).

Increased demand led to greater production. Since industry in this period most often meant production of consumer necessities, it relied for its raw materials everywhere on the countryside. Agriculture produced the wool, flax, and leather that formed the basis of the clothing industries supplying rich and poor alike. It also provided the corn for the baker and barley for the brewer. Brewing was one of the few great capitalist industries employing intensive capital equipment in the centuries before the Industrial Revolution, and the great brewers of London and the large cities of Holland and Germany were among the largest contemporary capitalists. Vineyards supplied the wine industries of France, Italy, Spain, and Germany. In addition, princes and noble landowners owned the rights over minerals that lay under the soil of their estates. They, therefore, exploited their mines and the deposits themselves or (more commonly) sold concessions to urban capitalists to do it for them.

Brewing

Role of the entrepreneurs. Increasing demand raised the incomes not only of urban entrepreneurs, who seized the opportunities offered by new demands, but also of those noblemen and gentry who, by luck or shrewdness, extracted opportunity from their estates. Throughout the enormously varied mining and metallurgical enterprises of western and eastern Europe (including coal, iron, tin, silver, copper, lead, and alum) and the glass and ceramics, chemical, textile, paper-making, and many other industries, there is clear evidence of the increasing role played by the capitalist organizers. These consisted mainly of city merchants whose capital was increasingly required to finance growing output and new technology. Such changes are most clearly reflected in the growth of these merchants in cities like London; Antwerp; Amsterdam; Cologne, Augsburg, and Nürnberg (Germany); Lyons (France); and, to a lesser extent, in smaller cities such as Norwich (England), Leiden, Haarlem, Hamburg, Barcelona, and Milan. In the Dutch cities they formed after a generation or two a merchant elite influencing the policies of the state at home and abroad. The philosophy of the Dutch republic is most vividly and accurately represented in *Het Interest van Holland* (1662; *Political Maxims of the State of Holland*), allegedly by Johan de Witt. In reality, this was the work of a great Leiden textile entrepreneur, Pieter de la Court. Its theme was the need for a context of peace, neutrality, tolerance, and economic freedom in which trade and industry could flourish. In London, a representative figure earlier in the century was Alderman Sir William Cokayne, confidant of the King and the contriver of 12 great commercial and industrial schemes, including a project for modernizing and expanding English textile manufacture. This came hopelessly to grief, however, and precipitated one of the greatest crises of the age by 1618. Another entrepreneur was Sir Hugh Myddleton, brother of a lord mayor of London, a mining contractor of Welsh origin with great enterprises in Wales and founder of the New River Company, which between 1609 and 1620 dug a freshwater channel 40 miles (60 kilometres) long to supply London with drinking water. In Europe the south German bankers performed similar functions as financiers and organizers for German industry. Dutch capitalists originating from Liège similarly exploited the iron and copper resources of Sweden. The Trips and de Geers were the most prominent of a large group of Netherlanders who settled in Scandinavia as agents of the monarchy to develop mining and metallurgy.

Early industrial schemes in London

Use of capital. The accumulated wealth of these new merchant princes was either saved and loaned as capital to borrowers, including the state, traders, and industrialists, or spent on personal consumption. In England a good deal of their wealth was spent on social advancement. Cokayne, for example, succeeded in getting all his daughters married to peers. Great merchants commonly moved out of the city and bought country estates for themselves in the counties surrounding London. Dutch merchants, though tending to remain in trade, also built themselves country palaces on the Vecht River near Amsterdam, just as Venetian merchants built great mansions along the Brenta River. Both invested capital in the countryside, purchasing farms and undertaking drainage and general improvement schemes. In the middle of the 17th century, Amsterdam capitalists financed and implemented the drainage of great areas of the English Fenland under the eye of the great Brabant engineer Cornelius Vermuyden.

Rise of the landowner-entrepreneur. Such enterprises were not entirely limited to the urban merchant. Everywhere in Europe, landowners joined in exploiting their own mineral deposits, such as the Lowther family in northwest England and the Dudleys in the English Midlands. At Stolberg in Germany, the counts encouraged mining and iron working on their estates, while Duke Julius did much to organize and modernize mining in the Ober Harz. One of the most famous woollen mills in central Europe was that of Count Waldstein at Oberleutensdorf. Many other nobles used the forced labour of peasants to develop textile production in Bohemia and Moravia. Others, in Silesia and Bohemia, exploited clay deposits on their estates to develop famous porcelain manufactures. Many a princely palace had a *Porzellan-zimmer* ("porcelain room") exhibiting products from the estate. Especially in England, but in many other countries also, there was intermarriage between members of these commercially oriented noble families and their aspiring bourgeois partners.

Technological innovations and improvements. The early modern period was not an age of revolutionary invention, but industrial expansion in some cases led to a number of improvements, mostly of an empirical kind. In mining, galleries and shafts were improved. Hoists brought up the ore and water. As early as 1550, in Bohemia, pumps worked by water power made possible shafts sunk to a depth of 1,300 feet (400 metres). Waterwheels were used to drive hammer forges and rolling mills. New methods of making brass and copper and lead alloy were discovered. Blast furnaces replaced open hearths. Coke was substituted for charcoal by 1700 to smelt lead, tin, and copper ores. Later, Shropshire ironmasters smelted iron similarly. In the Netherlands windmills were improved and used for sawing timber. Everywhere textile industries developed improved equipment: fulling mills were driven by water; the Dutch at Leiden developed a multiple ribbon loom that was borrowed for English use; William Lee, an Englishman, had invented his frame knitting machine in 1589. In spite of opposition, mechanization slowly established itself in the succeeding centuries.

Use of windmills

Need for commercial capital. These technological improvements that accompanied and made possible economic expansion had one thing in common: they cost capital; and these higher costs, mainly for working capital but also for fixed plants, equipment, tools, and buildings, explain the need for a new organization in industry and for a new type of entrepreneur to carry it on. Probably the most highly capitalized industry of all was brewing. By the end of the 16th century, the great London brewers, many of them of Dutch or German extraction, were producing beer in breweries that already bore a resemblance to a modern plant. To a lesser extent, this was also true of the great glassworks of London and the English Midlands. A late 16th-century Leipzig merchant of great wealth, Henry Cramer, had a textile factory, representing a large capital outlay, that included fulling mills, weaving sheds, a dye plant, and a complete residential area for the workers. In the Swedish iron and copper industries, capital was provided by the so-called *Brukspatroner* (proprietor), who provided the necessary credit. In England, the Netherlands, and in a rather less sophisticated manner in many centres of France, Germany, Switzerland, and Bohemia, the complicated processes needed to produce a piece of cloth—wool sorting, carding or combing, spinning, weaving, fulling, dyeing, and finishing—were organized under the control of an urban capitalist. His function was to provide credit, pay wages, set the standards and designs to be followed, and, finally, to seek markets for the product.

The spread of industrial skills. Much transfer of skill was involved in the rise of the pre-Industrial Revolution's manufacturing system. The nurseries of technology can be identified as north Italy, the Low Countries, and south Germany. The 16th century had no blueprints, so both capital and technology were transmitted across national boundaries in the most highly personalized way. Colonies of Italian merchant bankers showed Antwerp and Bruges the secrets of double-entry bookkeeping, and Italians dominated the London money market until well into the 17th century. One-third of the population of Norwich in 1600 was of Dutch origin. There, as in London, Colchester, and many manufacturing centres in the east of England and the Midlands, Dutch, Flemish, and Walloon experts were to be found in textiles, brewing, glassblowing, printing and bookbinding, horticulture, and many other occupations. The Höchstetters and other south Germans bought concessions to develop the Cumberland mines of England, as they did in Spain and throughout the territories of the Holy Roman emperor. The process continued after the expulsion of the Huguenots from France in 1685, when another wave of highly skilled merchants, artisans, and professional men flooded into the Dutch republic, England, and Prussia, where they reinforced strongly (and in some cases originated) the processes of invention and development in such industries as linen and silk manufacture, clock making, paper making, and hat making.

Italian merchant bankers

The guild system and the labour market. Thus, nobles, merchants, and, in some cases, middlement rising from the ranks of industry itself, inaugurated major changes in the early modern economy throughout Europe. Rising demands caused industry to outrun the supply of skilled labour (journeymen) controlled by the urban guilds. Therefore, the unskilled and unorganized rural workers were recruited into a new industrial system known as the "putting-out" system, or domestic system. Under this system, the capital, material, and, sometimes, tools were supplied by a merchant capitalist, who coordinated the different processes necessary to manufacture and disposed of the final product on the market. The processes (*e.g.*, combing, spinning, weaving, etc.) were carried on by a widely dispersed system of cottage labour.

This did not mean the guilds immediately disappeared. In some places, for example London, they changed their nature as the great merchant companies gained control of the craft guilds through their control of capital and power over the market. In other English towns, after a long series of amalgamations, the guilds weakened and finally disappeared. There were few left by the end of the 17th century, and industry increasingly was left to its own devices. The Industrial Revolution of the 18th century was able to spread all the more rapidly because only the vestigial remains of the old guild system were left.

In France the economic reorganizations of Jean-Baptiste Colbert revived the guild structure largely to create revenue for the crown, but even in France guild power was weakened by the rise of the putting-out system in rural areas and the grant of licenses and exemptions by the crown to individual entrepreneurs in return for a fee. In Spain guilds actually increased—a characteristic symptom of Spanish backwardness. Likewise, in Germany and central Europe, the roots of the guild system lay deep and withered away only slowly as the enlightened despots of the 18th century introduced liberty of craftsmanship. In Italy the situation varied. In Rome guilds grew in number, whereas in Tuscany local rulers subordinated guilds to themselves. In Venice their power seems to have constituted a major obstacle to technological progress, as in textiles, for example. In Poland, as in Germany and Spain, the guilds remained strong. In Russia, oddly enough, there was far less regimentation until Peter I the Great reinforced the guild system as part of his westernization program.

Survival of the guilds

Broadly, guild power was undermined most easily in the great entrepôt ports of northwest Europe, where capital and enterprise were relatively plentiful and where sea and water transport enabled economic change to come about most easily. The putting-out system, which had existed here and there in the medieval economy, now spread to many branches of production—such as mining, metallurgy, textiles, printing, and paper making. These were all industries demanding capital for equipment, raw materials, the payment of a large labour force, and a knowledge of marketing. Under the new system, guild and free labour might be combined. Spinning and weaving could be done in the countryside; combing and dyeing, in the towns. Thus, hierarchies of workmen grew up appropriate to each individual industry. In the metal industry of Solingen (Germany) the swordsmith, the temperer, and the sword furbisher all took part in the manufacture of a sword, but only the last (the *Reider*) was allowed to market the product. The same tendency for the man who was nearest to the market to assume control of the industry can be seen throughout the Birmingham and Sheffield industries making small ironware.

Emergence of large-scale enterprises. Large-scale production was not typical of the 16th century. Here and there an entrepreneur might concentrate production under one roof, as the famous Tudor manufacturer Jack of Newbury (John Winchcombe) is said to have done, employing some 500 or 600 adults and another 400 or 500 children. Less spectacular instances were to be found in late medieval Florence and Flanders. In the late 17th century such examples multiplied not only in western Europe but also in Bohemia and Russia. Although such examples are exceptions to the general rule of a small unit of production, they show how industry was everywhere trying to burst out of its medieval straightjacket and assume the forms of organization most appropriate to the relatively economic and efficient use of capital, labour, and technology. Trans-

Factors influencing industrial locations

port problems tended to restrict industrial location to the places where raw materials, labour, fuel, and power were available, but, where goods could be carried by sea or canal or where workers could be attracted by better pay or conditions of life, industries grew up despite such locational restrictions. The desire of governments for greater income or more power likewise reinforced the tendency to set up industries in places not naturally suitable for them.

Unemployment and social problems. This new economy, larger but more flexible than its predecessors, provided greater opportunities for employment but had greater social consequences. The estimates of Gregory King, the late 17th-century English social statistician, suggest that at least one-third of the English population was unemployed or underemployed. This phenomenon was remarked on increasingly by many observers in England, Spain, Germany, and Italy in the 17th century. It accounted for the attempt to gather the poor together in workhouses that were supposed to combine the functions of poor relief and larger national production. Much criticized and only fitfully effective, it served as a model for the more efficient deployment of resources by private enterprise in factories that was to characterize the Industrial Revolution itself.

Capitalism and the Protestant Ethic. Historians and sociologists who have looked for the deeper motivations of 16th- and 17th-century capitalism have sometimes suggested that they may be found in Protestantism, especially Puritanism. In 1904 the German sociologist Max Weber put forward the proposition that the linked phenomena of capitalism, laissez-faire, and the justification of business as a "calling" all derived their warrant from these sources. In 1922, Richard Henry Tawney, an English economic historian, tried to substantiate this thesis. Calvinism, in particular, was designed for a rising bourgeois class that was "conscious of the contrast between its own standards and those of a laxer world, proud of its vocation as the standard-bearer of the economic virtues" (*Religion and the Rise of Capitalism* [1926]). In spite of counter-arguments, such theories have had wide influence. Yet, they now need to be re-examined in the light of the knowledge that has emerged since they were first put forward. This includes the realization that the growth of capitalism in the early modern world received many stimuli unknown to Weber and Tawney, including the growth of population. Some of the changes that were supposed to be specifically linked with north-European Protestantism also involved no real innovations, being rather a shift to northern Europe of economic practices well established in north Italy, the cradle of the modern European economic system.

The Weberian thesis

Calvinism. Further examination of the basic theology of Martin Luther and John Calvin suggests a medieval rather than a modern economic outlook, containing little to appeal to a rising bourgeoisie. Even Calvin gave his views on problems of economic morality with caution and reluctance. They occupy only a few pages in his 20 volumes of printed works. What Calvin did was to remove the question of usury from the complex of theological pedantry and place it on a basis of simple morality. Reasonable interest on a loan was no more unjust than a reasonable rent for land, but extortionate interest squeezed from the poor was "evil and foul." His disciples took a similar line. (The doyen of Dutch Calvinist theologians, Gisbertus Voetius, excommunicated a God-fearing woman in his congregation because her husband was a pawnbroker.) Generally, Protestant countries adopted attitudes to these problems very similar to the Catholic tradition, fixing maximum rates of interest, controlling prices, and setting up public pawnshops.

The Puritan societies of such areas as the Netherlands, East Anglia in England, New England in North America, and Huguenot parts of France likewise contradict the assumption that Calvinism was particularly associated with merchant capitalism. The Protestants who fled from the southern Netherlands before Spanish persecution into Holland and eastern England seemed to have been mainly skilled artisans. The capitalists among them, however, constituted only a small minority of the whole. Calvinist influence is clearly discernible among the personnel and policies of the Dutch West India Company, but, in general, dogmatic Calvinism was not characteristic of the rich merchant elite of the Netherlands. They were, for the most part, liberal and anticlerical in outlook, no more inclined to trust dynasticism or theocracy in Protestant form than in Catholic form. Indeed, in the 17th century, Dutch politics turned largely on the conflict between these "libertine" merchant princes of the Dutch republic and the party known as Orangists, led by the Calvinist ministers but composed largely of the humbler social orders in support of the House of Orange. The Orangists wanted to continue the religious crusade against Spain, which the great merchants realized would be disastrous to their business.

Protestant refugees from the Netherlands

The settlement in New England in North America was theologically Puritan and socially medieval. It was not until the middle of the 17th century that newer immigrants from the City of London began to challenge the older ideals of social stability, order, and discipline inherited from the Pilgrim Fathers. Like their London or Amsterdam contemporaries, these new capitalist elements wanted mobility, consumption, even luxury, all thoroughly deplored by men of the old dispensation, such as Gov. John Winthrop.

Similar conflicts may be found among the Huguenots of the areas around Bordeaux and Marseilles in France. Probably the majority of Huguenot support came, here as elsewhere, from the lower orders together with the lesser gentry, both hard hit by rising prices. Rich merchants may certainly be found, but they were probably no more important as an element than professional lawyers or doctors.

Origins of the Weber thesis. Such observations throw considerable doubt on the Weber thesis, which may have received some of its plausibility from later evidence of the predominance of Dissenters in 18th- and 19th-century British economic life. But much of this was Quaker or Methodist and based on a theology totally different from that of Calvin. It may well have been the result of the exclusion of Dissenters from many spheres of public life after 1660. In general, it looks as if the majority of the adherents to radical forms of Protestantism came from the ranks of displaced persons from the lower orders of society. The new economic developments tended to take place beyond the control of the old medieval towns and guilds. In what is now Belgium and, later, in Holland, there was a floating population from the ports and the countryside, much at the mercy of the economic cycles of alternating prosperity and depression. Religious persecution was another force turning thousands of artisans adrift in search of new places of settlement. The enforced mobility and restlessness of the times seemed to have given a special attraction to class, status, or wealth. Radical religions that emphasized the importance of character and conduct and that even preached socially egalitarian doctrines seemed to give purpose even to humble occupations. The doctrines of election and predestination had a special appeal to those who could believe that economic success based on thrift and sobriety was clear evidence of God's favour. It seems probable that in the casual, easy-going society of the early modern world, men thus motivated toward steady and methodical work would inevitably tend to rise in the social scale. On this interpretation, while the initial attraction of the new religions to capitalists may have been exaggerated, the practice of their beliefs and social habits may have contributed to the rapid growth of a class of capitalists later on. At the upper end of the social scale also, it has been argued that the appeal of Calvinism was not so much to the prosperous gentry as to those who were in difficulties through price inflation.

The Dissenters

The voyages of discovery and the price revolution. *The development of chartered companies.* The late 16th century saw the nations of western Europe—Spain, Portugal, England, and the emergent Dutch republic—locked in the first scramble for trade and empire. Some of the contestants were individual merchants who attempted to conduct their business in the new areas in the traditional way, either as individual adventurers or at most loosely associated with other merchants in a fellowship or society. This was the way the merchant adventurers had conducted a large part of England's export trade in cloth to northwest Europe. It was an association of individuals in which every member

traded alone with his own stock and employees, subject only to the regulations imposed by the company in order to secure benefits for all members. This was what was called the "regulated company," and it did not represent any accumulation of common capital. Such an institution had serious defects when it came to organizing and financing the much longer voyages, employing larger armed ships with larger crews and with larger cargoes at stake. Voyages to the new areas of discovery often necessitated heavy outlays on defensive forts and equipment to protect the adventurers against hostile attacks. Such ventures were more than an individual investor could finance, and they required the collection of capital from many investors and its professional management. Such methods had occasionally been employed in the Middle Ages. These joint-stock methods now became far more common. In the second half of the 16th century, London capitalists, aristocratic and mercantile, raised money jointly to finance Sir John Hawkins' slave journeys, Sir Martin Frobisher's search for the Northwest Passage, Sir Francis Drake's raids on Spanish America, Sir Walter Raleigh's colonization of North America, and the trade enterprises to Russia and the Levant. Similar methods were followed by the adventurers of France and Holland, but very few of them succeeded.

The enterprises most significant for the immediate future were those to the East Indies. In Holland 12 groups of investors in the 1590s joined to finance such voyages by a separate parcel of capital, but the profits were sadly reduced by the competitive buying and selling of the valuable spices by the rival entrepreneurs. In 1602, therefore, they were amalgamated into the United East India Company. Like most Dutch institutions, this was a federation—six "chambers" situated in six different towns or provinces, each with its own organization and capital and subject only to general control from the central body. The need for permanent fixed capital for forts, ships, and arms suggested that the capital should also be permanent. A stockholder who wanted to get his money back could only do so by selling his claim on a share of the capital to somebody else at the price it would fetch on the market at the time of selling. Thus, the East India Company shares became one of the first and largest blocks of share capital to be traded on the new Amsterdam Bourse.

The United East India Company

Anglo-Dutch rivalry. The English East India Company obtained its charter on the last day of 1600. A company of 220 adventurers was established, which sounded very like a regulated company, but they recognized that India was too far away to be exploited by individual enterprise. Therefore, there was to be "a joint and united stock," though each voyage remained a separate capital investment. It was more than 50 years before the English adopted the Dutch method of a permanent capital fund.

The Dutch were the pacemakers under the vigorous, ruthless leadership of Jan Pieterszoon Coen, governor in the East Indies until 1629. By 1680 they had a monopoly of the spice-producing regions of the Malay Peninsula and Archipelago. They held Ceylon and many points on the mainland of India, the Persian Gulf, the Red Sea, China, and Japan. They employed every device to maximize profits on the cargoes of Japanese copper, silk, and porcelain; Chinese tea, pottery, and wallpaper; Indian cottons and spices; Persian carpets; Arabian coffee; Malayan tin; but, above all, the precious spices of the Malayan Islands, which left Asia at Christmas each year.

The English company was less successful. It managed to make high profits on the early voyages and set up many trading posts in the East, but it was evicted by Japan and driven out of the Spice Islands by the Dutch. On the Indian mainland the costs of defense were high. Lacking the expertise and the resources that enabled the Dutch to organize a self-balancing trade in many Eastern areas, the English company was always under pressure to export much larger quantities of silver to pay for its Eastern purchases than the Dutch. Throughout the 17th and 18th centuries it faced constant criticism for draining England of silver. Its reply was that it resold a large proportion of the spices, textiles, tea, coffee, and porcelain that it brought back from India in other European markets, thereby winning a net surplus of treasure.

The Dutch were also active in North America, where colonists had settled in the New Netherlands, along the Hudson River, trading with Newfoundland, Virginia, and the West Indies. Their hold was not strong, and it was easily broken by the English in 1664. Nor were their enterprises in the West Indies and South America completely successful. The Dutch West India Company was formed as much to fight Spain as to develop trade. Large areas of Brazil were annexed but lost again to Portugal. The sugar market was a dangerously fluctuating one. Dutch Guiana, with its coffee, cacao, and cotton, produced better results, as did the slaving ports on the coast of West Africa, which were a main source of supply to America and the West Indies. But the West India Company was not, in the main, successful.

North American trade

Success and failure of the companies. Indeed, many of the European chartered companies suffered results varying from barely successful to disastrous. The Virginia Company was a costly failure. The 30 or more French companies set up in the 17th century, including an East India, West India, and Senegal, did little but consume French capital. The English Royal African Company had a checkered career, as did competing companies formed in Denmark and Prussia to exploit Africa and the East Indies.

Somewhat late in the field, France managed to retrieve an otherwise dismal string of failures in the Caribbean. In spite of the collapse of Colbert's West India Company, individual French traders did well in what was known as the Sugar Bowl, developing sugar plantations on Martinique, Guadeloupe, Haiti, and other smaller Caribbean islands.

By 1700 a century of company activity by the Western nations in America, India, Asia, and Africa had left indelible marks. South America and the West Indies had been designated forever as "Latin" America. With the Dutch trading stations eliminated, North America's future was poised between England and France. England was firmly entrenched on the Indian subcontinent, while to the East the Dutch were equally the masters of the Malay Peninsula and Archipelago, with regular trade connections to China and Japan. It is likely that the Dutch East India Company had the best record of profit. None of the other company enterprises had anything but a patchy record, and some had lost enormous sums of capital and seen little, if any, profit. Some individual merchants in Amsterdam, Middelburg (Holland), Rouen and Nantes (France), London, and Bristol (England) had made personal fortunes. Others had lost them.

Success of the Dutch East India Company

But, if the colonial trades were by no means the easy gold rush they have sometimes been thought, it must be remembered that the capital investment they represented was still only a small part of the total trade of the Western world. The bulk of trade and shipping was still inter-European. The spices, sugar, cotton, and other goods were commodities that leavened the lump, but they were far from being the dominant influence.

The influx of silver and price inflation. One commodity produced in the New World nevertheless had a direct bearing upon an economic movement that, in turn, had incalculable effects upon the economy and society of the 16th and 17th centuries. The relationship between the flow of Spanish-American silver and the price inflation of the 16th century is still a matter of debate, but many historians still maintain that the major cause of the price inflation lies in this addition to the monetary supply of the world; and most others would agree that it played at least an important role. The precise dimensions of the inflation are not easy to establish, but in Spain, for example, prices at the end of the century were between three and four times greater than those at the beginning; elsewhere in France, England, Holland, Alsace, Italy, Germany, and Poland, they ranged from two to three times their 1500 level at least. The movement was not uniform or smooth. It began about 1480 in Germany, England, and Poland, about 1500 in Spain, and about 1530 in Italy (which generally experienced a smaller rise than most other places). Everywhere, the sharpest rise came between about 1540 and the 1570s. The inflation ended, as it began, at different times in different places: in Germany as early as the 1620s and in England and Poland by the 1640s. After the mid-

17th century the price level almost everywhere remained steady or even declined for more than a century.

Basing their arguments on the theory that prices move broadly in relation to the volume of money in circulation and the velocity of that circulation, some observers from the 16th to the 20th century have seen a major cause of inflation in the swelling stream of silver from Spanish America. They include Francisco López de Gomara, a Spanish historiographer, writing in 1558, Jean Bodin in his dispute with Malestroit in 1568–78, the author of the famous English *Dialogue of the Common Weal* (1581), and the followers of Earl Jefferson Hamilton, a U.S. scholar who has done most to reveal the dimensions of the problem in the 20th century.

Imports of silver from Spanish America

The sequence of events was that the conquistadores, finding silver and gold plates and statues relatively common in Spanish America, began very soon after their arrival to mine precious metals. Boom levels were reached by 1550, after the discovery of rich silver fields in Bolivia and Mexico coincided with a new method of extracting silver through the use of mercury. Up to the 1630s large supplies of silver were mined and sent to Europe. The peak years, about the turn of the century, saw an annual flow of about 36,000,000 pesos. Thereafter, the flow began to dwindle until it fell to a relative trickle by 1660. During this whole period some 18,000 tons of silver (roughly the equivalent of one year's output from present-day South African mines) was added to Europe's monetary stocks. Of the total, about one-fifth was taken by the Spanish crown, some circulated in Spanish America, while the rest was convoyed twice a year to Seville, from where it was distributed throughout Spain and ultimately throughout Europe and to the East.

Causes of inflation. The relationship of this flow to the inflation nevertheless raises certain difficulties. It has been noted, for example, that in some countries the price rise began at least 75 years before 1570, yet Hamilton himself is inclined to minimize the export of bullion from Spain before the latter years of the 16th century. Again, the dimensions of the price rise varied not only between countries but also between commodities. Thus, in general, every price investigation has confirmed that grain and other food prices rose a good deal more than metals, textiles, industrial goods, and colonial commodities, such as spices.

Clearly the influx of silver from the New World does not answer all the questions about the inflation. The growing output of the mines of Germany between 1480 and 1540, which reached its peak in the early 1540s, may help to explain why German and Polish prices rose earlier than Spanish prices, but it is still necessary to explain the impetus behind the continental mining of silver itself; and the demand for silver detracts from the purely monetary and supply side of the problem. Turning to the demand side of the equation, the important increases in population and changes in income distribution obviously played a role. Everywhere in Spain, Germany, Poland, Holland, and England, the larger cities show a rapid growth. Recent research has tended to suggest that the most important nonmonetary change that made it possible for increased supplies of bullion to infiltrate the economy and drive up prices was a general increase of population, associated with growing demand, larger capital investment, and larger national incomes.

Effects of the price inflation. All over Europe landlords' profits grew and with them rural investment and consumption. Customary tenants and freeholders also frequently enjoyed the benefits of rising prices. Entrepreneurs, businessmen, and speculators reaped some harvest from the gap that often opened between prices and costs, though wages sooner or later caught up with prices. Everywhere governments had to face increased expenditure, and, since their incomes were slow to grow, they often added to the inflationary pressures by debasing their coinage, as did the English Tudors in the 1540s and 1550s. Such debasements reached their climax in the notorious monetary manipulations known as the *Kipper und Wipper Zeit* (see-saw time) of the early 17th century. Larger rural incomes together with larger urban incomes promoted the production and consumption of more luxury goods. Thus, any satisfactory explanation of the inflation must include these demand factors as well as the changes in monetary supply.

Debasement of the coinage

Few contemporaries grasped the underlying causes of the inflation. Naturally, they tended to blame it all on human wickedness and greed, passing legislation to hold down prices, rents, and wages, all to little effect. The inflation and its social consequences continued. Generally, those who could adjust their incomes to the changing price level benefitted most, such as landlords who could force or persuade their tenants to accept flexible commercial leases or tenancies; tenants with security of tenure, who could enjoy higher profits if they had surplus produce to sell, while still paying fixed rents; and tradesmen, who could put up prices and keep costs down. The sufferers were landowners, whose *rentier* incomes were limited by custom, and wage earners whose wages stuck at customary levels while the price of necessities rose. It must be remembered, however, that the wage earner completely reliant on a money wage was still the exception rather than the rule in most societies. Much payment in kind was still in force. Many workers were still rural peasants with a small holding to provide them with at least a subsistence living.

The decline of Spain. It has been argued that the decline of Spain in the 17th century from its 16th-century peak of power and prosperity was fundamentally due to economic causes. The silver influx is claimed to have brought about a high degree of inflation, and, since costs rose with prices, Spain suffered a loss of economic strength that brought about political decline. This theory is not universally accepted, and other historians have argued that Spain's problems arose from the misguided determination of Philip II and his successors to burden Spain with such heavy costs of war and extravagance that the consequential high taxation and poverty drove out all enterprise and large numbers of valuable skilled workers until Spain was to become a proud but arid desert, inhabited by bankrupts, monks, and paupers. This picture, though in some respects exaggerated, gains some credibility from comparisons with other countries, such as the Dutch republic; for there is a fair measure of agreement that the same price inflation that is alleged to have ruined Spain was, at the very same time, exerting a powerful natural influence that added daily to the wealth of the Dutch. (C.H.Wi.)

THE RENAISSANCE

The Italian Renaissance. *Development of the Italian cities.* Medieval Italy was a land of cities. The urban imprint of Roman times, never totally erased during some 500 years of barbarian invasions and settlement, began to reassert itself in Italy by the 10th century. New towns and old ones newly revived began to dot the spiny Italian landscape—striking creations of a population that was burgeoning in numbers and brimming with new energies. As in Roman times, the medieval Italian town lived in close relation to its surrounding rural area, or *contado;* Italian city folk seldom relinquished their ties to the land from which they and their families had sprung. Rare was a successful tradesman or banker who not invest some of his profits in his family farm or a rural noble who did not spend part of his year in his tower house inside city walls. In Italian towns, nobles, merchants, *rentiers,* and skilled craftsmen lived and worked side by side, fought in the same militia, and married into each other's families. Social hierarchy there was, but it was a tangled system with no simple division between noble and commoner, between landed and commercial wealth. That nobles took part in civic affairs helps explain the early militancy of the townfolk in resisting the local bishop, who was usually the principal claimant to power in the community. Political action against a common enemy tended to fuse townspeople with a sense of community and civic loyalty. By the end of the 11th century civic patriotism began to express itself in literature; city chronicles combined fact and legend to stress a city's Roman origins and, in some cases, its inheritance of Rome's special mission to rule. Such motifs reflect the cities' achievement of autonomy from their respective episcopal or secular feudal overlords and, probably, the growth of rivalries between neighbouring communities.

Urban growth

This in turn was part of the expansion into the neighbouring countryside, with the smaller and weaker towns submitting to the domination of the larger and stronger. As the activity of the towns became more complex, sporadic political action was replaced by permanent civic institutions. Typically, the first of these was an executive magistracy, named the consulate (to stress the continuity with republican Rome). In the late 11th and early 12th centuries, this process—consisting of the establishment of juridical autonomy, the emergence of a a permanent officialdom, and the spread of power beyond the walls of the city to the *contado* and neighbouring towns—was completed for about a dozen Italian centres and underway for some dozens more; the loose urban community was becoming a corporate entity, or *commune;* the city was becoming a city-state. The typical 13th century city-state was a republic administering a territory of dependent towns; whether it was a democracy is a question of definition. The idea of popular sovereignty existed in political thought and was reflected in the practice of calling a *parlamento,* or mass meeting, of the populace in times of emergency; but in none of the republics were the people as a whole admitted to regular participation in government. On the other hand, the 13th century saw the establishment, after considerable struggle, of assemblies in which some portion of the citizenry, determined by property and other qualifications, took part in debate, legislation, and the selection of officials. Most offices were filled by citizens serving on a rotating, short-term basis. If the almost universal obligation of service in the civic militia is also considered, it becomes clear that participation in the public life of the commune was shared by a considerable part of the population. Moreover, most of the city republics were small enough (in 1300 Florence, one of the very largest, had perhaps 100,000 people; Padua, nearer the average, had about 15,000) so that public business was conducted by and for citizens who knew each other, and civic issues were a matter of widespread and intense personal concern.

A darker but ever-present side of this intense community involvement was conflict. It became a cliché of contemporary observers that when the citizens were not fighting wars with their neighbours they were fighting each other. Machiavelli explained this as the result of the natural enmity between nobles and "the people—the former desiring to command, the latter unwilling to obey." Although this is too simple, it contains an essential truth: the basic problem was the unequal distribution of power and privilege, complicated by the persistence of violent feudal ways (the nobles' militant style was widely imitated as a standard of behaviour). The inability to contain conflict within peaceable limits resulted in bloody strife between members of rival factions, such as the Guelfs and Ghibellines, with those on the losing side often forced into exile and suffering the confiscation of their property.

Enmity between nobles and the people

During the 14th century a number of cities, despairing of finding a solution to the problem of civic strife, were turning from republicanism to *signoria,* the rule of one man. The *signore,* or lord, was usually a member of a local feudal family that was also a power in the commune; thus, lordship did not appear to be an abnormal development, particularly if the *signore* chose, as most did, to rule through existing republican institutions. Sometimes a *signoria* was established as the result of one noble faction's victory over another, while in a few cases a feudal noble who had been hired by the republic as its *condottiere,* or military captain, became its master. Whatever the process, hereditary lordship had become the common condition and free republicanism the exception by the late 14th century. Contrary to what Burckhardt believed, Italy in the 14th century had not shaken off feudalism. In the south, feudalism was entrenched in the loosely centralized Kingdom of Naples, successor state to the Hohenstaufen and Norman kingdoms. In central and northern Italy, feudal lordship and knightly values merged with medieval communal institutions to produce the typical state of the Renaissance—a state that was a compromise between conflicting tendencies. Where the nobles were excluded by law from political participation in the commune, as in the Tuscan cities of Florence, Siena, Pisa, and Lucca, parliamentary republicanism had a longer life; but even these bastions of liberty had their intervals of disguised or open lordship. The great maritime republic of Venice reversed the usual process by increasing the powers of its councils at the expense of the doge (Latin *dux,* leader). But Venice never had a feudal nobility, only a merchant aristocracy that called itself noble and jealously guarded its hereditary sovereignty against incursions from below.

Wars of expansion. There were new as well as traditional elements in the Renaissance city-state. Changes in the political and economic situation affected the evolution of government, while the growth of the Humanist movement influenced conceptions of citizenship, patriotism, and civic history. The decline in the ability of both the empire and the papacy to dominate Italian affairs as they had done in the past left each state free to pursue its own goals within the limits of its resources. These goals were, invariably, the security and power of each state vis-à-vis its neighbours. Diplomacy became a skilled game of experts; rivalries were deadly, and warfare was endemic. Because the costs of war were all-consuming, particularly as mercenary troops replaced citizen militias, the states had to find new sources of revenue and to develop methods of securing public credit. New officials were required to administer these revenues and to gather information and keep records. The city-state came to take over many of the functions formerly performed by associations of private citizens—the kinship groups, tower consortiums, guilds, and political parties that had regulated social relations—leaving individuals to confront the state alone and without intermediaries. If Renaissance man became conscious of himself as an individual, as Burckhardt declared, he also became inescapably conscious of his relation to the state, which became father, mother, and family to everyone under its jurisdiction.

In place of the prevailing anarchy, the Italian states had begun to evolve a new pattern by the 14th century. In place of the dual orbits of empire and papacy in which most of them had revolved, regional powers emerged, with the stronger or more ambitious from time to time bidding for domination of the peninsula. The most sustained effort of aggrandizement was that of Milan under the lordship of the Visconti. In the 1380s and 1390s Gian Galeazzo Visconti pushed Milanese hegemony eastward as far as Padua, at the very doorstep of Venice, and southward to the Tuscan cities of Lucca, Pisa, and Siena and even to Perugia in papal territory. Some believed that Gian Galeazzo meant to be king of Italy; whether or not this is true, he would probably have overrun Florence, the last outpost of resistance in central Italy, had he not died suddenly in 1402 leaving a divided inheritance and much confusion. In the 1420s, under Filippo Maria, Milan began to expand again; but by then Venice, with territorial ambitions of its own, had joined with Florence to block Milan's advance, while the other Italian states took sides or remained neutral according to their own interests. The mid-15th century saw the Italian peninsula embroiled in a turmoil of intrigues, plots, revolts, wars, and shifting alliances, of which the most sensational was the reversal that brought the two old enemies, Florence and Milan, together against Venetian expansion. This "diplomatic revolution," engineered by Cosimo de' Medici (1389–1464), the unofficial head of the Florentine republic, is the most significant illustration of the emergence of balance of power diplomacy in Renaissance Italy.

Emergence of regional powers

Italian Humanism and scholarship. As seen above, the notion that ancient wisdom and eloquence lay slumbering in the Dark Ages until awakened in the Renaissance was the creation of the Renaissance itself. The idea of the revival of classical antiquity was one of those great myths, comparable to the idea of the universal civilizing mission of imperial Rome or to the idea of progress in a modern industrial society, by which an era defines itself in history. Like all such myths, it was a blend of fact and invention. Classical thought and style permeated medieval culture in ways past counting. Most of the authors known to the Renaissance were known to the Middle Ages as well, while the classical works "discovered" by the Humanists were not originals but medieval copies preserved in monastic

Earlier revivals of classical antiquity

or cathedral libraries. Moreover, the Middle Ages had produced at least two earlier revivals of classical antiquity. The so-called Carolingian Renaissance of the late 8th and 9th centuries saved many ancient works from destruction or oblivion, passing them down to posterity in its beautiful minuscule script (which influenced the Humanist scripts of the Renaissance). A 12th-century Renaissance saw the revival of Roman law, Latin poetry, and Greek science, including almost the whole corpus of Aristotelian writings known today.

Growth of literacy. Nevertheless, the classical revival of the Italian Renaissance was so different from these earlier movements in spirit and substance that the Humanists understandably felt it was original and unique. During most of the Middle Ages, classical studies and virtually all intellectual activities were carried on by churchmen, usually members of the regular orders. In the Italian cities this monopoly was partially breached by the growth of a literate laity with some taste and need for literary culture. New professions reflected the growth of both literary and specialized lay education—the *dictatores,* or teachers of practical rhetoric, and lawyers, and the ever present notary (a combination of accountant, solicitor, and public recorder). These, and not Burckhardt's wandering scholar-clerics, were the true predecessors of the Humanists.

In Padua a kind of early Humanism emerged, flourished, and declined between the late 13th and early 14th centuries. Paduan classicism was a product of the vigorous republican life of the commune, and its decline coincided with the loss of the city's liberty. A group of Paduan jurists, lawyers, and notaries—all trained as *dictatores*—developed a taste for classical literature that probably stemmed from their professional interest in Roman law and their affinity for the history of the Roman republic. The most famous of these Paduan classicists was Albertino Mussato, a poet, historian, and playwright, as well as lawyer and politician, whose play *Ecerinis,* modelled on Seneca, has been called the first Renaissance tragedy. By reviving several types of ancient literary forms and by promoting the use of classical models for poetry and rhetoric, the Paduan Humanists helped make the 14th-century Italians more conscious of their classical heritage; in other respects, however, they remained close to their medieval antecedents, showing little comprehension of the vast cultural and historical gulf that separated them from the ancients.

Language and eloquence. It was Petrarch who first understood fully that antiquity was a civilization apart and, understanding it, outlined a program of classically oriented studies that would lay bare its spirit. The focus of Petrarch's insight was language: if classical antiquity was to be understood in its own terms it would be through the speech with which the ancients had communicated their thoughts. This meant that the languages of antiquity had to be studied as the ancients had used them and not as vehicles for carrying modern thoughts. Thus, grammar, which included the reading and careful imitation of ancient authors from a linguistic point of view, was the basis of Petrarch's entire program.

Eloquence is the union of elegance, power, and virtue

From the mastery of language one moved on to the attainment of eloquence. For Petrarch, as for Cicero, eloquence was not merely the possession of an elegant style, nor yet the power of persuasion, but the union of elegance and power together with virtue. One who studied language and rhetoric in the tradition of the great orators of antiquity did so for a moral purpose—to persuade men to the good life—for, said Petrarch in a dictum that could stand as the slogan of Renaissance Humanism, "it is better to will the good than to know the truth."

The humanities. To will the good, one must first know it; and so there could be no true eloquence without wisdom. According to Leonardo Bruni, a leading Humanist of the next generation, Petrarch "opened the way for us to show in what manner we might acquire learning." Petrarch's union of rhetoric and philosophy, modelled on the classical ideal of eloquence, provided the Humanists with an intellectual dignity and a moral ethos lacking to the medieval *dictatores* and classicists. It also pointed the way toward a program of studies—the *studia humanitatis*—by which the ideal might be achieved. As elaborated by Bruni, Pier Paolo Vergerio, and others, the notion of the humanities was based on classical models—the tradition of a liberal arts curriculum conceived by the Greeks and elaborated by Cicero and Quintilian. Medieval scholars had been fascinated by the notion that there were seven liberal arts, no more and no less, although they did not always agree as to which they were. The Humanists had their own favourites, which invariably included grammar, rhetoric, poetry, moral philosophy, and history, with a nod or two toward music and mathematics. They also had their own ideas about methods of teaching and study. They insisted upon the mastery of Classical Latin and, where possible, Greek, which began to be studied again in the West in 1397, when the Greek scholar Manuel Chrysoloras was invited to lecture in Florence. They also insisted upon the study of classical authors at first hand, banishing the medieval textbooks and compendiums from their schools. This greatly increased the demand for classical texts, which was first met by copying manuscript books in the newly developed Humanistic scripts and then, after the mid-15th century, by the method of printing with movable type. Thus, while it is true that most of the ancient authors were already known in the Middle Ages, there was an all-important difference between circulating a book in many copies to a reading public and jealously guarding a single exemplar as a prized possession in some remote monastery library.

The term humanist (Italian *umanista,* Latin *humanista*) first occurs in 15th-century documents to refer to a teacher of the humanities. Humanists taught in a variety of ways. Some founded their own schools, as Vittorino da Feltre did in Mantua in 1423 and Guarino Veronese in Ferrara in 1429, where students could study the new curriculum at both elementary and advanced levels. Some Humanists taught in universities, which, while remaining strongholds of specialization in law, medicine, and theology, had begun to make a place for the new disciplines by the late 14th century. Still others were employed in private households, as was the great Politian (Angelo Poliziano), who was tutor to the Medici children as well as a university professor.

Literary works of the Humanists

Formal education was only one of several ways in which the Humanists shaped the minds of their age. Many were themselves fine literary artists who exemplified the eloquence they were trying to foster in their students. Renaissance Latin poetry, for example, nowadays dismissed—usually unread—as imitative and formalistic, contains much graceful and lyrical expression by such Humanists as Politian, Giovanni Pontano, and Jacopo Sannazzaro. In drama, Politian, Pontano, and Pietro Bembo were important innovators, and the Humanists were in their element in the composition of elegant letters, dialogues, and discourses. By the late 15th century, Humanists were beginning to apply their ideas about language and literature to composition in Italian as well as in Latin, demonstrating that the "vulgar" tongue could be as supple and as elegant in poetry and prose as was Classical Latin.

Classical scholarship. Not every Humanist was a poet, but most were classical scholars. Classical scholarship consisted of a set of related, specialized techniques by which the cultural heritage of antiquity was made available for convenient use. Essentially, in addition to searching out and authenticating ancient authors and works, this meant editing—comparing variant manuscripts of a work, correcting faulty or doubtful passages, and commenting in notes or in separate treatises on the style, meaning, and context of an author's thought. Obviously, this demanded not only superb mastery of the languages involved and a command of classical literature but also a knowledge of the culture that formed the ancient author's mind and influenced his writing. Consequently, the Humanists created a vast scholarly literature devoted to these matters and instructive in the critical techniques of classical philology, the study of ancient texts.

The study of man through his behaviour

The Humanists' conception of man. Beginning with Petrarch, Humanist thought approached the subject of man through introspection and an examination of actual behaviour rather than through doctrinaire formulas. Striving for the good life, yet torn by selfish passions, caught

between desires for immortality and for earthly fame, alternating between glory and despair—this was man as Petrarch knew him because the subject of his inquiry was himself. As orators, poets, historians, and moralists the Humanists dealt with man acting, willing, creating his own beauty and his own worldly destiny. Humanist psychology tended to stress the volitional and emotional rather than the rational side of man's nature. Reason was important but limited; it could neither master the passions nor grasp the ultimate mysteries. Reason was subordinate to the will, and the will was free to determine man's destiny. To quote Petrarch again, "It is better to will the good than to know the truth."

This voluntarist, moralist conception of man reflects the Humanists' function as spokesmen of an urban, literate laity. To those who had found rewarding social roles in the public world of the city-state, the conception of human life elaborated by medieval theologians was no more useful than an educational system in the service of monastic and priestly values. The Humanists' conception of man as actor and creator was the counterpart of their definition of a new curriculum of liberal studies, with its emphasis upon the relation between culture and the good life. Here the Renaissance myth of antiquity served the Humanists in two ways: first, as a summation of, or way of access to, an extraordinary range of experience (since they believed that the ancients had achieved everything worthwhile in this life); second, as a legitimating authority for modes of thought and action that were unknown or disapproved of in traditional Christian doctrine.

The Humanists were secularists who found in classical antiquity a conception of human life that was congenial and supportive; but they were also Christians, and in their use of ancient thought they showed an independent judgment that belies the old notion of a "pagan Renaissance." In fact, some of their favourite sources were post-classical and Christian. Even the most celebrated of Renaissance themes, the idea of "the dignity of man," best known in the *Oration* of Pico della Mirandola, was derived in part from St. Augustine and other Church Fathers. Created in the image and likeness of God, man was free to shape his own destiny; but the definition of that destiny was very much in the Christian tradition:

> You will have the power to sink to the lower forms of life, which are brutish. You will have the power, through your own judgment, to be reborn into the higher forms, which are divine.

Political thought. Pico envisioned the potential divinity of man; Niccolo Machiavelli looked unblinkingly at his actual behaviour; Francesco Guicciardini saw him as a victim of that behaviour.

The author of *The Prince,* a treatise on how to get power and keep it, Machiavelli so shocked his readers—not because he described behaviour that was unfamiliar to them but because he dared to advocate it—that they coined his name into synonyms for the devil (Old Nick) and for crafty, unscrupulous tactics (Machiavellian). No other name but that of Borgia so invariably evokes the image of the wicked Renaissance, and, indeed, Cesare Borgia was Machiavelli's chief model for *The Prince.* Yet Machiavelli, too, was influenced by Humanism—in particular, by Humanist voluntarist psychology and faith in human freedom. He was also a devotee of the cult of antiquity, which he reverenced chiefly in the ancient historians for their examples of political wisdom and military valour. From the example of Rome he derived the laws of political behaviour by which, he believed, his countrymen must live if they were to recover their civic virtue and free themselves from the yoke of the "barbarians" who were overrunning Italy.

Machiavelli's ideas of the uses of the ancient past were indebted to a Florentine tradition of Civic Humanism that, by his time, was a century old. A line of Humanists had expounded the ideals of republican citizenship and the meaning of classical studies for the public life. In the years of Milanese aggression against Florence, Coluccio Salutati, serving as chancellor of the republic, had rallied the Florentines by reminding them of the legend that their city was "the daughter of Rome" and urging upon them the Roman legacy of justice and liberty. Salutati's pupil, Leonardo Bruni, who also served as chancellor, expounded many of the tenets of Civic Humanism in his *History of the Florentine People* and his panegyrics of Florence. The roots of Florentine liberty, he maintained, were deep in the soil of Tuscany, where, even before the rise of Rome, the Etruscans had founded free cities. In Florence, declared Bruni, equality was recognized in justice and opportunity for all citizens, while the claims of individual excellence were rewarded by preferment to public office and in public honours. Thus, the relation between freedom and achievement was close, and this explained Florence's pre-eminence in culture as well as in political liberty. Florence, observed Bruni, was the home of Italy's greatest poets, the pioneer in both vernacular and Latin literature, and the seat of the Greek revival as well as of eloquence. It was, in short, the centre of the *studia humanitatis,* those studies by and for a free man.

Civic Humanism

As a theory of political life, Civic Humanism represented the ideal rather than the reality of 15th-century communal politics. Even in Florence, where, after 1434, the Medici family took a grip on the city's republican institutions, the emphasis shifted from activism to the kind of Utopian mysticism represented by Pico's *Oration* and to the millennialist fantasies most vividly expressed in the late-15th-century preaching of Fra Girolamo Savonarola. Nevertheless, in providing ways of thinking about the republic and its history, the Humanist chancellors had contributed to a tradition of civic thought that the Medici had failed to extinguish. Machiavelli, himself a secretary in the chancellery of the anti-Medicean republic of 1494–1512 and a member of the group of florentine patricians and Humanists that met in the Rucellai gardens to talk about politics, was deeply influenced by it. In his *Florentine History,* in the *Art of War,* and above all in the *Discourses on the First Ten Books of Livy,* Machiavelli is best seen in the context of the Florentine Humanist tradition. In the *Discourses,* where Machiavelli examines the whole range of political possibilities, it is clear that his own preference in forms of government is for republics. The key to this preference is his idea of man as a political being, a conception he shared with Bruni and indeed with Bruni's source—Aristotle. To participate in the public life, to interact with one's fellowmen in making decisions, was to fulfill one's human nature. For this the best setting was the well-ordered republic, in which no one had a monopoly of power and citizens were devoted to the welfare and service of the community. But well-ordered republics were scarce in 16th-century Italy, as scarce as *virtù,* the political energy that made them possible.

Conflict between Christian and political morality

Machiavelli believed that this scarcity derived from the modern disposition to follow the precepts of conventional Christian morality rather than the more relevant example of ancient political experience. He said that in politics antiquity was more admired than imitated, whereas the teachings of religion had made states weak and sluggish. His solution was to expound Livy, the classical historian of the Roman Republic, in order to determine which examples were applicable to his own time. In this, he saw himself as setting out on a new route, but one that paralleled the paths already taken by modern jurisprudence and medicine, which had already created science by studying ancient laws and the knowledge of the ancient physicians; he proposed to do the same for politics. Thus, for Machiavelli, statecraft was a discipline based on timeless rules or laws and was no more to be subordinated to Christian ethics than were jurisprudence or medicine. The simplest example of the conflict between Christian and political morality is provided by warfare, where the use of deception, so detestable in every other kind of action, is necessary, praiseworthy, and even glorious. Machiavelli's political morality may be summed up in the *Discourses,* where, commenting upon a Roman defeat, he writes,

> This is worth noting by every citizen who is called upon to give counsel to his country, for when the very safety of the country is at stake there should be no question of justice or injustice, of mercy or cruelty, of honour or disgrace, but putting every other consideration aside, that course should be followed which will save her life and liberty.

Machiavelli's own country was Florence; when he wrote that he loved his country more than he loved his soul, he was consciously forsaking Christian ethics for the morality of civic virtue. His friend and countryman Francesco Guicciardini shared his political morality and his concern for politics but lacked his faith that a knowledge of ancient political wisdom would redeem the liberty of Italy. Guicciardini was an upper class Florentine who chose a career in public administration and devoted his leisure to writing history and reflecting on politics. He was steeped in the Humanist traditions of Florence and was a dedicated republican, despite the fact—or perhaps because of it—that he spent his entire career in the service of the Medici and rose to high positions under them. But Guicciardini, more skeptical and aristocratic than Machiavelli, was also half a generation younger, and he was schooled in an age that was already witnessing the decline of Italian autonomy.

In 1527 Florence revolted against the Medici a second time and established a republic. As a confidant of the Medici, Guicciardini was passed over for public office and retired to his estate. One of the fruits of this enforced leisure was the so-called *Cose fiorentine* (*Florentine Affairs*), an unfinished manuscript on Florentine history. While it generally follows the classic form of Humanist civic history, the fragment contains some significant departures from this tradition. No longer is the history of the city treated in isolation; Guicciardini was becoming aware that the political fortunes of Florence were interwoven with those of Italy as a whole and that the French invasion of Italy was a turning point in Italian history. He returned to public life with the restoration of the Medici in 1530 and was involved in the events leading to the tightening of the imperial grip upon Italy, the humbling of the papacy, and the final transformation of the republic of Florence into a hereditary Medici dukedom. Frustrated in his efforts to influence the rulers of Florence, he retired to his villa to write; but instead of taking up the unfinished manuscript on Florentine history, he chose a subject commensurate with his changed perspective on Italian affairs. The result was his *History of Italy*. Though still in the Humanist form and style, it was in substance a fulfillment of the new tendencies already evident in the earlier work—criticism of sources, great attention to detail, avoidance of moral generalizations, shrewd analysis of character and motive.

The *History of Italy* has rightly been called a tragedy by Felix Gilbert, for it demonstrates how, out of stupidity and weakness, men make mistakes that gradually narrow the range of their freedom to choose alternative courses and thus to influence events until, finally, they are trapped in the web of Fortune. This was already far from the world of Machiavelli, not to mention that of the Civic Humanists. Where the Humanists believed that *virtù* could master Fortune, Guicciardini was skeptical about men's ability to learn from the past and pessimistic about their power to influence the course of their own destinies. All that was left, he believed, was to understand. Guicciardini wrote history to show what men were like and to explain how they had reached their present circumstances. Man's dignity, then, consisted not in the exercise of his will to shape his destiny but in the use of his reason to contemplate and perhaps to tolerate his fate. In taking a new, hard look at the human condition, Guicciardini represents the decline of the Humanist view of man.

Guicciardini's pessimism

Arts and letters. As pointed out above, classicism and the literary impulse went hand in hand. From Lovato Lovati and Albertino Mussato to Politian and Pontano, Humanists wrote Latin poetry and drama with considerable grace and power (Politian wrote in Greek as well), while others composed epistles, essays, dialogues, treatises, and histories on classical models. In fact, it is fair to say that the development of an elegant, nonclassical style of prose writing was the major literary achievement of Humanism and that the epistle was its typical literary form. Petrarch's practice of collecting, reordering, and even rewriting his letters—of treating them as works of art—was widely imitated.

For lengthier discussions the Humanist was likely to compose a formal treatise or a dialogue—a classical form that provided the opportunity to combine literary imagination with the discussion of weighty matters. The most famous example of this type is *The Courtier,* published by Baldassare Castiglione in 1528; a graceful discussion of love, courtly manners, and the ideal education for a perfect gentleman, it had enormous influence all over Europe. Castiglione had a Humanist education, but he wrote *The Courtier* in Italian, the language Bembo chose for his dialogue on love, *Gli Asolani* (1505), and Ludovico Ariosto chose for his delightful epic, *Orlando furioso,* completed in 1516. The vernacular was coming of age as a literary medium.

According to some a life-and-death struggle between Latin and Italian began in the 14th century, while the mortal enemies of Italian were the Humanists, who impeded the natural growth of the vernacular after its brilliant beginning with Dante, Petrarch, and Boccaccio. In this view, the choice of Italian by such great 16th-century writers as Castiglione, Ariosto, and Machiavelli represents the final "triumph" of the vernacular and the restoration of contact between Renaissance culture and its native roots. The reality is somewhat less dramatic and more complicated. Most Italian writers regarded Latin as being as much a part of their culture as the vernacular, and most of them wrote in both languages. It should also be remembered that Italy was a land of powerful regional dialect traditions; until the late 13th century, Latin was the only language common to all Italians. By the end of that century, however, Tuscan was emerging as the primary vernacular, and Dante's choice of it for his *Divine Comedy* ensured its pre-eminence. Of lyric poets writing in Tuscan (hereafter called Italian), the greatest was Petrarch. His *canzoni,* or songs, and sonnets in praise of Laura are revealing studies of the effect of love upon the lover; his *Italia mia* is a plea for peace that evokes the beauties of his native land; his religious songs reveal his deep spiritual feeling.

Emergence of Tuscan as the vernacular

Petrarch's friend and admirer Giovanni Boccaccio is best known for his *Decameron;* but he pioneered in adapting classical forms to Italian usage, including the hunting poem, romance, idyll, and pastoral, whereas some of his themes, most notably the story of Troilus and Cressida, were borrowed by other poets, including Chaucer and Tasso.

The scarcity of first-rate Italian poetry throughout most of the 15th century has caused a number of historians to regret the passing of "il buon secolo," the great age of the language, which supposedly came to an end with the ascendancy of Humanist classicism. For every Humanist who disdained the vernacular, however, there was a Leonardo Bruni to maintain its excellence or a Poggio Bracciolini to prove it in his own Italian writings. Indeed, there was an absence of first-rate Latin poets until the late 15th century, which suggests a general lack of poetic creativity in this period and not of Italian poetry alone. It may be that both Italian and Latin poets needed time to absorb and assimilate the various new tendencies of the preceding period. Tuscan was as much a new language for many as was Classical Latin, and there was a variety of literary forms to be mastered.

With Lorenzo de' Medici the period of tutelage came to an end. The Magnificent Lorenzo, virtual ruler of Florence in the late 15th century, was one of the fine poets of his time. His sonnets show that he had felt Petrarch's influence but transformed it with his own genius. His poetry epitomizes the Renaissance ideal of *l'uomo universale,* the many-sided man. Love of nature, love of women, love of life are the principal themes reflecting the experience of the man. The woodland settings and hunting scenes of his poems suggest how he found relief from a busy public life; his love songs to his mistresses and his bawdy carnival ballads show the other face of a devoted father and affectionate husband. The celebration of youth in his most famous poem was etched with the sad realization that time passes swiftly:

Oh, how fair is youth, and yet how fleeting!
Let yourself be joyous if you feel it:
Of tomorrow there is no certainty—

Florence was only one centre of the flowering of the vernacular. Ferrara saw literature and art flourish under the patronage of the ruling Este family and before the end of

the 15th century counted at least one major poet, Matteo Boiardo, author of the *Orlando innamorato,* an epic of Roland. A blending of the Arthurian and Carolingian epic traditions, Boiardo's *Orlando* inspired Ludovico Ariosto to take up the same themes. The result was the finest of all Italian epics, *Orlando furioso.* The ability of the medieval epic and folk traditions to inspire the poets of such sophisticated centres as Florence and Ferrara suggests that Humanist disdain for the Dark Ages notwithstanding, Renaissance Italians did not allow classicism to cut them off from their medieval roots.

The northern Renaissance. *Political, economic, and social background.* In 1494 King Charles VIII of France led an army southward over the Alps, seeking the Neapolitan crown and glory. Many believed that this barely literate gnome of a man, hunched over his horse, was the Second Charlemagne, whose coming had been long predicted by French and Italian prophets. Apparently, Charles himself believed it; it is recorded that when he was chastised by the fiery preacher Savonarola for delaying his divine mission of reform and crusade in Florence, the King burst into tears and soon went on his way. He found the Kingdom of Naples easy to take and impossible to hold; frightened by local uprisings, by a new Italian coalition, and by the massing of Spanish troops in Sicily, he left Naples in the spring of 1495, bound not for the Holy Land, as the prophecies had predicted, but for home, never to return to Italy. In 1498 Savonarola was tortured, hanged, and burned as a false prophet for predicting that Charles would complete his mission. Conceived amid dreams of chivalric glory and crusade, the Italian expedition of Charles VIII was the venture of a medieval king—romantic, poorly planned, and totally irrelevant to the real needs of his subjects.

New phase of European politics

The French invasion of Italy marked the beginning of a new phase of European politics, during which the Valois kings of France and the Habsburgs of Germany fought each other, with the Italian states as their reluctant pawns. For the next 60 years the dream of Italian conquest was pursued by every French king, none of them having learned anything from Charles VIII's misadventure except that the road southward was open and paved with easy victories. For even longer Italy would be the keystone of the arch that the Habsburgs tried to erect across Europe from the Danube to the Strait of Gibraltar in order to link the Spanish and German inheritance of Charles V. In destroying the autonomy of Italian politics, the invasions also ended the Italian state system, which was absorbed into the larger European system that now took shape. Its members adopted the balance of power diplomacy first evolved by the Italians as well as the Italian practice of using resident ambassadors who combined diplomacy with the gathering of intelligence by fair means or foul. In the art of war, also, the Italians were the schoolmasters of Europe, with their innovations in the use of mercenary troops, cannonry, bastioned fortresses, and field fortification. French artillery was already the best in Europe by 1494, whereas the Spaniards developed the *tercio,* an infantry unit that combined the most effective field fortifications and weaponry of the Italians and Swiss.

Thus, old and new ways were fused in the bloody crucible of the Italian Wars. Rulers who lived by medieval codes of chivalry adopted Renaissance techniques of diplomacy and warfare to satisfy their lust for glory and dynastic power. Even the lure of Italy was an old obsession; only the size and vigour of the 16th-century expeditions were new. Rulers were now able to command vast quantities of men and resources because they were becoming masters of their own domains. The nature and degree of this mastery varied according to local circumstances; but all over Europe the New Monarchs, as they are called, were reasserting kingship as the dominant form of political leadership after a long period of floundering and uncertainty.

By the end of the 15th century the Valois kings of France had expelled the English from all their soil except for the port of Calais, concluding the Hundred Years' War (1453); had incorporated the fertile lands of the duchy of Burgundy to the east and of Brittany to the north; and had extended the French kingdom from the Atlantic and the English Channel to the Pyrenees and the Rhine. To rule this vast territory they created a professional machinery of state, converting wartime taxing privileges into permanent prerogative, freeing their royal council from supervision by the States General, appointing a host of officials who crisscrossed the kingdom in the service of the crown, and establishing their right to appoint and tax the French clergy. They did not achieve anything like complete centralization; but in 1576 Jean Bodin was able to write, in his *Six Books of the Commonweal,* that the king of France had absolute sovereignty because he alone in the kingdom had the power to give law unto all of his subjects in general and to every one of them in particular.

Absolute sovereignty

Bodin might also have made his case by citing the example of another impressive autocrat of his time, Philip II of Spain. Though descended from warrior kings, Philip spent his days at his writing desk poring over dispatches from his governors in the Low Countries, Sicily, Naples, Milan, Peru, Mexico, and the Philippines and drafting his orders to them in letters signed "I the King." The founding of this mighty empire went back more than a century to 1469, when Ferdinand II of Aragon and Isabella of Castile brought two great Hispanic kingdoms together under a single dynasty. Castile, an arid land of sheepherders, great landowning churchmen, and crusading knights, and Aragon, with its Catalan miners and its strong ties to Mediterranean Europe, made uneasy partners; but a series of rapid and energetic actions forced the process of national consolidation and catapulted the new nation into a position of world prominence for which it was poorly prepared. Within the last decade of the 15th century the Spaniards took the kingdom of Navarre in the north; stormed the last Muslim stronghold in Spain, the kingdom of Granada; and launched a campaign of religious unification by pressing tens of thousands of Muslims and Jews to choose between Baptism and expulsion, at the same time establishing a new Inquisition under royal control. They also sent Columbus on voyages of discovery to the Western Hemisphere, thereby opening a new frontier just as the domestic frontier of Reconquest was closing. Finally, the crown linked its destinies with the Habsburgs by a double marriage, thus projecting Spain into the heart of European politics. In the following decades Castilian *hidalgos* (lower nobles), whose fathers had crusaded against the Moors in Spain, streamed across the Atlantic to make their fortunes out of the land and sweat of the American Indians, while others marched in the armies and sailed in the ships of their king, Charles I, who, as Charles V, was elected Holy Roman emperor in 1519 at the age of 19. In this youth the vast dual inheritance of the Spanish and Habsburg empires came together. The grandson of Ferdinand and Isabella on his mother's side and of the emperor Maximilian I on his father's, Charles was duke of Burgundy, head of five Austrian dukedoms (which he ceded to his brother), king of Naples, Sicily, and Sardinia, and claimant to the duchy of Milan as well as king of Aragon and Castile and German king and emperor. To administer this enormous legacy, he presided over an ever-increasing bureaucracy of viceroys, governors, judges, military captains, and an army of clerks. The New World lands were governed by a separate Council of the Indies after 1524, which, like Charles' other royal councils, combined judicial, legislative, military, and fiscal functions.

The empire under Charles V

The yield in American treasure was enormous, especially after the opening of the silver mines of Mexico and what is now Bolivia halfway through the 16th century. The crown skimmed off a lion's share—usually a fifth—which it paid out immediately to its creditors because everything Charles could raise by taxing or borrowing was sucked up by his wars against the French in Italy and Burgundy, the Protestant princes in Germany, the Turks on the Austrian border, and the Barbary pirates in the Mediterranean. By 1555 both Charles and his credit were exhausted, and he began to relinquish his titles—Spain and the Netherlands to his son Philip, Germany and the imperial title to his brother Ferdinand I. American silver did little for Spain except to pay the wages of soldiers and sailors; the goods and services that kept the Spanish armies in the field and the ships afloat were largely supplied by foreigners,

who reaped the profits. But for the rest of the century Spain continued to dazzle the world, and few could see the chinks in the armour; for this was an age of kings, in which bold deeds, not balance sheets, made history.

The growth of centralized monarchy claiming absolute sovereignty over its subjects may be observed in other places, from the England of Henry VIII on the extreme west of Europe to the Muscovite kingdom of Ivan III the Great on its eastern edge, for the New Monarchy was one aspect of a more general phenomenon—a great recovery of energy that surged through Europe in the 15th century. No single cause can be adduced to explain it. Some historians believe it was simply the upturn in the natural cycle of growth: the great medieval population boom had overextended Europe's productive capacities; the depression of the 14th and early 15th centuries had corrected this condition through famines and epidemics, leading to depopulation; now the cycle of growth was beginning again.

The effects of increased food production and new technology

Once more, growing numbers of people, burgeoning cities, and ambitious governments were demanding food, goods, and services—a demand that was met by both old and new methods of production. In agriculture, the shift toward commercial crops such as wool and grains, the investment of capital, and the emancipation of servile labour completed the transformation of the manorial system already in decline. (In eastern Europe, however, the formerly free peasantry was now forced into serfdom by an alliance between the monarchy and the landed gentry, as huge agrarian estates were formed to raise grain for an expanding Western market.) Manufacturing boomed, especially of those goods used in the outfitting of armies and fleets—cloth, armour, weapons, and ships. New mining and metalworking technology made possible the profitable exploitation of the rich iron, copper, gold, and silver deposits of central Germany, Hungary, and Austria, affording the opportunity for large-scale investment of capital.

One index of Europe's recovery is the spectacular growth of certain cities. Antwerp, for example, more than doubled its population in the second half of the 15th century and doubled it again by 1560. Under Habsburg patronage Antwerp became the chief European entrepôt for English cloth, the hub of an international banking network and the principal Western market for German copper and silver, Portuguese spices, and Italian alum. By 1500 the Antwerp Bourse was the central money market for much of Europe. Other cities profited from their special circumstances, too: Lisbon as the home port for the Portuguese maritime empire; Seville, the Spaniards' gateway to the New World; London, the capital of the Tudors and gathering point for England's clothmaking and banking activity; Lyons, favoured by the French kings as a market centre and capital of the silk industry; Augsburg, the principal north-south trade route in Germany and the home city of the Fugger merchant-bankers.

Northern Humanists. Cities were also markets for culture. The resumption of urban growth in the second half of the 15th century coincided with the diffusion of Renaissance ideas and educational values. Humanism offered linguistic and rhetorical skills that were becoming indispensable for nobles and commoners seeking careers in diplomacy and government administration, while the Renaissance ideal of the perfect gentleman was a cultural style that had great appeal in this age of growing courtly refinement. At first those who wanted a Humanist education had to go to Italy, and many foreign names appear on the rosters of the Italian universities. By the end of the century, however, such northern cities as London, Paris, Antwerp, and Augsburg were becoming Humanist centres in their own right. The development of printing, by making books cheaper and more plentiful, also quickened the diffusion of Humanism.

A textbook convention, heavily armoured against truth by constant reiteration, states that northern Humanism—*i.e.,* Humanism outside Italy—was essentially Christian in spirit and purpose, in contrast to the essentially secular nature of Italian Humanism. In fact, however, the program of Christian Humanism had been laid out by Italian Humanists of the stamp of Lorenzo Valla, one of the founders of classical philology, who showed how the critical methods used to study the classics ought to be applied to problems of biblical exegesis and translation as well as church history. That this program only began to be carried out in the 16th century, particularly in the countries of northern Europe (and Spain), is a matter of chronology rather than of geography. In the 15th century the necessary skills, particularly the knowledge of Greek, were possessed by a few scholars; a century later, Greek was a regular part of the Humanist curriculum, and Hebrew was becoming much better known, particularly after Johannes Reuchlin published his Hebrew grammar in 1506. Here, too, printing was a crucial factor, for it made available a host of lexicographical and grammatical handbooks and allowed the establishment of normative biblical texts and the comparison of different versions of the Bible.

Christian Humanism

Christian Humanism was more than a program of scholarship, however; it was fundamentally a conception of the Christian life that was grounded in the rhetorical, historical, and ethical orientation of Humanism itself. That it came to the fore in the early 16th century was the result of a variety of factors, including the spiritual stresses of rapid social change and the inability of the ecclesiastical establishment to cope with the religious needs of an increasingly literate and self-confident laity. By restoring the gospel to the centre of Christian piety, the Humanists believed they were better serving the needs of ordinary people. They attacked Scholastic theology as an arid intellectualization of simple faith, and they deplored the tendency of religion to become a ritual practiced vicariously through a priest. They also despised the whole late-medieval apparatus of relic mongering, hagiology, indulgences, and image worship, and they ridiculed it in their writings, sometimes with devastating effect. According to the Christian Humanists, the fundamental law of Christianity was the law of love as revealed by Jesus Christ in the Gospel. Love, peace, and simplicity should be the aims of the good Christian and the life of Christ his perfect model. The chief spokesman for this point of view was Desiderius Erasmus, the most influential Humanist of his day. Erasmus and his colleagues were uninterested in dogmatic differences and were early champions of religious toleration. In this they were not in tune with the changing times, for the outbreak of the Reformation polarized European society along confessional lines, with the paradoxical result that the Christian Humanists, who had done so much to lay the groundwork for religious reform, ended by being suspect on both sides—by the Catholics as subversives who (as it was said of Erasmus) had "laid the egg that Luther hatched," and by the Protestants as hypocrites who had abandoned the cause of reformation out of cowardice or ambition. Toleration belonged to the future, after the killing in the name of Christ sickened and passions had cooled.

Christian mystics. The quickening of the religious impulse that gave rise to Christian Humanism was also manifested in a variety of forms of religious devotion among the laity, including mysticism. In the 14th century a wave of mystical ardour seemed to course down the valley of the Rhine, enveloping men and women in the rapture of intense, direct experience of the divine Spirit. It centred in the houses of the Dominican order, where friars and sisters practiced the mystical way of their great teacher, Meister Eckehart. This wave of Rhenish mysticism radiated beyond convent walls to the marketplaces and hearths of the laity. Eckehart had the gift of making his abstruse doctrines understandable to a wider public than was usual for mystics; moreover, he was fortunate in having some disciples of a genius almost equal to his own—the great preacher of practical piety, Johann Tauler, and Heinrich Suso, whose devotional books, such as *The Little Book of Truth* and *The Little Book of Eternal Wisdom,* reached eager lay readers hungry for spiritual consolation and religious excitement. Some found it by joining the Dominicans; others, remaining in the everyday world, joined with like-spirited brothers and sisters in groups known collectively as the Friends of God, where they practiced methodical contemplation, or, as it was widely known, mental prayer. Probably few reached, or even hoped to reach, the ecstasy of mystical union, which was limited to those with the appropriate psychological or spiritual gifts.

Spread of mysticism

Out of these circles came the anonymous *German Theology,* from which Luther was to say that he had learned more about man and God than from any book except the Bible and the writings of St. Augustine.

In the Netherlands the mystical impulse awakened chiefly under the stimulus of another great teacher, Gerhard Groote. Not a monk nor even a priest, Groote gave the mystical movement a different direction by teaching that true spiritual communion must be combined with moral action, for this was the whole lesson of the Gospel. At his death a group of followers formed the Brethren of the Common Life. These were laymen and laywomen, married and single, earning their livings in the world but united by a simple rule that required them to pool their earnings and devote themselves to spiritual works, teaching, and charity. Houses of Brothers and Sisters of the Common Life spread through the cities and towns of the Netherlands and Germany, and a monastic counterpart was founded in the order of Canons Regular of St. Augustine, known as the Windesheim Congregation, which, in the second half of the 15th century numbered some 82 priories. The Brethren were particularly successful as schoolmasters, combining some of the new linguistic methods of the Humanists with a strong emphasis upon Bible study. Among the generations of children who absorbed the New Piety (*devotio moderna*) in their schools were Erasmus, and, briefly, Luther. In the ambience of the *devotio moderna* appeared one of the most influential books of piety ever written, *The Imitation of Christ,* attributed to Thomas à Kempis, a monk of the Windesheim Congregation.

One man whose life was changed by *The Imitation* was the 16th-century Spaniard Ignatius Loyola. After reading it Loyola founded the Society of Jesus, and wrote his own book of methodical prayer, *Spiritual Exercises.* Thus, Spanish piety was in some ways connected with that of the Netherlands; but the extraordinary outburst of mystical and contemplative activity in 16th-century Spain was mainly an expression of the intense religious exaltation of the Spanish people themselves as they confronted the tasks of reform, Counter-Reformation, and world leadership. Spanish mysticism belies the usual picture of the mystic as a withdrawn contemplative, with his or her head literally in the clouds. Not only Loyola but also St. Teresa of Avila and her disciple, St. John of the Cross, were tough, activist Reformers who regarded their mystical experiences as means of fortifying themselves for their practical tasks. They were also prolific writers who could communicate their experiences and analyze them for the benefit of others. This is especially true of St. John of the Cross, whose mystical poetry is one of the glories of Spanish literature.

The growth of vernacular literature. In literature, medieval forms continued to dominate the artistic imagination throughout the 15th century. Besides the vast devotional literature of the period—the books on *The Art of Dying Well,* the saints' lives, and manuals of methodical prayer and spiritual consolation—the most popular reading of noble and burgher alike was the 13th-century love allegory, the *Roman de le rose.* Despite a promising start in the late Middle Ages, literary creativity suffered from the domination of Latin as the language of "serious" expression, with the result that if the vernacular attracted writers, they tended to overload it with Latinisms and artificially applied rhetorical forms. This was the case with the so-called *grande rhetoriqueurs* of Burgundy and France. One exception is 14th-century England, where a national literature made a brilliant showing in the works of William Langland, John Gower, and, above all, Geoffrey Chaucer; but the troubled 15th century produced only feeble imitations. Another exception is the vigorous tradition of chronicle writing in French, distinguished by such eminently readable works as the chronicle of Jean Froissart and the memoirs of Philippe de Commynes. In France, too, around the middle of the 15th century there lived the vagabond François Villon, a great poet about whom next to nothing is known. In Germany *The Ship of Fools,* by Sebastian Brant, was a lone masterpiece.

The 16th century saw a true renaissance of national literatures. In Protestant countries the Reformation had an enormous impact upon the quantity and quality of literary output. If Luther's rebellion destroyed the chances of unifying the nation politically, his translation of the Bible into German created a national language. Biblical translations, vernacular liturgies, hymns, and sacred drama had analogous effects elsewhere. For Catholics, especially in Spain, the Reformation was a time of deep religious emotion expressed in art and literature. On all sides of the religious controversy, chroniclers and historians writing in the vernacular were recording their versions for posterity. Renaissance of national literatures

While the Reformation was providing a subject matter, the Italian Renaissance was providing literary methods and models. The Petrarchan sonnet inspired French, English, and Spanish poets, while the Renaissance Neoclassical drama finally began to end the reign of the medieval mystery play. Ultimately, of course, the works of real genius were the result of a crossing of native traditions and new forms. The Frenchman François Rabelais assimilated all the themes of his day—and mocked them all—in his story of the giants Gargantua and Pantagruel. The Spaniard Miguel de Cervantes, in *Don Quixote,* drew a composite portrait of his countrymen, which caught their exact mixture of idealism and realism. In England, Christopher Marlowe and William Shakespeare used Renaissance drama to probe the deeper levels of their countrymen's character and experiences.

Renaissance science and technology. To the medieval mind, matter was composed of four elements—earth, air, fire, and water—whose combinations and permutations made up the world of visible objects. The cosmos was a series of concentric spheres in motion, the farther ones carrying the stars around in their daily courses; and at the centre of all was the globe of Earth, heavy and static. Motion was either perfectly circular, as in the heavens, or irregular and naturally downward, as on the Earth. The Earth was made up of three landmasses—Europe, Asia, and Africa—and was unknown and uninhabitable in its southern zones. Man, the object of all creation, was composed of four humours—black and yellow bile, phlegm, and blood—and his personality and health were determined by the relative proportions he had of each. The cosmos was alive with a common consciousness, and the stars influenced the course of events as well as the fortunes of men (although the church frowned on this denial of free will). Man might influence the spirits in nature through magic—black for demons, white for the benevolent spirits—although the church preferred that the Christian seek his well-being through faith, the sacraments, and the intercession of Mary and the saints.

These views were an amalgam of Aristotelian physics, Galenic medicine, Ptolemaic astronomy, and Christian theology. Together they ruled man's understanding and directed his experience of phenomena, until they all were overthrown and replaced by the new mechanistic conceptions of Copernicus, William Harvey, Galileo, and Isaac Newton. Only the first of these great scientists was born in the period discussed here as the Renaissance; the Scientific Revolution was largely the achievement of the 17th century. The persistence of the medieval model of the cosmos through the Renaissance ought not, however, to obscure the period's real contributions. Humanist scholarship provided both originals and translations of ancient Greek scientific works—which enormously increased the fund of knowledge in physics, astronomy, medicine, botany, and other disciplines—and presented as well alternative theories to those of Ptolemy and Aristotle. Thus, the revival of ancient science brought heliocentric astronomy to the fore again after almost two millennia. Renaissance philosophers, most notably Jacopo Zabarella, analyzed and formulated the rules of the deductive and inductive methods by which scientists worked, while certain ancient philosophies enriched the ways in which scientists conceived of phenomena. Pythagoreanism, for example, conveyed a vision of a harmonious geometric universe that helped form the mind of Copernicus. New concepts of natural phenomena

In mathematics the Renaissance made its greatest contribution to the rise of modern science. Humanists included arithmetic and geometry in the liberal arts curriculum; artists furthered the geometrization of space in their work on perspective; Leonardo da Vinci perceived, however

faintly, that the world was ruled by "number." The interest in algebra in the Renaissance universities, according to the 20th-century historian of science George Sarton, "was creating a kind of fever." It produced some mathematical theorists of the first rank, including Niccolò Tartaglia and Girolamo Cardano. If they had done nothing else, Renaissance scholars would have made a great contribution to mathematics by translating and publishing, in 1544, some previously unknown works of Archimedes, perhaps the most important of the ancients in this field.

If the Renaissance role in the rise of modern science was more of midwife than of parent, in the more practical realm of technology the proper image is the Renaissance magus, manipulator of the hidden forces of nature. Working within the confines of the medieval world view, engineers and technicans of the 15th and 16th centuries achieved remarkable results, which in some ways had more to do with changing the social environment than the theories of pure science. The most important technological advance of all, because it underlay progress in so many other fields, strictly speaking had little to do with nature at all. This was the development of printing, with movable metal type, around the mid-15th century in Germany. Johann Gutenberg is usually called its inventor, but in fact many people and many steps were involved. Block printing on wood came to the West from China between 1250 and 1350, papermaking also came from China by way of the Arabs in 12th-century Spain, whereas the Flemish technique of oil painting was the origin of the new printers' ink. Three men of Mainz—Gutenberg and his contemporaries Johann Fust and Peter Schöffer—seen to have taken the final steps, casting metal type and locking it into a wooden press. The invention spread like the wind, reaching Italy by 1467, Hungary and Poland in the 1470s, and Scandinavia by 1483. By 1500 the presses of Europe had produced some 6,000,000 books. Without the printing press it is impossible to conceive that the Reformation would have ever been more than a monkish quarrel or that the Scientific Revolution, which was a cooperative effort of an international community, would have occurred at all. In short, the development of printing amounted to a communications revolution of the order of the invention of writing; and like that prehistoric discovery it transformed the conditions of life. (D.We./Ed.)

Development of printing

The great age of monarchy, 1648–1789

CHRONOLOGY OF THE AGE OF MONARCHY

By the Peace of Westphalia in 1648 Calvinism had been accepted under the terms by which Lutheranism had earlier obtained recognition in the Peace of Augsburg (1555). Germany was to remain a mosaic of petty states, each with its established religion in conformity with that of its ruler. The independence of the Swiss cantons and the United Provinces had been confirmed.

It is symbolic of a new period in European history that no ruler, whether Catholic or Protestant, paid heed to the Pope's denunciation of the Peace of Westphalia. Though political upheavals continued after 1648, the modern sovereign state had emerged as the continent's most powerful institution, with little room for rivals or rebels.

Control of the state. The growth of the state had been inextricably bound up with the problem of who controlled it. Deeply rooted in European history was the principle of the contractual nature of the royal power. The need to secure consent to important actions and, concurrently, the need to get help with administrative work resulted in a blanketing of Europe with political assemblies at all levels. But the challenge to royal ambitions represented by these assemblies had caused princes to set out to reduce or destroy them, and by the mid-17th century only England and the Netherlands showed effective resistance to the symptoms of decay.

Dutch burghers and English gentlemen could not set the pattern for the 17th century. One of the first victims of the Thirty Years' War had been the estates assembly of Bohemia, which had supposed that it had the power to depose and elect kings without consulting the Habsburgs. Soon afterward in Denmark-Norway the king brushed aside his quarrelling estates and set up rigorous absolutism. At the same time the princes of Germany took up the offensive, and by the end of the century only five had failed to shake their assemblies.

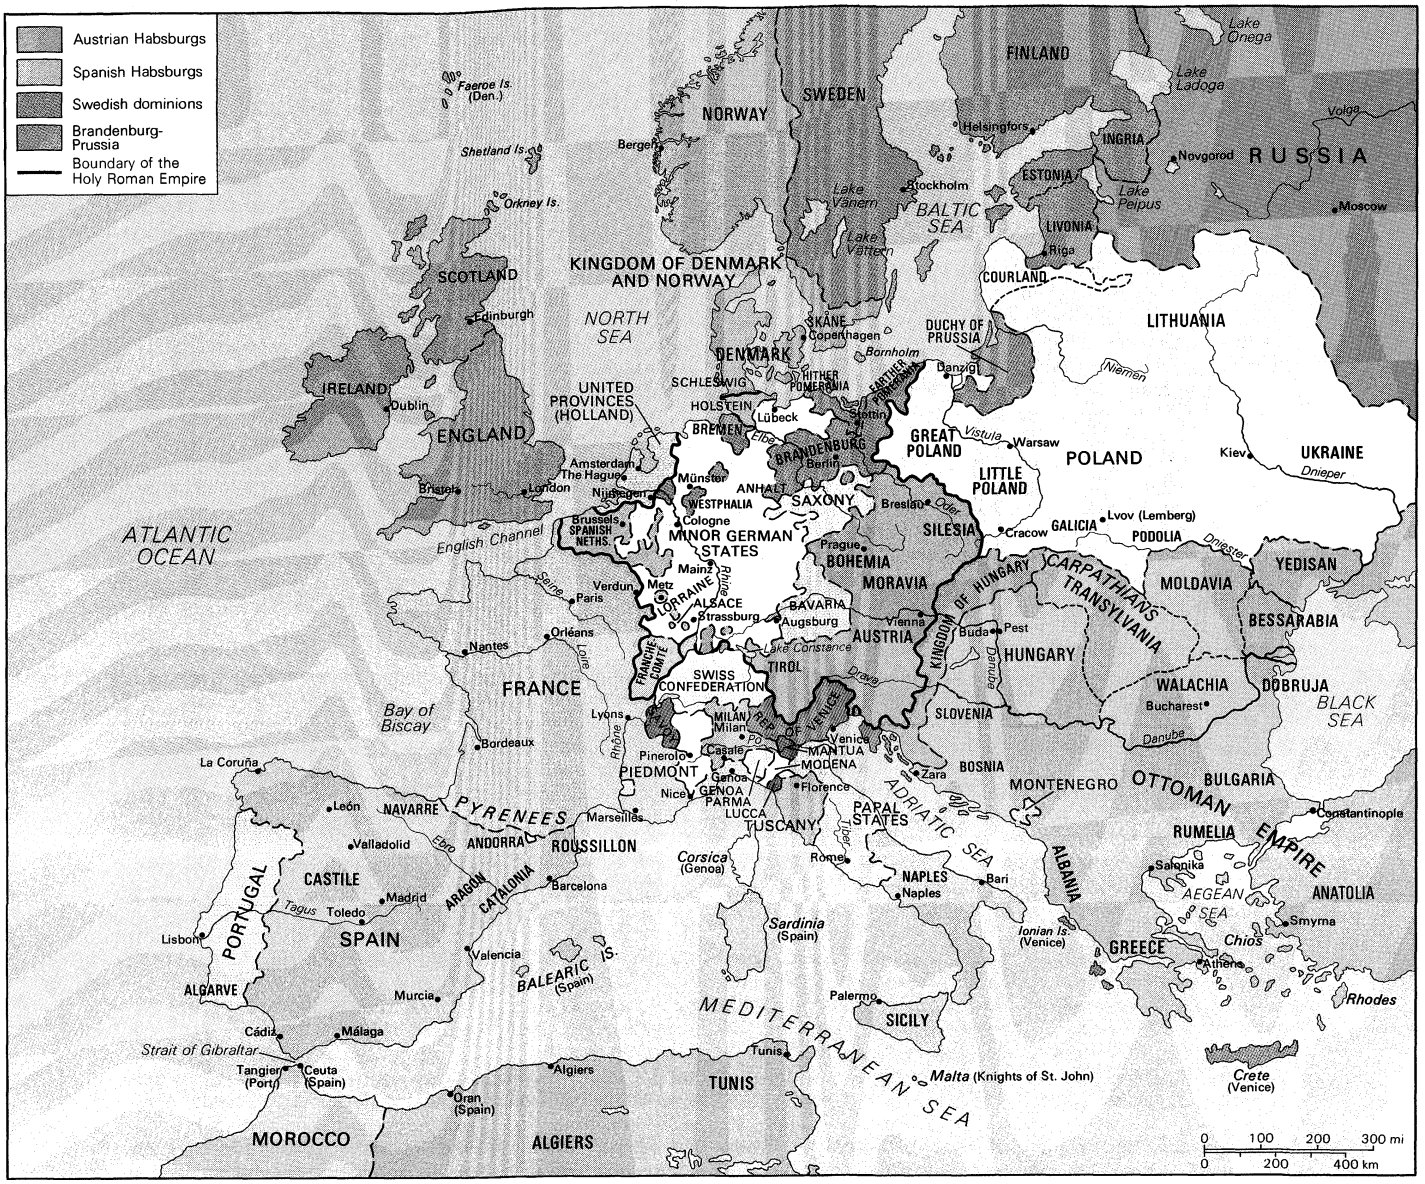
In the 18th century the estate assemblies continued their downward course. In the three continental lands where they maintained their power, they proved to be disastrously incompetent. In the Netherlands, declining economically, the parochial-minded assemblies fought the leadership of the House of Orange, and the country was headed for a revolution of its own when it was overwhelmed by that of France. Sweden, in turn, had been undoubtedly the most advanced state of Europe, but the death of Gustav II Adolf (1632) opened the door to domestic as well as international troubles. Social quarrels led in 1680 to a virtual absolutism, but the events of Charles XII's reign returned dominant power in 1719 to the Riksdag (parliament). Continuing social tensions, however, were reflected in quarrels within parliament which opened the door for French and Russian competitive corruption, and the country was saved from disintegration only by a royal coup d'état in 1772. The estates of Poland, meanwhile, had brought themselves to the point where a last-minute rescue was impossible. By the 18th century the nobles' zeal for golden liberty had reached the absurdity of the liberum veto; one dissident voice could not only block a legislative act but also "explode" the assembly. Surrounded by three hungry and militarily strong neighbours, the Polish nobles by their corruption and their divisions invited the disaster of the partitions from 1772 to 1795.

The decline of assemblies representative of estates was counter-balanced by the rise of absolute monarchy. This shift had not come about simply by default of the estates; a vital part of the story was a millennium of dynamic energy that Europe's crowned heads had thrown into the struggle for power, of which Louis XIV was the brilliant embodiment. Not very intelligent, he had, nonetheless, the talent to make his people confuse God's rule and that of the king of France. In his thirst for glory, he made his whole life a ritual of Byzantine majesty. He was a master builder whose works reflected his grandeur; he patronized the arts; he tamed disorders in his own land; and he sent his armies abroad. The lesser sovereigns found in him their model. They learned French; they copied, as far as their incomes allowed, the buildings and the manners of Versailles; and, above all, they laboured to imitate Louis's climactic achievement, his despotism.

Louis XIV

Machinery of the state. Being an absolute monarch required more than postures and parades. Success largely depended on the nature and the quality of governmental machinery. The tendency of 17th-century Europe was to assign the major tasks of government to councils or commissions. In Sweden a reorganization in 1632 had set up five ministerial colleges that were so effective that they became the model for eastern Europe and notably for Peter the Great in his efforts to reform Russia. In Spain a multiplicity of councils had stemmed from the formative days of the monarchy, and in France Richelieu adopted the Spanish style as a means of allowing his subordinates to restrain each other. Louis XIV, heir to this calculated confusion, did much of his royal business in five separate bodies. Likewise in England, both before and after the Stuart Restoration of 1660, boards and commissions were the favoured agencies. Such machinery, evolving in response to the growth of the state's business, was cumbersome, often overlapping, and prone to paralysis. As a means for coping with the resultant difficulties, the late 17th century and the 18th turned increasingly to a single minister or secretary of state. Reform not infrequently turned out to be merely an exchange of one confusion for another.

The state's supreme domestic problem was to provide a coherent direction for this inefficient machinery. The English had found an effective answer: policy formulation came from a group, or cabinet, composed of men who individually managed the great departments. The rising importance of political parties tended to bring like-minded men to office, and when George I (1714–27) absented himself from Cabinet meetings active leadership fell to a prime minister.



Europe in 1648.

In France Richelieu and Mazarin had served as over-all directing ministers, but Louis XIV found such an office incompatible with his majesty and after the death of Mazarin no one took his place. This jealousy of powerful ministers meant that the king alone not only decided policy but also carried the burdens of a chief coordinating administrator. In this respect also, Louis XIV set the precedent for the 18th century. Occasionally there was a chief minister in some capital, but the despotic temper of royalty disliked the expedient. For the same reason, royal councils as well as guiding ministers went into decline. Various attempts continued to be made in the 18th century to coordinate central functions, but royal impatience blocked the way to success. Accordingly, as continental governments faced ever-mounting obligations, the sovereign had no escape from the role of first servant of the state. In England it came to be of relatively little importance who wore the crown, but on the continent the prosperity of a country depended almost entirely on the personal qualities of the monarch.

Provincial government. Out of special circumstances federalism became established in the two republics that gained their formal independence in 1648, Switzerland and the Netherlands. Elsewhere in Europe the drive had been toward the unitary state, with immediate control from the centre. The difficulties had been enormous, because the great states of Europe were synthetic creations pulled together out of diverse territories whose institutions the king was generally bound to respect.

The English arrived least painfully at a solution. The crucial achievement of medieval English kings had been the supremacy of the law. This enabled the central government to leave local administration to the justices of the peace and the town councils. On the continent local legal variations had been too strongly embedded, and some other means was necessary for achieving unity. That means was the dispatch from the capital of a corps of loyal agents. Sweden could do this as early as the 16th century because of the small influence of feudalism in that country. Ferdinand and Isabella began in Spain by establishing their own corregidores in the municipalities, but traditional divisions of the joint monarchy made for slow progress. In France the procedure developed over centuries. The first intendants to go out from Paris were merely reporters; Henry IV and Richelieu used them as temporary agents for dealing with emergencies, and it was not until Louis XIV's reign that they became institutionalized as permanent officials superimposed upon, and therefore handicapped by, the old provinicial governments.

While Louis XIV was installing his intendants, the Great Elector of Brandenburg-Prussia began to send out war commissioners, at first to receive tax payments but soon to settle down as local officials. A second bureaucratic machine had been set up to administer the elector's patri-

monial lands, and in 1723 both were combined under one central Directorium. The directory itself was cumbersome and inefficient, but its civil service, the best in Europe, took the royal will throughout the kingdom.

In the Habsburg dominions peculiarly formidable barriers stood in the way of a centrally controlled provincial administration because of the unassimilated diversity of titles and crowns. When Maria Theresa (1740–80) undertook the creation of a comprehensive central government, she also began to move against the confusion of provincial immunities. Fairly successfully she introduced district captains as immediate agents of Vienna into the western part of her inheritance, but she hesitated to send them into Hungary, where high sheriffs drawn from the local nobility administered the counties. Her son Joseph II had no patience with such softness and sent in his German-speaking bureaucrats—to the lasting misfortune of central Europe. In these Habsburg lands above all others, some accommodation of local differences was essential, but the spirit of 18th-century despotism demanded a rational uniformity.

Maria Theresa

Government officials. In the early labours of statemaking and administration, the medieval kings had had to depend for aid on the nobility and the clergy, neither of which was single-mindedly devoted to the royal interests. With the development of urban life there had appeared as competitors of the higher orders for governmental posts members of the bourgeoisie who could offer unqualified loyalty and technical skills in law and finance. Louis XIV, who never forgot the Fronde, the nobles' revolt of his childhood, and who was jealous of any light that was not a reflection of his own, went to the extreme of closing the doors of his councils to the French grandees and transacted the state's business with "vile bourgeois." In turn the intendants carried to their offices in the provinces the same nonnoble stamp. But even Louis could not deny the spirit of the times altogether; and, following precedent, he sold to his bourgeois officials their positions and titles of nobility. This created a second aristocracy, known as the nobility of the robe because of the gown of office. The old nobility of the sword greeted the robe with a disdain that was fully reciprocated. Before the middle of the 18th century the two nobilities were uniting to oppose the remnants of Louis XIV's bourgeois policy. Increasingly arrogant about the importance of ancestors, they harried the king into giving them a virtual monopoly of the important state posts.

Louis XIV's antinoble prejudice had run aground on the stronger prejudice that nobles were the only fit companions of a king. The simplest means of meeting it was to elevate commoners as they rose in the hierarchy, and this practice became universal. In a number of countries the scale of title-making was such as to constitute, as in France, a new aristocracy. Ivan IV the Terrible had raised up a second Russian nobility committed to state obligations, but the two groups amalgamated; and Peter I the Great shortly after 1700 had the task to do over again. He attempted it in substantially the same spirit; the public servant received a status in the hierarchy of nobility in accord with his grade in the state service.

The role of the nobility

High state office, therefore, was an almost exclusive prerogative of the nobles old and new, except in England. The nobles' attitude toward their right varied from country to country. For the English gentleman public activity was a matter of personal sense of duty. The Prussian nobles, happy in their new alliance, served their king with military devotion. The Russians, resentful of service, wheedled the foolish Peter III into releasing them. The Poles constituted a special anarchistic group, and the Hungarians were potential rebels against Habsburg encroachments. The French nobility was moving into a dissident role before the death of Louis XV (1774). Through the Parlement of Paris, the chief law court, it was beginning to challenge the king's despotism.

Internal functions of the state. The growth of governmental machinery reflected the ever-broadening functions of the state. The intensified search for money led to the invasion of provincial and local government and to the endless work of tax-collecting. The maintenance of a properly majestic establishment for royalty was a state duty; though the scale varied, the style of life led to mounting extravagance in almost every land. Yet such expenditures were not to be compared to the outlays for military purposes. One of the most portentous innovations was the nationalization of the European army. By the end of the Thiry Years' War the change from older forms of organization was well advanced and the state was becoming the great consumer of the goods as well as the services and the blood of its subjects.

The oldest state functions had stemmed from the concept of the king as the fountain of justice. Concurrently with the building of a royal court system, the bitter issue of the competence of the king's courts as against traditional noble and church jurisdictions had been fought. By 1648 the major contest had been settled, although important fragments of the old order remained. Over much of Europe the nobles maintained manorial courts in which they administered justice to their peasants and serfs. The church had lost its vast legal competence but continued to bring into its own tribunals religious cases, defined more broadly than a later time would allow.

The tide continued to favour the state in its contest with the church. In Lutheran countries the state churches of the Reformation lived on without political crises. By an implied contract the princes looked after the administration, and the ministers preached submission to God and to his divinely ordained regents on earth. In England the established church was yet more clearly the creature of the state in that even its creed was a product of parliamentary legislation. Temporarily broken during the Commonwealth, restored under Charles II, and then seriously menaced by the Roman Catholic James II, Anglicanism was saved by the Glorious Revolution of 1688, and it gratefully put itself at the service of the new order. During their ascendancy in the 18th century the Whigs took over the church as well as the state, and the bishops in the House of Lords dutifully supported the government.

In Russia the outcome was even more devastating for the authority and the moral position of the church. With a patriarchate of its own after 1589, Russian Christianity had tried, in the face of state encroachments, to argue for dual, independent spiritual and secular realms. An old tension came to the breaking point when the patriarch Nikon, elevated in 1652, introduced modifications in ritual for political ends. The government's quarrels were not with the reforms but with Nikon's arrogance, and the Tsar dismissed him. The church was split, but neither branch was prepared to accept the Westernizing infamies of Peter I the Great. He responded to opposition by abolishing the patriarchate in 1721 and by putting the church under a Holy Synod. Soon a lay procurator became the president of the synod and the controversy was resolved for the life of the tsarist regime: the Russian church was little more than the spiritual arm of the secular order.

The Russian patriarchate

In Roman Catholic territories the state, of course, had to reckon with a powerful international organization. The papacy, shaken by the Reformation to its foundations, had been able to restore and even strengthen its position. A proud pope and a Louis XIV believing in divine right were bound to collide. Louis's extension to the whole kingdom of his right to control the affairs of vacant bishoprics precipitated a new chapter of the conflict. In 1682 an assembly of the French clergy, prodded by Louis, stated in four points the so-called ancient liberties of the Gallican Church and reasserted the principle of the subordination of the papacy to a general council. The Pope again protested vigorously, and Louis threatened to set up an autonomous national church. For 10 years relations between Rome and Versailles were suspended. At last, however, Louis's embroilment in war led him to the motions of capitulating to a new pope. The controversy involved no suspicion of heresy; at its height Louis repealed Henry IV's edict of toleration of Protestants.

Louis's zealous orthodoxy confused and then transformed the whole church-state issue in France. He was so hostile to the doctrines of Jansenism that he appealed to the Pope for support against a vigorous segment of his own subjects. Papal bulls of condemnation inspired an alliance of

Jansenists and nationalist Gallicans, and their resistance to combined royal and papal pressures stirred a discord that lasted until the eve of the French Revolution and that did great damage to the spiritual force of official Catholicism. Anticlericalism and Deism were the end products.

While France's religious problem was taking this special turn, in the other Catholic countries the debate remained centred on the old issue of the papacy and its powers. A stream of books attacked the allegedly swollen pretensions of Rome. The most noted of them came in 1763 from a Catholic bishop, J.N. von Hontheim, writing under the name of Justinus Febronius. Febronius would allow the pope only the first honour among equals; the church's council stood above him, and the time had come to restore the bishops to their usurped position. No less vigorously did he champion the rights of secular princes in the external affairs of the church, and he invited them to suspend obedience to Rome if the pope proved adamant. The clerical opposition within the church and a whole phalanx of Catholic rulers found in Febronius practically every known justification for their ambitions and their encroachments. In 18th-century Naples and Sardinia, in Portugal and Spain, the kings extended their powers of church nominations and other functions. During the peace negotiations in 1713 at Utrecht, the state delegations excluded the papal nuncio altogether and set a precedent for the rest of the century by ignoring Rome's claims to overlordship over various Italian territories.

Nowhere was the papacy more disappointed than in the Habsburg dominions, where, since the Reformation, the ruling family had vigorously supported Catholicism. Maria Theresa was personally dedicated to the church, but as sovereign she was sensitive to the slightest hint of papal intervention. Joseph II elevated Febronianism into Josephism. He closed monasteries, sent theological candidates to Rationalist state seminaries, and even decided matters of church ritual. Joseph II, like Louis XIV, lost the support of his people, and his brother Leopold II, succeeding him in 1790, had to salvage what he could by abandoning Joseph's excesses.

The Jesuit controversy

Meanwhile the Society of Jesus had come under disastrous fire. Some of the Jesuit doctrines and tactics had inspired criticisms within the church and even rebukes from the papacy. Certain Jesuit political teachings and activities had created ill will among secular authorities. Catastrophe began in Portugal, a country the Jesuits had dominated for a century, and it came at the hands of one of their students, the reforming Marquês de Pombal. Making use of difficulties in Paraguay and alleged complicity in an attack on the king, Pombal expelled the Jesuits from Portugal and its colonies in 1759–61 and for a decade suspended all ties with Rome. In France, Jansenism, Gallicanism, and anticlerical Rationalism united in a long-sustained attack brought to its climax by the bankruptcy of a Jesuit commercial firm. The Paris law court found the society subversive and ordered its expropriation and expulsion (1764). Three years later the Bourbon king of Spain drove out nearly 6,000 Jesuits, and shortly Naples and Parma followed suit. The Bourbon sovereigns then jointly demanded the suppression of the society, and in 1773 Pope Clement XIV, a Franciscan little disposed toward the Jesuits, acquiesced.

In addition to these concerns with the administration of the church, the state also had the traditional function of defense of correct Christian belief. The Reformation had given the rulers of Europe an opportunity to decide, each for himself, what was correct, and the starting assumption was that subject would bow to the decision of sovereign. It had been increasingly difficult, however, to impose a single form of faith. In the Low Countries a formal Edict of Toleration in 1614 arose out of very practical economic and political considerations. In England shifts of official religion from Henry VIII's break with Rome to the Glorious Revolution had strewn the land with a diversity of churches; and the Act of Toleration in 1689 simply regularized an inescapable reality. In Germany the Peace of Westphalia had allowed the princes of the Holy Roman Empire to impose on their subjects their own choice among three religions. In the regions devastated by the Thirty Years' War there was acute need for population increase, and the Great Elector of Brandenburg-Prussia was more interested in an immigrant's ability to work and pay taxes than in the minutiae of his Christian convictions. In the next century the personal indifference of Frederick II the Great gave new force to old policy; as long as the churches supported the monarchy, he was content to allow freedom of religious expression.

The Roman Catholic states lagged behind this Protestant march toward toleration. Louis XIV's economically injurious resolution in 1685 to destroy Protestantism was unrevoked for 102 years, until weariness with religious quarrels, the undermining thrusts of Rationalism, and the commanding power of secularization forced Louis XVI to restore a limited tolerance. In Austria, Maria Theresa saw in tolerance only sinful indifference; but Joseph II, who had no patience with his mother's anxieties, issued the Patent of Tolerance in 1781, which gave to non-Catholics a measure of religious freedom and an improved civil status. This caprice of his religious policy brought the Pope himself on a protest mission to Vienna, but to no avail.

The state in its external relations. The Peace of 1648 revealed in unclouded sharpness the sovereign independence of the European state. The old claimants to universal authority, the empire and the papacy, had withered into impotence, and by recognized right the state defined its own interests and decided how best to protect them.

For the conduct of peaceful international relations, mechanisms and procedures had been developing since Renaissance days in Italy. The basic institution was the foreign ministry, which emerged out of the administrative uncertainties of the major continental capitals around 1700. England lagged behind; two secretaries of state divided external affairs until 1782. But the evolution of a central agency was no guarantee of system and order. Foreign affairs always had been a jealously guarded prerogative of the crown, and policy decisions normally remained subject to those calculations and accidents that moved a king. The second instrument of diplomacy was the ambassador, by custom a man of high birth. Long experience had defined the ambassador's duties and conferred on him privileges and immunities. The charge to report significant developments gave him the aura—and the functions—of a spy, and the obligation to protect his sovereign's honour made him truculent about the honours due to himself. About 1500 the papacy had devised a strict order of precedence for all emissaries in Rome, but toward 1648 this scheme of relative merit was no longer acceptable to Europe's monarchs, filled as each was with a sense of personal majesty. Fierceness about questions of rank made it necessary to hold two peace conferences in Westphalia, and at each the delegates bickered over places in ceremonial processions and even over how far a host should accompany a retiring guest toward his carriage. Forethought and practical expedients eased some of the tensions in the 18th century, but only later times fully solved the problems in terms of the equality that proud kings had so long demanded.

Military establishment. The organization of a satisfactory military establishment proved a difficult task. The feudal system still existed, although largely on paper, in several parts of Europe until about 1700, but for centuries it had been of little value. The state groped toward a better solution when it began to create an army of its own. There were a few standing companies in France by 1500 and more in 16th-century Spain, but the senior regiments of Prussia and Austria dated from the Thirty Years' War. A fully state-owned and operated army came only slowly in the 18th century.

For the officers' corps tradition designated nobles, but sons of the bourgeoisie had moved in when the aristocrats showed incompetence in the skills of artillery and engineering and when, in some armies, commissions were sold as private property. In England this intrusion was merely disliked, but on the continent resentments grew as the lines of social exclusiveness hardened. In France the nobles in 1781 at last wheedled out of Louis XVI an edict limiting commissions to men able to prove 16 quarterings of nobility. Meanwhile they had gained another victory:

the multiplication of posts until the corps became a vast program of relief, and the higher commands had to be rotated frequently to give a semblance of duty. In Prussia the nobles also enjoyed a strong preference, but the results differed markedly from those in France. Instead of granting demoralizing sinecures, the Prussian kings demanded a total dedication to duty and paid for it by recognizing in their brothers-in-arms the foremost order of the realm. In the other European armies the prevailing aristocratic stamp suffered little damage.

The nationalized army

The common soldier came from, and lived in, another world. The nationalized army began under the theory of volunteer long-term enlistments, but very early free decision did not produce enough soldiers. Public policy disapproved of taking useful workers, and other sources had to be tapped. Enlisting foreigners proved an effective resort; their proportion in the continental armies ran at times from one-quarter to two-thirds. Within the country the preferred solution was a roundup of the economically nonproductive. Local authorities collected jailbirds and paupers and misfits, while recruiting sergeants took in by tricks, and if necessary by violence, the innocent and the unwary. The inadequacy of such devices gradually forced the state into instituting compulsory service. Sweden was an innovator in a systematically operated draft, but the more momentous step occurred in Prussia around 1730: a regularized conscription based on the principle of universal liability. A generation later Joseph II took the same course. The inclusion of peasants and artisans, however, remained a disagreeable necessity; until the French Revolution Europe preferred for its armies the local tatterdemalions and the foreign adventurers. No one had any illusions about the quality of this raw material, but ways had been devised to cope with it. The first was discipline so rigid and brutal that the soldier had to fear his officer more than the enemy. The second was drill and yet more drill until the men became cogs in a precision machine. Even so, in tactical operations little was possible beyond marching onto a field and firing volleys; any break in the ranks usually resulted in wholesale desertions.

Strategy was limited. An army was far too expensive to be thrown recklessly into battle or taken far from its base of supplies, since foraging meant decamping. Supplies, in turn, meant transport, and therefore a campaign had to close at the onset of autumn. This sense of limited objectives both in battles and campaigns meant that in the 18th century no one thought of a total defeat or of exacting severe penalties from a fallen enemy. War, whatever its dimensions, nonetheless continued after 1648 to be a ready resort of state policy. It had its critics as well as its glorifiers. In the 17th century Henry IV's great minister Sully published a project attributed to the king of a "great design" for the reconstruction of Europe and the creation of an international council to restrict warfare to Crusades against the Turks. In the generations between Sully and Immanuel Kant, men repeatedly issued their own impassioned versions of the great design for an organized peace; the dream would not die, but the reality of those generations paid it no attention.

The dream of an organized peace

Balance of power. The best device for peace and protection seemed to be the balance of power. The principle, as old as Western culture, had reappeared as conscious policy in Renaissance Italy and had moved to transalpine Europe about 1500. Its need had become apparent when the emperor Charles V inherited so many dominions on all sides of France. War resulted, and the conflict went on for so long that Franco-Habsburg hostility seemed unending and inevitable. Finally the Peace of Westphalia ended any conceivable menace to France from the German Habsburgs; and the Peace of the Pyrenees in 1659 won France some territorial advantages and a royal marriage from the Spanish. These settlements confirmed a shift in the directon of French external ambitions from Italy to the northeastern frontier.

Louis XIV began his personal rule in 1661. The threat to the balance that then appeared was of Louis's own making, and one coaliton after another rose up to resist his aggressions in the War of Devolution (1667–68), the Dutch War (1672–78), and the War of the Grand Alliance (1689–97). By the time of the Peace of Rijswijk in 1697, Louis's drive had been fairly effectively checked, but the death of Charles II in Spain in 1700 reopened the struggle. Obliged to designate an heir to his many crowns, the childless king Charles in his last days chose a grandson of Louis, his brother-in-law Philippe, duc d'Anjou. Louis's greedy response indicated the greatest upset to the balance of power since Charles V, and the widespread War of the Spanish Succession ensued.

This multiplication of battlefields was the work of England. In the 16th century imperial friction and religious animus had made Spain the great enemy; in the 17th century commercial competition had made the Dutch the prime enemy of both Oliver Cromwell and the Restoration monarchy. As Louis XIV began his depredations, he bought the support of his cousin, the English king Charles II, but on the question of France, as on so many others, Charles and his subjects drifted apart. Religious feeling, economic and colonial friction, and the French threat to the Low Countries all indicated to English opinion the emergence of a new enemy. In 1688 the Glorious Revolution placed on the throne Louis's most implacable enemy, William III of Orange, and before a year was out the new king took England into his old struggle. Thus began that Anglo-French contest that went on until Waterloo in 1815.

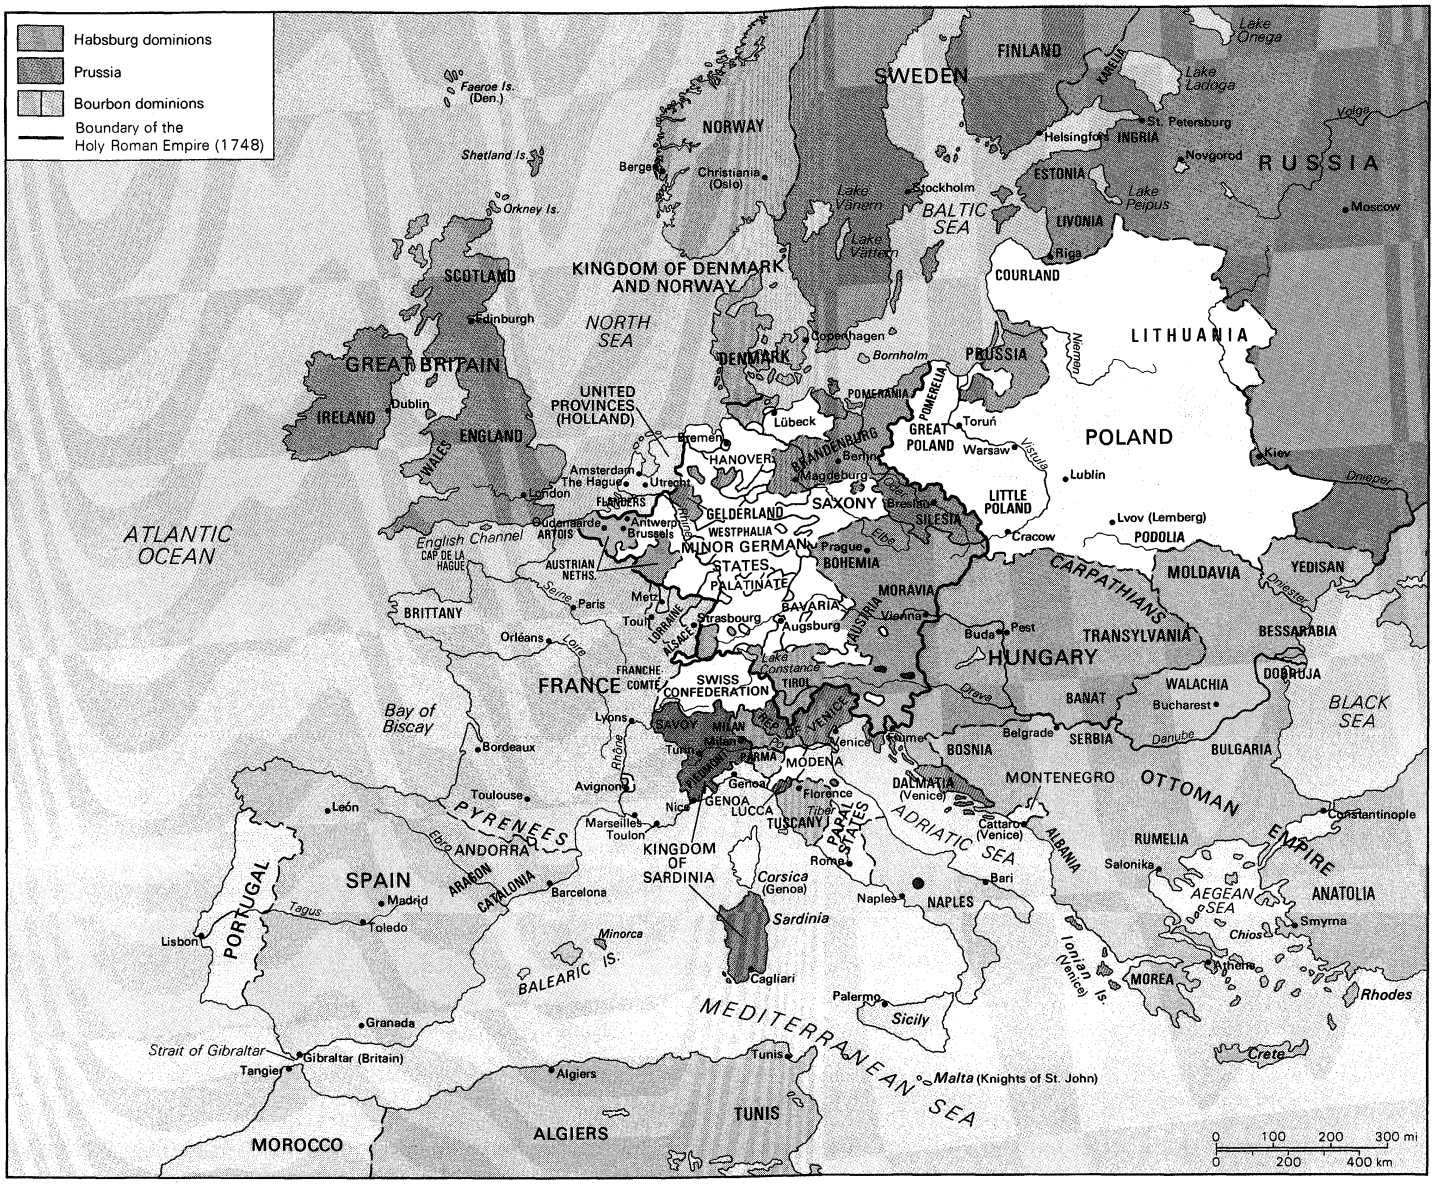
The Glorious Revolution

When exhaustion and allied cross-purposes brought the War of the Spanish Succession to an end at Utrecht in 1713, the treaties proclaimed a "just equilibrium of power." Historically conceived, as a deterrent to war, the principle of the balance as invoked at Utrecht determined the distribution of territorial compensations at the end of a war. Repeatedly thereafter until the final partition of Poland (1795) numerous crises arose from demands to restore the balance in this manner.

The Treaties of Utrecht introduced a period of cooperation between Britain and France, but unresolved imperial rivalries allowed it only a passing term. Deteriorating relations led first to the War of Jenkins' Ear between Britain and Spain in the West Indies in 1739 and shortly to world-wide conflict between Britain and France. Meanwhile Frederick II the Great of Prussia in 1740 had precipitated a second European war, the War of the Austrian Succession, by overrunning Silesia at the expense of the empress Maria Theresa. For hotheads in Paris this was an opportunity for a new attack on the Habsburgs, and soon French military successes in Germany warned of a dangerous upset to the balance of power. British interest required assistance to the empress, and the two wars intermingled. In 1748 general weariness forced the Treaty of Aix-la-Chapelle. The British had tired of the Austrian cause and Frederick kept Silesia, but otherwise the peace terms required mutual restoration of conquests. (Da.H./Ed.)

The "Diplomatic Revolution." In the years immediately following Aix-la-Chapelle, the only force that seriously threatened the peace was the studied resolution of the Austrian chancellor Wenzel Anton, Graf von Kaunitz, to win back Silesia. To be sure, an undeclared war between England and France was being fought in America (the so-called French and Indian War), but, far from desiring to have it spread to Europe, England shrank from that prospect. The English were fearful that in the event of war on the Continent either France or France's ally Prussia might overrun the Duchy of Hanover to which the English king held title and, also, perhaps occupy the Netherlands. As England's own ally, Austria, could not give adequate assurances of military aid, England turned to Russia. By the Subsidy Treaty of September 1755 England purchased the services of 50,000 Russian soldiers, who aligned themselves on the border of East Prussia, poised to advance into Prussian territory. The English did not regard these arrangements with Russia as incompatible with friendly relations with the Habsburgs. The arrangement was designed to give England double assurance.

Developments belied intentions. Prussia saw in the arrangements not a defensive move but a threat. Frederick already knew of a secret Russian–Austrian understanding against Prussia. His sense of security gave way to a deep fear of an unwanted war against Russia. The way out, he reacted in his fear, was to undercut Russia



Europe in 1748.

by offering England the assurances concerning Hanover. Since Prussian troops would be appreciably closer to Hanover than the distant Russians, England readily accepted Frederick's proffered assistance. The two states accordingly signed the Convention of Westminster (January 1756), in which Prussia agreed to deny entry into and passage through Germany of any foreign troops (*i.e.,* Russians). England obtained the desired guarantees, and its relief was great. Frederick's was equally great. He saw in the Convention an instrument to keep the peace.

The Convention of Westminster

Westminster, however, did not produce the desired effect. It was a bombshell. Vienna was outraged, or professed to be, by the "treachery" of its English ally. Louis XV and Versailles bristled over the seeming defection of Prussia, and, fearing an English–Prussian combination, France turned toward Austria as a shield.

France contracted a defensive alliance with Austria, the First Treaty of Versailles (May 1756), by which France agreed to come to the assistance of Austria if the Habsburgs were attacked. To defend Austria, so French calculations ran, was also to protect themselves. Thus, out of this reflex of fear, France took the first long step toward a reversal of alliances and the abandonment of its centuries-old anti-Habsburg policy.

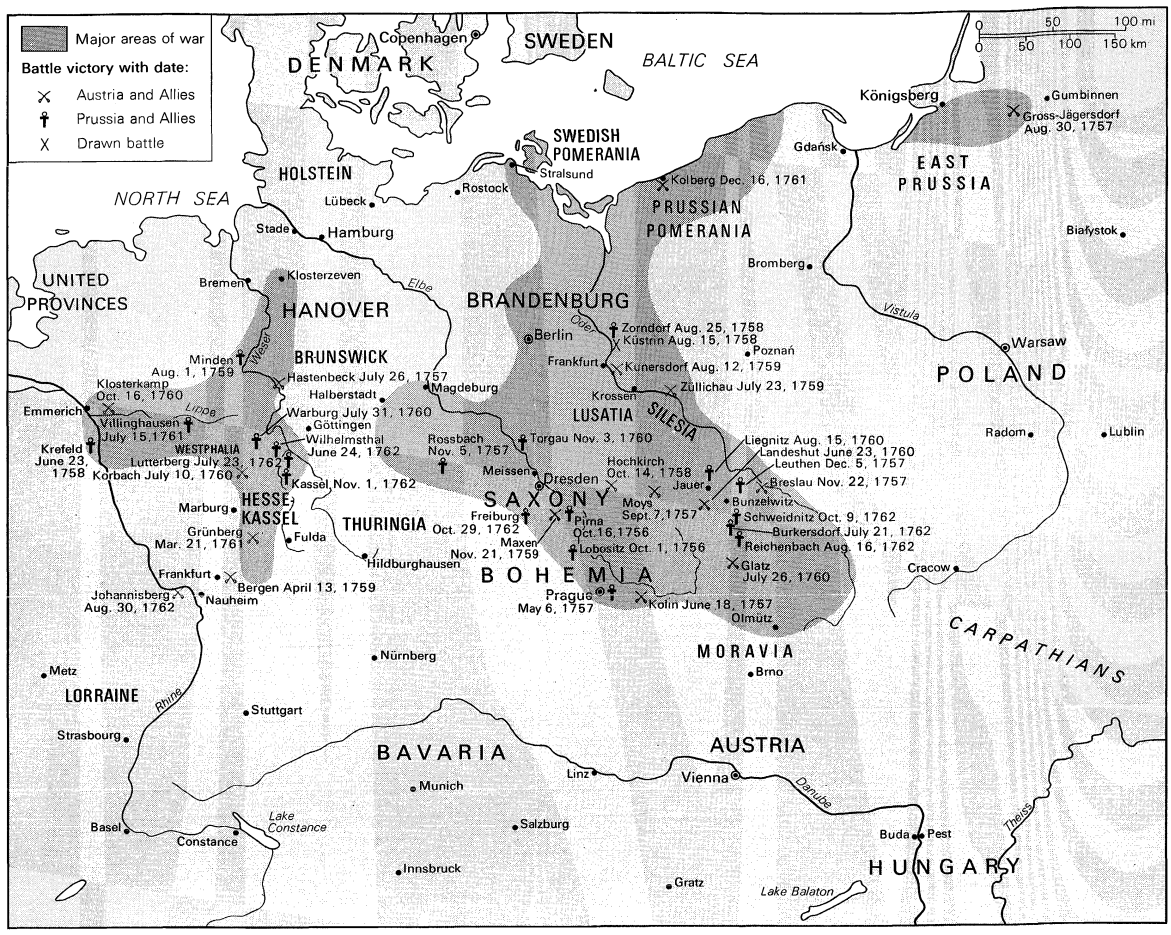
Reversal of Bourbon–Habsburg enmity

St. Petersburg's reaction was, if anything, more violent still. To Russian eyes, Westminster was clearly an unscrupulous repudiation of earlier English policy. Thus, a third set of fears obtruded on the diplomatic scene—Russia's fears that it might have to fight alone against Prussia covered by England. Russia thus turned to Austria for self-protection; in May 1756 Russia agreed to give Austria limited military aid in the event of a Prussian attack.

Frederick did not wait to be attacked first. In August 1756 he invaded Saxony, which he considered the centre of plotting against him. It was now too late for diplomacy: the generals had taken over. France contracted a full military alliance with Russia in the fall of that year. In the following spring, before the campaign began, France signed the Second Treaty of Versailles with Austria, a full offensive–defensive military accord. By this agreement, the last of the three bilateral pacts, the reversal of alliances had become a *fait accompli.*

This diplomatic revolution was a lesson in futility, revealing the fatal inadequacy of the balance of power. Seeking peace, the great states were led to create a situation beyond their control. Obsessed by reciprocal mistrust, they made the appeal to arms inescapable.

The Seven Years' War and the Peace of Paris. Frederick's invasion of Saxony opened the war on the Continent, which merged with the commercial–imperial conflict into the Seven Years' War (1756–63). In the European theatre, the Austrians at once invoked the provisions of the mil-



Main areas and sites in central Europe associated with the Seven Years' War.

itary agreements that bound them to France and Russia. Frederick, for his part, demanded and obtained English aid in the form of large subsidies and a small task force dispatched to the Continent. French tactics envisaged a rapid campaign for the conquest of Hanover. Military calculations in England were initially divided, veering after Frederick's great victories at Rossbach and Leuthen in 1757 toward a full military understanding with Prussia and the use of Hanover as the base of operations for a large-scale military diversion to contain the enemy.

Frederick's stubborn defense

Frederick's conduct of the war was heroic for its daring, flexibility, and dauntless courage against overwhelming odds. It was victorious, too, for a brief span of years. Operating on inner lines until 1759, he prevented the Austrian and Russian armies from joining forces. In 1759 the Russians inflicted a shattering defeat upon him at the Battle of Kunersdorf, and his future seemed hopeless. Yet somehow he held on, suffering defeat after defeat but refusing to sue for peace. For three years the war in Europe was a protracted and ruinous combat in which the Prussian and Austro-Russian armies confronted each other in the east, while French and Anglo-Hanoverian troops effectively neutralized each other in the west. In Prussia's exhaustion Frederick could not have resisted indefinitely, particularly since England withdrew its financial support, but on January 5, 1762, "the miracle of the House of Brandenburg," as patriotic Prussian historians call it, or "her sacred majesty, chance," as Frederick put it, saved him. Tsarina Elizabeth died and was succeeded by her deranged nephew Peter III, an unmeasured admirer of Frederick. With Peter's accession the anti-Prussian coalition fell apart. After signing immediate peace with Prussia the Tsar restored all Russian conquests and placed the Russian army at Frederick's disposal. Though Peter was assassinated within a half year, Peter's wife and successor Catherine II the Great wanted no renewal of a war in which her country would be fighting against Austria for the benefit of Prussia. Prussia's eastern front was at last secure. "Thanks to providence," Frederick jubilantly cried out, "our back is free."

The major war in the Germanies now virtually ceased, but the fighting for empire continued on the seas in America, the West Indies, Africa, and India. The British conquests outside Europe propelled William Pitt the Elder, Britain's war leader, into the pages of history as the great empire builder. On the other hand, in France the dictatorship of Étienne-François, duc de Choiseul, not less embracing and intransigent than Pitt's, failed to win security for France. With rising opposition at home, defeats on the high seas, and the failure of a direct invasion of England and Scotland, Choiseul made overtures for peace early in 1760, not without first playing the Spanish card in his negotiations. Fortunately for England, Pitt's fears of Spanish might were exaggerated. Spain suffered crushing defeats on all fronts in its brief military venture.

After these reverses nothing remained but for Choiseul to sue for immediate peace, which was signed on February 10, 1763. The end of the war between England and France did not come, however, until John Stuart, 3rd earl of Bute, the chief English negotiator, had already taken his country out of all fighting on the Continent. He broke completely with Prussia, cutting off all subsidies and leaving his erstwhile ally to its own resources. Austria, too, was then ready for negotiations, for after Catherine's withdrawal of Russian troops the Habsburgs stood alone in Europe.

The Treaty of Paris was less severe than might have been expected in view of Britain's overwhelming victories. The peace was the handiwork of Lord Bute and of still lesser men who had forced Pitt from office and were prepared, to secure their advancement, to sacrifice if necessary some of the imperial interests that Pitt had so tenaciously and energetically pursued. The guiding consideration of Bute was to turn the diplomatic negotiations to the account of his young royal master, George III. The tactics of the

imaginative Choiseul, the chief French negotiator, were to drive a wedge between the British peacemakers and exploit to the full their fear that Pitt might be returned to office and reopen the war. For Choiseul the peace was to be only a respite from actual fighting, an armistice so to speak, which France would terminate when it was again prepared to reopen the duel for overseas empire. Though he made bitter concessions to the victor, he saved France from the status of a second-rate power, which Pitt had planned. Though Britain did not obtain the Carthaginian peace that Pitt would have imposed, it had emerged as the leading commercial and colonial power in the Western World.

The emergence of Britain's colonial supremacy

In North America, Britain became master of the vast territory east of the Mississippi as well as "the frozen acres" of Canada. Patriots angrily clamoured that their country also retain the captured West Indies sugar islands; however, despite the great strategic naval importance of Guadeloupe and Martinique, the sugar bloc in Parliament sacrificed imperial interests to financial profits and voted their return to France. Moreover, France was permitted to keep the island of Gorée, commanding the slave trade of Senegal, along with a number of trading posts on the eastern coast of India.

Spain, too, fared better by the peace terms than might have been expected by virtue of its overwhelming defeat. The Spanish lost Florida to England and gave up their old claims to the Newfoundland fisheries, but they kept their South American colonies and islands in the West Indies. The victor restored Cuba and the Philippines to Spanish rule. Choiseul, in order to place a lien upon his Bourbon ally's goodwill, ceded to Spain that part of the French territory of Louisiana, including the port of New Orleans, which lay west of the Mississippi.

Prussia also ended the war a victor, for the separate Treaty of Hubertusburg (February 15, 1763) formally recognized Frederick's conquest of Silesia. In Prussia there was great devastation and suffering, but that did not last. What lasted was "the miracle of the House of Brandenburg," the survival of Prussia, its new status as a great power, and the continuing confrontation of Prussia and Austria for mastery of Germany.

Renewal of Anglo-French competition. Choiseul was the directing intelligence behind his country's foreign and colonial policy during the 1760s. He counted heavily on the Habsburg alliance of 1756 and on the network of Habsburg–Bourbon dynastic marriages to cover French security on the Continent and leave France free for action outside Europe. Working via the Pacte de Famille with Spain, Choiseul looked ahead toward a joint Bourbon thrust against England and bent every energy toward restoring the shattered might of French armed services and strengthening the bases for naval operations. This aggressive policy could not be implemented, however, and under Charles Gravier, comte de Vergennes, who took over in 1774, it was toned down. On the Continent Vergennes relied less on the Habsburg alliance (which he feared would entangle France in Austrian intrigues) and more on developing friendly relations with Prussia, with the German states along the Rhine, and, most of all, with Russia. There was appeasement in this approach, but he was prepared to pay the price of lessened French prestige and influence to obtain economic benefits. "In the present state of affairs," he declared, "commercial questions are political questions and as such are within the province of foreign affairs."

The U.S. War of Independence

Vergennes's great opportunity to strike directly against England came in 1776 with the armed resistance of the American colonies to British rule. Initially, he adopted a policy of open non-belligerency against England and more or less secret assistance for the Americans. The decisive change from secret aid to open alliance came after the U.S. Declaration of Independence in July 1776 and Gen. John Burgoyne's defeat at Saratoga in 1777. In February 1778 Louis XVI signed treaties of alliance and commerce with the Americans, and within a few months France was openly at war with England. Vergennes had not miscalculated on the Bourbon ally. In 1779 Spain contracted an open alliance, contributing with the United States 40 ships of the line that gave the associates naval superiority. In return, Spain obtained from Vergennes a reluctant agreement not to withdraw from the war until Gibraltar had been retaken from the British.

In 1780 England declared war against the United Provinces, who had built up a lucrative trade conveying supplies to the colonists and allowing American privateers to refit in Dutch ports in both Europe and the West Indies. But Vergennes appealed to the neutrals to encompass England's defeat by turning them against "the tyrant of the seas." Here his warm relations with Russia stood France in good stead, and Russia was persuaded to sign the declaration that established the League of Armed Neutrality. By the terms of the declaration, contraband was narrowly restricted to munitions and arms, and the armed neutrals regarded themselves as free to navigate along the coasts and to the very ports of all belligerents. Vergennes had gone far toward arraying the Continent against England.

The peace treaties of 1783, signed by England, France, Spain, and the Netherlands, ended the fighting. The treaties recognized the independence of the colonists. Spain retained Minorca and Florida. To France England ceded Tobago and Senegal. England retained bitter memories of a long and humiliating series of naval reverses. Though Adm. George Brydges Rodney's victories in 1782 restored English superiority, the antiwar mood of shame and humiliation was deep. The English wit Horace Walpole caught it in a striking phrase: "You must be happy now," he wrote, "not to have a son who would live to grovel in the dregs of England." England's enemies were jubilant, more jubilant than reality warranted. "Thus is the great power . . .fallen completely and forever," wrote Leopold of Tuscany, " . . . sunk to the ranks of a second class power . . . . France, delivered for all time of that formidable adversary, thereby doubles her intrinsic strength, her commerce, her authority, and her prestige . . . ."

The growth of French commerce

France did not double its "intrinsic strength," least of all in the military affairs of eastern Europe. With respect to the French commercial position between 1783 and 1789, however, Vergennes's policy did add greatly to the strength of the country. He negotiated a trade treaty with Russia that gave French merchants terms as good as those given to the English. By opening trading facilities to foreigners in its West Indies colonies (1784) and concluding a practically free-trade treaty with England in 1786, France accelerated the remarkable increase in the volume and value of its commerce. And England was far from "fallen completely and forever." By skillful diplomacy England formed a triple alliance with Prussia and the United Provinces. As an ally of the United Provinces, England was assured of navigation on the Scheldt and a point of entry for trade with the Continent. As an associate of Prussia and in possession of Hanover, England could build a trading clientele in the Germanies. A dominant member of the alliance and Russia's greatest customer, England pursued active trade relations in the North Sea and the Baltic. With Gibraltar in their hands and with the support of Portugal, the English also held Spain in check. By supporting the territorial integrity of the Porte (Ottoman government) they had access to the eastern Mediterranean, and their share in the trade with free America surpassed the total reached before 1776. On the eve of 1789 the two maritime states still confronted each other in the competition for empire. (L.Ge.)

Eastern Europe and the Eastern Question. A new period in eastern Europe was also opening toward the middle of the 17th century. Poland, once stretching over the vast plains from the Baltic to the Black Sea, was beginning to pay the price of its consitutional follies as one neighbour after another carved for itself slices of the country. In contrast Sweden entered the political scene with its drive to dominate the Baltic. High moment and disaster came in rapid succession after Charles XII came to the throne in 1697. He struck at foes from Denmark to Russia, but in his second campaign against Russia—in the Second, or Great, Northern War—he marched deeply into southern Russia to join the Cossack Ivan Mazepa and his army and suffered annihilation at Poltava in 1709. Charles was one of the few to escape, but his glory had departed. The Treaty of Nystad, made in 1721 after his death, merely

confirmed the fact that Russia had taken the eastern shore of the Baltic, where already the tsar Peter I the Great was building his new capital of St. Petersburg. Charles by invading the heart of Russia had opened the way of Russia into Europe. Russia was also in those years expanding southward. In 1677 the Russians stumbled into their first encounter with the Ottoman Turks, and this scuffle launched a new theme of European history. Peter took up the challenge and by 1697, after bitter reverses, had fought his way down to the Sea of Azov. Already a Russo-Turkish war was caught up in a broader context. Habsburg armies were also on the march against the Ottoman Empire, and the consequence was a question laden with implications: how were these enemies of Turkey going to deal with each other?

In 1683 The Turks began their second Siege of Vienna; and, when King John III Sobieski appeared to relieve the city, Ottoman power collapsed. In pursuit, the Christian forces pushed down the Danube to liberate most of Hungary. The eternal necessity of Austria to face both East and West interrupted the work—Louis XIV was making trouble—and it was not until 1697 that the emperor Leopold I was ready to strike a decisive blow. Meanwhile Peter I the Great, desirous of promoting a Grand Crusade, had sent an emissary to Vienna, and there the two enemies of Turkey signed a three-year alliance. The Austrians inflicted a crushing defeat on the Sultan at Zenta; but then, to the consternation of Peter, Leopold insisted on making peace; he had to prepare for the death of the King of Spain. In the Treaty of Carlowitz (1699) the Emperor recovered Hungary, and the Tsar had to content himself with Azov. This first essay in cooperation, therefore, turned out badly. In 1710, when the Sultan declared war on Russia, Peter proposed a new alliance; but the War of the Spanish Succession was absorbing all of Austria's energies, and he had to fight alone. Suddenly caught by the Ottomans on the Pruth River, Peter bought his escape by surrendering Azov; when, a few years later, there came an Austro-Turkish explosion the Tsar remained at home. There was again, consequently, a separate war, but this time, after Eugene of Savoy had won more brilliant victories, Austria at the Peace of Passarowitz (1718) gained possessions in Bosnia and Serbia including the citadel of Belgrade.

After Peter's death (1725) the ruling clique in Russia rekindled the anti-Turkish fires and, in preparation for fresh conflict, negotiated a defense treaty with Austria. When in 1735 the Russians were the aggressors, Austria was not bound to fight, but Vienna discovered a powerful argument for war: there would be great danger in allowing Russia to fight its way down to the Danube and there dictate a private peace; cooperation in the war would ensure cooperation in the peacemaking. Calculations and hopes alike went awry. There were bickerings between the allies over their uncoordinated efforts; and, just as the Russians had won a solid victory in Moldavia, panic seized the Austrian army. Amid great confusions an emissary signed the Treaty of Belgrade (1739), which returned to Turkey almost all of the gains of 1718. Unable to carry on alone, the Russians went home, and St. Petersburg made peace with the small comfort of recovering Azov.

For a generation the two former allies had no time for Turks, but in 1768 Catherine II's activities against the Poles set off a new Russo-Turkish conflict. Within a year Russian troops stood on the Danube and, in gravest alarm, the Austrians made an alliance with the Sultan, pledging themselves to rescue Poland and to defend the territories of Turkey. Instead of fighting, however, Joseph II and Maria Theresa turned around and joined Russia and Prussia in the first partition of Poland (1772). Catherine was then free to settle alone with Turkey, and in the Treaty of Küçük Kaynarca (1774) she won spectacular territorial and commercial gains and, most ominous of all, secured a vaguely defined right to make representations on behalf of the Greek Orthodox Christians of Turkey.

Joseph II had walked out on his ally but justified himself on the ground that he had moderated Catherine's demands. It seemed to the emperor better to work with the empress than against her, but over several years of negotiations they could not agree on objectives. When Catherine in 1787 provoked a new war, Austrian forces, nonetheless, also took to the field. Neither army fought well, however, and suddenly the new king of Prussia, Frederick William II, struck at them by allying with Turkey. In the midst of these and other misfortunes the dispirited Joseph II died and his brother Leopold II, abandoning the Russian accomplice, made peace at Sistova in 1791 on the basis of the *status quo ante.* Catherine in the subsequent Treaty of Jassy (1792) settled for a Black Sea fortress and its hinterland. Already the French Revolution and a new partition of Poland were capturing Europe's attention, and the Eastern Question passed unresolved to a later day.

(Da.H./Ed.)

ECONOMIC NATIONALISM AND MERCANTILISM

The growth of economic nationalism. The early modern age was a time of conscious state building. One after another, governments attempted to assert control over larger areas, and the new absolutisms tried to combine economic policies designed to achieve increasing national wealth with political programs aimed at increased power at home and abroad.

England was quick to achieve a high degree of unification, and this was confirmed as the Tudors strengthened their hold on Wales, Ireland, and the northern counties. Dynastic union with Scotland came with the Stuarts; and full legislative union in 1707. It cannot be claimed that the economic policies that were promulgated for this increasing area were always satisfactorily implemented, but a national policy was, at any rate, outlined in matters of tariffs, employment and poor relief, price and wage regulations, and the subordination of local authorities, municipalities, guilds, and companies to the will of the national government.

Union with Scotland

Elsewhere, progress was slower. During the reign of Henry IV in France, a significant practical contribution was made (in the shape of road and bridge building) to a concrete national economy. Under Colbert, principal economic minister to Louis XIV, something was done to unify weights and measures, to continue Maximilien de Béthune, duc de Sully's work of transport improvements, and to reduce divisive local tolls on roads and rivers. Even so, and in spite of French absolutism, France remained, in many respects, a large collection of provinces representing a great and varied wealth of natural resources but much divided by internal economic obstructions.

Even the Dutch republic, the model of economic modernity of the period, deferred to much local option in the shape of powerful cities and provinces. Real economic unity was achieved only by the predominance of the powerful and wealthy province of Holland. Both Spain and Italy faced insuperable geographical obstacles to any real economic unification, both countries being divided by mountain ranges. In general, the farther east the countries were, the more backward were their economies and societies. Germany in the 17th and 18th centuries still consisted of some 2,000 independent states of widely varying size, each with its duke, count, landgrave, bishop, or abbot among others. Russia, in spite of some rapid but exceptional projects of industrialization by Peter I the Great, was not modernized until after the Crimean War. Central and eastern Europe remained a society of lord and peasant (almost lord and slave), much of its business still conducted on the basis of barter or payment in kind.

Backwardness, however, was itself the stimulus to economic change. The examples of north Italy and the Netherlands—especially the Dutch republic—were constantly before the eyes of princes, bureaucrats, and even merchants struggling to cope with natural obstacles to transport, compounded by the remains of man-made obstacles surviving from years of fiscal impositions. In France and Germany, in particular, trade was constantly obstructed by internal tolls on roads, rivers, and canals. In 1685 it was calculated that out of a cargo of 60 logs, floated down from Saxony to Hamburg, only 6 remained after the customs officers at innumerable points had taken off their share as a tax contribution. Everywhere petty fiscalism obstructed the free flow of goods, and only at sea did cargoes move relatively freely (though even these were

Customs and tariffs

frequently subject to the attentions of privateers, pirates, and enemy warships).

The development of mercantilist theories. The 17th and 18th centuries nevertheless saw the rulers of these imperfectly integrated territories evolving a set of ideas with a remarkably high degree of common content. The theories were those that have come to be called mercantilist, though in practice they were as much the creation of ministers and administrators as of merchants, and their objectives were political and strategic as much as economic. In an age when war was almost continuous (the 17th century is said to have enjoyed only four years of peace), economic principles that rested on the assumption that wealth could be pursued in the abstract, without regard to the means to procure it, maintain it, and protect it by force, had little appeal to rulers. The mixture of politics and economics in mercantilism varied from state to state according to the resources, situation, and mode of government in force. In the Dutch republic the power of the state was most subordinated to the needs of trade. In England, France and, later, in Prussia and Russia, the economic initiative of the state was seen essentially as the indispensable other arm of the military and, often, aggressive intentions of the state toward its neighbours.

In spite of such differences of emphasis, however, mercantilist programs in most countries came to turn upon the concept known as the balance of trade. This concept was most clearly analyzed in the large volume of economic literature that appeared in England between the mid-16th and the mid-18th century. It may be discerned in the *Dialogue of the Common Weal* (1549–81) and is stated clearly by Thomas Mun in his *England's Treasure by Forraign Trade* (1664). The central theme is that, if the nation's exports exceed its imports, the nation will grow rich by reason of the influx of bullion that will result. But if the nation's imports exceed its exports, the nation will grow poor because of the loss of bullion that will necessarily follow. The next 150 years saw many refinements in the presentation of this simple proposition, as Mun's essay was discussed by scores of English writers and translated into French, German, Spanish, and Italian. But the basic concept of the "balance," supported by new bookkeeping practices and even by the notions of the new physics and mathematics, remained central to economic thought and policy down to the emergence of the classical economists and the ideas of the self-regulating economic mechanism introduced by David Hume and Adam Smith.

From this concept emerged, in turn, a series of economic measures designed to expand and adjust the national economy to meet the needs of the state and society. In its fully fashioned version, the mercantilist program aimed at encouraging the maximum influx of raw materials for industry by the removal of import duties and the imposition of export duties on local raw materials, wool being a frequent object of attention. Local manufactures, on the other hand, were to be encouraged by the imposition of protective tariffs against foreign competition and the grant of subsidies and export bounties to assist local manufacturers. An abundant supply of skilled labour should be provided by a large population, and, as the difficulties of calculating an exact monetary balance became fully appreciated, the main practical objective of mercantilists everywhere tended to become the employment of a larger and better trained labour force.

Export duties

This central core of ideas is common to the English mercantilists and to French writers such as Barthélemy de Laffemas and Antoine de Monchrétien in the time of Henry IV, the two most notable forerunners of the greatest French mercantilist, Colbert. They are repeated in the writings of the Austrian and German economists Johann Joachim Becher, Wilhelm Freiherr von Schröder, Philippe Wilhelm von Hörnigk, and the German cameralists, whose ideas powerfully influenced the ambitious economic programs of Frederick II the Great of Prussia. They appear constantly in the writings of the Spanish neomercantilists, Jerónimo Uztáriz and Bernardo de Ulloa, toward the middle of the 18th century.

In all these states successive attempts to turn mercantilist ideas into legislative form may be found between 1600 and the French Revolution in 1789. In France and in England such programs were most concentrated in the century between 1660 and 1760. The years from the Restoration to 1714 in England have been called the age of commercial and financial revolution. The emphasis there was on the regulation of trade (especially foreign), while industry was increasingly left to its own devices and largely freed from guild or government interference. The most important group of laws were those passed between 1660 and 1663, which developed in practical, enforceable form the ideas behind the Navigation Act of 1651—basically encouraging the growth of the mercantile marine by the compulsory channelling of trade between England and the outside world (especially British colonies) into English ships manned by English officers and crews. The use of foreign-built (mostly Dutch) ships was prohibited in order to boost English shipbuilding. Specified commodities of economic or strategic importance (sugar, cotton, timber, dyestuffs, naval stores) were enumerated so that their illegal carriage in foreign ships could be easily checked. At the same time, shipping was encouraged and agriculture boosted by the grant of bounties on exported corn (1673), and subsidies and protection were granted to a large range of industries including woollen textiles, linen, sailcloth, paper, metal manufactures, and many other products. Thus, a whole program of import substitution was launched and developed well before the Industrial Revolution. Between 1660 and 1700 exports and re-exports rose from rather more than £6,000,000 annually, while imports rose only from about £4,000,000 to £5,000,000 annually. This increase in export values continued, though at varying rates, until 1760, when they reached a figure of nearly £15,000,000.

English mercantilist legislation

The French program of Colbert was very different. Colbert was essentially the royal servant, ministering to royal needs, and his major task was to reform the tax system to improve the royal revenues. This he aimed to do by promoting manufactures through tariffs, privileges, and the import of skilled artisans, so that industry should be a source of national wealth and social contentment. It would be regulated through a universal guild system that would bring not only discipline to industry but also revenue to the crown and a reputation for high quality to French producers of luxury goods. Colbert was by no means the pacifist he has sometimes been thought, and he placed the whole of his regulated economy behind his master's aggressions in Europe, believing, as he did, that the amount of world trade was fixed and that France would only enlarge its share at the expense of the Dutch and English by force.

Financing of French wars

The results of mercantilist policies remain debatable. England certainly enjoyed a century of economic development. French industries likewise spread and, in some cases, seem to have benefitted, as did their English competitors, by the vigorous application of intelligence to their promotion. In an age when invention was limited and the price level stagnant or declining, it is impossible to deny that the mercantilists seem to have brought great stimulus to economic development. In Russia, the imitative mercantilism of Peter the Great has been seen by recent scholars as a remarkable example of state-promoted economic advance. In the Prussia of Frederick the Great, many attempts at unsuitable industrial development, such as silk manufacture, copied slavishly from French models, proved hopelessly unsuccessful, but the works of improvement to harbours, roads, and canals, the clearance of forests, the drainage of marshes, and the settlement of colonies of thousands of industrious Huguenots laid the basis for the industrial future of a united Germany.

It is no longer possible to write off mercantilism as an ignorant contradiction of self-evident economic truth as revealed by orthodox economic theory. Its political, military, and fiscal preoccupations were nevertheless dangerous, and, in an age when public opinion had only limited means to challenge the vested interests of bureaucracy, authority, and private monopoly, mercantilist institutions could easily become a hindrance to further economic progress. The French economy, in particular, was to suffer from the growing burden of ossified insti-

tutions, obsolete laws, and harmful privileges corruptly bought and sold.

Decline of Italy and the Dutch republic. The first half of the 18th century saw the completion of certain momentous developments. Internationally, trade moved away from north Italy and the Low Countries to centre more positively around the two foremost expanding nation-states, France and Britain. By 1700 there was no doubt that, commercially and industrially, Italy was in a state of relative decline. The great cloth-producing centres at Florence, Venice, and Como had all virtually ceased production, though silk manufacturing continued, often outside the old cities. Venice had finally ceased to be an entrepôt of world importance. In north Europe, the Dutch republic, heir to the Italian legacy, had lost its former dynamism. Essentially a middleman economy, it was now feeling the draft of competition from Britain and France. Merchants from these and other countries, who had formerly relied on the intermediary services of Amsterdam, were now trading directly with one another. Dutch foreign trade, while not positively collapsing, remained at about its mid-17th-century level. Agriculture even prospered, but the once-great industries of Leiden and Haarlem suffered badly. Although no longer the leaders of trade and manufactures, the Dutch continued to finance an important part of the needs of other states, especially for war. Dutch investors held an important stake in the rapidly growing English national debt, and there were few smaller governments that did not at one time or another turn to Amsterdam for loans.

Anglo-French competition

Italy and Holland may be regarded as examples of relative decline. Only Spain seems to present a picture of absolute decline from which there was to be no significant recovery even in the 19th century.

British economic and industrial growth. True expansion was evident only in Britain and France, and even there the early 18th century was punctuated by hesitations and losses. Everywhere population growth had slowed down. Cities frequently seemed to have reached the limits of expansion for the time being. London, for example, after a period of unprecedented population growth to over 500,000 people, had reached a point of overcrowding that threatened health and a point of general congestion on the Thames River that threatened profits. The new century brought about little expansion of its activities and with its stagnation went a levelling off of London demand for food and drink, necessities and luxuries. Breakneck expansion gave way to consolidation and more intensive development. These changes had their effects on agriculture, industry, and population throughout the Home Counties and East Anglia, and until 1750 landlords and tenants alike faced more years of depression than of prosperity.

Population growth

The total population of England and Wales may have grown by perhaps 1,000,000 to its 6,700,000 figure of 1760. It now seems probable that this continuing, though still modest, increase was due to a fall in deaths (33 per 1,000 in 1730 to 27 per 1,000 by the 1760s), whereas the birth rate rose from a low figure of 28 per 1,000 in 1710 to over 33 per 1,000 in the 1760s. In contrast to the deceleration of London, provincial cities had begun to grow. Norwich flourished on agricultural progress and its "new draperies," but the most significant vigour was to be found on the west coast, where Bristol, Liverpool, Whitehaven, and Glasgow in Scotland were all growing rapidly on the profits of the Atlantic trade—American and West Indian sugar, cotton, and tobacco and the provision of African slaves for the plantation economies of those areas. There was also a marked shift of manufactures, especially cheaper and lighter textiles such as linens, cottons, and fustians into the hinterlands of Lancashire and Scotland to meet the demand for exports to the new colonies. Ironware, hardware, nails, tin, glass, and small arms also filled the holds of Bristol ships sailing for West Africa, America, and the West Indies.

The western ports therefore accounted for a good proportion of the total increase in British shipping, which rose from about 320,000 tons in 1700 to just under 500,000 tons by the 1760s. Another important contributor to shipping demand continued to be the coal trade. Colliers taking northeastern coal from Newcastle to London had provided a major natural stimulus to English shipping and shipbuilding from 1550 to 1700. This cheap transport had, in turn, stimulated British coal production to a 14-fold increase by 1700. This expansion continued in the 18th century and was unparalleled in Europe; however, it took a new direction. Northeastern coal production, based on the London demand, grew less rapidly, while new coalfields, especially in the Midlands, ministered to the needs of an expanding pattern of output from a range of industries of widely varying type: sugar boiling, salt refining, brewing, and many small manufactures based on iron, such as tool making and lock, chain, nail, gun, and sword making. Abraham Darby discovered how to smelt iron ore with coke in 1709, but it took between another 50 and 100 years for the invention to penetrate widely throughout the iron industry.

Nevertheless, by the midcentury there were already signs that the growing markets at home and overseas were beginning to interact. As machines and engines called for more metal and fuel, coal output, in turn, responded, and this drew forth more demand for transport and labour. There was a notable increase in labour-saving mechanization everywhere, but, in spite of a few large-scale enterprises utilizing true factories, such as the Lombes's silk mill at Derby (1724), Wedgwood at Burslem (1759), and Boulton at Soho (1762), the new industries still grew by multiplying the number of relatively small units of production, employing new labour, and exploiting established technologies, such as dyeing, that were capable of improvement and expansion. All this new growth tended to provoke manufacturers and traders to challenge the older ideas of state paternalism and company monopoly, which now seemed to be a brake on output and profit rather than a help to their efforts.

Mechanization

Expansion of French trade and industry. In spite of the pattern of technical conservatism that state and guild control imposed on the French economy during the post-Colbert period, France also shared in the general expansion of trade and industry in the 18th century. From Labrador down to the Caribbean, the French participated in the trans-Atlantic trades, importing fish, furs, tobacco, sugar, coffee, indigo, and cotton. The French ports of Saint-Malo, Nantes, and, above all, Bordeaux rose on the new trades. Even Marseilles, though centred on the Levant and Mediterranean trade, benefitted from the re-export trade in West Indian sugar and coffee.

Certainly in the first half of the 18th century, the output of French cotton and iron was also greater than that of the rival industries of Britain. Some French industries were hindered by the rigid, monopolistic, secretive, and legalistic guild system that cramped enterprise and made it impossible to follow fashion. But elsewhere, French industry, like its English rival, sought expansion through rural development and the putting-out system. It enjoyed the great advantage of a large domestic market (three or four times the population of Britain and more than ten times that of the Dutch republic) and rich natural resources. Probably the expansion of the French export trade was even greater than that of the English, before the 1789 Revolution. French capacity for invention, especially in industrial chemistry and such ancillary processes as textile printing, was truly remarkable. Yet, in certain respects, French development may be seen in retrospect to have had less potential than its English rival. Shipping and shipbuilding were less closely geared to industry, and the same was true of the relationship between coal output and coal-using industries. The French pattern of manufacture was therefore less adaptable to the growth of mass demand. The custom known as *dérogation,* which penalized aristocrats who participated in trade or industry below the level of the great state colonial trading companies, may well have deprived the French economy of valuable financial aid and initiative of the kind that came from the shrewder members of the British nobility, such as that of Francis Egerton, 3rd duke of Bridgwater, the great canal promoter, or of the coal-owning Lowthers.

Anglo-French rivalry. Two other related weaknesses may be discerned in the French economic structure. En-

gland between 1688 and 1750 had developed a surprisingly well-balanced system of public finance, based on a well-managed public debt, an evolving system of taxation (both direct and indirect), the Bank of England, and the great trading companies, together with a widespread system of private banking. French financial institutions, on the other hand, did not succeed to anything like the same extent. Indeed, some contemporary observers saw in the weakness of French public finance and its inability to raise the great masses of capital represented by the growth in the English national debt (£12,000,000 to £132,000,000 in 1763) a major reason for British military and economic superiority that was to emerge decisively at the Treaty of Paris, which brought an end to the Seven Years' War in 1763. Militarily, France suffered in its overseas possessions—in the West Indies, North America, and India—by reason of this financial weakness, and military defeat was certainly reflected in overseas trade, not least in India, where sea power, especially, gave England the whiphand by 1761.

The national debt

The observer of these events in historic retrospect must nevertheless be careful. By 1750 the future of world power and of European control of trade both within Europe and in the colonial world beyond was still in suspense between the two great powers, France and Britain. It is not easy to determine how much of Britain's success in overtaking its rivals was inherent in the situation in 1750 and how much was enveloped in the events and developments that took place subsequently.

Modest though the advance of these two and a half centuries seems compared with what was to follow, it was by contemporary standards truly momentous. Europe's population very nearly doubled, to reach 140,000,000 by 1750. The growth in the area and volume of international trade and shipping was without precedent. The roles of capitalists and capital in the changing industrial system were as revolutionary as those of entrepreneurs and factories in the next phase of development. Finally, the men of the 17th century had begun to grasp how scientific method could be applied not only to the problems of agriculture and industry but also to those of society itself, a realization pregnant with possibilities for the future.

(C.H.Wi.)

THE ENLIGHTENMENT

The Enlightenment was a movement of thought and belief concerned with the interrelated concepts of God, reason, nature, and man that claimed wide assent among European intellectuals in the 17th and 18th centuries. Although diverse in emphases and interests, the Enlightenment attacked the established ways of European life and, in its conviction that right reason could discover useful knowledge, aspired to the conquest of man's happiness through freedom.

Ancestral roots. The roots of the Enlightenment date from the days when Greek philosophers discovered a regularity in nature and concluded that its governing principle was the reasoning mind and when, under the promptings of Socrates, they turned to consider man and ascribed a high value to his intellectual powers. Individual philosophers and their schools raised Greece to a brilliant eminence, but its glory faded and Rome emerged as the heir. The Romans saved much, adapted much, and made contributions of their own; but the Greco-Roman culture finally lost its vitality, and an unheralded tide of Eastern religions emerged, preaching doctrines of personal salvation. Christianity won the competition for converts, however, and before the end of the 4th century it became the exclusive religion of the empire. Christianity developed from an environment totally alien to that of the Greeks and Romans, and its purposes were so contrary to theirs that many fervent Christians wanted to repudiate pagan writings altogether. But the overwhelming majority of the converts were Greeks and Romans, for whom a radical break with their past was unthinkable; pagan literature was the only available source for philosophical justifications and for educational materials. And so Christianity had to make a cultural accommodation, but it tried to suppress the most immoral aspects of paganism and to bend the rest to the special purposes of the faith. The greatest achievement was that in the 13th century when Thomas Aquinas took up newly found manuscripts of Aristotle and made them into the very fundament of Christian philosophy.

Again, intellectual history moved from triumphs to reverses. More scholastic disputation badly injured Thomas' dominion; the papacy was moved to Avignon in 1309 (the discreditable "Babylonian Captivity"), and, worse still, expanding secular concerns in the 14th century shook the old order, nowhere more disruptingly than in Italy. Symptomatic of this change of atmosphere was Petrarch's newborn zest for classical letters and the response to it on the part of countless enthusiasts who roamed far and wide in search of forgotten manuscripts. Several revivals of classical letters during the Middle Ages had rescued many works from destruction, but the old religious purposes were not that of Petrarch and his friends, who wanted the ancient authors stripped of the distortions wrought upon them through the centuries of Christian editing and interpretation. These new men, the Humanists, sought to recapture the spirit of Greece and Rome, which had been expressed with such wisdom and beauty; and they produced a magnificent body of criticism and letters, historiography and science that made a glorious epoch in European history.

Petrarch's role in the revival of classical learning

But after about a century, intellectual life in Italy suffered ruinously from political turmoil, and Humanism went over the Alps to find congenial homes in Germany and elsewhere in western Europe. There the central purpose of Humanism was to serve religion, and this was especially true for Erasmus, who wanted to perfect a philosophy of Christ. Erasmus saw many things to reform, but when, in 1517, Martin Luther raised the standard of revolt, Erasmus drew back in horror.

The turbulent Luther unleashed more furies than he could have anticipated. A century later the old ecumenical church of the West was broken. The Protestants were appealing to the authority of the Scriptures, and the Catholics were invoking the authority of the organic church; the Council of Trent (1545–63) closed the door on useful dialogue between them. Meanwhile, the course of the Reformation had thrown up problems of its own, and debates over would-be solutions had scattered cross-purposes and confusion. By the 17th century Europe had no community of thought. The Renaissance had spread the diverse stream of Greek philosophizing, and Platonism, Stoicism, and Epicureanism competed for a hearing. Catholics and Protestants discharged their guns across an unbridgeable chasm; newer political questions raised up a veritable Pandora's box of conflicting opinions.

The decision of the Renaissance had been to keep the synthesis between classical letters and the Christian faith, but later developments had injured that hope. Inescapably, the need for an intelligible and accepted medium of communication sent men back to classical points of view, points of view not necessarily in conflict with Christian judgment but at the same time independent of it. One notable appeal to the minds of all Europeans was couched in terms of revived Stoicism. It was made by Hugo Grotius, a noble and scholarly Dutch jurist. In his *De Jure Belli ac Pacis* (1625) he invoked natural law as the rule governing international relations. For 2,000 years no one had denied the existence of natural law, but there was a fresh significance in the emphasis Grotius placed on its primacy and on its independence of Christian theology. This law, said the devoutly Christian Grotius, was so immutable that God himself could not change it.

Grotius' appeal to natural law

The scientific revolution. Another development was working out a new frame of reference—the beginning of modern science, a discipline that soon lost patience with religious quibbling and, no less, with the absurdities of Greek and Roman science.

Bacon and Descartes. The great prophet of this newest learning, the man who stirred the imagination of the next generations by painting the enrichment of human life through new discoveries, was Francis Bacon. Suspicious of the mathematics that had been making great technical strides, he proposed an all-comprehending method of induction. In contrast, Descartes drove from his mind everything except simple ideas, whose truth was undeni-

able, and he proceeded by rigorous deduction to work out his whole philosophic system. Despite the gulf between these two methods, Bacon and Descartes were allied in basic purpose and in influence. Both were at war with what they considered a harmful past; both dreamed of improvement in man's lot as the duty of science; both separated science from theology. Both, too, saw the need for practical experiment, and neither had a useful notion of how to go about it.

Galileo. The honour of fundamental pioneering belongs to Galileo Galilei, a man of genius, piety, and truculence. Taking up the old figure of speech that God had given man two books, Holy Writ and nature, he insisted emphatically tht the language of the book of nature was mathematics. For his purposes, Galileo limited his world of nature to properties capable of mathematical analysis, such as extension and motion, and therefore capable of being described in terms of precise natural laws. His method of research he elegantly demonstrated in working out the law of falling bodies by mathematical analysis of hypotheses and checking by experiment.

Such achievements should have been renown enough for any man, but Galileo had yet another triumph. As a starting point for it he had the astronomical work of Copernicus, Tycho Brahe, and Kepler. Their studies had done mortal damage to the Ptolemaic notion of a universe rotating around the Earth, but these great explorers had left behind them not only a storm of emotional resistance but also a number of crucial unanswered questions. Report had come to Galileo of a new invention called a telescope, and he made one for himself. In a few nights of peering into the heavens he saw a system of structure and motion that proved the Copernican heliocentric explanation to all but the most hidebound defenders of the old order. With the discredit of the Ptolemaic astronomy, the whole of Aristotelian natural philosophy became untenable, and Galileo in 1632 recklessly set down his views in *Dialogo sopra i due massimi sistemi del mondo, tolemaico e copernicano.* He dedicated his book to the Pope, but that act of courtesy availed him little. He was called before the Inquisition to hear a verdict already prepared; but the broader significance of the trial was that Galileo's new scientific way of thinking had gone so far from inherited modes that no reasoned interchange was possible, and the church based its condemnation on fear.

Newton. Another difficult problem remained: the need to construct a general system of mechanics that could account for the motions of the stars in terms of observed behaviour of matter on Earth. A number of scientists worked at it, but it fell to Isaac Newton to win the honour of success. In 1687 the Royal Society, under the authorization of its secretary Samuel Pepys, published Newton's *Philosophiae Naturalis Principia Mathematica.* In this work, with prodigious mathematical reasoning, Newton presented the law of universal gravitation.

The effect of Newton's discovery of the law of gravitation

Newton modestly confessed that he did not know what gravitation was, and when his calculations indicated some irregularities that seemed to require the direct intervention of God to set them right, he was honest enough to say so. The German scientist and philosopher Gottfried Wilhelm Leibniz, who had quarrelled with him over priority in the invention of the calculus, attacked Newton harshly for picturing God as a clumsy watchmaker, but few had patience with such small matters. Newton had explained the universe; he had vindicated the rationality of nature; and he was, said the zealous Voltaire, the greatest man who had ever lived. Behind this enthusiasm for Newton and for natural philosophy there lay a serious question. The mounting tide of discoveries in physics pressed toward the autonomy and the moral neutrality of science, but the spirit of the time could not allow this kind of isolation for so wonderful an instrument of knowledge. The by-product of science had been the destruction of wide domains of medieval error; perhaps its methods, its experimental reasoning, could be used for all of man's problems. Indeed, Newton himself had suggested the possibility.

Enlightened religion. The Christian faith showed a powerful tenacity when confronted by this avalanche of new facts and new conclusions, but it could not fail to be acutely sensitive to the changing intellectual fashions. By the early 18th century, radical ideas hitherto submerged came into the open and precipitated a debate fraught with great consequences. Hitherto, the rationalists had had no base for comparison except their knowledge of the ancient world. Latterly, they had become acquainted (in considerable measure through Jesuit missionaries) with pious Egyptians and Siamese and with Chinese, who, they said, had no real religion at all but were still men of exemplary virtue. More recently still, another stock character came upon the European stage: the noble savage, truly a child of innocence who worshipped his god in simple faith and obeyed the precepts of Mother Nature. And, finally, this growing breed of scientists was steadily grinding out disturbing implications. Good Christians though most of them were, they showed that Christianity's views of nature could not stand up under the tests of experimental reason.

The rise of Deism. Such considerations led dissatisfied men to assume that, beneath the world's religious diversities, there was a common body of beliefs, a religion planted by nature in all men everywhere. In 1624, while Grotius was preparing his case for natural law in international relations, Lord Herbert of Cherbury published his *De Veritate,* a definition of natural religion. He said that certain beliefs are so manifest that all men of reason accept them: the existence of one God who dispenses rewards and punishments, and the obligation resting on man to worship him in repentant piety and virtue. These articles sufficed for a religious life in the present world and for salvation in the hereafter. Deism, as this doctrine came to be called, did not always radiate Herbert's lofty Stoic tone, but his statement was so representative that it persisted until Thomas Paine, in his *Age of Reason* (1794–96), wrote the swan song of the movement.

The Deists' views

The Deists maintained the old synthesis between God, reason, and nature, but, reasoning from a mathematically ordered nature to its architect, they allowed the architect only the qualities manifest in his handiwork. Grand metaphysical systems fell under the ban as mere extravagant nonsense; philosophizing, said the dominant voice, should follow the method of the natural sciences. Such convictions led inescapably to relentless warfare on those beliefs that were unique to Christianity. The Holy Writ of the Christians suffered denunciation as groundless historical confusion; but the Old Testament came in for special attention—it was scornfully dismissed as a repository of the crimes and obscenities in which God connived with the so-called chosen people. With equal vigour the Deists ridiculed biblical prophecy out of court; the notion that God would make revelations in such a book, or in later manifestations, was utterly offensive to the rational mind. Miracles, therefore, were unthinkable. It would do violence to reason to suppose that God would, or could, set aside the laws that gave expression to his own eternal being.

Deism was never an organized movement. Its first home was among English intellectuals. Around 1700 a series of books appeared that hit ruthlessly at what they held to be the misconceptions and offenses of orthodox Christianity and argued for a depersonalized God, whom anyone could discern for himself. Some of the authors offended good taste and the law by their blasphemies; some wrote with calculated prudence. But during a half century the central core of their argument remained essentially unchanged: Christianity was an indefensible burden on the back of natural religion. But then English Deism went quietly into decline, in part because public disputation was reduced to tedious repetition and in part because the Anglican Church was too preoccupied with political advantages and social dominance to wish to disturb its fat slumber by theological contentiousness. England in 1688–89, with its Glorious Revolution, had settled its wracking political issue, and it was time to relax. The clergy preached coolly on the prudential morality of the Christian life, while Joseph Addison taught his readers the affable urbanity appropriate to a civilized society in an age of reason. Deism moved its headquarters to the Continent.

France had its own native roots of Deism, which grew vigorously on the disillusionments and discontents of the reign of Louis XIV. Voltaire was already committed to

an anti-Christian Rationalism before he sought a haven in England in 1726. On his return after two years of exile he wrote a sparkling report, *Lettres philosophiques,* which reaffirmed his commitment to the Deist view of religion. Through his remaining years, his faith remained inflexible. Pressed by more radical opinions, he held steadfastly, in the end somewhat frenziedly, to the God whose evidence he saw in nature and whose existence he deemed necessary to preserve the social order. His one change of emphasis was in the growing vehemence of his anti-clericalism. In the 1760s he completed his *Dictionnaire philosophique,* a witty but earnest compendium of malice toward Christianity, and at the same time, poltroon though he frequently was, he entered the public lists to bring justice to several persons he considered to be victims of ecclesiastical murder. By then he had adopted in rage the motto *Écrasez l'infâme!:* "Every sensible man, every honourable man, must hold the Christian sect in horror."

No one was more temperamentally removed from Voltaire than Jean-Jacques Rousseau, but when he included a profession of Deist faith in his novel *Émile,* Voltaire sent him an enthusiastic compliment. Rousseau's profession was a manifesto for reason as the only reliable test for religious truth and equally an attack on all doctrines and clerical institutions that stood between autonomous man and God. Rousseau characteristically made a place for heightened emotion in such passages as the invitation to go to the sublime book of nature and learn there to worship the Creator; but the overtone of anti-intellectualism did not obscure the rational doctrine of Deism. Throughout France opposition to the church

The spread of Deism

spread, drawing strength from the debilities of the *ancien régime,* and the Deist faith went on to the culturally less well prepared soil of Germany and to the British colonies in America. The movement kept up its momentum far into the second half of the 18th century, but it then paid the price of its lack of organization and the weakness of its emotional impact on uncritical minds. Without a sacred text, without a compelling leader, Deism was always a matter of individual judgment and thereby vulnerable to centrifugal forces.

The Christian response

Naturally, when established societies felt the shock of Deist subversion, they resorted to the time-honoured methods of defense. First came Christianity's dogmatic assertion of truth from pulpit and press (*e.g.,* in 1770 French publishers brought out 90 books in support of the Catholic faith). Behind such gentle measures, however, there were, in considerable diversity, grimmer ways of suppressing dissent. Grimmest was the vengeance of the Inquisition, but hardly less so was the possibility of civil judgments, including the death penalty. And then came the *Index Librorum Prohibitorum* (*Index of Forbidden Books*), ecclesiastical and state censorship and licenses to print, and book burnings. Much skilled and harsh determination went into devising means to stifle corrupting thought. Many individuals suffered many punishments, but heresy was a hydra-headed monster, thriving on persecution and on the stupidities of its enemies.

In Vienna in 1772 the political authorities suddenly realized that they had to put their own *Catalogue of Forbidden Books* in that self-same *Catalogue,* because the impure of heart were finding it a useful guide to spirited reading. Administrative inefficiency and, notably in France, competing authorities helped to dent the cutting edge of tyranny, but the greatest aid for those dealing in illicit materials was their own ingenuity in adapting the arts of the smuggler and the forger into their affairs. Books sold under the table, books without authors, books with false places of publications—all were commodities that did well. In these deceptions Voltaire was by no means alone, but he was a superior master. His brilliant style was more clearly his own than was an acknowledged signature, but in edition after edition he denied writing the *Dictionnaire philosophique,* and no policeman challenged his audacity.

Such cat-and-mouse antics were not the whole story of this confrontation. The real trouble was more subtle. Christianity was rooted in both reason and revelation, and, according to the Fathers and the doctors of the church, these sources were not in conflict; revelation simply had the higher truths. Now came Deism, professing to have the full credentials of reason and demanding that the Christians show how they could, in reason, defend revelation. Again the first battleground was England. Increasingly, supporters of the Christian faith found themselves driven to admit the validity of natural religion and then to search out reasonable grounds for adding revelation. John Tillotson, future archbishop of Canterbury, spoke for many when he stated that Christianity was needed to complete the findings of natural religion: its service was to test the reasoning process and to give a supplementary motive for a moral life. Tillotson conceded much, but his contemporary and fellow Christian John Locke went even further when he accepted reason as the judge of things above reason. Bishop Butler's *Analogy of Religion Natural and Revealed* (1736) offered a fresh line of Christian defense. It became a famous book, but, despite the kindly Bishop's Christian dedication, it did not demolish many Deists. In the pinch, he did not venture into dogmatic assertions based on the usual Christian sources; he took his stand on probability, and he reminded his readers that there were things in natural religion and in nature just as difficult to believe as was orthodox Christian doctrine: after all, Newton could not explain gravitation. Comparable gestures toward a friendly view of the rational standard appeared in Holland, in Germany with a group of prominent Lutheran pastors, and in France, where the Jesuits had a high skill in reasoned debate until their expulsion in 1762. The consequence was that, on the Continent as in England, the theological content of practical, daily religion declined significantly. The popular preachers discoursed in muted tones of reasonableness on the beauties of Christian virtue.

While Deists and Christians were exchanging blows, they tended to agree that God in his benevolence had designed the Earth for man's happiness; "the best of all possible worlds," Leibniz said. Another said that the sun rises and shines for men, and still others pointed to the evidence of the Creator's forethought—the density of water to facilitate navigation; the shape of the melon to make it easy to cut. Even Voltaire, having no conception of change in the universe, surveyed the mountains and saw in them the wisdom and the benevolence of God.

Atheism. Both Deists and Christians heard with anxiety that their happy assumptions were threatened by the upsurge of atheism. Materialism was an ancient philosophy. Epicurus had propounded it, and his Roman disciple Lucretius had put it into his poem *De rerum natura,* which, still later, had excited the Renaissance enthusiasts for classical letters. Throughout the whole of its history, Epicureanism had been a scandal for the mass of literate people, but a notable moment came in 1563, when a French Humanist published a new edition of Lucretius and urged his readers to forget the absurd ideas and concentrate on the poetry. The plea helped a bit, but a far more significant work of salvage was done in the 17th century by Pierre Gassendi, a Catholic priest of blameless repute. Boldly, Gassendi said that Epicurus had not been an advocate of vice but had cultivated the virtues of honesty and inner peace. His Materialism, Gassendi went on, was erroneous; but he shrewdly suggested that it could be made palatable by postulating Divine Providence behind Epicurus' atoms and voids. Descartes would not admit a void in his universe, but he made a contribution, however unwillingly, by his dualism of spirit and matter, which made all animals, including physical man, into purely mechanical structures. With the growth of science, the 18th century took kindly to Gassendi's revival of atomistic philosophy and to the Cartesian mechanistic view of nature. In England David Hartley rewrote Lockean psychology and explained mental life in terms of physical vibrations building complex patterns by the equally mechanical processes of association. In France another physician, La Mettrie, brazenly spelled out the title of his book, *L'Homme-machine* (1747), and stated that man, like everything else, was reducible to matter in motion. "We are no more committing a crime," he wrote, "when we obey our primitive instincts than the Nile is committing a crime with its floods, or the sea with its ravages." Voltaire would not entertain what was to him

The rise of Materialism

an offensive notion, but the Encyclopaedist Denis Diderot was tempted and succumbed. The most powerful atheist influence was that of Baron d'Holbach, a wealthy German who had settled in Paris to wage war against God. He commissioned the publication of a whole library of books in addition to those he wrote himself; his only criterion was that a book should serve the cause. In his eyes, religion was the main source of degradation. Rumours circulated about his dinner parties, and ordinary folk felt uneasy when they passed his house, but d'Holbach went further in his anger against Christianity than many men were willing to go.

Skepticism. One further, and more powerful, threat to both Deism and Christianity was skepticism, also a philosophic doctrine that had ancient roots. Because of the lasting popularity of Montaigne's essays of the 16th century, one must see in the meditations of this gentle devotee of ancient letters a fresh source for modern doubt. As he mused on human folly and fanaticism, he repeatedly threw in his personal conclusion, "What do I know?" It was a diffident question, but over several generations it prodded many minds.

The influence of Pierre Bayle

A century later, subdued reflection gave way to a noisy uproar. The cause was Pierre Bayle, whose course from Protestantism to Catholicism and back to Protestantism sent him into a life of exile and of hostility to all religions. His instrument of vengeance was his *Dictionnaire historique et critique,* the first edition of which appeared in 1697. In form it was a collection of biographical sketches with comments, but the individuals chosen and the amount of space given to each reflected Bayle's deadly purpose—to demolish the vices of religion. With learning and wit and with a titillating spice of salaciousness, Bayle drove his sword at every exposed surface of the erstwhile eternal verities. Perhaps nowhere did he hit harder than at the Old Testament when he asked how it was that, when Holy Writ chronicles the morally offensive record of King David, it goes on to call him a man after God's heart.

Bayle's *Dictionnaire* had an extraordinary success. It was soon expanded in new editions, translated into English and German, and boiled down into abridgments and digests. The rollcall of those who read it was a veritable *Who's Who* of the 18th century. Frederick II of Prussia commissioned two abridgments; Benjamin Franklin and Thomas Jefferson recommended it to their friends; Voltaire drew inspiration from it for his own *Dictionnaire philosophique;* Diderot wrote a lyrical article on Bayle for the *Encyclopédie* and was enraged when the rascally publisher suppressed the main substance. No one, however, was more persuaded than the Scottish former Presbyterian David Hume.

At 28 Hume published the first two volumes of *A Treatise of Human Nature.* The subtitle showed the cast of a mind that never changed: *an Attempt to introduce the experimental Method of Reasoning into moral subjects.* From this first, and unsuccessful, book to his posthumous *Dialogues concerning Natural Religion* (1779), Hume, with amiable reasonableness, dissected all certainty from human affairs. Down went the concept of cause and effect, an idea seemingly essential to all rational thinking; down went the celebrated powers of human reason. But the realm of belief suffered most notoriously in this raging storm of doubt. The miracles of so-called revealed religion he subjected to the test of experience, and they dissolved beyond rescue except for the most willful believers. Even natural religion could not stand up to the test of fact; there was no universal consensus supporting it. According to Hume, primitive men, in their fear, invented gods, many gods, to gain protection, and it was only a long time later that monotheism emerged from ignoble calculations. The great trouble, said Hume, was that men assumed that the Supreme Being gave his qualities to them as an endowment of the creation, whereas in reality men ascribed to God their own values. Here, then, was a repugnant philosophy; nothing was left but mere uncertainty and probability at best. The only saving grace, Hume puckishly admitted, was that one could not be a skeptic all the time.

Christian defenses. In the eyes of orthodox believers in Christ, the new trends were all manifestations of a perverse spirit that incited defiance as well as consternation. From Christians little moved to dispute came an assertion that their religion did not need to submit to these debasing tests of rationality. The mystics and others of unassailable conviction went their own ways, indifferent to foolish clamours. Still, it was not always easy. Blaise Pascal, mathematical genius and convert to the rigorous faith of the Jansenists of France, had felt agonizingly the tension between the old ways and the new. He had been convinced that human reason could not explain the ultimate philosophic questions, and he sought for moral certainty in Christian revelation. The universe was vast and men were insignificant, but they had souls and they were dependent on God. In his fear of the vastness of space, Pascal committed himself to a supreme act of faith: "The heart has its reasons which reason does not know." As a student of the law of probability derived from the gambling table, Pascal took refuge in his wager on the existence of God: "if I lost I would have lost little; if I had won I would have gained eternal life."

Chief of those who a century after Pascal would not accept the threatened demolition of the Christian faith was John Wesley, an Oxford student of the classics, early given to piety and a second-time convert through the Moravian Brethren (a German pietist sect). It was no novelty when Wesley said that reason could not produce the love of God, but it was strangely exhilarating when he told his spiritually hungry followers, "A true and living faith in Christ is inseparable from a sense of pardon from all past and freedom from all present sins." For 50 years Wesley preached his simple message of the love of God manifested in Christ, and the humble folk found consolation as Wesley travelled up and down England preaching an average of 1,000 sermons a year.

And so before the end of the 18th century something less than success had crowned the efforts of those earnest men who used emancipated reason and the methods of science to explain God and the ancient mysteries of the universe. The old faith had been buffeted, but Wesley's was only one of the first announcements of a religious trend toward the unleashed emotional flights of the Romantics.

The investigation of man. Meanwhile, the attempt to examine the nature of man in the light of new thought raised difficult problems. The old and continuing Christian view had a harsh consistency: man carried in him the stamp of Adam's sin until the hour of redemption through Christ's atonement arrived. The Renaissance concept of the dignity of man was an implied criticism of the old belief. But now, in the heady days of rationalistic deductions, it seemed axiomatic that God had implanted his reason and his goodness in man. In this view there was no place for original sin; were it otherwise, the creation would have been monstrously unjust, and that was unthinkable. But the difficulty about this happy analysis was to find men who were convincing demonstrations of the thesis.

The notion of the goodness of man

Locke's epistemology. Because a priori reasoning about man was not very profitable, it was in order to utilize Newton's new scientific method to study human nature. The pioneer was John Locke, and his vehicle was *An Essay Concerning Human Understanding* (1690). Locke's purpose was to determine the scope and limitation of human knowledge through an investigation of the workings of the mind. In the end he set a low limit to knowledge, but what made him the great teacher of the 18th century was his description of the mental process: all knowledge arises from experience, from sensations sorted and combined by reflection. There are no innate ideas; every child is born with a mind like a blank sheet of paper on which the impingement of the external world inscribes the data of life's accumulation of learning. Bishop Berkeley attacked Locke for assuming a world of substance as the source of sensations when that world was beyond the reach of knowledge; but aside from Berkeley's criticism, the psychology of the next century was essentially a gloss on Locke.

The Lockean investigation had demolished not only innate ideas but also innate depravity. Environment made the man, and the most obvious corollary was that the way to improve man was to improve the environment. It was a lesson that gave new dimension to human possibilities

and therefore a strong impetus to the zeal for humanitarian reform.

Ethical questions. Locke was primarily concerned with epistemology and gave little attention to the nonmental aspects of man. The language of the day spoke of the passions—the emotions—and their role became increasingly important as the study of human behaviour continued. The rationalist deduction held to man's inherent goodness by virtue of his reason: to know what was right was to do what was right. This statement hardly fitted the observable facts, and a qualification was added: when reason was not obscured, it would tell man what was right and he would act accordingly. But, again, this revision was short of full accuracy: it was established fact that a man who clearly knows the truth may not serve it. It was therefore in order to investigate more carefully the inner sources of moral action. Even exalted rationalists had to admit the existence of ethical promptings in the nonintellectual side of human nature (*i.e.,* in the passions), and two generations and more sought a precise explanation. Early in the 18th century, the 3rd Earl of Shaftesbury found it in an instinctive love for the good because of its inherent worth, its beauty, and its reflection of nature. Bishop Butler pointed to the conscience, the voice of God speaking to the human soul. Even David Hume turned from his skepticism long enough to ascribe to man an innate sentiment for humanity, and his friend Adam Smith, the calculating economist, gained his first celebrity in 1759 from a book that asserted that sympathy was a guiding emotion in human conduct. Across the channel, Voltaire, that alleged prince of cynics, found in man a natural benevolence never seen in the beasts, and the radical Morelly wrote in his *Code de la nature* (1775), "In the natural order the idea of active or passive benevolence precedes every other idea, even that of Divinity."

Running through these comforting reassurances was perforce a question of the relation between this ethical faculty, rooted in the emotional impulses, and reason. Shaftesbury was persuaded that rationality and moral emotion could never be at odds because both were the gifts of nature. Butler contended that conscience had its own power of reasoning. In the second half of the century the common voice began to falter. Adam Smith could not say that sympathy and reason would invariably counsel the same moral decision, and Hume, returned to his most destructive vein, wrote in his *Treatise,* "We speak not strictly and philosophically when we talk of the combat of passion and of reason. Reason is, and ought only to be, the slave of the passions, and can never pretend to any other office than to serve and obey them." Many of Rousseau's passages implied, however unphilosophically from Hume's point of view, an open conflict between reason and the passions. Under the inspiration of Rousseau's idealized man of virtue, novelists were soon playing variations on the theme that goodness was merely a matter of opening the heart's emotional spigots.

Conflict between reason and the passions

Meanwhile, the discussion of ethics had addressed itself to an even more important theme. Christianity had always made its basic appeal to man's desire for the happiness of heaven and his fear of the torments of hell. It was easy to generalize this human predilection and say simply that the dynamic force in life was the desire to secure pleasure and to avoid pain. Christian John Locke agreed: "Pleasure and pain and that which causes them, good and evil, are the hinges on which our passions turn." With a boldness that threatened to become unseemly, numerous writers, notably the exuberant Diderot, sang praises of the passions and in so doing obliquely discounted reason.

It was necessary to think of the ethical implications. Few were ready to make the pursuit of pleasure a moral code in itself. The extravagant determinists could argue that man's decisions and acts were simply the consequences of matter in motion and that there could thus be no question of morality in human life; but most reflections on ethics, despite Hume, assigned to reason some kind of brake on personal misbehaviour. Others contended that the experience of living with people taught men the need they had of each other and the ensuing necessity for reciprocal obligations. In addition, as a justification to some and a reassurance to others, there circulated an assumption of a mysterious harmony between self-interest and the common good. Montesquieu wrote, "Everyone pursues the common good under the impression that he is following his own private advantage." The impudent Bernard de Mandeville expressed the same conviction in his *Fable of the Bees* and summarized the whole matter in his pithy aphorism: "Private vices, Publick benefits." Alexander Pope was more eloquent: "Thus God and Nature link'd the gen'ral frame/And bade Self-love and Social be the same."

The brave Newtonians had confidently set out to create a science of morals, but they had only created confusion. Another question arose: if there was this anxiety about the capacity of the individual to find within himself a reassuring incentive to ethical conduct, was it possible to find a source external to the individual? For believing Christians the answer was simple: God through the Holy Scriptures and his providential governance of the world has given his commands, and it was man's duty to obey them. It was a far more difficult task for the would-be scientific thinkers, who had broken relations with the Christian God. Thomas Hobbes in the mid-17th century had left a suggestion. In a bit of hypothetical history he told of people who in the state of nature were, each and every one, under the sovereignty of pleasure and pain. The consequence was war of all against all, and life was "solitary, poor, nasty, brutish, and short." To escape from this deadly plight, these people set up a state and consigned to it an all-comprehensive power to rule. The compact created obligation. Hobbes's successors faced the same problem. To restrain moral anarchy it was imperative to design a code based on the welfare of the community. The expression "the greatest happiness for the greatest number" had first appeared in the 1730s, and Claude-Adrien Helvétius made an ominous suggestion. In his book *De l'esprit* (1758), burned by the parlement of Paris and anathematized in Rome, Helvétius explained how to take this self-centred creature man and make out of him a social being: "It is solely through good laws that one can form virtuous men. Thus the whole art of the legislator consists of forcing men, by the sentiment of self-love, to be always just to one another." Out of such materials Jeremy Bentham drew his blueprint for a laissez-faire democracy.

Humanitarianism. It was perhaps less important that these 18th-century thinkers could not fashion an agreed science of morals than that so many people were deeply concerned. The Deist search for natural religion had led to wide-ranging investigations of peoples all over the Earth, with investigations centred not on manifest differences in colour and customs but on what people had in common. And they found much. "It is universally acknowledged," Hume wrote in 1748, "that there is a great uniformity among the acts of men, in all nations and ages, and that human nature remains still the same in its principles and operations. History informs us of nothing new or strange in this particular. Its chief use is only to discover the constant and universal principles of human nature." The sum totality of all men made up humanity, and humanity, by some subtlety, inspired loyalty and compassion. Under this influence, vaunted reason was turning itself unobtrusively into reasonableness. When the concept of natural law was applied to social problems it underwent a significant modification. It no longer stated what was, but what ought to be; and since in so many respects the human condition fell far short of the ought, the Enlightenment became critical, reformist, and eventually revolutionary.

Universal principles of human nature

Locke's demonstration that environment made men provided the dynamic inspiration for a vast attack on prevailing abuses. In the presence of disinterested compassion, those laboured analyses of man chained forever to his pleasures and pains seemed sterile and irrelevant. The long, ceaseless campaigns waged by the intellectuals for freedom of religion and speech might appear to a cynic to be breast-beating exercises to secure their own privileges and rights, but certainly the cynic's yardstick could not measure a countless list of self-jeopardizing acts by men working to increase individual freedom for the simple reason that individual freedom was good. Out of that same

simple reasoning came an attack on the inhumanity of Europe's brutal administration of brutal law.

One blind spot, as later generations would call it, was the Enlightenment's little thought for the misfortunes of the lesser rungs of the European social ladder. The poor Europe had had with it always. Sympathy leaped more readily over the horizon to embrace people of dark hue whose status touched the European conscience. Atheist and Christian equally agreed that slavery was morally wrong, and they made common cause against it.

The religious radicals and their Christian enemies also shared an insistent sense of all men linked together in universal brotherhood. Standing in the way of the ideal were many grim realities, but the most baffling was the sovereign state, which demanded the obedience and, far too often, the blood of its people. Despite early warnings of a ferment of nationalism, men of many divergent persuasions toward other issues sounded their defiant calls to world citizenship. Invoking the spirit of Grotius, the Swiss lawyer Vattel pleaded for a society of states living together in peace under the morally binding prescriptions of natural law. Other men who loved peace recalled a proposal attributed to Henry IV of France to establish a formal international confederation that would make war in Europe impossible; the Abbé de Saint-Pierre revived this project in 1713 and worked at his cause for 30 years without gaining many converts. Rousseau published a rather lukewarm restatement, and there the peace campaign rested until 1795, when Immanuel Kant spoke the final word for the Enlightenment in "Zum ewigen Frieden." But Kant's eloquence was to no purpose, for at the time Europe was already two years into a war that would not end until 1815.

Social thinking. The application of the Enlightenment's rationalistic and scientific tools to social fields led to no settled agreement, either as to method or to conclusions.

Political thought. The Reformation had thrown up doctrines ranging from primitive communism to the divine right of kings. Bishop Bossuet restated with the best French eloquence of the 17th century the special relation between God and Louis XIV, but the ancient principle of the natural law went on talking about the state of nature, the social contract, and natural rights. The weight of these theories were, by their very nature, on the side of radicalism. Yet a curious thing happened—the first notable statement of political philosophy in the new age of mathematical rationalism was a secularized theory of absolutism. The author was Thomas Hobbes, who became a rigorous reasoner when, in middle age, he chanced upon Euclid's *Elements.* Hobbes started with natural law but, as indicated above, he admitted no "ought to be." The law imposed a sleepless search for pleasure and the passionate desire to escape pain. The people caught in the desperate consequences of this rule of life made a social compact whereby all resigned their individual powers into the hands of a sovereign outside the compact, whose authority for all practical purposes was unlimited. Hobbes had many acute insights into human affairs, but Charles II, whom he was trying to support in the distress of his exile in France, was so scandalized that Hobbes had to flee the royal presence and take refuge with Oliver Cromwell.

The social compact

Half a century later John Locke accepted Hobbes's strong sense of individualism and his conception of the state as a mere mechanical convenience rather than a divine institution, but in all other respects his arguments went back to pre-Hobbesian terms. The state of nature, said Locke in the second of his *Two Treatises of Government,* was a social regime of men of good will; in it, natural law had endowed men with rights, principal among which were life, liberty, and property. Certain confusions arose when every man defined for himself and tried to protect his own rights, and it was minor difficulties and not desperation that inspired the formation of a political community specifically and exclusively for the protection of individual rights. Government was derived from the consent of the people, and it functioned by majority rule. Locke's purpose had been to compose a challenge to Charles II's brother, who was heir apparent; but the *Treatises* were not published until 1690, and by that time the Glorious Revolution had closed a troubled period and Locke's revolutionary tract was appropriated as a defense of the Revolution. Thereafter, England settled down for a long time to enterprises requiring no new political philosophizing.

While England was relaxing into complacency, most of the Continent still remained too bound to a lethargic inheritance to think of formal political theory. A few Germans, a few men of the Low Countries, an occasional Italian rose sufficiently above their bleak routines to more systematic thought, but it is best, for summary purposes, to concentrate on the affairs of France. Long before the death of Louis XIV, times were out of joint and remained so, with few respites, to the end of the monarchy. There were paralyzing difficulties, however, in finding the causes of the disturbed temper of the 18th century and proposing suitable remedies. The French monarchy had done too well in that it had stifled all prospects of generally popular institutions and had made public discussion a hazardous occupation. The monarchy had done badly in that it had not rooted out the mentality and the vested interests and important agencies of feudalism. The monarchy had also done badly in that its close ties with the Catholic Church made every grievance against the church either obliquely or overtly a grievance against the royal structure of power. The consequences were disastrous for judicious thinking about politics.

All his life Voltaire unremittingly poured his energy into supporting the powers of the crown against the parlements, the medieval law courts that had become citadels of aristocratic resistance. Montesquieu wanted a greater role in government for the nobility of which he was a member; for that reason he held the British House of Lords in high esteem. Diderot, not by instinct a political animal, never understood the contest between king and nobles and always blew hot or cold as immediate circumstances prompted him. And yet for him, as for Voltaire, realism bade him acknowledge that all kings of France, even Louis XIV, had faults; but he never revealed doubts about the monarchy. He had courted Louis XV for preferments and had got them, and he took pride in the fact that Frederick II of Prussia had courted him. A new trend stretching across Europe from Spain to Russia gave plausibility to the thought that man's best hope for reforms lay in the vigorous sovereign. In the most unexpected capitals, rulers were reorganizing their governments, removing tax and other burdens on trade, and restraining the brutalities of the law. No enlightened Philosophe in France could complain until he realized that these so-called enlightened despots had another, and a repugnant, face turned toward war and conquest.

What was left for France to talk about, and to write about on condition of prudence, were the abuses of political power along with those of ecclesiastical power. Despite this dejecting atmosphere, in 1762 a new kind of political book appeared in Paris. It was called *Du contrat social* and its author was the difficult, emotionally unstable Jean-Jacques Rousseau, who had first won fame by a perfervid attack on the evil consequences of civilization. Rousseau proposed a society able to cultivate the individual's moral stature without injury to his freedom. It was a fresh effort at that knottiest problem of political philosophy. For a solution he returned to the old, and now somewhat derided, idea of a social contract. According to Rousseau, each individual ceded his rights and powers to a general will of which he was part—that is, an equal participant in the political life. As he stated the terms, they logically ruled out a distinction between rights and powers reserved to the individual and the authority and functions assigned to the community, that issue which was of paramount importance to Locke. By Rousseau's reckoning, the individual was as free after the contract as he had been in the state of nature; he had merely substituted for natural freedom a civic freedom by which he was elevated into a moral being. Some later readers have found in *Du contrat social* dangerous undertones of totalitarianism because of the equivocal place of the individual in relation to the general will, because of the axiom that the general will was right, and because of a prescription of a civic religion with penalties for defiance. Other latter-day students have

Rousseau's *Du contrat social*

rejected the imputation. It may be permissible to conclude that Rousseau, in writing ostensibly a book on political theory, did not really have his mind on politics. In one respect, nonetheless, he gained in clarity over John Locke. The *Two Treatises of Government* had referred to the powers of an undefined majority; *Du contrat social* wound up in an emotionally suffused claim for political democracy.

Both men had their triumphs. In America Thomas Jefferson incorporated strict Lockean doctrine in the Declaration of Independence. When shortly thereafter the French revolutionaries wrote their own declaration, they made a place for Rousseau's general will and sovereignty of the nation. On both sides of the Atlantic, however, there was fumbling over the fundamental question of popular government: who was to have the right to vote.

The mainstream of Enlightened thought had no quarrel with Locke's assertion that property was a natural right. Yet Rousseau, in agreement with Hume, was uneasy. Although he did not write down specific remedies, he was persuaded that political democracy could not work without a relative economic equality. In the seething atmosphere of the second half of the 18th century, a little band of dissenters took their criticisms far beyond Rousseau's doubts. In 1755 the obscure Morelly, in *Le Code de la nature,* attacked property as the mother of all crimes tormenting the world, and he made a proposal that was to have a long history: let every man contribute to the commonweal according to his abilities and receive according to his needs. Two decades later the Abbé de Mably, starting with equality as the law of nature, contended along with Morelly—and, for that matter, with the early Rousseau—that the introduction of property had destroyed the golden age of man. Soon, François-Noël Babeuf, civil servant turned radical journalist, tried to organize a revolution within a revolution to secure the true equality ordained by nature. In England William Godwin, taking his stand on the immutable laws of the universe, rigorously pushed reason into condemning not only property but even the state and marriage. Such scandalous utterances, however, were only tiny specks in the sky. As the old century was dying, property seemed to be resting on a firm ground of support.

The law. For the Enlightenment, the law under which men actually lived required urgent consideration. There could hardly have been a greater contrast between the law of the courts and that which reason allegedly perceived in nature. Once Grotius had given his definition, the law of all lands was summoned to the supreme tribunal of reason. Man-made law, said the indictment, was valid only insofar as it conformed with nature's law. Even the famous jurist William Blackstone, steeped in the English common law, accepted the argument. On the Continent, where there was little ground for contentment, the spirit of legal thought was uncompromising; the law, said the zealots, was not made by edicts and legislative enactments but was discovered by right reason. The instrument of reform was a rigorous code, a summation of legal wisdom that could be administered with mechanical precision. The outcome was partial victory in the Prussian and Austrian codes and in the Code Napoléon.

Economic theory. Another aspect of human affairs that the Enlightenment sought to judge was the economic. The practical background was a long history of extensive state intervention in economic pursuits—mercantilism—and a recent history of middle class dissatisfactions. In France the wars of Louis XIV had wrought great misery, and even before the King's death, critics had dared to propose reforms. Among the first to apply rationalist criteria was the Sieur de Boisguillebert, in whose judgment state interference did violence to the law of nature, which prescribed a harmony of interests; right reasoning under the stimulus of free competition was the proper guide to economic behaviour. A half century later Louis XV's physician, François Quesnay, founded the physiocratic school on essentially the same assumptions. The physiocrats' economic man was motivated by self-interest but lived under nature's dictate of harmony; it followed, therefore, that unfettered private activity was the certain means to the commonweal.

The question of state interference

Adam Smith's *Inquiry into the nature and causes of the Wealth of Nations* (1776), a declaration of economic independence, criticized the physiocrats' emphasis on the unique importance of land but otherwise revealed Smith's kinship. Smith began with the butcher and the baker intent on their own good and went on to demonstrate the merit of "the system of natural liberty." Sharing the British dislike of extremes, he was not dogmatic; but behind his array of observations and utilitarian arguments there lurked the old rational conviction about "the great Director of Nature" leading men "by an invisible hand" to serve a wider cause than their immediate own. Smith had no illusions about the way men conducted their business affairs, and he wanted the state to protect the weak against the strong. Nonetheless, his bias was for the free individual determining his own destiny. Smith spoke at the right moment and became a revered teacher of the following generations.

The meaning of history. The Enlightenment's thought about history began with a dilemma. The basic rationalist values were timeless, and the practical purpose of examining the world's past experience was to strip away the accidents of time and place and lay bare Hume's "constant and universal principles of human nature." Another service from studying history was required: when real men were so far removed from the man of reason and nature, it was the task of the historians to explain the causes of the gap. To their labours most of the students of the past brought a point of view that suggested the answers in advance. As a result, numerous historical works glossed the theme of the evil consequences of religious and political benightedness. The histories of such as Voltaire, Guillaume Raynal, Hume, and Edward Gibbon, who recorded the triumph of barbarism and religion, were heavy guns in the arsenal of the Enlightenment. They were not, however, simply camouflaged propaganda. The Reformation had inspired solid historical scholarship, even if its purpose had been partisan, and the grave scholars of the 17th century had built on it to amass documentary materials and to broaden the skills of criticism. The luminous names of the 18th century had a surer grasp, and their masterpieces—for such many were—made Europe conscious of the pleasure and the importance of reading history.

This quietly intruding sense of historical change prompted reflection, not only on the relation of the Enlightenment to the past but also on what mankind could expect in the future. Earlier speculations were not useful guides for the latter. The ancient world had generally thought in terms of cycles in which there was a deterioration of ages from gold to iron. The Christians accepted from their predecessors the idea of cosmic cataclysm, but they would admit just one, which would come at God's own appointed time; in the meanwhile, the only significance of human history was the drama of salvation for individual souls. The Renaissance tended to return to the idea of the cycle, but it was that of youth, maturity, and decay of states after the manner of Aristotle's history of the Greek polis rather than the total upheaval of the cosmos assumed by the ancient world. The happy rebirth in 15th-century Italy was, then, merely the beginning of a new cycle. Still in the 18th century, when Montesquieu reflected on the causes of the greatness and decadence of the Romans, his interpretation continued the Renaissance approach to history.

The harbinger of a new way of thinking was Francis Bacon, the aforementioned prophet of science. The Greeks and Romans, he contended, belonged to the youth of the world, and his own generation was the heir of all accumulated knowledge. It was a mistake to be chained to the hopelessness of the notion of the cycle; by the proper method of inquiry, man could move on to great benefits through the conquest of nature. It was significant that whereas Thomas More had constructed his *Utopia* in a remote setting, Bacon put his *New Atlantis* in the future.

The idea of progress

Bacon had been thinking in terms of useful knowledge, and he found the Greeks and Romans the children and not the adults of time. Such talk was offensive to the literate community that had been raised on classical literature. For such people a comparison between the two ages had to be a comparison of their literatures, and for those

spiritually suckled on Homer and Virgil there was no comparison. By the late 17th century, brazen writers began to defend the literature of their own time, and for a whole century cultural Europe resounded with the cut and thrust of the warfare between the "ancients" and the "moderns." The battles raged on the subjective field of taste, and a clear-cut victory was manifestly out of the question. Long before the end of this contest Bernard Fontenelle, permanent secretary of the Académie des Sciences, had shifted the ground from letters to scientific achievement, and few could deny him his claim for progress up to his day. But more significantly, Fontenelle was primarily concerned with the future, and for its course he detected a law of progress that would guide man's destiny to still better things.

As social dissatisfaction, and hopes, mounted late in the 18th century, the idea of scientific and intellectual progress quietly slipped into a belief in the general progress of mankind, moral no less than material. Hardheaded realists like Voltaire were too oppressed with the continuing perversities of the world to fall into an easy optimism; knowledge could be used for bad purposes as well as for good, and future improvements were dependent on the role of sound reason. Such a qualification, however, had little restraining value for those whose vision of the future had become assured. Young Anne-Robert-Jacques Turgot, the future minister of Louis XVI, surveyed all human history and found it a record of the progress of the race toward perfection; even in ages of apparent barbarism, men and society had moved, however slowly, in the right direction and in the future would continue to do so under a law of acceleration. Turgot's friend the Marquis de Condorcet converted these calm anticipations into fervent prophecy. Hiding in 1793 from the revolution that he had joyfully served, Condorcet hastily composed his *Esquisse d'un tableau historique des progrès de l'esprit humain.* He saw mankind facing its tenth and culminating epoch—a new day in which the steady march toward perfectibility could not be stopped. The time would come, said this man under sentence of death, when the sun would shine only on free men who knew no master but their reason.

The end of the Enlightenment. A chronology of the disintegration of the Enlightenment is impossible. For all of its belief in eternals, it was from the beginning a flow of ideas in which emphases shifted and trains of thought broke under the impact of new evidence and new insights. Newton's physics and Locke's epistemology were absorbed into the uneasy synthesis, but eventually they bore a heavy responsibility for the decay. Natural law as perceived by right reason was, for many of the latter-day lovers of science, sinking into a bloodless cliché, while the pleasure-pain doctrine built up its empire of utilitarianism. At the high noon of religious rationalism, John Wesley cried defiance with his emotional Methodism. Nature, once considered a synonym of reason and visible proof of the existence of God and his benevolence, broke up into something to be studied with scientific objectivity and something to be enjoyed in romantic indulgence. Not by any means the least blow to the Enlightenment's timeless verities was the revolutionary growth of historical mindedness, of the turn toward rethinking all mortal affairs as well as scientific questions in terms of ceaseless change. In the dying days of the Enlightenment the Western mind was setting out on the road that led to Edmund Burke and Hegel and to Darwin and Marx.

Later times have ridiculed a naïve epoch, but the Enlightenment's moral and intellectual significance is high because it tried to rethink in new idioms the oldest values and beliefs in the history of Western civilization.

Revolution, reaction, and nationalism, 1789–1871

CHRONOLOGY OF THE REVOLUTION AND THE 19TH CENTURY

The French Revolution was more than a sequence of events in France between 1789 and 1795. It was one of the greatest upheavals of modern history, complex and far-reaching in importance for the whole of European civilization. It was part of a wider trend of democratic movements affecting many other countries, including North America, during the later 18th century. Modern historians see it as a continuing process, beginning in the 1770s, comprising in 1787–88 a reaction of the privileged classes of nobles, clergy, and officeholders against Louis XVI and his ministers, and passing through several phases between 1789 and 1799, with later reverberations throughout the 19th century. Events between 1789 and 1795 are the central, especially dramatic, act in a larger drama.

The Revolution in France. The importance of the meeting of the States General in May 1789 was that it brought to one focal point all the political and social conflicts of the ancien régime in France. From the only nationally representative body known to France, though it had not met since 1614, the King hoped to find an escape from his chronic insolvency. The ecclesiastical, lay, and judicial aristocracy hoped, by means of the traditional method of voting by separate estates, to block the reforms that they feared. The Third Estate, especially the middle class of officials, traders, and professional people, welcomed this opportunity to ventilate grievances and demand reforms. From this tangle of conflicting expectations derived a series of constitutional and political crises. Nobody wanted a revolution; at first nobody wanted to overthrow the monarchy and set up a republic. The hope was for peaceful changes to satisfy the various sectional interests. Yet within the next four years the surge of events and circumstances swept away first the privileges of the aristocracy and the church and then the monarchy; produced civil war and the Reign of Terror; engaged France in war with its neighbours; and spread revolutionary ideals to the rest of Europe. These unforeseen and unintended developments, the classical French Revolution, came about because of the interplay of conflicting ideological and social forces.

The first group to emerge, the enlightened liberal Constitutionalists led by such men as the Marquis de Lafayette, Bishop Talleyrand, and Abbé Sieyès, triumphed in June 1789, when the Third Estate constituted itself as the National Assembly, and in July, when it undertook to remodel the constitution. The Assembly wanted a limited constitutional monarchy on the English model. But it was soon submerged by other more violent elements in French society. The Paris mob scored a symbolic victory with the fall of the Bastille on July 14. The peasants indulged in local frenzies of destruction in the Great Fear of July and August. There were revolts in provincial towns. There began a flight of émigrés from France. When representatives of the aristocracy and clergy, on August 4, voluntarily surrendered feudal rights and privileges, they were prompted as much by fear as by generous idealism.

The forces of violence drew strength from economic conditions. The years 1787–89 were a time of bad harvests and severe food shortages, of high prices, bad trade, and unemployment. There was a slump in the textile industries. The peasants, for two decades and more, had suffered from a long-term inflationary trend that forced down their standard of living. Economic distress, deepened by the upheavals of currency, civil strife, and war in the 1790s, was the background to the political turmoil; and it, too, had its roots in the years before 1789.

The Terror. There arose within the Assembly a more extreme democratic movement, headed by the Jacobins, demanding the rule of liberty and equality and asserting the principle of "sovereignty of the people." The new constitution proclaimed in September 1791 was in essence a parliamentary constitutional monarchy; but by then the royal family, by open support of the émigrés, had destroyed the confidence between king and parliament necessary if such a regime was to work. The King was virtually held captive in Paris, and in April 1792 war was declared on Austria. The emergencies of war led to the prison massacres of September 1792 and the declaration of a republic. Louis XVI was executed in January 1793. A new assembly, known as the Convention and dominated by the Jacobins in the course of 1793, instituted the Reign of Terror under the dictatorial rule of Maximilien Robespierre. The Terror swelled the tide of émigrés, who

now included, like the victims of the Terror, people drawn from all classes. (D.Tn.)

The Revolutionary wars. Meanwhile, Revolutionary France and the monarchical powers of Europe had been engaged in a war of nerves, trading threats of increasing asperity. Direct responsibility for going beyond this war of nerves lay with the bloc of Girondin deputies in the Legislative Assembly who deliberately initiated a policy to provoke Austria into intervention and war. They were not alone in wishing that course to be followed. They themselves counted on a victorious war that would unmask what they called "the treason" of Louis XVI and Marie Antoinette and give them control over French policy. Military leaders like the Marquis de Lafayette, Louis, comte de Narbonne, and Charles-François du Périer Dumouriez, who also desired war, did so out of their conviction that France would be defeated and a grateful nation would then turn to them.

The Holy Roman emperor Leopold II, while still holding to his tactic of verbal denunciation of "the pernicious sect of Jacobins," nevertheless tightened his military alliance with Prussia, while the Prussian king Frederick William II went further and drew up a plan of campaign. The Girondins then presented an ultimatum to the Emperor, summoning him not only to renounce the Austrian-Prussian alliance but also all other treaties that threatened "the sovereignty, independence, and security of the nation." They counted on Leopold's rejection; and, when the response of Leopold's son and successor, Francis II, was held "unsatisfactory" on April 20, 1792, France declared war on "the king of Bohemia and Hungary." The deputies defined the war as "the just defense of a free people against the unjust aggression of a king."

The early fighting against the Austrians was disastrous on the northeast front, and Prussia's entry in the war greatly intensified the military danger. As the steady Prussian advance brought their troops onto French soil and as the great fortress of Verdun fell into their hands, it seemed as though only a miracle could save Paris and the entire Revolution. The "miracle" occurred on September 20 at Valmy in the passes of the Argonne. The raw French recruits held firm against the Prussian line while their artillery fire stopped the enemy advance. Though only a minor skirmish, Valmy was in effect the decisive watershed of the war. The Prussians yielded their position and began a long retreat back to the frontier. As they retreated, the French advanced in a three-pronged offensive. Savoy fell to them, the Middle Rhine, too, and most important, the Austrian Netherlands, which Dumouriez overran.

The fall of Verdun

The problem then arose in all the conquered territory of future relations between the Gallic liberators and the pro-French native sympathizers. The solution came in a momentous declaration of policy. By the decree of November 19, 1792, the new assembly of the French Republic declared "in the name of the French nation that it will bring fraternity and aid to all peoples that wish to recover their liberty . . . ." This memorable decree threw down the gauntlet to the powers. It proclaimed an ideological crusade against the old European regime of kings and privileged order of society. A complementary decree (December 15) put teeth into the declaration of policy. It stated that in all occupied territory the system of taxation, the tithe, the titles of nobility, and all special privileges and feudal dues would be abolished, and all property belonging to local rulers was to be taken over by the agents of the French Republic. These self-styled "Friends of Liberty" would institute the new administrative system, and all who resisted them would be treated as enemies.

This mystique of a crusade, coupled with the older *politique* of conquest and annexation, laid down the bases for the war of Revolutionary France against all European states, immediately against England. Threatened by the French occupation of the Austrian Netherlands and by the opening of the Scheldt to French commerce, England prepared to fight. The Convention declared war on February 1, 1793, including the United Provinces in the declaration. A month later Spain, too, was at war, then (in rapid succession) Sardinia and Naples, the lesser Italian States, Denmark, Sweden, and the Ottoman Empire. England contracted treaties of alliance and subsidy with the member states of this First Coalition. From a limited war between France and Austria, the conflict had broadened into a confrontation over two conceptions of human relations.

War with England

The defeat of the First Coalition. The fighting was a succession of defeats on all fronts. With Paris again exposed to direct attack and England declaring all France under a state of blockade, the Convention rescinded the decrees of November and December. The allies refused to negotiate: they were now discussing plans for a partition.

At this desperate juncture the Convention voted the decree of the *leveé en masse* (August 23), which was designed to transform France into an armed camp. "All Frenchmen," it read, "both sexes, all ages are called by the *patrie* to defend liberty." Implemented systematically, this declaration of total war released untapped vital energy, and the tide of battle turned to victory. By the last days of 1793 the invaders were beaten back on all fronts. Toulon was recaptured from the English, a young captain of artillery, Napoleon Bonaparte, distinguishing himself in the final attack. The Spanish withdrew to the Pyrenees and Savoy was cleared.

The élan of 1793 carried the Republican troops to victories in 1794. As the armies repulsed the invaders, they took the offensive. The line of the Rhine was regained. The Republican armies overwhelmed all of Italy. The Dutch fleet surrendered. Prussia was the first of the allies to sue for peace in the autumn of 1794. The supporters of a separate peace in Prussia reasoned that to give up territory along the left bank of the Rhine and later to receive compensation within Germany by the terms of a general European peace was a satisfactory end of the fighting.

For France the Peace of Basel (April 1795) was fully acceptable: it kept open the line of armed advance along the Rhine. To Prussia it brought the end of war and the highly advantageous status of being a neutral. By the Treaty of The Hague (May 1795), the United Provinces was compelled to cede strategic bits of territory and pay a heavy war indemnity. The reorganized Dutch government, called the Batavian Republic, was then bound to France by an alliance that drew the Dutch and their great resources into the war against England. A month later, in June, it was the turn of Spain, which had to recognize the French Republic and cede to it the Spanish part of Santo Domingo (Hispaniola). The final step taken by the French annexationists (in October) was to vote the incorporation of the Austrian Netherlands as an integral part of the territory of the Republic. The language of the French crusade to liberate enslaved peoples was kept in all these transactions; but the deeds of the liberators resembled nothing so much as the play of old-fashioned power politics.

Annexation of the Netherlands

The government of the Directory, the conservative government that came to power in France in 1795 after the Terror had run its tragic course, set its sights on a general European peace. The two allies still in the field were also eager for a comprehensive settlement, but they were not ready to accept the pre-established terms set by France. So the Directory prepared to continue the fighting. Since victory on the seas was unlikely, the French plan of campaign called for limited naval operations. The main thrust was to be on the Continent. The major attack was directed against Austria, where in a broad pincer movement two great French armies were to converge upon Vienna. A minor supporting campaign was envisaged in Italy, where the assignment given to Bonaparte, who was in command of the Army of Italy, was to conquer Lombardy. The ultimate political aim of these military operations was to compel defeated Austria to retain Lombardy in return for its acceptance of France's retention of the annexed Austrian Netherlands.

It was not only the military genius of Bonaparte but also his views concerning the territorial settlement that completely upset the plans of the Directory. As he was winning his resounding victories in northern Italy in 1796 and 1797, his thinking ranged far beyond the objectives of his government. He agreed that the conquered Rhineland would be retained. He would not, however, acquiesce in installing Austria in conquered Lombardy. He intended

to retain French military control over the territory that he was reorganizing as the Cisalpine Republic and to use it, along with French-occupied territory on the Adriatic and in the Ionian Islands, as a stepping-stone toward Egypt. For he planned to turn next to the east and strike at England by severing its imperial communications.

With such projects in mind he carried on negotiations with Austria in the summer of 1797 that eventuated in October with the Treaty of Campo Formio. Austria recognized the French annexation of the Austrian Netherlands and agreed (in secret articles) to cede approximately two-thirds of the imperial territory on the left bank of the Rhine, provided that this cession were ratified at an imperial congress to be held at Rastatt. The ousted German princes were to receive compensation elsewhere within the empire. Prussia, however (and this, too, in a secret article), was not to share in the dismemberment as the Treaty of Basel had stipulated. In Italy, Austria received Istria, Dalmatia, and the Venetian mainland in return for the loss of Lombardy. The Cisalpine Republic was formally recognized by Austria. The Ionian Islands that Bonaparte was so anxious to gain went to France.

Treaty of Campo Formio

Such were the main provisions of Campo Formio that the Directory reluctantly ratified. It was an imperialistic peace, a sorry end to the crusade for liberty. The French statesman Emmanuel-Joseph Sieyès spoke wisely when he said: "This treaty is not peace; it is a call to a new war."

The Second Coalition, 1798–1802. The Peace of Campo Formio was an interlude. While Bonaparte went off on his romantic odyssey to wrest Egypt from the Porte (Turkish government), in his absence the agents of the Directory mercilessly victimized the satellite republics set up by the military commanders. Threatened again by all these acts, Austria, England, and Russia formed the Second Coalition (1798), to which the Porte, Naples, and Sardinia adhered. Though in the early months of 1799 the allies pushed back the French on several fronts and by mid-year republican defenses were crumbling, the allied victories were transitory. By early fall, when Bonaparte returned from his Egyptian fiasco, French victories had dispelled the military danger. France was secure against invasion and could negotiate for peace from strength.

The great majority of Frenchmen yearned for peace, but not Bonaparte. He needed a major military victory to consolidate the power he had seized by the coup d'etat of Brumaire in November 1799. He drew up plans for the campaign of 1800. Once again, as in 1796 and 1797, his spectacular victories in Italy were decisive. And again, as four years earlier, Austria asked for peace. Negotiations ended with the Treaty of Lunéville (February 1801). The salient terms of Campo Formio were reaffirmed. The piecemeal ousting of Austria from the Italian peninsula continued, but more important than its expulsion from the Duchy of Tuscany was the Habsburg recognition of the new Italian republics as sovereign powers.

The Treaty of Lunéville

Only England remained at war, and the English government had to yield to the insistent clamour for an end to the struggle. Peace talks were begun a month after Lunéville. The preliminaries of October 1801 were converted into the definitive Treaty of Amiens on March 27, 1802. The provisions were harsh. Egypt was restored to the Ottoman Empire. Both Malta, which went to the Knights of St. John, and the Cape of Good Hope were restored under conditions that made their future security precarious. Save for Ceylon and Trinidad, England restored its maritime conquests. Moreover, England tacitly accepted the main territorial changes on the Continent as they had been agreed upon at Lunéville. Amiens contained no provisions

for a favourable commercial treaty that would reopen the continental markets for English goods.

In the circumstances, a chorus of recrimination fell upon the government. England obtained, so it seemed, only what Bonaparte gave it: peace on his terms. After ten years of war England's great rival and competitor emerged as the most powerful state in Europe. "One may state without the slightest exaggeration," Talleyrand was to write later, "that at the time of the Peace of Amiens, France enjoyed abroad, thanks to its military supremacy, such power, glory, and influence that the most ambitious person could desire nothing more for his country." Bonaparte, however, desired more. (L.Ge.)

Napoleon in power: Lunéville to Tilsit. Neither the Treaty of Lunéville nor that of Amiens contained the seeds of a long-term peace—the first, because Napoleon gradually broke all its terms in the interests of French aggrandizement; the second, because both parties had signed it out of temporary exhaustion and did not regard it as satisfactory.

Consolidation and strengthening of French power

After Lunéville Napoleon, who became first consul for life in 1802 and emperor in 1804, lost no time in consolidating and strengthening French power, particularly in Germany and Italy. In February 1803 the Diet of Regensburg approved French plans for the reorganization of Germany, which led to the formal death of the Holy Roman Empire in 1806. This reorganization, to some extent made necessary by French expansion to the Rhine, led to the suppression of ecclesiastical states and to considerable gains by the more important lay princes. In the process, French patronage became the controlling influence in Germany. The United Provinces—now the Batavian Republic—was bound yet closer to France by late 1801. In 1802 the Cisalpine Republic became the Italian Republic, with Napoleon as its president. In 1802 Piedmont was also incorporated into France. In 1803 Napoleon mediated in a civil war in the Helvetic Republic (which then became Helvetia) and followed that action with a new constitution strengthening French influence there. Later in 1803 the French entered Hanover and took it under French protection. (Small wonder that the governments of other European countries felt that there was no predictable limit to the ambitions of the first consul.)

After Amiens Britain, although nominally at peace with France, found no basis of mutual trust for the future. Apart from Napoleon's continued aggression on the Continent, he was already imposing restrictions on British trade and, in 1803, was suspected of encouraging rebellion in Ireland. Napoleon complained that the British had not surrendered Alexandria or Malta (he was correct) and that Britain was sheltering and encouraging French émigrés. It was not therefore surprising that

the two powers found themselves at war again in May 1803.

The war against Britain, to Trafalgar. At this stage Britain had no allies and would have none for nearly two years. Hostilities with France on this one-to-one basis revealed more clearly than before the stalemate that could be reached in a situation in which a great land power was opposed to a great sea power with neither able seriously to oppose the other in its own element. Napoleon could assemble 100,000 men at Boulogne—a far larger and more experienced army than anything Britain could oppose him with—but had no way of getting his soldiers into action. The Royal Navy could prevent the French Army from crossing the English Channel but had no means of attempting, let along ensuring, the defeat of that force.

The British, first with Henry Addington and then (from May 1804) with William Pitt as prime minister, set about sweeping up the remaining French colonial possessions. St. Lucia, Tobago, and Guiana were taken in 1803 in the Western Hemisphere; in the same year French influence in India was further weakened by the defeat of its friends there. Then, beginning in mid-1804, Pitt began his attempts to divert and thus weaken Napoleon by rebuilding a continental coalition. In June 1804 he had reached an understanding with Russia that was converted into a formal alliance in April 1805. That August Austria joined again, and the Third Coalition was in being.

The Third Coalition

Meanwhile the war at sea continued. Napoleon attempted to stop Britain's trade with the Continent: he seized Cuxhaven for this purpose, only to meet with a British blockade of the mouths of the Elbe and Weser, which considerably damaged Napoleon's friend Prussia. The French also continued their attacks on British seaborne trade by means of privateers. The most important aspects of this war between France and Britain, however, were French preparations for an invasion of Britain by a cross-channel attack and Britain's blockade of the ports of France and her allies.

The naval defeats of the 1790s had not persuaded Napoleon against building new fleets. Nevertheless, his resources were decidedly inferior to those of the Royal Navy in all classes of vessels, and his own admirals preferred a defensive "fleet-in-being" strategy combined with occasional brief sorties. For Napoleon himself the chief hope lay in a possible invasion; during 1803–04 troops were assembled in the Boulogne area, together with 2,000 transports. His plans for invasion varied between one employing a heavily protected force and one conducted simply in small boats, on their own, while French squadrons provided diversions elsewhere and drew away the blockading British squadrons. The right combination of successful diversion, weather, and tide was never found. Napoleon had broken camp at Boulogne and begun a long march to the Danube against Austria seven weeks before Nelson won a great victory at Trafalgar.

For Britain the basic response to invasion was the blockade, both close and distant. British squadrons were spaced off major naval ports—from the Texel along the French and Spanish coasts off Brest, Ferrol, Cádiz, and Toulon—to prevent French and Spanish squadrons from putting to sea with supporting frigates for intercommunication. Because invasion of England or Ireland was the chief danger, it was established that squadrons would fall back to a position off Ushant if one or more powerful squadrons broke the blockade and thus threatened to act as an invasion escort. (Allowing for all the differences between warfare at sea and on land, this was not dissimilar to some important aspects of Napoleon's own strategy.) A constantly successful blockade, however, was too much to expect, and both Napoleon and the Royal Navy knew that. British forces had to be split into small squadrons. Long periods at sea meant ships would sometimes be absent for refitting without adequate replacements, and the uncertainties of the weather sometimes helped the blockaded. Once the French were at sea, the Royal Navy, despite all its precautions, was almost inevitably caught in some degree of uncertainty as to where the French would go.

On March 31, 1805, Adm. Pierre-Charles Villeneuve, commanding the French squadron in Toulon, evaded Nelson's blockade and broke out of the Mediterranean, heading for the West Indies. Meanwhile, the other major French squadron was blockaded in Brest. Nelson chased Villeneuve to the West Indies and back, while other Royal Navy squadrons swarmed in the Channel to prevent a French concentration that could be used to convey an invasion force. Villeneuve returned and took refuge in Cádiz; and Nelson, convinced that the French had plans for the Mediterranean, followed him there. On October 20 Villeneuve, who could not stay in Cádiz because he lacked supplies and facilities, left there and was caught by Nelson off Cape Trafalgar. The French had 33 ships of the line to 27 of the British; but the latter had a tactical plan, and Villeneuve lacked one. In the Battle of Trafalgar (October 21), 18 French ships were totally lost and the rest fought their last action. This was the last battlefleet action of these wars, and the danger of an invasion of England was ended.

End of the war at sea

The campaign against Austria, 1805. As a result of its defeat in 1800–01, Austria's influence in Germany had been greatly weakened. The old Holy Roman Empire in practice no longer existed, a fact recognized by Francis II himself when he was proclaimed emperor of Austria in August 1804. During this time Britain and Russia were drawing closer together; Alexander I of Russia broke off diplomatic relations with France in the autumn of 1804 and signed a treaty of alliance with Britain in 1805 designed to drive the French from northern Germany, Holland, Switzerland, and Naples. Austria, still weakened by the effects of past defeats, hung back. But, when Napoleon had himself crowned king of Italy in 1805 and then incorporated Genoa and the Ligurian Republic into France, Austria finally entered the Third Coalition with Britain and Russia in August of that year. Napoleon gave up his plans for invading England to deal with Austria and Russia. Writing to the French statesman Talleyrand on August 13, Napoleon announced,

> My course is settled. I shall raise my camps [*i.e.*, at Boulogne] . . . by 23rd September I shall be in Germany with 200,000 men, and have 23,000 men in Italy . . . I shall march on Vienna and compel Austria to sue for peace.

The campaign conformed very nearly to that forecast.

The army corps system

Napoleon was faced with three problems. First he had to keep the Austrian Army separated from the Russians and persuade it to fight on its own; he planned to advance from the Middle Rhine on Vienna, if possible cutting the Austrian line of communication with Vienna somewhere east of Ulm, thus catching the Austrian Army with an attack from its rear as he had done at Marengo. The second problem was to move 200,000 men across Europe from the Channel coast to the Middle Danube in the space of about six weeks and yet retain the ability to concentrate this vast army, if necessary within a day or two, at the critical time and place; he planned to make maximum use of the army corps system, the corps having become a unit of all arms, capable both of combining with other corps in a major battle and of operating on its own, even if only in a holding or defensive capacity, against a major enemy force. The final problem was that of provisioning so many men during so rapid an advance.

Regarding provisions, each corps had its own wagon train, and magazines were sometimes established at the most important towns en route. That provisioning system, however, did not always provide enough; if magazines were not available, French armies, using this blitzkrieg strategy, had to live off the land by requisitions. Each corps was allotted a requisition area strictly in relation to its prescribed line of advance. Commenting on this later, Napoleon wrote,

> We have marched without magazines; circumstances have forced us to do this; but although we have been continually victorious and found vegetables in the fields, we have nevertheless suffered a great deal, and, in a season when potatoes cannot be had from the fields a lack of magazines would lead us into the greatest misfortune.

Gen. Karl Mack, commanding the Austrian Army of about 85,000 men, played into Napoleon's hands. At the beginning of September he advanced westward through Bavaria toward Ulm without waiting for his Russian allies.

At Ulm he hoped to command the line of the Danube, with his front and right protected by the Black Forest. By this advance, however, he had greatly lengthened his line of communications; and, even as late as October 9, he was still separated from his Russian allies, who were at Linz, by nearly 200 miles (322 kilometres).

Austrian defeat

Meanwhile, Napoleon's advance guard crossed the Rhine on September 24, and his army advanced on the Danube from the north and west on its prescribed corps fronts. On October 6 his forces were in the area of Donauwörth-Neuberg and then crossed the Danube, leaving Gen. Michel Ney with 40,000 men to cover Austrian escape routes to the north. Napoleon then continued to envelop Mack in the south. Mack made two unsuccessful attempts to break out of the ring and then capitulated at Ulm on October 20 with 50,000 men. (If great victories consist of beating an enemy at a minimum cost in actual fighting, then Ulm was one of the greatest of Napoleon's victories.)

Austria was not yet completely defeated. On November 13, three weeks after Trafalgar, Napoleon entered Vienna; but he still faced a combination of Russians commanded by Gen. Mikhail Kutuzov and two Austrian armies from Italy and the Tirol. Moreover, Napoleon himself was now operating at the end of a long line of communications. Had the Allies waited—they were, after all, on their own ground—time would almost certainly have been on their side; but some of them, particularly Tsar Alexander, were impatient and chose to attack. On December 2 Napoleon routed them at Austerlitz, a battlefield victory even more complete than the victory at Ulm.

In the resulting Peace of Pressburg, signed at the end of 1805, Austria ceded its last Italian possession, Venetía (Venice), to France, gave the Tirol to Bavaria, and recognized the rulers of Bavaria and Württemberg as independent kings. Already cut off from the Rhineland, Austria was excluded from Italy and gravely weakened in southern Germany.

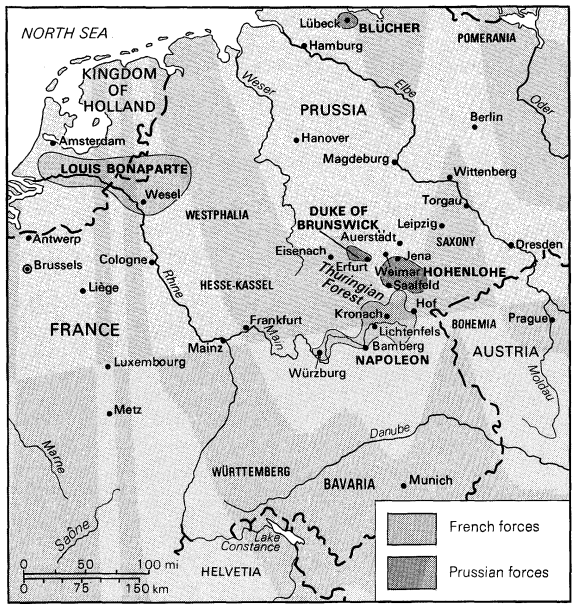
The campaigns against Prussia and Russia, 1806–07. During the 1805 campaign Prussia had been tempted to join the Allies; such a move might have threatened Napoleon's left flank as he moved along the Danube Valley and perhaps even have denied him victory. Frederick William III, however, delayed acting until after Austria had been defeated, thus weakening his position when he himself was attacked.

Throughout 1806, relations between France and Prussia steadily worsened. Despite his continued gestures of friendship toward Prussia, Napoleon appeared determined to weaken Prussian influence in northern Germany, and his independent negotiations with Britain over Hanover underlined this. Furthermore, after Austerlitz Napoleon kept the bulk of his army in Germany, stretched out along the line of the Main River; by October 1806 he had about 200,000 men on a line running from Lichtenfels through Bamberg to Würzburg. The Prussians regarded this troop concentration as a threatening gesture; Russia, too, was suspicious of Napoleon's intentions. On September 26, Frederick William III of Prussia sent an ultimatum to Napoleon demanding that the French withdraw west of the Rhine and agree to the formation of a north German confederacy under Prussian leadership. Napoleon rejected the ultimatum. On October 8 Prussia, in alliance with Russia, declared war on France.

The overall stategic situation was not unlike that in 1805. With promises of help from Russia and from Sweden and Britain too, there was much to be said for the Prussians staying on the defensive on the line of the Elbe and waiting until help arrived. The Elbe formed the great natural defense of Prussia against attack from the west, and the main passages across the river were guarded by the fortresses of Magdeburg, Wittenberg, Torgau, and Dresden, which also controlled the principal routes into Berlin and East Prussia. The one advantage of advancing west of the Elbe was that Saxony and Hesse-Kassel might join with Prussia if protected in this way but probably not otherwise. Indeed, Saxony could help Napoleon directly by offering him an unopposed passage of the Elbe at Dresden.

Prussian advance

In fact the Duke of Brunswick, in command of the Prussian army, advanced west across the Elbe, then divided his forces in two—the main part under his command concentrated in the area of Erfurt, the other part south of him, commanded by F.L. Hohenlohe-Ingelfingen and concentrated between Hof and Saalfeld in the Upper Saale Valley. These two forces were separated by the difficult terrain of the Thuringian Forest.



The location of troops on October 8, 1806.

Adapted from V. Esposito and J. Elting, *A Military History and Atlas of the Napoleonic Wars* (1964); Praeger Publishers

For Napoleon the possible routes from the Rhine into Prussia were either from Wesel across Westphalia and Hanover, from Frankfurt via Eisenach and Weimar to Leipzig, or from Frankfurt via Bamberg to the south of the Thuringian Forest and thence either by Leipzig or Dresden. He treated the first route, the most northerly, as cover against possible enemy retaliation, leaving a corps under E.A. Mortier to link up with a force under Louis Bonaparte, whom Napoleon had made king of Holland. This tactic meant that, with a northern escape route safe, he could risk his other lines of communication. He then planned his advance along the third route, telling Louis weeks in advance that he intended to be in position to attack the Prussians on October 12. He left Mainz on October 1, used magazines at Würzburg and Kronach on the way, and crossed the frontier of Saxony on October 8. His rapid deployment took the Prussians by surprise, and Hohenlohe promptly began to retreat northeastward toward the Elbe when contact was established on October 12, as Napoleon had predicted. On October 14 Napoleon overwhelmed Hohenlohe at Jena, while Louis-Nicolas Davout, sent round the flank to block a Prussian retreat, encountered the main Prussian force at Auerstädt and defeated them also. The battle had not gone quite in detail as Napoleon planned, but in general execution he had dictated the critical time and place and had made the Prussians conform to his own movements.

Prussian retreat followed. On October 25 Napoleon entered Berlin, and ten days later the Prussian rear guard under Gebhard Leberecht von Blücher capitulated at Lübeck. Prussian resistance was at an end. Russia, however, was still in the war; in November Napoleon invaded East Prussia and then Russian-controlled Poland, occupying Warsaw a week before Christmas. Marching still farther eastward, he met the Russian Army under Leonty Leontyevich Bennigsen at Eylau (February 8, 1807), fighting a bloody and indecisive battle. In mid-June, despite his long line of communications and his earlier losses, Napoleon routed Bennigsen at Friedland, driving the Russians back across the Niemen while he himself entered Königsberg.

The Treaty of Tilsit

The war was over, and peace was signed at the Treaty of Tilsit on July 9. This treaty really dealt with Prussia rather than Russia. Prussia lost all its territory west of the Elbe and the part of Poland it had gained most re-

cently. Its territory was thus halved and its army reduced to 40,000 men, one-fifth of its previous size. (Prussia lost more, at one blow, than any other of Napoleon's principal enemies.)

Russia emerged virtually unscathed from the 1806–07 campaign. Indeed, it became an ally of France, and the events of the next few years were, to some considerable extent, based upon this Franco-Russian alliance.

The Napoleonic coercion of Europe, 1807–11. With the signing of the Treaty of Tilsit, Napoleon found himself at the peak of his power. So long as he and Alexander I could agree and, in agreeing, coordinate their policies, Napoleon could anticipate a time when all continental Europe would lie under his control. The Continental System that he organized in detail was the most obvious expression of his power. The first signs of decline, however, coincided with the period of ostensibly greatest power. As the expansion of French power became increasingly identified with blatant imperialism, the seeds of nationalist revolt began to bear fruit—first in Spain and then in Austria—producing movements that, in the end, broke Napoleon's power. Moreover, the Continental System was too ambitious politically, administratively, and economically, and it weakened its creator as much as it strengthened him.

The peak of Napoleon's power

The Continental System. Trade war against Britain was not initiated by Napoleon. After war broke out between Britain and France in 1793, the republic did its best to exclude British goods from the areas under its control. The Directory stepped up measures against British trade and ordered the seizure of all vessels that put in at British ports and then sailed on to France. Moreover, the theoretical inspiration of this kind of warfare was similar both before and after Napoleon became first consul. A well-established mercantilist strain in French thinking on these matters held that the best way to defeat a major trading power such as Britain was to stifle or cut off its exports and thus reduce its stocks of gold; this view was itself based on the theory that gold, produced by a favourable balance of trade, was a vital indicator of national power. Napoleon based his Continental System on these theories. The difference between him and his predecessors was a practical one—his conquests and particularly his conquest of Prussia and subsequent agreement with Russia enabled him to apply such a policy on a genuinely continental scale. Although he was a radical in his approach to methods, he remained a conservative (some would say a reactionary) in his economic theories. Finally, after Trafalgar and even more so after Britain's seizure of the Danish fleet in 1807, Napoleon had no reasonable hope of resuming normal warfare at sea; and even the threat of his privateers was severely reduced in face of an increasingly effective convoy system carried out by the Royal Navy. To that extent and whatever Napoleon's original hopes of its success, the Continental System can be regarded as a method adopted for lack of something better.

The defeat of Prussia at Jena meant that Napoleon could control a long stretch of the Baltic coast. On November 21, 1806, Napoleon issued his Berlin Decree, which placed the British Isles in a state of blockade. This action meant that trade with Britain was prohibited and that all vessels coming to ports under French control directly from Britain or its colonies would be seized. With Russia adhering to the System and with Portugal and Spain coming under French control in 1808, Napoleon could well claim that he hoped to conquer the sea by the land. The government in London retaliated with a series of Orders in Council in 1807, the object of which was essentially to bring seaborne trade with Europe as far as possible under British control by allowing such trade in neutral ships to take place only by license. This neutral trade was considerable—in 1807 about 44 percent of all trade passing through British ports was in neutral ships, and these ships were to come under British direction as well as provide a useful source of income for the treasury through the issue of licenses.

The Berlin Decree

Napoleon's reply to the Orders in Council was to take his own system a stage further. By the Fontainebleau and Milan decrees of 1807, he ordered that all neutral ships conforming with the rules laid down by the Orders in Council should be treated as enemy ships and, where possible, seized. Thus, neutrals had either to risk detention by the British or confiscation by the French; and that dilemma applied particularly to U.S. vessels. A further Fontainebleau decree of October 1810 strengthened the law against contraband and also ordered the public burning of captured British manufactures. Other decrees that year were designed to tighten up Napoleon's own system of import and export licenses.

The restrictions imposed by the Continental System and by Britain's countermeasures had serious effects upon Britain and also upon France and its continental allies and satellites. During 1808 there was a considerable drop in British exports—a fall of about 10 percent from 1806. Cotton and grain imports were also affected, leading to shortages, high prices, and unemployment. The shortage of timber hit hard at both naval and merchant shipbuilding. There was an improvement from Britain's point of view in 1809, when Portugal, Spain, and Spain's colonies escaped from French control and when the Ottoman Empire signed an agreement with Britain.

But 1811 was the most critical year of all for Britain. Its Baltic trade suffered a severe blow when Sweden was included in Napoleon's System. In that year exports to northern Europe were only one-fifth of the previous year's total, and exports to the United States were down by a quarter. Overall, British exports dropped by about a third. The trade crisis was worsened by a monetary crisis in which the pound depreciated and reserves dropped dangerously low. Many Britons talked of peace at any price; had Napoleon—who had recently agreed to the export of French grain to Britain partly to placate French farmers and partly in pursuit of his mercantilist theories—chosen to deny wheat exports to Britain at this point, hunger riots might have tipped the scale in forcing the British to make peace.

While it did produce these undoubtedly serious effects, the Continental System failed in its prime objective of defeating Britain by crippling its trade and thus ruining its credit. Napoleon's unsuccessful attack on Russia in 1812 meant that the sizable cracks in the System that had already appeared in Europe became great holes. This situation helped offset some of the effects of the outbreak of war in that year between Britain and the United States, itself a result partly of disputes about the freedom of the seas. Behind these important ups and downs of fortune, however, lay one constant factor—Britain's command of the sea. As the U.S. naval historian Alfred Thayer Mahan has pointed out, Napoleon was bound to lose a trade war against a country that, because of its vast navy and mercantile marine, could offset losses in one area of the world by opening up opportunities elsewhere. And that is precisely what Britain did. Its national debt grew enormously; but basic prosperity was founded upon increasing industrial production and trade, and Britain emerged from the war much wealthier and stronger than it had entered it.

Failure of the Continental System

The effects of the Continental System upon France itself were more generally damaging. Napoleon faced two problems. The first was how to make his allies and satellites continue to accept restrictions that were often harmful to them; in the end resentment about the System helped to turn allies into enemies. The second problem was in France, where his situation was equally difficult. It is true that he was always willing, perhaps wisely in a political sense, to sacrifice the interests of his European allies to those of France itself. This favouritism came out quite clearly in licenses granted much more freely to French traders. This preference, however, made little difference to French trade in the long run. At first some French traders welcomed the advantage conferred by the removal of British competition; but France, like other European countries, needed markets and colonial raw materials such as cotton and sugar. Customs receipts and exports fell drastically. Gradually Napoleon lost the support of the middle class, who had gained so much from the Revolution and on whose efficiency and loyalty Napoleon himself depended. Ersatz industries were an adventurous experiment, and some came to stay. By and large, however, the Continental System undermined—or certainly was thought to

undermine—prosperity, and Napoleon could not afford that.

Austrian opportunity for revenge

Austria's war of liberation, 1809. Angered by the terms imposed upon Austria after Ulm and Austerlitz and offended even more by Napoleon's further aggrandizement after the defeat of Prussia, the emperor Francis of Austria and his advisers thought they saw an opportunity for revenge in 1809. The French Army was heavily committed in Spain; and there was rising discontent in Germany, as elsewhere, from the effects of the Continental System. Moreover, the Austrian government had carried out reforms in the army after 1806 and had a military-reserve system by 1808. The tide of public opinion was moving against Napoleon; and, although there was no strong German nationalism evident in Austria or elsewhere at that stage, there was much local patriotism—for example, in the Tirol.

Napoleon was aware of events in Austria and had carefully made his plans by assuring himself of Russia's neutrality. Prussia could safely be ignored for the time being. Moreover, although he spent the winter of 1808–09 in Spain, Napoleon was back in Paris before Austria declared war on France in April 1809. By calling up 150,000 conscripts, he had 300,000 men at his command for operations in central Europe, in addition to the troops committed in Spain.

The Austrian plan was to attack the French in Italy and Dalmatia; to advance into Poland, forestalling help from Russia and the Grand Duchy of Warsaw; and to advance westward along the Danube Valley to drive back the French concentrated at Regensburg and Augsburg before Napoleon could cross the Rhine and come to their aid. The archduke Charles, in command of this last Austrian army, was much too dilatory and allowed Napoleon to join up with Davout's forward army corps. By mid-April Napoleon had concentrated his forces and advanced toward Vienna, defeating the Archduke at Eckmühl on April 22. The Archduke was forced north of the Danube, and Napoleon entered Vienna on May 13.

The Austrians remained strong both north of the Danube and farther south in the Tirol. Napoleon concentrated his attention on the archduke Charles and his army north of the Danube. On May 20 Napoleon crossed the river by the island of Lobau, and a battle took place at Essling-Aspern on May 21–22 in which, though not completely defeated, Napoleon was mauled seriously enough to retrace his steps across the river. He then fortified his position and, in early July, was reinforced by the army of Eugène de Beauharnais, which had come up from the south. On July 5 Napoleon crossed the Danube again with an army of more than 150,000 men and the next day defeated the archduke Charles at Wagram. An armistice was signed a few days later.

By the Peace of Schönbrunn (October 1809) Austria was yet further humiliated. It lost its Illyrian provinces and ceded much of Upper Austria to Bavaria and most of western Galicia to the Grand Duchy of Warsaw. Its efforts, however, had not been in vain; French troops were withdrawn from Spain. Moreover, Napoleon's greed in taking more Austrian territory for his satellites offended his friends as well as his enemies.

The Spanish rising and the Peninsular Campaign. A more prolonged and in many ways very different campaign was meanwhile going on in Spain and Portugal. Spain had been entirely subservient to French policies since 1796; and, although there was a flicker of resistance during the campaign against Prussia, the French victory at Jena brought Spain once more to heel. By then Napoleon was intent on compelling all Europe to accept the Continental System, and Portugal, for so long the ally of England, was an obvious gap in the System. By the Treaty of Fontainebleau of 1807, the Spanish government agreed that French troops could cross Spain on their way to conquer Portugal, and in November the French entered Lisbon. These policies led to deep differences in Spain. In May 1808 the king, Charles IV, abdicated, and in June Napoleon appointed his own brother Joseph as king of Spain. There had already been a popular rising against the French at Aranjuez in March 1808, and the events of that summer spread the flames of insurrection against what was regarded as French tyranny. A national rising against France was the result.

War in Spain

The importance of war in Spain was twofold. Politically it was the clearest indication to date of nationalist resistance to Napoleonic domination, even though it was not a national movement inspired by liberalism. Militarily, it afforded Britain an opportunity to undertake land operations on the mainland of Europe that, at last, were significant in relation to the operations of its allies. For the first time sea power was directly related to land power. The Iberian Peninsula was easy for Britain to get to and to use, and it was difficult for Napoleon to defend. The logistic and military basis of Britain's whole operation was Portugal, which offered a first-rate entry, via the Tagus and Lisbon, and a sound defensive position.

Napoleon himself took command in Spain late in 1808 and very nearly caught a British force before it managed to escape via Coruña. Early in 1809, however, he returned to Paris. In April 1809 Sir Arthur Wellesley (later the duke of Wellington) landed at Lisbon and took command of all British and Portuguese forces there; he had come carefully prepared and had already formed some views about the best ways to fight the hitherto invincible armies of Napoleon.

At a tactical level, Wellesley believed in the value of highly disciplined firepower delivered by an infantry line protected, wherever possible, by natural features or by such man-made features as walls; and he also believed in the importance of light infantry. Secondly, Wellesley was determined to establish an efficient supply system within his army so that it became independent, as far as possible, of army requisitions and could thus move or stay in its positions as the military situation demanded. He abhorred the French system of living off the land, and he considered that it forced the French to move when often they would have served their military purposes better by staying in position. Thirdly, he developed a highly efficient staff system, all the more necessary in a campaign with frequently divided forces; and his staff gave him, among other things, an invaluable series of maps that enabled him to move in difficult country with certainty and speed.

Wellesley's strategy

Wellesley's strategy was to use Portugal as his base, with its land frontier defended by a number of great fortresses and with a final defensive area behind the lines of Torres Vedras around Lisbon. The sea was his chief line of supply. In 1809 Wellesley (Viscount Wellington from September 1809) had some early success, driving the French from Portugal and in July defeating them at Talavera; but by the autumn he was back behind the Portuguese frontier.

In 1810, with Austria defeated at Wagram, Napoleon sent reinforcements to Spain; and the positions were reversed. By that autumn the French had captured the Portuguese frontier fortresses and then occupied all of Portugal except the area behind the lines of Torres Vedras.

From then on, Wellington was more certain of his own strength and of enemy weaknesses. In 1811 he began the process of recovering Portugal and, principally, its frontier fortresses. In May he defeated André Masséna at Fuentes d'Onoro and captured Almeida—the first in a series of defeats suffered by the French. In 1812 he captured Ciudad Rodrigo and Badajoz before the end of April, and, in July, he routed the French at Salamanca, going on to enter Madrid in August, thus compelling French forces to withdraw from southern Spain. In the autumn of 1812, however, Wellington ran into strong French resistance as he tried to capture Burgos, and once more he withdrew to winter quarters in Portugal. In 1813 he advanced again, defeated the French at Vitoria, forced them to evacuate central Spain, and began an invasion of southern France across the Pyrenees; by the end of the year he was threatening Bayonne, and in February 1814 he captured Bordeaux. The Peninsular Campaign was now complete. Wellington's advance had been fused into the general Allied attack on France that was to bring about Napoleon's first abdication.

The defeat of Napoleon, 1812–15. Although the Treaty of Tilsit had been, ostensibly, a Franco-Russian alliance and although Alexander I had refrained from embarrass-

Causes of Franco-Russian disagreement

ing Napoleon in the difficult situation of 1809, there were increasing causes of tension between Napoleon and the Tsar. Alexander was anxious to extend Russian influence southward through the Balkans, and Napoleon wanted to prevent that influence from reaching the Mediterranean. Napoleon had created the Grand Duchy of Warsaw, and Alexander was suspicious of French influence so close at hand, particularly if Napoleon had it in mind to re-establish the old Kingdom of Poland. Finally, the working of the Continental System produced as much discontent in Russia and in areas of Russian influence as it did elsewhere.

The Russian Campaign, 1812. These general causes of disagreement partly came to a head in 1810–11. In February 1811 Napoleon seized the Hanse towns and the lands of the Tsar's brother-in-law—the Duke of Oldenburg. That May, when a Frenchman, Jean Bernadotte, became crown prince of Sweden, it seemed to Alexander a French step toward encircling him—although, in fact, Bernadotte proved no friend to Napoleon. In January 1812 Napoleon issued a list of grievances against Russia to his German allies, and in April Alexander presented an ultimatum to Napoleon demanding French evacuation of Prussia, compensation for Oldenburg, and virtually the creation of a neutral zone between the two power blocs. In May, Russia concluded a treaty with the Ottoman Empire and thus freed itself from trouble in the Balkans. In July 1812 a treaty of alliance was signed among Sweden, Russia, and Great Britain.

Meanwhile, Napoleon had already decided that he would invade Russia in June, and he concentrated a vast army of about 600,000 men in the Grand Duchy of Warsaw, drawing heavily on troops from allies and satellites. About 450,000 men actually crossed the Niemen River at the beginning of the campaign and were opposed by fewer than half that number in the Russian forces.

Napoleon had the choice of three good roads leading from west to east and toward Moscow—from Kovno via Vilna, Vitebsk, and Smolensk; from Grodno via Minsk and so to Vitebsk; and from Brest-Litovsk via Kiev to Smolensk. He decided to take the first, the most northerly route, using the Grand Duchy of Warsaw as his strategic base and with his lines of communication lying back through what he thought were friendly areas of Poland and Prussia. His strategic approach, after assembling his armies behind the line of the Vistula from Warsaw to the coast, was to use his right flank as a defense and to attack on his left flank from Kovno eastward with his largest army under his own command.

The Russian forces were deployed in two armies. The larger of the two, commanded by Mikhail Barclay de Tolly, was along the line of the Niemen north of the Pinsk Marshes (*i.e.,* on the right, or north, flank) and comprised about 135,000 men. The Russian left-flank army, commanded by Pyotr Ivanovich Bagration, was to the south of the Pinsk Marshes in Volynia and had a smaller force of about 50,000 men. From the start, the Russian commanders were well aware of the risk of separation and envelopment and were determined on a strategy of withdrawal upon converging lines. Writing to the King of Prussia months before the campaign began, the Tsar said,

Russian strategy

> The system which has made Wellington victorious in Spain, and exhausted the French armies, is what I intend to follow—avoid pitched battles and organise long lines of communication for retreat, leading to entrenched camps.

Quite apart from avoiding the risk of defeat on the battlefield, such a strategy was bound to impose a heavy strain on Napoleon's forces in their search for food and fodder and in a constantly lengthening communications system in an enemy country. (When Clausewitz wrote some years later that one of the main strategic advantages of the defensive was the ability to make use of the goodwill of the local population, he almost certainly had this particular campaign in mind.)

Two further points of general strategic importance can be made. First, the roads in areas in which Napoleon planned to operate were mostly of poor quality and distinctly inferior in standard to the road systems of western and central Europe. Second, it was normally possible to continue campaigning in western Europe until late in the year without serious inconvenience, but, in Russian winter conditions, victory consisted of survival rather than of defeating the enemy forces; and in the search for survival Napoleon's troops were at a great disadvantage.

On June 24–25 the entire French left wing crossed the Niemen at Kovno almost unopposed. Napoleon expected soon to be behind Barclay, but, when he arrived at Vilna on June 28, he found that Barclay had moved eastward and escaped the net. Moreover and despite the summer weather, logistic problems were already retarding the speed of Napoleon's movement. Although continuing his advance against Barclay, Napoleon turned his attention southward to Bagration, wrongly supposing that the latter was retreating in a northeasterly direction and planning to prevent the two Russian armies from uniting in the area east of Vilna. But Bagration had gone southeastward instead via Minsk, thus escaping in his turn. Moving again to the north, Napoleon tried to encircle Barclay both at Vitebsk in late July and at Smolensk in mid-August. On both occasions the Russians slipped out of the net again and retreated toward Moscow.

By then the French advance was running into serious supply difficulties, which robbed Napoleon of mobility and imposed on him a blunt frontal attack strategy in place of envelopment. After a bloody action at Borodino on September 7, the Russians continued their retreat; and the pursuing French at last reached Moscow in mid-September. There they found the city devastated by fire but showing no sign of capitulation. After a month in Moscow, Napoleon himself began to retreat, and, although he was at no time defeated by the Russians, he was forced, by the fact that they followed fast on his heels and preyed on his flanks, to follow the route by which he had earlier advanced, but now substantially denuded of supplies. This fact and the severe weather conditions took their toll. Napoleon reached Smolensk on November 8 and crossed the Beresina on the 17th. On December 5, hearing rumours of a conspiracy against him in Paris, Napoleon left his army and made for home. That army was now experiencing the Russian winter; by the time it reached and crossed the Niemen in mid-December, the temperature was −30° F (−35° C), and only about 30,000 men had survived out of the 600,000 Napoleon had so hopefully assembled the previous summer. At the Niemen the Russian pursuit stopped, and the remaining French forces continued their wretched withdrawal unopposed.

The French in Moscow

Napoleon's military power was not annihilated, as the campaigns of 1813–14 were to demonstrate. But he had lost invaluable troops; his reputation was at last open to question; and his enemies had been given a morale boost that it would take many French victories to destroy. The Russian Campaign was the real turning point in Europe's wars against France.

The campaigns of 1813–14 and Napoleon's surrender. Napoleon's prospects were not hopeless in the spring of 1813. Opinion in Prussia was still divided about the advisability of declaring war on France. Russia itself had suffered severely during the 1812 campaign, and many influential Russians argued that, their country once made safe, there was no point in fighting to save the rest of Europe. Austrian attitudes were equivocal; Metternich showed no eagerness to join a crusade against France and seems, in some ways, to have preferred the prospect of a negotiated peace leaving Napoleon in power as emperor. (After all, Napoleon was by then married to an Austrian princess—the archduchess Marie-Louise.) Russia and Prussia did, however, conclude the Treaty of Kalisch in February 1813, which was a treaty of alliance against France. During March 1813 the French forces in Prussia were driven back westward, and by mid-March they were back on the line of the Elbe. Meanwhile, Sweden had joined the Allies.

Napoleon's choices, although not entirely clear, were by no means unpromising. His opponents were divided in their political aims, as they later demonstrated at the Congress of Vienna (1814–15). He might have negotiated with them separately, thus dividing them and achieving at least a compromise peace for himself; or he could have

Napoleon's choices in 1813

cut his losses in Spain and restricted his fighting to the area east of the Rhine. But he was unwilling to accept the limitations implicit in such choices, and he chose instead to attempt everything without negotiation.

The campaign of 1813 consisted of two parts. The first part began when Napoleon arrived on the line of the Elbe on April 28. He had by then called up the conscripts of the classes of 1813 and 1814 and had 150,000 men at his disposal in Germany. He wanted to cross the Elbe again, strike at the heart of Prussia before it was fully ready for war, and, by threatening the Russian line of communications, draw both Prussian and Russian armies away from Austria, whose neutrality might thus be maintained. One way to do this was to advance directly on Leipzig and Dresden, compelling his enemies to accept battle or withdraw beyond the Elbe. An outright victory was an essential part of this strategy and was necessary to keep Austria and the states in the Confederation of the Rhine friendly toward France; but that victory was denied to Napoleon. Two inconclusive battles took place—the first at Lützen, southeast of Leipzig, on May 2, in which the Allies were worsted but withdrew in good order; the second at Bautzen on May 20–21, with much the same result. But Napoleon had accepted heavy losses in these battles, and he was at that point much less able to accept them than were the Allies. Further, he signed an armistice with Prussia and Russia at Pläswitz on June 4, which lasted until August 20; this, too, was more helpful to his enemies than to himself—it gave time for Prussia to mobilize its reserves and for Austria to decide to join the Allies—and, when the armistice ended, Napoleon was relatively worse off than when it had begun.

In the second part of the campaign of 1813 the Allies put three armies into the field, comprising some 600,000 men, against whom Napoleon mustered 400,000. The Allies planned to converge from Prussia and Silesia upon Dresden; as on previous occasions, Napoleon's plan was to engage and defeat them separately. A number of distinct but related battles followed. On August 26 and 27 an Austrian army was defeated at Dresden, but on August 30 and then on September 6 the French were defeated, first at Kulm and then at Dennewitz. For Napoleon these defeats were more important than the earlier victory because the Allies continued to threaten him, gaining relatively in strength all the time. During the first part of October the Allies converged on Leipzig, where the Battle of the Nations (October 16–19) took place. By then Bavaria had joined the Allied cause, and Napoleon found himself fighting with an army of 160,000 against combined enemies who could bring against him double that number. Moreover, his enemies knew the danger of accepting battle separately and the need to maintain contact with each other.

Retreat to France

At first Napoleon held his own. But on October 18 the Saxon forces went over to the Allies and on October 19 Napoleon was forced to retreat toward France, defeating a Bavarian force at Hanau on October 30. On November 2 Napoleon's army fell back across the Rhine at Mainz with fewer than 80,000 of the men with whom he had begun the campaign. By then virtually deprived of allies, this campaign was a blow, added to the disaster of 1812, from which Napoleon could hardly hope to recover.

Yet the Allies themselves were still not set upon the overthrow of Napoleon. In November 1813 they offered him peace if France surrendered all its conquests beyond the Rhine, the Alps, and the Pyrenees. As Napoleon knew, however, there were some among the Allies who advocated harsher terms; the British, for example, were anxious to achieve the independence of French-held Dutch and Belgian regions, and that entailed further French concessions. In the end, between Allied differences of view and Napoleon's own doubts about the possibility of continuing in power on such terms, the Allies failed to provide a basis for peace, and they determined to invade France in 1814.

The campaign of 1814, like that of the previous year, was divided into two parts. The Allies planned to move into France from the north via Dutch and Belgian territory, across the Middle Rhine in the area of Mainz and from Switzerland around the Jura Mountains—an overall plan similar to the one they would adopt in 1815. Napoleon, fighting with numerically inferior forces, decided to tackle the Allied armies separately. In the first part of the campaign (late January and February 1814) Napoleon inflicted heavy defeats on the Prussian and Austrian armies advancing from the Middle and Upper Rhine. The Allies appeared to be breaking up at this stage until more determined counsels prevailed. On March 1 Prussia, Russia, Austria, and Great Britain signed a new alliance committing themselves to war and to peace terms only on conditions agreed to by them all.

Napoleon's abdication and exile

The Allies were then set on attacking Paris, and the second stage of the campaign began. Napoleon hoped to draw them off by moving into Lorraine and thus threatening their line of communication, while Paris accepted siege and resisted. The Allies, however, were not diverted by this threat, despite minor local reverses. Moreover, they were by now aware of Napoleon's plan, having captured some of his dispatches; and they also knew that many in Paris were anxious for peace. On March 30 the Allied armies reached the Paris suburbs, and resistance there soon ceased. On April 6 Napoleon abdicated and was soon on his way to exile on the island of Elba, while Louis XVIII returned to Paris as king on May 3.

Meanwhile, the Allies settled down to the task of resettling Europe after the long wars; they were still arguing the details when they found themselves at war with Napoleon again.

The Waterloo Campaign. On February 26, 1815, Napoleon escaped from Elba; he landed on the mainland of France near Antibes on March 1. He set out for Paris via the Dauphiné and on March 7 entered Grenoble without any opposition. With towns and garrisons welcoming Napoleon in what proved to be a triumphal journey, Louis XVIII left Paris on March 19; Napoleon entered the capital the next day. A week before that, the representatives of the Allies at Vienna declared Napoleon an outlaw, describing him as "the enemy and disturber of the peace of the world." The three eastern monarchies—Russia, Prussia, and Austria—together with Great Britain, made a new defensive alliance against Napoleon (only a few weeks before, those same powers had been acting more like enemies than friends in their attempts to settle the affairs of Europe), and each undertook to supply 150,000 men for the armies of the alliance and to keep them in the field until Napoleon was finally defeated.

After the failure of some diplomatic manoeuvres designed to detach Britain and Austria from the alliance, Napoleon realized that there was no alternative to fighting; and he prepared himself for an offensive campaign. First, however, he had to raise armies and equip them. There were many veterans of the Prussian and Italian campaigns in France, a large number of them already committed to serving Louis XVIII, and Napoleon found no difficulty in winning them back to his cause. Conscription of new recruits was politically dangerous; and, if Napoleon planned an early offensive, new recruits could hardly be trained in time anyway. So the existing regulars were supplemented by recalling all undischarged soldiers and those who had deserted since April 1814. Thus expanded, Napoleon's army for the 1815 campaign totalled about 250,000, of whom roughly half were available for his striking force and the rest for frontier and garrison duty. In fact, Napoleon did call up the class of 1815 at the end of May, and during June about 50,000 of them were in barracks; but they played no part in the Waterloo Campaign.

The Allied Coalition

The Allied Coalition—the seventh formed against France between 1792 and 1815—planned to raise five armies. An Anglo-Dutch army of 90,000 men commanded by Wellington and a Prussian army of 120,000 commanded by Gebhard Leberecht von Blücher were to operate from the Brussels region into France; an Austrian army of 225,000 men commanded by Karl Philipp zu Schwarzenberg was to operate on the Upper and Middle Rhine; a Russian army of 170,000 men under Barclay de Tolly was to form a strategic reserve; and, finally, an Austro-Italian army of 60,000 commanded by Johann Maria Frimont was to operate from northern Italy. The Allies planned a concentric advance on Paris beginning in late June. Early in April, Wellington left Vienna on his way to Brussels; he

met Blücher at Tirlemont on May 3. These two did not expect Napoleon to take the offensive against them but agreed that, if he should do so, they would concentrate on the line between Quatre-Bras and Sombreffe. Accordingly, Blücher moved his headquarters from Liège to Namur, and Wellington established his headquarters at Brussels.

Napoleon's plans, as seen above, were basically offensive. He wanted to meet and defeat some of his enemies before the others were ready and then to go on to deal with them piecemeal while they were still concentrating. The enemy armies posing the most immediate threat were those of Wellington and Blücher. Napoleon therefore decided to attack the combined Prussian and Anglo-Dutch forces himself, in command of the Army of the North, 125,000 strong. Leaving generals Jean Rapp and Louis-Gabriel Suchet on the defensive along the Rhine and opposite the approaches from Switzerland and Italy, Napoleon's approach in the theatre he was directly concerned with was in principle similar to his first great campaign in northern Italy in 1796. He faced an enemy stronger than himself but composed of two armies converging on a common line of advance into France. If those two armies could be attacked at their "hinge" (*i.e.*, where their lines of advance converged and joined) and all the more so if they could be attacked separately, they might be prevented from combining and even be driven back upon their divergent lines of communication. Wellington's line ran back through Brussels to Antwerp; Blücher's, via Namur, Liège, and Cologne. Napoleon's aim, therefore, was to advance from Paris to Charleroi and there force himself between the two enemy armies. If they could both be defeated, he would turn back southeastward, join Rapp opposing Schwarzenberg, and then deal with the latter. This strategy was an adventurous approach because Napoleon had few of his old marshals with him, training time had been short, and many of his senior officers were strangers to the men they led.

On June 3 Napoleon ordered the Army of the North to concentrate in the area Maubeuge-Avesnes, about 25 miles (40 kilometres) southwest of Charleroi. On June 14 he moved his own headquarters to the Charleroi area, with Wellington and Blücher still unaware of what the French were doing. By nightfall on June 15, Napoleon's forces were disposed in such a way that they could manoeuvre against either enemy as circumstances dictated. Wellington, in fact, had unintentionally helped—fearing that Napoleon might outflank him on the right and so cut off his line of retreat to Antwerp and the sea, Wellington detached a corps to cover the roads leading from Mons and Ath to Brussels, thus moving his centre of gravity eastward and away from Blücher.

Napoleon's mistakes

Instructing Michel Ney, on the left, to occupy Quatre Bras and thus block Wellington from using the Nivelles–Namur road, Napoleon attacked the Prussians at Ligny, on the Allied left or eastern flank, on June 16. The purpose of this operation was to drive Blücher back eastward and northeastward away from Wellington, and Napoleon counted on support from Ney to reinforce his own left wing to make this possible. The Battle of Ligny was indecisive: the Prussians were, indeed, driven back, but Ney failed to understand Napoleon's strategic plans and did not send the help that might have turned the Prussian retreat into a rout. The next mistake was Napoleon's. He had assumed that, once forced back, Blücher would retreat roughly northeastward via Namur and so move away from Wellington. The Prussian commander, however, was aware of the vital need to maintain contact with Wellington and chose, therefore, to retreat northward in the direction of Wavre. Marshal Emmanuel de Grouchy, who had been instructed to pursue the Prussians, thus took the wrong road; and Napoleon realized too late that his assumption was incorrect.

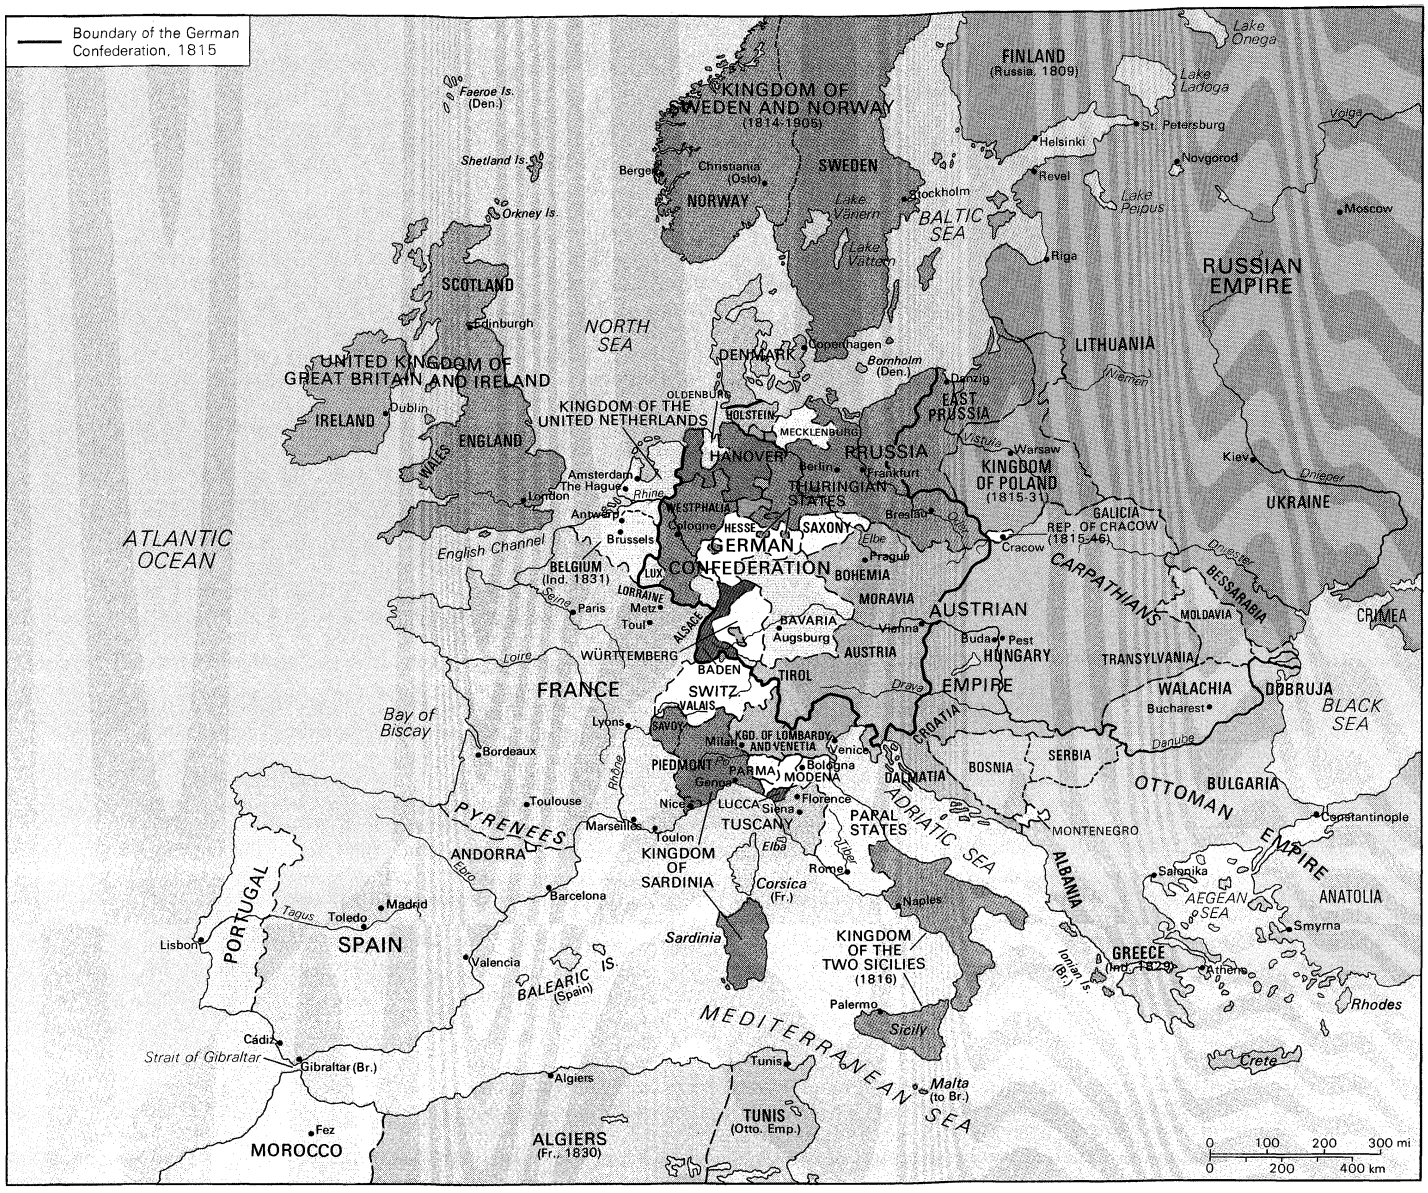
The third mistake was also Napoleon's. The essence of his earlier strategy in such a situation was to act more quickly than his enemies and, by gaining even a few hours, to deny them time to settle down and recover. This time Napoleon's conduct of operations fell below his own best standards. The night of June 16 and the morning of June 17 were wasted. When at last Napoleon began to move toward his left at about noon on June 17—a move designed to attack and defeat Wellington—the latter was already well aware of Napoleon's plans and had been given time to draw his army up in a strong defensive position just south of Waterloo. Moreover, Napoleon's march, already begun late, was further hampered by heavy rain. As a result, when the Battle of Waterloo was fought on June 18 all element of surprise had been lost. And by the early evening on the 17th Blücher kept his promise to Wellington and appeared on the battlefield with invaluable reinforcements, turning the scales against Napoleon at the critical time. Waterloo was Napoleon's last battle.

Up to the morning of June 16 Napoleon's preparations for the Ligny–Waterloo Campaign suggested that his military genius was unimpaired. He moved faster than his opponents, and, as far as it lay in his power, he laid the foundations of victory. It was in his conduct of operations from the evening of the 16th until midday on the 17th that he failed.

After Waterloo, Napoleon retreated southward, and on June 21 he entered Paris. The next day he abdicated. A fortnight later Wellington and Blücher also entered Paris, bringing Louis XVIII back with them; 23 years of war were ended. (N.H.G.)

The peoples and states of Europe that had experienced the events of the French Revolutionary and Napoleonic era, however, would never be the same again. In 1806 the Holy Roman Empire had been destroyed, never to be restored. The multitude of little German states, pounded by Napoleon's conquests, grouped into new formations. Prussia had undergone drastic reorganization and emerged with new prestige and strength. Through the legal codes and administrative systems that Napoleon had introduced into conquered territories, new ideas and standards of government had become familiar and popular. Even the revolutionary ideals of popular sovereignty and national rights had been spread by his conquests, and his harsh rule had stirred a new spirit of national solidarity and resentment.

Napoleon's despotism was in many respects paternalist and reminiscent of the prerevolutionary benevolent despots. He patronized the arts and encouraged scientific research. He carried out schemes of public works and rationalized civil administration. In other ways he foreshadowed the tyrants of the 20th century, for he governed through a police state, censorship, manipulated elections, and plebiscites. The extent of his conquests was due in part to his genius for war and diplomacy but in part



Europe after the Congress of Vienna.

also to the selfish quarrelsomeness and ambitions of his adversaries. Prussia sought gains at the expense of Austria, Russia at the expense of Turkey and Poland, while Great Britain expanded its commercial empire and its sea power. Only experience of repeated separate defeats forced the powers into coalition against him. But in the end he was defeated by the professonal armies of the major powers. It was the old-time dynastic monarchs of Europe who assembled as the victors to reconstruct a shattered Europe. Yet it was a new Europe, seething with new ideas and beset with new needs, that confronted the peacemakers of Vienna in 1815.

The Restoration. A quarter-century of revolutionary ferment and recurrent warfare not only made reconstruction and restoration very difficult: it foredoomed to failure any such labours that did not recognize the extent of the transformation these upheavals had brought about. The generation after Waterloo was one of peace between the powers; to that extent the Vienna settlement succeeded. It was also one of restlessness and revolt within most states and of deep social conflicts; this was the irrepressible aftermath of the events of 1789–1815. These internal disturbances in turn affected relations between the powers and brought about the downfall of the "congress system" by which the peacemakers hoped to preserve the peace. Though there was no war between the major powers until the Crimean War, peace was bought at the price first of general repression and the subordination to Austria of the German Confederation, then of periodic crises and realignments of the powers.

The Congress of Vienna

The Treaty of Paris of November 1815 pushed back French power to the frontiers of 1790 and exacted a large indemnity. The Treaty of Vienna of June 1815 was agreed to, in effect, by the representaives of the five major powers at the Congress of Vienna: the tsar Alexander I of Russia; Metternich, the chancellor of Austria; Karl August von Hardenberg, acting for the king of Prussia; Lord Castlereagh for Great Britain; and Talleyrand, the wily spokesman of France. In the general Congress nearly every European state was represented, and its purpose was a general settlement of European affairs.

The guiding principles were to prevent a recurrence of French aggression, to restore territories as far as possible to their legitimist rulers, and to establish a balance of power between the major states. To these ends territories were allocated among the powers regardless of the wishes of their inhabitants. Belgium and Holland were combined into the Kingdom of The Netherlands, as a buffer state against France. Norway was transferred from Denmark to Sweden. The Palatinate on the left bank of the Rhine went to Bavaria. The German provinces of Saxony, Westphalia, and the Rhineland as well as the Polish provinces of Poz-

nan (Posen) and Pomorze and the remainder of Swedish Pomerania, went to Prussia. Germany was formed into a German Confederation of states dominated by Austria, which also took Lombardy and Venetia. Poland again disappeared from the map as an independent state. Russia and Great Britain kept their conquests: Britain thus gaining Malta and Heligoland, the Dutch colonies at the Cape, Ceylon, and Mauritius, Russia obtaining Finland, the major part of Poland, and Bessarabia.

The spoils having been divided on a nice calculation of mutual gains and a judicious balance of power, the settlement was to be preserved by periodic meetings of the major powers to discuss any unsettling issues that might arise. By the terms of the Quadruple Alliance, Great Britain, Prussia, Austria, and Russia pledged themselves to maintain, by force, the terms of the settlement for a period of 20 years. But the concert of Europe, to be conducted at periodic congresses, soon broke down. Britain differed fundamentally from its allies about their readiness to intervene in the internal affairs of other states (even of France) in order to keep the settlement intact. At the Congress of Aix-la-Chapelle in 1818 and again at the Congress of Troppau in 1820, Britain refused to take part in the policing of Europe. This main task fell on Austria, which accepted it willingly enough, and Metternich established his famous system of espionage and repression for dealing with any signs of agitation or insurrection.

The greatest weakness of the Restoration was that it was wedded to dynastic principles at a time when all the main forces of change were opposed to dynasticism. In France Louis XVIII issued a charter of rights and set up a limited parliamentary regime. Patently owing his restoration to the allies and arousing more apprehension than loyalty in his subjects, he survived by treading warily and restraining the extremists. Other restored monarchs, less shrewd than he, such as Ferdinand VII of Spain and his uncle Ferdinand I of Naples and Sicily, stored up trouble for themselves or their successors by policies of vindictiveness and blind reaction. Napoleon, by his own upstart dynasticism, which led him to put members of his own family on the thrones of conquered countries and to marry, in 1810, a Habsburg archduchess, had done as much as the Revolutionaries to discredit dynastic monarchy and destroy its mystique.

Revival of church power

The Restoration brought back the church as well as the monarchy, for the alliance between altar and throne was still traditional in Europe. The Roman Catholic Church regained a highly privileged position; and, where, as in France, it could not recover all its lands and property, it was generously supported by the state and resumed its control over education. It reaped some of the ultimate advantages of having been persecuted and of enjoying the prevalent reaction against the rationalism and free thinking of the 18th century. Faith revived, as did clericalist sympathies; though soon Ultramontane claims met resistance even from the restored monarchs.

Liberalism and nationalism. Europe of the Restoration was a collection of old bottles filled with new wine, and trouble was soon fermenting. In Spain, Portugal, Piedmont, and Naples in 1820–21 revolts broke out, demanding democratic constitutions, the model for which was the abortive Spanish constitution of 1812. Austrian troops quelled the uprisings in Piedmont and Naples, but those in Spain and Portugal temporarily succeeded, because Great Britain and France refused to join in repressive intervention. In 1821 the Greeks rebelled against their Turkish rulers, raising for the powers the greater peril that Russia would take the chance to attack Turkey in the popular cause of a Christian nationalist movement against infidel misrule. The Spanish and Greek risings were the chief concern of the Congress of Verona in 1822. In 1823 France invaded Spain and restored King Ferdinand VII.

Austrian domination was confirmed by the suppression of revolution in Italy and Spain, but Great Britain emerged as a champion of movements for national independence and constitutional government in Greece and Portugal. Both the Quadruple Alliance and the congress system were disrupted by these events. The Greeks fought on, rousing Philhellenic enthusiasm throughout Europe by their heroism; and, when they won independence in 1830, it was because Britain, Russia, and France went to war with Turkey and forced it to make concessions in the Treaty of Edirne (September 1829). In 1826–27 Britain had also to intervene in Portugal to preserve the forms of constitutional government.

Disruption of the new system paved the way for wider movements of insurrection in 1830. France raised the flag of revolution in protest against the Ultramontane and aristocratic reaction of Charles X, who had succeeded his more tactful brother in 1824. The liberal opposition could take its stand on the charter of June 1814. In July 1830 republican groups in Paris seized the Hôtel de Ville and raised the tricolour flag of the Revolution. By a manoeuvre of the moderate liberal politicians, journalists, and bankers, Charles, who fled to England, was replaced not by a republic but by Louis-Philippe, representative of the Orleanist branch of the royal family, a more accommodating, liberal-minded man than his immediate predecessors on the throne.

Britain's Parliament gained greater control over government and rested on a wider (though still restricted) franchise. The new regime closely resembled the limited constitutional monarchy of Great Britain after the Reform Act of 1832 widened the electorate.

In 1830, too, in addition to the Greeks' attainment of independence, the Belgians won their independence from the Dutch (so destroying one provision of the Vienna settlement). Ripples of revolution, stirred by these events, spread even to lands under the watchful eye and the heavy hand of Metternich. In Brunswick, Hanover, Saxony, and other states of the German confederation, local revolts forced concessions from reluctant rulers. In such states as Baden and Bavaria, which already had parliamentary systems, liberal oppositions gained in elections and the press became more openly critical of their governments. In 1832 Prussia and Austria got the Diet of the German Confederation at Frankfurt to pass the "six acts," curbing press and opposition in all German states. By 1835 Metternich's system was again secure in Germany. In Italy, too, it faced revolts in Modena and Parma and in papal territories, but these Austria quickly quelled. A Polish insurrection was similarly crushed by Russia in 1831. Only in free Switzerland did most of the cantons succeed in setting up more liberal constitutions.

By the 1830s domestic conflicts between conservative, dynastic, and clericalist forces on one side and liberal, nationalist, and republican movements on the other had become a general pattern in European politics. Internationally, this same division was reflected in the realignment of Great Britain, France, and Belgium as against Austria, Prussia, and Russia. It was a pattern very different from anything envisaged in 1815. Most liberals (seeking parliamentary and more representative constitutions) were also nationalists (seeking the unification and independence of all communities feeling themselves to be distinct nationalities). The ideal of popular sovereignty, born of the French Revolution, implied both internal and external self-government. Government and governed were to be brought into closer reciprocal relations, in the name both of democracy and of national self-determination.

International realignment

A link between domestic forces of revolution in different lands was formed by the secret societies, which flourished because the police states of the Restoration drove all rebels undergound. It was a golden age of insurrectionary conspiracies and feverish plots, many of them wild and impracticably idealistic, though the Carbonari in Italy and Spain were at times both active and effective. Metternich's spies were equally active internationally against the secret societies; and, if he sometimes exaggerated the danger, it was to justify his own penetration of other regimes. In such societies cultured aristocrats, intellectuals, and poets mingled strangely with cutthroats and adventurers, many of them spending a large portion of their lives in prison or exile.

This sensational quality of the politics of the time matched the mood of the Romantic Movement in culture, though it had close affinities with both liberalism and nationalism (see below). The nationalist poets of France, Poland, and Greece were romantics, hostile to the Restoration as well

as to Napoleon because they exulted in individual freedom and personal heroism. They dreamed of a society of free and equal individuals as well as of free and independent peoples. Many, like the French poet Lamartine, who became minister of foreign affairs in the Second French Republic of 1848, assumed leading roles in politics. The prototype of the romantic liberal patriot was Giuseppe Mazzini, a member of the Carbonari and founder of the Young Italy movement for Italian unification under a democratic republic. Such men played a central role in the events of the great year of revolutions—1848.

The spread of revolt

In 1848, as in 1830, discontent grew from bad economic conditions as well as from liberal and nationalist aspirations. The flames of revolt spread fast from one city to another—for it was mainly a revolt of the towns, where social distress was acute and where organized insurrection could more readily occur. In January 1848 the King of Naples again faced open rebellion, and within a month riots took place in nearly all the large Italian cities. In February Paris put up barricades and overthrew Louis-Philippe, proclaiming a Second Republic. Within the year both types of revolt—national revolt against foreign rule and the dreary repressiveness of Metternich's agents and democratic revolt against the inadequacies of middle-class government—were repeated elsewhere. Disturbances in Great Britain (where the Chartist movement for radical political reforms had been vainly active for more than a decade) and in Belgium and Switzerland were on the French pattern. The movement failed in Great Britain. It succeeded in France only until 1851, when Louis-Napoléon, nephew of the great Napoleon, seized power. Switzerland alone achieved the lasting result of a new federal constitution (1848). The importance of the revolutions lay in the outburst of national enthusiasm, which spelled the end of Metternich's systems in Europe, and in the schisms that they caused between liberalism and nationalism.

The Italian risings revealed throughout the whole peninsula enthusiasm for national independence but deep differences as regards the means to this end. A party of conservative liberals pinned its hopes on Charles Albert, king of Piedmont and Sardinia; a party of Catholic federalists looked to leadership from the papacy; yet a third party, composed of Mazzinian republicans, fought for a democratic republic. Weakened by these divisions, the revolution was eventually crushed by Austria. Within the nationally diversified empire of the Habsburgs the risings were violent enough in Vienna to force the resignation of Metternich himself and to exact the promise of a new constitution; while in Hungary a new national leader appeared in Lajos Kossuth demanding home rule for the Hungarian population at the expense of Slav minorities within the kingdom. Here, too, deep divisions brought disaster to the nationalist cause, and by 1849 the Habsburgs were back in power, ruling through the army and the bureaucracy.

In Germany a body representing the aspirations of all nationally minded Germans met at Frankfurt in May 1848 and sat for a year. But irreconcilable divisions appeared between the "great Germans," who wanted a federal state including all Austrian lands except Hungary, and the "little Germans," who looked to Prussia for leadership and wished to omit the mixed peoples of Austria in order to unify Germany tightly. Roman Catholics tended to favour Austrian leadership, Protestants to favour Prussian. By 1849 the King of Prussia had withdrawn concessions made within his own kingdom and refused the crown of a united Germany. Liberal nationalism was discredited throughout Germany.

The paradoxical outcome of the year of revolutions was military rule in Prussia and Austria, a restored confederation in Germany, and a revived Bonapartism in France, But though frustrated in 1848 and subjected to even more severe repression by 1850, nationalists everywhere now had a clearer vision of how their aims could be reached. Governments, having tasted the strength of nationalist feeling, were forced to consider how they could harness it instead of merely crushing it. The system of Metternich had gone and seemed even more old-fashioned than the heroics of Romantic poets and secret societies. A mood of grimmer realism pervaded European affairs after 1850.

In 1850, as in 1815, it was the professional armies of monarchical governments that won; the intellectuals and romantic idealists went down in defeat. Again, strong monarchies seemed reaffirmed in their lease of power; and the power of the Roman Catholic Church revived, and its role in education grew. Yet a certain residue of more liberal government remained. Universal suffrage and parliamentary institutions were not abolished in France, though the emperor Napoleon III (as Louis-Napoléon became) blunted their edge. In Prussia, as in Sardinia, parliamentary institutions remained. In Austria seigniorial rights were not restored, and the new rulers of these countries differed in temperament and methods from the traditionalist monarchies of the restoration. Above all, the forces of profound economic change were now at work throughout the whole of Europe, making further changes in politics and in mental attitude inevitable.

New national states in the Balkans. From the end of the 18th century the Turkish power was crumbling in southeastern Europe, and the rival ambitions among the powers increased. Great Britain and France were interested in Egypt and the Levant, Austria and Russia in the Middle East and the Balkans. These problems entered a new phase with the stirring of liberal and nationalist movements in eastern Europe, especially in Poland and Greece. Greek independence involved joint action by Britain, France, and Russia against Turkey. When, in December 1832, an internal crisis in Turkey prompted the Sultan to appeal to Russia for help, the tsar Nicholas I sent an army and a fleet to defend Constantinople. In 1833 Sultan and Tsar signed a treaty closing the straits to other powers and creating a masked Russian protectorate. Seven years later Great Britain joined with Russia, Prussia, and Austria to intervene and make a convention (1841) with the Sultan whereby he undertook to close the straits to all warships. Each power showed its willingness to interfere in Turkish affairs when it felt that its own interests might be affected, and each feared the machinations of the others in this turbulent area.

The Crimean War

It was these entangled interests that led, in 1854, to the first war between the former allies of 1815—the Crimean War—in which Britain, France, and Sardinia, allied to Turkey, made war on Russia. The Russians, defeated by the Turks on the Danube, evacuated the Romanian principalities that they had occupied, but the war continued in the Crimea until the fall of Sevastopol. Austria, as a nonbelligerent, discussed with the allies conditions of peace to be imposed on Russia. In 1855, when the tsar Alexander II succeeded his father, Russia agreed to the terms proposed; and at the Congress of Paris (1856) the great powers, with Sardinia and the Sultan, made a peace treaty with Russia. The Sultan promised reforms in return for a guarantee by the powers of the integrity of his empire. The Black Sea was neutralized and closed to ships of war. The Romanian principalities were declared autonomous, and Russia restored part of Bessarabia to Moldavia. The Congress was a revival of the idea of a concert of Europe, and its declaration respecting maritime law revived concern for a public law of Europe. None of the settlement was to prove durable. The chief beneficiaries of the war were Napoleon III and the King of Sardinia, both of whom gained in prestige. The Eastern Question was not settled.

This became apparent in 1876, when the Slav Christian subjects of Turkey in Serbia and Bulgaria again rebelled, and their savage suppression by Turkey attracted the attention of the powers. Russia went to war, and in the Treaty of San Stefano (1878) arranged for the formation of an enlarged Bulgaria under Russian protection. Again the concert of Europe revived at the Congress of Berlin, attended by all the great powers, including the new Italy and the new Germany, the only two powers that left it without some territorial gains. The settlement, however, left each power dissatisfied and more anxious than before.

The remaking of central Europe, 1850–71. The schism between the forces of liberalism and nationalism, which appeared by 1850, and the breaking of the spell of peace between the powers by the Crimean War inaugurated a new era in great-power relationships. To forge nation-states and win their independence became the task of

strong leaders of existing states, with armies and economic resources of their own, not the dreams of exiles or conspirators. Diplomacy and war were the new agencies of successful nationalism.

Economic changes reinforced this tendency. Railways made it possible to transport men and goods—including armies and war materials—rapidly from one part of Europe to almost any other. The expansion of industrial productivity opened the way for the rapid growth of the economy of any state ready to take advantage of these new opportunites. France under Napoleon III was well placed to seize these opportunities, and the Second Empire (1852–70) was an era of growth, prosperity, and expansion under a paternalist, if harsh, regime. Exports exceeded imports, so that France, like Great Britain, could invest capital abroad. The Comité des Forges, heading France's great iron industry, was formed in 1864 and extended its interests into Belgium and Germany. A new French colonial empire was built up. Algeria was completely taken over by 1857; Tahiti and the Ivory Coast had been added earlier. Expeditions went to Peking in 1859–60 and to Syria in 1861. Explorers went to West Africa, and new settlements were made in Dahomey and the Guinea coast. New Caledonia was occupied in 1853. From 1859 onward three provinces were annexed in Cochin China, and a protectorate was set up over Cambodia (1863). At home the Emperor perpetuated Bonapartist traditions by his schemes of public works, notably the replanning of Paris. France in those years became, like Great Britain, a world colonial power and a larger, richer, more powerful state.

French colonial empire

In central Europe two states were advantageously placed to seize the new opportunities of growth. One was the constitutional monarchy of Sardinia, Piedmont, and Savoy, with its favourable strategic position in northern Italy, its enlightened government anxious to westernize the country, and its prestige as a leader of Italian hopes of national unification. The other was the kingdom of Prussia, already advanced in internal administration and in fiscal and military organization. With territories and interests widespread throughout Germany, it was the natural focus for all hopes of national unity excluding Austria. Austria of the Habsburgs was precluded from being a champion of nationalist aspirations anywhere, because its sprawling domains included peoples of many races and national loyalties and because its survival as an empire depended on discouraging and suppressing movements of emancipation.

In 1852 Count Camillo di Cavour became premier of Piedmont; in 1862 Otto von Bismarck became prime minister of Prussia. The reshaping of central Europe, achieved by 1871, was preeminently the work of these two states and these two men.

Cavour, as Piedmont's minister of agriculture, commerce, and marine in 1850 and soon also as minister of finance and premier, developed intensively his country's whole economy. He built or improved railways, roads, ports, docks; he expanded trade and linked Piedmont to the West by loans and commercial treaties. He spent money generously on the army, especially after his successes in the Crimean War. He agreed with Napoleon III in 1858 to make war jointly on Austria and then provoked Austria into war (1859). After six weeks of fighting the Austrians were driven from Lombardy, and Napoleon abruptly made terms with Austria, on his own, at Villafranca. But he had precipitated the first triumph of Italian nationalism. Cavour gained Lombardy but not, as he had hoped, Venetia. In 1860 Parma, Modena, Tuscany, and Romagna adhered to his cause, while Giuseppe Garibaldi conquered Sicily and Naples, and Cavour annexed all the central Italian states except Rome itself. When the first Italian parliament met at Turin in January 1861, the new kingdom included all the Italian peninsula except Venetia and the papal city of Rome. Cavour died in June 1861. The business that he left unfinished was completed by 1870 under the momentum he had given: Venetia was added in 1866 when Prussia defeated Austria; and in 1870 Germany's defeat of France left open the road to Rome.

Bismarck, as a loyal servant of Prussia, regarded it as his duty to assert Prussian as against Austrian leadership of Germany. To this end he sought alliances with France and Russia. Prussia was growing in population and in power. Since 1815 its population had risen from 11,000,000 to 18,000,000. Its economy had expanded; and, like Cavour, Bismarck was convinced of the need to spend lavishly on armaments and the army. He despised parliamentary assemblies and liberal ideas and believed in the traditional Junker (Squire) values of order, discipline, service, and duty. But his task was formidable. Since 1815 Germany had been divided into 38 states, unequal in size and diverse in constitution, bound together loosely within the German Confederation (Bund), which included Austria as well as Prussia.

Bismarck's first task was to drive Austria from the Bund. First Prussia joined Austria in defeating Denmark in 1864. As a result (Convention of Gastein, 1865) they took control of the duchies of Schleswig and Holstein, Prussia being responsible for the administration of Schleswig, Austria for that of Holstein. The future of the duchies remained the joint concern of Austria and Prussia—a convenient bone of contention for future use. Then Bismarck isolated Austria diplomatically by promising Italy Venetia in return for Italian help against Austria and by ensuring French neutrality. In June 1866 he forced the issue by proposing an end of the Bund and the election of a German assembly to draft a new consitution excluding Austria. After defeating Austria at Königgrätz (Sadowa) on July 2, he made the Treaty of Prague in August, annexing both Schleswig and Holstein and setting up a North German Confederation under Prussian leadership. The southern German states formed a looser association "with an independent international existence." Austria undertook to claim no further part in German affairs and surrendered Venetia to Napoleon to hand on to Italy. The efficiency of the Prussian Army, the precision of the campaign, and the skill of Bismarck's diplomacy achieved no less (and no more) than Bismarck intended. The war was a sharp blow to French prestige. It brought Italian and German unity one step nearer. It helped to bring about reorganization of the Habsburg Empire into the dual monarchy of Austria-Hungary in 1867.

The process of German unification was completed by the Franco-German War of 1870. Napoleon III—his government at home weakened by growing liberal and republican opposition, his prestige shattered by the failure of his Mexican expedition and by the demonstration of Prussian power at Königgrätz sought feverishly but fumblingly for some form of compensation. The conventions of diplomacy and the concepts of a balance of power required France to seek some material gains to offset the recent accessions of power to Prussia and Italy. Bismarck used these anxieties to precipitate war with France—a war in which France appeared as the aggressor. The pretext for conflict was the candidacy of Leopold of Hohenzollern for the vacant throne of Spain; the possibility of a German prince on the Spanish throne infuriated France. But even when Leopold withdrew, the war parties of Paris and Berlin were so intransigent, the public feelings of the two countries so frantic, that France declared war in July. At the Battle of Sedan the main French Army and even Napoleon III himself were captured; and the war would have ended then had not a new republican government of national defense in France continued hostilities until February 1871.

The Battle of Sedan

The war achieved Bismarck's aim. In January 1871 King William I of Prussia was proclaimed German emperor at Versailles. Germany was united under Prussian hegemony when the southern states combined with the North German Confederation within a new imperial constitution. France, after an interlude of civil war in the Paris Commune of 1871, set up the Third Republic in 1875—a parliamentary regime of a moderate, conservative kind. Russia took the chance to repudiate the Black Sea clauses of the Treaty of Paris of 1856, and the other powers were too much preoccupied to do more than protest. A completely new balance of power existed in Europe, with Germany overshadowing France and Russia overshadowing Austria.

Rise of Socialism. The history of European Socialism,

like that of liberalism and of nationalism, entered a new phase around 1850. Before midcentury, Socialist ideals derived partly from the democratic ideals of the French Revolution and partly from a wide variety of humanitarian, philanthropic, and idealistic trends of thought and action. The leading Socialist thinkers had been men like Robert Owen in England and Charles Fourier in France, stirred by the social injustices and individual hardships of the Industrial Revolution (see below) with its exploitation of unorganized labour. They looked to enlightened employers, public conscience, or new modes of economic and political organization to improve the material lot of the working classes. They went beyond this, too, and saw in a transformation of social ideas and habits the only path to a more just way of life for all. They pinned their faith on free association and education to bring progress. They wanted a new kind of society.

By midcentury, Socialist thought, like nationalist thought, was moving toward greater reliance on state action and legislation. Louis Blanc in France and radical reformers in Great Britain came to urge more positive action by governments to protect workers in factories. They sought to implement the "right to work" by policies of poor relief and provision of employment in national workshops. These more empirical and realistic proposals were in sharp contrast with two other strands of Socialism: the idealist and visionary Socialists, who encouraged migration to the American frontier to form simple egalitarian communities practicing communism in primitive agrarian conditions, and the Socialists of the secret societies and underground conspiracies, who plotted mass uprisings in the capitals of Europe to overthrow existing regimes and establish extreme democratic republics based on universal suffrage.

All alike suffered severe reverses in the debacle of 1848–49. The insurrectionary followers of Auguste Blanqui in France and the international supporters of Filippo Buonarroti in France, Italy, and Belgium attempted risings that were brutally crushed. Louis Blanc, who served for a time in the provisional government of the Second French Republic of 1848, found his aims frustrated and discredited. The only successful Socialist movements by midcentury were the moderate trade-union movements and the cooperative movement promoted in Great Britain by Robert Owen. They were not revolutionary and not even political in purpose. The Industrial Revolution had not yet produced the social conditions needed for a broad and effective Socialist movement anywhere. In every European country approximation to universal male suffrage gave power to the peasants, who proved, by their support of reaction in France or in Hungary in 1849, to be a predominantly conservative force. But the movement from countryside to town continued everywhere, and the existence of large industrial urban populations would change the whole situation.

The Communist Manifesto

In 1848, on the eve of the ill-fated revolutions, Karl Marx and Friedrich Engels issued *The Communist Manifesto.* It attacked all previous Socialist movements as "utopian" and based its program of revolution on an analysis of the inherent tendencies in capitalist society. Finding in private ownership of the means of production the source of inevitable class war between those who own the means of production (bourgeoisie) and those who have only their labour to sell (proletariat), they saw in the growing class of industrial workers and landless peasants the truly revolutionary class of the future. Only when this class seized power, liquidated the bourgeoisie and instituted a dictatorship of the proletariat could modern society move forward to a completely classless, Communist society.

Their famous pamphlet had no effect in 1848. But in the aftermath of disillusionment during the 1850s their arguments found readier adherents. An industrial exhibition in London in 1862 brought together British and French working-class leaders, and by 1864 the International Working Men's Association was formed by delegates from Great Britain, France, Germany, Poland, Italy, and other countries. Marx drafted its rules; it organized periodic conferences and became the basis of the First International. Marx deepened and strengthened his analysis in his study of *Das Kapital* (of which the first volume appeared in 1867). He began to attract disciples in various countries, especially in his native Germany.

The events of 1870–71 had both adverse and beneficial effects on the fortunes of Socialism and Communism. The Paris Commune of 1871 was not essentially Marxist in its inspiration, though some Marxists took part in it. Its defeat was a grave reverse for all Socialist and working-class movements in France. Marx depicted it (in *The Civil War in France*) as a prototype of the new proletarian revolutonary technique and hailed it as a sign of hope. In fact, it was the last flicker of the old Jacobin tradition of the barricades, and by leading to the killing or exiling of Socialist leaders and discrediting revolution it secured a highly conservative regime in France for the next 70 years. On the other hand, the creation of unified states in Italy and Germany, each with parliamentary institutions within which Socialist parties could operate, paved the way for the growth of large and powerful Social Democratic parties during the next generation. (D.Tn.)

Events outside Europe. Outside of Europe some developments of considerable significance, especially for the longer term, also took place. The long self-imposed isolation of Japan came to an end when, in 1854, the American commodore Perry succeeded in negotiating the Treaty of Kanagawa. After a period of hesitation, in 1868 Japan deliberately embarked upon the path of Western imitation as the only manner in which it could retain its independence.

The opening of Japan

In China, a process of decline and disintegration continued reminiscent of that of the Ottoman Empire. The Taiping Rebellion eventually led to foreign intervention, mainly Anglo-French, the forcible opening of China, and the imposition upon that country of discriminatory treaties. The Russians were expanding in Siberia, securing the boundary of the Amur River. Vladivostok, on the Pacific, was founded in 1860.

In Southeast Asia the British influence was reaching out from India, reorganized after the great Indian Mutiny of 1857, toward Burma and Siam, while the French established themselves in Cochin China and Cambodia, thinking of the Mekong River as a possible southern route of access to China.

The American continent was supposedly out of bounds for European intervention, but the British and French maintained interests in Mexico and in Texas; Britain's maritime and commercial empire made the possibility of an isthmian canal of equal interest to Britain and to the United States. Manifest destiny meant territorial expansion for the latter, mainly at the expense of Mexico, but domestic issues exploded into civil war between the North and the South in 1861. Aware of the potential rivalry of the United States, the British and the French, at the governmental level at least, tended to be sympathetic to the fragmentation of U.S. power and toyed with recognition of the South. The war gave rise to some incidents—the "Trent" affair and the "Alabama" claims—but the ultimate success of the North preserved the unity of the country while laying the bases for its subsequent astounding growth. The emergence of the United States, Germany, and Japan within less than a decade is worth noting.

The French in Mexico

The U.S. Civil War facilitated French intervention in Mexico, and Napoleon III succeeded in placing his candidate, Archduke Maximilian of Austria, on the Mexican throne in 1863—an action highly unwelcome in the United States. The termination of the Civil War and the menace of a united Germany induced Napoleon III to recall the French force from Mexico, and, lacking local support, luckless Maximilian was captured and executed. The Mexican episode contributed to the impression of the French emperor as a meddler, a factor that, in turn, contributed to British and American indifference during the Franco-German War of 1870–71. (Ed.)

THE INDUSTRIAL REVOLUTION

From the mid-18th century until World War I, economic history centres around a group of changes known as the Industrial Revolution. The term industrial revolution is commonly used to denote those changes in the processes and organization of production that mark the passage from

an agrarian, handicraft economy to one dominated by industry and machine manufacture, from what is sometimes called a premodern or traditional economy to a modern one. The term, when capitalized, refers specifically to the first historical instance of this transformation, which began in Britain in the 18th century, spread from there to the Continent and to offshoots of Europe overseas (the United States, in particular), and transformed in the span of a century the life of Western man, the nature of his society, and his relationship to the other peoples of the world.

At the heart of the Industrial Revolution was a cluster of innovations in the technique and mode of industrial production: (1) the substitution of inanimate for animal sources of power (in particular, the introduction of steam power fuelled by coal), (2) the substitution of machines for human skills and strength, (3) the invention of new methods for transforming matter (in particular, new ways of making iron and steel and industrial chemicals), and (4) the organization of work in large, centrally powered units (factories, forges, mills) that made possible the immediate supervision of the production process and a more efficient division of labour. These innovations in industry promoted and were, in turn, supported by major changes in the technology of agriculture and transport.

Underlying all of this was the systematic application of knowledge to the devising of more efficient production. In the first part of the Industrial Revolution, the knowledge was mostly the result of practical experience and informed empiricism. With time, however, beginning in such industries as chemical manufacture, applications were derived from pure science, and, by the end of the Industrial Revolution, the relationship was reversed. Theory had moved ahead of practice in most domains, and inventors were tapping the pool of scientific knowledge for usable ideas and information.

The Industrial Revolution was essentially completed in the first industrializing countries by the late 19th century. By then they had made their passage to the new technology and were pursuing new paths of change. Again, there was a clustering of innovations that gave the impetus to this further growth: electrical power, the internal-combustion engine, petroleum fuel, the automobile, and science-based chemical manufacture (the first synthetics). Some have called this array of changes a second Industrial Revolution. In the second half of the 20th century, a similar clustering of innovations (*e.g.*, atomic power, electronics, and computers), is effecting perhaps a third Industrial Revolution. Each of these stages has been marked by important gains in the production and delivery of energy; in the speed, precision, and convenience of tools and machines; and in the effectiveness and usability of final products (standardization of parts, refinements of tolerances, miniaturization of components).

Changes in productivity

All of these technological advances translated into economic growth—that is, increased productivity and income per head. Productivity is measured by the ratio of output to one or more factors of input (labour, capital, materials). As a result of the Industrial Revolution, labour productivity increased thousands of times in some branches of industry (cotton spinning, for example), hundreds of times in others (weaving, steelmaking, chemicals), with corresponding decreases in the cost of manufacture. By contrast, those activities little affected by the new techniques—skilled arts and crafts, for example, or barbering—showed almost no gain in productivity and little reduction in costs. The effect was a massive shift of demand in the direction of those products and services the costs of which fell the most and an increase in the numbers of persons and amount of capital employed in the branches furnishing these products and services. This shift was reinforced by the gains in income per head, which made it possible for the populations of advanced industrial countries to devote a smaller portion of their income to necessities, and to spend more of it on luxuries or "extras." This expenditure over and above the requirements of subsistence is especially responsive to the changes in relative prices entailed by changes in relative costs of production. The effect was a substantial growth of those branches most affected by the new technology and, in general, a shift of resources (including labour) out of agriculture into industry and services and a movement of population from the countryside into the cities and towns.

The Industrial Revolution in Britain. The first country to make the transition to modern industry and economic growth was Britain. The reasons for this precocity were partly material, partly social and institutional. Britain was favoured by its oceanic position, which gave the country easy access to markets and suppliers overseas; by its modest size and highly indented coastline, which placed most of the country within easy reach of water transport; and by the abundance of those natural resources that proved to be particularly important for the new industrial technology. These included water (for waterpower, chemical processes, textile finishing, and, in the form of high humidity, for the spinning of yarn); salt, for the manufacture of industrial alkalis and acids; china clay; iron and nonferrous ores; and, above all, huge, accessible deposits of coal, for use as fuel and as a source of carbon in the smelting of iron. The one resource Britain lacked was timber, but this very handicap was turned to an advantage by the precocious recourse to fossil fuel.

At the beginning of the 18th century, Britain was a medium-sized nation. Its population of nearly 6,000,000 people was less than one-third that of France; yet, Britain constituted the biggest single market in the world, not only because of the island's compactness but also because the movement of goods through the country was unimpeded by man-made obstacles. France, Britain's chief political and economic rival, was divided into three major customs areas, and traffic was further trammelled by a multiplicity of special tolls and by customary restraints on the shipment of critical commodities such as grain. Most of central Europe was even more fragmented, and the burden of feudal tolls was such as to make traffic shun the rivers (though they were more navigable than those of France and Britain) and opt for the costly and uncomfortable alternative of land transport.

The internal free trade of Britain

This large market was also the richest in purchasing power per head. Insofar as one can estimate the incomes of mid-18th-century Europe, the average Briton would seem to have been receiving some £12 to £13 per year (perhaps $300 in today's money), half again as much as a Frenchman and more, in proportion, as one moves eastward or southward to the poorer nations of the Continent. The greater purchasing power of the Englishman was shown in his diet—he ate white wheaten bread and much meat, where the Frenchman ate dark bread and soup; and in his consumption of manufactures—he wore leather shoes rather than clogs, wool rather than linen, and used some 13 kilograms of iron per head (as against 2.7 kilograms in France) in the late 1780s. This was far more than even the rapidly growing domestic industry could supply, and the difference was made up by imports from Russia and Sweden.

The purchasing power of the British population was, in its mass, an important stimulus to agricultural and industrial production. The effect was reinforced by the relatively wide distribution of wealth, both socially and geographically. Unlike most European nations, Britain was not polarized between a small class of wealthy consumers of highly individualistic, labour-intensive luxury products and a large mass of poor peasants with little to spare for manufactures and those only the highly differentiated products of local industry. British society was more complex in its structure, with a large and heterogeneous middle class, and the peasantry was, in many parts, fully integrated into the national market. This, in turn, reflected the precocious commercialization of agriculture, which learned early to specialize in cash crops, above all for the great London market. Specialization means dependency on the outside, and one of the striking features of the English countryside in the 18th century was the extent to which not only itinerant peddlers but even fixed shops (which, of their nature, are evidence of a substantial and continuing trade) were catering to the rural population. All of this conduced to the breakdown of regional peculiarities and the homogenization of taste, which promoted a demand for the kind of standardized product that lent itself to machine production.

Social homogeneity

Coal and iron. This domestic demand, reinforced by a large and growing demand for British products abroad, placed heavy strains on the existing techniques and organization of production. One of the first industries to feel the pressure was mining, where the deeper one dug, the more difficult it became to drain the infiltrating underground water from the pits. Coal mines especially were in trouble. In one colliery, 500 horses were required to raise the water, bucket by bucket. The solution was to replace the animals with tireless machines. In 1698 Thomas Savery introduced his "fire engine," a steam pump rather than a true prime mover; and then, in 1705, Thomas Newcomen invented his atmospheric steam engine, which worked a piston up and down a cylinder, alternately raising and lowering another piston that did the actual pumping. By 1767 there were 57 of these in the Newcastle coal basin alone, supplying some 1,200 horsepower, and there were probably hundreds of them in operation throughout the kingdom. The Newcomen engine was simple and sturdy. Some of them remained in use for half a century or more. But it was wasteful of energy, and as thus largely confined to the coal pits, where fuel was almost a free good. James Watt's invention of the separate condenser (patent 1769; first commercial application, 1776), cut fuel consumption 75 percent, freed steam power from this constraint, and made possible the industrial city; and it was Watt again who first succeeded (patents of 1782 and 1784) in converting the reciprocating (back-and-forth) movement of the piston into rotary motion, so that steam could be used not only to pump mines or blow furnaces but also to drive the wheels of industry.

Another industry that felt the strain of increased demand was ironmaking. Here, the most acute bottleneck was the shortage of cheap fuel and carbon. Since England had long since cut down most of its timber, repeated efforts were made to use coke in smelting, but the necessity of mixing the fuel with the ore in the furnace made it difficult to cope with the impurities in the coke. It was not until 1709, when Abraham Darby, a Quaker ironmaster at Coalbrookdale, Shropshire, had the good fortune to work with a fairly clean mix that coke smelting became a commercial possibility. Even so, other ironworks found it hard to follow suit, and it was not until more powerful bellows became available in the 1760s that the technique spread widely. By the end of the century, the old charcoal smelting had almost entirely ceased, and British production of pig iron, once also stagnant, was growing rapidly: approximately 25,000 to 68,300 tons from 1720 to 1788 (1.5 percent per year) to about 244,000 in 1806 (7.3 percent per year).

Effect of the use of coke on ironmaking

Pig iron, the product of the blast furnace, has serious limitations for industrial use. It is brittle, cannot be worked, and must be cast. It is suitable for objects such as pots or pipes that need not take pounding or stress, but it cannot serve to build machines, frame buildings, or carry vehicles. For these purposes, before the age of cheap steel, only wrought iron would do—that is, iron refined to eliminate the carbon imparted by the smelting process. The Industrial Revolution in iron manufacture, therefore, was not possible until a way was found to use coal here too. The breakthrough came in 1783–84, when Henry Cort patented the combined technique of puddling followed by rolling. The first decarburized the pig; the second squeezed out the remaining dross and forced the hot metal into the desired shapes.

The putting-out system. The scale of enterprise in coal mining and iron manufacture was already substantial even before the Industrial Revolution. The dependence on bulky raw materials required these branches to concentrate in those areas dictated by nature, and the technology called for a heavy investment in fixed plant and equipment. By contrast, light industries, such as textiles, were widely dispersed and relied extensively on the distribution (putting out) of raw materials to cottage workers, who turned them into semifinished and finished products. The so-called putting-out system offered the merchant-manufacturers two important advantages. First, it shifted the burden of fixed costs to the workers. All the merchant needed was a room to stock materials and finished goods. When the market was bad, the putter out simply held off, with few overhead charges to pay. Second, it gave the merchant-manufacturer access to a large pool of cheap labour. Country dwellers would work for far less than urban, not only because the cost of living was lower but also because the rhythm of agricultural labour was uneven and left long periods of relative underemployment that could be profitably used to eke out the income from the land.

The putting-out system marked a major advance over the artisan workshops of medieval towns. By freeing enterprise from the constraints of town guilds, it opened the way to growth and technological innovation. Britain's precocity in this regard (by 1400, over half the wool cloth made was woven in the countryside) changed what today would be called an underdeveloped country, exporting its raw wool to manufacturing centres abroad, into Europe's biggest producer of cheap textiles for export.

Textiles and machine technology. The growth of demand in the 18th century pushed rural putting out to its limits, especially in spinning, where it took four or five persons to keep one weaver supplied with yarn. Given the high cost of land transport, the extension of the radius of labour recruitment increased disproportionately the cost of distribution of materials and collection of finished work. Nor was it possible to get more work from those already engaged by increasing wages; on the contrary, the worker tended to set his task by his need, and increased payment only meant that he could earn what he needed with less work. At the same time, the tempation to embezzle the raw materials increased, at the expense of the quality of the final product.

It was in this context of frustrated entrepreneurial opportunity that manufacturers sought for some way to bring the labour force under control. One way was to concentrate work under one roof, so that the employer could supervise performance. This solution, however, was not feasible in the context of the old technology. So long as enlarged workshops had to rely on human power and on the same machines used in rural cottages, they could not compete, for they were burdened with higher fixed costs and had to pay their workers more to lure them into a disciplined environment. The answer was found in the invention of machines that grew to be too large and costly for cottage work—so big, indeed, that they had to be driven by animal or inanimate power: the spinning jenny, by James Hargreaves in 1765; the water frame, by Richard Arkwright in 1769 (the prototype of all modern ring spinning devices); and the mule (so-called because it was a hybrid of the two), by Samuel Crompton in 1779.

Machines for spinning

This sequence of inventions shifted the bottleneck from spinning to weaving, and, for a short while, weavers lived in unaccustomed affluence trying to keep up with the output of cheap yarn. But in 1787 Edmund Cartwright invented a machine loom, which, though it took some two decades to perfect, inexorably displaced the handloom weaver. The power loom was applied first to the coarser fabrics, for only the tougher yarns could stand up to the irregular motions of the shuttle. The machine builders, however, learned to solve this problem; and by the 1820s handloom weaving was a dying craft, and its practitioners were among the most pitiful victims of technological obsolescence.

The innovations in textiles were applied first in cotton, primarily because cotton fibres lend themselves well to mechanical handling. Wool, an animal fibre, is less uniform and tractable. It also was more costly than cotton and constituted a much larger share of total costs; so that the potential cost reductions offered by mechanization were smaller. Even so, the innovations in spinning offered gains in labour productivity of the order of over 100 to 1; those in weaving, up to 10 to 1; so that mechanization came to wool also, lagging about two decades behind cotton, and eventually extended to all the textiles. The effect of prior mechanization in cotton is shown by the change in the relative position of the two industries. Between 1769 and 1829 the value of wool exports increased from £3,897,000 to £5,362,000, while that of cotton grew from £212,000 to £37,269,000.

Similar changes took place in other industries: paper

manufacture, metalworking and woodworking, chemicals, machine building itself. The principles of mechanization were susceptible to wide ramification, and the factory context tended to promote change by restoring the link between enterprise and actual production that had been broken by putting out. In chemicals, more than in other branches, the lessons of science found application in industry. Here, too, the initial motivation came from a bottleneck: the high cost of washing, dyeing, and finishing the flood of fabrics engendered by mechanized spinning and weaving. The great innovations here consisted of the substitution of abundant mineral for scarce vegetable or animal resources: the French chemist Nicolas Leblanc's substitution of coal and salt for seaweed and wood in the manufacture of soda; bleaching by chlorine compounds instead of milk and sunshine; washing of wool with soap rather than urine. The manufacture of these new industrial compounds gave rise to considerable waste; the effort to dispose of these noisome by-products without damage to litigious neighbours, plus the desire to recover some of the potentially valuable components of the waste, proved one of the most powerful incentives to innovation in the chemical industry. Seen together, these technical changes made possible substantial gains in industrial output, overall product, and per capita income (see Table 1).

Table 1: Indicators of Economic Growth in Great Britain (1801–51)

	national income (£000,000; current prices)	population (000)	per capita income (£)	income from manufacture, mining, and building (£000,000)	share of manufacture, mining, and building (percentage)
1801	232.0	10,686	21.7	54.3	23.4
1811	301.1	12,146	24.8	62.5	20.8
1821	291.0	14,206	20.5	93.0	32.0
1831	340.0	16,368	20.8	117.1	34.4
1841	452.3	18,551	24.4	155.5	34.4
1851	523.3	20,879	25.1	179.5	34.3

Changes in transport. The growth of a modern industry in Britain generated a rapid increase in goods traffic. For all of Britain's natural advantages, the Industrial Revolution could not have taken place had there not been a concomitant improvement in facilities of transportation. Canals can be traced in Britain back to the 16th century, but the first truly industrial canal was the Sankey Canal (1757) from the Mersey to St. Helens, Lancashire, cut to bring Cheshire salt to Lancashire coal. This was followed in 1761 by the waterway that usually marks the beginning of the so-called canal age. This was the canal of Francis Egerton, the 3rd duke of Bridgewater, from his coal mines at Worsley to Manchester. By 1815 a network of some 2,200 miles crisscrossed the country, along with 2,000 miles of improved river navigation. The most prosperous links in the network were those that carried the heavy, bulk commodities of industry—coal, above all.

Canals and land transport

For many commodities, however, as well as for persons, only land transport was fast enough. The road network inherited from the pre-industrial economy was manifestly unable to handle the increase in traffic, and restrictions on vehicles (the imposition of wide wheels, for example, that would cut less into the road surface) were at best a palliative. Here, the answer was found, as in canals, in private enterprise. In the first half of the 18th century, Parliament averaged eight road acts a year, most of them authorizing new turnpikes; from 1750 to 1790, almost 40 acts a year were passed; and, from 1791 to 1810, the figure jumped to 55. Even so, the wear and tear played havoc with traditional road surfaces, and it was not until John Loudon McAdam and Thomas Telford introduced their new hard-packed surfaces in the 1790s that roads began to be built that could stand industrial traffic. By 1815 there may have been 1,000 miles of highway built to this standard.

All this time, the pressure built up to speed communication and travel. Coaches were built to make better times; horses were driven harder; connections were improved so that the trip from London to Birmingham, which took two days in the 1740s, was cut to 19 hours in the 1780s. By the early decades of the 19th century, these efforts had reached a limit, and the newspapers of the period are sprinkled with gruesome stories of horses snapping their legs or dying of exhaustion on the fast routes.

Railways

It was this apparently insatiable demand for speed that made the railway an instant success for passengers as well as goods. The use of rails to facilitate the movement of heavy vehicles went back centuries in mining districts; rails diminish considerably the force required to haul a given load. What made the modern railway, however, was the invention of locomotive traction introduced in 1825 on the Stockton and Darlington Railway line (primarily for coal haulage) and then, triumphantly, in 1829 on the new Liverpool and Manchester Railway. This was the beginning of the railway era. The new line had been intended for the transport of goods; but to everyone's astonishment passenger revenues exceeded freight receipts. By 1845, 1,000,000 persons were using the London and Birmingham Railway line alone; by 1850, 6,559 miles of track were in service.

The railway was probably the most impressive and significant technical innovation of its time. Not only did it enable the economy to move the unprecedented volume of goods required and produced by the new techniques, but also its demand for iron (for rails, engines, rolling stock), coal, wood, brick, and other materials stimulated other industries. The requirements of a railway roadbed, in particular the need for level track, inspired some of the most spectacular engineering achievements of the age. The construction of the roadbed (including tunnels, bridges, viaducts, etc.) called for large gangs of labourers and proved to be a laboratory for new techniques of industrial management. Similarly, the unprecedented costs of railway construction called for new methods of mobilizing capital and pushed Britain in the direction of corporate business enterprise with limited liability.

All of these connections of the railway with the rest of the economy made it the most important single determinant of the level of business activity. At the peak of the railway boom of the 1840s, the industry employed some 300,000 men in construction alone—more than in the entire cotton industry—and absorbed about half the country's total investment; that is, between 5 and 7 percent of the national income. It was also a potent force for geographical mobility and contributed thereby to the efficiency of the labour market and the democratization of society—this, in spite of segregation of passengers into different price classes.

Improvements in agriculture. The revolution in industrial technology was accompanied by important changes in the agricultural sector. Indeed, these were indispensable to the expansion of manufacturing; the new industrial work force was cut off from the land and depended for existence on the production of a food surplus and on such victuals as could be purchased abroad. The problem was aggravated by a rapid growth of population, beginning in the middle of the 18th century, and by the constriction of overseas supplies during the period of the French Revolutionary and Napoleonic Wars (1792–1815).

At the start of the 18th century, Britain, in years of good harvest, was still able to send food abroad. Agriculture was highly commercialized and specialized, and the techniques of cultivation were among the most advanced in Europe. Some scholars have even argued that the innovations of the previous period—water meadows plus mixed farming, new crop rotations, marling—were more important than the better-publicized advances of the so-called agricultural revolution of the 18th century.

New farming techniques of the 18th century

Over the course of the 18th century, the techniques of agriculture continued to advance. Certain names stand out: Jethro Tull, who advocated drilling seed rather than sowing it broadcast and who also advocated light iron horse-drawn implements instead of cumbersome wooden tools drawn by slow oxen; Charles ("Turnip") Townshend, 2nd viscount Townshend, who learned about turnips and

clover in Holland and helped popularize them in England; Robert Bakewell (1725–95), the most prominent livestock breeder of his day, the creator of four new breeds of sheep selected for meat instead of wool; Thomas William Coke of Holkham, the personification of the gentleman farmer and chief exponent of the so-called Norfolk system of rotation. But what really made an agricultural revolution possible was not these few public figures but the large number of anonymous improvers, adopting and adapting the new methods with an alacrity and vigour that reflected both the enhanced market incentives and a veritable agronomania, which found expression in and was nourished by a flowering of agricultural societies and publications. In all of this, the emphasis was on rational accounting procedures that could provide the basis for an exact comparison between old ways and new: the reports of a contemporary observer such as Arthur Young consisted in large part of records of outlays and receipts, county by county, farm by farm.

The introduction of these new techniques encountered a serious obstacle in much of England in the prevailing pattern of dispersed, fragmented land tenure and open fields subject to common rights of usufruct. These arrangements went back to the Middle Ages or even beyond. They reflected, no doubt, an effort to equalize the quality of soils allocated to the different members of the village community: each received a piece of each of the different kinds of land cleared for cultivation. The common rights of usufruct followed: this was the only feasible way to permit each man to pasture his livestock on the stubble after harvest. Common rights of pasture, in turn, implied concurrent sowing and harvesting, hence a common pattern of crop rotation, which usually entailed one year of three in fallow. This wasteful system locked the farmer into a vicious circle of low yields—insufficient food for wintering livestock—low output of dung—inadequate fertilizer—low yields. By contrast, introduction of clover or root crops not only did away with fallow but provided additional food to keep the animals over the winter, to build up the herds and flocks, and to accumulate stocks of dung for the growing season.

The enclosure movement

The attempt to free land from these communal servitudes and regroup holdings gave rise to what was known as the enclosure movement. In village after village, in an area covering perhaps one-third of the arable land in England, the major landholders agreed to regroup holdings into contiguous parcels that could then be "enclosed" by hedges or ditches and farmed as the owner saw fit; at the same time, meadowland and wastes held in common were divided among the landholders in proportion to their holdings. This was not the first such wave of enclosure in English history: perhaps half of the arable land had already been converted by 1750. These earlier enclosures—in the 16th century especially—had aimed at converting arable land into large sheepwalks, to meet the growing demand for wool. The enclosures of the 18th century, however, were intended to increase cultivation.

Although enclosures were perhaps the greatest single factor in permitting and encouraging the diffusion of the new agricultural techniques, they entailed a heavy charge on the smaller landholders, who could not easily afford the legal costs and outlays for surveying, hedging, ditching, and the like. Even worse was the situation of the landless cottar or bordar, who lived by a kind of tolerance on common land, was permitted to pasture a few animals, and worked as a day labourer in the fields of his propertied neighbours. Enclosure settlements were scrupulous in their protection of the rights of those who owned land but were equally rigorous in their exclusion of those who did not. As a result, many small holders were forced to sell their parcels to those who could afford the costs of enclosure; and many more landless labourers had to leave their homes and take service elsewhere. For a long time, it was thought that these uprooted victims of enclosure provided the basis of the factory labour force. This has been disproved by the census data, which show the population of areas of enclosure growing throughout this period. This is exactly what one would expect of an institutional change that increased the demand for farm labour. Even so, agricultural employment could not keep up with increasing manpower, and it was the surplus population of the countryside that flowed to the cities. Enclosure selected many of those who chose to go; but, on balance, the agricultural revolution it helped make possible slowed the course of rural emigration.

There are no official figures on British farm output in this period, but it is estimated that wheat production, for example, almost doubled from 1700 to 1820—13 million to 25 million quarters. Even so, the agricultural sector could not supply the growing food needs of the country, and, from the 1770s on, Britain was on balance an importer of grain. To be sure, imports represented a small fraction of overall wheat consumption—less than 5 percent of home demand in the period from the end of the French Revolutionary Wars to the abolition of the Corn Laws (tariffs on imported grain) in 1846. Yet, the proportion would have been significantly larger had it not been for these protective duties, which constituted a subsidy to British farming and kept British prices higher than they would have been in a free market.

Abolition of the Corn Laws

The abolition of the Corn Laws and the introduction of almost complete free trade in manufactures in 1845–49 marked the substantial completion of Britain's Industrial Revolution and its economic pre-eminence at midcentury. The first signalled the victory of the manufacturing interest over the agricultural: as early as the second decade of the century, employment in industry exceeded that in agriculture; by 1851 it was twice as large, as was the share of manufacturing in the national product. If one added trade, transport, and other predominantly urban activities to the balance sheet, the disparity would be much greater. Understandably, the modern sector refused to go on paying tribute to the land.

The second was testimony to Britain's confidence and superiority in the world market; no one could undersell its wares (some 93 percent of British exports were manufactures). At this point, this small country, with less than 10 percent of the population of Europe, accounted for two-thirds of the coal mined in the world, half the make of iron, half the market of cotton cloth, and over one-quarter of the goods in international trade. It was a moment of dominance without parallel before or since.

Continental Europe. *The Continent until 1815.* The other countries of Europe actually took a long time effecting their industrial revolutions. The rapidity with which some of them moved once the new technology took hold—Germany is the usual example—is deceptive. The hard job was to start moving. By comparison with Britain, the Continent was severely handicapped: geography, political boundaries, and a legacy of medieval tolls were barriers to the movement of persons and goods; forests were relatively abundant but coal scarce; incomes were lower; labour was cheaper and labour-saving devices were thus less advantageous; society was more rigidly divided by status and occupation; it was more rural, and country dwellers made poor or tight-fisted consumers; social attitudes were less favourable to business enterprise. In the lands east of the Elbe, the persistence of serfdom locked the greater part of the population into agriculture, so that the potential supply of labour to industry was drastically curtailed; moreover, since unfree men do not work so well as free, productivity was low, and the people were impoverished. Even in the freer lands to the west, however, the rural economy could not be compared with that of England. Subsistence farming predominated; there was considerably less regional specialization; techniques were less productive, and there was nothing like England's fascination with improvement. Commerce and industry had scarcely begun to penetrate the countryside.

Government sponsorship of manufacture

By the mid-18th century, even earlier in some countries, the governments of Europe were seeking systematically to promote industrial development. The reasons were primarily political: industrial growth and economic prosperity generated revenue and employed men, and money and men were the sinews of war, hence of power. The measures varied with and are a good reflection of the needs and shortcomings of these economies: subsidies in the form of money, gifts, low-cost loans, exemptions from taxes, use

of public buildings, or free machines; technical assistance and the imposition of compulsory standards and quality control (particularly important in France); monopoly privileges to innovators of new products or techniques; an assured supply of labour, by assignment of serfs, prisoners, vagabonds, or such public charges as orphans and the residents of poorhouses (especially in central and western Europe); exemption of the work force from military service and the plant itself from the burdens of quartering troops; special privileges to immigrant artisans and entrepreneurs (Huguenots in Berlin, Germans in Russia, Jews throughout central Europe); an assured market via government or army orders or compulsory purchase by such unfree subjects as Jews (Germany especially); the award of places and honours to industrialists and of patents of distinction to their products. In some fields, particularly those linked to armament (powder works, arsenals) and to the supply of luxuries to the court (glass and mirror manufacture, tapestries and carpets, porcelain), the state itself became entrepreneur. In other branches, the state relied on private initiative and, when this failed to respond to the incentives offered, might order aristocrats or court purveyors or Jews or such others as were in no position to refuse to start putting their money and efforts into manufacture.

Much of this development from above was misdirected. Technical knowledge and managerial talent were in short supply, and the effort to force progress inevitably led to misallocation of resources and the manufacture of goods of poor quality at high cost. Subsidies only encouraged waste and inefficiency, while monopoly privileges eliminated the competition that might have compelled better performance. The difficulty was compounded by the preference of most rulers and their officials for large, centralized establishments—visible symbols of industrial achievement. The "manufactories," so called to distinguish them from true factories, were not centrally powered and were ordinarily equipped with the same devices used in conventional workshops. They had, therefore, no technical advantage over dispersed cottage manufacture yet were burdened with higher capital costs and were far less attractive to workers, who resented supervision and discipline—hence the need to assign labour, which was invariably sullen and unproductive. Most of these hothouse enterprises collapsed as soon as the state withdrew its support, and the setback was proportional to the amount of support. In Prussia, which was the greatest exponent of forced development, the death of Frederick II the Great, in 1786, was followed by a hecatomb of bankruptcies and liquidations.

This is not to say that the whole effort of state sponsorship of industry was pointless. The privileged manufactories left behind a legacy of knowledge and skills. Many of the men who were trained in them constituted a second generation of entrepreneurs, less spoiled, more hardheaded, and far more successful.

On the Continent, as in Britain, the real progenitor of modern industry was the putting-out system. It had always been inhibited by the privileges of urban manufacturing centres and the efforts of the state to control the standards of production; but, beginning in the late 17th century, industry gained a foothold in the French, Walloon, Rhenish, and Swiss countrysides. In France, the prosperity and influence of this partially illicit industry was recognized by a law of 1762, which legalized the fait accompli. By this time, the efforts of merchant-manufacturers to reach farther afield for their labour (Norman clothiers were drawing some of their yarn from as far away as Picardy) were producing the same kinds of bottlenecks that had moved British manufacturers to turn to machinery and the factory, and there is no doubt that the same changes would have occurred on the Continent had the economy simply continued to develop along these lines. But this process was interrupted, first, by the British innovations and, then, by the French wars of 1792–1815. The first changed completely the conditions of international competition. It was at once apparent that any nation that wanted to maintain itself as a power, political as well as economic, would have to learn the new technology. The second, however, worked against this by cutting much of the Continent off from Britain for a generation and diverting resources into familiar but profitable techniques rather than more hazardous innovations.

The spread of British techniques

The extension of the Industrial Revolution to the Continent may be viewed as a process of cultural diffusion. The continental countries already had a pool of skilled artisans who might learn and apply the new techniques—clockmakers, instrument makers, millwrights, joiners, metalworkers. Even so, they needed considerable help to bring them to the British level. This was accomplished by missions of inquiry to Britain or by placing workers in British plants, by a certain amount of industrial espionage, by the purchase of British machines (usually illegally), and by engaging Britons to work in continental enterprises.

The first fruits of this diffusion were already seen before the French Revolution: a few steam engines, including some built in Europe; some thousands of mechanized spindles for spinning cotton; the first, abortive attempt at smelting iron ore with coal at Le Creusot in France (1785). During the French wars, the interruption of British imports permitted certain branches, textiles especially, to develop in a kind of splendid isolation—that is, to modernize with old-fashioned equipment. Such crucial branches as engineering and iron manufacture, however, made little headway. The one area in which isolation paid was chemicals, where the French responded to the shortage of alkalis by developing the Leblanc soda process.

The continental revolution, 1815–50. The return of peace brought both opportunity and peril: on the one hand, communications with Britain were open once again, and, on the other, British manufactures were so much cheaper and often better than continental wares that the infant industries of the Napoleonic era were menaced with liquidation. Most of the continental countries responded by setting up prohibitive tariff barriers; at the same time, both government and private enterprise bent every effort to import British skills and experience or to spy out the secrets of British technology. To combat this potential loss of superiority, the British had long since passed laws against the migration of skilled artisans or the export of machinery; but these could do no more than impede the process. By 1825 Britain's attempt to maintain a monopoly of the new technology was clearly a failure, and the ban on the emigration of artisans was lifted. Machines took longer, but in 1842 pressure from a machine-building industry whose capacity had outstripped home demand persuaded the Parliament to annul the prohibition on exports.

Determinants of continental changes

The rate of assimilation and adoption of the new technology in continental Europe varied widely. Among the more important determinants were (1) the degree of economic and technological backwardness; (2) the degree of exposure to British competition (too much could be fatal, but a certain amount could be stimulating, as in Belgium and Switzerland); (3) relative factor costs (if labour was cheap enough or capital too scarce and dear, it did not pay to install machines); (4) the political pressures for modernization (the rulers of smaller states, such as Belgium, Switzerland, and Sweden, not caught up in the competition for power, were willing to let economic development take its course); (5) the political pressures for conservatism (old-fashioned landed magnates in such countries as Austria and Russia correctly perceived industrialization as socially and politically subversive); (6) the resource base (other things equal, a goodly supply of coal, as in Belgium and Westphalia, was a potent incentive to the adoption of the new technology); (7) the size of the market (the unification of most of Germany into a customs union [Zollverein] by 1833 gave a powerful impetus to trade and regional specialization of industry); (8) the character of demand (peasants made poor customers for manufactures); and (9) the ability of the society to generate entrepreneurs (weakest in eastern Europe but also constrained in countries such as France by hostility to unbridled competition and by the conservatism of family enterprise).

The years from 1815 to 1850 saw several of the continental countries initiate their own industrial revolutions. Belgium was first, in the 1820s and '30s, with a marked emphasis on coal mining and metallurgy. France followed and, being poor in coal, concentrated on textiles and other

light industries. From the 1830s on, the Swiss moved along the same path. Finally, Prussia, with large coal resources in Silesia and Westphalia, developed from the 1840s on a pattern similar to Belgium's. In all of these, railway construction was an important stimulus to development. Belgium, compact and densely populated, built its trunk network by the early 1840s. Germany was almost as quick, so that by midcentury one could cross the entire country by rail, east–west or north–south. France, by contrast, had only stubs of lines radiating from Paris and isolated stretches in the provinces. In the rest of Europe, the new technology was still exceptional, stunted by material and institutional obstacles.

The middle decades, the 1850s and 1860s. The decades of the 1850s and '60s were a period of catching up for continental Europe—not that Britain was standing still. Easy money favoured expansion: the effect of the gold discoveries in California and Australia (1848–49) was multiplied by the readiness of credit institutions to lend in a highly liquid market. The contrast was especially marked with the crisis years of the 1840s, when bad harvests, the collapse of a speculative boom in railway shares, and, finally, an epidemic of political revolutions in 1848 had first contracted the economy and then just about brought it to a standstill. Now confidence reigned everywhere, and promoters hastened to bring new commercial and industrial enterprises to the attention of investors. A striking feature of this renewed expansion was the role played by joint-stock, limited-liability corporations. These were not new; they went back to the chartered trading and colonial companies of the 17th century. But they had always been exceptional, subversive of a commercial morality that held a businessman personally liable for his losses "to the last shilling and acre." They had required the express authorization of the state and had been reserved for those few activities that could not be handled even by the collective resources of a partnership. Railway construction was one of these, and the railway did more than anything else to naturalize the limited-liability corporation. The principle was susceptible, however, of much wider application, the more so as technological advance and economies of scale increased the threshold investment required to found competitive enterprises. The contribution of limited liability was far more important on the Continent than in Britain, which had built its industrial establishment from the ground up, plowing back profits into firms that began small and grew with the changing technology. Britain was also richer and possessed the most efficient money and capital markets in the world, so that industrial enterprises could count on generous bank credit, nominally short-term, but, in fact, renewed to cover medium- and long-term investments. By contrast, the follower countries across the Channel, which had to bridge the technological gap, were confronted with the task of paying for costly installations, not only with the industrial profits of yesterday but also with such resources as could be mustered from outside the industrial sector. In such circumstances, limited liability and joint stock were indispensable, and institutions had to be developed to take up the task of mobilizing capital and channelling it to potentially profitable ventures—hence, the importance of the corporate investment bank, already successful in Belgium but taking a new departure in the 1850s with the establishment of the Crédit Mobilier in Paris (1852) and the Bank für Industrie und Handel in Darmstadt (the Darmstädter Bank, 1853). These were followed by (and, in numerous instances, helped found) similar development banks throughout Europe. Some of them concentrated more on speculative promotions than on industrial development; the Crédit Mobilier itself, eponymous model for the new species, foundered in 1867 because of its vain effort to keep up profits and appearances by stock-market coups. Others worked better, especially in Germany, where the rapid growth of capital-intensive heavy industry, above all in metallurgy and mining, provided a large field of opportunity.

The role of limited-liability corporations

Free trade

The rapid economic expansion of these years set the stage for a major departure from the conventional wisdom of high protection. The key move was not Britain's unilateral step toward free trade in 1845–49 but rather the Anglo-French Treaty of 1860, which was swiftly followed by a series of similar agreements between the leading European economies, including the Zollverein. These were accompanied by reciprocal legislation to facilitate capital movements across national borders and by international monetary agreements providing for standardization and simplified exchange of currencies. This was not yet complete free trade, but it did bring closer the kind of international market that would, in turn, promote technological rationalization and diffusion. The Cassandras who predicted that the protected industries of France and the Zollverein would simply be crushed under the weight of British imports were proved wrong; the most efficient and strongest continental enterprises invested heavily in new plants and did better than ever. There was, however, a purge of smaller, marginally inefficient firms unable or unwilling to meet the new competition.

Improved transport

This purge of the old technology was further hastened by the vast improvement in transport technology that marked these years, in particular, by the competition of the trunk rail network of western and central Europe. The track mileage rose sharply, but more important than this was the completion of key connections and the consequent growth of passenger and goods traffic: 65,000,000 to 169,000,000 tons in Britain from 1855 to 1870; 4,000,000 to 44,000,000 in France from 1850 to 1870. Nothing did more to break down the autonomy of regional markets and promote the mobility of persons; internal migration, up to then confined largely to short intraregional movements, began now to develop along interregional routes. The railway, in combination with the steamship, also moved a rising current of transoceanic migrants—108,000 per year from Europe to the United States, 1830–49; 218,000 per year, 1850–69. This exodus, as much as modern market competition, hastened the demise of old trades in low-wage rural areas.

Table 2: Growth of Railway Networks in the 19th Century, Selected Countries
(in kilometres)

	1840	1850	1860	1870	1880	1890	1900
Great Britain	2,410*	9,791	14,595	21,826	25,046	27,811	30,063
France	499†	2,915	9,167	15,544	23,089	33,280	38,109
Belgium	325	625	747	869	2,724	3,249	4,060
Germany	549	6,044	11,633	19,575	33,838	42,869	51,391

Although the middle decades of the 19th century were dominated by the extension of known techniques to new enterprises and areas and within existing enterprises, technical advance did not cease. For one thing, considerable improvement was built into the very process of expansion; it is hard to build a new edition of an old model without incorporating improvements. For another, no technique or machine is usable without some adjustment to the specific conditions in which it is to be used, and this adjustment often entails improvements. In the meantime, the pressures of demand continued to stimulate invention. An excellent example is steelmaking, where the traditional cementation and crucible techniques could produce only small pieces at high cost, used in shears, razors, swords, watch springs, and the like. The development of high-speed machinery and vehicles, however, created a need for steel in far greater sizes and amounts than customary. From the 1830s on, then, metallurgists in several countries bent their efforts to the problem. The definitive solution was found at about the same time by William Kelly of the United States (*c.* 1851) and Henry Bessemer of England (*c.* 1854), who was looking for a way to make a better cannon: by blowing air through a furnace containing molten pig iron, the oxidation of the carbon would proceed without the application of any external heat; hence, Bessemer's claim to make steel "without fuel." Though taken up eagerly, the new technique needed some additional touches before it was

Cheap steel

susceptible of general application: first, Robert Mushet's clever trick of burning off all the carbon and then adding it as desired made possible a standardized product, and, much later, the Thomas–Gilchrist process (1878–79) enabled steelmakers to work with phosphoric iron ores and opened the greater part of the world's iron resources to the new technique. In the next decade, a second way was found to produce cheap steel, this time with even closer quality control: first, a new "regenerative" oven invented by William Siemens (mid-1850s) yielded much higher temperatures, so that iron could be refined in huge open hearths; and here again, it was a second inventor, Pierre Émile Martin of France, who worked out the technique of adjusting the mix by the admixture of scrap so as to yield a standard product (1864). The whole story of cheap steel is almost an ideal case study in the dynamics of invention: (1) the importance of serendipity, (2) the role of multiple invention, and (3) the incompleteness of initial solutions and the indispensability of subsequent improvement.

The chemical industry

The chemical industry also moved ahead; in the 1850s and 1860s artificial, synthesized dyes were developed, first in England, then in Germany. Much more than in steel-making, however, technical advance in chemistry depended on scientific knowledge and systematic experiment: artificial dyes were only the first application of the new science of organic chemistry. These first dyes, then, were a promise not only of what would rapidly become one of the most creative and flourishing branches of industry but also of a new approach to invention.

By 1870 the more advanced industrial countries of continental Europe had reached a point at which they could compete with Britain on reasonably equal terms. The scale of their enterprises was still smaller, as was the place of industry in the larger economy. Yet, they had assimilated the essential techniques of machine manufacture and adapted them to their circumstances; and, where before they had been almost exclusively learners, they were now generating innovations of their own.

Social consequences of the Industrial Revolution. The question of the social consequences of the Industrial Revolution has been hotly debated since its effects were first noted in the early 19th century, and the issue is still alive. The split has been political, with the right usually giving a favourable judgment, the left a negative one. The question is beset by difficult problems of interpretation, value judgments, and criteria, but the following general observations may be made concerning the impact of the Industrial Revolution in Britain.

Standards of living

First, wage data indicate that, on balance, those workers who shifted out of agriculture or pre-mechanized industry into the modern branches of industry improved their earnings significantly. The gap was largest for those who came from the most backward rural areas in western and southern Ireland or the Highlands of Scotland. Those who stayed behind in agriculture benefitted to the extent that labour could easily take advantage of job opportunities in manufacturing: rural wages were highest in those parts of England adjacent to the great industrial centres.

Second, the worst losers were workers in bypassed trades, such as handloom weaving. By 1830, tens of thousands of these were living on the edge of survival.

Third, real earnings fluctuated with prices, particularly food prices, and the level of employment, as they always had. Real wages were thus at their lowest during the period of the French wars, when wheat prices reached record heights, rose over the next 15 years, fell again in the depression of the late 1830s (despite falling prices), then moved back up from the trough of 1842. There is no agreement on what the composite trend was from, say, 1790 to 1850, though no one would argue for a marked shift either up or down; the consensus, however, is that real wages rose substantially from the middle of the century on.

Fourth, consumption of the major food staples seems to have increased, partly owing to new sources of nourishment (potatoes and fish, in particular). Consumption of textiles grew even faster, and the generalization of the use of washable undergarments thanks to cheap cotton fabrics constituted a major advance in comfort and health.

Fifth, on the other hand, housing deteriorated as thousands of migrants poured into swollen urban centres that could not grow fast enough to accommodate the influx. The population of 103 cities of over 20,000 (including London) rose from 3.5 million in 1821 to 6.8 in 1851 to 9.5 in 1871. (This, it should be noted, is a general characteristic of all industrial revolutions: because construction technology does not advance as rapidly as that of other branches, investment in housing is less profitable than other investments or can be made profitable only at the sacrifice of quality and space—this, both for systems of private enterprise and state planning.) The poor either jammed into old structures, filling every vacant space by building sheds in courtyards or converting cellars into dwellings, or moved into little jerry-built row houses that were slums before they were finished. Water supply and sewage disposal were grossly inadequate: the life of the urban poor was a compound of damp, filth, and nasty smells. All of these inconveniences were an old story; rural housing was often even more primitive; but 100 hovels scattered over the hillsides were a much less serious problem than back-to-back tenements. Density bred discomfort, disease, and neurosis. Urban death rates actually rose in Britain in the 1820s and 1830s.

Working conditions

Sixth, the conditions of work in the modern industrial sector varied widely. Generally, the larger and more modern the enterprise, the roomier, clearer, and safer the workrooms, the shorter the hours, and the higher the wages. The weaker, less-efficient firms had to save on their wage bill in order to compete. Over time, therefore, the construction of new plants and increasing scales of production yielded as a by-product a substantial improvement in working conditions. The worst feature of the new mode of production was the extensive reliance on women and children. In itself, this was not new: women and children had always worked hard and long in cottage industry. Nevertheless, the discipline of the factory (a discipline often imposed by strangers), the remorseless monotony of many of the tasks, and the physical hazard and discomfort of some of the new processes took a heavy toll.

By the first decade of the 19th century, the abuses of factory labour were already a cause of public concern in Britain. The government was at first reluctant to intervene, for fear of breaching the sanctity of private contracts, but, beginning with parish apprentices in 1802, then continuing with other children in 1819 and 1833 and with women (in mines) in 1842 and (in textile factories) in 1847, Parliament gradually increased its purview. The most important step was the passage of the Factory Act of 1833, which set a minimum age of nine years, limited the hours of children to eight per day, required employers to provide schooling for their young workers, and, most decisive, established the principle of official inspection to ensure compliance. Unfortunately, the law aimed at first to protect only workers in centrally powered textile factories, so that older modes of production were enabled to persist in abusive working conditions until the passage of more comprehensive legislation later in the century.

In general, the social consequences of the Industrial Revolution were not so uniformly bad as they have been made out but were far worse than they had to be. They reflected the unpreparedness of British society, the ideological commitment to laissez-faire, and the natural indifference of most beneficiaries of industrialization to the sufferings of those who paid the bill.

Across the Channel, observers of the British scene were inclined to congratulate themselves on being spared the "white slavery" of the cotton proletariat. Yet, their poverty problem was even more severe—though more widely distributed, hence, less visible. Their industrial labour force was paid less and worked harder, and more of their children died younger. Yet data on the consumption of necessities, such as wheat, potatoes, and textiles, show substantial increases per head over time; and, since these gains could not have been confined to the well-to-do, one must conclude that people were eating more and dressing better. Housing, as always, was a dark spot, with death rates varying widely between rich and poor neighbourhoods. Much depended on the level of economic activity:

the late 1830s were hard years, and the mid-1840s, with their bad harvests and business contraction, produced in some areas (Flanders, Silesia) a Malthusian peak in mortality. Things picked up thereafter.

Another test of the effects of industrialization is the hypothetical question: what would have been the condition of the population had there been no Industrial Revolution? It is nearly impossible to conjecture an answer. One approach is to consider the fate of those parts of Europe, or even of the United Kingdom, that did not keep pace with the new technology. These proved invariably to be the poorest areas—sloughs of overpopulation, endemic underemployment, and undernourishment. Like Silesia in 1844 or Flanders and Ireland in 1846, they had no reserves in time of want and fell easy prey to famine and disease. There was an autonomy to the population growth that began in the mid-18th century that made some kind of revolution in productivity indispensable if Europe was not to lose the slow gains of a millennium and sink back to the poverty of the Middle Ages. (D.S.La.)

ROMANTICISM AND REALISM

The legacy of the French Revolution. To make the story of 19th-century culture start in the year of the French Revolution is at once convenient and accurate, even though nothing in history "starts" at a precise moment. For although the Revolution itself had its beginnings in ideas and conditions preceding that date, it is clear that the events of 1789 brought together and crystallized a multitude of hopes, fears, and desires into something visible, potent, and irreversible. To say that in 1789 reform becomes revolt is to record a positive change, a genuine starting point. One who lived through the change, Liancourt, was even sharper in his vision when (as the story goes) he answered Louis XVI, who had asked whether the tumult outside was a revolt: "No, sire, it is a revolution." In cultural history as in political, significance is properly said to reside in events; that is, in the acts of certain men or the appearance of certain works that not only embody the feelings of the hour but also prevent other acts or works from having importance or effect. To take an example from English poetry, after Wordsworth and Coleridge's *Lyrical Ballads,* which appeared in 1798 and remained a long while obscure, the writing of heroic couplets in the 18th-century manner could be but a pastime—not poetry, as it had once been. A good many such "punctuation marks" can be noted in the text of cultural activity and in its context of political and social life.

To say, then, that the cultural history of the later modern age—1789 to the present—begins with the French Revolution is to discuss that Revolution's ideas rather than the details of its onward march during its first 10 years. These ideas are: the recognition of individual rights, the sovereignty of the people, and the universal applicability of this pair of propositions. In politics the powerful combination of all three brings about a permanent state of affairs: "the revolution" as defined here has not yet stopped. It continues to move the minds of men, in the West and beyond. The revolution is "dynamic" because it does not simply change rulers or codes of law but it also arouses a demand and a hope in every man and every people. When the daily paper tells of another new nation born by breaking away, violently or not, from some other group, the Revolutionary doctrine of the sovereignty of the people may be observed still at work after two centuries.

The ideas of the French Revolution

Cultural nationalism. The counterpart of this political idea in the 19th century is cultural nationalism. The phrase denotes the belief that each nation in Europe had from its earliest formation developed a culture of its own, with features as unique as its language, even though its language and culture might have near relatives over the frontier. Europe was thus seen as a bouquet of diverse flowers harmoniously bunched, rather than as a uniform civilization stretching from Paris to St. Petersburg, from London to Rome, and from Berlin to Lisbon—wherever "polite society" could be found, a society acknowledging the same artistic ideals and speaking French. In still other words, the Revolutionary idea of the people as the source of power ended the idea of a cosmopolitan Europe.

The "uniform" conception presupposed a class or elite transcending boundaries; the "diverse" implied a nation of citizens attached to their native soil and having an inborn and exclusive understanding of all that had been produced on it. In each nation it is the people as a whole, not just the educated class, that is deemed the creator and repository of culture; and that culture is not a conscious product fashioned by the court artists of the moment: it is the slow growth of centuries. Thus can be seen one of the motives of the post-Revolutionary passion for historical studies—the change to cultural populism as the replacement of a single horizontal, Europe-wide, and "sophisticated" culture by a series of vertical, national cultures, popular not only in their generality but also in their simplicity.

Beginnings of cultural nationalism

This new outlook, though propagated by the Revolution, began as one of those subdued feelings mentioned earlier, as undercurrents beneath Enlightenment doctrine. In England and Germany especially, a taste developed for folk literature—the border ballads, the legends and love songs of the people, their dialects and superstitions. Educated gentlemen collected and published these materials; poets and storytellers imitated them. Horace Walpole in *The Castle of Otranto,* Macpherson in *Ossian,* Chatterton in his forgeries of early verse, and Goethe in his lyrics exploited this new vein of picturesque sentiment. A scholar such as Herder or a poet-dramatist such as Schiller drew lessons of moral, psychological, and philosophical import from the wisdom found in the subculture of *das Volk.* The folk or people was not as yet very clearly defined, but the Revolution would shortly take care of this omission.

In France, where the Revolution occurred, the situation was somewhat different. There were no collectors of border ballads or exploiters of Gothic superstitions. France by 1789 had been for more than a century the cultural dictator of Europe, and it is clear that in England and Germany the search for native sources of art was stimulated by the desire to break the tyranny of the French language and literature. The rediscovery of Shakespeare, for example, was in part a move in the liberation from French classical tragedy.

Simplicity and truth. But it was also the expression of a genuine desire for simplicity and truth and for the release of feelings that the confidence of the Enlightenment in the power of reason had tended to suppress. Two 18th-century figures tapped this fount of emotion, Richardson and Rousseau. The novels of Richardson, in which innocent girls are portrayed as withstanding the artful seductions of titled gentlemen, might be said to foreshadow in symbolic form the struggle between high cosmopolitan culture and the new popular simplicity. These novels were best sellers in France, and Rousseau's *Nouvelle Héloïse* followed in their wake, as did the bourgeois dramas of Diderot, Beaumarchais's satirical comedies about the plebeian Figaro, and the peasant narratives of Restif de la Bretonne, to mention only the most striking exemplars of the new simplicity.

At the very centre of sophistication the simple life became a fad, the French court (including Marie-Antoinette) dressing up and playing at the rustic existence of milkmaids and shepherds. However silly the symptoms, the underlying passion was real. It was the periodic urge of complex civilizations to strip off the social mask and recover the happiness imagined as still dwelling among the humble. What was held up to admiration was honesty and sincerity, the strong and pure feelings of people unspoiled by city and court life. Literature therefore came to express an acute sensitivity to scenes of undeserved misfortune, of heroic self-sacrifice, of virtue unexpectedly rewarded—a sensitivity marked by tearfulness, actual or "literary."

Back-to-nature movement

This surge of self-consciousness about sophisticated culture has often been confused with an idealization of primitive man and attributed to Rousseau. But contrary to common opinion, the so-called back-to-nature movement does not at all echo the noble-savage doctrine of the 17th century. Rousseau's attack on "civilization," which evoked such a powerful response in the latent feelings of his contemporaries, goes with a characterization of the savage as stupid, coarse, and amoral. In Rousseau and his abettors, what is preached is the simple life. What nature

and the natural really are remains to be found by trial and error—the fit methods and forms of religion, marriage, child-rearing, hygiene, and daily work.

Populism. It is easy to see in these beliefs and sentiments (which often passed into sentimentality) additional materials for the populism that the Revolution fostered. Revolution, to begin with, is also an urge to simplify. The Revolutionary style was necessarily populist—Marat's newspaper was called "The Friend of the People." The visible signs that a revolution had occurred included the wearing of natural hair instead of wigs and of common trousers instead of silk breeches, as well as the use of the title of *citoyen* instead of *Monsieur* or any other term of rank. Now, equality coupled with sincerity and simplicity logically leads to fraternity, just as honest feeling coupled with devotion to the people leads to puritanism: a good and true citizen behaves like a moral man. He is, under the Revolutionary principles, a responsible unit in the nation, a conscious particle of the will of the sovereign people, and as such his most compelling obligation is love of country—patriotism.

With this last word the circle of ideas making up the cultural ambient of the French Revolution might seem to be complete. But in the effort to trace back and interweave the strands of feeling and opinion that make up populism, one must not overlook the first political axiom of revolutionary thought, which is the recognition of individual rights, often said to be natural rights as well. Their essence is a subject for political theory. Here their cultural role is of interest, and it can be stated in a very obvious way: individual rights generate individualism. The "ism" rightly suggests an attitude or doctrine—sometimes a passionate faith—asserting that every human being is an object of interest in himself, an end in himself. What is more, the truly valuable part of each individual is his uniqueness, which is entitled to thrive and develop free of oppression. That is why the state guarantees the citizen rights as against itself and other citizens. Again, this power accrues to him for himself because he is inherently important—not because he is son or father, peasant or overlord, member of a clan or a guild.

Doctrine of individualism

These ideas shift the emphasis of several thousand years of social beliefs and let loose innumerable implications. Individualism lowers the value of tradition and puts a premium on novelty. True, the individual soul had long been held unique and precious by Christian theology, but Christian society had not extended the doctrine to every man's mundane comings and goings. Nor were his practical rights and powers attached to him as a man but, rather, to his status within the social scheme. Now the human being as such was being officially considered self-contained and self-propelling; it was a new regime and its name was liberty.

Nature of the changes. The contents and implications of these potent words—liberty, equality, and fraternity, individualism and populism, simplicity and naturalness—aid in the understanding of the cultural situation of Europe at the dawn of the era under review. But these continuing ideas necessarily modified each other and in different times and countries were subject to still other influences.

For example, the active phase of the Revolution in France—say, 1789 to 1804—was influenced by the classical education of most of its public men. They had been brought up on Roman history and the tales of Plutarch's republican heroes, so that when catapulted into a republic of their own making, the symbols and myths of Rome were often their most natural means of expression. The eloquence of the successive national assemblies is full of Roman allusions. Later, when General Bonaparte let it be seen that he meant to rule France, he was denounced in the Chamber as a Caesar; when he succeeded, he took care to make himself first consul, flanked by two other consuls, to show that Caesar was in abeyance.

Changes in the fine arts

In the fine arts this Roman symbolism facilitated a thorough change of taste and technique. The former "grand style" of painting had been derived from royal and aristocratic elegance, and its allusions to the ancient classical past were gentle and distant, architectural and mythological. Now, under the leadership of the painter David, the great dramatic scenes of ancient history were portrayed in sharp, uncompromising outlines that struck the beholder as the utmost realism of the day.

In David's "Death of Socrates" and "Oath of the Horatii" civic and military courage are the respective subjects; in his pencil sketches of the victims of the Terror as they were led to execution, reportorial realism dominates; and, in his designs for the setting of huge popular festivals, David, in collaboration with the musicians Méhul and Grétry, provided the first examples of an art in scale with the new populism: the taste of the court and the city was transcended by the needs of the nation.

But it must be added that except for a few canvases and a few tunes (including the "Marseillaise") the quality of French Revolutionary art was not on a par with its aspirations. Literature in particular showed the limitations under which revolutionary artists must work: political doctrine takes precedence over truth, and the broad effects required to move the masses encourage banality. There is no French poetry in this period except the odes of Chénier, whom the Revolution promptly guillotined, as it did France's greatest scientist, Lavoisier. The French stage was flourishing but not with plays that can still be read. The Revolutionary playwrights only increased the dose of sentiment and melodrama that had characterized the stage at the close of the old regime. The aim was to hold up priests and kings to execration and to portray examples of superhuman courage and virtue. Modern opera goers who know the plot of Beethoven's *Fidelio* can judge from that sample what the French theatre of the Revolutionary years thrived on. Others can imagine for themselves Molière's *Misanthrope* rewritten so as to make Alceste a pure patriot and hero, undermined by the intrigues of the vile courtier Philinte.

It may seem odd that once the Revolution was under way there should be so much indignation and protest against courtiers, priests, and kings and such fulsome homage paid to virtue and patriotism. What accounts for it is the difficulty of transforming culture overnight. People have to be persuaded out of old habits—and must keep on persuading themselves. Even politically, the Revolution proceeded by phases and experienced regressions. Manners and customs themselves did not change uniformly, as one can see from portraits of Robespierre at the height of his power wearing a short wig and knee breeches, republican and Rousseauist though he was.

Napoleon's influence. After Bonaparte's coup d'etat tension eased as the high ideals dropped to a more workaday level, just as the puritanism was replaced by moral license. And, as a by-product of Bonaparte's expeditions to Egypt in 1798–99, a new stylistic influence was added to the Roman: sphinxes and the lion-claw motif appeared in furniture, and the Near East began to attract attention. The Roman idea itself shifted from republic to empire as the successful general and consul Bonaparte made himself into Napoleon.

Bonaparte's coup d'etat

The Emperor had an extraordinary capacity for attending to all things, and he was concerned that his regime should be distinguished in the arts. He accordingly gave them a sustained patronage such as a Revolutionary party rent by internal struggles could not provide. But Napoleon had tastes of his own, and he had to control public opinion besides. In literature (he had been a poet and scribbler in his youth), he relished the Celtic legends of *Ossian* and encouraged his official composer Lesueur in the composition of the opera *Ossian ou les Bardes.* In painting, he favoured the surviving David and the younger men Gros and Géricault, both "realists" concerned with perpetuating the colour and drama of imperial life, including the life of the battlefield. But to depict contemporary issues on the stage (except perhaps in the ballet, which was flourishing) did not prove possible, for the stage must present genuine moral conflict if it is to produce great works, and moral issues are not discussable under a political censorship.

The paradox of the Napoleonic period is that its most lasting cultural contributions were side effects and not the result of imperial intentions. Two of these contributions were books. One, Chateaubriand's *Génie du christianisme* (1802; *The Genius of Christianity*), was a long tract de-

signed to make the author's peace with the ruler and revigorate Catholic faith. The other, Madame de Staël's *De l'Allemagne,* was a description of the new culture in Germany. Napoleon prohibited the circulation of the book in France, but its message easily survived. The two other sources of future light were men. One was the group of philosophers known as Idéologues, who were scientific materialists and concerned with abnormal psychology. The other was Napoleon Bonaparte himself, or rather the figure of Napoleon as seen by his age after Waterloo.

General character of the Romantic movement. The mention of Waterloo (1815) suggests the need to make clear a number of chronological discrepancies. It has been possible so far to discuss the general shift in the temper of European life without naming fixed points. It sufficed to say "before or after 1789" or "from 1789 to the Napoleonic Empire." But from now on the generations of culture makers and the dates of some of their works must be duly situated, without on that account losing sight of unities and similarities in the onward march of artistic and intellectual movements. If, for example, one takes the Romantic poets, one finds that Goethe came to maturity in the 1770s, when the English Romantics were just beginning to be born. Their French, Italian, Russian, Polish, and Spanish counterparts were, in turn, born about the year 1800, when the English were already in mid-career. The same irregularity in the onset of Romanticism is found in the other arts, and it is complicated (at least superficially) by the names given to various movements and persons in the different countries of Europe. Thus, in Germany the term *Romantismus* is applied to only a small group of writers, and Goethe and Schiller are called classic. In Poland and in Russia, classic is likewise the label for the great writers whose characteristics in fact align them with the Romantics elsewhere.

Chronological discrepancies in the Romantic movement

All these accidents of birth and nomenclature can be taken in stride by remembering the patterns found in each country or decade and the reasons for their appearance at that time and place. Within the slightly more than half century between 1789 and 1848, the phenomenon of Romanticism occurred and developed its first phase. Those who made it may have come early or late, belonged to this or that nationality, proved to be originators or synthesizers of existing elements—all such considerations appertain to individual biography or the history of a particular art or nation. What matters in the evolution of European culture considered as a whole is the orchestration of all the voices as they come in to swell the ensemble.

The main purport of the Romantic movement is said to be a revolt against 18th-century Rationalism and a resulting variety of new attitudes and activities: a turning in upon the self, a love of nature, the rediscovery of the Middle Ages, the cult of art, a taste for the exotic, a return to religion, a fresh sense of history, a yearning for the infinite, a maudlin sentimentality, an overvaluing of emotion as such, a liberal outlook in politics, a conservative outlook, a reactionary outlook, a Socialist-utopian outlook, and several other "characteristic features."

It is clear that not all of these can be equally true, characteristic, or important, since some contradict the others. At the same time it was inevitable that so sweeping a cultural revolution as Romanticism should contain incompatible elements. For instance, the political opinions enumerated above did in fact win the allegiance of different groups among the Romantic artists and thinkers for a longer or shorter time. But—to take note of other supposed definitions—not all Romanticists returned to religion: Goethe and Berlioz were pantheists; Byron and Heine, atheists; and Victor Hugo, a sort of Swedenborgian. As for sentimentality, its occurrence was rather a hangover from the 18th century than a new fashion of feeling, for the Romantic cult of art and of strong emotion goes dead against the weak sentimental mood. Similarly, the taste for history, for the Middle Ages, and for the exotic shows a strong curiosity about the particulars of what is real though ignored by previous conventions. All critics, however, are agreed upon one Romantic trait: individualism. And it is here that the figure of Napoleon plays its cultural role.

Incompatible elements of Romanticism

Napoleon was regarded as the model of a new man, even during his life, because his career was manifestly the product of his own thought and will working against the greatest imaginable resistance. He typified the individual challenging the world and subduing it by his genius. A movement that numbered as many artists and geniuses as did Romanticism was bound to find in Napoleon the individual par excellence or, as might be said in modern jargon, a supremely autonomous personality. This perception explains why nearly all the great names of the first half of the 19th century are found on the roster of those who praised Napoleon—from Beethoven and Byron to Hazlitt and Stendhal and Manzoni. Some who were politically his enemies—Sir Walter Scott, for example—nonetheless respected and pondered over the miracle of his achievements. No comparable attention has been paid to the dictators of the 20th century, a fact sufficiently explained by the real difference between Napoleon and them. Stendhal, who had taken part in the Russian Campaign of 1812, analyzed that difference ahead of time: Napoleon had intellectual power—and not merely political and military. In whatever he did, he showed originality of conception, a stupendous grasp of detail in execution, and the utmost speed in acting out his vision. This sequence, translated to other realms, was the very pattern of the creative imagination. It also seemed the vindication of individualism as a philosophy of life: open the world to the individual and the world will witness marvels unimagined before.

These remarks about Napoleon should convey a sense of the Romantics' attitude toward themselves and their situation. It is true that culturally they stood in opposition to their immediate forebears. But all generations do the same, and yet it is only once in a while that the conflict produces great things. Romanticism had the paradoxical advantage of making its way during and after the 25 years of Revolutionary and Napoleonic wars. For the tumult of battle and political overturns did its share to clear the ground for artistic innovation. When habits and expectations are repeatedly upset and frustrated in the broad public realm, the general mind opens up to novelty offered in other realms. That is one avenue of cultural, stylistic, and emotional change. When Stendhal was expounding Romanticism to the French in 1822, he argued that to go on writing in the Neoclassic vein was "to provide literary pleasure for one's grandfather." His remark was readily understood—at least by his young readers. Mighty events had dug a chasm between past and present, making plain the remoteness of the 18th century.

The Romantics' attitude toward themselves

And yet a paradox remains. When the Romantic innovator produced his first characteristic work—say Wordsworth with the *Lyrical Ballads* of 1798—he had to wait a good while for a hearing though his sense of the death of Neoclassicism was clear; it arose from a poet's quick perception of the decay of forms. Already in 1783 Blake had written of contemporary English verse that "The sound is forced, the notes are few." But these two poets' estimate of the state of poetry was not widely shared till the passage of time—*i.e.,* of men, and events—had worn down old routines. It is generally said that Blake and Wordsworth and most other Romantic artists were ahead of their time; it would be more accurate to say "ahead of their audience."

This phenomenon, characteristic of the modern age, further complicates the question of when Romanticism emerged or was established in different countries. Even so, it is possible to assign, with sufficient reason, a particular decade when in a given nation the movement was in being and active in the production of important works, though not necessarily accepted by a large public. In England and Germany that decade was the 1790s: Blake, Wordsworth, and Coleridge; Goethe (with the first fragment of *Faust*), Schiller, Herder, Jean Paul (Richter), Beethoven, Tieck, Wackenroder, Hölderlin, Schelling, Schleiermacher, together with the beginning of a German translation of Shakespeare by Tieck and Schlegel, mark the advent of the new age.

In Italy, France, and Russia, the decisive years opened in 1820. They are signallized in Russia by the abundant poetic output of Pushkin, in Italy by the work of Manzoni and Leopardi and by the surrounding discussions of literary theory, and in France by the poems of Lamartine,

Vigny, Victor Hugo, and Mme Desbordes-Valmore. The paintings of Delacroix, the first compositions of Berlioz, and Balzac's *Chouans* show that a new spirit was at work. Finally, in the 1830s, Poland—through its poet and novelist Mickiewicz—and Spain—through the works of Rivas, Espronceda, José de Larra, and Zorrilla—joined the rest of Europe in its richest artistic flowering since the Renaissance: the leading nations can boast one or more Romantic artists of the first magnitude.

The fundamental Romantic purpose

Romanticism in literature and the arts. The fundamental Romantic purpose was to grasp and render the many kinds of experience that classicism had neglected or had stylized. Romanticism was the first upsurge of realism—exploratory and imaginative as to subject matter and inventive as to forms and techniques. The exploration of reality surveyed both the external world of peoples and places and the internal world of man. The Scottish and medieval novels of Sir Walter Scott, beginning with *Waverley* in 1814, illustrate the range of the new curiosity, for Scotland was a "wild" place, outside the centres of civilization, and the Middle Ages were similarly "barbarous" and distant in time. When Byron went to the Near East and used it as the setting of his adventure poems, he was creating the same sort of interest, this time in a region as real and "central" (to itself) as Paris and London. In both these writers, factual detail is essential to the new sort of effect: the scenery is observably true, and so is the history, given through local colour. As Byron said when criticized: "I don't care two lumps of sugar for my poetry, but my costume is correct." Blake, 20 years earlier, had taken a stand against Sir Joshua Reynold's academic doctrine that the highest form of painting depicted the broadest general truth. Said Blake: "To particularize is the only merit."

Particulars, moreover, are all equally proper for the artist; the use he makes of them is what matters. When Wordsworth and Coleridge sought to revivify English poetry, they hit upon two divergent kinds of subject: Coleridge took superstition and the folk tale and wrote "The Rime of the Ancient Mariner" in the form of an old ballad; Wordsworth took the modern street ballad—a kind of rhymed newspaper—and produced his versified incidents of common life in common speech. In France, where the division of the vocabulary into "noble" and "common" (*i.e.*, unfit for poetry) had been made and recorded in dictionaries, the Romantics led by Hugo used the prohibited words whenever they saw fit. Hugo's verse drama *Hernani* (1830) created a scandal in the audience when the heroine was heard to speak of her handkerchief and when a character did not use a roundabout phrase about the march of the hours to say: "It is midnight."

The rediscovery of Shakespeare

The importance of such details can hardly be exaggerated and can perhaps be best understood by recalling what the rediscovery of Shakespeare meant to the Romantics. His rise from grudging esteem, even in England, to European idolatry by 1830 had a significance beyond the one already mentioned of serving to put down French classical tragedy and, with it, French cultural tyranny. The German scholar, critic, and playwright Lessing was among the first to use Shakespeare for that purpose, but the arguments in his theatre reviews, called *Hamburgische Dramaturgie,* sprang from critical genius and not mere national resentment. Shakespeare spelled freedom from narrow conventions—the set verse form in couplets, the lofty language and long declamations, the adherence to verse throughout, the exclusion of low characters, comic effects, and violent action—or, in a word, from the atmosphere of the court and the aristocratic etiquette.

What Shakespeare typified (and not in poetry or plays alone—witness his influence on Berlioz) was the right of the creative artist to invent his own forms, loosen the joints of grammar and metric (or the canons of any art), follow the promptings of his spirit (tragic or gay, vulgar or mysterious, but in any case venturesome), and see where this emancipation from artificial rules led the muse. There was danger in freedom, as always; the conventions ensure safety. But the aim of the Romantic genius was not to play safe or even to succeed; it was to explore and invent, multiply modes of feeling and truth, and thereby revigorate a dead or dying culture. The motto was not common sense but courage. This resolve explains why the men who came to idolize Shakespeare also rediscovered Rabelais and Villon and revalued Spinoza, the lone dissenter who had worshipped a God pervading the cosmos; Benvenuto Cellini, the fearless artist at grips with the principalities and powers; and "Rameau's Nephew," the ambiguous hero of Diderot's posthumous dialogue, a strange figure disturbingly in touch with the dark forces of the creative unconscious.

Drama. With so much feeling astir and so many novel ideas being agitated, it might seem logical to expect a flourishing school of Romantic drama. But only a few isolated works, more interesting than irreplaceable, compose the dramatic output of the Romanticists—Shelley's *Cenci,* Byron's *Manfred,* and Kleist's brilliant pieces in several genres. Ironically, Shakespeare's new role as emancipator had a curiously paralyzing effect on the theatre down to the middle of the century and beyond. In England, poet after poet tried his hand at poetic drama, only to fail from stage fright at the thought of Shakespeare. On the Continent, various misconceptions about him and old habits of classical tragedy prevented a new drama from coming to life. Victor Hugo's plays contained brilliant verse, and their form influenced grand opera (Wagner's no less than Verdi's), but the fact remained: the dramatic quality could be found everywhere in Romanticist art except on the stage.

Reflection on this point suggests that, quite apart from Shakespeare, the very concern of the Romantics with exploring the inner and outer worlds precluded the writing of great plays. These perhaps require that one world or the other be taken as settled, at least at the start of the dramatic action. Be that as it may, the double reality in flux was the stimulus of all Romanticist endeavour.

Painting. This generality holds for the painters as well; their "reality," too, was by no means "given," so that the notation of fresh detail and the study of new means to transmute the visible into art occupied all those who came after David. Goya led the way in Spain by depicting the vulgarity of court figures and the horrors of the Peninsular War. In England, Constable painted country scenes with a vividness at first unacceptable to connoisseurs. He had to argue with his patron, Sir George Beaumont, about the actual colour of grass. To prove that it was not of the conventional brownish tint used by academicians, he seized a violin, ran out of the room with it, and laid it on the lawn, forcing the unaccustomed eye to perceive the difference between chlorophyll and old varnish. At the same time, Géricault astonished the Parisians by painting, in harrowing detail, "The Raft of the Medusa," not an antique and noble subject but a recent event: the survivors of a shipwreck adrift and starving on a raft.

The new "reality" in painting

The young Delacroix was emboldened by the example and, inspired also by the work of his English friend Bonington, began to paint contemporary scenes of vivid realism—*e.g.,* the Turkish massacre of the Greek peasants at Chios. Later, Delacroix was to visit Morocco (exoticism again) and to discover there the secret of coloured shadows and other pre-Impressionist techniques. His English counterpart, J.M.W. Turner, was pursuing the same goal of realistic truth, though along a different path that nonetheless also led to Impressionism—and beyond. When asked one day why he had pasted a scrap of black paper on a portion of his canvas, he replied that ordinary pigment was not black enough. And he added: "If I could find something even blacker, I would use that."

Sculpture and architecture. No similar transformations of the visual occurred in sculpture or architecture. Canova and Thorvaldsen continued to produce figures and busts on Neoclassical lines; and only Barye, the great sculptor of animals, and Rude, the creator of the Marseillaise panel on the Arc de Triomphe, showed any signs of the new passions. As for architecture, it may have been the love of history that prevented distinctive work. Pugin and Viollet-le-Duc did grasp the principles of what a new style should be, the former's love of Gothic reinstating the merit of framework construction and the latter's breadth of vision as a restorer leading him to predict that iron construction would one day pass from mere utility to high art.

It was actually in railway construction that the seeds of a new architecture were sown. Tunnels and bridges and terminals were needed as early as the mid-1830s, and unassuming engineers such as the Brunels and Robert Stephenson set to work to design them. All they had for solving the new and awkward problems of topography, speed, and cost were the ideas they drew from machinery and the vulgar materials they knew how to handle. The results were often remarkable, and they remained to inspire the makers of 20th-century steel and concrete architecture.

Music. It may seem as if the art of music by its nature would not lend itself to the exploration and expression of reality characteristic of Romanticism, but that is not so. True, music does not tell stories or paint pictures, but it stirs feelings and evokes moods, through both of which various kinds of reality can be rendered or expressed. It was in the Rationalist 18th century that musicians rather mechanically attempted to reproduce stories and subjects in sound. These literal renderings naturally failed, and the Romanticists profited from the error. Their discovery of new realms of experience proved communicable in the first place because they were in touch with the spirit of renovation, particularly through poetry. What Goethe meant to Beethoven and Berlioz and what German folk tales and contemporary lyricists meant to Weber, Schumann, and Schubert are familiar to all who are acquainted with the music of these men.

Changes in the relationship between music and literature

There is, of course, no way to demonstrate that Beethoven's *Egmont* music—or, indeed, its overture alone—corresponds to Goethe's drama and thereby enlarges the hearer's consciousness of it; but it cannot be an accident or an aberration that the greatest composers of the period employed the resources of their art for the creation of works expressly related to such lyrical and dramatic subjects. Similarly, the love of nature stirred Beethoven, Weber, and Berlioz, and here too the correspondence is felt and persuades the fit listener that his own experience is being expanded. The words of the creators themselves record this new comprehensiveness. Beethoven referred to his activity of mingled contemplation and composition as *dichten,* making a poem; and Berlioz tells in his *Memoires* of the impetus given to his genius by the revelation not only of Beethoven's and Weber's music but also of Goethe's and Shakespeare's works and—not least—of the spectacle of nature. Nor did the public that ultimately understood their works gainsay their claims.

It must be added that the Romantic musicians—including Chopin, Mendelssohn, Glinka, and Liszt—had at their disposal greatly improved instruments. The beginning of the 19th century produced the modern piano, of greater range and dynamics than heretofore, and made all wind instruments more exact and powerful by the use of keys and valves. The modern full orchestra was the result. Berlioz, whose classic treatise on instrumentation and orchestration helped to give it definitive form, was also the first to exploit its resources to the full, in the *Symphonie fantastique* of 1830. That work, besides its technical significance just mentioned, can also be regarded as uniting the characteristics of Romanticism in music: it is both lyrical and dramatic, and although it makes use of a "story," that use is not to describe the scenes but to connect them; its slow movement is a "nature poem" in the Beethovenian manner; the second, fourth, and fifth movements include "realistic" detail of the most vivid kind; and the opening one is an introspective reverie.

Self-analysis. In this Romantic investigation of the self, some critics have seen little more than excessive ego or, in modern terms, a tiresome Narcissism. No doubt certain Romantic works arouse boredom or disgust with hair-splitting analysis. But the boredom is often due to the fact that after a hundred years the discoveries have staled. When fresh, they came as a revelation; in the works of the great poets and novelists, in Hazlitt's essays and Jean Paul's fictions, and the irony of Byron's letters or Heine's journalism, the truth has not grown dim or platitudinous.

Desirability of self-analysis

It was in any case desirable that this extensive analysis of the self sould be attempted then, for only an age in which individualism was both theoretical and passionate could see the logic of the undertaking and act upon it. The logic was this: given the autonomous and unique individual, a search by himself into his moods, motives, fears, and loves must bring forth data otherwise unobtainable. Add these results together, and you have a repertory of clues to the inner life of mankind as a whole. For the uniqueness of each individual is bounded by traits he shares with his fellows, and this common element enables the psychologist to connect and organize the reports of the self-searchers. It is on this hypothesis, incidentally, that the demand for originality in art has continued unabated since the Romanticists. Forget the model, for there is no such thing; avoid conformity; discover your true self, the buried child; be authentic and sincere—these precepts, which still govern art and criticism, are the legacy of Romantic individualism.

Introspection naturally implies an inner life worth looking into, and most Romantic artists brought forth extraordinary findings. They form the groundwork of modern thought. One cannot easily imagine Freud or Joyce, much less the degree of self-consciousness shared by Western men today, without the deliverances of Blake, Wordsworth, Keats, Leopardi, Stendhal, Benjamin Constant, Sainte-Beuve, Heine, and innumerable other writers of the early 19th century. And towering above them as the creator of the prototype of Romantic introspection is Goethe with his Faust.

Faust was the figure in which a whole age recognized its mind and soul; and the adjective Faustian, as Spengler's use of it makes clear, still describes tendencies at work in culture today. The principal one, already mentioned, self-consciousness—the identity crisis—remains. The belief, moreover, that movement, activity, is better than repose and that striving is better than achieving is clearly the great postulate of contemporary civilization. Faust himself ends by giving his life to practical works in behalf of his fellow man. But he sets himself on that path only after a slow and deep analysis of his divided soul, which has been ruled together or in turn by despair, lust, superstition and the forces of the unconscious, the love of innocence, the conviction of sin and crime, the horrors of hypocrisy and conventional life, the temptations of wealth and power, the disgust with pedantry and established religion, the yearning for infinite knowledge, and through knowledge, peace. Faust, in short, traverses the whole cosmos, made up of the inner and outer worlds, to find in the act of self-dedication to humanity the justification of his existence.

Early 19th-century social and political thought. The Romantics who studied society through the novel or discoursed about it in essays and pamphlets were also devoted to the cause of humanity, but they arrived at politically different conclusions from Goethe's and from one another's. Scott and Disraeli were forerunners of Tory democracy as Burke was of liberal conservatism. Dickens, a passionate humanitarian, stirred the masses with his examples of the law's stupid cruelty, but he proposed no agency of betterment, content to despise Parliament, the law courts, and the complacency of the wealthy. Balzac wrote his "social zoology," *La Comédie humaine,* to show that society becomes a bloody jungle without the church and the monarchy to restrain human passions.

The cause of humanity

Stendhal noted the same reality but was more concerned with the free play of individual genius; he resigned himself to the social struggle, provided not too many stupid men ran the inevitably heavy-handed regimes. Freedom might be found by the happy few through the loopholes of a mixed government such as England's, whereas in the ostensibly free United States there was no protection against social pressure and no likelihood of genius, in art or in politics.

The great authority on American democracy was Tocqueville, whose astonishing survey in two volumes is still packed with useful lessons. Tocqueville confirmed Stendhal's low estimate of freedom of thought in America, but he foresaw in the United States the first example of a type of democracy that would surely overtake the Western world. He found in such a future many good things and many defects; he predicted a day when slavery would threaten disaster to America; he foretold what kind of poetry a democracy would produce and delineated the art of

Walt Whitman; he apprehended the complication of laws and the declining quality of justice; but he was reconciled to what must be.

Post-Revolutionary thinking. What lay behind all 19th-century writings on politics and society was the shadow of the French Revolution. In the 1790s the Revolution had aroused Burke to write his famous *Reflections* and Joseph de Maistre his *Considérations sur la France.* They differed on many points, but what both saw, like their successors, was that revolution was self-perpetuating. There is no way to stop it, because liberty and equality can be endlessly claimed by group after group that feels deprived or degraded. And the idea that these principles are universally applicable removes any braking power that national tradition or circumstance might afford.

Proof that the revolution marched on, slow or fast, could be read (as it still can be) in every issue of the daily paper since 1789. In the early 19th century the greatest pressure came from the liberals, whether students, bankers, manufacturers, or workmen enlisted in their cause. They wanted written constitutions, an extension of the suffrage, civil rights, and from time to time wars of national liberation or aggrandizement in the name of cultural and linguistic unity. For example, all the intellect of western Europe sided with Greece in the 1820s when it began its war of emancipation from Turkey. Byron himself died at Missolonghi while helping the Greeks. Poets wrote odes, and painters painted scenes of war. Between liberalism and national liberation the line could not be clearly drawn. In Italy, Germany, Poland, Russia, Spain, Portugal, and South America, revolt in the name of liberty was endemic until the middle of the century. Only England escaped, but it was by a narrow margin, after threats and violent incidents expressing the same animus as elsewhere.

Industrialization

Meanwhile, the first disturbances resulting from machine industry—sabotage, strikes, and conspiracies (for trade unions were generally held illegal)—reinforced the Revolutionary momentum, not only in fact but also in theory. As early as 1810 the business cycle, the doctrine of the exploitation of the worker, and the degradation of life in industrial societies had been noted and discussed. By 1825 the writings of the Comte de Saint-Simon, which proposed a reorganization of society to cure these evils, had won adherents; by 1830 the Saint-Simonians were an acknowledged party with sympathizers abroad, and by 1832 the words Socialism and Socialist were in use.

The Saint-Simonian doctrine relied on a benevolent dictatorship of industrialists and scientists to remove the inequities of the free-for-all liberal system. Other reformers, such as the practical Robert Owen, who organized successful communities in Scotland and the United States, depended on a strong leader using ad hoc methods. Still others, such as Leroux and Cabet, were Communists of divergent kinds seeking to carry out elaborate theories of the perfect state. Proudhon denounced the state, as such, and all private property. As a philosophical anarchist, he wished to substitute free association and contract for all legal compulsions. In England, the school of Bentham and Mill—Utilitarians or Philosophical Radicals—attacked existing institutions in the name of the greatest good for the greatest number, and by their arguments they succeeded in reforming the top-heavy legal system. Without doctrine but moved by a similar sense of wrong, Thomas Carlyle fought the Utilitarians for their materialistic expediency and himself sought light on the common problem by pondering the lessons of the French Revolution and publishing in 1837 what is still the greatest account of its catastrophic course. Later, Carlyle gave in *Past and Present* a suggestive picture of what he deemed a true community: quasi-medieval, based on the Faustian joy of work, and relying for its cohesion on its leader's genius and strength of soul.

Numerous other schemes of reform or revolt could be mentioned. One irony about them is that the name that has clung to most of them is utopian Socialism, which suggests unrealizable visions, whereas the historical fact is that a great many were tried out in practice, and some lasted for a considerable time. As in Carlyle's book, the force of character of one man (Owen was a striking example) usually proved to be the efficient cause of success.

Throughout this social theorizing, whatever the means or ends proposed, two assumptions hold: one is that men have a duty to change European society, to purge it of its evils; the other is that men *can* change society—they need only come together and decide what form the change shall take. These axioms by themselves, without the memory of 1789, were enough to keep alive in European culture the hope and the threat of continuing revolution.

The principle of evolution. Yet it should not be imagined that revolution by force inspired every thinking European. Even if liberals and reactionaries were still ready to take to the barricades to achieve their ends, the conservatives were not, except in self-defense. The conservative philosophy, stemming from Burke and reinforced by modern historical studies, maintained the contrary principle of evolution. Evolution indeed swayed as many 19th-century minds as its rival, and it was sometimes the same minds.

Evolution was the belief that lasting and beneficial change comes about by slow and small degrees. It is often imperceptible and therefore congenial to human habits. It breaks no heads and spills no blood; it is natural, organic. In truth, the idea of evolution is patterned on biology—the slow growth and decay of living things. More than that, evolution in the zoological sense of "descent with modification" had been a recognized speculation among men of science since 1750, when Buffon included it in his *Histoire naturelle.* Lamarck had elaborated the idea at the turn of the 18th century, while Erasmus Darwin, the grandfather of Charles, had by 1796 worked out for himself a compendious theory of similar import. In 1830–33 the geologist Lyell, setting forth the corresponding notion that changes in the Earth take place through the operation of constant and not cataclysmic causes, devoted a chapter to Lamarckian biology—to the evolution of species by imperceptible steps.

Revival of interest in history

As if these teachings were not enough to implant a form of thought, the revival of interest in history made easy and obvious the transition from the world of nature to that of man. It seemed logical to think of both as evolutions and even to liken the state to an organism. Certainly the student of institutions finds them steadily and profoundly altered by minute incidents and variations. Compared to these causes, the violent breaks made by war and revolution seem more superficial and less permanent.

The evolutionary scheme permitted several other beliefs while affording a number of arguments and conveniences. Anyone who had inherited from the previous era a faith in progress could now attach it to this motive power, evolution. Anyone who wished to classify nations or institutions by rank could place them as he thought proper on an evolutionary scale. Anyone who resisted change or wished to speed it up could be admonished with some evolutionary yardstick. Finally, anyone who intended to write a work of history or propaganda found his organizing principle ready-made for him. In the first half of the 19th century, every subject of interest, from costume to the criminal law, was presented in innumerable studies as proceeding majestically at an evolutionary pace.

Another way of stating the influence of this great idea is to say that the mind of Europe had experienced the "biological revolution." Whereas in the 17th century the Newtonian revolution had imposed the model of mechanics and mathematics, what impressed itself on the 19th century was the living organism—change and variety as against fixity and regularity. The logic of preferring "biology" to "mechanics" in an age of individualism, of realism about concrete particulars, and of passionate imagination and introspection need only be stated to be evident.

Science. This is not to say that the science of physics stood still during the Romanticist period. It was the time when the conservation of energy was established and the mechanical equivalent of heat demonstrated. There also prevailed the "physical" pseudo-science of phrenology, which professed to relate individual attributes to bumps and hollows in the skull, and which led to the physical anthropology that defined three, 10, 20, and 100 different races of man by the end of the century. Still, the 19th was more emphatically the century that furnished the theory of the cell (Schleiden and Schwann, 1838–39), which led

ultimately to the notion of microscopic creatures responsible for putrefaction and disease and, later still, to cytology and genetics.

It is noteworthy, too, that the 19th century saw the establishment of chemistry on the Daltonian hypothesis of the atom, but it was coloured by the "biological" notion of elective affinities to explain compounds. Goethe, who was an early evolutionist and the scientific expositor of the metamorphosis of plants, called his last novel of human love *Elective Affinities.*

Poetic ideals versus science

On the surface the poetic mind of the age seemed hostile to both science and technology. Wordsworth looks like an enemy of science when he says: "We murder to dissect" and deprecates the man who is willing to "peep and botanize upon his mother's grave." But reflection shows that the animus here is not so much against science as for the science of life. And to make the effort of recapturing the temper of the times is to be at once struck by the precarious status of science itself. Thought in the 18th century had ended in materialism and skepticism. Some writers, such as d'Holbach, had reduced all phenomena to the interaction of hard and unfeeling particles; others, such as David Hume, had "proved" that man can know nothing beyond his impressions and therefore can have no certainty about the truth of cause and effect, on which scientific statements depend. The Romanticist generations could neither agree that life was a concourse of unfeeling atoms nor trust the physicists' assertions based on a law of causation that the most acute thinkers discredited.

Such were the iron constraints within which the famous "crises of the soul" and conversions to religions new or old took place in the '20s and '30s of the last century. Carlyle, Mill, Lamennais, and many others described them in autobiographical works. The choice seemed to be a blind and meaningless universe or a meaning restricted to the motions of matter, equally blind. Even if the latter scheme "explained," it was vulnerable to David Hume's irrefutable doubts.

Early 19th-century philosophy. What enabled 19th-century culture to pursue the scientific quest and regain confidence in spiritual truth was the work of the German Idealistic philosophers, beginning with Immanuel Kant.

Kant. Kant took up Hume's challenge and showed that although we may never know "things as they are," we can know truthfully and reliably the data of experience. The reason for this certitude is that the mind imposes its categories of time and space and causation on the flowing stream and gives it shape. Science, therefore, is not a guess, nor is human knowledge a dream. Both are solid and verifiable. Indeed, certainty, according to Kant, extends as far as morals and aesthetics. The essence of morals is the commandment not to perform any act that one would not want to become a precedent for all human action and always to consider an individual as an end in himself, not as the instrument of another's purpose. The fusion in Kant of ideas stemming from Rousseau and the Enlightenment with ideas fitting the needs of the coming century (Kant died in 1804) made him the fountainhead of European philosophy for 50 years.

Kant's disciples. His disciples—Fichte, Hegel, Schopenhauer—twisted or amplified his teachings. Coleridge in England and Victor Cousin in France adapted to home use what seemed fitting. The school as a whole was known

German Idealism

as German Idealism because it relied on the distinction between the thinking subject and the perceived object; "idea" and "thing" were unlike, but idea (or the mind) played a role in shaping the reality of things, from which derived all stability and regularity in the universe.

Stability was desirable as a guarantor of natural science, but to any observer of human history it seemed contradicted by events, especially those since the French Revolution. Hegel, coming after Kant and witnessing Napoleon's victory at Jena in 1806, was therefore impelled to modify the Kantian logic. To account for the great torrent of human history, he imagined a logic of movement, by which opposing forces are in perpetual battle. Neither side wins, but the upshot of their struggle is an amalgam of their rival intentions. Hegel called the pros and the cons and their survivors thesis, antithesis, and synthesis. Human affairs are ever in dialectic (dialoguing) progression. At times a "world-historical figure" (Luther, Napoleon) embodies the aspirations of the masses and gives them effect through war, revolution, or religious reformation. But throughout the succession of events, what is taking place is the unfolding of Spirit or Idea taking on itself the concrete forms of the real. Hegel's was another version of evolution and progress, for he foretold the extension of liberty to all men as the fulfillment of history. It is interesting to note that until 1848 or '50 Hegel was generally considered a dangerous revolutionary, a believer in an irresistible progress that mankind must earn by blood and battle. Karl Marx, as a younger Hegelian, was to carry out Hegel's unspoken promise on a different base.

Other branches of the all-powerful German philosophy deserve attention but can be spoken of only as they relate to high Romantic themes. Fichte's modification of Kant made the ego the "creator" of the world, an extreme extension or generalization of individualism. At the other extreme, but more in tune with contemporary science and art, Schelling made nature the source of all energy, from which individual consciousness takes off to become the observer of the universe. Nature is a work of art and man is, so to say, its critic, and because human consciousness results from an act of self-limitation, it perceives moral duty and feels the need to worship.

Religion and its alternatives. That need made itself felt ecumenically throughout Europe from the beginning of the 19th century. It had indeed been prepared by the writings of Rousseau as early as 1762 and the pastoral work of John and Charles Wesley much earlier. The atheism and materialism of the late 18th century was in truth far more responsible for the religious revival of the 1800s than the brief secularism of the French Revolution itself, so that when the Catholic writings of Chateaubriand and Lamennais in France, the neo-Catholic Tractarian movement in England, and the writings of Schleiermacher and his followers in Germany began to take effect, their success was due to the same conditions that made Romanticist art, German idealism, and all the "biological" analogies succeed: the great thirst caused by dry abstractions in the Age of Reason needed quenching. Religious fervour, artistic passion, and "gothic" systems of philosophy filled a void created by the previous simple and mechanical formulas.

The political consequences of the religious revivals

The religious revivals, Catholic or Protestant, also aimed at political ends. Their participants feared the continuation in the 19th century of secularism and wholly material plans. In every country the liberals proposed to set up in the name of tolerance ("indifference," said the Christian believers) governments that would serve exclusively practical (indeed commercial) interests. Church and state were to be separated, education was to be secular, which would really mean anti-religious. National traditions would be broken, forgotten, and youth would grow into "economic man," Benthamite Utilitarian man, with no intuition of unseen realities, no sensitivity to art or nature, no humility, and no inbred morals or sanction for their dictates.

Scientific Positivism. The alternatives to the richness of a life lived within traditional religion were two: scientific Positivism and the cult of art. The name Positivism is the creation of Auguste Comte, a French thinker of mathematical cast of mind, who in 1824 began to supply a philosophy of the natural sciences opposed to all metaphysics. Science, according to Comte, delivers unshakable truth by limiting itself to the statement of relations among phenomena. It does not explain but describes—and that is all mankind needs to know. From the physical sciences rise the social and mental sciences in regular gradation (Comte coined the word sociology), and from these man will learn, in time, how to live in society.

Having elaborated this austere system, Comte discovered the softer emotions through a woman's love, and he amended his scheme to provide a "religion of humanity" with the worship of secular saints, under a political arrangement that the sympathetic John Stuart Mill nonetheless described as "the government of a beleaguered town." Comte did not attract many orthodox disciples, but the influence of his Positivism was very great down to recent times. Not alone in Europe but also in South America it

formed a certain type of mind that survives to this day among scientists and engineers.

The cult of art. The second "religious" alternative, the cult of art, has had even greater potency, being at the present time the main outlet for spirituality among Western intellectuals. In the Romantic period this fervour was allied with the love of nature and the idolatrous admiration of the man of genius, beginning with Napoleon. A writer as sober as Scott, a thinker as cogent as Hegel, and an artist as skeptical as Berlioz could all say that to them art and its masters were a religion; and they were not alone. At the death of Goethe in 1832, Heine inveighed against the great man's followers who made art the only reality. In the second and third Romantic generations, born around 1820, the religion of art grew still more pronounced and took on an antisocial tone that became more and more emphatic as time passed. "Art for art's sake" ended by signifying, among other things, "art the judge of society and the state." This doctrine was expounded in full detail by the Romantic poet Gautier as early as 1835 in the preface to his entertaining and sexually daring novel, *Mademoiselle de Maupin.* In those pages the familiar argument against bourgeois philistinism, against practical utility, against the prevailing dullness, ugliness, and wrongness of daily life was set forth with much wit and that spirited defiance of all established things which is associated rather with the 1890s and the present day than with Romantic passion. Its occurrence then is but another proof that Romanticism was the comprehensive culture from which later styles, thoughts, and isms have sprung—down to our own time.

"Art for art's sake"

The middle 19th century. During the half century when Romanticism was deploying its talents and ideas, the political minds inside or outside Romanticist culture were engaged in the effort to settle—each party or group or theory in its own way—the legacy of 1789. There were at least half a dozen great issues claiming attention and arousing passion. One was the fulfillment of the Revolutionary promise to give all Europe political liberty—the vote for all, a free press, a parliament, and a written constitution. Between 1815 and 1848 many outbreaks occurred for this cause. Steadily successful in France and England, they were put down in central and eastern Europe under the repressive system of Metternich.

A second issue was the maintenance of the territorial arrangements of the treaties made at the Congress of Vienna in 1815. Metternich's spies and generals also worked to keep this part of the post-Napoleonic world intact; that is, the boundaries that often linked (or separated) national groups in order to buttress dynastic interests. Except in Belgium, the surge of national, as distinct from liberal, aspirations throughout Europe was unsuccessful in the 1830s. But defeats only strengthened resolve, particularly in Germany and Italy, where the repeated invasions by the French during the Revolutionary period had led to reforms and stimulated alike royal and popular ambitions. In these two regions, liberalism and nationalism merged into one unceasing agitation that involved not merely the politically militant but the intellectual elite. Poets and musicians, students and lawyers joined with journalists, artisans, and good bourgeois in open or secret societies working for independence: they were all patriots and all more or less imbued with a Romanticist regard for the people as the originator of the living culture, which the nation was to enshrine and protect.

Merger of liberalism and nationalism

To be sure, this patriotic union of hearts did not mean agreement on the details of future political states, and the same disunion existed to the west, in England and France, where liberals, only half satisfied by the compromises of 1830 and 1832, felt the push of new radical demands: of the Socialists, Communists, and anarchists. Reinforcing these pressures was the unrest caused by industrialization—the workingman's claims on society, expressed in strikes, trade unions, or (in England) Chartist groups. This cluster of parties agitated for a change that went well beyond what the advanced liberals themselves had not yet won. Add to these movements those that purposed to hold still or to restore former systems of monarchy, religion, or aristocracy, and it is not hard to understand why the great revolutionary furnace of 1848–52 was a catastrophe for European culture. The four years of war, exile, deportation, betrayals, coups d'etat, and summary executions shattered not only lives and regimes but also the heart and will of the survivors. The hoped-for evolution of culture was broken and, with all other hopes and imaginings, rendered ridiculous. The search began for new ways to achieve, on the one side, stability and, on the opposite, the final desperate revolution that would usher in the good society.

For although they seemed decisive, the battles of '48 and after did not, in fact, test the worth of any one idea. Nationalism won and lost in different parts of Europe. Liberalism gained in Italy and Switzerland, but was set back in Germany and France. English Chartism seemed to collapse, yet its demands began to be carried out. The Socialist experiment in France (Louis Blanc's national workshops) also seemed discredited; yet the ensuing regime of Napoleon III made attempts, however clumsy, to deal with poverty by welfare methods. Repression had shifted men and territories—Metternich was gone from Austria—but Germany and France were not on that account flourishing under liberty, equality, and fraternity. There was peace, but war was imminent; and subversive groups continued to plot and publish and frighten the bourgeois, while industry and urbanization contributed their gains at the cost of the now familiar miseries and sordor.

In these circumstances the mind of Europe suffered an eclipse, followed by a protracted mood of despondency. Many established or emerging artists and thinkers had been killed or torn from their homes or deprived of their livelihood. Richard Wagner fleeing Dresden, where he conducted the opera; Chopin and Berlioz at loose ends in London, because in Paris music other than opera was moribund; Verdi going back to Milan with high patriotic hopes and returning to Paris in a few months, utterly disillusioned; and Victor Hugo in exile in Belgium and later in Guernsey—all typify the vicissitudes in which men of reputation found themselves in mid-career. For the young and unknown, such as the poet Baudelaire or the English painters who formed the Pre-Raphaelite Brotherhood, it was no time to invite the public to admire boldness and accept innovation. Critics and public alike were all nerves and hostility to subversion. To read Flaubert's masterpiece, *L'Éducation sentimentale,* is to understand the atmosphere in which the first phase of Romanticism ended and its ramified sequels came into being.

Mood of despondency

Realism and Realpolitik. The dominant feeling was that high hopes had perished in gunfire, and this realization bred the thought that hope itself was an error. Any new effort must therefore stay close to the possible, the "real." Realism with a capital *R* and *Realpolitik* together sink their roots in a distrust of man's imagination. This grim caution born of harsh experience coincided with a sense of fatigue that made Romanticist work seem like the foolishness of youth.

The appropriate cultural note must no longer be the infinite or heroic or colourful but rather their opposites. If the commonly accepted term Realism for this reaction of the 1850s is used, it must be with these presuppositions in mind. For the Romantic passion for the particular and exact was a realism, too; it was what Dr. Johnson much earlier had called "vehement real life." The Realism of the disillusioned '50s dropped the vehement, the passionate and, in order to run no risk of further illusion, limited what it called real to what could be readily seen and felt: the commonplace, the normal, the workaday, and often the sordid.

Limitation of "real"

In the same spirit *Realpolitik* rejected principles. The word did not mean "real" in the English sense; in German it connotes "things"—hence a politics of adaptation to existing facts, pursuing plain objects, admitting no obligation to ideals. In this light we can understand the unexpected epithet "scientific" that Marx and his followers bestowed on their brand of Socialism. It was a science not merely because it was presumably based on the laws of history but even more because in its view the advent of the Socialist state was to result from the interaction of things (classes, means of production, and economic necessity)

and not, as in earlier socialism, from the will (that is, the imaginative efforts of thinking men). The "objective" appearance given to the new politics of things, Socialist or other, generated that tough, no-nonsense atmosphere, which men then wanted as a source of reassurance in all their dealings.

Scientific Materialism. This search for certainty went with a swinging back of the pendulum in science itself from the vitalism of the previous period to the Materialism of the midcentury. German philosophers derided Idealism and taught the equivalence of consciousness and chemistry: "without phosphorus, no thinking." The machine once more became the great model of thought and analogy—and nowhere more vividly and persuasively than in biology, where Darwin's advocacy of natural selection won the day because it provided a mechanical means for the march of evolution. The struggle for life (Spencer's phrase of 1850, adopted by Darwin in his subtitle) obviously had the requisite "toughness" to convince and, like *Realpolitik,* it followed no principle—whoever survived survived. That Darwin to the very last included other factors in his theory of evolution—Lamarckian "use and disuse" as well as direct environmental forces—carried no weight with a generation bent upon machine certainty. These secondary explanations were ignored, in the usual way of cultural single-mindedness, and for 30 years after the publication of the *Origin of Species* in 1859, an orthodoxy of universal mechanism reigned over all departments of thought.

It prevented the recognition of Mendel's work on genetics; it put religious, philosophical, and ethical thought on the defensive—only what was "positive" (*i.e.,* material) held a presumption of being real and true. The same reasoning produced a school of social Darwinists who saw war between nations and economic struggle among men as beneficent competition leading to the survival of "favoured races"—another phrase from Darwin's subtitle.

The "really real"

And by a final twist of logic, Materialism reinforced the moral gloom of the period by casting doubt on both the permanence and the validity of all that was being redefined as "really real." For on the one side, the second law of thermodynamics guaranteed the cooling of the Sun and the pulverization of the cosmos into cold and motionless bits of matter; and, on the other, orthodox "machineism" brought its leading prophets, Huxley and Tyndall, to consider men and animals as automatons moved as helplessly as atoms and planets. Consciousness is an epiphenomenon—in plain word, an illusion—precisely as in Karl Marx consciousness and culture are illusions floating above the reality of economic relations.

Victorian morality. To be sure, not everybody in Europe believed or cared about these affirmations. And although ideas long debated do in the end filter down to the least intellectual layers of the population, the time and place of triumph for a philosophy are limited by this cultural lag—a fortunate delay, without which whole societies might collapse soon after the publication of a single book. What kept mid-19th-century civilization whole was a subdued faith in the reality of all the things Realism and materialistic science denied: religious belief, civic and social habits, the dogma of moral responsibility, and the hope that consciousness and will did exist.

The sum of these invisible forces is conveniently known as the Victorian ethos or morality, a formula applicable to the Continent as well as Britain and one whose meaning antedates not only the midcentury revolutions but also the accession of Queen Victoria in 1837. Like Romanticism, this powerful moralism had its roots in the late 18th century—in Wesleyan Methodism, the Evangelical movement, in Rousseau, Schiller, and Kant. Its earnestness was of popular origin; it was anti-aristocratic in manners, and it sought the good and the true in a simple, direct, unhesitating way. Perceiving with warm feeling that all men are brothers under God, the moral man saw that slavery was wrong; and having so concluded, he proceeded to have it abolished by act of Parliament (Britain, 1833).

Such fervent convictions when widely shared exert tremendous power, and this concentration of belief and emotion made Victorian morality long impregnable. As Chesterton said of the Victorian painter Watts:

> He has the one great certainty which marks off all the great Victorians from those who have come after them: he may not be certain that he is successful, or certain that he is great, or certain that he is good, or certain that he is capable: but he is certain that he is right.

The sense of rightness generated a sense of power, which the Victorians applied to the monumental task of keeping order in a post-revolutionary society.

Partly by taking thought and partly by instinct, they perceived that the drive to revolution and the sexual urge were somehow linked. Therefore they repressed sexuality; that is, repressed it in themselves and their literature, while containing it within specified limits in society. Further, they knew that the successful working of the vast industrial machine required a strict, inhuman discipline. The idolatry of respectability was the answer to natural waywardness. To pay one's bills, wear dark clothes, stifle individual fancy, go to church regularly, and turn aggression upon oneself in the form of worry about salvation became the approved common modes of pursuing the pilgrimage of life.

Idolatry of respectability

It could not be expected that everybody would or could conform. From its beginning to the end, the Victorian age numbered a galaxy of dissenters and critics who scorned the conformity, called the religion a sham, and viewed respectability as mere hypocrisy. But the front held, and the massed forces behind it were at their strongest after the multiplied assaults of 1848.

Nothing gives a better idea of the astonishing moral structure called Victorianism than the development of the London Metropolitan Police, begun under Sir Robert Peel in 1829. A lawyer and a former captain who had fought in the Peninsular War were the first joint commissioners and creators of the force. At first they had to weed out the drunks and the bullies who had been the main types of recruit in earlier attempts at policing cities. At first, too, the people both ridiculed and fought with the new police. Gradually, the "peelers" came to be trusted; they remained unarmed regardless of circumstances; they learned to handle rioters without shedding blood; and in the putting down of crime they finally enlisted the public on their side. For something less than a century this unique relationship lasted, in which "law-abiding" and "police" were terms of respect—correlative terms, since the peelers (later "bobbies") could not have become what they were without the self-discipline and moral cohesion of the "respectable."

The upheavals of the midcentury, cultural as well as political, put Victorianism to a severe test, for after wars and civil disorders laxity is natural, and ensuing despair induces a reckless fatalism. There was cause indeed for apprehension. When the Great Exhibition of 1851 was planned on a scale hitherto unattempted, many expressed the fear that to allow tens of thousands from all over Europe to come together under the Crystal Palace was to invite massive riots. Ministers and heads of state would be assassinated. In the event, no protracted assembly of common people and their leaders was ever so quiet and orderly. The moral machinery worked as efficiently as that which was on display under the glass dome.

The advance of democracy. Yet, while a stringent moralism held in check endemic subversion and anarchy, Darwinism and the machine analogy stimulated endless forms of self-consciousness. If man could fashion and continually improve these engines, perhaps he could also engineer an improved society. Because evolution was at last "proved," thanks to Darwin, perhaps it also gave warrant for social and political progress by gradual steps. Spencer's all-inclusive philosophy, likened then to Aristotle's, foresaw an inevitable movement from the simple and undifferentiated to the complex and specialized—as in modern life. Clearly, whether automatons or not, men kept thinking and having purposes; and among evolutionists and scientific socialists alike, thought and purpose included the hastening by voluntary action of what was sure to come by force of natural laws. These and other desires acting in the light of Realism and taking shape in the increasing organization of the toiling masses brought Europe to accept democracy as inevitable.

Evolution as a warrant for social and political progress

The word democracy is used here in a cultural sense. It does not imply a set of political institutions so much as the signs and the agencies that herald the coming populist state of our day: for example, the extension of the franchise, in parliamentary or plebiscite form; the secret ballot; the legalization of trade unions; the rise of a Catholic social movement; the passage of education acts providing free, public, and compulsory schooling; the formulation of Tory democracy as a cure for the evils of free-for-all economic liberalism; the beginnings of welfare legislation (in France under Napoleon III, in Germany under Bismarck); the secularization of life by state action, by the prestige of science, and also by the liberal movements within the churches themselves; and finally, after a decade or so of public education, the great extension and popularization of the press. At the passage of the Reform Act of 1867 in Britain, which gave the vote to urban workingmen, Robert Lowe had said, "Now we must educate our masters." In a parliamentary system the means to that education cannot be the schools alone. The adult "common man" must continually be informed and appealed to for his satisfaction as well as for coherent policy in government. The instrument for this purpose was the new journalism. The quarterlies of the early 19th century gave way to the monthlies in the '60s and they in turn to the weeklies, while the daily papers, costing now but a penny and simplifying all they touched, began to reach the millions.

Realism in the arts and philosophy. In the period of so-called Realism, the arts and philosophy as usual gave both form and substance to the prevailing fears and desires. The mood of soberness and objectivity was alone acceptable, and what art presented to the public confirmed the reasonableness of the mood.

Literature. This interaction accounts for such things as the marked change of tone in Dickens' novels that occurs between *David Copperfield* (1850) and *Bleak House* (1853). The temper expressed in most concentrated form the very next year in *Hard Times* now dominates Dickens' mind and works to the end: life is a dreary sort of underworld; happy endings are artificial conventions not to be believed.

The same mood explains why Flaubert's *Madame Bovary,* which ranks today as the realistic novel par excellence, and is on all counts grim enough in its rendering of boredom and vulgar misery, was judged "too artistic" by some contemporary critics, not close enough to the most common of realities, that of common speech.

Yet the evolution of Flaubert's work remains instructive for an understanding of Realism as a literary creed. Flaubert had begun by writing a highly coloured, imaginative story on *La Tentation de Saint Antoine,* which the author's friends advised him to burn, tone down, or rewrite. Flaubert put it aside and began the novel that became *Madame Bovary.* Its setting was the provincial world around him, not the Egyptian desert; the characters were of the most ordinary type, not an improbable Christian ascetic haunted by visions. But even in the working out of his plain tale Flaubert had to subdue his lyrical Romantic genius to the discipline he had adopted. The description of a rainstorm, for instance, had to be done over and over again so that it would not stand out and be "interesting" by virtue of the observer's mind. It had to be made ordinary and the observer kept outside, just as in science. *Madame Bovary,* begun as a magazine serial, was soon censored by the editor and then prosecuted as immoral by the state. For Flaubert's Realism had gone so far as to portray in no flattering colours the dreary lives and motives of average provincials of both sexes, and the picture violated the rules of the indispensable moralism. What is more, the fate of Flaubert's unhappy heroine symbolized what had happened to the more daring and poetic-glorious time before 1848: as Flaubert said, Emma Bovary was himself.

The significance of *Madame Bovary*

His novel is thus simultaneously a model and a critique of the new genre—a critique, too, of the state of Europe that produced it. Many other writers between 1850 and 1890 pursued matter-of-factness without this ulterior effect and rendered the details of middling life with such impassiveness and fidelity that to this day many use "realistic" as a synonym for dreary or sordid and regard "the novel" as a reliable historical source. On the precise definition of Realism, George Gissing gave, through a character in one of his own novels, a brilliant commentary: the character is at work on a novel which shall be so true to the dullness of daily life that no one will be able to read it.

Painting and sculpture. The term Realism applies no less to the plastic arts than to literature, but in painting and sculpture it proved difficult to give form overnight to the change of attitude just noticed in literature and political life. The transition between the passionate poetry and drama of Géricault and Delacroix and the Realism of Courbet and Manet was gradual. It came by way of the "open-air" school of Barbizon, whose landscapes seemed arid (at least to the classically trained academic painters of the day) and pointless in the sense that they depicted the commonplace. Still, when the full shock of Realism inflicted by the works of Courbet and Manet occurred, it was severe: here were coarseness and violence in manner and subject. Courbet's backgrounds are thick and his people drab; Manet's nude "Olympia" is no goddess nor even a beautiful woman; she is a prostitute, and her name seems like a piece of irony. The portrait of his parents is a painful representation of simple poverty unrelieved by any glow of spirit or intelligence—yet the work itself is beautiful: such was, throughout, the aim and achievement of Realism.

The gradual transition to Realism in painting

In England, by an historical accident, pictorial realism was embodied in subjects that seem far removed from the commonplace. The school that took up the challenge against academic painting and modified the vision of Constable and Turner called itself Pre-Raphaelite. Its members were Holman Hunt, John Millais, and Dante Gabriel Rossetti, and the name they took for their "brotherhood" expressed their resolve to paint like the masters who came before the imitators of Raphael. It is necessary to put it in this clumsy way in order to make clear that Raphael himself was not being condemned, but only his academic followers who introduced "unreality."

To be a Pre-Raphaelite was to see the world with a sharp eye and an undistorting mind and to render it with intense application to solidity of form, bright colour, and natural pose and grouping. All this was to be understood from the motto *Death to Slosh!* In order to make the new virtues vividly clear and also because the Pre-Raphaelites were reared on great literature, their subjects tended to draw upon legend, or Dante, or the New Testament. It was the conception and treatment that constituted the innovation. Everybody could see it, because it went against the habit of "pretty-pretty" illustration. In fact the nominal subject dropped out of sight in the startled response to form and colour. Paradoxically, then, the commonplace subjects of the French realists and the legendary ones of the English Pre-Raphaelites were alike insignificant when compared with the effort to re-create by art the texture and "feel" of actuality—and nothing more. Such was precisely the goal Flaubert pursued and reached in *Madame Bovary.*

Popular art. It hardly needs to be added that this conscious purpose of high art could interest but a relatively small portion of the public and that, for the growing mass of readers of fiction and viewers of art, other kinds of satisfaction were necessary. The ordinary three-volume novel from the lending library and the continued serial in the magazine or newspaper supplied the demand by aping, adapting, and diluting not one but half a dozen literary tendencies, old and new. The number of novels produced in all languages in the 19th century has never been estimated, but it surely must be of the order of astronomical magnitudes. And the whole output was realistic in the sense that it professed to impart the real truth about life. It was contemporary in setting and speech, took the form of a history, and taught its readers how other people lived. The pictorial counterpart was the "chromo," the cheap colour lithograph that illustrated either fiction or news stories in forms which, however false they must seem to a critical eye, again gave the illusion of commonplace reality.

Growth of the novel in the 19th century

Music. At first sight, it would seem as if music were a medium in its nature resistant to Realism. But that is

to reckon without the obvious use that music has always made of sounds directly associated with life—church bells, hunting horns, military bands, and the like. In an age when Realism was at a premium, the opera would be the form where these and other associations easily found their place. So it was in midcentury Europe, where Meyerbeer and others provided the effects to suit the fussily "real" staging of all plays, musical or not. Clocks, tables, animals, waterfalls, and especially costume could be relied on to be genuine up to the limit of the possible: live bullets for real deaths were shied away from, and real lightning was out of reach.

But a genius who is often mistakenly grouped with the Romantics, Richard Wagner, supplied this ultimate deficiency—and by musical means. As critics have pointed out, Wagner's system of leitmotives, or musical tags that denoted an object, a person, or an idea, was consciously or unconsciously an accommodation of Realist intent to operatic understanding. This is true not simply because the musical notes "wave" up and down as Isolde waves her scarf at Tristan—a trivial enough device of a sort found in many composers; it is also true in the deeper sense, which constitutes Wagner's unique genius, namely that he was able to compose great music that was steadily and precisely denotative of items in the story by repeating and interweaving their assigned musical tags. (J.Ba.)

The modern age

CHRONOLOGY OF THE MODERN AGE

During the 19th century economic change had an overwhelming impact on international affairs. At the opening of the century, Britain had been the foremost commercial state in the world, and British wealth had been the mainstay of the coalitions against Napoleon. Britain had been the first nation to undergo the Industrial Revolution, and its early lead in this field, combined with its far-flung empire, ensured its primacy of power in Europe and the world for the rest of the century. Britain was also dedicated to the policy of free trade, adopted in the 1840s.

After 1870 Britain retained its primacy, but the margin of its advantage diminished, challenged in the main from three quarters—the United States, Japan, and Germany. But the impact of the first two is essentially a 20th-century story; the German, on the other hand, was quite clear, sharpened before 1914 by the German policy of naval construction; thus Germany, after unification, lay at the centre of international politics.

The European record over 100 years seemed to belie the gloomy predictions of overpopulation made by Thomas Malthus at the beginning of the century. Although some 50,000,000 Europeans swarmed to other continents, the population of Europe roughly trebled. But the condition of the masses generally improved. The fundamental reason for the change, allowing for political agitation and some humanitarian pressure, lay in the increase in the production of wealth, industrialization most of all. The 19th-century experience of Europe on this score constitutes a perhaps exceptionally fortunate accident, for industrial Europe could draw on the resources of the outer world for food and raw materials.

This growing wealth had other repercussions besides that of raising the standard of living. The combined impact of the rights of man and of scientific and technological development was favourable to the rise of the masses, one aspect of which was the spread of literacy, education in general, and a cheap press. The business of government became less and less the appanage of a restricted privileged class, though the conduct of foreign affairs continued to be a largely esoteric preserve. Yet, at election time and as the franchise spread, the temptation could not be resisted to appeal to the masses. The obverse facet of the democratic coin is demagoguery. How to conduct foreign policy in a democratic milieu has been an increasingly delicate and complicated problem. In the age of nationalism, the simplest way to arouse the masses was to appeal to their national prejudices and emotions. The enthusiasm with which the peoples of Europe responded to the outbreak of World War I in August 1914 bears out the point.

Outside of the United States and Japan, Europe was the mistress and the powerhouse of the planet. The state of European culture, both in the scientific domain and in the letters and the arts, was added grist to the mill of those who confidently believed that Europe *was* civilization, even if this civilization was an increasingly materialistic, godless one. As to the proliferation of arms, it was used as an argument for confidence in the lastingness of peace, ensured by what is now called the balance of terror, although the phrase itself is of later coinage.

There were Cassandras to be sure, and in the end they were, at least in a sense, to be proved right; but, at the time, they were mainly voices crying in the wilderness. When they went to war in 1914, the peoples and the governments of Europe had little inkling that they were initiating the closing chapter of the European Age.

The Bismarckian period, 1870–90. *Bismarck's system of alliances.* Otto von Bismarck, the German chancellor, was a practical man rather than one dedicated to abstract principle. His social bent was undoubtedly conservative, but he understood the active forces of the modern world. Having achieved his purpose of Prussian enhancement in the form of uniting Germany under the Hohenzollern crown, he was now satisfied and entertained no further aggressive designs. He believed that the maintenance of peace and the status quo would provide the best climate in which the new Germany could thrive. Bismarck's peace policy

During the 20 years that he remained in charge, his skillful diplomacy dominated the international scene.

Germany had no enemies save France, which had been humiliated in 1870 and stripped of Alsace-Lorraine. Bismarck had no fear of France if France could be kept in isolation. In France he preferred the republican government and even favoured colonial ambitions, which he hoped would divert French attention away from the Rhine and revanche while possibly embroiling France with others. As for the British, Bismarck was content to leave to them their monopoly of empire.

His relations with Russia were good, and in the new hyphenated Austria-Hungary the Hungarian half was satisfied with the *Ausgleich* (Compromise of 1867) and would emphasize a compensating interest toward the southeast—the Balkans. This would, however, give added point to possible Austro-Russian rivalry. Bismarck's own solution for this problem was simple: divide the Balkan apple of discord between the two contenders—he would be Austrian in Serbia and Russian in Bulgaria. Moreover, the three great conservative states of Europe shared an outlook reminiscent of the Metternichian.

These thoughts bore fruit in 1873 in the Dreikaiserbund (League of the Three Emperors). But agreement was not long lasting, for by 1876 local Balkan events resulted in a falling out between Austria and Russia. Bismarck's control had limits. If he must choose between the two, though he would rather not, he would opt for the wholly European and partly Germanic Dual Monarchy. The Austro-German Alliance was concluded in 1879, henceforth the cornerstone of German foreign policy. In Bismarck's eyes it was undoubtedly a defensive alliance, designed as much to reassure as to restrain Austria.

Within two years Bismarck was able to revive the tripartite connection, but the second Dreikaiserbund foundered, like the first, over local Balkan differences—this time over a war between Bulgaria and Serbia in which Serbia was rescued by Austrian diplomatic intervention.

This drove Bismarck into an extremely complicated scheme. His alliance with Austria was a fixed point, and he even informed the Russians of its terms. But in order to insure against the nightmare of the war on two fronts—a Franco-Russian coalition—he contrived an understanding between himself and Russia, the Reinsurance Treaty of 1887. This treaty has been described by some as Bismarck's greatest diplomatic achievement, by others as an attempt at political bigamy. It was a tightrope-walking act and lasted only as long as Bismarck himself was in power. The Austro-Serbian Alliance and the connection with Romania rounded out the Bismarckian network of eastern alliances. The Reinsurance Treaty

Italy had a low power rating in Bismarck's eyes, but, in

order to secure Austria's rear and to prevent a possible Franco-Italian connection, he enlisted Italy as well in his camp. The Triple Alliance of 1882, made possible in part by Italian fears of French designs, implied a stabilization of the still-existing Austro-Italian antagonism (a legacy of the Risorgimento) and a muting of the Italian irredentist claim against Austria. Italy also fitted into Bismarck's desire for general stability in the south.

Balkan problems. Ottoman affairs, particularly in the Balkans, which were still in the process of achieving national emancipation, continued to be a sensitive and unstable area. In the mid-1870s, revolts flared up in Bosnia and in Bulgaria, out of which ensued a Russo-Turkish war in 1877–78. The victorious Russians imposed the Treaty of San Stefano on the Turks. The treaty called for a drastic rearrangement of the Balkans, whereby a large Bulgaria would be created under the protection of Russia. But the Russian gains in the treaty alarmed the powers. In the face of determined British opposition, the Russians therefore agreed to a collective European revision of the treaty. The powers met at the Congress of Berlin in 1878 and produced a new Balkan arrangement: a much smaller Bulgaria was created and a series of compensations arranged for some of the powers, both large and small. The Balkan provinces of Bosnia and Hercegovina were put under Austrian occupation and administration, and Cyprus was "temporarily" occupied by the British. The Treaty of Berlin was a source of dissatisfaction to the Russians, who, after all, had won the war, and the Dreikaiserbund was a victim.

Seven years later, the Balkans flared up again, though the fighting, Serbo-Bulgarian, remained confined to their locale, and Bulgaria, joined by Eastern Rumelia, achieved full independence from the Sultan. As mentioned above, these episodes dissolved the second Dreikaiserbund.

The new imperialism. Events in the more peripheral regions of the Ottoman Empire are perhaps better placed within the purview of colonial activity. At Berlin in 1878 it had been suggested to the French, by both the Germans and the British, that Tunisia might be suitable compensation for them. Italy was also interested in Tunis, where the reality of an Ottoman connection was cloudy.

In France there were those who insisted that revanche and the German danger should be the first cares of French policy, while a colonial party thought this a sterile attitude that merely prevented France from taking part in Europe's growing interest in the wider world. In 1881 the latter group scored a success with the establishment of a protectorate over Tunisia. Italy was annoyed and joined the Triple Alliance, but there were no repercussions in Constantinople.

In the 1870s both the French and British became deeply involved in Egypt. The French interest was of long standing, and the Suez Canal was mainly used by British shipping. The Khedive's finances were mismanaged and the British and the French intervened to impose a joint Anglo-French supervision of Egyptian finances. Local Egyptian conditions led to further Anglo-French interference, and in 1882 the British took military action, the French having declined at the last moment to join them. This was the beginning of the effective British control of Egypt, for the supposedly temporary occupation of the country proved to be but the initiation of a continuing and deepening involvement.

Anglo-French involvement in Egypt

The cases of Tunis and Egypt may be conveniently regarded as the launching of the new imperialism, a vigorous recrudescence of Europe's imperial activity. The longer established British and French priority in the imperial domain was being emulated by others. Even initially anti-colonial Bismarck yielded to the pressure generated by the rapidity of German economic growth; by the mid-1880s Germany claimed various areas in Africa, and even Italy was developing an interest around and in Abyssinia.

In modern garb the age of discovery and conquest had returned, and the partition of Africa was under way. With a view to avoiding conflict, acknowledging the equal right of all, the powers met in Berlin in an attempt to put some order in the process. Actually, the Berlin West Africa Conference (1884–85), the result of a Franco-German initiative, affirmed the freedom of navigation and trade in the basins of the Congo and Niger rivers. The Free State of the Congo, the outcome of a private initiative headed by King Leopold II of the Belgians, achieved international recognition, and general rules for the establishment of colonial claims were agreed upon.

Penetration of Asia

There were manifestations of imperial activity (primarily British, Russian, and French) in Asia as well. The penetration of China was continuing, as was Russian expansion in Central Asia. This last, pushing toward the western and northern back doors of India, was a source of concern to the British, who found themselves involved in protective, "defensive" expansion. The two influences met in Afghanistan. Likewise, on the opposite side of India, a British protectorate over Burma was proclaimed in 1885, while the French became involved in war with China as a result of their activity in Tonkin.

This colonial activity was largely conducted by a handful of men with small bodies of troops. The peoples of Europe to a large extent were unaware of this aspect of the activity of foreign and colonial offices and had in general no consciousness of being involved in war. While there were also critics of imperialism among Europeans, theirs was but a small voice.

The conscious leaders of Europe's imperial urge nurtured ambitious schemes. Granting the priority of the economic interest and the rationalization of the white man's burden, or *mission civilisatrice,* the factor of national interest, of prestige and pride, should not be minimized. Control of Egypt meant control of the vital artery of the Nile. It was not long before the British were involved in The Sudan, where they suffered a temporary setback. They were also active at the southern tip of the African continent, where Cecil Rhodes, businessman and statesman of ruthless vision, was at work. From these two points as bases, Cairo and the Cape, plus British East Africa, the vision of a vast empire, roughly the eastern half of Africa, symbolized by the Cape-to-Cairo railway project, was born.

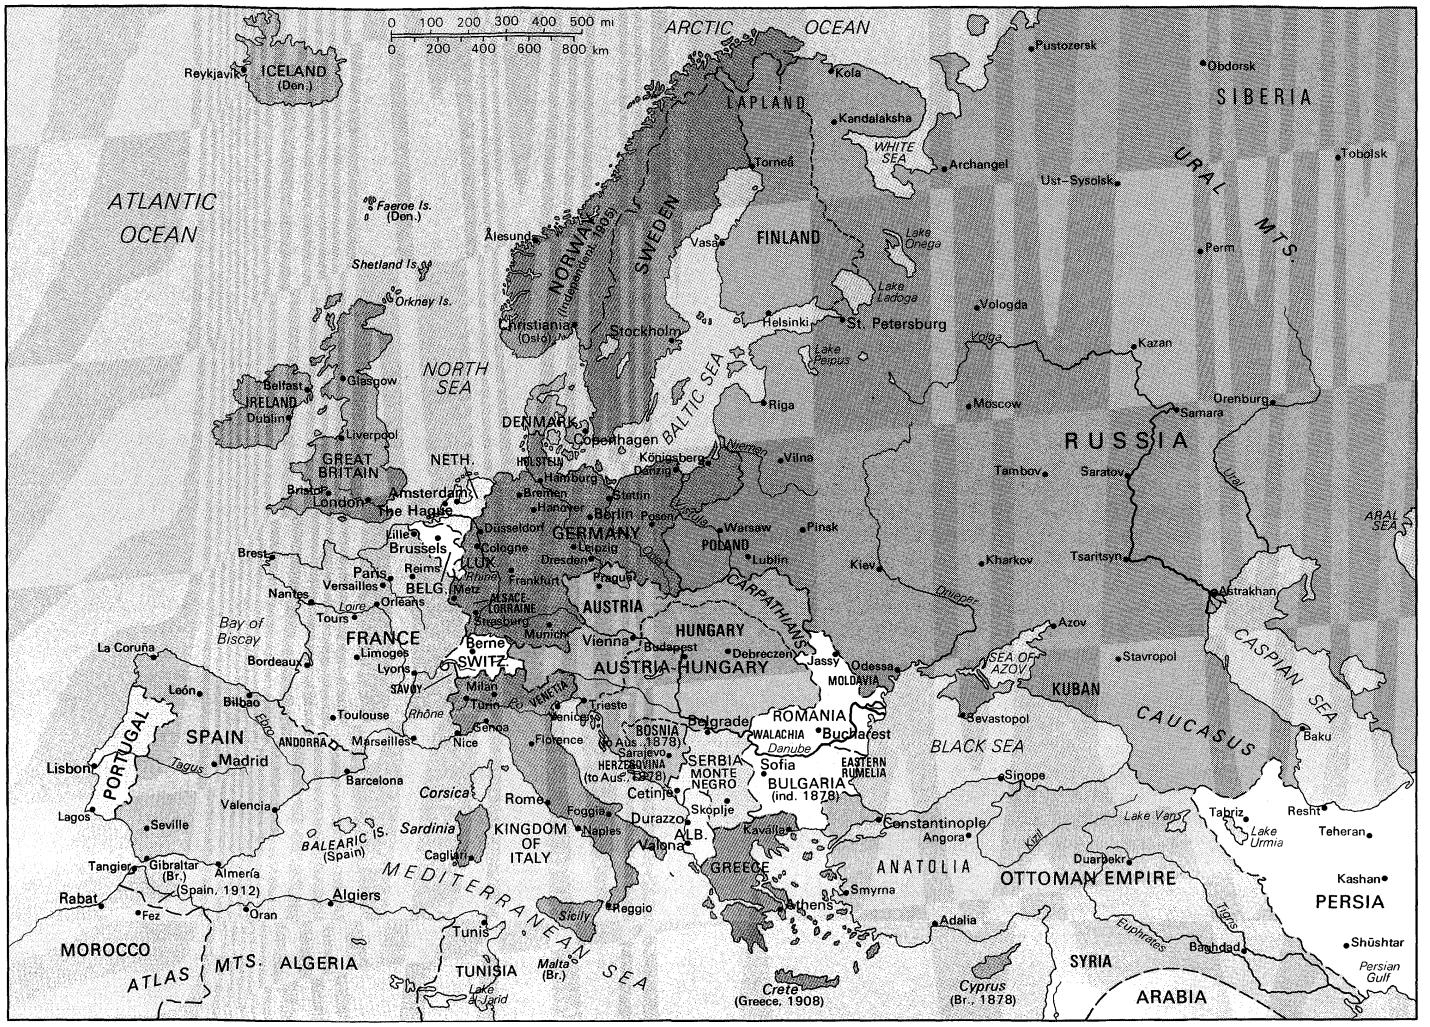
The French could entertain a comparable dream, an extension of France across the Mediterranean all the way to the Congo. Around the sources of the Nile, British, French, German, and Belgian influences met, to which the Italian may be added. Here was incipient rivalry and a potential source of conflicts, but these did not flare up until the 1890s, when exploring activity had laid sufficient bases for overlapping political claims.

Meanwhile, the focus of international relations, over which Bismarck presided, was still predominantly in Europe. But already the seeds of disintegration of the Bismarckian system were planted. The combination of the Triple Alliance, his own treaty with Russia, and the Mediterranean agreements constituted a fragile edifice, undermined by inner inconsistencies. Russia and France were the two revisionist states that Britain was willing, to a degree at least, to help contain. But difficulties, of an economic nature at first and not necessarily irretrievable, began to appear in the Russo-German relationship. Bismarck's dismissal in March 1890 opened a new chapter in the relations among the European powers.

The German challenge. *The period of transition, 1890–1904.* It is a proper measure of the authoritarian nature of the German state that Bismarck could be dismissed from office by the emperor; no constitutional issue was at stake. Bismarck's own place in the roster of statesmen is secure; if personally not a very attractive character, his rank nevertheless belongs among the first: like a good craftsman, he used the proper tool for the right job at the right time; war having served his purpose, he endeavoured to maintain the peace, all the while directing the energies released by the very fact of his unifying success.

Assessment of Bismarck

One reason for his dismissal was the advent, in 1888, of a new emperor, William II. Friction developed between the crusty old man and his young, arrogant, touchy, and romantic new master. The last Hohenzollern proved to be, in a sense, the most adequate and, for that very reason, the most unfortunate embodiment of the insecure, arrogant success that was Wilhelmine Germany, all too effectively conveying to others an impression of aggressive intent out of proportion to the reality of that intent.



Europe, 1871–1914.

A major foreign-policy decision faced the new German administration—whether or not to renew the Reinsurance Treaty with Russia. There were solid arguments pro and con, and the Tsar was desirous of renewal; but the German answer was finally refusal. This decision compounded the uneasiness that had already begun to cloud Russo-German relations before 1890, one consequence of which was the fact that Paris took the place of Berlin in the financing of Russia.

France had been anxious to escape from the isolation in which Bismarck had successfully kept it confined. But France and Russia had few common interests. Russia felt as little concern for French revanche as France did for Russia's Central Asian expansion, with its consequence of Anglo-Russian friction. The focus of France's rivalry was also Britain, to be sure, but it lay mainly in Africa, where Russia had no interest. The only possible binder of a Franco-Russian connection was common fear of Germany, which in the Russian case could arise from the Austro-German alliance.

The Franco-Russian connection began with a series of loans, launched on the Paris market, from 1888 on. A Russian purchase of French arms in 1889 was the next step, followed by military conversations, the elaboration of a contingency plan. The Tsar felt little attraction for what he considered a godless republic, but, eventually, in 1893, he underwrote the results of the military discussions, while the French, on their side, evaded their own constitutional issue through the contention that no formal political alliance was involved, thereby bypassing parliament. Yet from 1893 it is proper to speak of a Franco-Russian alliance as existing. This was the first major breach in the Bismarckian system, made possible in part by the confident but incorrect German assumption that such a possibility was excluded. Like all such instruments at this time it was defensive, and the terms of it were secret.

Franco-Russian alliance

But the situation was still very fluid, and the focus of European rivalries was becoming increasingly extra-European. The Russians were pleased when, in 1893, friction developed between France and Britain in Southeast Asia. The difference was composed, however, and Siam, as a buffer, retained its independence.

By this time the Japanese had made sufficient progress in their imitation of European ways to have developed imperial ambitions of their own. They turned to China, with which they dealt successfully in war, imposing upon it their demands in the Treaty of Shimonoseki in 1895. This Japanese success was of concern to Russia, and an unexpected combination ensued, for Germany—this was its way to weaken or undo the newly formed Franco-Russian connection—gave Russia support in opposing Japan, while France, rather embarrassedly, followed suit. The tripartite combination, Britain excluded, was successful in frustrating Japan of some of its gains; it had special appeal to the German Kaiser, who again and again returned to his project of a continental league.

Africa was at this time also the locale of a similar imperial competition. When in 1894 the British arranged for the purchase of a strip of the Belgian Congo that would connect their African holdings in the north and the south—the Cape-to-Cairo scheme—joint Franco-German pressure caused them to abandon the plan.

The Fashoda incident

But, on the entire course of the Nile, Britain would not allow any control other than its own. When in 1895 the French launched from Gabon an expedition led by Capt. Jean-Baptiste Marchand that was to march across Africa, effecting a connection with their East African base of Djibouti, a cautionary warning was issued in London. But in

September 1898 Captain Marchand reached the Nile at Fashoda, near where British forces under Lord Kitchener had been conducting operations. The confrontation of two handfuls of men on the Nile grew into a major clash between Paris and London.

It was a delicate passage. In Paris the French foreign minister, Théophile Delcassé, a convinced colonialist, came to the conclusion that war with Britain was not desirable. In the face of British intransigence, there was nothing to do but yield. French feeling ran high, but French prestige was seriously injured. Yet out of this situation was to develop one of the most important changes in European power relationships.

Britain's interest in South Africa had been enhanced by the discovery of gold and diamonds in the Transvaal, and Britain was thus brought into collision with that little Boer republic and its twin, the Orange Free State. The South African War began in 1899, after the Fashoda incident had been settled. The British underestimated the guerrilla capacity of the Boers. As a consequence, the protracted conflict entailed a far greater effort on Britain's part than had been thought necessary. In the end the Boers could not stand up unassisted against the resources of Britain. In 1902 the Boer republics were annexed into the colony of the Cape.

The episode had important repercussions. In Britain it led to soul-searching, arousing both strong criticism and nationalistic emotions. Of greater significance was its impact on Britain's international position. The worldwide sympathy for the Boers drove home to Britain the fact of its diplomatic isolation. Britain's traditional stance, that of preferring to remain uncommitted and to eschew alliances in peacetime, might stand in need of reconsideration in the light of the range of Britain's worldwide commitments and of challenges from a variety of quarters. Britain's margin of advantage was diminishing in the face of other rising powers.

Three powers—the United States, Germany, and Japan—were growing at a faster rate than others but at the moment it was Germany that mattered. Since the traditional rivalries with France and Russia still existed, the possibility of a German one being added was a proper source for concern in Britain, especially if it should develop into the Kaiser's plan of a continental league. Preservation of the divisions of Europe, the balance of power, had long been the first directing rule in the defense of Britain's interest.

The German challenge had two aspects. The first was commericial, an expression of the faster German economic growth. It could hardly be expected that Germany should deliberately restrain its expansion in that domain. The other, not unrelated to the first, was in essence political, reflecting the German desire for recognition by others of its right to a place in the sun. Such expressions as *Weltpolitik* and "our future lies on the water," fondly espoused by the Kaiser, expressed it to perfection. In concrete terms, it took the form, in 1898, of embarking on the building of a large navy; it was a considered decision, taken in full awareness of its political implications, the credit—or blame—for which was shared by the Emperor himself and Adm. Alfred von Tirpitz, the father of the German navy. It could hardly be expected that Britain would remain indifferent to such a decision.

Thus, the British reaction to the shifting relationships of power was to re-examine the merits of isolation; put in different form, to reduce the range of commitments by coming to terms with one of the rivals. Bearing in mind Fashoda and the rivalry with Russia across the breadth of Asia, not to mention the currently popular view of the racial affinity and superiority of the Nordic peoples and the tradition of friendly relations with Prussia, Germany was the logical candidate for an approach.

Joseph Chamberlain, a convinced imperialist, opened negotiations with the Germans. Discussions took place on three occasions between 1899 and 1901 but resulted in failure to reach an understanding, a failure that was in large measure due to German psychological misjudgment. The advice of the German chancellor, Bernhard, Fürst von Bülow, to the Kaiser to hold the bid high, regarding Britain as a demandant from whom a political commitment of abstention from continental involvement could be extracted, had a counterproducing effect. Proud Britain may have had difficulties but, after all, had had its way with both the French and the Boers. Even Chamberlain, a Britisher above all in the last analysis, had cautioned his German interlocutors that there were possibilities other than Germany open to Britain.

The first possibility materialized in an unexpected quarter. In 1902 an Anglo-Japanese alliance was concluded that was not even secret. Though the alliance represented a break in the traditional British avoidance of peacetime alliances, it did lighten the burden of British responsibilities in the Far East and thus enhanced Britain's freedom of action in Europe.

The opening years of the century witnessed a marked shift in the power relationships of Europe. Following nearly a decade of unfriendly relations with France, Italy put an end to the tariff war with the conclusion of a commercial treaty; it also reached an understanding with France over Tunis. Francesco Crispi's dream of an East African empire was frustrated by the defeat of Adowa in 1896. In 1900 Italy further acknowledged France's interest in Morocco in exchange for a reciprocal French acceptance of Italian hopes in Tripoli. The ambiguous Interpretation of the Triple Alliance that Italy gave France in 1902 to a considerable degree voided that pact of content, though it was simultaneously renewed. Bülow urbanely turned a good face on Italy's potential infidelity, but Germany entertained few illusions on the score of Italian dependability; Italy's position has aptly been described as being "on the fence."

Franco-Italian relations

In Serbia a domestic upset resulted in the murder of the pro-Austrian king, an Obrenović, and his replacement by the representative of the rival Karageorgević house; henceforth, Serbia abandoned its subservient Austrian allegiance and turned to Russia for protection.

The most important diplomatic shift at the opening of the century, however, was in Anglo-French relations. Fashoda convinced Delcassé that France should eliminate its traditional rivalry with England. He was ably assisted in this policy by Paul Cambon, his ambassador in London, who found receptive ears in Britain, especially after Chamberlain's failure with Germany.

Unlike the Germans, the French did not insist on a political commitment from England. Protracted Anglo-French discussions resulted in the Entente Cordiale of 1904, whereby France agreed to abandon its withering Egyptian hopes, Britain, in turn, sanctioned French ambitions in Morocco, and a number of other important differences were settled. In the context of the imperial activity of the day, this was a fair and reasonable quid pro quo. The understanding contained no hint of an alliance; it was a public document, but secret clauses were attached to it.

The meaning of this in 1904 was problematic, and it might have proved to be no more than a passing flirtation. Time and succeeding events proved it otherwise, however, and it became the opening of a significant new chapter in the affairs of Europe. The British and the French continued to differ on many things, but what gave solidity to the Entente was the fundamental fact that, allowing for differences of power in 1904, the two countries were increasingly finding themselves placed in a similar defensive position vis-à-vis the rising powers. With a time lag of roughly 50 years, the relative decline of the French power position was followed by a comparable British decline. Here was not a passing condition but rather a long-term change in the position of both countries.

The last decade of peace, 1904–14. Two fundamental assumptions of German policy—the impossibility of either a Franco-Russian or an Anglo-French connection—had proved mistaken. The precise nature of the second was uncertain, but Bülow soon had the opportunity to clarify its meaning. The proximity of two dates is significant: in February 1904 the Japanese, without warning, attacked and destroyed a Russian squadron in Port Arthur; in April the Entente agreement was concluded. France's ally, Russia, was at war with Britain's ally, Japan. The Anglo-Japanese alliance had a restraining effect on the possibility of French assistance to Russia; Britain and France shared

The Russo-Japanese War

a common interest in Russo-Japanese accommodation, and the Far Eastern conflict remained localized.

To the surprise of much of the world, the "little yellow men" inflicted a series of defeats on a major European power. To be sure, Russia was handicapped by logistics—the difficulty of supplying a theatre of war over a still incomplete Trans-Siberian Railroad—while the Japanese enjoyed the converse advantage of proximity, hence, of shorter lines of communication. They controlled the sea as well; the pathetic odyssey of Russia's Baltic fleet, sailing halfway around the world, ended in its destruction in the Battle of Tsushima Strait (May 27, 1905). There was nothing for it but to acknowledge defeat, all the more so as internal Russian conditions were taking on a revolutionary hue in 1905. The interposition of American good offices brought the belligerents together at Portsmouth (New Hampshire), where Japan collected the fruits of its competent preparations, having passed the test that insured great-power status. Manchuria and Morocco are far apart, but the simultaneity of the two situations created a connection between them. Britain could indeed renounce its own claims in Morocco; it could certainly not dispose of the rights of third parties. In the form of an ostentatious visit that the German kaiser paid to the Sultan of Morocco, Germany asserted its claim to an equal position in Morocco. The French tactics had been to isolate Germany, and this had been one of their purposes in reaching understandings with Britain, Italy, and Spain in regard to Morocco. On both sides of the Rhine there was complete understanding of the facts and the realities of the Moroccan situation; while Germany felt that Morocco logically "belonged" to France, it would claim a price, as others had, for its consent to that outcome. The issue was, precisely what price? The highest possible was the German view; the smallest was the French.

But Morocco was also a pretext. By asserting equal rights in Morocco, Germany could discover the depth of Britain's commitment in support of France. Bülow himself described his stance as that of "the Sphinx": keep others in uncertainty, and frighten the French; either or both of two results might thereby be achieved: a wrecking of the budding Anglo-French Entente, or the securing of a high price for Morocco.

The Moroccan crises

This is the substance of the First Moroccan Crisis, which meant on the German side raising the spectre of possible war. The French were indeed frightened, to the extent that Delcassé found himself alone among his Cabinet colleagues in opposing a policy of accommodation, insisting that Bülow's tactics were bluff. Properly, he resigned. In what had come to be a duel between two men, the German chancellor had scored the major victory of forcing the resignation of the French foreign minister. But, unwisely, Bülow sought to push his advantage too far, for, if the French yielded to the German demand for an international conference, they were resentful of what they considered undue foreign interference in their domestic affairs.

The Conference of Algeciras in 1906 was a surprise to Germany, which found itself virtually isolated, and the resulting Act of Algeciras, in effect, enhanced the French position in Morocco. Bülow had been all too successful in conveying abroad the impression of German aggressive intent, implemented by tactics of intimidation, the mailed fist, and sabre rattling. One result of the episode was the strengthening of the Entente, the opposite of his intentions; Anglo-French military discussions, again a contingency plan, began in 1906.

After a few years of quiescence, the Moroccan issue flared up again when the French moved in to restore order in the country. The Agadir Crisis of 1911 bears close resemblance in its unfolding to the one just outlined. Sending a German gunboat (the "Panther") to Agadir was a way of asserting a German claim equal to that of the French. From the very outset of the crisis, Britain took a much stronger position in support of France than it had in 1905, and after a tense passage the issue was finally resolved as it might have been in the first place, through a bilateral Franco-German understanding: Morocco to France in exchange for a substantial section of the French Congo to Germany. But the manner in which that result had been procured left a legacy of bitterness and suspicion, especially in Franco-German relations; in France there soon followed the *réveil national,* a resurgence of nationalistic feeling. Between the two Moroccan crises a good deal else had happened.

The impact of the impression created by German tactics in the First Moroccan Crisis and the continued growth of the German navy are to be largely credited for another development. Britain would maintain its naval superiority but proceeded further to reduce the range of its commitments. The Anglo-Russian agreement of August 1907 brought into existence the Triple Entente. The Anglo-Russian understanding is comparable to the Anglo-French one of 1904, dealing with Asiatic rivalries in this case. The heart of it was a division of Persia into three zones—British, Russian, and neutralized. The cry went up in Germany of *Einkreisung,* and indeed encirclement it was, though not with aggressive intent but rather as a response to German impatience expressed in tactics that to others seemed aggressive. Appearance can count for more than reality, and a vicious circle of misunderstanding was closing.

German encirclement

The forces of nationalism, meantime, continued to threaten both the Ottoman and the Habsburg empires. The policy of the latter oscillated between the grant of belated and insufficient concessions and repression. The South Slavs in particular were a troublesome problem, which the shifting of Serbia into the Russian camp in 1903 served to accentuate.

In 1897 Austria and Russia had together "put the Balkans on ice," but the Russian defeat in the Russo-Japanese War shifted the focus of Russian policy back toward Europe. In 1906 the Russian and the Austrian foreign ministers, Aleksandr Izvolsky and Aloys Lexa von Aehrenthal, met and agreed on a scheme for certain changes in the arrangements of 1878. Where Austria was concerned, it would put an end to the ambiguity of its position in Bosnia-Hercegovina by outright annexation of these provinces. The looseness of the understanding and the uncertainties arising from a successful Young Turk takeover in Constantinople—formal title to Bosnia-Hercegovina was still Turkish—induced Austria to create the *fait accompli* of annexation in October. This was the opening gun of the Bosnian annexation crisis of that year and the following. Russia this time, as Germany had done in the case of Morocco, demanded a European conference, which Austria, like France in 1905, was seeking to avoid. The tension lasted until the following spring, when Russia, militarily unprepared and but lukewarmly supported by France, felt that it could not face the prospect of hostilities when Germany took a determined stand in support of its own ally.

The outcome was an undoubted success for the Austro-German combination—a preview in many respects of July 1914—emphasized by a Serbian surrender to an Austrian ultimatum that demanded formal acknowledgment of satisfaction with the annexation. Germany had been the key factor in the resolution of the crisis, but it had acted in support of an initiative that was Austrian; the Bismarckian direction of the alliance had been reversed, in part because Germany considered that in the existing constellation of powers it could not afford to allow its one dependable ally to suffer a setback. But, as a consequence, the distrust and resentment of which Germany was the focus had been deepened.

There followed a two-year lull in the accelerating tempo of crises, during which, however, the arms race was intensified. In 1912 Viscount Haldane, the British war minister, visited Germany in yet another attempt to moderate the naval competition. The effort foundered on the usual reef of the German demand for a political commitment on England's part. Meanwhile, the Agadir Crisis had again raised the spectre of war. Though also resolved, as has been indicated, that confrontation may be regarded as the opening of the last chapter in the story of nearly a half-century of peace.

The Franco-German agreement had not even been concluded when Italy declared war on Turkey for the purpose of acquiring the vilayets of Tripoli and Cyrenaica. The Italians' diplomatic preparations had been adequate, all

the powers having at various times acknowledged the validity of the Italian claim. With some difficulty Italy had its way, and the war was concluded with the surrender of Libya by Turkey in October 1912.

The Italo-Turkish War and the Balkan Wars

The Italo-Turkish War was unpopular with the powers, who feared that an attack on the Ottoman Empire might lead to larger complications. These fears were wholly justified. In March 1912, the Russians scored a notable diplomatic success in contriving a Serbo-Bulgarian alliance, which was joined by Greece within two months. It was clearly an offensive alliance, and in October the Balkan allies went to war against Turkey. A final attempt by Austria and Russia to restrain them came too late.

The allies were surprisingly successful. By December, save for a few isolated centres of resistance, the Turks were defeated and surrendered the entirety of their Balkan holdings with the exception of their capital and the straits connecting the Mediterranean with the Black Sea.

The prearranged division of the spoils, underwritten by Russia, proved unacceptable to some of the other powers. Austria, supported by Italy in this case, interposed a veto on Serbian access to the Adriatic. The Balkan allies fell out. Bulgaria, unwisely, attacked the Serbs and the Greeks and found itself confronted with the Turks and the Romanians as well and shortly went down in defeat. The Treaty of Bucharest (August 1913) settled matters for Bulgaria, but in the western Balkans the powers imposed their own will by creating the state of Albania.

This settlement may be considered as the last instance of the successful operation of the Concert of Europe. The outcome of the Balkan wars was, nevertheless, regarded on the whole as a setback for the Austro-German combination, and the specific form of the settlement had the effect of exacerbating Serbian feeling toward Austria, now the exclusive focus of South Slav irredentism.

Outbreak of World War I

The explosion of the powder keg of Europe, the Balkans, in 1912–13 had failed to ignite the whole continent. But it was only six months before Austria decided to give its own South Slavs a demonstration of its power and determination. On June 28, 1914, the heir to the Habsburg crown, Archduke Francis Ferdinand, visited Sarajevo, the capital of Bosnia, to review army manoeuvres. Some young and irresponsible nationalists, idealistic martyrs to a cause in another view, succeeded in carrying out their plot. Francis Ferdinand and his wife fell victims to their pistol shots—shots that, more than an earlier one, truly were destined to ring around the world. The opening week of August saw all the major powers of Europe, save one, and two minor ones at war. The last chapter of the European Age had begun. (R.A.-C.)

World War I and the Russian Revolution. The war that began in 1914 was the first war of the masses, the first between nation-states able to command the energies of all their subjects and the resources of modern industrial technology, the first on a scale large enough to disrupt the world economy that now hinged on Europe. It differed completely from the wars of the second half of the 19th century; these had been engagements limited in purpose and scope, whereas the War of the Grand Alliances was as complex in purpose as it was unlimited in commitment. It was unprecedented in European history. (See INTERNATIONAL RELATIONS.)

Russia, France, and Great Britain being allies, Germany was from the start confronted with a war on two fronts. Its inevitable purpose was to crush France before Russian resources could be fully brought to action in the east. Its initial effort to achieve this by means of the Schlieffen Plan failed in 1914. Thereafter, fighting on the western front became a war of attrition, with millions on both sides locked in close and indecisive stuggles extravagant in men and materials. Artillery and the machine gun made each attack so costly in lives and munitions that soon each side had to recruit mass armies and expand munitions production on a scale neither had anticipated. On the eastern fronts warfare was more mobile but hardly less expensive in human life.

The strain on national resources, financial and industrial, but even more on discipline and morale, was immense. In the end it shattered the cohesion of the weaker dynastic empires of Turkey, Austria-Hungary, and Russia, and even the more solid Western states experienced mutinies and political crises. Yet the most remarkable feature of the war was the amount of hardship and sacrifice modern society could endure without disintegrating. The German submarine war on British, Allied, and eventually neutral shipping and the Franco-British blockade of the central powers imposed on civilian populations severe shortages of food and supplies. For all these reasons a new concept of total war emerged. Governments controlled or commandeered supplies, trade, credit, transport, and manpower more fully than ever before. The war accustomed nations to centralized power and widespread governmental activities. Total war made possible the 20th-century conception of the totalitarian state. Walter Rathenau, the industrialist who organized the German economy for war, was the forerunner of Lenin, who made Russia, after 1917, the first of the single-party totalitarian states.

The Turkish question. The first war problem confronting the Entente Powers was to clarify their alliance. On september 5, 1914, they signed the Declaration of London, by which they agreed not to conclude separate peace. The Allies second problem was to secure the neutrality of Turkey. The German-Turkish alliance was still unknown to the Allies. The Turks used the negotiations with the Entente to complete their mobilization. Complications arose when two German cruisers that had fled into the Dardanelles were bought by the Turks but continued to be manned by German crews. On October 29 these German warships, together with the Turkish fleet, bombarded Odessa. Russia, Britain, and France declared war on Turkey early in November. The Sultan proclaimed a "holy war" but could not subvert the Muslim subjects of the Allies.

The Dardanelles campaign

Because Turkey's entry into the war closed Russia's main supply line, the Western Allies decided to open the Dardanelles by force. This posed a ticklish problem, since a successful campaign would have brought Anglo-French forces to Constantinople, age-old goal of Russian ambitions. Britain and France promised the straits to Russia, which consented that Constantinople should be a free port and recognized Anglo-French demands for territories in Turkish Asia. This first of the secret treaties between the Allies was never carried out because the Dardanelles campaign failed. When the British Navy finally reached Constantinople in 1918, Russia had become an enemy of the Allies. The closure of the straits in 1914 had been one of the most potent contributory causes of Russia's defeat and hence of the Bolshevik Revolution.

Italy's entry into the war. The Allies were more successful in securing the adherence of Italy. Initially Italy would have been content to remain neutral, at the price of the Austrian Trentino. A grudging Austrian promise to surrender some territories served the Italian foreign minister to extract favourable terms from the Allies (secret Treaty of London, April 26, 1915). Italy was promised southern Tirol, Istria (excluding Fiume), parts of Dalmatia and Albania, and the Dodecanese Islands (occupied since 1912), as well as a share of Turkey and of the German colonies. While Italy would have redeemed the entire Italian *irredenta,* it also would have obtained German-Austrian and Slavic populations. Italian public opinion clamoured for war on Austria, which was declared on May 23, 1915. War against Germany was delayed until August 1916.

Balkan developments. Allied negotiations with Romania, Bulgaria, and Greece proved unsuccessful. The Germans, however, persuaded the Turks to cede territory along the Maritsa River to Bulgaria and held out the lure of even more booty, especially Macedonia. Bulgaria therefore attacked Serbia (October 14, 1915), coincident with an Austro-German offensive. The Serbian Army was evacuated to the Greek island of Corfu, temporarily seized by France. Under the influence of King Constantine I, brother-in-law of Germany's William II, the Greeks played a double game and prevented Franco-British forces that had landed at Salonika from taking the offensive in support of Serbia.

Romania secured a favourable position by selling oil and grain to the Central Powers and obtaining arms from the

Allies. Having been promised Transylvania, the Banat of Temesvar, and Hungarian lands along the Tisza River (Treaty of Bucharest, August 17, 1916), Romania declared war on the Central Powers (August 27) concurrently with a strong Russian offensive against Austria. Because the Western Allies were still halted at Salonika, Romania was speedily knocked out of the war.

The Polish question. Manpower shortages, coupled with the desire to establish a belt of buffer states (*Randstaatenpolitik*) between Germany and Russia, led Germany to suggest the creation of a kingdom of Poland (November 5, 1916). This kingdom was to be ruled by a Habsburg archduke, a provision heartily disliked by the German Army. Contrary to expectation the Poles did not enlist on the side of the Central Powers. The Central Powers had stumbled into one of their greatest blunders. Since Russia would have had to provide the territory for the new kingdom, it broke off secret peace negotiations. The Allies did not fail to take advantage of the situation and authorized the establishment of a Polish national committee under their tutelage. In March 1917 the provisional government of Russia recognized the independence of Poland.

Peace attempts and the U.S. declaration of war. The stalemate of the war led to an attempt to negotiate a compromise peace through the good offices of the United States (December 1916–January 1917), but neither side was yet willing to make sacrifices and to moderate its aims. The Germans were still committed to a Siegfrieden (victorious peace) at the expense of France, Belgium, and Russia.

Francis Joseph died on November 21, 1916. His successor, Charles, recognized that disintegrating Austria-Hungary could be preserved only by reconstruction and peace. He gained a short respite because the rule of the Romanovs over Russia was cracking even faster than the Dual monarchy. The Tsar was overthrown and a provisional government took power (March 14, 1917). Democratic Russia loyally continued the war and thereby made inevitable its own destruction; the strength of the Russian Army was broken. The Western Allies might have been defeated but by the fortuitous circumstance that Germany had declared unrestricted submarine warfare and offered an anti-American alliance to Mexico and Japan. Mexico was to retrieve its lost provinces. This provocation pushed even the pacifistic United States into the war (April 6, 1917). The Entente was becoming a league of nations in which the United States rapidly acquired leadership.

Overthrow of the Tsar

Germany's military and naval hopes again were disappointed. Emperor Charles contacted Paris and promised to support French claims to Alsace-Lorraine. Because Charles slighted Italian aspirations, the Allies declined the offer. Two other Austrian attempts also proved futile. The German Reichstag voted in favour of a peace without annexations, but the army under Gen. Erich Ludendorff's influence was still chasing the Siegfrieden and established tight control over domestic and foreign affairs. Pope Benedict XV vainly appealed to the belligerents to negotiate on the basis of arbitration, reparations, reciprocal restitution, and freedom of the seas. Germany was still too strong to be peaceful.

Bolshevik Revolution. The provisional government of Russia was unable to master the chaos caused by mass desertion, famine, shortages, administrative inefficiency, and political agitation. It put down a Bolshevik uprising in the summer of 1917 but grew increasingly powerless and was overthrown by Lenin (November 7). The Bolshevik government published the secret treaties concluded among the erstwhile Allies, including a Franco-Russian pact that provided for the dismemberment of Germany. This step greatly embarrassed the Western powers. Pres. Woodrow Wilson proclaimed his Fourteen Points, which were presumed by many to supplant the secret treaties.

The Bolsheviks called for general peace on the basis of "no annexations, no indemnities," and concluded an armistice with the Central Powers (December 15, 1917). An independent (non-Communist) Ukraine was proclaimed and concluded a separate peace with Germany and Austria (February 9, 1918). Still confident of victory, the Germans wanted to impose harsh conditions on Russia. Foreign Commissar Leon Trotsky refused to sign on the dotted line, simply declared the war at an end, and called on the German Army to mutiny. The Central Powers resumed operations threatening the survival of Bolshevism and forced Lenin to accept the terms of the Treaty of Brest-Litovsk. Russia surrendered Courland, Lithuania, and Poland and granted independence to Finland, Estonia, Livonia, and the Ukraine. Kars, Ardahan, and Batum were returned to Turkey.

End of the war. The Allies succeeded in deposing King Constantine; Eleuthérios Venizélos took Greece into the war and menaced the flank of the Central Powers. The Allies had not aimed at the destruction of Austria-Hungary, but they reversed their position and recognized the Czechoslovak national committee under Tomáš G. Masaryk and Edvard Beneš. The King of Spain transmitted new Austrian peace feelers to President Wilson. In April 1918 a congress of the oppressed nationalities of the Habsburg Empire was held in Rome. Wilson declared that all Slavs must be freed from Austrian and German rule (June 28).

The unsuccessful offensives of spring and summer 1918 exhausted Germany's last military resources. A powerful U.S. army appeared in France, and the German and Austrian governments realized that the war was lost. The German general staff still held out for further resistance, but when the main German defense line was broken, concurrently with the surrender of Bulgaria, Generals Hindenburg and Ludendorff precipitated a demand for an immediate armistice (September 29, 1918).

On October 16, Charles proclaimed the federalization of the Habsburg monarchy. Wilson replied that the United States had recognized Czechoslovakia as a belligerent and had admitted "the justice of the national aspirations of the southern Slavs." Czechoslovakia, Yugoslavia, and Hungary proclaimed their independence, and Turkey ceased fighting on October 30. The Austrian Army disintegrated on the Italian front and accepted an armistice (November 3). The fate of Austria-Hungary was sealed.

Despite opposition by the U.S. general John J. Pershing, who believed that Germany was not sufficiently beaten, terms were communicated to Germany on November 8. William II abdicated and fled to The Netherlands. Hoping to obtain better terms, the army helped in establishing a German republic. Fighting ceased on November 11. The Germans evacuated Allied territory and surrendered vast quantities of war materials, including most of the German fleet and all submarines. The Allies occupied the Rhineland.

Aftermath. After British small forces had landed at Murmansk and Archangel, the Bolsheviks declared that a state of war existed between Russia and the former Allies. About 100,000 Czech troops en route to Vladivostok began hostilities against the Bolsheviks. British, French, Japanese, and U.S. troops supported the counterrevolutionary forces of Adm. Alexander Kolchak, who temporarily overthrew the Communists in eastern Russia. British forces occupied Baku and Batum; Georgia, Armenia, and Azerbaijan declared their independence. Thus, by the end of the war the Allies were in a position to destroy the Communist regime. Yet the German retreat from Russia, unthinkingly imposed by the armistice, enabled the Communists to equip themselves with abandoned German weapons and to turn the tables on the White Russians, who in the end were deserted by the war-weary and vacillating Allies.

World War I changed the face of Europe. Austria-Hungary and the Ottoman Empire disappeared. Germany was defeated, but its basic strength remained unimpaired. Russia was dismembered and had fallen into misery and chaos; but the Communists, resolute and ruthless, were gradually tightening their hold over the vast land and, in blood and hunger, were creating the basis for a supreme threat to the European West. The erstwhile unity of Europe had been struck down by the horrors of fratricidal war.

Interwar years. The peace settlement was dictated by the Allies, mainly by the leaders of the Big Three powers: Pres. Woodrow Wilson of the United States; George Clemenceau, premier of France; and David Lloyd George,

prime minister of Great Britain. It was a compromise not only between the aims of these three men but also between the avowed peace aims of the victors and the brute facts of the situation at the end of the war. Many expectations were inevitably disappointed.

The map of Europe

The total number of European states was increased. Czechoslovakia, Poland, Estonia, Latvia, Lithuania, and Finland appeared on the map; Austria and Hungary survived as two small, separate, landlocked states, while European Turkey was restricted to a narrow coastal strip along the straits. Serbia, with the addition of the southern Slavs of Croatia and Slovenia, became Yugoslavia (though it did not adopt that name until 1929). Romania was increased in size at the expense of Hungary and Russia. France recovered Alsace-Lorraine; Belgium and Poland made gains at the expense of Germany; and the area of the Saar was temporarily taken over by an international commission. Otherwise Germany remained territorially intact and set up the democratic Weimar Republic. These arrangements left large national minorities on the wrong sides of frontiers—notably minorities of Germans and Ukrainians in Poland and of Hungarians in Romania. Although the new succession states made treaties governing their treatment of such minorities, the settlement involved one-sided violations of the principle of national self-determination to the consistent disadvantage of the defeated nations.

The new states, as well as Germany, adopted democratic constitutions. Democracy was in vogue, its reputation enhanced by the victory of the Western powers, its ideals trumpeted in Allied proclamations and translated into the Covenant of the new League of Nations, which, on Wilson's insistence, was included in each peace treaty. Events proved that the unfamiliar institutions, procedures, and values of democracy were in such countries fragile and ill-fitted to survive the turbulent aftermath of war. By the end of 1926 Hungary, Italy, Portugal, Poland, and Lithuania were all under authoritarian or dictatorial regimes; and elsewhere militarist and authoritarian forces challenged the working and the survival of democratic governments. The prevalence of democracy in Europe was short-lived.

The League of Nations

The League of Nations, too, quickly disappointed hopes that it would be an effective medium for cooperation among the major powers of the world. The U.S. Senate did not ratify the peace treaties by the necessary majority of two-thirds and so did not endorse the Covenant of the League. Not only was the United States never a member of the League but the U.S.S.R. was not admitted to membership until 1934, and by then Japan and Germany had ceased to be members. The League was much weakened in power and prestige by the absence of never fewer than two of the world's greatest powers. The task of making it work devolved on the main Western Allies, France and Great Britain; and their aims and policies diverged during the testing time of the 1920s.

The social and political consequences of the Great Depression were as disruptive as the economic consequences of the war. In Europe the aftermath of the economic depression was political revolution, first and most significantly in Germany. On January 30, 1933, Adolf Hitler, leader of the National Socialist Party, became chancellor. This movement, dating from the years of turmoil immediately after World War I, had sporadically gained in strength by exploiting every difficulty of the Weimar Republic. Appealing to the aggrieved nationalism of the military and conservative classes, the embittered and ruined middle classes, and the mass of unemployed workers, it was avowedly antiparliamentary, antidemocratic, anti-Socialist, and anti-Communist. It aimed at total overthrow of the Versailles settlement and the resurgence of Germany as the dominant power in Europe. By its violently anti-Semitic racial theory, Nazism exploited, through skilled propaganda, the deepest impulses of mass hysteria and blind hatred. With this dynamic, ruthless, revolutionary movement in control of Germany, the postwar era gave place to a prewar era—a change made doubly certain by the refusal of the Western powers to perceive that this was happening.

The recovery of Germany's power in Europe began with one false move, Hitler's attempt to bring about union (Anschluss) with Austria in 1934, which was frustrated by Austrian and Italian reactions; and with one legitimate concession—the return to Germany, by plebiscite, of the territory of the Saar (March 1935). On March 16 Hitler announced that Germany would no longer consider itself bound by the military clauses of the Versailles Treaty and embarked openly on rearmament, which had already, for many years, proceeded secretly. In 1936 he similarly repudiated the Locarno agreements of 1925 and reoccupied the Rhineland with German troops.

Germany's program of planned aggressions was facilitated by other developments, both national and international. France was beset by Paris riots in February 1934, which threatened the survival of parliament, and by a series of weak governments and prolonged ministerial crises. When, in 1935, Italy attacked Ethiopia, a fellow member of the League, the Council of the League belatedly and ineffectually imposed economic sanctions on Italy (November 1935). This did not prevent Italy's conquest of Ethiopia but led in October 1936 to the Rome-Berlin Axis, agreements to cooperate made with Hitler by the Fascist government of Benito Mussolini. Meanwhile the reality of this alignment of the dictatorships was proved by their joint support for Gen. Francisco Franco in the Spanish Civil War, which had begun in July 1936. France, under the Popular Front government of Léon Blum from May 1936 onward, was preoccupied with overdue domestic reforms. It felt obliged to follow, along with Great Britain, a policy of "nonintervention," though the U.S.S.R. sent assistance to the Spanish republican forces. The U.S.S.R. itself, in these years, was engaged in far-reaching party purges and sensational trials of military leaders. In most European countries native Fascist leagues and paramilitary groups rivalled Communist militants in causing internal disorder.

Hitler's aggressions

Taking advantage of these circumstances, Hitler proceeded rapidly with his aggressions. In March 1938 he invaded and annexed Austria. Six months later he launched a campaign against Czechoslovakia, demanding cession of the so-called Sudetenland; and by the Munich Agreements of September 1938 he contrived to involve Great Britain, France, and Italy in exacting this concession from Czechoslovakia. In March 1939 he invaded the remainder of Czechoslovakia in violation of assurances given; and the following month Mussolini took Albania. In August Hitler stunned the Western powers by making a pact with the U.S.S.R., hitherto presented by Nazi propaganda as Germany's deadliest enemy. On September 1, 1939, he attacked Poland. Because Great Britain and France had meanwhile guaranteed Poland against German attack and had come to see that German aggressions could be checked only by war, they declared war on Germany on September 3. Soviet troops occupied the eastern provinces of Poland, so completing yet a further partition of that unhappy country. Italy declared itself a nonbelligerent. World War II began, therefore, as a conflict between Germany and the Western allies of France and Great Britain, backed by the Commonwealth of Nations.

World War II. There were many affinities and parallels between the two great wars that engulfed Europe within a single generation. Both began in eastern Europe; both arose from treaty obligations of great powers; both involved an initial alliance between Great Britain and France against a German-dominated central Europe; both came to implicate Germany in a war on two fronts and were won by a Grand Alliance of Great Britain, the U.S.S.R. and the United States; both changed their dimensions and their character as they proceeded, until they engaged most nations of the world; both left behind tangled problems of reconstruction and resettlement and the seeds of future conflict; of each the outcome was largely unforeseen and unintended when it began. There were also important differences. The second, more truly than the first, was a world war, for it involved prolonged fighting in the Pacific as well as the Atlantic, in Asia and Africa as well as Europe, the defeat of Japan as well as Germany (see WORLD WARS, THE).

The war in Poland ended with the surrender of Warsaw (September 27, 1939). A brief war began between

the U.S.S.R. and Finland (November 1939–March 1940), for which the U.S.S.R. was expelled from the moribund League of Nations (December 1939). The small Baltic states signed treaties of mutual assistance with the U.S.S.R. Great Britain and France, unable to influence these events, hastily prepared for Hitler's expected onslaught in the West.

Until April 1940 little happened. These early months, known as the "phony war," gave the West more time to prepare but also sapped French morale, for the strain of full mobilization proved considerable. Then with great speed German forces in April invaded Norway and Denmark and in May struck at The Netherlands and France. In Great Britain, Winston Churchill had just succeeded the prewar premier, Neville Chamberlain, unhappily associated with the Munich Agreement and the policy of "appeasement." In France, Paul Reynaud tried to rally France for the blow. By June 17 the German Army, highly motorized and enjoying good air support, had swept into France; and a new government, headed by the aged Marshal Philippe Pétain, sought an armistice. It was signed on June 22. German forces occupied northern France, Paris, and a western coastal belt. A French government at Vichy, under Pétain, remained in office to govern France under these severe restrictions.

Because Great Britain, without a foothold on the continent after the retreat from Dunkirk (May 1940), refused to sue for peace, Germany launched a concentrated air bombardment of Britain in preparation for invasion by sea. By September the attempt to gain air supremacy over Britain had failed, and Hitler in October made an abortive offer of peace. Italy, having declared war on defeated France, now attacked Greece (October 28, 1940). But Greek forces inflicted defeat on the Italians, and in April 1941 Germany declared war on both Greece and Yugoslavia. British help proved of no avail, and by May 1941 British troops were expelled from the Balkans. By now, however, movements of internal resistance had formed in all the German-occupied countries. In London Gen. Charles de Gaulle had formed a Free French movement challenging the authority of Vichy, while in Yugoslavia guerrilla war started against the Germans and Italians.

The war entered a new phase during the second half of 1941. On June 22 Germany attacked and invaded the U.S.S.R.—at first winning great victories. On December 7, Japanese aircraft attacked U.S. warships in Pearl Harbor, Hawaii. The United States declared war on Japan (December 8), and three days later Germany and Italy declared war on the United States. With dramatic suddenness the war was transformed from a war in Europe and the Atlantic to a World War involving all the great powers on all the oceans of the world. The United States, already an "arsenal of the democracies," now became an ally.

United States entry

In November 1942 the Allies, led by U.S. commanders, invaded French North Africa, and British forces won victories in Egypt. The Germans occupied the whole of France, but in the Soviet Union, at Stalingrad, they suffered their greatest defeat yet. Thereafter the tide of war began to favour the Western Allies. Italy, suffering severe defeats at sea and invaded in Sicily (July 1943), overthrew Mussolini and disbanded the Fascist Party. Marshal Pietro Badoglio took charge, surrendered on September 8, and on October 13 declared war on Germany, which occupied northern Italy.

The Western air forces, with strong bases in North Africa and southern Italy as well as in Britain, launched concentrated bombing attacks on Germany, in preparation for invasion of German-occupied Europe. On June 6, 1944, the Allies landed in Normandy and by August 25 liberated Paris. At the same time Soviet forces, having expelled the Germans from Russian soil, reached the suburbs of Warsaw. The final year of the war brought a mighty convergence of Allied armies upon Germany—Soviet from the east, Anglo-U.S. from the south and west. The Soviet Army occupied Romania in August 1944 and Bulgaria (although that country had remained neutral) in September. Greece lapsed into civil war between Communists and anti-Communists. As a result of the Yalta Conference (February 1945) of Churchill, Pres. Franklin D. Roosevelt, and Stalin, Poland fell virtually under Soviet control, yielding eastern territories to the U.S.S.R. but receiving Silesia, Pomerania, and the bulk of East Prussia from Germany. In Yugoslavia Tito, the Communist leader of resistance against Germany, was acknowledged ruler of the country. Stalin installed a Communist government in Hungary soon after Yalta. Soviet power had replaced German power in eastern Europe even before the war ended.

On May 2, 1945, fighting stopped in Italy; on May 7 the German high command surrendered unconditionally. Hitler had committed suicide when the Russians reached Berlin. The extensive campaigns against Japan in the Far East and the Pacific continued. Two days after the first U.S. atomic bomb had been dropped on Hiroshima (August 6) the U.S.S.R. declared war on Japan and invaded Manchuria. Japan surrendered on August 14. The settlement had to be global in character as war itself had been. To achieve such an aim a new international organization, the United Nations, was prepared at the conference of San Francisco (June 1945). Its charter was signed by representatives of 50 nation-states. Special agencies, such as the UN Relief and Rehabilitation Administration (UNRRA) of 1943, already existed to deal with immediate relief work.

Communism and Europe. The wartime agreements of the Allies envisaged a lengthy postwar period of concerted action for a wide variety of tasks: during the "temporary period of instability in liberated Europe" (Yalta, February 1945); for the joint administration of occupied Germany (Potsdam, August 1945); for conclusion of treaties of peace with other former enemy states; and, within the United Nations and its several agencies, for continued cooperation of many kinds. This policy failed after two years, but during those years it set the political pattern of the postwar world.

It settled, first, the pattern of state frontiers. During 1946 the major powers prepared peace treaties with Finland, Hungary, Romania, Bulgaria, and Italy; these were signed in February 1947 in Paris. The provisional settlement with Germany was dictated at Potsdam. The general outcome was that the U.S.S.R. acquired direct control over the whole belt of the eastern marchlands comprising Petsamo and eastern Karelia; the three Baltic states of Estonia, Latvia, and Lithuania; the northern part of East Prussia; the eastern part of Poland; the Carpatho-Ukrainian area of Czechoslovakia, Bessarabia, and northern Bukovina. Apart from adjustments to the Polish and Czechoslovak and the Italian and Yugoslav frontiers, prewar frontiers were broadly restored. In western Europe the Saar was at first (1947) established as an autonomous territory in economic union with France, but in 1957 it was reunited with West Germany. Germany, at first divided into four separate zones of occupation by Soviet, U.S., British, and French forces, was in 1949 constituted as two distinct states, the Federal Republic of Germany comprising the three western zones, and the German Democratic Republic comprising the eastern zone. Berlin, itself divided at first into four zones and jointly administered by the four powers, was similarly split into two zones—West and East—by 1949.

A divided Germany

The policy determined, secondly, the pattern of postwar regimes in Europe. In most liberated or conquered countries governments were at first coalitions of Communists, Socialists, and Christian Democrats or Peasant parties. In most Western countries (including France) and some Eastern countries (Hungary, Czechoslovakia, Poland) such governments were set up by more or less free elections. They usually carried through important reforms, redistributing the land or nationalizing industries and instituting provisions for social welfare. In these years the welfare state became the prevalent pattern in Europe. In Great Britain active Labour governments (1945–51) achieved comparable reorganization.

After 1947 the contrasts between East and West became sharper in domestic as well as in international affairs. In Eastern lands, under Soviet control or influence, non-Communists were removed from power and the whole area east of the Elbe and the Adriatic, with the exception of Greece and Turkey, fell under the control of Communist parties. In the West the contrary process occurred.

Communist parties were excluded from a share in power in France, Belgium, and Italy in the spring of 1947 and in the Federal Republic of Germany in 1949. They had never been strong in the Scandinavian countries and did not appear in Portugal and Spain until the 1970s. Internal economic policies changed correspondingly in the two halves of the continent: increasingly restorative and moderate in the West, increasingly revolutionary in the East. In Germany economic divergence culminated in the introduction of separate currencies in June 1948. By 1949 the era of Cold War between East and West had set in, and the iron curtain from Stettin to Trieste divided Europe into two worlds.

North Atlantic Treaty Organization

In April 1949, the North Atlantic Treaty Organization (NATO), a defensive alliance providing for common strategy and joint military forces under a unified command, was set up. From the first it included the United States, Canada, the United Kingdom, France, Belgium, Luxembourg, Denmark, Norway, Iceland, Italy, The Netherlands, and Portugal; later it was joined by Greece and Turkey (1952) and the Federal Republic of Germany (1955). The Warsaw Treaty Organization (May 1955) created its formal counterpart for eastern Europe, comprising the Soviet Union, Poland, Czechoslovakia, Hungary, Romania, Bulgaria, Albania (which withdrew in the 1960s), and the German Democratic Republic. The settlement was one of partition and armed deadlock.

The partition of Europe, thus consolidated by midcentury, brought about new relationships between Europe as a whole and the continents of Asia and Africa. The colonial revolution, dramatically advanced by the war, had already gone far. Former colonial territories asserted their independence and joined the United Nations as separate states. The diminished status of Europe in the world was emphasized by the growing importance in world affairs of the new Afro-Asian states.

Awareness both of the threat of Communism and of this changing balance of world forces fostered, during the 1950s, movements for closer European union. The Council of Europe dated from 1949, the European Coal and Steel Community from its signing in 1951. Western European Union (WEU) was set up in 1955, organizations for a Common Market, or European Economic Community (EEC), and for joint development of atomic energy (Euratom) followed in 1958. In economic, military, and social cooperation the peoples of western Europe equipped themselves with abundant machinery and facilities. By the early 1960s their economic recovery seemed complete, and productivity surpassed all former levels. Social services and welfare provisions made for a higher standard of living and of social security. Despite lavish expenditure on armaments and national defense, the peoples of western Europe experienced considerable material prosperity.

Throughout the late 20th century the relative ascendancy over Europe of the United States and the Soviet Union was emphasized by such developments as the space race between them (in which Europeans could scarcely afford to join), the thrust of U.S. economic expansion into Europe, the invasion of Czechoslovakia by Soviet and other Warsaw Pact troops in 1968, and the repressive measures in Poland in 1981–82. Clearly, Europe no longer counted for as much in the world as it had before 1939. Yet this ascendancy, too, was in fact counterbalanced by other world forces: the rise of Communist China as an enemy of both the superpowers, severe internal tensions within the Communist world and within the United States itself, and the readiness of various countries to exploit such conditions for national advantage. The world balance of power was shifting; it was not destroyed. (D.Tn./Ed.)

MODERN ECONOMIC GROWTH AND DEVELOPMENT

The course of industrialization, 1870–1914. *The changing balance of economic power.* The last part of the 19th century saw the further ramification of the Industrial Revolution into the peripheral European lands, the offshoots of Europe overseas, and—for the first time—a non-Western society, Japan. The result of this geographical extension, combined with differing national rates of productivity change and industrial growth, was a drastic revision of the international balance of economic and political power.

Within Europe, these decades brought an important realignment of economic power as the first follower nations (Germany, France, Belgium) completed their industrial revolutions and new entrants (Sweden, Italy, Holland, Hungary) made their appearance. Britain, the first industrial nation, continued to develop and grow, though more slowly than its rivals. By the 1890s Germany had passed Britain in iron and steel manufacture, and, from then on, the gap between the two countries widened steadily. The result was a shift in the balance of political power that generated international anxiety and conflict and contributed to the outbreak of World War I.

The pressure of international competition was felt most keenly in Great Britain, which, as the dominant industrial power, had most to lose. The sense of loss was the stronger because these were decades of slow growth of manufactures (1.8 percent a year), declining prices (the wholesale index for manufactures fell from 127 in 1873 to 71 in 1894), protracted slumps, and small profits—hence, the traditional designation "the great depression."

Business cycles

Some scholars have viewed the great depression as a European phenomenon, but the course of economic activity in the continental countries was quite different from what it was in Britain. German industry did suffer a severe setback after the crash of 1873, a typical catharsis after some three years of enthusiastic company promotion (the *Gründerjahre*) fuelled by the large French war indemnity. Beginning in the 1880s, however, rapid growth resumed, and profit levels picked up, with no further serious interruptions until the crisis of 1900–02. France, by way of contrast, had much less trouble in the 1870s, was hard hit by a financial crisis in 1882, had another, smaller shock in the mid-1890s, and then another, more protracted, in the first years of the new century. On the whole, these were years of below-average growth for manufactures.

A second Industrial Revolution. Insofar as the Industrial Revolution spread during these decades to newly industrializing countries, its outlines were substantially the same as they had been earlier; that is, the first advances typically took place in food processing and textiles (cotton especially), with further extension into metallurgy, machine building, and chemicals. Within each of these branches, the techniques and equipment introduced were largely the classic elements: spinning machines and power looms, coke blast furnaces, and rolling mills. But the equipment itself had grown bigger, faster, more accurate and dependable, while the array of techniques had vastly proliferated, so that newly industrializing nations adopted, alongside these classic items, such newer ones as the steam hammer (an invention of the 1840s), the sewing machine, the milling cutter (for metal as well as wood), and the new technology of steelmaking. As a result of these changes, the threshold scale of production had grown considerably, and each piece of equipment cost substantially more. In short, though the lineaments of these later industrial revolutions were the same as earlier, the content was quite different.

In the meantime, the technology of the advanced nations continued to evolve in the same direction, although the gains achieved in the older branches were shrinking relative to previous advances. The spindles could turn a little faster; the furnaces could be built higher; but the increment entailed a smaller proportional increase in profit than the radical changes of an earlier era. The place of the old staple industries was shrinking, and the rate of growth of a given economy depended on its ability to develop newer lines of production.

These constituted, toward the end of the 19th century, an innovational cluster important enough to warrant perhaps the designation of a second Industrial Revolution. As before, the critical advances occurred in the fundamental sphere of energy conversion and distribution: on the one hand, the production and use of electricity as a source of motive power and, on the other, the invention of the internal-combustion engine as a prime mover. The first had revolutionary consequences for both industrial technique and domestic life. Not only was electrical transmission of energy more efficient and safer than conventional direct

Electrical power

drive by shafts and belts but it also could be effected over long distances, so that the production of energy could be centralized and power distributed to small units (households and shops, as well as mills and forges) as needed. Electrical current, moreover, was far more versatile than steam power, for it could be used to produce not only motion but also light, sound, and heat, and it made possible a revolution in communication (telegraph, telephone, radio, television, radar, telex, etc.), as well as some notable advances in chemical manufacture. Whereas steam power was necessarily concentrated in large production units, hence, in a few power-intensive industries, electric motors were useful and profitable in a much wider range of activities; thus, in 1889, the five leading power-using branches (lumber, food, iron and steel, textiles, paper) held 73.5 percent of total primary-power capacity in manufacturing; by 1929 this share had fallen to 58 percent. Germany took the lead both in production and use of electrical power and in the production of electrical equipment. German industry was marked by thorough exploitation of by-product energy produced by heat-generating industries, large distribution nets with high-use factors, and early standardization of current characteristics.

Internal-combustion engine

The second major innovation in the generation of power was the internal-combustion motor, so called because the driving force is obtained by controlled explosions within the motor itself. The first such device was Étienne Lenoir's gas engine of 1859, but the critical conceptual advance came with Alphonse Beau de Rochas' four-stroke cycle, which found application in Nikolaus August Otto's "silent" gas engine of 1876. This was a tremendous success from the outset, for it was far more efficient than the steam engine when working intermittently or at less than full load, conditions typical of small industry. The gas engine was tied to its source of fuel, but the internal-combustion motor was compact and had potential mobility. These possibilities were realized with the adoption of oil fuel. The result was a revolution in transportation (marine engines, the airplane, and, above all, the automobile), which liberated land transport from rail routes and the individual traveller from dependence on common carriers. The impact of the automobile was only beginning to be felt in the period before World War I; but the introduction of the cheap passenger car (Henry Ford's Model T, from 1908) was a promise (or warning) of things to come. The automobile quickly became the most important single product of the manufacturing industry, generating investment and growth by its demand for raw materials and highways (including bridges and tunnels) to match the burgeoning volume of traffic. Output of petroleum products, rubber, cement, asphalt, steel, glass, and even textiles waxed (and sometimes waned) in sympathy with the demand for and use of automotive vehicles of all sorts, to say nothing of a large service sector (insurance, law and litigation, medical care, auto repair, garages, and parking lots) devoted partially or exclusively to meeting the needs and correcting the misdeeds of auto users. At the same time, the process of manufacturing automobiles called for innovations in materials and techniques important in themselves and susceptible of application in other industries: line assembly, new alloys, special-purpose tools, advances in grinding and stamping, and standardization of parts.

Importance of the automobile

As important as the automobile industry came to be, two other new branches of manufacture can be compared to it in range of influence and potential for growth. One was organic chemicals and the manufacture of synthetics. Again, the pre-World War I years gave just a hint of what was to come: celluloid (John Wesley Hyatt, 1868); artificial silk or rayon (Hilaire, comte de Chardonnet, 1889–90); bakelite, the first synthetic resin (Leo Hendrik Baekeland, 1909); cellophane (J.E. Brandenberger, 1912). These artificial fibres and plastics were the first fruits of what would be a new kind of industry, based on increasingly heavy investment in laboratory research and turning out new products to order, primarily for consumer use.

The second was the equally versatile electronics industry, in its infancy in the early years of the 20th century, when its only application was still wireless communication. The key innovation here was the tube or valve, so called because it channelled the flow of electric current in one direction and made possible the construction of complex circuits. Synthetics and electronics did not fully develop until the interwar years and the post-World War II period and might better be seen as part of a new major cluster of innovations (including atomic energy and computers) that some regard as constituting a third Industrial Revolution.

Along with these and other innovations in technique and product went new patterns of industrial and business organization. The old trend to bigness continued as better but costlier production equipment raised the price of entry

The trend toward bigness

Population changes in Europe, 1870–1925.

and offered new economies of scale, while improvements in communication enhanced the possibilities of centralized management. Economies of scale—in marketing and administration as well as production—were only part of the story, however. Equally important were market considerations, in particular, the desire to stabilize profits and minimize competition, either by absorbing or eliminating competitors or by organizing cartels, trusts, and similar combinations in restraint of trade. The merger and cartel movements were especially strong in Germany. By 1905 there were some 366 industrial cartels operating in Germany; some of them controlled prices, others output, many both. In Germany, the trend to bigness and combination was so powerful and the role of the so-called great banks (themselves the result of numerous mergers) so influential that contemporary observers thought they saw the appearance of a new stage in economic development, the era of finance capitalism.

Finance capitalism

The term was somewhat premature. Although similar trends were to be found in the other major European industrial economies, they were substantially weaker. In both Britain and France, for example, the stress on family ownership and identification posed a barrier both to financial intervention in industrial management and to disciplined participation in cartel agreements. In Britain, when mergers did come, they were often a response to contraction rather than an act of expansion: independent firms reluctantly combined their resources to meet falling prices and profits and then spent years fighting over the appropriate allocation of authority and returns.

Industrialization on the eve of World War I. The position of the different nations in this process of social as well as economic transformation may be measured by the position of industry relative to agriculture and the ratio of urban to rural population. In regard to the first, one can discriminate among four categories.

First, there were countries in which the industrial labour force was already greater than that in agriculture: Great Britain, which had reached this position by 1820, is the best example, but Belgium had pushed its industrialization almost as far. The United States and Germany, in spite of substantial advantages in agriculture, had long since entered this group. France had not quite made it and would not do so until after World War II. Each of these countries had increased product per head by three to five times over the course of the preceding century.

Second, there were countries whose agricultural population was still about twice as great as its industrial: Sweden, Italy, and Austria all fell into this category. Each nation had developed by this time a large, modern industrial sector, and Sweden and the Czech lands, particularly, had enterprises that were technologically at a level with the best European practice.

Third, there were countries that had entered on the Industrial Revolution but were still primarily pre-industrial. Russia was a good case in point, with a few completely modern plants, especially in the young iron-and-steel industry of the Donets Basin. Hungary also had, in the Ganz electrical works of Budapest, one of the more progressive enterprises in Europe. But these were predominantly peasant societies; skilled industrial labour was scarce; and industry was still dependent on strong tariff protection and artificial support.

Fourth, there were countries almost exclusively dependent on agriculture: such Balkan nations as Greece and Bulgaria, the colonial lands of Asia and Africa, and the more backward countries of Latin America—in short, what would later be called the Third World. With rare exceptions, industrial production consisted almost entirely of domestic handicrafts and artisanal work.

Concomitant with the shift of resources to industry went a movement of population to urban centres. The development of a predominantly urban society entailed substantial costs to physical and psychic health, while the convenience of concentration was offset by the impediments of high density of living and movement. Even so, urbanization contributed to the increase in productivity and wealth by intensifying contacts and information flows between innovators in knowledge and its applications and by nourishing and propagating new attitudes toward family size and population control. (D.S.La./Ed.)

The aftermath of World War I. The outbreak of war in 1914 ended a distinct era in economic history and ushered in a period of instability, uncertainty, and unexampled change that could hardly have been foreseen before the conflict began. Trends that might have been gradual were telescoped into a few years. A further impetus was given to the concentration of production in large-scale units and to the decline of competition. State intervention in the economy, prominent for the first time under modern conditions during the war, was to assume a more definite and permanent character. Technological change became more firmly linked to the giant advances in the physical sciences and permanently molded life in the advanced regions of the world.

Only the most technologically and industrially advanced nations could wage wars of the type of 1914–18 and 1939–45. Germany's ability to hold out so long was a tribute to its industrial strength as much as to its military competence in both wars. The decisive role of the United States as an arsenal and its rapid industrial growth in both wars is again highly significant. France held out in World War I thanks to its allies' economic support; its collapse in World War II was as much economic as it was military. With or without the atomic bombs, Japan would have been defeated because of its overstretched resources.

In this period, economic history cannot be separated from military history, and into both the major wars there entered deep economic rivalries. War also provided an overwhelming stimulus to maximize production and make full use of scientific knowledge. Mechanization, rationalization, and standardization were imposed by the conditions of war production, and the interruption of normal trade channels intensified the search for substitute materials and the development of synthetics, from which are descended some of the fast-growing industries of the period. The "new industries" early in the century expanded rapidly.

The conditions of war production

The diminution of European power. It was the world economy that experienced the most profound changes after the war. The most outstanding was the financial and industrial upsurge of the United States and the decline of Europe, transformed from a creditor to a debtor. The world monetary and trading system centred on Europe had been seriously dislocated, and frontier changes had increased the tariff barriers dividing the Continent. The Bolshevik Revolution had taken Russia out of world capitalism and threatened to spread westward in the postwar atmosphere of discontent and near chaos. Finally, industrialization had gone ahead in other parts of the world, closing old markets and rearing up new competitors. Most ominous of all was the emergence of Japan as a vigorous competitor in world markets.

Of immediate significance in the postwar decade was the need to restore the old pattern of trade and payments. This was taken to mean, first, the restoration of the gold standard upon which prewar currency stability and convertibility had been based. But war finance had caused inflation in the belligerent countries, and there could be no return to gold without currency stability. Second, Europe was unable to resume its prewar position as an international creditor. U.S. capital played a vital part in European reconstruction and subscribed heavily to the international loans that enabled Germany to make scaled-down reparations payments. Stabilization and expansion in the 1920s was thus underpinned by an outflow of funds from the United States. Funds returned to take advantage of the capital gains realizable in the U.S., and when the crash came in 1929 one of the main props of the central European banking structure was removed, and the stage was set for the financial collapse of 1931.

The role of U.S. capital

War finance had been inherently inflationary, and, once controls were removed, prices began to soar. Moreover, social breakdown in eastern Europe and the Soviet Union had resulted in money printing and inflation. The occupation of the Ruhr by French troops in 1923 precipitated a hyperinflation in Germany that broke all records. In the final stages Germany resorted to the printing press on a massive scale, and the rise in prices was such that workers

collected their wages in suitcases and spent them at once. In November 1923 a determined and successful effort was made to stabilize the currency, and Germany entered a new period. Industry had meanwhile wiped off its debts and made considerable windfall profits. Thanks to this and to the inflow of U.S. funds, industry was modernized and expanded. Inflation had disastrous effects for those who held their savings in state bonds or fixed interest securities or who lived on fixed incomes. At the same time, speculators and profiteers did well, and some made fortunes overnight. The "new rich" of the inflationary years prospered; their social juxtaposition with impoverished middle-class people helps to explain the political upheavals that followed. The outstanding feature of the inflation was its undermining of the old virtues of thrift and savings, which had been capitalism's most valuable moral supports.

The changing world picture. The primary producing countries had boomed during and immediately after the war and had increased their capacity. The European recession that began in 1921 after the postwar restocking boom was a sign that things had changed. Most of the producing countries were in a colonial or dependent relationship to the advanced European countries, and in a number of them a nationalist movement had appeared. Where some industrial growth had taken place, as in India, protection of the home market and government encouragement of industrialization were needed.

Nationalist movements

Some economists have linked Europe's interwar difficulties with the disappointing performance of primary producers. Had the European countries adapted to changes in technology and world demand, they would have increased their demand for primary products and enabled their producers to buy more manufactured goods. As it was, world trade was the worst victim of the war and the biggest casualty in the Depression of the 1930s. To make matters worse, the industrial countries protected their own producers, and, when the slump came, there was a general retreat to the home market with higher tariff barriers, quotas, and administrative devices to keep imports down. Primary producers responded by encouraging their own industries as well as keeping up prices by restrictive schemes.

The beginnings of social welfare. The economic experience of the war years did not shake the general assumption that, in peacetime conditions, state intervention was unnecessary and harmful. But it had been shown that in certain circumstances business might benefit from the activities of the state. Until the Depression of the 1930s, however, there was no desire to see the state permanently endowed with more extensive economic powers. It was not the success of state intervention in the war but the breakdown of market forces in the 1930s that opened the way for regulated capitalism.

The extent of state intervention varied greatly; some countries had operated the railway system for many years, and there were state monopolies for fiscal purposes. But the main economic intervention continued to be the tariff. Even Britain had imposed protective tariffs on luxury items during World War I and in the 1920s began "safeguarding" industries from unfair foreign competition. There was also a steady underlying trend toward greater state involvement in the economy, influenced by the growing Socialist and trade union movements. The way was being prepared for the wider intervention by the state characteristic of the Depression decade.

The use of tariffs

State provision for social welfare had a much wider measure of acceptance in the 1920s and steadily became more systematic. It was understood that the sanctity of private property and the pursuit of profit might be threatened if society did not make adequate provision for its casualties. By the 1920s most states had social security or insurance systems of various degrees of comprehensiveness. Increasingly, such welfare provision became a matter of legislation laying down minimum standards. Wartime experience, in which all members of a society were taken to be in solidarity against a common enemy and thus entitled to its support, exercised an important influence on the development of social security systems.

The state's tendency to assume social responsibilities was persistent and continuous in the period after World War I, and, with the establishment of the International Labour Office in Geneva, a beginning was made in establishing uniform standards between countries. Partly under labour union pressure, industrial regulation became more comprehensive and better enforced. Public and local authorities were also assuming greater responsibility in transport and the provision of water, gas, and electricity; in education; and in housing, made necessary by the chronic and widespread postwar shortage. Investment in human capital, if not yet a common phrase, was being taken more seriously than ever before; but, like all similar trends, it was uneven.

During the 1920s, as recovery and inflation took place, production and productivity again began to grow in the advanced countries, and incomes rose. Meanwhile, the new technologies began to influence social life more fully. Road transport made its effects felt through the bus and the truck; rural areas were brought into closer contact with urban influences; and personal and labour mobility increased. Marketing and distribution changed as farm produce could be collected more regularly and moved more quickly to urban markets. Electric power brought new flexibility to industry and opened an industrial vocation to hitherto predominantly agrarian areas. The cinema and the radio transformed entertainment patterns as well as the supply of information or propaganda. Professional sports became a growing industry. Service trades of all kinds grew most rapidly in the advanced countries with high incomes.

The new technologies

This expansion of the "tertiary sector" was one of the most notable trends of this period. Consumers, with increased incomes, spent more on services. Former household activities became specialized marketed services; retail outlets multiplied; old-style services expanded, and new ones appeared. As the activities of governments became more complex, so their employees increased; and even business employed a growing bureaucracy of its own. In other words, the white collar element in the labour market grew and was symbolic of changes in life-style in societies with a relatively high and growing per capita income. Expectations grew, too, even faster than possibilities for their realization. Workers became better organized and more demanding, installment selling enabled people to spend ahead of their incomes, and the Depression caught all these developments in full flood.

The Great Depression. The stabilization of capitalism after World War I was short-lived, for the world economy plunged into the worst depression in its history. Although heralded by the Wall Street crash in the autumn of 1929, it was some years before it became apparent that this was no ordinary cyclical downturn. It afflicted every capitalist country, and its depth and length still challenge those seeking its explanation. Even on the outbreak of World War II, despite the recovery from the trough of 1932–34, the Depression had not been conquered. So far from new government policies for full employment and economic growth being effective, it seemed rather that purely national remedies, the resort to beggar-my-neighbour policies and, more especially, the drive to rearm—which arose out of the political upheavals of the Depression—prepared the way for the new war.

What does seem to be accepted is that, although depression was centred in the United States, it was the special and intimate relationships established between the U.S. and other capitalist economies after World War I that accounted for its rapid diffusion and harsh impact. It is equally apparent that the stabilization that had taken place in the other countries and the boom conditions of many, in the late 1920s, concealed serious weaknesses. The British economy's failure to resume capital exports in the old way, the decline of its basic industries, the consequences of the overvaluation of sterling—all weakened the world economy and thrust greater responsibilities upon the United States. The investment boom in European countries following reconstruction could only continue so long as markets could be found; a cyclical downturn was inevitable sooner or later. The problems of the primary producers (now weak sellers as a result of overproduction)

International economic weaknesses

reduced the market for manufactured goods and slowed their growth rate.

In the return to gold, some currencies had been overvalued, others undervalued, and the Depression came before adjustments could be made. Moreover, international financial relations were no longer on prewar lines. War debts and reparations weakened capitalist countries, leaving the United States as the major creditor and financier of the 1920s' boom in Europe. Once the U.S. economy slumped, there was no prospect of maintaining prosperity elsewhere.

The collapse of the world market. The contraction of world trade was the most general expression of the crisis, hitting hardest the primary producers and those industries depending upon exports. Thus, outside the United States, the Depression was worst in Germany and Britain. The sharpest contraction was in the export trades and the capital goods industries, as well as in shipping and shipbuilding. Activities turned mainly toward the domestic market suffered less, and so "sheltered" and "unsheltered" industries were distinguished. The former, least affected by depression, were also the easiest to help. The recovery of the export and capital goods industries was much more difficult to engineer.

For most countries, the more prosperous conditions had been before 1929 the sharper was the decline in the following years, but a large agrarian sector—as in France—could provide some shelter from the blizzard. Germany was the worst hit European country, and there the Depression was a social and political calamity. Britain was aided by the abandonment of gold and the devaluation of sterling; the adoption of protection that stimulated home industry; a delayed development of the technologically more advanced industries; a building boom assisted by cheap money; and the ability to take advantage of the low prices of imported foodstuffs and raw materials while using accumulated reserves to avoid a balance of payments problem.

The Depression was traumatic because it contradicted deeply held beliefs in unlimited expansion and also brought poverty, hardship, and hopelessness to millions. The Depression had such severe social consequences that even reluctant governments, formerly tied to laissez-faire ideas, could not stand aside. The price of nonintervention was social revolution, and intervention was, or could be, a weapon of counterrevolution, as under the Nazi regime in Germany. Intervention, therefore, took place pragmatically, and its forms were at first "orthodox" in that they consisted of old, well-tried methods. First, the tendency toward economic nationalism was reinforced as governments imposed tariffs or raised existing ones and added quotas and other devices to protect home producers. As the Depression continued, protection tended to be used increasingly aggressively to bargain with other countries and penetrate foreign markets. The disintegration of multilateralism, which was often replaced by bilateral trading agreements, accompanied the decline of world trade. The immediate effect of these measures was to reduce the volume of international trade and create trade war.

Parallel to this went the breakdown of the gold standard. In the autumn of 1931 the overvalued pound sterling was driven off gold, starting a succession of devaluations as countries learned that an undervalued currency gave a temporary advantage in the struggle for markets. Currencies became subject to government action, and some form of exchange control had to be established if balance of payments difficulties were not to be exaggerated by speculation. Countries like France, which delayed establishing exchange control, did so to their cost. Nazi Germany, on the other hand, by means of rigid controls, could operate parallel exchange rates to its advantage and at the expense of weaker trading partners.

The conditions of recovery. The Great Depression of the 1930s shook capitalism to its foundations and was the major formative influence on political and social as well as economic life. Already undermined by World War I and its aftermath, many of the old certainties derived from 19th-century liberalism disappeared. Despite millions of unemployed throughout the decade—in many of the most advanced areas of the world—and the triumph of Fascism in Germany and the subsequent drive to war, most years of the 1930s were, however, years of low-level recovery. Indeed, the slump itself had prepared the conditions for recovery through the normal cyclical process: after a few years, in which investment falls to a low level or even becomes negative, stocks are used up, equipment grows obsolete and has to be replaced, and prices reach bottom, the possibilities for profitable investment begin to improve. Unsound firms have disappeared, the financial excesses of the boom have been liquidated, a shift of resources from the unprofitable sectors has been affected, old plant has to be renewed, and confidence revives. Thus, the classic conditions for recovery began to operate independently of government action.

Recovery came slowly and in many countries was far from complete by World War II. Until there was a revival of world trade, the primary producers could not raise their incomes. On the other hand, in the advanced countries, even those as export dependent as Britain and Germany, it was possible to find a substitute for exports. In Germany this was chiefly war production. In Britain, although rearmament in the late 1930s helped recovery, it had earlier depended upon an expansion of the home market, the shift to new industries, and the continuous rise in service activities, even in the "depressed areas."

As a major importer of foodstuffs and raw materials, Britain was able to take advantage of the deterioration in the terms of trade of primary products. This enabled consumers to spend more of their income on nonfood items and expanded the consumer goods and services market, creating new opportunities for profitable investment and employment. It assisted manufacturers directly and consumers indirectly through the relative cheapening of imported raw materials. Given that this took place with a resumption of technological advance and innovation, Britain could enjoy a limited recovery. Almost all persons could thus improve their real income, at the expense, in part, of primary producers abroad. Where those primary producers were to a large extent at home, as in France, these conditions for recovery did not exist.

All governments realized that something had to be done to relieve what amounted to a national catastrophe. The Soviet Union's example had begun to turn thoughts toward planning, even of capitalism, as a possibility. In the early years of the Depression the instinctive reaction of politicians was still strongly orthodox. In Britain, proposals for positive steps to overcome unemployment through public works were rejected by a Labour government. The watchword virtually everywhere was to keep the budget balanced and avoid interference with free market forces. Policy was thus generally deflationary: government expenditures were vigorously reduced, and the more consistently such remedies were applied, as in France, the more they aggravated the disease. In some cases, however, governments did inadvertently run budget deficits through emergency action, and where they did so they began, possibly unwittingly, to assist recovery.

The orthodoxy of political reaction

The industrialization of the Soviet Union. The Bolshevik Revolution, which in 1917 took Russia out of the capitalist world, and Russia's transformation into a leading industrial power have had enormous significance in the 20th century. In the early years the very existence of the new regime weakened capitalism; and later the viability of the alternative system was demonstrated in the carrying out, through nationalized property relations, of planned large-scale industrialization. Whether or not Premier Joseph Stalin's tyrannical methods were necessary to the process, the results were impressive, indicating to less developed countries that there was an alternative to capitalist industrialization. Elsewhere, too, planning was turned from vague concept to practical reality, acquiring exceptional prestige even in capitalist countries.

The early days. The economic steps taken by the Bolsheviks in their first year included nationalization of all industries employing more than five people, of banks and foreign trade, and of the land. A large part of the country, however, was outside the new Soviet government's control, and civil war continued until 1920. There was,

in fact, virtual economic breakdown, with many factories closed or producing only a trickle. Priority was given to the front for supplies available in what was substantially a siege economy named "War Communism." The government appropriated what revenue it required either by requisition or by printing money. The black market engulfed supplies, stocks were hoarded, and galloping inflation began. As production fell and goods disappeared from the shops, workers who had not been drafted into the army or employed in the new administration drifted back to the villages. The hardships of the period were only made bearable by promises of a better life in the future. Discontent, already growing, now became more open. The mutiny at the Kronstadt naval base in February 1921 was the final danger signal. War Communism was abandoned and replaced by the New Economic Policy (NEP).

The NEP was generally admitted as a retreat. Its basis was that it permitted private enterprise in internal trade and to some extent in industry. It also encouraged the peasants to produce a surplus for sale and offered opportunities for their enrichment. Nepmen (private businessmen) and kulaks accumulated capital.

Central planning. It was axiomatic that the U.S.S.R. could only overcome its historical backwardness through industrialization and that this should take place under the control of a central planning agency and on the foundation of a nationalized industry. The NEP stood by this principle.

The establishment of Gosplan

In fact, the State Planning Committee (Gosplan) was set up in February 1921 to "work out a single general state economic plan and methods and means of implementing it." What was at issue was the rate of industrialization, the tempo of growth, which could not in practice be separated from the path that was to be chosen.

After Lenin's death in 1924, Joseph Stalin strengthened his hold on party and state apparatus and formulated the theory of "Socialism in one country"—concentration on building up the Soviet economy at the expense of the international goals of Communism. He was supported by Nikolay Ivanovich Bukharin and others on the right wing of the party, which assumed that NEP would last for a considerable time. Industrialization, therefore, could take place only by slow stages in which the peasantry was encouraged to market its surplus and nationalized industry produced the consumer goods it required in exchange. These perspectives were opposed by the left opposition, whose leader was Leon Trotsky. "Socialism in one country" was rejected as a revision of Marxism because it placed internal interests before those of world revolution. The policy of concessions to the kulaks and the adoption of a slow industrialization tempo were equally condemned, and a program for more rapid industrialization and planning and the encouragement of voluntary collectivization was substituted. Finally, the left opposition was defeated, and Stalin emerged as the master of the party apparatus. Free debate was stifled, and the dead hand of orthodoxy gripped Soviet political economy.

Meanwhile, the New Economic Policy enabled recovery to proceed fastest of all in agriculture but also in industry. Once the prewar levels had been attained (from about 1925), decisions had to be made on the rate of growth. This depended upon how much grain surplus the peasants were prepared to part with. And that in turn depended upon the ability of industry to supply industrial goods. The main emphasis would have to be upon consumer goods production, and capital formation would be a dependent variable and not the main determinant. If, however, economic policy continued along these lines, industrialization would be slow, and the U.S.S.R. would be vulnerable to capitalist pressure or even attack. Meanwhile, the growing prosperity of the kulaks and the Nepmen would undermine the nationalized property relations upon which the state was founded.

Stalin's change of course

These dangers prompted Stalin to make a brusque alteration of course, taking over much of the policy of the defeated left opposition and applying it with a brutality they had never advocated. From 1928, therefore, the Soviet Union suffered a new period of strain and sacrifice in which, under conditions approaching civil war, agriculture was collectivized and the first stages of planned industrialization were forced through. From this caldron the U.S.S.R. emerged to face the German attack of 1941 with a much more powerful industry than before. The basis had been laid for it to become the second largest industrial power, but the social and human price had been tremendous.

The drafting of the First Five-Year Plan was begun by Gosplan in 1927; the starting date was from October 1 of the following year, but the campaign did not get under way until 1929. At the end of that year, the plan targets were revised upward at about the same time that Stalin ordered forced collectivization.

A whirlwind descended on the Soviet countryside. The peasants were forced into new collective farms set up without adequate technical means or experienced leadership, and kulaks were forced off the land and deported in large numbers to Siberia. Their resistance was shown by their mass slaughter of their animals, which set back the production of meat and milk products for years. Soviet industry was unable to supply enough equipment, fertilizers, and insectides to raise the technical level of the new collective farms above that of the former peasant holdings, so agricultural production declined sharply, and bitter resentment long remained among the peasantry.

In industry there was certainly more enthusiasm for the change; but the emphasis of the first and subsequent plans was upon endowing the Soviet Union with heavy industry, not with increasing consumer goods production. This made high growth rates possible, since a large part of production went into new investment. Sacrifices were imposed not only on the peasantry but also upon the working class, including the huge new labour forces drained from the countryside into overcrowded industrial towns. Propaganda explained that these sacrifices would provide a better life in the future.

Social upheaval and oppression. At the price of a gigantic social upheaval the economy was transformed and entered upon a long period of expansion. The First Five-Year Plan, only unevenly fulfilled, was followed by a second in 1933 and a third still incomplete when war came. These plans maintained the priority of heavy industry, with a shift toward defense. While the capitalist world was plunged into depression, the Soviet Union grew rapidly. The growth record was impressive. Although per capita consumption may have declined and agriculture stagnated, industry—and especially heavy industry—showed a formidable advance. The development of social and community services supplemented real wages. Large numbers of people acquired new skills, as well as literacy, while a new managerial and technical elite was trained.

The Second and Third Five-Year Plans

Industrialization was achieved without foreign capital. The expected revolution in Europe had not taken place, and the isolation of the U.S.S.R. was intensified with the rise of Nazi Germany and the growth of armaments in the capitalist countries in the late 1930s. It remained economically inferior to the advanced capitalist countries despite the five-year plans.

Soviet life in the 1930s was lived under the shadow of political repression and terror unjustified by the pressures of industrialization. The arbitrary arrests, purges, trials, prison camps, and mass executions were necessary instruments for Stalin in maintaining his personal ascendancy over the new ruling stratum and the masses. But Stalinism was a burden on the economy; and it is no accident that the height of the purges is paralleled by a dip in the indexes of industrial production.

Purges and executions

Many criticisms can be made of Soviet planning. The priority given to heavy industry and armaments meant that the Soviet consumer had to suffer. Labour discipline was severe. The high output encouraged in the 1930s by the Stakhanovite Movement made for inequality of earnings. Complaints of wasteful use of productive capacity and materials and of mismanagement and corruption have frequently been made by the leaders themselves. Especially during the purges, initiative and responsibility were impaired by the fear of punishment. Bureaucratic heavy-handedness, unevenness of production and work loads made necessary by sudden spurts to achieve plan targets, production of goods not really required, and difficulties in

coordinating the requirements of different enterprises—these are among the criticisms made of Soviet planning.

The later stages of Communism. By the time Germany attacked the U.S.S.R. in June 1941 the five-year plans had given the Soviet Union a powerful industrial base. Whatever the revulsion against Stalin's crimes and the excesses and mistakes of the plans, it had been shown that an alternative to a privately-owned economy was viable. But the Soviet Union was still considerably behind the advanced capitalist countries in per capita output and labour productivity, although the gap had been narrowed. Nevertheless, without the accelerated industrialization that the plans made possible the defeat of the U.S.S.R. in 1941 or 1942 would have been certain.

At the end of the war the Soviet Union faced a tremendous task of reconstruction that again postponed the improvement in consumer goods output; but the war had spurred industrial and technological advance, and the planning apparatus was well able to meet the postwar challenge. Within a few years, however, resources were once again being diverted by the Cold War. Stalin's death in 1953 initiated a period of economic reforms. With consumer needs still generally receiving a low priority, the Soviet Union showed its strength in other directions. The sustained and rapid growth of the 1950s, the development of nuclear weapons, and finally the launching of a space satellite caused concern and even alarm in Western countries: the Soviet Union did seem to be catching up to the West.

Reforms after Stalin's death

The postwar years saw the establishment of nationalized and planned economies in eastern European countries. East Germany and Czechoslovakia apart, these countries had been predominantly agrarian, though, except for Albania, they had some industrial towns or areas. Yugoslavia broke with the Soviet Union in 1949; Albania adopted a pro-Chinese policy after the Sino-Soviet schism of the 1960s; and Romania has tended to pursue its own course. Each of the east European countries adopted the Stalinist model of "Socialism in one country" in what appeared to be an attempt to establish replicas of the Soviet Union in the "Peoples' Democracies."

The strains and tensions in Soviet society after Stalin's death were even more pronounced in a number of the east European countries. When the east European Council for Mutual Economic Assistance (CMEA) was established in 1949, much was heard about the need to develop "an international Socialist division of labour." In fact, the economic development of Czechoslovakia, Poland, Hungary, Romania, and Bulgaria had been adversely affected not only by a fundamental change in their international economic relations but also by their comparative isolation from each other. While achieving rapid rates of growth and overcoming their former underdevelopment to a considerable extent, development of these countries was uneven.

The economic history of the Soviet Union and the east European countries must be viewed against events in the capitalist world. The Cold War reduced the volume of exchanges with the capitalist countries and thus the possibility of remedying their deficiencies through trade. Moreover, scarce resources and highly trained manpower were drained away into armaments production. The easing of international tension during the late 20th century opened up the prospect of widening trade links, for which provision was made in economic plans. Growing inflation and recession abroad, however, raised the prices of sought-after imports, while making it difficult to sell the goods necessary to pay for them. Some of the price increases were passed on to consumers, and there was a tendency to run trade deficits, financed by credits from the international capital market. These difficulties were aggravated by shortfalls in the Soviet Union's harvests in some years, making necessary large grain purchases on the world market. On the other hand, as a large oil producer, the Soviet Union held a strong position vis-à-vis its trading partners in CMEA, enabling it to raise prices in line with world trends.

All these countries ran into problems in the late 20th century, and while growth was maintained, it was generally at a lower rate than in the past. Former methods of planning were revealed as overcentralized and cumbersome. Repeated attempts at reform, improving management techniques, and allowing greater play for market forces were made with indifferent success. Continued technological advance elsewhere revealed serious industrial deficiencies in fields such as computers, electronics, plastics, and petrochemicals. Great efforts were deployed to remedy such weaknesses, including the purchase of complete industrial plants from western Europe and the United States. The task of catching up with and outstripping the capitalist countries proved to be unending.

The lack of consumer goods, dissatisfaction with living conditions, and resistance to bureaucratic management produced labour problems, indicated by the low productivity often complained of in official reports and in the difficulty experienced in reaching plan targets. Rising consumer levels in western Europe had a "demonstration" effect, and the east European countries and the Soviet Union continued to be outclassed in shop-window competition. This imbalance was partially responsible for popular uprisings, but concessions to consumers continued to be limited by high armaments expenditure and the need for a high rate of investment. Consequently, automobiles and many consumer durables were available only to a privileged minority or through access to special shops. Necessities might be in adequate supply, cultural goods (such as books and records) inexpensive, social services adequate, and accommodation cheap if not abundant, but the range of goods and services the Western consumer could spend his money on was still not available.

World War II and after. The improvised character of the economic policies of the belligerents in World War I was almost entirely absent in World War II. War experience had been digested, and further lessons had been learned from the Great Depression. Perhaps most important of all, World War II had been anticipated with some deliberation by the main participants. In the end, it was the sheer weight of resources that the Allied powers were able to bring to bear that ended the war.

Economic mobilization

In the capitalist states, economic mobilization imposed unprecedented centralized control and planning. Production was regulated by a priorities system, labour was directed, and scarce commodities were rationed. Prices and wages were controlled and foreign trade was curtailed to strategic needs. The market mechanism was largely superseded, but private property rights were preserved, and, although some war factories were state owned, military contracts were generally fulfilled by private, profit-making industry. The war economy thus remained, in Germany as in Britain and the United States, a capitalist economy.

The desire to knock out the enemy's economic nerve centres and to demoralize, or even destroy, the workers upon whom the armed forces depended accounts for much of the destructiveness of World War II. Modern technology provided supremely powerful weapons that, even before the atomic bomb, could reduce whole cities to rubble in a few hours. The wide-ranging nature of the fighting, together with the effects of bombing, extended the area of destruction far more than previous wars as well as making it more complete. At the end of the war, therefore, the European countries and the Soviet Union faced an unprecedented mass of destruction. To this were added the losses from the sea war and the dislocation and disruption of prewar trade patterns.

The recovery. The recuperative powers of advanced industrial societies, however, are remarkable. The effect of bombing on machines and industrial equipment was less severe than on dwellings and other buildings. Given the human skills available and an abundant supply of people with the incentive to reshape shattered lives and earn enough to buy necessities, it was possible to restore industry and reconstruct the social infrastructure comparatively quickly. From the ruins emerged, in fact, a larger and more advanced industry than in peacetime. It was even claimed that the more devastated regions, such as western Germany, had the advantage over the less battered industries in Britain, which brought much obsolete equipment and plant intact into the postwar years. Such an explanation of British industrial problems, which were to limit its

growth in the period after 1945, was, however, too facile.

The European belligerents endured severe upheavals and hardships in the later stages of the war and the first years of peace. This was a period of general penury, of rationing and the black market, during which, in some places, money virtually lost all value, and some people returned to a barter economy. Only United States loans and aid prevented economic and social breakdown. Meanwhile, large transfers of population took place, particularly from eastern Germany and Czechoslovakia to the West, and large numbers of displaced persons had to be resettled. The many millions of rootless and penniless people provided, however, a mobile and adaptable labour force. Growth was not held back by labour scarcity, and the bargaining power of workers was held in check until full employment levels were reached.

At the end of the war a tremendous disparity existed between the United States and the dislocated economy of impoverished Europe. Only the United States could supply the foodstuffs, raw materials, semifinished products, machinery, and machine tools that were in scarce supply. The capacity of the belligerent countries to earn foreign exchange, particularly dollars, had been greatly impaired; and they needed loans or aid if reconstruction was to be carried through without balance of payments difficulties. U.S. lend-lease, under which supplies had been made available during the war, ended shortly after Japan's capitulation. Spurred by the growing tension of the Cold War, the European Recovery Program, or Marshall Plan, was proposed in 1947 (administered April 1948–December 1951) to continue reconstruction and rescue capitalism in western Europe.

The Marshall Plan

The outstanding fact was that the reconstruction boom was succeeded not by a crisis of overproduction and a return to high unemployment but by expansion that continued through the 1950s and 1960s.

Postwar monetary systems. The governments of the Allied countries in the postwar world saw that the currency chaos and beggar-my-neighbour policies of the 1930s must be avoided. First, the reconstruction of the world monetary system was needed, and the United Nations Monetary and Financial Conference held at Bretton Woods in July 1944 sought to do this through the establishment of the International Monetary Fund and the International Bank for Reconstruction and Development (World Bank). The former set out to establish monetary stability and to remove exchange restrictions that hampered world trade. It established new rules for adjusting exchange rates without a return to the old gold standard. Although each national currency was to be expressed in terms of gold, it was the dollar price of gold and the convertibility of the dollar that together provided the essence of the postwar monetary system.

The recovery of the world market was much more rapid than after World War I. In an atmosphere of expansion, international trade was liberalized through the General Agreement on Tariffs and Trade (GATT), and other agencies made possible a greater degree of international economic cooperation. Some, such as the Organisation for European Economic Cooperation (OEEC), were mainly consultative bodies. More important was the movement toward economic integration in Europe that led to the Treaty of Rome in 1957 and the setting up of the European Economic Community (EEC, or the Common Market) in 1957.

Economic expansion. From the early 1950s a long-term expansion began in the industrialized countries. Particularly rapid growth rates were achieved by advanced countries that were incompletely industrialized. Western Germany resumed its place as the hub of industrial northwest Europe. The Scandinavian countries continued with their solid prosperity. The fringe countries of southern Europe, still relatively backward, began to speed into the 20th century. Such older industrial areas as Britain and Belgium experienced growth, too, but at a rate that compared unfavourably with that of the rest of western Europe.

The roots of the sustained growth of the advanced industrial countries in the 1950s and 1960s seem to have been laid in the war and even as far back as the Depression. A long period in which investment was at a low level and, in some fields, actually negative had cleared the way. In some countries the war had added to industrial capacity; machines and machine tools were available to produce new consumer goods. Despite the destruction in Germany, there was more plant and equipment available for production than in the 1930s. British industry, which had not entirely thrown off the Depression in 1939, entered the postwar world in a sellers' market, and unemployment was minimal until the late 1960s.

Background of postwar expansion

Interrelated developments in varied fields tended to make industry much more science based than ever before. This enabled the logic in the industrial system to be worked out more fully, culminating in the fully automated computer-controlled process. But highly sophisticated machines had only a partial application and represented an enormous outlay of capital. Perhaps more important in raising total output was the steady increase of productivity levels over almost the whole of industry. Into this there entered not only straight technology but also changes in business organization, administration, and management, and a better educated and more adaptable labour force.

Postwar capitalism was characterized by almost uninterrupted output and productivity growth and high levels of investment. As the expansion continued its momentum, workers had to be mobilized from further afield. Germany and France each attracted some 3,000,000 immigrants to meet a chronic labour shortage. In particular, steady and prolonged employment became a part of the expected order of things. Full employment greatly enhanced trade-union power as well as making employers compete for labour. Some economists claimed that "wage push" was a main factor in the inflationary pressures of the late 20th century; but the whole situation was inherently inflationary, and governments that attempted to deal with it merely checked expansion and created a recession. It was generally accepted, therefore, that some inflation was unavoidable if growth and full employment were to be maintained. Government expenditures, especially on armaments, when financed by credit expansion, fed the inflationary trend and were probably its basic source. The ability to increase the money supply was made possible by the currency arrangements established by Bretton Woods and particularly by the outflow of dollars from the United States.

Internationalism. The European Economic Community, or Common Market, was in the first place a customs union whose members reduced (and were finally to abolish) duties on their own trade while a common external tariff was to be maintained against imports. The original signatories of the Treaty of Rome—France, West Germany, Italy, Belgium, The Netherlands, and Luxembourg—also intended to develop policies to achieve full economic integration. It was hoped that the establishment of a unified market area would yield benefits comparable to those gained by the United States. Great Britain, Denmark, and Ireland joined the Common Market in 1973, and Greece in 1981.

The Treaty of Rome

The giant international firm was another focal point of public interest. These firms were particularly strong in the industries that were in the vanguard of technical progress, such as computers, motor vehicles, and electronics.

As incomes in Europe rose, more was spent on luxury goods; and the extent to which a country was equipped with different types of such goods became a reliable index of its per capita income. Even advanced European countries were poorly equipped with washing machines, refrigerators, vacuum cleaners, and the like after World War II, and thus a big field was open for new investment and large-scale production, with U.S. capital often taking a leading part. As a result, European consumption moved closer to U.S. patterns. Europeans also spent more on services of various kinds, so that there was a continuous growth of the "tertiary" sector in Europe and industrialization itself resulted in a fall in the proportion of the occupied population working in manufacturing industry.

The uncertain future. By the early 1970s it was clear that the long-sustained postwar expansion had come to an end. Most countries were subject to higher inflation

rates coupled with slower, or arrested, growth—a situation described by some economists as "stagflation"—and unemployment reappeared as a serious problem. Heavy industries such as steel and shipbuilding were hardest hit as investment rates declined, as were some traditional consumer-goods industries subject to sharper foreign competition. What was spoken of as a "crisis" worsened with the decision of the Organization of Petroleum Exporting Countries (OPEC) to increase prices fourfold following the Arab–Israeli War of 1973. Importing countries were faced with the problem of how to meet the higher payments, while the oil producers acquired large liquid reserves, mainly in dollars, the movements of which imposed further strain on the already dislocated international monetary system. Continued inflation tended to reduce the real cost of oil imports, and OPEC replied with further price increases. The oil-importing countries that had strong exports responded by increasing their foreign earnings to cover the higher import bill. Oil-importing countries with weaker economies suffered balance of payments deficits that weakened their currencies and drove them into debt.

During the late 20th century the governments of the economically advanced countries agreed that the struggle against inflation would have to take priority over the maintenance of full employment. Clear-cut policies were slow to take shape, but there was no doubt that the influence of Keynesian economics and the use of its remedies against recession had waned. In general, government withdrawal took the form of abstention from new measures of intervention to meet recession or deal with unemployment and some dismantling of existing controls. These policies met with opposition, especially from organized labour, whose cartel-like methods in wage bargaining were also under attack. Economic issues bound up with inflation and unemployment were very much at the centre of political debate and were likely to remain so in the late 20th century. (T.Ke./Ed.)

MODERN CULTURE

In the last quarter of the 19th century European thought and art became infused with doubt and decadence. Writers as different as Baudelaire and Matthew Arnold, Henry Adams and Flaubert, Ruskin and Nietzsche were exasperated by the banality and smugness of surrounding humanity. It seemed as if with the onset of Positivism and science, *Realpolitik* and Darwinism, realistic art and popular culture, all noble thought and true emotion had been suffocated. The only things that stood out from banality and smugness were their own appalling extremes—vulgarity and arrogance—against which all the weapons of the mind seemed powerless.

The diminished influence of the intellectuals

Such intellectuals and artists were hopelessly outnumbered not only in the literal sense but also in the means of influencing culture. A newspaper that reached half a million readers with its cliches, its serial story, and its garish illustrations "educated" the people in a fashion that actively prevented any understanding of any part of true culture. The barrier was far more insurmountable than mere ignorance or illiteracy; and it was cutting off not just the populace but also—to use Arnold's terms—the barbarian upper class and the Philistine middle class. Similarly, Nietzsche anatomized the culture Philistine; that is, the person whose mind was being filled by the mediocre thoughts of writers and artists high in repute and generally believed to be leaders of civilization. In other words, the prudent, self-limiting impulse of Realism after 1848 had generated the middlebrow, while the evolution of industrial democracy had generated the mass man. By the late 1880s the gap between this compact army with its honoured officers and common soldiers and the hostile, half-visible avant-garde was a permanent feature of cultural evolution.

The individual expressions of disgust with the former age of Realism naturally took many forms, but they can be grouped into half a dozen kinds, not all on the same plane and only some of which have come to bear distinctive names. Some artists retreated from the ugly world into a species of Neoclassicism. Such were the French poets known as Parnassiens. Strict form, antique subjects, and the pose of impassivity constitute their hallmark. In painting, the work of Puvis de Chavannes stands in parallel.

In music, the explicit revolt against Wagner and Liszt, of which Brahms was made the torchbearer, offers similarities, particularly in the desire to learn and employ the "purer" forms of an earlier time. Likewise, the shift in tone and temper of the later poems of Tennyson, Arnold, or Gautier; the resurgence of Thomist orthodoxy in Catholic thought; the haughty detachment in the plays of Becque and those of Ibsen's middle period, all suggest a search for stability, for a fixed point from which to judge and condemn contemporary "progress."

Symbolism and Impressionism. It was also possible, after withdrawing by conscious effort from any struggle with vulgar actuality, to make art itself an independent and inhabitable world and to escape alienation in beauty. This cult of beauty goes by the names of Symbolism and Impressionism. The Impressionists were able to take as subjects some of the sights that most depressed their fellow man and by recomposing them in brilliant, shimmering colour to create a refreshing world of new sensation. Subject once again mercifully disappeared. As Monet said: "The principal subject in a painting is light."

The Symbolists in literature had a more difficult task than the painters, because their medium, words, must be shared with all those who speak the language for ordinary purposes. To disinfect grammar and vocabulary for poetry and "art prose" required severe measures. All set phrases had to be broken up, unusual words revived or common ones used in archaic or etymological senses; syntax had to be bent to permit fresh juxtapositions from which new meanings might emerge; above all, the familiar rhetoric and rhythms had to be avoided, until the literary work, poetry or prose, created the desired "new world." It is a world difficult to access but worth exploring, all its tangible parts being the symbols of a radiant reality beyond—in short, the antithesis of a newspaper editorial.

In music there was no need of any indirect device to establish the mood of Impressionism. It was already to be found here and there in the great Romantics, and when the new generation began to compose on themes drawn from literature, the hints and opportunities needed only a delicate genius to develop them into a style. Debussy was that genius, soon followed by Ravel, Delius, Hugo Wolf, and others. Alike, yet independently of one another, they replaced eloquence, melodic clarity, and harmonic consecutiveness by capricious melodic contour and pointillist chord progressions to produce the shimmer and mystery of musical Impressionism.

Aestheticism. To those who dedicated their lives to Symbolist literature and criticism the name of aesthetes is often given, for it was at this time, from 1870 to the end of the century, that questions of aesthetics became the intense concern of artists, critics, and a portion of the public. The old Romanticist phrase "art for art's sake" was revived; many persons not themselves artists confessed to a "cult of art"; much time was devoted—necessarily—to deciphering, commenting, and discriminating, for much of the new art was obscure and arcane and took time to master and enjoy. Other observers called these manifestations decadent—some with contempt, others with pride. For a time, a group of French artists took the name to themselves as a badge of honour.

But aestheticism was by no means as languid and fatalistic as it tried to appear. At its centre stands the active figure of Oscar Wilde, whom it is easy, because of his notoriety on many counts, to dismiss as colourful but ephemeral. Yet he is far more than a symptomatic figure; he is a representative one, and a good part of his work, namely his entire critical output, some of his fiction, one or two poems, the autobiographical *De Profundis,* and the greatest farce in the language, *The Importance of Being Earnest,* deserves to last. What Wilde accomplished through these works was the liberation of English literature from ancestral (and not merely Victorian) preconceptions. He reconnected England with the Continent artistically by phrasing with finality their different assumptions. He showed that art could be morally responsible only by discarding moralism. In a word, he played again in 1890

the role Gautier had played in France in 1835 with his art for art's sake diatribe in *Mademoiselle de Maupin.* Whoever, starting with Wilde or Gautier, wishes to follow the historical sequence and recapture the atmosphere in which this activity went on will find no better source than the journal of the Goncourt brothers, the inventors of "art prose" as well as the recorders of contemporary lives, characters, and gossip.

But the reader of their voluminous pages will also find there references to the movement called Naturalism, which does not merely parallel but also intermingles with Symbolism and Impressionism. The Goncourts themselves wrote a number of Naturalistic novels; their friend Zola was the theorist and greatest master of the genre; another novelist, J.-K. Huysmans, passed from Naturalism to Symbolism, as did several other writers. In the poets Rimbaud and Verlaine, as later in the Irish Yeats, the elements of the two tendencies alternated or mixed.

Naturalism. The name Naturalism suggests the philosophy of science, and the connection is genuine. Zola thought that in his great series of novels, *Les Rougon-Macquart,* he was studying the "natural and social history" of a family during the time of Napoleon III. The claim was bolstered by the method Zola used of gathering data like a scientist—every material fact could be proved by reference to actuality or statistics. Naturalism would thus appear to be an intensification of Realism, as indeed it was—more "research." But it differed markedly in spirit. Realism professed to be depiction of the commonplace in a mood of stoicism or indifference—a photographic plate from a camera held almost at random in front of unselected mediocrity; it was, as Flaubert was the first to say, a refusal to share previous Romanticist hopes and interests. Naturalism, on the contrary, readmitted purpose and selectivity. Each novel was a "study" designed to show up and denounce the dismal truths of social existence, for which purpose the worst are the best. Zola's novels throb with a passionate love of life, a life which he showed as tortured and twisted by character and condition. In the end he defined his scientific or "experimental" novel as "nature seen through a temperament."

In the plastic arts, a plausible counterpart of Naturalism is the work of those known as Postimpressionists, notably Cézanne and van Gogh in painting, Rodin and Maillol in sculpture. Their various styles and aims had a common result in restoring solidity and "weight" to the visual object after the fluidity and lightness of Impressionism.

Musical naturalism was, by contrast, an attempt at dramatic literalness. Richard Strauss boasted that he could render a soup spoon in music if he wanted to; but he could not and he did not. The noises of his *Sinfonia Domestica* are standard orchestral sounds fitted with a preliminary explanation, like the libretto or synopsis of a Wagnerian or other opera. When the sheep bleat in Strauss's *Don Quixote,* the clarinets play notes that are decorative on their own account and do not in the least suggest wool. It is rather the thickness of Strauss's orchestration and chromatic harmony that connect him with naturalist doctrine—the headlong embrace with matter. And so it is also in the operas of Bruneau or Charpentier or in the *verismo* of Puccini and the late Italian school generally. Music remains atmospheric; never, except in Wagner's system, denotative.

This definition of Naturalism, coupled with the aesthetic, or "art for art's sake," impetus in Symbolism and with the Impressionists' transmutation of concreteness into light, justifies the name of Neo-romanticism that has been given to the cultural temper with which the 19th century ended. After the glum self-repression of the middle period, it was an outburst of vehement self-assertion, whether directed inward or outward. "Art for art's sake" and Naturalism are indeed but twin branches of one doctrine: art for life's sake.

The new century. In 1895 George Bernard Shaw said: "France is certainly decadent if she thinks she is." The remark is characteristic of Shaw, but also symptomatic of a new wave of energy. From under the despair and decadence, the scattered retreats and the violent nihilism, the same human strength that produced Symbolist and Naturalist art was trying to reshape the civilization that all found so unsatisfactory.

In England, the Fabians, of whom Shaw was one, were preaching the "inevitableness of gradualism" toward the socialist state. It was they, seconded by the growing strength of the trade unions after a spectacular dock strike of 1889, who paved the way to Labour governments and the British welfare state. Throughout Europe, Socialism was no longer the creed of a lunatic fringe but was the ideal of many among the masses and the intellectuals. The original fight for liberty and democracy in political action had turned into a fight for economic democracy—freedom from want. Laissez faire liberalism had turned inside out, and the liberal imagination at work in the many brands of socialism now demanded state interference to remove the appalling conditions causing all the despair.

The growth of Socialism

Arts and Crafts movement. Among the Socialists belonging to no party, Ruskin and William Morris worked also to effect immediate changes in the quality of their surroundings: they started the so-called Arts and Crafts movement, whose aim was to make objects once again beautiful. Because machine industry produced only the cheap and nasty, they tried by hand to produce the cheap and handsome—good furniture, hangings, and household articles; fast dyes of good colour; well-printed books on good paper; and jewelry and ornaments of all kinds that showed visual talent as well as manual skill. In a word, the movement reinstated the ideal of design and succeeded in forcing it on machine industry itself. Within two decades manufacturers began to hire artists as designers, and by 1910 the 20th-century omnipresence of design, from clothes to print and from gadgetry to packaging, was a *fait accompli.* The visual revolution can be seen easily by looking back with modern eyes to a page of advertising at the turn of the century.

New trends in technology and science. In parallel with the new craftsmanship, the new technology of the 1900s began to give hope of wider improvements. The use and transmission of electric power suggested the possibility of the clean factory, all glass and white tile. Better machines, new materials and alloys, a greatly expanded chemical industry—all supplied more exact, more functional, less hazardous objects of use and consumption, while the application of science to medicine nourished the hope of greatly reducing the physical sores of mankind. Those closest to all these developments were certainly not among the despairers and fugitives from the world. Like all men who struggle successfully with difficulties, they were inspirited by what they knew to be demonstrable progress along their chosen lines.

The same outlook animated workers in the natural and social sciences. It was for both a time of transformation, and genuine novelty exerted its usual invigorating effect. From the '80s onward it had been clear that simple mechanistic explanations based on "dead" matter were inadequate. The Michelson-Morley experiment of 1887 had given the *coup de grace* to the mere push-pull principle by showing that, though light consisted of waves, the waves were not in or of anything, such as the ether, which did not exist. Even earlier, James Clerk Maxwell's attempt to work out the facts of electromagnetism on Newtonian principles had failed. And on the philosophic front, the notion of natural "laws" was being radically modified by thinkers such as Poincaré, Boutroux, Ernst Mach, Bergson, and William James. All this prepared the ground for the twin revolutions of relativity and quantum theory on which the 20th-century scientific regime is established.

The decline of the machine analogy had its counterpart in the biological sciences. With narrow Darwinian dogmas in abeyance, the genetics of Gregor Mendel were rediscovered, and a new science was born. The fixity of species was again regarded as important (Bateson), while the phenomenon of large mutations (de Vries) caught the public imagination, as the opposite slow, small changes had done 60 years earlier. The mysterious "fitness of the environment" was held deserving of study, and new formulas for evolution—emergent, creative—received serious attention. Vitalism once more reasserted its claims, as it seems bound to do in an eternal seesaw with mechanism.

Rediscovery of genetics

The social sciences. Finally, in the social sciences, fresh starts were made on new premises. Anthropology dropped its concern with physique and race and turned to "culture" as the proper unit of scientific study. Similarly in sociology, Durkheim, seconded by Tönnies, Tarde, and Le Bon, concentrated on "the social fact" as an independent and measurable reality equivalent to a physical datum. Psychology, also long under the exclusive sway of physics and physiology, now established at the hands of William James that the irreducible element of its subject matter was the "stream of consciousness"—not a compound of atomized "ideas" or "impressions" or "mind-stuff" but a live force in which image and feeling, subconscious drive and purposive interest, were not separable except abstractly. A last domain of research was mythology, to the existence of which James George Frazer's *Golden Bough* gave massive witness, thereby exerting proportional influence on literature and criticism.

Reexamination of the universe. The net effect of these innovations in the sciences of man and of nature was liberating. Whatever each specialty or subspecialty meant to its practitioners, the persons who carry in their minds the general culture of an age took the new message to mean that the universe, formerly closed forever, had been reopened, and that on fresh inspection it had proved more alive than dead. These conclusions offered a field for strong individual action. Subjective choice became again respectable as a genuine fact. Truth, God, beauty, and immortality obviously were in need of reexamination.

In philosophy, politics, and criticism this reexamination may be called the pragmatic revolution; in social and moral life, the liquidation of Victorianism. But the Pragmatic Revolution must not be thought of as being only the work of those who, like James, called themselves Pragmatists. Nietzsche, Samuel Butler, Shaw, Bergson, and others constitute the headwaters of the stream of thought that issues in present-day Existentialism. The common features are the turning away from absolutes and unities to pluralisms and the method of testing by consequences. Subjective and objective tests looking to future thought and action—not authority or antecedents—are to decide the true, the good, and the beautiful.

Turning away from absolutes

Such an outlook, of which the refinements are, like the defects, beyond the scope of this article, is the logical and appropriate one for an age of reconstruction. It boils down to trying all things new and holding fast to that which is good. But it presupposes the creation of new things to try, and here it is allied to the liquidation of Victorianism. In morals the work of destruction generally begins by affirming the opposite of the accepted rule. An excellent source book for this attitude is Samuel Butler's *Way of All Flesh,* written in 1885 but not published till 1903. The Victorian Tennyson had said: "'Tis better to have loved and lost than never to have loved at all." Butler said: "'Tis better to have loved and lost than never to have lost at all." This inversion of values—don't weep over loss; there are plenty of loves to be had and the more the merrier—is but an indication of method. At first the denial was uttered as humour and paradox: Butler's *Note-books,* Shaw's *Arms and the Man* (the soldier wants chocolate, not ammunition), Wilde's *Importance of Being Earnest,* Jarry's *Ubu roi,* Strindberg's tragicomedies—to cite but a few subverters of the Victorian—all used derision and topsy-turviness to make their point.

But underneath the joke was the new purpose, which soon found open expression in positive utterance and action. In the plays of Hauptmann and Brieux, the novels and anticipations of H.G. Wells, the essays of Tolstoy, Péguy, Georges Sorel, Ellen Key, Havelock Ellis, Unamuno, Ortega y Gasset, or Shaw, the new modes of feeling and the new scale of virtues and vices are set forth with as much earnestness and vigour as the old Victorian kind.

Nor did action wait until all the books were out. From the onset of the overturn, say 1890 onward, the rebellion was a biographical fact. People braved public opinion and got divorced, lived together unmarried, practiced and preached contraception, studied the psychology of sex, and defended homosexuality. Or again, the sons of the rich turned Socialist, became labour leaders, and fomented syndicalist (*i.e.,* direct action) strikes, while the daughters demanded the vote as suffragettes, assaulted policemen, and went to jail for chaining themselves to door handles. Meanwhile, students rioted about international incidents or university affairs; schools were subjected to the devastation of the softer pedagogies; "rational clothing" exhibited itself in spite of derision, like the bicycle and the newfangled automobile; and new cults multiplied like mushrooms—outdoor sports, nudism, Theosophy, esoteric Buddhism, Rosicrucianism, New Thought, the Society for Psychical Research, Christian Science, the Salvation Army, and the "Maximinism" of Stefan George.

Of these, hardly any need explanation here. But a word must be added about Theosophy if only because of its historical importance in developing Yeats's genius and for expressing once again the attraction that the "wisdom of the East" has for Westerners. Not that the doctrine elaborated by Madame Blavatsky rested on any genuine knowledge of Hindu religion and philosophy. That is not its point. The point is rather that Theosophy supplied the need for quietude, mystery, transcendence, and immortality in the wearied souls of Europeans. In Theosophy the doctrine of reincarnation offers satisfaction of immortal longings and inspires to wisdom, the demands of which are periodically revealed by mahatmas, or holy men.

Theosophy

As for the poet Stefan George's worship of his young friend Maximin, who died at 15, it answers a similar impulse to permanent truth but with the additional urge to abolish (rather than escape) "contemporary materialism." George was but one among many European writers who wanted to found a new society in place of the actual one. What has fitly been called the politics of cultural despair fastened on a great many saviours as the new hope—monarchy, "integral nationalism," a new aristocracy (usually tinged with intellect), technocracy (rule by science and the engineers), the proletariat (in syndicalist "cells" or communist collectives), trade and professional guilds federated in a corporate state, or again the mystic unity of "blood" and "race." In all these creeds, at least at their beginnings, the thirst for the ideal is evident: together they formed a new utopianism, of which the later fruits are familiar but quite other than those predicted: Soviet and Chinese Communism, Italian Fascism, German National Socialism. Beyond them, in the present, elements of this second wave of cultist thought and practical utopianism that ushered in our century are easily discerned.

In one country, as the 19th century passed into the 20th, all the energies seeking an ideal found an unexpected outlet. The occasion for battle was the conviction of a French officer for espionage; *i.e.,* the Dreyfus affair. Its cultural suggestiveness is apparent: on one side, the ideal of justice and the regard for the individual as an end in himself; on the other, the social or collective ideal typified by the army and the nation; throughout, the ideal of truth—the facts—pursued, lost, and found again in an embittered struggle that threw up a host of endemic prejudices—about race, about class, for and against intellect—to say nothing of individual egotisms and obsessions that had been charged with the force of pent-up aggression.

The prewar period. The same universal aggressiveness was to have its field day in the coming war of nations, but in the intervening decade (1905–14) occurred the remarkable outburst of a creativeness, which, for the first time since 1789, had its source elsewhere than in Romanticism. The "Cubist decade" (as it has been conveniently called) gave the models and the methods of a new art, just as the natural and social sciences had begun to do for science a little earlier. Cubism in painting defined itself as a new classicism, but it was obviously not Neoclassical. In painting and sculpture, in music and poetry, and in architecture especially, the new qualities were: simplicity, abstraction, and the importance of mass.

The Cubist decade

Since the artists at work were numerous and diverse, in both origins and purpose, it is idle to try to derive their productions from any single set of conditions. Clearly, the Cubist painters found encouragement in the canvases and ideas of their immediate predecessors, the Postimpressionists. But the new architects found it rather in new materials—reinforced concrete and the steel constructions of the

engineers. Some of the poets (Futurists, Unanimists, Simultanists) were influenced by sociological theories about the group; others (and novelists too) read the new psychologists and philosophers. The sculptors responded to African and Javanese artifacts. And the musicians perceived at once the exhaustion of a system of harmony, the impact of the crowd and the primitive, and the opportunities offered by using and making sounds hitherto ignored by composers. In a culture as cosmopolitan and quick-witted as that of Europe before 1914, it is unlikely that any important concept or speculation should not have found its mark somewhere in art, even if the individual artist did not consciously record it.

Consequently, it is not arbitrary to say that the Cubist decade was stimulated and prepared for its characteristic work by everything that was pouring in upon it—motion pictures and the airplane, X rays and organ transplants, the philosophy of time and space in relativity and Bergsonism, the wireless and the Eiffel Tower, the Jamesian "stream of consciousness" and Le Bon's analyses of the crowd, the importations of colonial art and the European discovery of Walt Whitman, the myths in Frazer and the double personalities in the psychopathic clinics, the fever of revolution and of sexuality reacknowledged, the transcendental visions of various orientalisms and the vitalist current that was reanimating the cosmos and authorizing an infinite number of geometries. Multiplicity outside, bottomless depths within, equally validated by science and intuition, furnished unlimited scope to perceptive genius; it was only a question of pondering, choosing, and creating fit forms.

The impact of war. To the many-sided productiveness the war of 1914 put an instantaneous stop. It was a war of a sort Europe had not known since 1815—the nation in arms. And at that earlier time, the absence of large industry had precluded the involvement, physical and mental, of every adult citizen simultaneously throughout Europe. In 1914 Beethoven, Hegel, and Goethe would have been in the trenches.

The death of Renaissance high civilization

The cessation of cultural activities; their replacement everywhere by a propaganda of hate; the rapid decimation of talent and genius in the murderous warfare of bombardment and infantry assault; the gradual demoralization through four years of less and less intelligible war aims; and after the Armistice, the long sequel of horrors—starvation, dispersion, disease, and massacre—together shattered the high civilization born of the Renaissance and based on the idea of the national state. Too many able men and women had been killed at the start or at the peak of their creative powers for the continuity of culture. Too many intimate faiths and civil traditions had been ground down for any recovery of self-confidence and public hope to be possible. Skepticism about this conclusion is easily met by reference to the present-day view of "the human condition" as it is reflected in novels and plays.

The period "between wars"—1920 to 1939—gave sufficient indications that forward direction had been lost. It combined a frivolous neo-decadence (if the term may be allowed) with a restless search for starting points. The artists who survived were unable to pursue their individual development from the point of its interruption, whether physical or spiritual. Many felt a kind of shame to be busy with art after the human disaster they had witnessed. This feeling accounts for the tiresome mocking of oneself and one's work that marks the production of the 1920s and '30s. Nothing being important, everything is silly, and it can be offered at all only if one laughs at it first. Hence the appearance of Dada, the meaning of which is that the thing is a harmless and even childish obsession.

More serious minds—Stravinsky's, for example—looked farther back than prewar times for possible models: the 18th century or the late Middle Ages. Playwrights took up the ready-made of antiquity, like 17th-century "ancients," but turned the plots inside out or upside down, those acrobatics mirroring their times and their souls simultaneously. T.S. Eliot, after expressing his disgust at all he saw and felt, declared himself a royalist, an Anglo-Catholic, and a Neoclassicist. In all the arts, eclecticism and, even more, allusiveness were the preferred methods. The partakers' enjoyment came from recognizing the borrowed plums. To this device the sole alternative was to deny the validity of art itself, as in Surrealism, which relied for its deliverances on automatic writing uncensored by the conscious mind. The ultimate creator was believed to be the dark side of our common nature.

Culture since 1920. It is always true, of course, that as the observer comes nearer to his own times his blindness increases. When he has said his say, it turns out that something or someone remarkable has been overlooked—Blake or Kierkegaard, the aesthetics of Poe and Whitman, or the scientific truths of Mendel or Semmelweis—all delayed by the myopia of the ignorant and the well informed. Therefore, any generalities made about the period since 1920 are and ought to remain suspect for a good while. Still, they are not without value for the present for two reasons: they are suggestive and they allow for a sifting through of a variety of tenable views. In addition, such conclusions inform later comers of how things seemed before time had cleared away the rubble.

The most important truth about culture since 1920 is the so-called cultural lag. The meaning of the term is simple: culture in any sense at all is being made somewhere and it takes five, 10, or 20 years to become known and diffused. The contributions of Freud and Einstein, for example, did not enter the public domain until 1920, though clearly perceivable by 1905. Subtracting five years for war and peace leaves a net lag of a whole decade. Again, there is the North Atlantic cultural lag. Until the first war sent American youth to Europe and conscious expatriation followed, the lag between the continents was 20 years or more. But since 1920, in both Europe and America, a different kind of cultural lag has been noticeable. It is the joint result of swift social evolution and failure to move creatively beyond the Cubist decade.

The "cultural lag"

The social evolution has consisted in bringing new layers of the population in contact with cultural affairs. The mass media have done the work of popularizing—radio, television, and magazines have reached the millions and told them in words and pictures "all about art"; while display advertising has quietly adapted the tone and techniques of modern literature and painting to charm and seduce the customer. The schools, including the universities, have likewise "gone modern" and bred in their students a taste for novelty in place of the classics. It could be argued that for 80 years or more, the preponderance of effort has been aimed at making an end of the aristocratic, elitist high culture of Renaissance man and his successors. That that culture has democratized itself and brought to the fore all the ideas of liberty, equality, social responsibility, humaneness, world unity, and cosmic brotherhood has not helped to save it.

In such a state of affairs, only one supposition may be possible: European man has thrived for half a millennium on the principle of individualism and has exhausted all its possibilities. A new type of man, actuated by a different principle, is required to cope with the conditions created by his predecessor. If he arises, a new culture—art, science, philosophy, social and moral relations, and political state—will follow. (J.Ba.)

BIBLIOGRAPHY

Ancient history: J. BOHM and S.J. DE LAET (eds.), *L'Europe à la fin de l'âge de pierre* (1961), numerous articles by specialists covering the later Neolithic settlement of Europe, mainly on central Europe and the Balkans; V.G. CHILDE, *The Dawn of European Civilization* (1957), the last (6th) edition of Gordon Childe's classic work, still the best survey of European prehistory from the Mesolithic to the Early Bronze Age; G. CLARK, *World Prehistory: A New Outline,* ch. 6–7 (1969), a description of the settled communities of prehistoric Europe before and after *c.* 1500 BC, and with S. PIGGOTT, *Prehistoric Societies,* ch. 10–13 (1970), on the peasant societies of prehistoric Europe; J.G.D. CLARK, *Prehistoric Europe: The Economic Basis* (1952), on the subsistence economies and technology of prehistoric Europeans from the Neolithic to Iron Age; M. GIMBUTAS, *Bronze Age Cultures in Central and Eastern Europe* (1965), especially valuable as a summary of sources originally published in Russian and other eastern European languages; S. PIGGOTT, *Ancient Europe* (1965), aspects of the cultural history of prehistoric Europe from Neolithic times to the Celtic period; N.K. SANDARS, *Prehistoric Art in Europe* (1968), especially valuable for Neolithic Balkans and for La Tène art.

Middle Ages: The fullest account of medieval Europe in English is that of the *Cambridge Medieval History,* 8 vol. (1924–36; 2nd ed., 1966–), of which only the Byzantine volumes have been re-edited, as has the first volume of the companion *Cambridge Economic History of Europe* (1966). GEORGES DUBY, *L'Économie rurale et la vie des campagnes dans l'occident médiéval,* 2 vol. (1962; Eng. trans., *Rural Economy and Country Life in the Medieval West,* 1968), summarizes much recent work and shows well the directions of current research; FRANCOIS L. GANSHOF, *Qu'est-ce que la féodalité?,* 2nd ed. (1947; Eng. trans., *Feudalism,* 1952), is the classic analysis of the structures of feudal tenure. FRITZ KERN, *Gottesgnadentum und Widerstandsrecht im früheren mittelalter* (1914; Eng. trans., *Kingship and Law in the Middle Ages,* 1939, reprinted 1968), is the most convenient introduction to its subject. *The Handbook of Church History,* ed. by HUBERT JEDIN and JOHN DOLAN (1965–), gives a full and recent account of the period from the 8th to the 12th centuries; for the later period, A.C. FLICK, *The Decline of the Medieval Church* (1930), is still useful; R.W. SOUTHERN, *Western Society and the Church in the Middle Ages* (1970), gives a more general introduction. On the towns HENRI PIRENNE, *Medieval Cities* (1925, reprinted 1956), has lost little of its value; DANIEL P. WALEY, *The Italian City-Republics* (1969), covers the period between the 11th and the 14th centuries in greater detail. GEOFFREY BARRACLOUGH (trans.), *Medieval Germany, 911–1250: Essays by German Historians* (1961); JOHANNES HALLER, *Die Epochen der deutschen Geschichte* (1928; Eng. trans., *The Epochs of German History,* 1930); ROBERT FAWTIER, *Les Capétiens et la France* (1942; Eng. trans., *The Capetian Kings of France,* 1960); and EDOUARD PERROY, *La Guerre de cent ans* (1945; Eng. trans., *The Hundred Years War,* 1951), give useful examples of national history. On England the first 5 volumes of the *Oxford History of England* (1937–59), are authoritative. JOHAN HUIZINGA, *Herfsttij der Middeleeuwen* (1950; Eng. trans., *The Waning of the Middle Ages,* 1954), is a controversial classic. The largest and most representative collection of medieval texts in translation is that in the Columbia "Records of Civilization" series, supplemented by that of the *Oxford* (formerly *Nelson*) *Medieval Texts.* The standard English bibliography of medieval history is L.J. PAETOW, *A Guide to the Study of Medieval History,* rev. ed. (1931, reprinted 1964). See also P.H. SAWYER, *Kings and Vikings: Scandinavia and Europe, A.D. 700–1100* (1983).

History, 1500–1648: The following general works include their own bibliographies: *The New Cambridge Modern History:* vol. 1, *The Renaissance, 1493–1520;* vol. 2, *The Reformation, 1520–1559;* vol. 3, *The Counter-Reformation and Price Revolution, 1559–1610;* and vol. 4, *The Decline of Spain and the Thirty Years War, 1609–1648/59* (1957–70), the best recent textbook of general history written in English; *Handbuch der mittelalterlichen und neueren Geschichte,* vol. 2, *Geschichte des europäischen Staatensystems von 1492–1559* (1919; Italian trans., 1932); WALTER PLATZHOFF, *Geschichte des europäischen Staaten-Systems, 1559–1660* (1928, reprinted 1968), a concise, useful account of international relations; GASTON ZELLER, *Les Temps modernes,* vol. 1, *De Christophe Colomb à Cromwell* (1953), a critical and stimulating study; and HENRI HAUSER, *La Prépondérance espagnole, 1559–1660* (1933, reprinted 1972), most illuminating. ERIC R. WOLF, *Europe and the People Without History* (1982), is a cultural history since 1400.

Renaissance: HANS BARON, *The Crisis of the Early Italian Renaissance,* 2nd ed. (1966), a brilliant interpretation of the rise of civic Humanism; R.R. BOLGAR, *The Classical Heritage and Its Beneficiaries* (1954), a useful survey of classical scholarship and education; ERNST CASSIRER, *Individuum und Kosmos in der Philosophie der Renaissance,* 2nd ed. (1963; Eng. trans., *The Individual and the Cosmos in Renaissance Philosophy,* 1963), not confined to Italy—the central figure is the German Nicholas of Cusa; EUGENIO GARIN, *L'umanesimo italiano,* 2nd ed. (1958; Eng. trans., *Italian Humanism,* 1965), a major interpretation of Renaissance Humanism by a leading historian; FELIX GILBERT, *Machiavelli and Guicciardini: Politics and History in Sixteenth-Century Florence* (1965), chiefly concerned with the two Florentines as historians but contains a great deal more on the historical context of their lives and thought; PAUL OSKAR KRISTELLER, *Renaissance Thought,* 2 vol. (1961–65), the best introduction to the work of a leading historian of Renaissance Humanism and philosophy; GINO LUZZATTO, *Breve storia economica d'Italia: dalla caduta dell'Impero romano al principio del cinquecento* (1958; Eng. trans., *An Economic History of Italy: From the Fall of the Roman Empire to the Beginning of the Sixteenth Century,* 1961), an excellent survey; GARRETT MATTINGLY, *Renaissance Diplomacy* (1955), the best introduction to the subject by a brilliant historian and writer; ERWIN PANOFSKY, *Renaissance and Renascences in Western Art,* 2nd ed., 2 vol. (1965), an eminent art historian on the distinctive nature of Italian Renaissance art; DANIEL P. WALEY, *The Italian City-Republics* (1969), the best introduction to the medieval development of Italian city-states; J.H. WHITFIELD, *Petrarch and the Renascence* (1943), an excellent study by a leading historian of Renaissance literature; PHILIP ZIEGLER, *The Black Death* (1969), a good popular account. ROLAND H. BAINTON, *Erasmus of Christendom* (1969), one of the most recent and readable of the many books on Erasmus; OTTO BENESCH, *The Art of the Renaissance in Northern Europe,* rev. ed. (1965), a major study by a leading scholar; KARL BRANDI, *Kaiser Karl V,* 2 vol. (1937–41; Eng. trans., *The Emperor Charles V,* 1939), a superb biography of a pivotal 16th-century figure; J.M. CLARK, *The Great German Mystics: Eckhart, Tauler and Suso* (1949), a good introduction to the three founders of the German school; J.H. ELLIOTT, *Imperial Spain, 1469–1716* (1963), the best short account in English; H.A. MISKIMIN, *The Economy of Early Renaissance Europe, 1300–1460* (1969), a brief, up-to-date survey; E. ALLISON PEERS, *Studies of the Spanish Mystics,* 3 vol. (1927–60), the classic work in the field; GUSTAVE REESE, *Music in the Renaissance* (1954), an excellent, comprehensive introduction to the subject. PIERCE BUTLER, *The Origin of Printing in Europe* (1940), a standard work on the subject; HERBERT BUTTERFIELD, *The Origins of Modern Science, 1300–1800* (1949), the best non-technical introduction; CARLO M. CIPOLLA, *Guns, Sails and Empires: Technological Innovation and the Early Phases of European Expansion, 1400–1700* (1966), explores the technological origins of Western supremacy; J.H. PARRY, *The Age of Reconaissance,* 2nd ed. (1966), full of information on navigation, shipbuilding, and exploration. PAUL O. KRISTELLER, *Renaissance Thought and Its Sources* (1979), is a collection of essays discussing Renaissance philosophy, theology, science, and literature.

History, 1648–1815: Two multivolume series cover this period in its entirety: *The Rise of Modern Europe,* ed. by W.L. LANGER, 20 vol. (1936–71); and *The New Cambridge Modern History,* planned by SIR GEORGE N. CLARK, 14 vol. (1957–). Each set deals at length with diplomatic and military developments. The annotated bibliographies in the Langer series are useful and valuable. For special studies of war and diplomacy, see GASTON ZELLER, *Les Temps modernes,* vol. 2, *De Louis XIV à 1789* (1955); and ANDRE FUGIER, *La Révolution française et l'Empire Napoléonien* (1954), both diplomatic and military histories at their broadest, linking them to economic organization and social forces. JOHN U. NEF, *War and Human Progress* (1950); and SIR GEORGE N. CLARK, *War and Society in the Seventeenth Century* (1958), convincingly refute the traditional thesis that war and militarism were the matrix of cultural progress. The later 17th century is treated in two admirable studies by JOHN B. WOLF: *The Emergence of the Great Powers, 1685–1715* (1951) and *Louis XIV* (1968). Both are broadly conceived, rich in details, and persuasively written. Also balanced and judicious is PIERRE GOUBERT, *Louis XIV et vingt millions de français* (Eng. trans., *Louis XIV and Twenty Million Frenchmen,* 1970), which makes a strong case for the greatness of Louis XIV. For Marlborough there is WINSTON CHURCHILL's six-volume authoritative tribute to his ancestor, *Marlborough: His Life and Times* (1933–38). The old study by ALFRED ARNETH, *Prinz Eugen von Savoyen,* new ed., 3 vol. (1864), is still basic. Three consecutive volumes in the Langer series deal with the period from the 18th century to the French Revolution: PENFIELD ROBERTS, *The Quest for Security, 1715–1740* (1947); WALTER L. DORN, *Competition for Empire, 1740–1763* (1940); and LEO GERSHOY, *From Despotism to Revolution, 1763–1789* (1944)—all have chapters on the central themes of balance of power diplomacy, competitive militarism, and the global war for markets and colonial goods. Prussia's place in the wars is discussed acutely in PIERRE GAXOTTE, *Frédéric II* (1938; Eng. trans., 1942). V.O. KLIUCHEVSKY, *A History of Russia,* vol. 5 (Eng. trans., 1931), deals with the diplomacy and wars of Catherine II. For orderly introductions to the troubled years from 1789 to 1815, there are LEO GERSHOY, *The French Revolution and Napoleon,* rev. ed. (1964); and GEOFFREY BRUUN, *Europe and the French Imperium, 1799–1814* (1938). Commercial war is discussed with fresh acumen by ELI F. HECKSCHER, in *The Continental System: An Economic Interpretation* (1922, reprinted 1964). There are many reprints of the once authoritative *The Influence of Sea Power upon the French Revolution and Empire, 1793–1812,* by ALFRED T. MAHAN, 2 vol. (1892). ROBERT B. MOWAT, *The Diplomacy of Napoleon* (1924, reprinted 1971), is a useful brief introduction; while EDOUARD DRIAULT, *Napoléon et l'Europe,* 5 vol. (1910–27), is a storehouse of details. Still quite useful and authoritative is THEODORE A. DODGE, *Napoleon: A History of the Art of War,* 4 vol. (1904–07). The settlement at the Congress of Vienna is studied in CHARLES K. WEBSTER, *The Congress of Vienna, 1814–1815* (1919, reprinted 1963); and, in a pragmatic temper, in HENRY A. KISSINGER, *A World Restored: Metternich, Castlereagh and the Problems of Peace, 1812–1822* (1957). GEOFFREY BEST, *War and Society in Revolutionary Europe: 1770–1870* (1982), studies the social effects of frequent military activity.

Enlightenment: NORMAN HAMPSON, *The Enlightenment,* vol. 4 of the *Pelican History of European Thought* (1968), an introduction to the 18th century—full of knowledge and spirit; PRESERVED SMITH, *A History of Modern Culture,* 2 vol. (1930–34), wisdom expressed in good style is not soon out of date; PETER GAY, *The Enlightenment,* vol. 1, *The Rise of Modern Paganism* (1966), vol. 2, *The Science of Freedom* (1969), a work of distinguished scholarly labour mindful of the complexities in the century's struggle to repudiate Christianity and to rise above classical thought to modernity—the critical bibliographical essays are indispensable for any serious student; ERNST CASSIRER, *Die Philosophie der Aufklärung* (1932; Eng. trans., *The Philosophy of the Enlightenment,* 1951), a classic work by a profound German scholar; PAUL HAZARD, *La Crise de la conscience européenne* (1935; Eng. trans., *The European Mind, 1680–1715,* 1953) and *La Pensée européenne au XVIIIéme siècle, de Montesquieu à Lessing* (1946; Eng. trans., *European Thought in the Eighteenth Century, from Montesquieu to Lessing,* 1954), by a contrasting French scholar who puts a light touch on learning; CARL LOTUS BECKER, *The Heavenly City of the Eighteenth Century Philosophers* (1932; paperback reprint, 1959), a much appreciated set of lectures in which a gentle cynic finds it amusing that the philosophers were doing essentially what their forebears had been doing (PETER GAY has reproved him in *The Party of Humanity: Essays in the French Enlightenment,* 1964); GEORGE R. HAVENS, *The Age of Ideas* (1955), scholarly but perhaps over-enthusiastic biographies of the principal French *philosophes;* GEORGE H. SABINE, *A History of Political Theory,* 3rd ed. (1961), the best survey of this vast field by a philosopher of great and dispassionate learning; A.R. HALL, *The Scientific Revolution, 1500–1800,* 2nd ed. (1962), a standard work on an essential aspect of the Enlightenment; J.B. BURY, *The Idea of Progress: An Inquiry into Its Origin and Growth* (1920), the famous classic, which might profitably be read with CHARLES FRANKEL, *The Faith of Reason: The Idea of Progress in the French Enlightenment* (1948); and HENRY VYVERBERG, *Historical Pessimism in the French Enlightenment* (1958). MARGARET C. JACOB, *The Radical Enlightenment* (1981), is a study of how the more radical thinkers of the Enlightenment affected subsequent history.

History, 1815–1914: The best comprehensive treatment of the subject is contained in the two volumes by PIERRE RENOUVIN: *Le XIX^e Siècle:* vol. 1, *De 1815 à 1871* (1954) and vol. 2, *De 1871 à 1914* (1955). A.J.P. TAYLOR, *The Struggle for Mastery in Europe, 1848–1918* (1954), covers most of the period in the author's provocative, if unorthodox, fashion. RENE ALBRECHT-CARRIE, *A Diplomatic History of Europe Since the Congress of Vienna,* 2nd ed. (1973), which covers the 20th century as well, is a dependable, balanced treatment; it can be supplemented by the same author's *Concert of Europe* (1968), a critical documentary collection that deals with the major episodes and settlements of 19th-century international affairs of Europe. ROBERT B. MOWAT, *A History of European Diplomacy, 1815–1914* (1922), is still useful though dated. Two works dealing with British policy, both of them of high quality, deserve special mention: ADOLPHUS WARD and GEORGE P. GOOCH (eds.), *The Cambridge History of British Foreign Policy, 1783–1919,* 3 vol. (1922–23, reprinted 1970); and ROBERT W. SETON-WATSON, *Britain in Europe, 1789–1914* (1937, reprinted 1968). The second half of the first, and the second and third volumes of a collective Russian work, published under the editorship of VLADIMIR P. POTEMKIN and available in French translation, *Histoire de la diplomatie* (1946–47), covers the 19th century; it has the advantages and the limitations that can be expected of a Soviet treatise in this domain. Two books with a revisionist approach are the pioneering work of SIDNEY B. FAY, *The Origins of the World War,* 2nd ed. rev., 2 vol. (1966); and of ERICH BRANDENBURG, *Von Bismarck zum Weltkriege* (1924; Eng. trans., *From Bismarck to the World War,* 1927). The two masterful volumes by WILLIAM L. LANGER, *European Alliances and Alignments, 1871–1890,* 2nd ed. (1950), and *The Diplomacy of Imperialism, 1890–1902,* 2nd ed. (1951), which are also somewhat informed by the revisionist tendency, are very detailed and dependable. Representing a different orientation, but of similarly high quality, is BERNADOTTE E. SCHMITT, *Triple Alliance and Triple Entente* (1934, reprinted 1971). PIERRE RENOUVIN, *Les Origines immédiates de la guerre, 28 juin–4 août, 1914,* 2nd ed. rev. (1927; Eng. trans., *The Immediate Origins of the War, 28 June–4 August 1914,* 1928) deals exclusively with the July 1914 crisis. The single best and most balanced work is LUIGI ALBERTINI, *Le origini della guerra del 1914,* 3 vol. (1942–43; Eng. trans., *The Origins of the War of 1914,* 3 vol., 1952–57), which has the merit of having had at its disposal a fuller documentation. The last two volumes of it, like the second of Fay's work, deal with the July crisis. V.G. KIERNAN, *From Conquest to Collapse: European Empires from 1815 to 1960* (1982), is a thorough investigation of military aspects of colonial rule.

European culture since 1800: EUGEN WEBER, *Paths to the Present* (1960), is a full and well-organized collection of documents and extracts covering the period from Romanticism to Existentialism. For the corresponding historical narrative, the *Columbia History of the World,* ch. 66–101 (1972), together with E.J. HOBSBAWM, *The Age of Revolution, 1789–1848* (1962), is useful. HAROLD T. PARKER, *The Cult of Antiquity and the French Revolutionaries* (1937, reprinted 1965), is an excellent introduction; as is CRANE BRINTON, *The Political Ideas of the English Romanticists,* rev. ed. (1962). JACQUES BARZUN, *Classic, Romantic, and Modern,* rev. ed. (1962), fills out the interpretation given in the present article. ROBERT C. BINKLEY, *Realism and Nationalism: 1852–1871* (1935); and C.J.H. HAYES, *A Generation of Materialism: 1871–1900* (1941), amplify the political and economic narrative and also interpret culture. EGON FRIEDELL, *Kulturgeschichte der Neuzeit: Die Krisis der europäischen Seele von der schwarzen Pest bis zum Weltkrieg,* 3 vol. (1927–31; Eng. trans., *A Cultural History of the Modern Age,* 3 vol., 1930–32, reprinted 1952–54), is uneven in pace but full of brilliant insights.

History since 1914: The causes of World War I, from 1878, are best presented by LUIGI ALBERTINI, *Le origini della guerra del 1914,* 3 vol. (1942–43; Eng. trans., *The Origins of the War of 1914,* 3 vol., 1952–57). More controversial is FRITZ FISCHER, *Griff nach der Weltmacht,* 3rd ed. On the peacemaking after World War I, the standard narrative in English remains that of H.W.V. TEMPERLEY (ed.), *A History of the Peace Conference of Paris,* 6 vol. (1920–24); which, however, is supplemented by ARNO J. MAYER, *Politics and Diplomacy of Peacemaking: Containment and Counter-revolution at Versailles, 1918–1919* (1967). For the 1920s and 1930s, the reader should first consult PIERRE RENOUVIN, *Les Crises du XX^e siècle,* 2 vol. (1957–58; Eng. trans., *War and Aftermath, 1914–1929* and *World War II and Its Origins: International Relations 1929–45,* both 1968). A less dispassionate account is given by WINSTON CHURCHILL in *The Gathering Storm* (1948). ARNOLD WOLFERS, *Britain and France Between Two Wars: Conflicting Strategies of Peace Since Versailles* (1940), explains the weakness of the West. For World War II there is a good survey for the general reader by BASIL COLLIER, *A Short History of the Second World War* (1967). On the decline of Europe as the historical centre of world politics, see HAJO HOLBORN, *The Political Collapse of Europe* (1959), and JOHN LUKACS, *The Last European War: September 1939–December 1941* (1976). ROLAND N. STROMBERG, *Redemption by War: The Intellectuals and 1914* (1982), studies the widespread support given war efforts by European intellectuals.

The History of European Overseas Exploration and Empires

The motives that spur human beings to examine their environment are many. Strong among them are the satisfaction of curiosity, the pursuit of trade, the spread of religion, and the desire for security and political power. At different times and in different places, different motives are dominant. Sometimes one motive inspires the promoters of discovery, and another motive may inspire the individuals who carry out the search. Still other motives draw settlers to the new territory.

Since the settlement of the European continent, its people have shown an inclination to explore and expand from their geographic centre. Exploration of the Mediterranean world led to contacts with northern and western Europeans that extended the knowledge and culture of both groups. The impetus toward expansion, demonstrated in the establishment of the Hellenistic and Roman empires, continued as Christianity spread through Europe and beyond. Colonization of conquered territories was undertaken, especially by the Romans, but on a much smaller scale than that which followed in the early modern world. The major benefit of early, indeed of all, European expansion was the cultural enrichment that resulted from contact with other civilizations. (J.B.Mi./Ed.)

The major period of European colonization had its origin with the Renaissance, the development of modern science, and the great voyages of discovery. This period began about 1500 and reached its peak in the early 1900s, when the last independent territories of Asia and Africa were parcelled out. Following World War II the strengthening of nationalistic movements opposed to colonialism and the erosion of dominance caused by the modernization of economic systems brought about the decline of the colonial empires.

For a discussion of the society that engaged in these explorations, and their effects on intra-European affairs, see EUROPEAN HISTORY AND CULTURE. The earliest European empires are discussed in GREEK AND ROMAN CIVILIZATIONS, ANCIENT.

For coverage of related topics in the *Macropædia* and *Micropædia,* see the *Propædia,* section 961, and the *Index.*

This article is divided into the following sections:

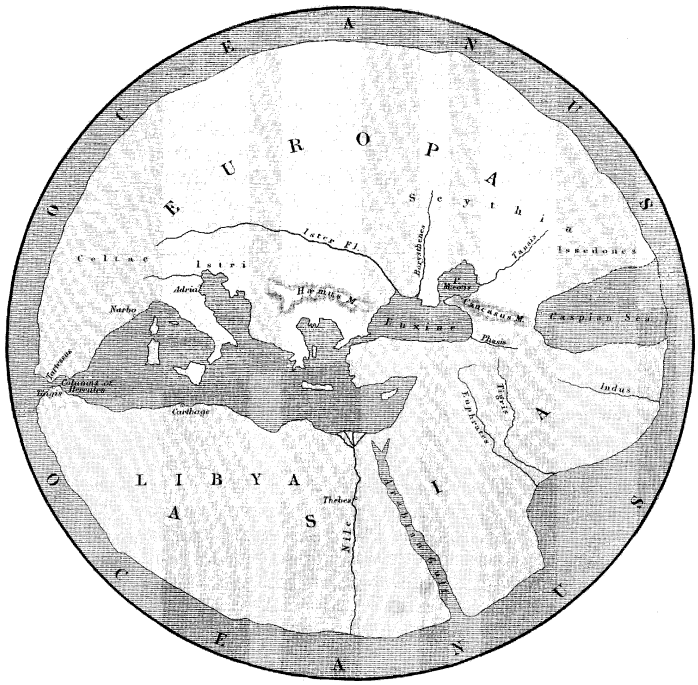
EUROPEAN EXPLORATION

The threads of geographical exploration are continuous and, being entwined one with another, are difficult to separate; three major phases of investigation may nevertheless be distinguished. The first phase is the exploration of the Old World centred on the Mediterranean Sea; the second is the so-called Age of Discovery, during which, in the search for sea routes to Cathay (the name by which China was known to medieval Europe), a New World was found; the third is the establishment of the political, social, and commercial relationships of the New World to the Old and the elucidation of the major physical features of the continental interiors—in short, the delineation of the modern world.

The exploration of the Old World

From the time of the earliest recorded history to the beginning of the 15th century, Western knowledge of the world widened from a river valley surrounded by mountains or desert (the views of Babylonia and Egypt) to a Mediterranean world with hinterlands extending from the Sahara to the Gobi deserts and from the Atlantic to the Indian oceans (the view of Greece and Rome). It later expanded again to include the far northern lands beyond the Baltic and another and dazzling civilization in the Far East (the medieval view).

The earliest known surviving map, dating probably from



Map showing the geographical knowledge of the world derived from the writings of Hecataeus of Miletus, *c.* 500 BC.
By courtesy of the Library of Congress, Washington, D.C.

The earliest known map

the time of Sargon of Akkad (about 2334–2279 BC), shows canals or rivers—perhaps the Tigris and a tributary—and surrounding mountains. The rapid colonization of the shores of the Mediterranean and of the Black Sea by Phoenicia and the Greek city-states in the first millennium BC must have been accompanied by the exploration of their hinterlands by countless unknown soliders and traders. Herodotus prefaces his *History* (written in the 5th century BC) with a geographical description of the then known world: this introductory material reveals that the coastlines of the Mediterranean and the Black Sea had by then been explored.

Stories survive of a few men who are credited with bringing new knowledge from distant journeys. Herodotus tells of five young adventurers of the tribe of the Nasamones living on the desert edge of Cyrenaica in North Africa, who journeyed southwest for many months across the desert, reaching a great river flowing from west to east; this presumably was the Niger, although Herodotus thought it to be the Upper Nile.

EXPLORATION OF THE ATLANTIC COASTLINES

Beyond the Pillars of Hercules (the Strait of Gibraltar), the Carthaginians (from the Phoenician city of Carthage in what is now Tunisia), holding both shores of the strait, early ventured out into the Atlantic. A Greek translation of a Punic (Carthaginian) inscription states that Hanno, a Carthaginian, was sent forth about 500 BC with 60 ships and 30,000 colonists "to found cities." Even allowing for a possible great exaggeration of numbers, this expedition, if it occurred, can hardly have been the first exploratory voyage along the coast of West Africa; indeed, Herodotus reports that Phoenicians circumnavigated the continent about 600 BC. Some scholars think that Hanno reached only the desert edge south of the Atlas; other scholars identify the "deep river infested with crocodiles and hippopotamuses" with the Sénégal River; and still others believe that the island where men "scampered up steep rocks and pelted us with stones" was an island off the coast of Sierra Leone. There is no record that Hanno's voyage was followed up before the era of Henry the Navigator, a Portuguese prince of the 15th century.

About the same time, Himilco, another Carthaginian, set forth on a voyage northward; he explored the coast of Spain, reached Brittany, and in his four-month cruise may have visited Britain. Two centuries later, about 300 BC, Carthaginian power at the gate of the Mediterranean temporarily slackened as a result of squabbles with the Greek city of Syracuse on the island of Sicily, so Pytheas, a Greek explorer of Massilia (Marseille), sailed through. His story is known only from fragments of the work of a contemporary historian, Timaeus (who lived in the 4th and 3rd centuries BC), as retold by the Roman savant Pliny the Elder, the Greek geographer Strabo, and the Greek historian Diodorus Siculus, all of whom were critical of its truth. It is probable that Pytheas, having coasted the shores of the Bay of Biscay, crossed from the island of Ouessant (Ushant), off the French coast of Brittany, to Cornwall in southwestern England, perhaps seeking tin. He may have sailed around Britain; he describes it as a triangle and also relates that the inhabitants "harvest grain crops by cutting off the ears . . . and storing them in covered granges." Around Thule, "the northernmost of the British Isles, six days sail from Britain," there is "neither sea nor air but a mixture like sea-lung . . . binds everything together," a reference perhaps to drift ice or dense sea fog. Thule has been identified with Iceland (too far north), with Mainland island of the Shetland group (too far south), and perhaps, most plausibly, with Norway. Pytheas returned to Brittany and explored "beyond the Rhine"; he may have reached the Elbe. The voyage of Pytheas, like that of Hanno, does not seem to have been followed up. Herodotus concludes by saying, "whether the sea girds Europe round on the north none can tell."

The Northmen

It was not Mediterranean folk but Northmen from Scandinavia, emigrating from their difficult lands centuries later, who carried exploration farther in the North Atlantic. From the 8th to the 11th century bands of Northmen, mainly Swedish, trading southeastward across the Russian plains, were active under the name of Varangians in the ports of the Black Sea. At the same time other groups, mainly Danish, raiding, trading, and settling along the coasts of the North Sea, arrived in the Mediterranean in the guise of Normans. Neither the Swedes nor the Danes travelling in these regions were exploring lands that were unknown to civilized Europeans, but it is doubtless that contact with them brought to these Europeans new knowledge of the distant northern lands.

It was the Norsemen of Norway who were the true explorers though, since little of their exploits was known to contemporaries and that little soon forgotten, they perhaps added less to the common store of Europe's knowledge than their less adventurous compatriots. About AD 890, Ohthere of Norway, "desirous to try how far that country extended north," sailed round the North Cape, along the coast of Lapland to the White Sea. But most Norsemen sailing in high latitudes explored not eastward but westward. Sweeping down the outer edge of Britain, settling in Orkney, Shetland, the Hebrides, and Ireland, they then voyaged on to Iceland, where in 870 they settled among Irish colonists who had preceded them by some two centuries. The Norsemen may well have arrived piloted by Irish sailors; and Irish refugees from Iceland, fleeing before the Norsemen, may have been the first discoverers of Greenland and Newfoundland, although this is mere surmise. The saga of Erik the Red (*Eiríks saga rauda;* also called *Thorfinns saga Karlsefnis*), gives the story of the Norse discovery of Greenland in 982; the west coast was explored, and at least two settlements were established on it. About AD 1000, one Bjarni Herjulfsson, on his way from Iceland to Greenland, was blown off course far to the southwest; he saw an unknown shore and returned to tell his tale. Leif, Erik's son, together with some 30 others, set out in 1001 to explore. They probably reached the coasts of Labrador and Newfoundland; some think that the farthest point south reached by the settlers, as described in the sagas, fits best with Maryland or Virginia, but others contend that the lands about the Gulf of St. Lawrence are more probably designated. The area was named Vinland, as grapes grew there, but it has been suggested that the "grapes" referred to were in fact cranberries. Attempts at colonization were unsuccessful; the Norsemen withdrew; and, although the Greenland colonies lingered on for some four centuries, little knowledge of these first discoveries came down to colour the vision of the seamen of

Cádiz or Bristol; the voyages of Christopher Columbus and John Cabot had their strongest inspirations in quite other traditions.

THE EXPLORATION OF THE COASTLINES OF THE INDIAN OCEAN AND THE CHINA SEA

Trade, across the land bridges and through the gulfs linking those parts of Asia, Africa, and Europe that lie between the Mediterranean and Arabian seas, was actively pursued from very early times. It is therefore not surprising that exploratory voyages early revealed the coastlines of the Indian Ocean. Herodotus wrote of Necho II, king of Egypt in the late 7th and early 6th centuries BC, that "when he stopped digging the canal . . . from the Nile to the Arabian Gulf . . . [he] sent forth Phoenician men in ships ordering them to sail back by the Pillars of Hercules." According to the story, this, in three years, they did. Upon their return, "they told things . . . unbelievable by me," says Herodotus, "namely that in sailing round Libya they had the sun on the right hand." Whatever he thought of the story of the sun, Herodotus was inclined to believe in the voyage: "Libya, that is Africa, shows that it has sea all round except the part that borders on Asia." Strabo records another story with the same theme: one Eudoxus, returning from a voyage to India in about 108 BC, was blown far to the south of Cape Guardafui. Where he landed he found a wooden prow with a horse carved on it, and he was told by the Africans that it came from a wrecked ship of men from the west.

The campaigns of Alexander the Great

About 510 BC, Darius the Great, king of Persia, sent one of his officers, Scylax of Caria, to explore the Indus. Scylax travelled overland to the Kabul River, reached the Indus, followed it to the sea, sailed westward, and, passing by the Persian Gulf (which was already well known), explored the Red Sea, finally arriving at Arsinoë, near modern Suez. The greater part of the campaigns of the famous conqueror Alexander the Great were military exploratory journeys. The earlier expeditions through Babylonia and Persia were through regions already familiar to the Greeks, but later ones through the great tract of land from the south of the Caspian Sea to the mountains of the Hindu Kush brought the Greeks much new geographical knowledge. Alexander and his army crossed the mountains to the Indus Valley and then made a westward march from the lower Indus to Susa through the desolate country along the southern edge of the Iranian plateau; Nearchus, his admiral, in command of the naval forces of the expedition, waited for the favourable monsoon and then sailed from the mouth of the Indus to the mouth of the Euphrates, exploring the northern coast of the Persian Gulf on his way.

As Roman power grew, increasing wealth brought increasing demands for Oriental luxuries; this led to great commercial activity in the eastern seas. As the coasts became well known, the seasonal character of the monsoonal winds was skillfully used; the southwest monsoon was long known as Hippalus, named for a sailor who was credited with being the first to sail with it direct from the Gulf of Aden to the coast of the Indian peninsula. During the reign of the Roman emperor Hadrian in the 1st century BC, Western traders reached Siam (now Thailand), Cambodia (now Kampuchea), Sumatra, and Java; a few also seem to have penetrated northward to the coast of China. In AD 161, according to Chinese records, an "embassy" came from the Roman emperor Marcus Aurelius to the emperor Huan Ti, bearing goods that Huan Ti gratefully received as "tribute." Ptolemy, however, does not know of these voyages: he sweeps his peninsula of Colmorgo (Malay) southwestward to join the eastward trend of his coast of Africa, thus creating a closed Indian Ocean. He presumably did not believe the story of the circumnavigation of Africa. As the 2nd century AD passed, and Roman power declined, trade with the eastern seas did not cease but was gradually taken over by Ethiopians, Parthians, and Arabs. The Arabs, most successful of all, dominated eastern sea routes from the 3rd to the 15th century. In the tales of derring-do of Sindbad the Sailor (a hero of the collection of Arabian tales called *The Thousand and One Nights*), there may be found, behind the fiction, the knowledge of these adventurous Arab sailors and traders, supplying detail to fill in the outline of the geography of the Indian Ocean.

THE LAND ROUTES OF CENTRAL ASIA

The prelude to the Age of Discovery, however, is to be found neither in the Norse explorations in the Atlantic nor in the Arab activities in the Indian Ocean but, rather, in the land journeys of Italian missionaries and merchants that linked the Mediterranean coasts to the China Sea. Cosmas Indicopleustes, an Alexandrian geographer writing in the 6th century, knew that Tzinitza (China) could be reached by sailing eastward, but he added: "one who comes by the overland route from Tzinitza to Persia makes a very short cut." Goods had certainly passed this way since Roman times, but they usually changed hands at many a mart, for disorganized and often warring tribes lived along the routes. In the 13th century the political geography changed. In 1216 a Mongol chief assumed the title of Genghis Khan and, after campaigns in China that gave him control there, turned his conquering armies westward. He and his successors built up an enormous empire until, in the late 13th century, one of them, Kublai Khan, reigned supreme from the Black Sea to the Yellow Sea. Europeans of perspicacity saw the opportunities that friendship with the Mongol power might bring. If Christian Europe could only convert the Mongols, this would at one and the same time heavily tip the scales against Muslim and in favour of Christian power and also give political protection to Christian merchants along the silk routes to the legendary sources of wealth in China. With these opportunities in mind, Pope Innocent IV sent friars to "diligently search out all things that concerned the state of the Tartars," and to exhort them "to give over their bloody slaughter of mankind and to receive the Christian faith." Among others, Giovanni da Pian del Carpini in 1245 and Willem van Ruysbroeck in 1253 went forth to follow these instructions. Travelling the great caravan routes from southern Russia, north of the Caspian and Aral seas and north of the Tien Shan (Tien Mountains), both Carpini and Ruysbroeck eventually reached the court of the emperor at Karakorum. Carpini returned confident that the Emperor was about to become a Christian; Ruysbroeck told of the city in Cathay "having walls of silver and towers of gold"; he had not seen it but had been "credibly informed" of it.

Travels of the Polos

But the greatest of the 13th-century travellers in Asia were the Polos, wealthy merchants of Venice. In 1260 the brothers Nicolo and Maffeo Polo set out on a trading expedition to the Crimea. After two years they were ready to return to Venice, but, finding the way home blocked by war, they travelled eastward to Bukhara (now in the Uzbek Soviet Socialist Republic in the Soviet Union), where they spent another three years. They then accepted an invitation to accompany a party of Tatar envoys returning to the court of Kublai Khan at Cambaluc, near Peking. The Khan received them well, provided them with a gold tablet as a safe-conduct back to Europe, and gave them a letter begging the pope to send "some hundred wise men, learned in the law of Christ and conversant with the seven arts to preach to his people." The Polos arrived home, "having toiled three years on the way," to find that Pope Clement IV was dead. Two years later they set off again, travelling without the wise men but taking with them Nicolo's son, Marco Polo, then a youth of 17. (Marco kept detailed notes of all he saw and, late in life when a captive of the Genoese, dictated to a fellow prisoner a book containing an account of his travels.) This time the Polos took a different route: starting from the port of Hormuz on the Persian Gulf, they crossed Persia to the Pamirs and then followed a caravan route along the southern edge of the Tarim Basin and Gobi Desert to Cambaluc. Knowledge of the route is interesting, but the great contribution of Marco Polo to the geographical knowledge of the West lay in his vivid descriptions of the East. He had great opportunities of seeing China and appreciating its life, for he was taken into the service of the Khan and was sent as an administrator to great cities, busy ports, and remote provinces, with instructions to write full reports. In his book he described how, upon

every main highroad, at a distance apart of 25 or 30 miles (40 to 50 kilometres), there were stations, with houses of accommodation for travellers, with 400 good horses kept in constant readiness at each station. He also reported that, along the roads, the Great Khan had caused trees to be planted, both to provide shade in summer and to mark the route in winter when the ground was covered with snow. Marco Polo lived and worked in western China, visiting the provinces of Shensi, Szechwan, and Yunnan, as well as the borders of Burma. He frequently visited "the noble and magnificent city of Quinsay [Hang-chou], a name that signifies the Celestial City and which it merits from its pre-eminence to all others in the world in point of grandeur and beauty." Cipango (Japan) he did not visit, but he heard about it from merchants and sailors: "it is situated at a distance of 1,500 miles from the mainland.... They have gold in the greatest abundance, its sources being inexhaustible." The most detailed descriptions and the greatest superlatives were reserved for Cambaluc, capital of Cathay, whose splendours were beyond compare; to this city, he said,

> everything that is most rare and valuable in all parts of the world finds its way:... for not fewer than 1,000 carriages and pack-horses loaded with raw silk make their daily entry; and gold tissues and silks of various kinds are manufactured to an immense extent.

No wonder that, when Europe learned of these things, it became enthralled. After 17 years, the Venetians were permitted to depart; they returned to Europe by sea. After visiting Java they sailed through the Strait of Malacca (again proving the error of Ptolemy); and, landing at Hormuz, they travelled cross-country to Armenia, and so home to Venice, which they reached in 1295.

Other European travellers in Asia

A few travellers followed the Polos. Giovanni da Montecorvino, a Franciscan friar from Italy, became archbishop of Peking and lived in China from 1294 to 1328. Friar Oderic of Pordenone, an Italian monk, became a missionary, journeying throughout the greater part of Asia between 1316 and 1330. He reached Peking by way of India and Malaya, then travelled by sea to Canton; he returned to Europe by way of Central Asia, visiting Tibet in 1325—the first European to do so. Friar Oderic's account of his journeys had considerable influence in his day: it was from it that the spurious traveller, the English writer Sir John Mandeville, quarried most of his stories.

Ibn Baṭṭūṭah, an Arab of Tangier, journeyed farther perhaps than any other medieval traveller. In 1325 he set out to make the traditional pilgrimage to Mecca, and in some 30 years he visited the greater part of the Old World, covering, it has been said, more than 75,000 miles. He was the first to explore much of Arabia; he travelled extensively in India; he reached Java and Southeast Asia. Then toward the end of his life he returned to the west, where, after visiting Spain, he explored western Sudan "to the northernmost province of the Negroes." He reached the Niger, which he called the Nile, and was astonished by the huge hippopotamuses "taking them to be elephants." When he finally returned to Fès in Morocco he "kissed the hand of the Commander of the Faithful the Sultan... and settled down under the wing of his bounty." He wrote a vivid and perspicacious account of his travels, but his book did not become known to Christian Europe for centuries. It was Marco Polo's book that was the most popular of all. Some 138 manuscripts of it survive: it was translated before 1500 into Latin, German, and Spanish, and the first English translation was published in 1577. For centuries Europe's maps of the Far East were based on the information provided by Marco Polo; even as late as 1533 Johannes Schöner, the German maker of globes, wrote:

> Behind the Sinae and the Ceres [legendary cities of Central Asia]... many countries were discovered by one Marco Polo... and the sea coasts of these countries have now recently again been explored by Columbus and Amerigo Vespucci in navigating the Indian Ocean.

Columbus possessed and annotated a copy of the Latin edition (1483–85) of Marco Polo's book, and in his journal he identified many of his own discoveries with places that Marco Polo describes.

Thus, with Ptolemy in one hand and Marco Polo in the other, the European explorers of the Age of Discovery set forth to try to reach Cathay and Cipango by new ways; Ptolemy promised that the way was short; Marco Polo promised that the reward was great.

The Age of Discovery

In the 100 years from the mid-15th to the mid-16th century, a combination of circumstances stimulated men to seek new routes; and it was new routes rather than new lands that filled the minds of kings and commoners, scholars and seamen. First, toward the end of the 14th century, the vast empire of the Mongols was breaking up; thus, Western merchants could no longer be ensured of safe-conduct along the land routes. Second, the growing power of the Ottoman Turks, who were hostile to Christians, blocked yet more firmly the outlets to the Mediterranean of the ancient sea routes from the East. Third, new nations on the Atlantic shores of Europe were now ready to seek overseas trade and adventure.

THE SEA ROUTE EAST BY SOUTH TO CATHAY

Henry the Navigator

Henry the Navigator, prince of Portugal, initiated the first great enterprise of the Age of Discovery—the search for a sea route east by south to Cathay. His motives were mixed. He was curious about the world; he was interested in new navigational aids and better ship design and was eager to test them; he was also a crusader and hoped that, by sailing south and then east along the coast of Africa, Arab power in North Africa could be attacked from the rear. The promotion of profitable trade was yet another motive; he aimed to divert the Guinea trade in gold and ivory away from its routes across the Sahara to the Moors of Barbary (North Africa) and instead channel it via the sea route to Portugal.

Expedition after expedition was sent forth throughout the 15th century to explore the coast of Africa. In 1445 the Portuguese navigator Dinís Dias reached the mouth of the Sénégal, which "men say comes from the Nile, being one of the most glorious rivers of Earth, flowing from the Garden of Eden and the earthly paradise." Once the desert coast had been passed, the sailors pushed on: in 1455 and 1456 Alvise Ca' da Mosto made voyages to Gambia and the Cape Verde Islands. Prince Henry died in 1460 after a career that had brought the colonization of the Madeira Islands and the Azores and the traversal of the African coast to Sierra Leone. Henry's captain, Diogo Cão, discovered the Congo River in 1482. All seemed promising; trade was good with the riverine peoples, and the coast was trending hopefully eastward. Then the disappointing fact was realized: the head of a great gulf had been reached, and, beyond, the coast seemed to stretch endlessly southward. Yet, when Columbus sought backing for his plan to sail westward across the Atlantic to the Indies, he was refused—"seeing that King John II [of Portugal] ordered the coast of Africa to be explored with the intention of going by that route to India."

The search for routes to Asia

King John II sought to establish two routes: the first, a land and sea route through Egypt and Ethiopia to the Red Sea and the Indian Ocean and, the second, a sea route around the southern shores of Africa, the latter an act of faith, since Ptolemy's map showed a landlocked Indian Ocean. In 1487, a Portuguese emissary, Pêro da Covilhã, successfully followed the first route; but, on returning to Cairo, he reported that, in order to travel to India, the Portuguese "could navigate by their coasts and the seas of Guinea." In the same year another Portuguese navigator, Bartolomeu Dias, found encouraging evidence that this was so. In 1487 he rounded the Cape of Storms in such bad weather that he did not see it, but he satisfied himself that the coast was now trending northeastward; before turning back, he reached the Great Fish River, in what is now South Africa. On the return voyage, he sighted the Cape and set up a pillar upon it to mark its discovery.

The seaway was now open, but eight years were to elapse before it was exploited. In 1492 Columbus had apparently reached the East by a much easier route. By the end of the decade, however, doubts of the validity of Columbus' claim were current. Interest was therefore renewed

World map by J.M. Contarini, 1506, depicting the expanding horizons becoming known to European geographers in the Age of Discovery.

in establishing the sea route south by east to the known riches of India. In 1497 a Portuguese captain, Vasco da Gama, sailed in command of a fleet under instructions to reach Calicut, on India's west coast. This he did after a magnificent voyage around the Cape of Storms (which he renamed the Cape of Good Hope) and along the unknown coast of East Africa. Yet another Portuguese fleet set out in 1500, this one being under the command of Pedro Álvarez Cabral; on the advice of da Gama, Cabral steered southwestward to avoid the calms of the Guinea coast; thus, en route for Calicut, Brazil was discovered. Soon trading depots, known as factories, were built along the African coast, at the strategic entrances to the Red Sea and the Persian Gulf, and along the shores of the Indian peninsula. In 1511 the Portuguese established a base at Malacca (now Melaka, Malaysia), commanding the straits into the China Sea; in 1511 and 1512, the Moluccas, or Spice Islands, and Java were reached; in 1557 the trading port of Macau was founded at the mouth of the Canton River. Europe had arrived in the East. It was in the end the Portuguese, not the Turks, who destroyed the commercial supremacy of the Italian cities, which had been based on a monopoly of Europe's trade with the East by land. But Portugal was soon overextended; it was therefore the Dutch, the English, and the French who in the long run reaped the harvest of Portuguese enterprise.

Some idea of the knowledge that these trading explorers brought to the common store may be gained by a study of contemporary maps. The map of the German Henricus Martellus, published in 1492, shows the shores of North Africa and of the Gulf of Guinea more or less correctly and was probably taken from numerous seamen's charts. The delineation of the west coast of southern Africa from the Guinea Gulf to the Cape suggests a knowledge of the charts of the expedition of Bartolomeu Dias. The coastlines of the Indian Ocean are largely Ptolemaic with two exceptions: first, the Indian Ocean is no longer landlocked; and second, the Malay Peninsula is shown twice—once according to Ptolemy and once again, presumably, according to Marco Polo. The Contarini map of 1506 shows further advances; the shape of Africa is generally accurate, and there is new knowledge of the Indian Ocean, although it is curiously treated. Peninsular India (on which Cananor and Calicut are named) is shown; although too small, it is, however, recognizable. There is even an indication to the east of it of the Bay of Bengal, with a great river running into it. Eastward of this is Ptolemy's India, with the huge island of Taprobane—a muddled representation of the Indian peninsula and Ceylon (now Sri Lanka). East again, as on the map of Henricus Martellus, the Malay Peninsula appears twice. Ptolemy's bonds were hard to break.

THE SEA ROUTE WEST TO CATHAY

It is not known when the idea originated of sailing westward in order to reach Cathay. Many sailors set forth searching for islands in the west; and it was a commonplace among scientists that the east could be reached by sailing west, but to believe this a practicable voyage was an entirely different matter. Christopher Columbus, a Genoese who had settled in Lisbon about 1476, argued that Cipango lay a mere 2,500 nautical miles west of the Canary Islands in the eastern Atlantic. He took 45 instead of 60 nautical miles as the value of a degree; he accepted Ptolemy's exaggerated west–east extent of Asia and then added to it the lands described by Marco Polo, thus reducing the true distance between the Canaries and Cipango by about one-third. He could not convince the Portuguese scientists nor the merchants of Lisbon that his idea was worth backing; but eventually he obtained the support of King Ferdinand and Queen Isabella of Spain.

The sovereigns probably argued that the cost of equipping the expedition would not be very great; the loss, if it failed, could be borne; the gain, should it succeed, was incalculable—indeed, it might divert to Spain all the wealth of Asia.

The voyages of Columbus

On August 3, 1492, Columbus sailed from Palos, Spain, with three small ships manned by Spaniards. From the Canaries he sailed westward, for, on the evidence of the globes and maps in which he had faith, Japan was on the same latitude. If Japan should be missed, Columbus thought that the route adopted would land him, only a little further on, on the coast of China itself. Fair winds favoured him, the sea was calm, and, on October 12, landfall was made on the Bahama island of Guanahaní, which he renamed San Salvador (also called Watling Island, though Samana Cay and other islands have been identified as Guanahaní). With the help of the local Indians, the ships reached Cuba and then Haiti. Although there was no sign of the wealth of the lands of Kublai Khan, Columbus nevertheless seemed convinced that he had reached China, since, according to his reckoning, he was beyond Japan. A second voyage in 1493 and 1494, searching fruitlessly for the court of Kublai Khan, further explored the islands of "the Indies." Doubts seem to have arisen among the would-be colonists as to the identity of the islands since Columbus demanded that all take an oath that Cuba was the southeast promontory of Asia—the Golden Chersonese. On his third voyage, in 1498, Columbus sighted Trinidad, entered the Gulf of Paria, on the coast of what is now Venezuela, and annexed for Spain "a very great continent . . . until today unknown." On a fourth voyage, from 1502 to 1504, he explored the coast of Central America from Honduras to Darien on the Isthmus of Panama, seeking a navigable passage to the west. What passage he had in mind is obscure; if at this point he still believed he had reached Asia, it is conceivable that he sought a way through Ptolemy's Golden Chersonese into the Indian Ocean.

Columbus' tenacity, courage, and skill in navigation make him stand out among the few explorers who have changed substantially ideas about the world. At the time, however, his efforts must have seemed ill-rewarded: he found no emperor's court rich in spices, silks, gold, or precious stones but had to contend with mutinous sailors, dissident colonists, and disappointed sovereigns. He died at Valladolid in 1506. Did he believe to the end that he indeed had reached Cathay, or did he, however dimly, perceive that he had found a New World?

Whatever Columbus thought, it was clear to others that there was much to be investigated, and probably much to be gained, by exploration westward. Not only in Lisbon and Cádiz but also in other Atlantic ports, groups of men congregated in hopes of joining in the search. In England, Bristol, with its western outlook and Icelandic trade, was the port best placed to nurture adventurous seamen. In the latter part of the 15th century, John Cabot, with his wife and three sons, came to Bristol from Genoa or Venice. His project to sail west gained support, and with one small ship, the "Matthew," he set out in May 1497, taking a course due west from Dursey Head, Ireland. His landfall on the other side of the ocean was probably on the northern peninsula of what is now known as Newfoundland. From there, Cabot explored southward, perhaps encouraged to do so, even if seeking a westward passage, by ice in the Strait of Belle Isle. Little is known of John Cabot's first voyage, and almost nothing of his second, in 1498, from which he did not return, but his voyages in high latitudes represented almost as great a navigational feat as those of Columbus.

The coasts between the landfalls of Columbus and of John Cabot were charted in the first quarter of the 16th century by Italian, French, Spanish, and Portuguese sailors. Sebastian Cabot, son of John, gained a great reputation as a navigator and promoter of Atlantic exploration, but whether this was based primarily on his own experience or on the achievements of his father is uncertain. In 1499 Amerigo Vespucci, an Italian merchant living in Seville, together with the Spanish explorer Alonso de Ojeda, explored the north coast of South America from Suriname to the Golfo de Venezuela. His lively and embellished description of these lands became popular, and Waldseemüller, on his map of 1507, gave the name America to the southern part of the continent.

Contarini's map

The 1506 map of Contarini represented a brave attempt to collate the mass of new information, true and false, that accrued from these western voyages. The land explored by Columbus on his third voyage and by Vespucci and de Ojeda in 1499 is shown at the bottom left of the map as a promontory of a great northern bulge of a continent extending far to the south. The northeast coast of Asia at the top left is pulled out into a great peninsula on which is shown a big river and some mountains representing Contarini's concept of Newfoundland and the lands found by the Cabots and others. In the wide sea that separates these northern lands from South America, the West Indies are shown. Halfway between the Indies and the coast of Asia, Japan is drawn. A legend placed between Japan and China reveals the state of opinion among at least some contemporary geographers; it presumably refers to the fourth voyage of Columbus in 1502 and may be an addition to the map. It runs:

> Christopher Columbus, Viceroy of Spain, sailing westwards, reached the Spanish islands after many hardships and dangers. Weighing anchor thence he sailed to the province called Ciambra [a province which then adjoined Cochinchina].

Others did not agree with Contarini's interpretation. To more and more people it was becoming plain that a New World had been found, although for a long time there was little inclination to explore it but instead a great determination to find a way past it to the wealth of Asia. The voyage of the Portuguese navigator Ferdinand Magellan, from 1519 to 1521, dispelled two long-cherished illusions: first, that there was an easy way through the barrier and, second, that, once the barrier was passed, Cathay was near at hand.

Magellan's voyages

Ferdinand Magellan had served in the East Indies as a young man. Familiar with the long sea route to Asia eastward from Europe via the Cape of Good Hope, he was convinced that there must be an easier sea route westward. His plan was in accord with Spanish hopes; five Spanish ships were fitted out in Seville, and in August 1519 they sailed under his command first to the Cape Verde Islands and thence to Brazil. Standing offshore, they then sailed southward along the east coast of South America; the estuary of the Río de la Plata was explored in the vain hope that it might prove to be a strait leading to the Pacific. Magellan's ships then sailed south along the coast of Patagonia. The Gulf of St. George, and doubtless many more small embayments, raised hopes that a strait had been found, only to dash them; at last at Port Julian, at 49°15′ S, winter quarters were established. In September 1520 a southward course was set once more, until, finally, on October 21, Magellan found a strait leading westward. It proved to be an extremely difficult one: it was long, deep, tortuous, rock-walled, and bedevilled by icy squalls and dense fogs. It was a miracle that three of the five ships got through its 325-mile length. After 38 days, they sailed out into the open ocean. Once away from land, the ocean seemed calm enough; Magellan consequently named it the Pacific. The Pacific, however, proved to be of vast extent, and for 14 weeks the little ships sailed on a northwesterly course without encountering land. Short of food and water, the sailors ate sawdust mixed with ship's biscuits and chewed the leather parts of their gear to keep themselves alive. At last, on March 6, 1521, exhausted and scurvy-ridden, they landed at the island of Guam. Ten days later they reached the Philippines, where Magellan was killed in a local quarrel. The survivors, in two ships, sailed on to the Moluccas; thus, sailing westward, they arrived at last in territory already known to the Portuguese sailing eastward. One ship attempted, but failed, to return across the Pacific. The remaining ship, the "Vittoria," laden with spices, under the command of the Spanish navigator Juan Sebastián de Elcano, sailed alone across the Indian Ocean, rounded the Cape of Good Hope, and arrived at Seville on September 9, 1522, with a crew of four Indians and only 17 survivors of the 239 Europeans who had set sail with the expedition three years earlier. Elcano, not having

allowed for the fact that his circumnavigation had caused him to lose a day, was greatly puzzled to find that his carefully kept log was one day out; he was, however, delighted to discover that the cargo that he had brought back more than paid for the expenses of the voyage.

It is fitting to consider this first circumnavigation as marking the close of the Age of Discovery. Magellan and his men had demonstrated that Columbus had discovered a New World and not the route to China and that Columbus' "Indies"—the West Indies—were separated from the East Indies by a vast ocean.

Not all the major problems of world geography were, however, now solved. Two great questions still remained unanswered. Were there "northern passages" between the Atlantic and Pacific oceans more easily navigable than the dangerous Strait of Magellan to the south? Was there a great landmass somewhere in the vastness of the southern oceans—a Terra Australis ("southern land") that would balance the northern continents?

The emergence of the modern world

The centuries that have elapsed since the Age of Discovery have seen the end of dreams of easy routes to the East by the north, the discovery of Australasia and Antarctica in place of Terra Australis Incognita, and the identification of the major features of the continental interiors.

While, as in earlier centuries, traders and missionaries often proved themselves also to be intrepid explorers, in this period of geographical discovery the seeker after knowledge for its own sake played a greater part than ever before.

THE NORTHERN PASSAGES

Roger Barlow, in his *Briefe Summe of Geographie,* written in 1540–41, asserted that "the shortest route, the northern, has been reserved by Divine Providence for England."

The search for a Northeast Passage

The concept of a Northeast Passage was at first favoured by the English: it was thought that, although its entry was in high latitudes, it "turning itself, trendeth towards the southeast . . . and stretcheth directly to Cathay." It was also argued that the cold lands bordering this route would provide a much needed market for English cloth. In 1553 a trading company, later known as the Muscovy Company, was formed with Sebastian Cabot as its governor. Under its auspices numerous expeditions were sent out. In 1553 an expedition set sail under the command of Sir Hugh Willoughby; Willoughby's ship was lost, but the exploration continued under the leadership of its pilot general, Richard Chancellor. Chancellor and his men wintered in the White Sea, and next spring "after much adoe at last came to Mosco." Between 1557 and 1560, another English voyager, Anthony Jenkinson, following up this opening, travelled from the White Sea to Moscow, then to the Caspian, and so on to Bukhara, thus reaching the old east–west trade routes by a new way. Soon, attempts to find a passage to Cathay were replaced by efforts to divert the trade of the ancient silk routes from their traditional outlets on the Black Sea to new northern outlets on the White Sea.

The Dutch next took up the search for the passage. The Dutch navigator William Barents made three expeditions between 1594 and 1597 (when he died in Novaya Zemlya, modern Soviet Union). The English navigator Henry Hudson, in the employ of the Dutch, discovered between 1605 and 1607 that ice blocked the way both east and west of Svalbard (Spitsbergen). Between 1725 and 1729 and from 1734 to 1743, a series of expeditions inspired by the Danish-Russian explorer Vitus Bering attempted the passage from the eastern end, but it was not until 1878–79 that Baron Adolf Erik Nordenskiöld, the Finnish-Swedish scientist and explorer, sailed through it.

The Northwest Passage, on the other hand, also had its strong supporters. In 1576 Humphrey Gilbert, the English soldier and navigator, argued that "Mangia [South China], Quinzay [Hang-chou] and the Moluccas are nearer to us by the North West than by the North East," while John Dee in 1577 set out the view that the Strait of Anian, separating America from Asia, led southwest "along the backeside of Newfoundland." In 1534 Jacques Cartier, the French navigator, explored the St. Lawrence estuary. In 1576 the English explorer Sir Martin Frobisher found the bay named after him. Between 1585 and 1587, the English navigator John Davis explored Cumberland Sound and the western shore of Greenland to 73° N; although he met "a mighty block of ice," he reported that "the passage is most probable and the execution easy." In 1610 Henry Hudson sailed through Hudson Strait to Hudson Bay, confident, before he was set adrift by a mutinous crew, that success was at hand. Between 1612 and 1615, three English voyagers—Robert Bylot, Sir Thomas Button, and William Baffin—thoroughly explored the bay, returning convinced that there was no strait out of it leading westward. As in the quest for a Northeast Passage, interest turned from the search for a route leading to the riches of the East to the exploitation of local resources. Englishmen of the Hudson's Bay Company, founded in 1670 to trade in furs, explored the wide hinterlands of the St. Lawrence estuary and Hudson Bay. Further search for the passage itself did not take place until the 19th century: expeditions led by Sir William Parry (1819–25) and Sir John Franklin (1819–45), as well as more than 40 expeditions sent out to search for Franklin and his party, failed to find the passage. It was left to the Norwegian explorer Roald Amundsen to be the first to sail through the passage, which he did in 1903–05.

EASTWARD VOYAGES TO THE PACIFIC

The discovery of Australia

By the end of the 16th century, Portugal in the East held only the ports of Goa and Diu, in India, and Macau, in China. The English dominated the trade of India, and the Dutch that of the East Indies. It was the Dutch, trading on the fringes of the known world, who were the explorers. Victualling their ships at the Cape, they soon learned that, by sailing east for some 3,000 miles (5,000 kilometres) before turning north, they would encounter favourable winds in setting a course toward the Spice Islands (now the Moluccas). Before long, reports were received of landfalls made on an unknown coast; as early as 1618, a Dutch skipper suggested that "this land is a fit point to be made by ships . . . *in order* to get a fixed course for Java." Thereafter, the west coast of Australia was gradually charted: it was identified by some as the coast of the great southern continent shown on Mercator's map and, by others, as the continent of Loach or Beach mentioned by Marco Polo, interpreted as lying to the south of Malacca (Melaka); Polo, however, was probably describing the Malay Peninsula.

In 1642, a farsighted governor general of the Dutch East India Company, Anthony van Diemen, sent out the Dutch navigator Abel Tasman for the immediate purpose of making an exploratory voyage, but with the ultimate aim of developing trade. Sailing first south then east from Mauritius, Tasman landed on the coast of Tasmania, after which he coasted round the island to the south and, sailing east, discovered the South Island of New Zealand; "we trust that this is the mainland coast of the unknown South land," he wrote. He sailed north without finding Cook Strait, and, making a sweeping arc on his voyage back to the Dutch port of Batavia (now Jakarta, Indonesia), he discovered the Tonga and the Fiji Islands. In 1644, on a second voyage, he traced the north coast of Australia from Cape York (which he thought to be a part of New Guinea) to the North West Cape.

WESTWARD VOYAGES TO THE PACIFIC

The earlier European explorers in the Pacific were primarily in search of trade or booty; the later ones were primarily in search of information.

The traders, for the most part Spaniards, established land portages from harbours on the Caribbean to harbours on the west coast of Central and South America; from the Pacific coast ports of the Americas, they then set a course westward to the Philippines. Many of their ships crossed and recrossed the Pacific without making a landfall; many islands were found, named, and lost, only to be found again without recognition, renamed, and perhaps lost yet again. In the days before longitude could be accurately fixed, such uncertainty was not surprising.

Some voyages—for example, those of Álvaro de Mendaña de Neira, the Spanish explorer, in 1567 and 1568; Mendaña and the Portuguese navigator Pedro Fernández de Quirós in 1595; Quirós and another Portuguese explorer, Luis de Torres, in 1606—had, among other motives, the purpose of finding the great southern continent. Quirós was sure that in Espíritu Santo in the New Hebrides he had found his goal; he "took possession of the site on which is to be founded the New Jerusalem." Torres sailed from there to New Guinea and thence to Manila, in the Philippines. In doing so, he coasted the south shore of New Guinea, sailing through Torres Strait, unaware that another continent lay on his left hand.

The English were rivals of the Spaniards in the search for wealth in unknown lands in the Pacific. Two English seamen, Sir Francis Drake and Thomas Cavendish, circumnavigated the world from west to east in 1577 to 1580 and 1586 to 1588, respectively. One of Drake's avowed objects was the search for Terra Australis. Once he was through Magellan's straits, however, strong winds made him turn north—perhaps not reluctantly. He then sailed along the coast of Peru, surprising and plundering Spanish ships laden with gold, silver, precious stones, and pearls. His fortune made, Drake continued northward perhaps in search of the Northwest Passage. He explored the west coast of North America to 48° N. He returned south to winter in New Albion (California); the next summer he sailed on the Spanish route to Manila, then returned home by the Cape.

Despite the fact that he participated in several buccaneering voyages, the English seaman William Dampier, who was active in the late 17th and early 18th centuries, may be regarded as the first to travel mainly to satisfy scientific curiosity. He wrote: "I was well satisfied enough knowing that, the further we went, the more knowledge and experience I should get, which was the main thing I regarded." His book *A New Voyage Round the World,* published in 1697, further popularized the idea of a great southern continent.

In the late 18th century, the final phase of Pacific exploration occurred. The French sent the explorer Louis-Antoine de Bougainville to the Pacific in 1768. He appears to have been more of a skeptic than many of his contemporaries, for, while he agreed "that it is difficult to conceive such a number of low islands and almost drowned lands without a continent near them," at the same time he maintained that "if any considerable land existed hereabouts we could not fail meeting with it." The British, for their part, commissioned John Byron in 1764 and Samuel Wallis and Phillip Carteret in 1766 "to discover unknown lands and to explore the coast of New Albion." For all the navigational skill and personal endurance shown by captains and crews, the rewards of these voyages in increasing geographical knowledge were not great. The courses sailed were in the familiar waters of the southern tropics; none was through the dangerous waters of higher latitudes.

Cook's voyages in the Pacific

Capt. James Cook, the English navigator, in three magnificent voyages at long last succeeded in demolishing the fables about Pacific geography. He was given command of an expedition to observe the transit of the planet Venus at Tahiti on June 3, 1769; with the observation completed, he carried out his instructions to search the area between 40° and 35° S "until you discover it [Terra Australis] or fall in with the eastern side of the land discovered by Tasman and now called New Zealand." He reached New Zealand, circumnavigated both islands, sailed westward, and on April 19, 1770, made landfall on the eastern coast of Australia. He then turned northward, charting carefully, being well aware of the dangers of the Great Barrier Reef. At Cape York, Cook took possession of the whole eastern coast, to which he gave the name New South Wales. He sailed through Torres Strait, recognizing as he did so that New Guinea was an island. When Cook sailed back to England by Batavia and the Cape, the coastline of the fifth continent was almost complete; only in the south did it still remain unknown. In 1798 to 1799, two British navigators, George Bass and Matthew Flinders, circumnavigated Tasmania, and in 1801–03 Flinders charted the coast of the Great Australian Bight and circumnavigated the continent, thereby proving that there was no strait from the bight to the Gulf of Carpentaria.

In a second voyage, from 1772 to 1775, which in many ways was the greatest of the three, Cook searched systematically for the elusive continent that many still believed might exist. The first summer he examined the area to the south of the Indian Ocean; in the second, he searched the ocean between New Zealand and Cape Horn; and, in the third, the ocean between Cape Horn and the Cape of Good Hope. He sailed home convinced that the great South Pacific continent of the map makers was a fable.

With the exploration of the Pacific completed, interest in a Northwest Passage revived. In 1778 Cook proceeded to latitude 65° N, but he found no way through the ice barrier either to east or to west. He then sailed south to Hawaii, where he was killed in a dispute with the islanders.

Terra Australis Incognita had disappeared: there was now no unknown landmass in the southern oceans. It was Matthew Flinders who suggested that the fifth continent should be named Australia—a name that had long associations with the South Seas and that accorded well with the names of the other continents.

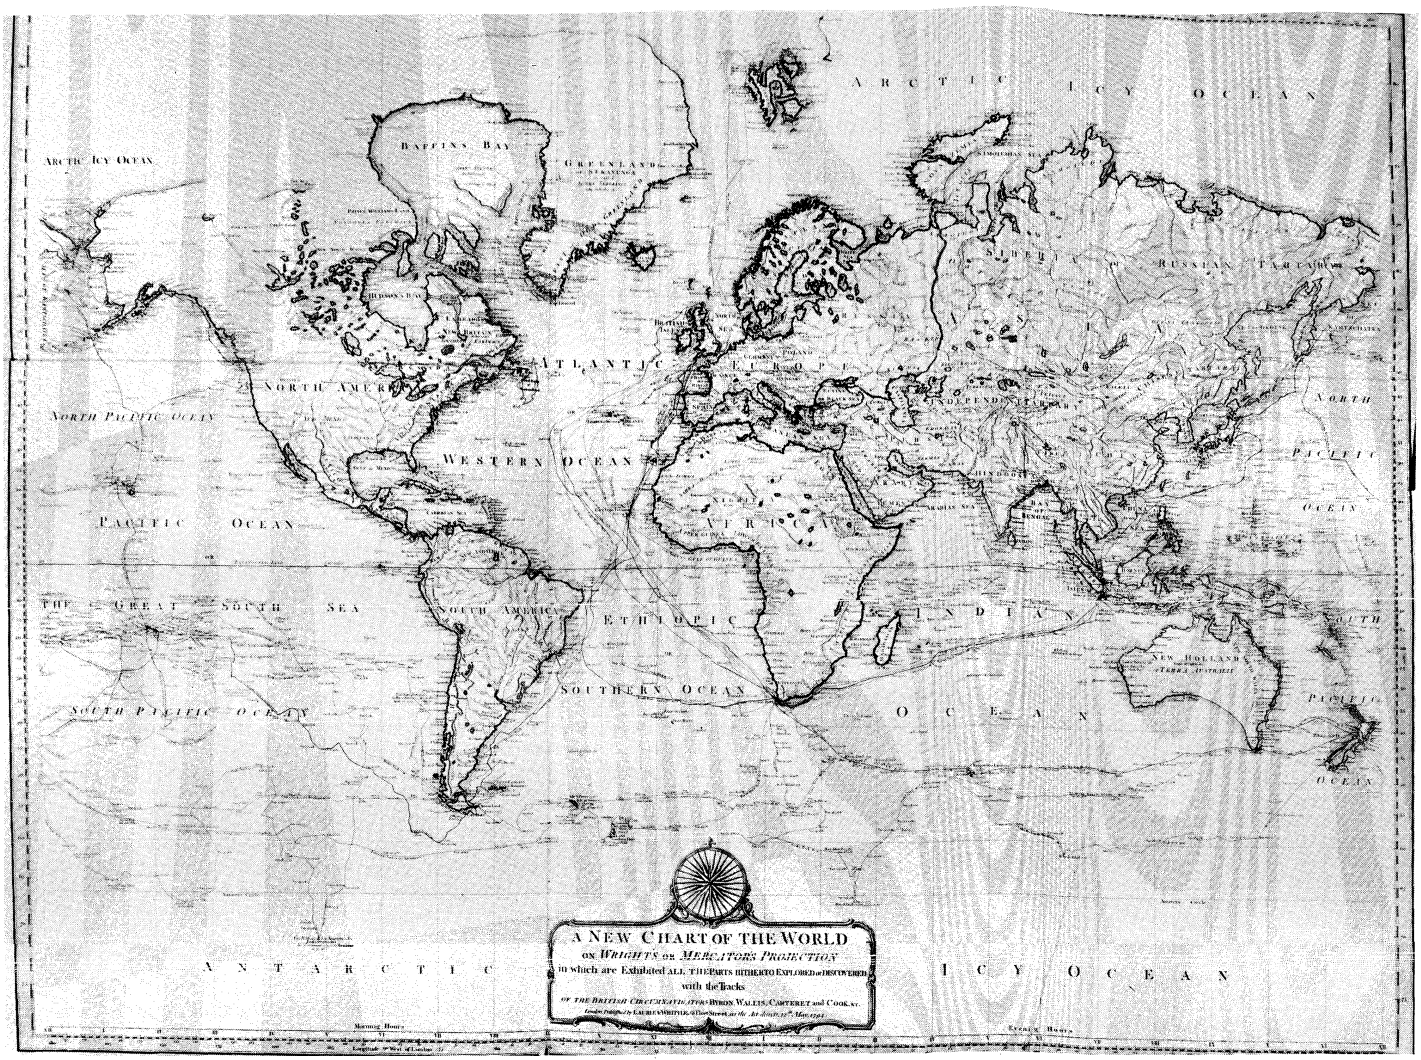
THE CONTINENTAL INTERIORS

At the opening of the 19th century, the major features of Europe, Asia, and North and South America were known; in Africa some classical misconceptions still persisted; inland Australia was still almost blank; and Antarctica was not on the map at all.

Africa. The river systems were the key to African geography. The existence of a great river in the interior of West Africa was known to the Greeks, but in which direction it flowed and whether it found an outlet in the Sénégal, the Gambia, the Congo, or even the Nile were in dispute. A young Scottish surgeon, Mungo Park, was asked to explore it by the African Association of London. In 1796 Park, who had travelled inland from the Gambia, saw "the long sought for majestic Niger flowing slowly *eastwards.*" On a second expedition, attempting to follow its course to the mouth, he was drowned near Bussa, in what is now Nigeria. In 1830 an English explorer, Richard Lander, travelled from the Bight of Benin, on the West African coast, to Bussa, and he then navigated the river down to its mouth, which was revealed as being one of the delta distributaries that, because of the trade in palm oil, were known to traders as "the oil rivers" on the Gulf of Guinea.

Exploration of the Zambezi

The Zambezi, in south central Africa, was not known at all until, in the mid-19th century, the Scottish missionary-explorer David Livingstone crossed the Kalahari from the south, found Lake Ngami, and, hearing of populous areas farther north, came upon the river in midcourse. On a great exploratory journey from 1852 to 1856, the main purpose of which was to expose the slave trade, he first travelled upstream, crossed the watershed between the tributaries of the upper Zambezi and those of the lower Congo, and reached the west coast at Luanda, Angola. From there a year's march brought him back to his starting point near the falls that the Africans called "smoke does sound" but that Livingstone prosaically renamed the Victoria Falls; from here he followed the Zambezi downstream, reaching the east coast at Quelimane, in Portuguese East Africa (Mozambique). On his second journey, sent out by the British government to test the navigability of the lower Zambezi, he explored the Shire (Chire) and Rovuma rivers and reached Lake Nyasa. His last journey, from 1865 to 1871, was undertaken at the behest of the president of Britain's Royal Geographical Society (successor to the African Association) "to solve a question of intense geographical interest . . . namely the watershed or watersheds of southern Africa." On this journey Livingstone investigated the complex drainage system between Lake Nyasa and Lake Tanganyika and explored the headwaters of the Congo. He refused to return to England with the Welsh explorer Henry Morton Stanley, who was sent to his rescue in 1871, because he was still uncertain of the position of the watershed between the Nile and the Congo; he wondered if the Lualaba was perhaps a headstream of the



Thomas Kitchin's "New Chart of the World" (published by Laurie and Whittle, London, 1794), illustrating the state of geographical knowledge before the exploration of Antarctica and some of the continental interiors.

Nile. He struggled back to the maze of waterways around Lake Bangweulu and died there in 1873.

The source of the Nile

The whereabouts of the source of the Nile had intrigued men since the days of the pharaohs. A Scottish explorer, James Bruce, travelling in Ethiopia in 1770, visited the two fountains in Lake Tana, the source of the Blue Nile, first discovered by the Portuguese priest Paez in 1618. The English explorers Richard Burton and John Speke discovered Lake Tanganyika in 1857. Speke then travelled north alone and reached the southern creek of a lake, which he named Victoria Nyanza. Without exploring farther, he returned to England, sure that he had found the source of the Nile. He was right—but he had not seen the outlet, and Burton did not believe him. In 1862 Speke, travelling with the Scottish explorer James Grant, found the Ripon Falls, in Uganda (now submerged following the construction of a dam for Owen Falls hydroelectric station), and "saw without any doubt that Old Father Nile rises in Victoria Nyanza." Stanley completed the puzzle in 1875; he circumnavigated Victoria Nyanza, crossed to the Lualaba, followed that river to the Congo, and then followed the Congo to its mouth. The pattern made by the river systems of Africa was elucidated at last.

Australia. The interior of Australia also posed a problem: was its heart an inland sea or a desert? This question did not arouse anything approaching the same degree of public interest that was taken in the geography of Africa. Exploration was slow; the early settlers on the east coast found that the valleys led to impassable walls at the valley heads. In 1813 the Australian explorer Gregory Blaxland successfully crossed the Blue Mountains by following a ridge instead of taking a valley route. Rivers were found beyond the mountains, but they did not behave as expected. Another explorer, the Australian John Oxley, in 1818 observed: "on every hill a spring, in every valley a rivulet, but the river itself disappears." He guessed that the great fan of rivers that drained the western slopes of the Great Dividing Range of eastern Australia fell into an inland sea. The Australian Charles Sturt resolved the problem by an imaginative journey made in 1829–30. He embarked on the Murrumbidgee River and was "hurried into a great and noble river [the Murray]." A week later he encountered another big river flowing into the Murray from the north, that he rightly concluded was the Darling, the middle course of which he had explored the year before. The voyage ended when he discovered that the Murray drained into Encounter Bay on the south coast. The heart of Australia was not an inland sea but a vast desert. Many more expeditions were needed to map the continent's major features, but two revealed its great extent. In 1840–41 the Australian Edward John Eyre travelled along the south coast from Adelaide to Albany, a distance of more than 1,300 miles (2,100 kilometres); the Australians Robert Burke and William John Wills travelled from Melbourne in the southeast to the Gulf of Carpentaria in the north.

Polar regions. The exploration of the polar regions was the work of the first half of the 20th century. Scientific curiosity mainly inspired the various enterprises, although political rivalry also played some part.

In the North Polar regions, the scientific age began with the voyaging of William Scoresby, an English whaler and scientist, who in 1806 reached 81°21′N. In 1828 an English explorer, Sir William Parry, travelling over drift ice from Svalbard, reached 82° N. The Norwegian explorer Fridtjof Nansen in 1893 attempted to reach the Pole by allowing his ship, the "Fram," to be frozen into the ice in the East Siberian Sea in the hope that a current would carry it over the Pole to east Greenland. At 84° N 102° E, Nansen with a companion left the ship and travelled by sled to 86°13′ N: the ship eventually emerged from the pack ice north of Svalbard. In 1909 an American explorer, Robert Peary, reached the North Pole by journeying by sled with 50 Eskimos from Ellesmere Island, northwest of Greenland. Soundings of 9,000 feet (2,700 metres) were made within five miles (eight kilometres) of the Pole; it seemed, therefore, that there could be no continent here. In 1958 the U.S. submarines "Skate" and "Nautilus" travelled across the Arctic Ocean under the ice cap.

Antarctica

The great southern continent, which Captain Cook demonstrated could not lie in the South Pacific, lay there neglected for some 50 years. From 1839 to 1843, the British rear admiral James Ross, in command of the ships "Erebus" and "Terror," explored the coast of Victoria Land. In 1894 Leonard Christensen, captain of a Norwegian whaler, landed a party at Cape Adare, the first to set foot on Antarctica. In the first decade of the 20th century, various explorers, including Britons such as William Bruce, Robert Falcon Scott, and Sir Ernest Henry Shackleton, the German Erich von Drygalski, and the Frenchman Jean-Baptiste Charcot, confirmed the existence of an ice cap of continental dimensions. In 1908–09 Shackleton led a brilliant expedition, during which he examined the Great Barrier, climbed to 11,000 feet (3,400 metres), and reached 88°23′ S. Scott and his party reached the Pole on January 17, 1912, only to find that the Norwegian explorer Roald Amundsen had already been there on December 14, 1911; Scott's party, caught in a blizzard, died on their return journey. In 1928 Sir Hubert Wilkins, the British explorer and aviator, flew over Grahamland, using Deception Island as a base. In 1957 and 1958 the British explorer Vivian Fuchs and Sir Edmund Hillary, the New Zealand mountaineer, travelled across the continent.

(J.B.Mi.)

EUROPEAN COLONIZATION

The age of modern colonialism began about 1500, following the European discoveries of a sea route around Africa's southern coast (1488) and of America (1492). With these events sea power shifted from the Mediterranean to the Atlantic and to the emerging nation-states of Portugal, Spain, the Dutch Republic, France, and England. By discovery, conquest, and settlement, these nations expanded and colonized throughout the world, spreading European institutions and culture.

European expansion before 1763

ANTECEDENTS OF EUROPEAN EXPANSION

Early communications with the Near East

Medieval Europe was largely self-contained until the First Crusade (1096–99), which opened new political and commercial communications with the Muslim Near East. Although Christian crusading states founded in Palestine and Syria proved ephemeral, commercial relations continued, and the European end of this trade fell largely into the hands of Italian cities.

Early European trade with Asia. The Oriental land and sea routes terminated at ports in the Crimea, until 1461 at Trebizond (now Trabzon, Turkey), Constantinople (now Istanbul), Asiatic Tripoli (in modern Lebanon), Antioch (in modern Turkey), Beirut (in modern Lebanon), and Alexandria (Egypt), where Italian galleys exchanged European for Eastern products.

Competition between Mediterranean nations for control of Asiatic commerce gradually narrowed to a contest between Venice and Genoa, with the former winning when it severely defeated its rival city in 1380; thereafter, in partnership with Egypt, Venice principally dominated the Oriental trade coming via the Indian Ocean and Red Sea to Alexandria.

Overland routes were not wholly closed, but the conquests of the central Asian warrior Timur (Tamerlane)—whose empire broke into warring fragments after his death in 1405—and the advantages of a nearly continuous sea voyage from the Middle and Far East to the Mediterranean gave Venice a virtual monopoly of some Oriental products, principally spices. The word spices then had a loose application and extended to many Oriental luxuries, but the most valuable European imports were pepper, nutmeg, cloves, and cinnamon.

The Venetians distributed these expensive condiments throughout the Mediterranean region and northern Europe; they were shipped to the latter first by pack trains up the Rhône Valley and, after 1314, by Flanders' galleys to the Low Countries, western Germany, France, and England. The fall of Constantinople to the Ottoman Turks in 1453 did not seriously affect Venetian control. Although other Europeans resented this dominance of the trade, even the Portuguese discovery and exploitation of the Cape of Good Hope route could not altogether break it.

Early Renaissance Europe was short of cash money, though it had substantial banks in northern Italy and southern Germany. Florence possessed aggregations of capital, and its Bardi bank in the 14th century and the Medici successor in the 15th financed much of the eastern Mediterranean trade.

Later, during the great discoveries, the Augsburg houses of Fugger and Welser furnished capital for voyages and New World enterprises.

Gold came from Central Africa by Saharan caravan from Upper Volta (Burkina Faso) near the Niger, and interested persons in Portugal knew something of this. When Prince Henry the Navigator undertook sponsorship of Portuguese discovery voyages down the west coast of Africa, a principal motive was to find the mouth of a river to be ascended to these mines.

Technological improvements. Europe had made some progress in discovery before the main age of exploration. The discoveries of the Madeira Islands and the Azores in the 14th century by Genoese seamen could not be followed up immediately, however, because they had been made in galleys built for the Mediterranean and ill suited to ocean travel; the numerous rowers that they required and their lack of substantial holds left only limited room for provisions and cargo. In the early 15th century all-sails vessels, the caravels, largely superseded galleys for Atlantic travel; these were light ships, having usually two but sometimes three masts, ordinarily equipped with lateen sails but occasionally square-rigged. When longer voyages began, the *nao,* or carrack, proved better than the caravel; it had three masts and square rigging and was a rounder, heavier ship, more fitted to cope with ocean winds.

Navigational instruments were improved. The compass, probably imported in primitive form from the Orient, was gradually developed until, by the 15th century, European pilots were using an iron pin that pivoted in a round box. They realized that it did not point to the true north, and no one at that time knew of the magnetic pole, but they learned approximately how to correct the readings. The astrolabe, used for determining latitude by the altitude of stars, had been known since Roman times, but its employment by seafarers was rare, even as late as 1300; it became more common during the next 50 years, though most pilots probably did not possess it and often did not need it because most voyages took place in the narrow waters of the Mediterranean or Baltic or along western European coasts. For longitude, then and many years thereafter, dead reckoning had to be employed, but this could be reasonably accurate when done by experts.

The typical medieval map had been the planisphere, or

Medieval maps

mappemonde, which arranged the three known continents in circular form on a disk surface and illustrated a concept more theological than geographical. The earliest surviving specimens of the portolanic, or harbour-finding, charts date from shortly before 1300 and are of Pisan and Genoese origin. Portolanic maps aided voyagers by showing Mediterranean coastlines with remarkable accuracy, but they gave no attention to hinterlands. As Atlantic sailings increased, the coasts of western Europe and Africa south of the Strait of Gibraltar were shown somewhat correctly, though less so than for the Mediterranean.

THE FIRST EUROPEAN EMPIRES (16TH CENTURY)

Portuguese dominance of Eastern commerce

Portugal's seaborne empire. Following Christopher Columbus' first voyage, the rulers of Portugal and Spain, by the Treaty of Tordesillas (1494), partitioned the non-Christian world between them by an imaginary line in the Atlantic, 370 leagues (about 1,300 miles) west of the Cape Verde Islands. Portugal could claim and occupy everything to the east of the line and Spain everything to the west (though no one then knew where the demarcation would bisect the other side of the globe). Portuguese rule in India, the East Indies, and Brazil rested on this treaty, as well as on Portuguese discoveries and on papal sanction (Pope Leo X, by a bull of 1514, forbade others to interfere with Portugal's possessions). Except for such minor incursions as those of Ferdinand Magellan's surviving ship in 1522 and the Englishman Sir Francis Drake's voyage around the world in 1577–80, the Portuguese operated in the East for nearly a century without European competition. They faced occasional Oriental enemies but weathered these dangers with their superior ships, gunnery, and seamanship.

Territorially, theirs was scarcely an empire; it was a commercial operation based on possession of fortifications and posts strategically situated for trade. This policy was carried out principally by two viceroys, Francisco de Almeida in 1505–09 and Afonso de Albuquerque in 1509–15. Almeida seized several eastern African and Indian points and defeated a Muslim naval coalition off Diu (now in Goa, Daman, and Diu union territory, India). Albuquerque endeavoured to gain a monopoly of European spice trade for his country by sealing off all entrances and exits of the Indian Ocean competing with the Portuguese route around the Cape of Good Hope. In 1510 he took Goa, in western India, which became the capital and stronghold of the Portuguese East, and in 1511 he captured Malacca at the farther end of the ocean. Later he subdued Hormuz (now in Iran), commanding the Persian Gulf. They brought soldiers from the home country in limited numbers; but the Portuguese also relied on alliances with native states and enlisted sepoy troops, a policy later followed by the French and English.

Portugal never fully dominated the Indian Ocean because it lacked warships necessary to control the vast water expanse. Albuquerque's failure to capture Aden at the Red Sea entrance allowed the old traffic through Egypt to Venice to resume following an initial dislocation, and this continued after the Ottoman Turks conquered Egypt in 1517. Much of the Indian Ocean trade was local and, until the Portuguese incursion, had been conducted by Arabs or at least by Muslims. The Portuguese, who at first had intended to oust the Arabs entirely, found it impossible to manage without them. The Hindus, whom they hoped to use for local trade purposes, proved unenterprising and had caste restrictions regarding sea voyages. Muslims were soon trafficking again vigorously, with Portuguese sanction.

Portuguese subjects also pressed beyond the Strait of Malacca to the East Indies, Siam (now Thailand), and Canton in Ming-dynasty China. Trade with the celestial empire, difficult at first because of China's exclusionist policies, at length grew, especially after Portugal in 1557 leased Macau, through which for the next 300 years passed much of the Occidental trade with China. Individual Portuguese reached Japan in 1542, followed by traders and Francis Xavier (later made a saint), a renowned Jesuit missionary who laboured with small success to make converts. In the 17th century, the Japanese adopted a rigorous exclusionist policy, although they allowed Portugal's successors, the Dutch, to conduct a limited trade from the small island of Deshima, near Nagasaki.

Partial domination of the Indian Ocean and much of its valuable trade did not bring Portugal's crown as much profit as had been anticipated. The intention had been to make Oriental trade a royal monopoly; but Portuguese, from viceroys to humble soldiers and seamen, became private merchants and lined their own pockets to the deprivation of the royal treasury. The Eastern footholds were expensive to maintain, and frequent mishaps to vessels of the Indian fleets, from shipwreck or enemies, reduced gains. The lack of a true monopoly prevented the Portuguese from charging the prices that they wished in European markets. Moreover, Lisbon, while an ideal starting point for voyages around the Cape, proved poorly situated as a distribution centre for spice to northern and central Europe. Antwerp, on the Scheldt, was far superior, and for a time Portugal maintained a trading house there; but Portuguese agents found spice sales taken out of their hands by more experienced Italian, German, and Flemish merchants, and the Antwerp establishment was closed in 1549.

It has been asserted that the Portuguese had no racial prejudice, but their record proves the opposite. In the 16th and 17th centuries, they could not be expected to be tolerant of Oriental religions, although they soon recognized that wholesale conversion to Catholicism was impossible. Some Africans and Asiatics became Christians and even entered the clergy; but seldom if ever did they rise above the status of parish priests. In other affairs the Portuguese generally treated the dark-skinned peoples as inferiors.

The east coast of Brazil belonged to Portugal by the Tordesillas pact. The government of Manuel I and his successor, John III (ruled 1521–57), paid it small attention for 30 years. It proved nearly useless as a way station to the Cape; its Indian population was savage, and its products, consisting chiefly of *pau-brasil* (Brazilian dyewood), yielded much less revenue than those of India. Threats of French and Spanish intrusion caused John III, in 1530, to send Martim Afonso de Sousa to make a careful survey of the Brazilian coast and to suggest sites for colonization. Next, the littoral was partitioned into strips called *capitanias,* each colonized and governed under feudal terms by a proprietor, or *donatário.* Some limited settlement followed, and in 1549 the *capitanias* were united under a governor general who established residence at Bahia (now Salvador, Brazil).

Portuguese colonization of Brazil

In 1580 Philip II of Spain seized the Portuguese throne, which had fallen vacant and to which he had some blood claim. Portugal remained theoretically independent, bound only by a personal union to its neighbour; but succeeding Spanish monarchs steadily encroached on its liberties until the small kingdom became, in effect, a conquered province. Spain's European enemies meanwhile descended on the Portuguese Empire and ended its Eastern supremacy before the restoration of Portugal's independence in 1640.

Beginnings of the Spanish conquest in America

Spain's American empire. *The conquests.* Only gradually did the Spaniards realize the possibilities of America. They had completed the occupation of the larger West Indian islands by 1512, though they largely ignored the smaller ones, to their ultimate regret. Thus far they had found lands nearly empty of treasure, populated by naked primitives who died off rapidly on contact with Europeans. In 1508 an expedition did leave Hispaniola to colonize the mainland, and, after hardship and decimation, the remnant settled at Darién on the Isthmus of Panama, from which in 1513 Vasco Núñez de Balboa made his famous march to the Pacific. On the Isthmus the Spaniards heard garbled reports of the wealth and splendour of Inca Peru. Balboa was succeeded (and judicially murdered) by Pedrarias Dávila, who turned his attention to Central America and founded Nicaragua.

Expeditions sent by Diego Velázquez, governor of Cuba, made contact with the decayed Mayan civilization of Yucatán and brought news of the cities and precious metals of Aztec Mexico. Hernán Cortés entered Mexico from Cuba in 1519 and spent two years overthrowing the Aztec confederation, which dominated Mexico's civilized heart-

land. The Spaniards used firearms effectively but did most of their fighting with pikes and blades, aided by numerous Indian allies who hated the dominant Aztecs. The conquest of Aztec Mexico led directly to that of Guatemala and about half of Yucatán, whose geography and warlike inhabitants slowed Spanish progress.

Mexico yielded much gold and silver, and the conquerors imagined still greater wealth and wonders to the north. None of this existed, but it seemed real when a northern wanderer, Alvar Núñez Cabeza de Vaca, in 1536 brought to Mexico an exciting but fanciful report of the fabulous lands. Expeditions explored northern Mexico and the southern part of what is now the United States—notably the expedition of Juan Rodríguez Cabrillo by sea along what are now the California and Oregon coasts and the expeditions of Hernando de Soto and Francisco Vázquez Coronado through the southeastern and southwestern U.S. regions. These brought geographical knowledge but nothing of value to the Spaniards, who for years thereafter ignored the northern regions.

Meanwhile, the Pizarro brothers—Francisco Pizarro and his half-brothers Gonzalo and Hernando—entered the Inca Empire from Panama in 1531 and proceeded with its conquest. Finding the huge realm divided by a recent civil war over the throne, they captured and executed the incumbent usurper, Atahualpa. But the conquest took years to complete; the Pizarros had to crush a formidable native rising and to defeat their erstwhile associate, Diego de Almagro, who felt cheated of his fair share of the spoils. The Pizarros and their followers took and divided a great amount of gold and silver, with prospects of more from the mines of Peru and Bolivia. By-products of the Inca conquest were the seizure of northern Chile by Pedro de Valdivia and the descent of the entire Amazon by Francisco de Orellana. Other conquistadors entered the regions of what became Ecuador, Colombia, and Argentina. (See LATIN AMERICA, THE HISTORY OF.)

A colonial period of nearly three centuries followed the major Spanish conquests. The empire was created in a time of rising European absolutism, which flourished in both Spain and Spanish America and reached its height in the 18th century. The overseas colonies became and remained the king's private estate.

Spanish colonial policies. Shortly before the death of Queen Isabella I in 1504, the Spanish sovereigns created the House of Trade (Casa de Contratación) to regulate commerce between Spain and the New World. Their purpose was to make the trade monopolistic and thus pour the maximum amount of bullion into the royal treasury. This policy, seemingly successful at first, fell short later because Spain failed to provide necessary manufactured goods for its colonies, foreign competitors appeared, and smuggling grew.

In 1524 Charles V created the Council of the Indies (Consejo de Indias) as a lawmaking body for the colonies. During the three centuries of its existence, this council enacted a massive amount of legislation, though much grew obsolete and became a dead letter. The industrious Philip II died in 1598, and his indolent or incompetent successors left American affairs to the Casa and Consejo; both proved generally conscientious and hard-working bodies, though, for a time in the 17th century, appointments to the legislating council could be purchased.

The viceregal system

The viceregal system dated from 1535, when Antonio de Mendoza was sent to govern New Spain, or Mexico, bypassing the still-vigorous Cortés. A second viceroy was named for Peru in 1542, and the viceroyalties of New Granada and Río de la Plata were formed in 1739 and 1776, respectively. By the 18th century, viceroys served average terms of five years, and under them functioned a hierarchy of bureaucrats, nearly all sent from Spain to occupy frequently lucrative posts. American-born Spaniards resented this favouritism shown the peninsular Spaniards, and their jealousy accounted in part for their later separation from Spain. Lower socially and economically than either white class were the mestizo offspring of white and Indian matings, and still lower were the Indians and black slaves.

Though a belief to the contrary exists, Spain sent many colonists to America. One indication of this is the number of new cities founded, distinct from the old Indian culture centres. A partial list of such cities, besides the early island ones, includes Vera Cruz, New Spain; Panama, Cartagena, and Guayaquil, in New Granada (in modern Panama, Colombia, and Ecuador, respectively); Lima, Peru; and all those of what are now Chile, Paraguay, Argentina, and Uruguay.

A problem early faced and never truly solved by Spain was that of the Indians. The home government was generally benevolent in legislating for their welfare but could not altogether enforce its humane policies in distant America. The foremost controversy in early decades involved the *encomienda,* by which Indian groups were entrusted to Spanish proprietors, who in theory cared for them physically and spiritually in return for rights to tribute and labour but who in practice often abused and enslaved them.

Spanish Dominican friars were the first to condemn the *encomienda* and work for its abolition; the outstanding reformer was a missionary, Bartolomé de Las Casas, who devoted most of his long life to the Indian cause. He secured passage of laws in 1542 ordering the early abolition of the *encomienda,* but efforts to enforce these brought noncompliance in New Spain and armed rebellion in Peru. A belief held by some Spanish theologians—that Indians were inferior beings who were destined to be natural slaves, to be subdued and forcibly converted to Christianity—generally prevailed over the opposition of Las Casas and fellow Dominicans. The *encomienda* or its equivalent endured, although this feudal institution declined as royal absolutism grew.

Diminution of the Indians

The Indians became real or nominal Christians, but their numbers shrank, less from slaughter and exploitation than from Old World diseases, frequently smallpox, for which they had no inherited immunity. The aboriginal West Indian population virtually disappeared in a few generations, to be replaced by black slaves. Indian numbers shrank in all mainland areas: at the beginning of Spanish settlement there were perhaps 50,000,000 aborigines; the figure had decreased to an estimated 4,000,000 in the 17th century, after which it slowly rose again. Meanwhile the hybrid mestizo element grew and—to a limited extent—replaced the Indians.

The Leyenda Negra (Black Legend) propagated by critics of Spanish policy still contributes to the general belief that Spain exceeded other nations in cruelty to subject populations; on the other hand, a review of Spain's record suggests that it was no worse than other nations and, in fact, produced a greater number of humanitarian reformers. When Dominican zeal declined, the new and powerful Jesuit order became the major Indian protector and led in missionary activity until its expulsion from the Spanish Empire in 1767; the Jesuits took charge of large converted native communities, notably in the area of the viceroyalty of Río de la Plata that is now Paraguay, in their paternalism often imposing stern discipline.

Effects of the discoveries and empires. Before the discovery of America and the sea route to Asia, the Mediterranean had been the trading and naval centre of Europe and the Near East. Italian seamen were rightly considered to be the best, and they commanded the first royally sponsored transatlantic expeditions—Columbus for Spain, John Cabot for England, and Giovanni da Verrazano for France.

Europe's shift to the Atlantic. Until then the Western countries had lain on the fringe of civilization, with nothing apparently beyond them but Iceland and small islands. With the discovery of the Cape route and America, nations formerly peripheral found themselves central, with geographical forces impelling them to leadership.

The Mediterranean did not become a backwater, and the Venetian republic remained a major commercial power in the 16th century. Venice's decline came in the 17th, though the Venetians were still formidable against the Turks. As the more powerful Dutch, French, and English replaced the Eastern pioneers of Portugal, however, the burden of competition became more than the venerable republic could bear. The last decisive naval battle fought

wholly by Mediterranean seamen was Lepanto (Náupaktos, Greece), where Don John of Austria, in 1571, commanding Spanish and Italian galleys, defeated an Ottoman fleet. Although Atlantic powers thereafter often fought in the Mediterranean, they mainly fought each other, while the Italian cities became pawns in international politics. The nation-state was superseding the small principality and city-state, a trend that had begun before the discoveries. The new nations lay on the Atlantic; and, though Spain and France had Mediterranean frontages, the advantage went to those seaports belonging to substantial countries with ready access to the outer world.

Changes in Europe. The opening of old lands in Asia and new ones in America changed Europe forever, and the Iberian countries understandably felt the changes first. The Portuguese government, for a time, made large profits from its Eastern trade, and individuals prospered; but Oriental luxuries were costly compared with the European goods that Portugal offered, and the balance had to be made up in specie. This eastward drain of gold and silver had gone on long before Portuguese imperial times, but it was now intensified. Much of the bullion reaching the Orient did not circulate but was hoarded or made into ornaments; consequently, there was no inflation in Asia, and prices there did not rise enough to create a demand for Western goods, which would have reversed the flow of bullion from the West. The Portuguese obtained most of the precious metal for this trade from spice sales through Antwerp and from Africa. The drain proved critical, and, by the reign of John III, the government found itself hard pressed economically and forced to abandon overseas posts that were a financial burden. Later, beginning in the 17th century, Portugal drew its own supply of jewels and gold from Brazil.

Eastward drain of Portuguese gold and silver

Spain's case was the reverse; although the first American lands discovered yielded little mineral wealth, the mines of Mexico by the 1520s and those of Potosí (in modern Bolivia) by the 1540s were shipping to Spain large quantities of bullion, much of it crown revenue. This did not furnish Charles V and Philip II their largest income; Spanish taxation still exceeded wealth from the New World, yet American silver and gold proved sufficient to cause a price revolution in Spain, where costs, depending on the region, were multiplied by three and five during the 16th century. The Spanish government wished to keep bullion from leaving the kingdom, but high prices in Spain made it a good market for outside products. Spanish industry declined in the 16th century, in part because of the sales taxes imposed by the crown, which necessitated more buying of foreign merchandise. Great quantities of bullion had to be poured out to finance the expensive Spanish European empire and the costly wars and diplomacy of Charles V and Philip II, both of whom were constantly in debt.

Price rises followed in other countries, largely from the influx of Spanish bullion. In England, where some statistics are available, costs by 1650 had risen by 250 percent over those of 1500.

The European commercial revolution, which brought increased industry, more trade, and larger banks, had begun before the discoveries, but it received stimulus from them. Bullion from America helped create a money economy, replacing the older and largely barter exchange—a trend accentuated by greater European mineral production in the early 16th century. The trade emporiums of Italy and the Baltic Hanseatic League declined and were largely replaced by those of the Dutch Republic, England, and France. Joint-stock companies made an impressive appearance, notably the East India Companies of the Dutch Republic, England, and France in the 17th century. The mercantile theory that precious metals constitute the true wealth, though it had attracted advocates for a long time, now came into full vogue and continued to dominate economic thinking.

New products for Europe

Discovery introduced Europe to new foods and beverages. Coffee, from Ethiopia, had been consumed in Arabia and Egypt before its wide European use began in the 17th century. Tobacco, an American plant smoked by Indians, won an Old World market despite many individual objectors; the same proved true of chocolate from Mexico and tea from Asia. The South American potato became a staple food in such places as Ireland and central Europe. Cotton, from the Old World, took firm root in the New, from which Europe received an enormously increased supply. Sugar, introduced to the American tropics, along with its molasses and rum derivatives, in time became the principal exports of those regions. Spice was certainly more plentiful than before the discoveries, though the Dutch, when they controlled the East Indies, were able to limit production and thus to keep the price of cloves and nutmegs high.

The influence of the discoveries permeated literature. Sir Thomas More's *Utopia,* printed in 1516 and dealing with an imaginary island, was suggested by South America. The Portuguese poet Luís de Camões recounted the voyage of Vasco da Gama, though fancifully, in epic verse. Michel de Montaigne discoursed upon American savages, some of whom he had seen in France. Christopher Marlowe's drama *Tamburlaine* (1587), though based on the life of the Asiatic conqueror, was an exhortation to his fellow Englishmen to penetrate the New World.

Historiography acquired a broader base by taking the newly discovered lands into account. Astronomy was revolutionized by European penetration of the Southern Hemisphere and discovery of constellations unknown before. Map makers, typified by the Fleming Gerardus Mercator and the Dutchman Abraham Ortelius, portrayed the world in terms that are still recognizable.

COLONIES FROM NORTHERN EUROPE AND MERCANTILISM (17TH CENTURY)

The northern Atlantic powers, for understandable reasons, acquired no permanent overseas possessions before 1600. The United Provinces of the Netherlands spent the final decades of the 16th century winning independence from Spain; France had constant European involvements and wars of religion; England, matrimonially allied with Spain as late as 1558, was undergoing its Protestant Reformation and long was unwilling to challenge predominant Spain openly in any manner.

The Dutch. Although England's defeat of Philip II's Armada in 1588 helped to lessen Spanish sea power, it was the Dutch who early in the next century really broke that power and became the world's foremost naval and commercial nation, with science and skills commensurate with their prowess. Only late in the 17th century did they decline, because of Holland's limited size and the inferiority of its geographical position to England's. The Dutch, meanwhile, penetrated all the known oceans, including the Arctic, and waged unrelenting war against the Iberian kingdoms.

The Dutch coveted the Portuguese commercial empire more than the Spanish continental one. They took much of the Portuguese East and invaded Brazil (1624–54), the richer half of which they controlled for a time. They also penetrated Portuguese Angola, which they desired because the slaves it exported were beginning to work the Brazilian plantations. They ultimately failed in the South Atlantic, though they gained Dutch Guiana (now Suriname), Curaçao, and what later became British Guiana (Guyana). Meanwhile, Willem Schouten, one of their free-lance voyagers, had made the discovery of Cape Horn in 1616.

Eastern pursuits. The Dutch States-General, in 1602, chartered the United East India Company (Vereenigde Oost-Indische Compagnie, popularly called the Dutch East India Company), a joint-stock enterprise with investment open to all. In control was a board of 17 directors, the so-called Heeren XVII, who received a monopoly of navigational rights eastward around the Cape of Good Hope and westward through the Strait of Magellan. They could make treaties with native princes on behalf of the States-General (from which they were scarcely separable), establish garrisoned forts, and appoint governors and justices. The company had no interest in extending Protestantism, and there was no mention of religious conversion, though Calvinist ministers later gained converts in the East, mostly in communities previously made Catholic by Portuguese Jesuits.

Formation of the United East India Company

The company established headquarters first at Bantam in Java in 1607, later moving them to Jacatra, renamed Batavia (now Jakarta), in the same island. Its two main objectives were the ouster of European competitors—Portuguese, English, and Spanish—and dominance of local trade, previously in native hands. Portuguese vigour had somewhat declined, and the Dutch were victorious in most armed encounters. They also squeezed out the English, whose own East India Company thereafter concentrated efforts in the Indian peninsula.

The principal builder of the Dutch Oriental empire was Jan Pieterszoon Coen, company governor general from 1618 to 1623 and again from 1627 until his death in 1629. Financially, local trade monopoly was even more important than the expulsion of white competitors. The extension of Dutch control to islands beyond Java had started before the governorship of Coen, who accentuated the process. He and other company officials behaved ruthlessly; for example, when the inhabitants of the nutmeg-growing island of Great Banda (modern Pulau Banda Besar in Indonesia) resisted the Dutch in 1621, Coen had 2,500 of the inhabitants massacred and 800 more transported to Batavia. Company policy was to restrict clove production to Amboina and a few neighbouring islands firmly under Dutch control. To insure this, about 65,000 clove trees were destroyed in the Moluccas, and Dutch subjection of Macassar made the monopoly virtually complete. In 1656 the famous Moluccas were described as a wilderness. Besides being a conqueror, Coen was an able businessman and an economist. When he died he was engaged in gaining a monopoly of the pepper of interior Sumatra, which was later sealed off securely by the fall of Portuguese Malacca in 1641.

Batavia as the focal point of the Dutch East

Batavia became the focal point of the Dutch East, and through it passed the commerce of China, Japan, India, Ceylon, and Persia, bound for Europe or other Oriental ports. The Dutch never monopolized the China trade because the Portuguese held Macau, the Spaniards held Manila, and the Japanese, for a time, engaged in this commerce. The Dutch gained a foothold in Formosa in 1624 but lost it to a Chinese pirate in 1662. After Japan became exclusionist in 1641, a trickle of Dutch trade continued to enter it through the small island of Deshima (now part of Nagasaki, Japan), even after the dissolution of the United East India Company in 1799.

The economy of Java changed somewhat after the importation of the coffee plant in 1696. Coffee, often simply called java, rapidly became a major island crop and was exported from there to Dutch America. The company had earlier brought coffee to Ceylon (now Sri Lanka), but that experiment had failed when a blight attacked its leaves. The company ousted the Portuguese from Ceylon and dominated the island until it was itself dispossessed by the British in 1796. Under its jurisdiction, as earlier, the major Ceylonese export was cinnamon, though the Dutch also dealt in jewels and pepper and carried on a trade in elephants.

In their constant search for commercial outlets, the company's officials sponsored new exploration. Coen's ablest successor, Antonio van Diemen, governor general in 1636–45, sent Abel Tasman to investigate the great land (Australia) previously sighted by Spanish, Portuguese, and Dutch seamen. Tasman sailed around the continent and discovered Van Diemen's Land (Tasmania), Staatenland (New Zealand), and the Tonga and Fiji Islands, but their commercial possibilities seemed insufficient to warrant further attention.

Dutch penetration of the East was not colonization; small farmers and artisans neither could nor would compete with the abundant, cheap native labour. Those Dutchmen going eastward were company officials, seamen and soldiers, overseers of plantations and commerce, and a few scientists and Calvinist clergymen; there was no place for others.

The Dutch moved into uninhabited Mauritius, which they later abandoned and saw pass first to France and finally to Great Britain. The Heeren XVII felt the need of a station on the arduous voyage between the home country and the East. They obtained it at Cape Town (founded in 1652 by Jan van Riebeeck), which company ships thereafter regularly visited for fresh meat and vegetables to reduce scurvy. The town did not altogether live up to first expectations because the harbour was exposed, but the hinterland possessed a good climate and no dangerous natives. Beginning in the 1680s the company encouraged a moderate influx by Dutch families and French Huguenot exiles. Although the British conquered the colony in 1806, the descendants of these early settlers remained the largest white element and spoke a variant of Dutch, which became Afrikaans.

Western pursuits. Dutch activity in the South Atlantic, Guyana, the West Indies, and New Netherland (New York) was the work of the West India Company (West-Indische Compagnie), founded in 1621. This never proved as successful as the Heeren XVII's generally profitable enterprise, but it did produce results. Except for the Cape, the only real Dutch colonization undertaking was New Netherland in North America, started in 1624 by the West India Company. Ft. Amsterdam, or New Amsterdam, was founded, and two years later the company agent Peter Minuit made a 60-guilder ($24) transaction with the local Indians for the purchase of Manhattan island. Dutch settlement along the Hudson from New Amsterdam to Ft. Orange (Albany) remained sparse; the company's insistence on monopolizing the Indian fur trade discouraged Dutchmen from migrating there. Further, the policy of creating large patroon land grants, five in all, along the river under feudal proprietors, limited settlement. New Amsterdam itself became fairly thriving because it possessed the best harbour in North America. Many besides Dutchmen settled there; some came from nearby New England, and there was a sprinkling of French, Scandinavian, Irish, German, and Jewish inhabitants. The city was weakly defended and fell rather easily to an English fleet in 1664; it was renamed New York. Although the Dutch retook it briefly in 1673–74, the colony became permanently English by the Treaty of Westminster in 1674. The West India Company was then dissolved, to be reconstituted for exploitation of the Caribbean holdings but to attempt no further territorial expansion.

Founding of the Dutch West India Company

The French. France probably could have become the leading European colonial power in the 17th and 18th centuries. It had the largest population and wealth, the best army while Louis XIV ruled, and, for a time in his reign, the strongest navy. But France pursued a spasmodic overseas policy because of an intense preoccupation with European affairs; England, France's ultimately successful rival, was freer of such entanglements.

Early settlements in the New World. Verrazano reconnoitered the North American coast for France in 1524, and in the next decade Jacques Cartier explored the St. Lawrence River; his plans to establish a colony, however, came to nothing. During most of the rest of the 16th century, French colonization efforts were confined to short-lived settlements at Guanabara Bay (Rio de Janeiro) and Florida; both met sad ends. France meanwhile was troubled by internal religious strife and, for a time, was influenced by Philip II of Spain. But at the beginning of the 17th century, with Spanish power declining and domestic religious peace restored by King Henry IV's Edict of Nantes (1598), granting religious liberty to the Huguenots, the King chartered a Compagnie d'Occident (Western Company). This led to further exploration and to a small Acadian (Nova Scotian) settlement, and in 1603 Samuel de Champlain went to Canada, called New France. Champlain became Canada's outstanding leader, founding Quebec in 1608, defeating the Iroquois of New York, stimulating fur trade, and exploring westward to Lake Huron in 1615. He introduced Recollet (Franciscan) friars for conversion of the American Indians, but the Jesuit order (the Society of Jesus) soon became the principal missionary body in Canada.

Under the ministership of Cardinal Richelieu (served 1624–42), a Council of Marine was created, with responsibility for colonial affairs. French West Indian settlement, following the activities of pirates and filibusters, began in 1625 with the admission of French settlers to St. Christopher (already settled by the British in 1623 and partitioned

French West Indian settlement

between the two countries until its cession to the British in 1713), and by 1664 France held 14 Antillean islands containing 7,000 whites, the principal possessions being Guadeloupe and Martinique. Saint-Domingue (Haiti), not yet annexed, contained numbers of Frenchmen, mostly buccaneers from Tortuga. Sugar became the main crop of the islands; the date when importation of black slaves began is uncertain, though some were sold at Guadeloupe as early as 1642.

French West Indian society was caste bound, with officials and large planters (*gros blancs*) at the top, followed, in descending order, by merchants, buccaneers, and small farmers (*petits blancs*). Lowest of all were contract labourers from France (*engagés*) and black slaves.

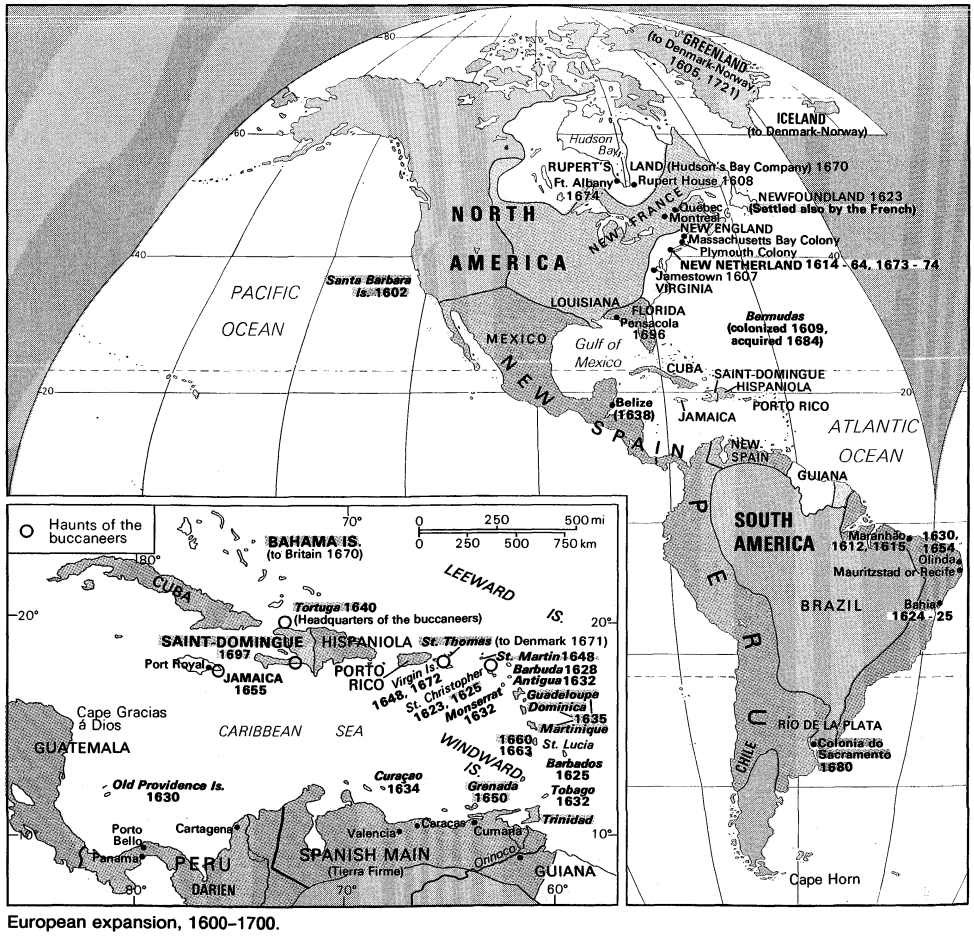
French Guiana was built around the Cayenne settlement, founded about 1637. There were other Frenchmen along the neighbouring coast at first, but, threatened by Dutchmen and natives, they finally took refuge at Cayenne. The Cayenne settlers, lacking any basis of prosperity, existed partly by raiding the Amazon Indians. The 18th century brought some improvement, but as late as 1743 French Guiana had only 600 whites, living by coffee and cacao culture and without means to import any but the crudest necessities.

Activities in India. Jean-Baptiste Colbert held a succession of high offices in France, including the ministry of marine, during the early reign of Louis XIV. Colbert was an archmercantilist and believed that an abundance of precious metals would enrich France. This required a favourable balance of trade and protective tariffs. Most of his policy applied to France itself, but he meant to supplement it with colonial markets protected by a strong navy. Colbert felt concern over the quantities of cash that Frenchmen paid the Dutch for Eastern products and intended for his countrymen to have a share of those profits. In 1664 he placed hopes in a new French Company of the East Indies (Compagnie Française des Indes Orientales), to which he personally subscribed and which bought out small predecessors. The company tried unsuccessfully to make Madagascar a great centre of trade, and the huge island became a stronghold of piracy, though the French acquired nearby Mauritius.

In the Indian peninsula, where the English East India Company had holdings, French progress was slow in Colbert's time and after, partly because the last great Mughal emperor, Aurangzeb, reigned and dominated India. The company did acquire Pondichéry and several other posts, however, and an affiliate opened a limited trade with China. When Aurangzeb died in 1707, his empire declined rapidly. Thereafter, the question of future control of India lay chiefly between the French company (reorganized and renamed the Compagnie Française des Indes in 1720) and the English company; both companies backed or opposed warring native rulers and exacted payment from them for financial support and for arming and drilling the native sepoy troops in the European manner. By the 1740s the French had gained the upper hand, and in the War of the Austrian Succession (1740–48; called King George's War in North America), the French governor general of India, Joseph-François Dupleix, captured Madras, the centre of British power. But in the ensuing Treaty of Aix-la-Chapelle the British, who had made gains in North America, recovered Madras. Never again did the French come so near success, and their fortunes soon declined. Their company had not made large profits because expensive wars and the costs of subsidizing native princes had consumed revenue. The home government seldom cooperated, and French investors on the whole declined to speculate in overseas ventures.

French and English rivalry

Colonization of New France. New France became a royal province in 1663, with both good and bad results. The arrival of troops in 1665 lessened the danger from the hostile Iroquois. Jean Talon, the powerful intendant sent by Colbert in the same year, strove to make Canada a self-sustaining economic structure, but his plan was finally thwarted by his home government's failure to supply fi-



European expansion, 1600–1700.

nancial means chiefly because of the King's extravagance and costly European wars.

Colbert gave some stimulus to colonization of New France. Grants of land, called *seigneuries,* with frontages on the St. Lawrence, were apportioned to proprietors, who then allotted holdings to small farmers, or habitants. More land came under cultivation, and the white population grew, though immigration from France declined sharply after 1681 because the home authorities were reluctant to spare manpower for empty Canada. After 1700 most French Canadians were North American born, a factor that weakened loyalty to the mother country.

North American exploration proceeded rapidly in Colbert's time. Fur traders had earlier reached Lake Superior; Louis Jolliet and Jacques Marquette now travelled the Fox and Wisconsin rivers to the Mississippi in 1673 and descended it to the Arkansas. Robert Cavelier, sieur de La Salle, followed the Mississippi to the Gulf of Mexico in 1682 and claimed the entire Mississippi River Basin, or Louisiana, for France; a later consequence was the founding of New Orleans (Nouvelle-Orléans) in 1718 by Jean-Baptiste Lemoyne, sieur de Bienville, the governor of Louisiana. French traders ultimately reached Santa Fe in Spanish New Mexico, and the sons of explorer Pierre Gaultier de Varennes, sieur de la Vérendrye—Louis-Joseph and François—visited the Black Hills of South Dakota and may have seen the Rocky Mountains.

The Roman Catholic Church became firmly rooted in Canada, without the intellectual opposition and anticlericalism that developed in 18th-century France. Jesuit mission work among the Indians, extending to the Middle West, saw more devotion and bravery by the priests than substantial results. Christianity made small appeal to most Indians, who could accept a supreme being but rejected the Christian ethic. Several zealous Jesuits became martyrs to the faith; genuine conversions were few and backslidings frequent.

Jesuit mission work

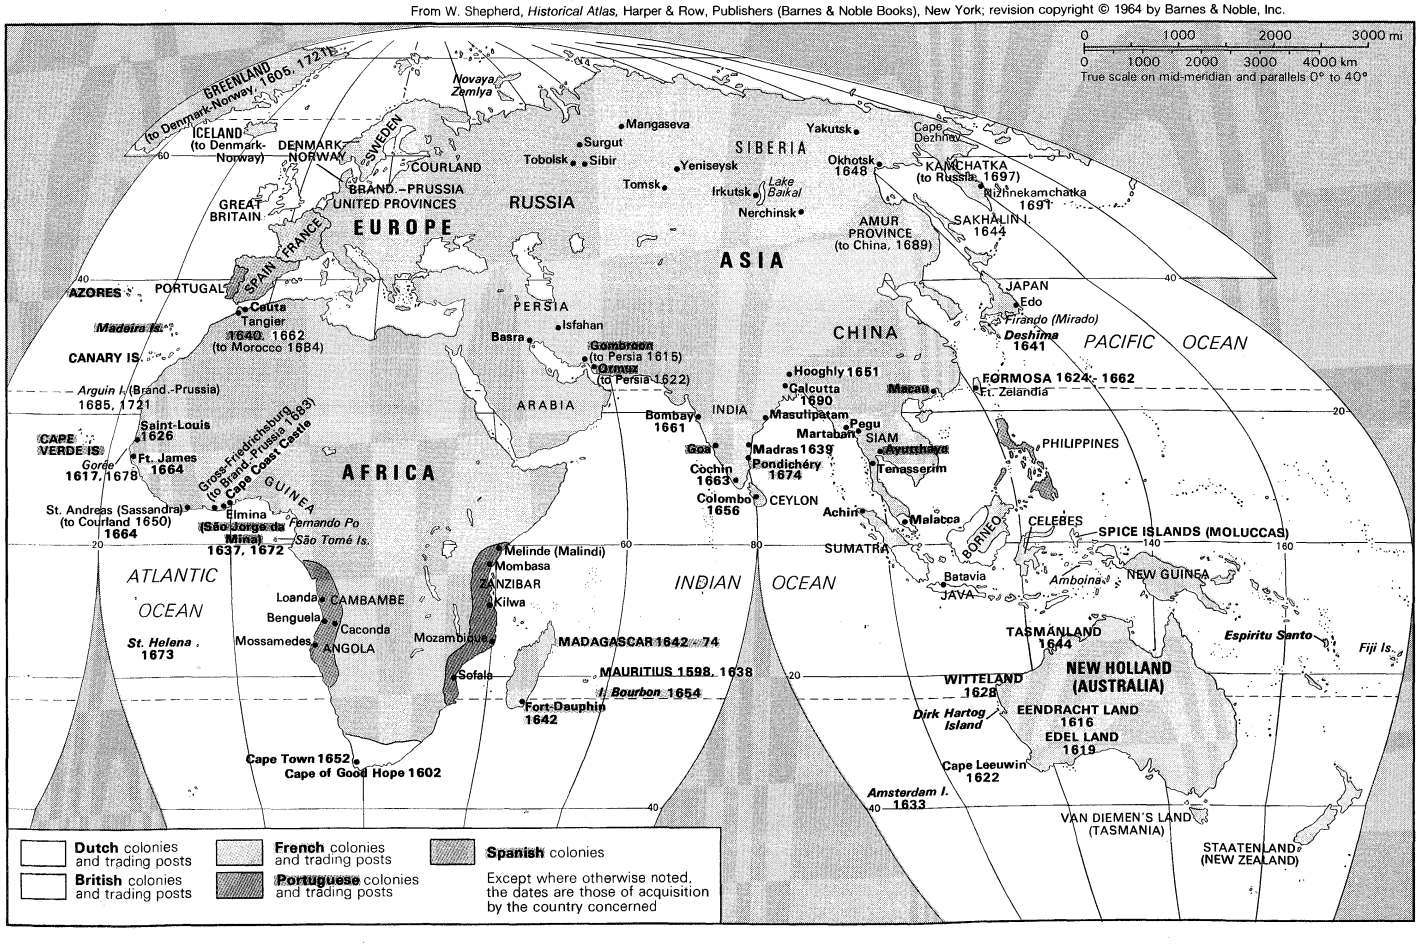
In the 18th century, with the pioneering period over, life in New France became easygoing and even pleasant, despite governmental absolutism. But the fur trade in the west drew vigorous young men from the seigneurial estates to become *coureurs de bois* (fur traders), and their loss crippled agriculture. Civil and religious authorities tried to hold settlers to farming because furs paid neither tithes nor seigneurial dues. This drainage of manpower partly explains the slow growth of New France, which, by a census of 1754, had only 55,000 whites.

The English. There is evidence that Bristol seamen reached Newfoundland before 1497, but John Cabot's Atlantic crossing in that year is the first recorded English exploration. After the death of Henry VII in 1509, England lost interest in discovery and did not resume it until 1553 and the formation of the Muscovy Company, which tried to find a Northeast Passage to Asia, discovered the island of Novaya Zemlya, and opened a small trade with Russia. The English also searched for a Northwest Passage, and Martin Frobisher sailed to Greenland, Baffin Island, and the adjacent mainland.

English ascendancy in India. Francis Drake and others raided the Spanish Main, and Drake and Thomas Cavendish sailed around the world. The defeat of Philip II's Armada in 1588, though less disastrous to Spain's seapower than commonly assumed, contributed to opening the way for English colonization of America. Interest in the Orient at first proved greater, however, and, in 1600, London merchants formed an East India Company. It could not compete with the rival Dutch company in the region of largest profits—the East Indies—so it transferred its emphasis to the Indian subcontinent. The English acquired Masulipatam in 1611 and Madras in 1639, having meanwhile destroyed Portuguese Hormuz in 1622. Charles II obtained Bombay in 1661, as part of his Portuguese queen's marriage dowry, and awarded it to the company.

Collapse of the Mughal Empire after 1707 led ultimately to armed conflict between the British and French companies for increased trade and influence. Dupleix had won

From W. Shepherd, *Historical Atlas,* Harper & Row, Publishers (Barnes & Noble Books), New York; revision copyright © 1964 by Barnes & Noble, Inc.



the upper hand for France by 1748; but in the ensuing Seven Years' War (1756–63), fought between the major European powers in various parts of the world, the British company gained ascendancy in India, thanks largely to the ability of Robert Clive, and held it thereafter. Pondichéry surrendered; and, though France recovered this post by the ensuing Treaty of Paris (1763), French power in India had shrunk almost to nothing, while the British company's was now rivalled only by that of the native Marāthā confederacy.

Company profits from India came first from the familiar spices, but after 1660, Indian textiles outstripped these in importance. Cheap cloths, mainly cottons, found a mass market among the English poorer classes, though dainty fabrics for the wealthy also paid well. Imports of calicoes (inexpensive cotton fabrics from Calicut) to England grew so large that in 1721 Parliament passed the Calico Act to protect English manufacturers, forbidding the use of calico in England for apparel or for domestic purposes (repeal of the act in 1774 coincided with inventions of mechanical devices that made possible English cloth production in successful competition with Eastern fabrics).

England's American colonies. The English West Indies for many years exceeded North America in economic importance. The Lesser Antilles, earlier passed over by Spain in favour of the larger islands, lay open to any colonizer, though their ferocious Carib inhabitants sometimes gave trouble. The Leeward Islands of Antigua, St. Kitts, Nevis, and Barbados, as well as the Bermudas, were settled by Englishmen between 1609 and 1632. Barbados, at first the most important, owed its prosperity to the introduction of sugar culture about 1637. The size of landholdings increased in all the islands, and the white populations accordingly diminished as slavery came to furnish most of the raw labour. When an expedition sent by Oliver Cromwell took Spanish Jamaica in 1655, that island became the English West Indian centre. Settlement of Belize (later British Honduras) by buccaneers and log cutters began in 1636, although more than a century elapsed before Spain acknowledged that the English indeed had the right to be there.

Settlements in the West Indies

The English islanders, to the envy of their Dutch and French neighbours, enjoyed such constitutional privileges as the right to elect semipopular assemblies. Barbados once hoped to have two representatives in Parliament, and some Barbadians, during the English (Glorious) Revolution (1688–89), thought of making their island an independent state, but nothing came of this.

The original English mainland colonies—Virginia (founded 1607), Plymouth (1620), and Massachusetts Bay (1630)—were founded by joint-stock companies. The later New England settlements—New Hampshire, New Haven, Connecticut, and Rhode Island—began as offshoots of Massachusetts, which acquired jurisdiction over the Maine territory. The New England colonies were first peopled partly by religious dissenters, but except for the separatist Plymouth Pilgrims they did not formally secede from the Church of England for the time being.

Proprietary colonies, under individual entrepreneurs, began with Maryland, founded in 1634 under the Catholic direction of Cecilius and Leonard Calvert. Also proprietary was Pennsylvania, which originally included Delaware, founded by the Quaker William Penn in 1682. Maryland and Pennsylvania, except for a brief royal interlude in Maryland, continued under Calvert and Penn heirs until the American Revolution; all other colonies except Connecticut and Rhode Island ultimately had royal governments. The Carolinas, after abortive attempts at colonization, were effectively founded in 1670 and became first proprietary and, later, royal colonies. Georgia, last of the 13, began in 1732, partly as a philanthropic enterprise headed by James Oglethorpe to furnish a rehabilitation home for debtors and other underprivileged Englishmen. All the mainland colonies eventually had representative assemblies, chosen by the propertied classes, to aid and often handicap their English governors.

The original settlers, predominantly English, were later supplemented by French Huguenots, Germans, and Scots-Irish, especially in western New York, Pennsylvania, and the southern colonies. New York, acquired from the United Provinces of the Netherlands and including New Jersey, continued to have some Dutch flavour long after the Dutch had become a small minority. By the French and Indian War (1754–63, the American portion of the Seven Years' War), the total population of the mainland colonies was estimated as 1,296,000 whites and 300,000 blacks, enormously in excess of the 55,000 whites inhabiting French Canada.

The only bond of union among the British colonies was their allegiance to the king, and in the wars with France (*c.* 1689–1763) it proved hard to unite them against the common enemy. All the colonies were agricultural, with New England being a region of small farms, the Middle Atlantic colonies having a larger scaled and more diversified farming, and the southern ones tending to plantations on which tobacco, rice, and indigo were raised by slaves (although slavery was legal throughout all the colonies). There was much colonial shipping, especially from New England, whose merchants and seamen traded with England, Africa, and the West Indies; Massachusetts shipbuilders had built more than 700 ships by 1675. By 1763 several towns had grown into cities, including Boston, New York City, Philadelphia, Baltimore, and Charleston, South Carolina.

Economic activities in the English colonies

Mercantilism. By the time the term mercantile system was coined in 1776 by the Scottish philosopher Adam Smith, European states had been trying for two centuries to put mercantile theory into practice. The basis of mercantilism was the notion that national wealth is measured by the amount of gold and silver a nation possesses. This seemed proven by the fact that Spain's most powerful years had occurred when it was first reaping a bullion harvest from its overseas possessions.

The mercantile theory held that colonies exist for the economic benefit of the mother country and are useless unless they help to achieve profit. The mother nation should draw raw materials from its possessions and sell them finished goods, with the balance favouring the European country. This trade should be monopolistic, with foreign intruders barred.

The Spanish fleet system. Spain acted upon the as-yet-undefined mercantile theory when, in 1565, it perfected the fleet (*flota*) system, by which all legal trade with its American colonies was restricted to two annual fleets between Seville and designated ports on the Gulf of Mexico and Caribbean. The outgoing ships bore manufactured articles; returning, their cargoes consisted partly of gold and silver bars. Though the system continued for nearly two centuries, Spain was a poor country by 1700.

French mercantilist activities. Ignoring this lesson, other European states adopted the mercantilist policy; the France of Louis XIV and Colbert is the outstanding example. Colbert, who dominated French policy for 20 years, strictly regulated the economy. He instituted protective tariffs and sponsored a monopolistic merchant marine. He regarded what few overseas possessions France then had as ultimate sources of liquid wealth, which they were poorly situated to furnish because they lacked such supplies of bullion as Spain controlled in Mexico and Peru.

The English navigation acts. England adhered to mercantilism for two centuries and, possessing a more lucrative empire than France, strove to implement the policy by a series of navigation acts. The first, passed by Oliver Cromwell's government in 1651, attempted chiefly to exclude the Dutch from England's carrying trade: goods imported from Africa, Asia, or America could be brought only in English ships, which included colonial vessels, thus giving the English North American merchant marine a substantial stimulus. After the royal Restoration in 1660, Parliament renewed and strengthened the Cromwellian measures. By then colonial American maritime competition with England had grown so severe that laws of 1663 required colonial ships carrying European goods to America to route them through English ports, where a duty had to be paid, but from lack of enforcement these soon became inoperative. In the early 18th century the English lost some of their enthusiasm for bullion alone and placed

chief emphasis on commerce and industry. The Molasses Act of 1733 was in the interest of the British West Indian sugar growers, who complained of the amount of French island molasses imported by the mainland colonies; the French planters had been buying fish, livestock, and lumber brought by North American ships and gladly exchanging their sugar products for them at low prices. Prohibition of colonial purchases of French molasses, though decreed, went largely unenforced, and New England, home of most of the carrying trade, continued prosperous.

THE OLD COLONIAL SYSTEM AND THE COMPETITION FOR EMPIRE (18TH CENTURY)

Faith in mercantilism waned during the 18th century, first because of the influence of French Physiocrats, who advocated the rule of nature, whereby trade and industry would be left to follow a natural course. François Quesnay, a physician at the court of Louis XV of France, led this school of thought, fundamentally advocating an agricultural economy and holding that productive land was the only genuine wealth, with trade and industry existing for the transfer of agricultural products.

Publication of *Wealth of Nations*

Adam Smith adopted some physiocratic ideas, but he considered labour very important and did not altogether accept land as the sole wealth. Smith's *Inquiry Into the Nature and Causes of the Wealth of Nations* (1776), appearing just as Britain was about to lose much of its older empire, established the basis of new economic thought—classical economics. This denigrated mercantilism and advocated free, or at least freer, trade and state noninterference with private enterprise. *Laisser-faire et laisser-aller* ("to let it alone and let it flow") became the slogan of this British economic school. Smith thought that regulation only reduced wealth, a view in part adopted by the British government 56 years after his death.

Slave trade. Slavery, though abundantly practiced in Africa itself and widespread in the ancient Mediterranean world, had nearly died out in medieval Europe. It was revived by the Portuguese in Prince Henry's time, beginning with the enslavement of Berbers in 1442. Portugal populated Cape Verde, Fernando Po (now Bioko), and São Tomé largely with black slaves and took many to the home country, especially to the regions south of the Tagus River.

New World black slavery began in 1502, when Gov. Nicolás de Ovando of Hispaniola imported a few evidently Spanish-born blacks from Spain. Rapid decimation of the Indian population of the Spanish West Indies created a labour shortage, ultimately remedied from Africa. The great reformer, Las Casas, advocated importation of blacks to replace the vanishing Indians, and he lived to regret having done so. The population of the Greater Antilles became largely black and mulatto; on the mainland, at least in the more populated parts, the Indians, supplemented by a growing mestizo caste that clung more tenaciously to life and seemed more suited to labour, kept African slavery somewhat confined to limited areas.

The Portuguese at first practiced Indian slavery in Brazil and continued to employ it partially until 1755. It was gradually replaced by the African variety, beginning prominently in the 17th century and coinciding with the rapid rise of Brazilian sugar culture.

As the English, French, Dutch, and, to a lesser extent, the Danes colonized the smaller West Indian islands, these became plantation settlements, largely cultivated by blacks. Before the latter arrived in great numbers, the bulk of manual labour, especially in the English islands, was performed by poor whites. Some were indentured, or contract, servants; some were redemptioners who agreed to pay ship captains their passage fees within a stated time or be sold to bidders; others were convicts. Some were kidnapped, with the tacit approval of the English authorities, in keeping with the mercantilist policy that advocated getting rid of the unemployed and vagrants. Black slavery eventually surpassed white servitude in the West Indies.

John Hawkins commanded the first English slave-trading expedition in 1562 and sold his cargo in the Spanish Indies. English slaving, nevertheless, remained minor until the establishment of the English island colonies in the reign of James I (ruled 1603–25). A Dutch captain sailed the first cargo of black slaves to Virginia in 1619, the year in which the colony exported 20,000 pounds (9,000 kilograms) of tobacco. The restored Stuart king, Charles II, gave English slave trade to a monopolistic company, the Royal Adventurers Trading to Africa, in 1663, but the Adventurers accomplished little because of the early outbreak of war with Holland (1665). Its successor, the Royal African Company, was founded in 1672 and held the English monopoly until 1698, when all Englishmen received the right to trade in slaves. The Royal African Company continued slaving until 1731, when it abandoned slaving in favour of traffic in ivory and gold dust. A new slaving company, the Merchants Trading to Africa (founded 1750), had directors in London, Liverpool, and Bristol, with Bristol furnishing the largest quota of ships, estimated at 237 in 1755. Jamaica offered the greatest single market for slaves and is believed to have received 610,000 between 1700 and 1786. The slave trade still flourished in 1763, when about 150 ships sailed yearly from British ports to Africa with capacity for nearly 40,000 slaves.

First blacks in English North America

There was no well-organized opposition to the slave trade before 1800, although some individuals and ephemeral societies condemned it. The Spanish church saw the importation of blacks as an opportunity for converting them. The English religionist George Fox, founder of Quakerism (founded in the 1650s), accepted the fact that his followers had bought slaves in Barbados, but he urged kind treatment. The English novelist and political pamphleteer Daniel Defoe later denounced the traffic but seemingly regarded slavery itself as inevitable. The English and Pennsylvania Quakers passed resolutions forbidding their members to engage in the trade, but their wording suggests that some were doing so; in fact, 84 of them were members of the Merchants Trading to Africa.

Those opposing the slave trade often objected on other than humanitarian grounds. Some colonials feared any further growth of the black percentage of the population. Others, who justified English slave sales to the Spanish colonies because payment was in cash, condemned the same traffic with French islanders, who paid in molasses and thus competed with nearby English sugar planters.

Colonial wars of the 18th century. From 1689 to 1763 the British and French fought four wars that were mainly European in origin but which determined the colonial situation, in some cases for two centuries. Spain entered all four, first in alliance with England and later in partnership with France, though it played a secondary role.

King William's War (War of the League of Augsburg). The war known in Europe as that of the Palatinate, League of Augsburg, or Grand Alliance, and in America as King William's War, ended indecisively, after eight years, with the Treaty of Rijswijk in 1697. No territorial changes occurred in America, and because the great Mughal emperor Aurangzeb reigned in India, very little of the conflict penetrated there.

Queen Anne's War (War of the Spanish Succession). Queen Anne's War, the American phase of the War of the Spanish Succession (1701–14), began in 1702. Childless king Charles II of Spain, dying in 1700, willed his entire possessions to Philip, grandson of Louis XIV of France. England, the United Provinces, and Austria intervened, fearing a virtual union between powerful Louis and Spain detrimental to the balance of power, and Queen Anne's War lasted until terminated by the Treaty of Utrecht in 1713. England (Great Britain after 1707) gained Gibraltar and Minorca and, in North America, acquired Newfoundland and French Acadia (renamed Nova Scotia). It also received clear title to the northern area being exploited by the Hudson's Bay Company. Bourbon prince Philip was recognized as king of Spain, but the British secured the important *asiento,* or right to supply Spanish America with slaves, for 30 years.

British gains in North America

King George's War (War of the Austrian Succession). There followed a peace almost unbroken until 1739, when, with the *asiento* about to expire and Spain unwilling to renew it, Great Britain and Spain went to war. The recent amputation of an English seaman's ear by a Spanish Caribbean coast guard caused the conflict to be named

the War of Jenkins' Ear. This merged in 1740 with the War of the Austrian Succession (called King George's War in America), between Frederick II the Great of Prussia and Maria Theresa of Austria over Silesia. France joined Spain and Prussia against Great Britain and Austria, and the war, which was terminated in 1748 by the Treaty of Aix-la-Chapelle, proved indecisive. New England colonials captured Louisbourg, the fortified French island commanding the St. Lawrence entrance, but France's progress in India counterbalanced this conquest. With the Mughal Empire now virtually extinct, the British and French East India Companies fought each other, the advantage going to the French under Dupleix, who captured Madras and nearly expelled the British. The peace treaty restored all conquests; France recovered Louisbourg, and the British regained Madras and with it another chance to become paramount in India.

The French and Indian War (the Seven Years' War). Until 1754, when the two powers resumed their conflict in the French and Indian War in America, the overseas possessions maintained a show of peace. During this prewar period the French attempted to increase their hold on the Ohio Valley and in 1754 built Fort-Duquesne at the future site of Pittsburgh. Lt. Col. George Washington with colonial forces, in 1754, and Gen. Edward Braddock with British regulars, in 1755, were defeated in attempts to dislodge them. Dupleix and his successor, Charles-Joseph Patissier, marquis de Bussy-Castelnau, increased their influence in India; but the recall of Dupleix in 1754 damaged French prospects there.

The Seven Years' War, fought in Europe by Frederick the Great of Prussia against Austria, France, and Russia, ended with his survival against overwhelming odds. His one ally, Great Britain, helped financially but could render small military assistance. Overseas, the British triumphed completely over France, aided by Spain in the last years of the war. The French at first had the upper hand in both India and America, but the turning point came after William Pitt the Elder, later earl of Chatham, assumed direction of the British war effort. In 1757 Clive won victory at Plassey over the Nawab of Bengal, an enemy of the British company; Sir Eyre Coote's victory at Wandewash in 1760, over the French governor Thomas Lally, was followed by the capture of Pondichéry.

Britain's overseas triumph over France

In America, thanks largely to the vigorous policy of Pitt, the British won repeated victories. The French forts Frontenac, Duquesne, and Carillon fell in 1758 and 1759. British generals Sir Jeffrey Amherst and James Wolfe took Louisbourg in 1758, Quebec in 1759, and Montreal in 1760, and the surrender of Montreal included that of the entire French colony. Meanwhile, Adm. Edward Hawke destroyed or immobilized the principal French line fleet at Quiberon Bay in 1759. Spanish intervention in the war in 1761 merely enabled the British to seize Havana and Manila.

The Treaty of Paris in 1763 gave Britain all North America east of the Mississippi, including Spanish Florida. France ceded the western Mississippi Valley to Spain as compensation for the loss of Florida. Besides having a clear path to domination of India in the Old World, Great Britain also gained African Senegal. In the West Indies, it returned Martinique and Guadeloupe to France for the sake of peace but remained easily second to Spain there in importance.

The first great era of colonial conflict had ended, and the British Empire, a century and a half old, had become the world's foremost overseas domain. Though exceeded in size by that of Spain, it was the wealthiest, backed by the overwhelming naval power of Great Britain. British prestige had reached a new height, greater perhaps than it would ever attain again.

(C.E.No./Ed.)

European expansion since 1763

Shift in colonial trade strategy

The global expansion of western Europe between the 1760s and the 1870s differed in several important ways from the expansionism and colonialism of previous centuries. Along with the rise of the Industrial Revolution, which economic historians generally trace to the 1760s, and the continuing spread of industrialization in the empire-building countries came a shift in the strategy of trade with the colonial world. Instead of being primarily buyers of colonial products (and frequently under strain to offer sufficient salable goods to balance the exchange), as in the past, the industrializing nations increasingly became sellers in search of markets for the growing volume of their machine-produced goods. Furthermore, over the years there occurred a decided shift in the composition of demand for goods produced in the colonial areas. Spices, sugar, and slaves became relatively less important with the advance of industrialization, concomitant with a rising demand for raw materials for industry (*e.g.*, cotton, wool, vegetable oils, jute, dyestuffs) and food for the swelling industrial areas (wheat, tea, coffee, cocoa, meat, butter).

This shift in trading patterns entailed in the long run changes in colonial policy and practice as well as in the nature of colonial acquisitions. The urgency to create markets and the incessant pressure for new materials and food were eventually reflected in colonial practices, which sought to adapt the colonial areas to the new priorities of the industrializing nations. Such adaptation involved major disruptions of existing social systems over wide areas of the globe. Before the impact of the Industrial Revolution, European activities in the rest of the world were largely confined to: (1) occupying areas that supplied precious metals, slaves, and tropical products then in large demand; (2) establishing white-settler colonies along the coast of North America; and (3) setting up trading posts and forts and applying superior military strength to achieve the transfer to European merchants of as much existing world trade as was feasible. However disruptive these changes may have been to the societies of Africa, South America, and the isolated plantation and white-settler colonies, the social systems over most of the Earth outside Europe nevertheless remained much the same as they had been for centuries (in some places for millennia). These societies, with their largely self-sufficient small communities based on subsistence agriculture and home industry, provided poor markets for the mass-produced goods flowing from the factories of the technologically advancing countries; nor were the existing social systems flexible enough to introduce and rapidly expand the commercial agriculture (and, later, mineral extraction) required to supply the food and raw material needs of the empire builders.

Adaptation of nonindustrialized regions

The adaptation of the nonindustrialized parts of the world to become more profitable adjuncts of the industrializing nations embraced, among other things: (1) overhaul of existing land and property arrangements, including the introduction of private property in land where it did not previously exist, as well as the expropriation of land for use by white settlers or for plantation agriculture; (2) creation of a labour supply for commercial agriculture and mining by means of direct forced labour and indirect measures aimed at generating a body of wage-seeking labourers; (3) spread of the use of money and exchange of commodities by imposing money payments for taxes and land rent and by inducing a decline of home industry; and (4) where the precolonial society already had a developed industry, curtailment of production and exports by native producers.

The classic illustration of this last policy is found in India. For centuries India had been an exporter of cotton goods, to such an extent that Great Britain for a long period imposed stiff tariff duties to protect its domestic manufacturers from Indian competition. Yet, by the middle of the 19th century, India was receiving one-fourth of all British exports of cotton piece goods and had lost its own export markets.

Clearly, such significant transformations could not get very far in the absence of appropriate political changes, such as the development of a sufficiently cooperative local elite, effective administrative techniques, and peace-keeping instruments that would assure social stability and environments conducive to the radical social changes imposed by a foreign power. Consistent with these purposes was the installation of new, or amendments of old, legal systems that would facilitate the operation of a money, business, and private land economy. Tying it all together

was the imposition of the culture and language of the dominant power.

New trends in colonial acquisitions

The changing nature of the relations between centres of empire and their colonies, under the impact of the unfolding Industrial Revolution, was also reflected in new trends in colonial acquisitions. While in preceding centuries colonies, trading posts, and settlements were in the main, except for South America, located along the coastline or on smaller islands, the expansions of the late 18th century and especially of the 19th century were distinguished by the spread of the colonizing powers, or of their emigrants, into the interior of continents. Such continental extensions, in general, took one of two forms, or some combination of the two: (1) the removal of the indigenous peoples by killing them off or forcing them into specially reserved areas, thus providing room for settlers from western Europe who then developed the agriculture and industry of these lands under the social system imported from the mother countries, or (2) the conquest of the indigenous peoples and the transformation of their existing societies to suit the changing needs of the more powerful militarily and technically advanced nations.

At the heart of Western expansionism was the growing disparity in technologies between those of the leading European nations and those of the rest of the world. Differences between the level of technology in Europe and some of the regions on other continents were not especially great in the early part of the 18th century. In fact, some of the crucial technical knowledge used in Europe at that time came originally from Asia. During the 18th century, however, and at an accelerating pace in the 19th and 20th centuries, the gap between the technologically advanced countries and technologically backward regions kept on increasing despite the diffusion of modern technology by the colonial powers. The most important aspect of this disparity was the technical superiority of Western armaments, for this superiority enabled the West to impose its will on the much larger colonial populations. Advances in communication and transportation, notably railroads, also became important tools for consolidating foreign rule over extensive territories. And along with the enormous technical superiority and the colonizing experience itself came important psychological instruments of minority rule by foreigners: racism and arrogance on the part of the colonizers and a resulting spirit of inferiority among the colonized.

Influences behind expansion policies

Naturally, the above description and summary telescope events that transpired over many decades and the incidence of the changes varied from territory to territory and from time to time, influenced by the special conditions in each area, by what took place in the process of conquest, by the circumstances at the time when economic exploitation of the possessions became desirable and feasible, and by the varying political considerations of the several occupying powers. Moreover, it should be emphasized that expansion policies and practices, while far from haphazard, were rarely the result of long-range and integrated planning. The drive for expansion was persistent, as were the pressures to get the greatest advantage possible out of the resulting opportunities. But the expansions arose in the midst of intense rivalry among major powers that were concerned with the distribution of power on the continent of Europe itself as well as with ownership of overseas territories. Thus, the issues of national power, national wealth, and military strength shifted more and more to the world stage as commerce and territorial acquisitions spread over larger segments of the globe. In fact, colonies were themselves often levers of military power—sources of military supplies and of military manpower and bases for navies and merchant marines. What appears, then, in tracing the concrete course of empire is an intertwining of the struggle for hegemony between competing national powers, the manoeuvring for preponderance of military strength, and the search for greatest advantage practically obtainable from the world's resources.

EUROPEAN COLONIAL ACTIVITY (1763–C. 1875)

Stages of history rarely, if ever, come in neat packages: the roots of new historical periods begin to form in earlier eras, while many aspects of an older phase linger on and help shape the new. Nonetheless, there was a convergence of developments in the early 1760s, which, despite many qualifications, delineates a new stage in European expansionism and especially in that of the most successful empire builder, Great Britain. It is not only the Industrial Revolution in Great Britain that can be traced to this period but also the consequences of England's decisive victory over France in the Seven Years' War and the beginnings of what turned out to be the second British Empire. As a result of the Treaty of Paris, France lost nearly all of its colonial empire, while Britain became, except for Spain, the largest colonial power in the world.

The second British Empire. The removal of threat from the strongest competing foreign power set the stage for Britain's conquest of India and for operations against the North American Indians to extend British settlement in Canada and westerly areas of the North American continent. In addition, the new commanding position on the seas provided an opportunity for Great Britain to probe for additional markets in Asia and Africa and to try to break the Spanish trade monopoly in South America. During this period, the scope of British world interests broadened dramatically to cover the South Pacific, the Far East, the South Atlantic, and the coast of Africa.

British naval superiority

The initial aim of this outburst of maritime activity was not so much the acquisition of extensive fresh territory as the attainment of a far-flung network of trading posts and maritime bases. The latter, it was hoped, would serve the interdependent aims of widening foreign commerce and controlling ocean shipping routes. But in the long run many of these initial bases turned out to be steppingstones to future territorial conquests. Because the indigenous populations did not always take kindly to foreign incursions into their homelands, even when the foreigners limited themselves to small enclaves, penetration of interiors was often necessary to secure base areas against attack.

Loss of the American colonies. The path of conquest and territorial growth was far from orderly. It was frequently diverted by the renewal or intensification of rivalry between, notably, England, France, Spain, and the Low Countries in colonial areas and on the European continent. The most severe blow to Great Britain's 18th-century dreams of empire, however, came from the revolt of the 13 American colonies. These contiguous colonies were at the heart of the old, or what is often referred to as the first, British Empire, which consisted primarily of Ireland, the North American colonies, and the plantation colonies of the West Indies. Ironically, the elimination of this core of the first British Empire was to a large extent influenced by the upsurge of empire building after the Seven Years' War. Great Britain harvested from its victory in that war a new expanse of territory about equal to its prewar possessions on the North American continent: French Canada, the Floridas, and the territory between the Alleghenies and the Mississippi River. The assimilation of the French Canadians, control of the Indians and settlement of the trans-Allegheny region, and the opening of new trade channels created a host of problems for the British government. Not the least of these were the burdensome costs to carry out this program on top of a huge national debt accumulated during the war. To cope with these problems, new imperial policies were adopted by the mother country: raising (for the first time) revenue from the colonies; tightening mercantile restrictions, imposing firm measures against smuggling (an important source of income for colonial merchants), and putting obstacles in the way of New England's substantial trade with the West Indies. The strains generated by these policies created or intensified the hardships of large sections of the colonial population and, in addition, disrupted the relative harmony of interests that had been built up between the mother country and important elite groups in the colonies. Two additional factors, not unrelated to the enlargement of the British Empire, fed the onset and success of the American War of Independence (1775–83): first, a lessening need for military support from the mother country once the menacing French were removed from the continent and, second, support for the American

Imperial policies in the late 18th century

Revolutionary forces from the French and Spanish, who had much to fear from the enhanced sea power and expansionism of the British.

The shock of defeat in North America was not the only problem confronting British society. Ireland—in effect, a colonial dependency—also experienced a revolutionary upsurge, giving added significance to attacks by leading British free traders against existing colonial policies and even at times against colonialism itself. But such criticism had little effect except as it may have hastened colonial administrative reforms to counteract real and potential independence movements in dependencies such as Canada and Ireland.

Conquest of India. Apart from reforms of this nature, the aftermath of American independence was a diversion of British imperial interests to other areas—the beginning of the settlement of Australia being a case in point. In terms of amount of effort and significance of results, however, the pursuit of conquest in India took first place. Starting with the assumption of control over the province of Bengal (after the Battle of Plassey, 1757) and especially after the virtual removal of French influence from the Indian Ocean, the British waged more or less continuous warfare against the Indian people and took over more and more of the interior. The Marāthās, the main source of resistance to foreign intrusion, were decisively defeated in 1803, but military resistance of one sort or another continued until the middle of the 19th century. The financing and even the military manpower for this prolonged undertaking came mainly from India itself. As British sovereignty spread, new land-revenue devices were soon instituted, which resulted in raising the revenue to finance the consolidation of power in India and the conquest of other regions, breaking up the old system of self-sufficient and self-perpetuating villages and supporting an elite whose self-interests would harmonize with British rule.

Defeat of the Marāthās

Global expansion. Except for the acquisition of additional territory in India and colonies in Sierra Leone and New South Wales, the important additions to British overseas possessions between the Seven Years' War and the end of the Napoleonic era came as prizes of victory in wars with rival European colonial powers. In 1763 the first British Empire primarily centred on North America. By 1815, despite the loss of the 13 colonies, Britain had a second empire, one that straddled the globe from Canada and the Caribbean in the Western Hemisphere around the Cape of Good Hope to India and Australia. This empire was sustained by and in turn was supported by maritime power that far exceeded that of any of Britain's European rivals.

Policy changes. The half century of global expansion is only one aspect of the transition to the second British Empire. The operations of the new empire in the longer run also reflected decisive changes in British society. The replacement of mercantile by industrial enterprise as the main source of national wealth entailed changes to make national and colonial policy more consistent with the new hierarchy of interests. The restrictive trade practices and monopolistic privileges that sustained the commercial explosion of the 16th and most of the 17th centuries—built around the slave trade, colonial plantations, and monopolistic trading companies—did not provide the most effective environment for a nation on its way to becoming the workshop of the world.

The desired restructuring of policies occurred over decades of intense political conflict: the issues were not always clearly delineated, interest groups frequently overlapped, and the balance of power between competing vested interests shifted from time to time. The issues were clearly drawn in some cases, as for example over the continuation of the British East India Company's trade monopoly. The company's export of Indian silk, muslins, and other cotton goods was seen by all who were involved in any way in the production of British textiles to be an obstacle to the development of markets for competing British manufactures. Political opposition to this monopoly was strong at the end of the 18th century, but the giant step on the road to free trade was not taken until the early decades of the 19th century (termination of the Indian trade monopoly, 1813; of the Chinese trade monopoly, 1833).

In contrast, the issues surrounding the strategic slave trade were much more complicated. The West Indies plantations relied on a steady flow of slaves from Africa. British merchants and ships profited not only from supplying these slaves but also from the slave trade with other colonies in the Western Hemisphere. The British were the leading slave traders, controlling at least half of the transatlantic slave trade by the end of the 18th century. But the influential planter and slave-trade interests had come under vigorous and unrelenting attack by religious and humanitarian leaders and organizations, who propelled the issue of abolition to the forefront of British politics around the turn of the 19th century. Historians are still unravelling the threads of conflicting arguments about the priority of causes in the final abolition of the slave trade and, later, of slavery itself, because economic as well as political issues were at play: glutted sugar markets (to which low-cost producers in competing colonies contributed) stimulated thoughts about controlling future output by limiting the supply of fresh slaves; the compensation paid to plantation owners by the British government at the time of the abolition of slavery rescued many planters from bankruptcy during a sugar crisis, with a substantial part of the compensation money being used to pay off planters' debts to London bankers. Moreover, the battle between proslavery and antislavery forces was fought in an environment in which free-trade interests were challenging established mercantilist practices and the West Indies sugar economy was in a secular decline.

Controversy over the slave trade

The British were not the first to abolish the slave trade. Denmark had ended it earlier, and the U.S. Constitution, written in 1787, had already provided for its termination in 1808. But the British Act of 1807 formally forbidding the slave trade was followed up by diplomatic and naval pressure to suppress the trade. By the 1820s Holland, Sweden, and France had also passed anti-slave-trade laws. Such laws and attempts to enforce them by no means stopped the trade, so long as there was buoyant demand for this commodity and good profit from dealing in it. Some decline in the demand for slaves did follow the final emancipation in 1833 of slaves in British possessions. On the other hand, the demand for slaves elsewhere in the Americas took on new life—*e.g.*, to work the virgin soils of Cuba and Brazil and to pick the rapidly expanding U.S. cotton crops to feed the voracious appetite of the British textile industry. Accordingly, the number of slaves shipped across the Atlantic accelerated at the same time Britain and other maritime powers outlawed this form of commerce.

Involvement in Africa. Although Britain's energetic activity to suppress the slave trade was far from effective, its diplomatic and military operations for this end led it to much greater involvement in African affairs. Additional colonies were acquired (Sierra Leone, 1808; Gambia, 1816; Gold Coast, 1821) to serve as bases for suppressing the slave trade and for stimulating substitute commerce. British naval squadrons touring the coast of Africa, stopping and inspecting suspected slavers of other nations, and forcing African tribal chiefs to sign antislavery treaties did not halt the expansion of the slave trade, but they did help Britain attain a commanding position along the west coast of Africa, which in turn contributed to the expansion of both its commercial and colonial empire.

The growth of informal empire. The transformation of the old colonial and mercantilist commercial system was completed when, in addition to the abolition of slavery and the slave trade, the Corn Laws and the Navigation Acts were repealed in the late 1840s. The repeal of the Navigation Acts acknowledged the new reality: the primacy of Britain's navy and merchant shipping. The repeal of the Corn Laws (which had protected agricultural interests) signalled the maturation of the Industrial Revolution. In the light of Britain's manufacturing supremacy, exclusivity and monopolistic trade restraints were less important than, and often detrimental to, the need for ever-expanding world markets and sources of inexpensive raw materials and food.

Repeal of the Navigation Acts and Corn Laws

With the new trade strategy, under the impetus of freer trade and technical progress, came a broadening of the concept of empire. It was found that the commercial and financial advantages of formal empire could often be derived by informal means. The development of a worldwide trade network, the growth of overseas banking, the export of capital to less advanced regions, the leading position of London's money markets—all under the shield of a powerful and mobile navy—led to Great Britain's economic preeminence and influence in many parts of the world, even in the absence of political control.

Anticolonial sentiment. The growing importance of informal empire went hand in hand with increased expressions of dissatisfaction with the formal colonial empire. The critical approach to empire came from leading statesmen, government officials in charge of colonial policy, the free traders, and the philosophic Radicals (the latter, a broad spectrum of opinion makers often labelled the Little Englanders, whose voices of dissent were most prominent in the years between 1840 and 1870). Taking the long view, however, some historians question just how much of this current of political thought was really concerned with the transformation of the British Empire into a Little England. Those who seriously considered colonial separation were for the most part thinking of the more recent white-settler colonies, such as Canada, Australia, and New Zealand, and definitely not of independence for India nor, for that matter, for Ireland. Differences of opinion among the various political factions naturally existed over the best use of limited government finance, colonial administrative tactics, how much foreign territory could in practice be controlled, and such issues as the costs of friction with the United States over Canada. Yet, while there were important differences of opinion on the choice between formal and informal empire, no important conflict arose over the desirability of continued expansion of Britain's world influence and foreign commercial activity. Indeed, during the most active period of what has been presumed to be anticolonialism, both the formal and informal empires grew substantially: new colonies were added, the territory of existing colonies was enlarged, and military campaigns were conducted to widen Britain's trading and investment area, as in the Opium Wars of the mid-19th century.

Continued imperial growth

Decline of colonial rivalry. An outstanding development in colonial and empire affairs during the period between the Napoleonic Wars and the 1870s was an evident lessening in conflict between European powers. Not that conflict disappeared entirely, but the period as a whole was one of relative calm compared with either the almost continuous wars for colonial possessions in the 18th century or the revival of intense rivalries during the latter part of the 19th and early 20th centuries. Instead of wars among colonial powers during this period, there were wars against colonized peoples and their societies, incident either to initial conquest or to the extension of territorial possessions farther into the interior. Examples are Great Britain in India, Burma, South Africa (Kaffir Wars), New Zealand (Maori Wars); France in Algeria and Indochina; the Low Countries in Indonesia; Russia in Central Asia; and the United States against the North American Indians.

Contributing to the abatement of intercolonial rivalries was the undisputable supremacy of the British Navy during these years. The increased use of steamships in the 19th century helped reinforce this supremacy: Great Britain's ample domestic coal supply and its numerous bases around the globe (already owned or newly obtained for this purpose) combined to make available needed coaling stations. Over several decades of the 19th century and until new developments toward the end of the century opened up a new age of naval rivalry, no country was in a position to challenge Britain's dominance of the seas. This may have temporarily weakened Britain's acquisitive drive: the motive of preclusive occupation of foreign territory still occurred, but it was not as pressing as at other times.

On the whole, despite the relative tranquillity and the rise of anticolonial sentiment in Britain, the era was marked by a notable wave of European expansionism. Thus, in 1800 Europe and its possessions, including former colonies, claimed title to about 55 percent of the Earth's land surface: Europe, North and South America, most of India, the Russian part of Asia, parts of the East Indies, and small sections along the coast of Africa. But much of this was merely claimed; effective control existed over a little less than 35 percent, most of which consisted of Europe itself. By 1878—that is, before the next major wave of European acquisitions began—an additional 6,500,000 square miles (16,800,000 square kilometres) were claimed; during this period, control was consolidated over the new claims and over all the territory claimed in 1800. Hence, from 1800 to 1878, actual European rule (including former colonies in North and South America) increased from 35 to 67 percent of the Earth's land surface.

Consolidation of European colonial rule

Decline of the Spanish and Portuguese empires. During the early 19th century, however, there was a conspicuous exception to the trend of colonial growth, and that was the decline of the Portuguese and Spanish empires in the Western Hemisphere. The occasion for the decolonization was provided by the Napoleonic Wars. The French occupation of the Iberian Peninsula in 1807, combined with the ensuing years of intense warfare until 1814 on that peninsula between the British and French and their respective allies, effectively isolated the colonies from their mother countries. During this isolation the long-smouldering discontents in the colonies erupted in influential nationalist movements, revolutions of independence, and civil wars. The stricken mother countries could hardly interfere with events on the South American continent, nor did they have the resources, even after the Peninsular War was over, to bring enough soldiers and armaments across the Atlantic to suppress the independence forces.

Great Britain could have intervened on behalf of Spain and Portugal, but it declined. British commerce with South America had blossomed during the Napoleonic Wars. New vistas of potentially profitable opportunities opened up in those years, in contrast with preceding decades when British penetration of Spanish colonial markets consisted largely of smuggling to get past Spain's mercantile restrictions. The British therefore now favoured independence for these colonies and had little interest in helping to reimpose colonial rule, with its accompanying limitations on British trade and investment. Support for colonial independence by the British came in several ways: merchants and financiers provided loans and supplies needed by insurrectionary governments; the Royal Navy protected the shipment of those supplies and the returning specie; and the British government made it clear to other nations that it considered South American countries independent. The British forthright position on independence, as well as the availability of the Royal Navy to support this policy, gave substance to the U.S. Monroe Doctrine (1823), which the United States had insufficient strength at that time to really enforce.

After some 15 years of uprisings and wars, Spain by 1825 no longer had any colonies in South America itself, retaining only the islands of Cuba and Puerto Rico. During the same period Brazil achieved its independence from Portugal. The advantages to the British economy made possible by the consequent opening up of the Latin-American ports were eagerly pursued, facilitated by commercial treaties signed with these young nations. The reluctance of France to recognize their new status delayed French penetration of their markets and gave an advantage to the British. In one liberated area after another, brokers and commercial agents arrived from England to ferret out business opportunities. Soon the continent was flooded with British goods, often competing with much weaker native industries. Actually, Latin America provided the largest single export market for British cotton textiles in the first half of the 19th century.

South American independence

Despite the absence of formal empire, the British were able to attain economic preeminence in South America. Spanish and Portuguese colonialism had left a heritage of disunity and conflict within regions of new nations and between nations, along with conditions that led to unstable alliances of ruling elite groups. While this combination of weaknesses militated against successful self-development,

it was fertile ground for energetic foreign entrepreneurs, especially those who had technically advanced manufacturing capacities, capital resources, international money markets, insurance and shipping facilities, plus supportive foreign policies. The early orgy of speculative loans and investments soon ended. But before long, British economic penetration entered into more lasting and self-perpetuating activities, such as promoting Latin-American exports, providing railroad equipment, constructing public works, and supplying banking networks. Thus, while the collapse of the Spanish and Portuguese empires led to the decline of colonialism in the Western Hemisphere, it also paved the way for a significant expansion of Britain's informal empire of trade, investment, and finance during the 19th century.

The emigration of European peoples. European influence around the globe increased with each new wave of emigration from Europe. Tides of settlers brought with them the Old World culture and, often, useful agricultural and industrial skills. An estimated 55,000,000 Europeans left their native lands in the 100 years after 1820, the product chiefly of two forces: (1) the push to emigrate as a result of difficulties arising from economic dislocations at home and (2) the pull of land, jobs, and recruitment activities of passenger shipping lines and agents of labour-hungry entrepreneurs in the New World. Other factors were also clearly at work, such as the search for religious freedom, escape from tyrannical governments, avoidance of military conscription, and the desire for greater upward social and economic mobility. Such motives had existed throughout the centuries, however, and they are insufficient to explain the massive population movements that characterized the 19th century. Unemployment induced by rapid technological changes in agriculture and industry was an important incentive for English emigration in the mid-1800s. The surge of German emigration at roughly the same time is largely attributable to an agricultural revolution in Germany, which nearly ruined many farmers on small holdings in southwestern Germany. Under English rule, the Irish were prevented from industrial development and were directed to an economy based on export of cereals grown on small holdings. A potato blight, followed by famine and eviction of farm tenants by landlords, gave large numbers of Irish no alternative other than emigration or starvation. These three nationalities—English, German, and Irish—composed the largest group of migrants in the 1850s. In later years Italians and Slavs contributed substantially to the population spillover. The emigrants spread throughout the world, but the bulk of the population transfer went to the Americas, Siberia, and Australasia. The population outflow, greatly facilitated by European supremacy outside Europe, helped ease the social pressures and probably abated the dangers of social upheaval in Europe itself.

Spread of European culture and technology

Advance of the U.S. frontier. The outward movement of European peoples in any substantial numbers naturally was tied in with conquest and, to a greater or lesser degree, with the displacement of indigenous populations. In the United States, where by far the largest number of European emigrants went, acquisition of space for development by white immigrants entailed activity on two fronts: competition with rival European nations and disposition of the Indians. During a large part of the 19th century, the United States remained alert to the danger of encirclement by Europeans, but in addition the search for more fertile land, pursuit of the fur trade, and desire for ports to serve commerce in the Atlantic and Pacific oceans nourished the drive to penetrate the American continent. The most pressing points of tension with European nations were eliminated during the first half of the century: purchase of the Louisiana Territory from France in 1803 gave the United States control over the heartland of the continent; settlement of the War of 1812 ended British claims south of the 49th parallel up to the Rocky Mountains; Spain's cession of the Floridas in 1819 rounded out the Atlantic coastal frontier; and Russia's (1824) and Great Britain's (1846) relinquishment of claims to the Oregon territory gave the United States its window on the Pacific. The expansion of the United States, however, was not confined to liquidating rival claims of overseas empires; it also involved taking territory from neighbouring Mexico. Settlers from the United States wrested Texas from Mexico (1836), and war against Mexico (1846–48) led to the U.S. annexation of the southwestern region between New Mexico and Utah to the Pacific Ocean.

Penetration of the American continent

Diplomatic and military victories over the European nations and Mexico were but one precondition for the transcontinental expansion of the United States. In addition, the Indian tribes sooner or later had to be rooted out to clear the new territory. At times, treaties were arranged with Indian tribes, by which vast areas were opened up for white settlement. But even where peaceful agreements had been reached, the persistent pressure of the search for land and commerce created recurrent wars with Indian tribes that were seeking to retain their homes and their land. Room for the new settlers was obtained by forced removal of natives to as yet non-white-settled land—a process that was repeated as white settlers occupied ever more territory. Massacres during wars, susceptibility to infectious European diseases, and hardships endured during forced migrations all contributed to the decline in the Indian population and the weakening of its resistance. Nevertheless, Indian wars occupied the U.S. Army's attention during most of the 19th century, ending with the eventual isolation of the surviving Indians on reservations set aside by the U.S. government.

THE NEW IMPERIALISM (C. 1875–1914)

Reemergence of colonial rivalries. Although there are sharp differences of opinion over the reasons for, and the significance of, the "new imperialism," there is little dispute that at least two developments in the late 19th and in the beginning of the 20th century signify a new departure: (1) notable speedup in colonial acquisitions; (2) an increase in the number of colonial powers.

New acquisitions. The annexations during this new phase of imperial growth differed significantly from the expansionism earlier in the 19th century. While the latter was substantial in magnitude, it was primarily devoted to the consolidation of claimed territory (by penetration of continental interiors and more effective rule over indigenous populations) and only secondarily to new acquisitions. On the other hand, the new imperialism was characterized by a burst of activity in carving up as yet independent areas: taking over almost all Africa, a good part of Asia, and many Pacific islands. This new vigour in the pursuit of colonies is reflected in the fact that the rate of new territorial acquisitions of the new imperialism was almost three times that of the earlier period. Thus, the increase in new territories claimed in the first 75 years of the 19th century averaged about 83,000 square miles (215,000 square kilometres) a year. As against this, the colonial powers added an average of about 240,000 square miles (620,000 square kilometres) a year between the late 1870s and World War I (1914–18). By the beginning of that war, the new territory claimed was for the most part fully conquered, and the main military resistance of the indigenous populations had been suppressed. Hence, in 1914, as a consequence of this new expansion and conquest on top of that of preceding centuries, the colonial powers, their colonies, and their former colonies extended over approximately 85 percent of the Earth's surface. Economic and political control by leading powers reached almost the entire globe, for, in addition to colonial rule, other means of domination were exercised in the form of spheres of influence, special commercial treaties, and the subordination that lenders often impose on debtor nations.

Increase in new territories in Africa and Asia

New colonial powers. This intensification of the drive for colonies reflected much more than a new wave of overseas activities by traditional colonial powers, including Russia. The new imperialism was distinguished particularly by the emergence of additional nations seeking slices of the colonial pie: Germany, the United States, Belgium, Italy, and, for the first time, an Asian power, Japan. Indeed, this very multiplication of colonial powers, occurring in a relatively short period, accelerated the tempo of colonial growth. Unoccupied space that could

potentially be colonized was limited. Therefore, the more nations there were seeking additional colonies at about the same time, the greater was the premium on speed. Thus, the rivalry among the colonizing nations reached new heights, which in turn strengthened the motivation for preclusive occupation of territory and for attempts to control territory useful for the military defense of existing empires against rivals.

The impact of the new upsurge of rivalry is well illustrated in the case of Great Britain. Relying on its economic preeminence in manufacturing, trade, and international finance as well as on its undisputed mastery of the seas during most of the 19th century, Great Britain could afford to relax in the search for new colonies, while concentrating on consolidation of the empire in hand and on building up an informal empire. But the challenge of new empire builders, backed up by increasing naval power, put a new priority on Britain's desire to extend its colonial empire. On the other hand, the more that potential colonial space shrank, the greater became the urge of lesser powers to remedy disparities in size of empires by redivision of the colonial world. The struggle over contested space and for redivision of empire generated an increase in wars among the colonial powers and an intensification of diplomatic manoeuvring.

Struggle over redivision of empire

Rise of new industrialized nations. Parallel with the emergence of new powers seeking a place in the colonial sun and the increasing rivalry among existing colonial powers was the rise of industrialized nations able and willing to challenge Great Britain's lead in industry, finance, and world trade. In the mid-19th century Britain's economy outdistanced by far its potential rivals. But, by the last quarter of that century, Britain was confronted by restless competitors seeking a greater share of world trade and finance; the Industrial Revolution had gained a strong foothold in these nations, which were spurred on to increasing industrialization with the spread of railroad lines and the maturation of integrated national markets.

Moreover, the major technological innovations of the late 19th and early 20th centuries improved the competitive potential of the newer industrial nations. Great Britain's advantage as the progenitor of the first Industrial Revolution diminished substantially as the newer products and sources of energy of what has been called a second Industrial Revolution began to dominate industrial activity. The late starters, having digested the first Industrial Revolution, now had a more equal footing with Great Britain: they were all starting out more or less from the same base to exploit the second Industrial Revolution. This new industrialism, notably featuring mass-produced steel, electric power and oil as sources of energy, industrial chemistry, and the internal-combustion engine, spread over western Europe, the United States, and eventually Japan.

Need for heavy capital investment

A world economy. To operate efficiently, the new industries required heavy capital investment in large-scale units. Accordingly, they encouraged the development of capital markets and banking institutions that were large and flexible enough to finance the new enterprises. The larger capital markets and industrial enterprises, in turn, helped push forward the geographic scale of operations of the industrialized nations: more capital could now be mobilized for foreign loans and investment, and the bigger businesses had the resources for the worldwide search for and development of the raw materials essential to the success and security of their investments. Not only did the new industrialism generate a voracious appetite for raw materials, but food for the swelling urban populations was now also sought in the far corners of the world. Advances in ship construction (steamships using steel hulls, twin screws, and compound engines) made feasible the inexpensive movement of bulk raw materials and food over long ocean distances. Under the pressures and opportunities of the later decades of the 19th century, more and more of the world was drawn upon as primary producers for the industrialized nations. Self-contained economic regions dissolved into a world economy, involving an international division of labour whereby the leading industrial nations made and sold manufactured products and the rest of the world supplied them with raw materials and food.

New militarism. The complex of social, political, and economic changes that accompanied the new industrialism and the vastly expanded and integrated world commerce also provided a setting for intensified commercial rivalry, the rebuilding of high tariff walls, and a revival of militarism. Of special importance militarily was the race in naval construction, which was propelled by the successful introduction and steady improvement of radically new warships that were steam driven, armour-plated, and equipped with weapons able to penetrate the new armour. Before the development of these new technologies, Britain's naval superiority was overwhelming and unchallengeable. But because Britain was now obliged in effect to build a completely new navy, other nations with adequate industrial capacities and the will to devote their resources to this purpose could challenge Britain's supremacy at sea.

The new militarism and the intensification of colonial rivalry signalled the end of the relatively peaceful conditions of the mid-19th century. The conflict over the partition of Africa, the South African War (the Boer War), the Sino-Japanese War, the Spanish-American War, and the Russo-Japanese War were among the indications that the new imperialism had opened a new era that was anything but peaceful.

The new imperialism also represented an intensification of tendencies that had originated in earlier periods. Thus, for example, the decision by the United States to go to war with Spain cannot be isolated from the long-standing interest of the United States in the Caribbean and the Pacific. The defeat of Spain and the suppression of the independence revolutions in Cuba and the Philippines gave substance to the Monroe Doctrine: the United States now became the dominant power in the Caribbean, and the door was opened for acquisition of greater influence in Latin America. Possession of the Philippines was consistent with the historic interest of the United States in the commerce of the Pacific, as it had already manifested by its long interest in Hawaii (annexed in 1898) and by an expedition by Commodore Matthew Perry to Japan (1853).

Historiographical debate. The new imperialism marked the end of vacillation over the choice of imperialist military and political policies; similar decisions to push imperialist programs to the forefront were made by the leading industrial nations over a relatively short period. This historical conjuncture requires explanation and still remains the subject of debate among historians and social scientists. The pivot of the controversy is the degree to which the new imperialism was the product of primarily economic forces and in particular whether it was a necessary attribute of the capitalist system.

Serious analysts on both sides of the argument recognize that there is a multitude of factors involved: the main protagonists of economic imperialism recognize that political, military, and ideological influences were also at work; similarly, many who dispute the economic imperialism thesis acknowledge that economic interests played a significant role. The problem, however, is one of assigning priority to causes.

Hobson's interpretation of the new imperialism

Economic imperialism. The father of the economic interpretation of the new imperialism was the British liberal economist John Atkinson Hobson. In his seminal study, *Imperialism, a Study* (first published in 1902), he pointed to the role of such drives as patriotism, philanthropy, and the spirit of adventure in advancing the imperialist cause. As he saw it, however, the critical question was why the energy of these active agents takes the particular form of imperialist expansion. Hobson located the answer in the financial interests of the capitalist class as "the governor of the imperial engine." Imperialist policy had to be considered irrational if viewed from the vantage point of the nation as a whole: the economic benefits derived were far less than the costs of wars and armaments; and needed social reforms were shunted aside in the excitement of imperial adventure. But it was rational, indeed, in the eyes of the minority of financial interest groups. The reason for this, in Hobson's view, was the persistent congestion of capital in manufacturing. The pressure of capital needing investment outlets arose in part from a maldistribution of

income: low mass consuming power blocks the absorption of goods and capital inside the country. Moreover, the practices of the larger firms, especially those operating in trusts and combines, foster restrictions on output, thus avoiding the risks and waste of overproduction. Because of this, the large firms are faced with limited opportunities to invest in expanding domestic production. The result of both the maldistribution of income and monopolistic behaviour is a need to open up new markets and new investment opportunities in foreign countries.

Hobson's study covered a broader spectrum than the analysis of what he called its economic taproot. It also examined the associated features of the new imperialism, such as political changes, racial attitudes, and nationalism. The book as a whole made a strong impression on, and greatly influenced, Marxist thinkers who were becoming more involved with the struggle against imperialism. The most influential of the Marxist studies was a small book published by Lenin in 1917, *Imperialism, the Highest Stage of Capitalism.* Despite many similarities, at bottom there is a wide gulf between Hobson's and Lenin's frameworks of analysis and also between their respective conclusions. While Hobson saw the new imperialism serving the interests of certain capitalist groups, he believed that imperialism could be eliminated by social reforms while maintaining the capitalist system. This would require restricting the profits of those classes whose interests were closely tied to imperialism and attaining a more equitable distribution of income so that consumers would be able to buy up a nation's production. Lenin, on the other hand, saw imperialism as being so closely integrated with the structure and normal functioning of an advanced capitalism that he believed that only the revolutionary overthrow of capitalism, with the substitution of Socialism, would rid the world of imperialism.

Marxist interpretation

Lenin placed the issues of imperialism in a context broader than the interests of a special sector of the capitalist class. According to Lenin, capitalism itself changed in the late 19th century; moreover, because this happened at pretty much the same time in several leading capitalist nations, it explains why the new phase of capitalist development came when it did. This new phase, Lenin believed, involves political and social as well as economic changes; but its economic essence is the replacement of competitive capitalism by monopoly capitalism, a more advanced stage in which finance capital, an alliance between large industrial and banking firms, dominates the economic and political life of society. Competition continues, but among a relatively small number of giants who are able to control large sectors of the national and international economy. It is this monopoly capitalism and the resulting rivalry generated among monopoly capitalist nations that foster imperialism; in turn, the processes of imperialism stimulate the further development of monopoly capital and its influence over the whole society.

The difference between Lenin's more complex paradigm and Hobson's shows up clearly in the treatment of capital export. Like Hobson, Lenin maintained that the increasing importance of capital exports is a key figure of imperialism, but he attributed the phenomenon to much more than pressure from an overabundance of capital. He also saw the acceleration of capital migration arising from the desire to obtain exclusive control over raw material sources and to get a tighter grip on foreign markets. He thus shifted the emphasis from the general problem of surplus capital, inherent in capitalism in all its stages, to the imperatives of control over raw materials and markets in the monopoly stage. With this perspective, Lenin also broadened the concept of imperialism. Because the thrust is to divide the world among monopoly interest groups, the ensuing rivalry extends to a struggle over markets in the leading capitalist nations as well as in the less advanced capitalist and colonial countries. This rivalry is intensified because of the uneven development of different capitalist nations: the latecomers aggressively seek a share of the markets and colonies controlled by those who got there first, who naturally resist such a redivision. Other forces—political, military, and ideological—are at play in shaping the contours of imperialist policy, but Lenin insisted that these influences germinate in the seedbed of monopoly capitalism.

Noneconomic imperialism. Perhaps the most systematic alternative theory of imperialism was proposed by Joseph Alois Schumpeter, one of the best known economists of the first half of the 20th century. His essay "Zur Soziologie des Imperialismus" ("The Sociology of Imperialism") was first published in Germany in the form of two articles in 1919. Although Schumpeter was probably not familiar with Lenin's *Imperialism* at the time he wrote his essay, his arguments were directed against the Marxist currents of thought of the early 20th century and in particular against the idea that imperialism grows naturally out of capitalism. Unlike other critics, however, Schumpeter accepted some of the components of the Marxist thesis, and to a certain extent he followed the Marxist tradition of looking for the influence of class forces and class interests as major levers of social change. In doing so, he in effect used the weapons of Marxist thought to rebut the essence of Marxist theory.

Schumpeter's interpretation

A survey of empires, beginning with the earliest days of written history, led Schumpeter to conclude that there are three generic characteristics of imperialism: (1) At root is a persistent tendency to war and conquest, often producing nonrational expansions that have no sound utilitarian aim. (2) These urges are not innate in man. They evolved from critical experiences when peoples and classes were molded into warriors to avoid extinction; the warrior mentality and the interests of warrior classes live on, however, and influence events even after the vital need for wars and conquests disappears. (3) The drift to war and conquest is sustained and conditioned by the domestic interests of ruling classes, often under the leadership of those individuals who have most to gain economically and socially from war. But for these factors, Schumpeter believed, imperialism would have been swept away into the dustbin of history as capitalist society ripened; for capitalism in its purest form is antithetical to imperialism: it thrives best with peace and free trade. Yet despite the innate peaceful nature of capitalism, interest groups do emerge that benefit from aggressive foreign conquests. Under monopoly capitalism the fusion of big banks and cartels creates a powerful and influential social group that pressures for exclusive control in colonies and protectorates, for the sake of higher profits.

Notwithstanding the resemblance between Schumpeter's discussion of monopoly and that of Lenin and other Marxists, a crucial difference does remain. Monopoly capitalism in Lenin's frame of reference is a natural outgrowth of the previous stage of competitive capitalism. But according to Schumpeter, it is an artificial graft on the more natural competitive capitalism, made possible by the catalytic effect of the residue from the preceding feudal society. Schumpeter argued that monopoly capitalism can only grow and prosper under the protection of high tariff walls; without that shield there would be large-scale industry but no cartels or other monopolistic arrangements. Because tariff walls are erected by political decisions, it is the state and not a natural economic process that promotes monopoly. Therefore, it is in the nature of the state—and especially those features that blend the heritage of the previous autocratic state, the old war machine, and feudal interests and ideas along with capitalist interests—that the cause of imperialism will be discovered. The particular form of imperialism in modern times is affected by capitalism, and capitalism itself is modified by the imperialist experience. In Schumpeter's analysis, however, imperialism is not an inevitable product of capitalism.

The state as the progenitor of imperialism

Quest for a general theory of imperialism. The main trend of academic thought in the Western world is to follow Schumpeter's conclusion—that modern imperialism is not a product of capitalism—without paying close attention to Schumpeter's sophisticated sociological analysis. Specialized studies have produced a variety of interpretations of the origin or reawakening of the new imperialism: for France, bolstering of national prestige after its defeat in the Franco-German War (1870–71); for Germany, Bismarck's design to stay in power when threatened by political rivals; for England, the desire for greater mili-

tary security in the Mediterranean and India. These reasons—along with other frequently mentioned contributing causes, such as the spirit of national and racial superiority and the drive for power—are still matters of controversy with respect to specific cases and to the problem of fitting them into a general theory of imperialism. For example, if it is found that a new colony was acquired for better military defense of existing colonies, the questions still remain as to why the existing colonies were acquired in the first place and why it was considered necessary to defend them rather than to give them up. Similarly, explanations in terms of the search for power still have to account for the close relationship between power and wealth, because in the real world adequate economic resources are needed for a nation to hold on to its power, let alone to increase it. Conversely, increasing a nation's wealth often requires power. As is characteristic of historical phenomena, imperialist expansion is conditioned by a nation's previous history and the particular situation preceding each expansionist move. Moreover, it is carried forth in the midst of a complex of political, military, economic, and psychological impulses. It would seem, therefore, that the attempt to arrive at a theory that explains each and every imperialist action—ranging from a semifeudal Russia to a relatively undeveloped Italy to an industrially powerful Germany—is a vain pursuit. But this does not eliminate the more important challenge of constructing a theory that will provide a meaningful interpretation of the almost simultaneous eruption of the new imperialism in a whole group of leading powers.

PENETRATION OF THE WEST IN ASIA

Russia's eastward expansion. European nations and Japan at the end of the 19th century spread their influence and control throughout the continent of Asia. Russia, because of its geographic position, was the only occupying power whose Asian conquests were overland.

Overland conquests

In that respect there is some similarity between Russia and the United States in the forcible outward push of their continental frontiers. But there is a significant difference: the United States advance displaced the indigenous population, with the remaining Indians becoming wards of the state. On the other hand, the Russian march across Asia resulted in the incorporation of alien cultures and societies as virtual colonies of the Russian Empire, while providing room for the absorption of Russian settlers.

Although the conquest of Siberia and the drive to the Pacific had been periodically absorbing Russia's military energies since the 16th century, the acquisition of additional Asian territory and the economic integration of previously acquired territory took a new turn in the 19th century. Previously, Russian influence in its occupied territory was quite limited, without marked alteration of the social and economic structure of the conquered peoples. Aside from looting and exacting tribute from subject tribes, the major objects of interest were the fur trade, increased commerce with China and in the Pacific, and land. But changes in 19th-century Russian society, especially those coming after the Crimean War (1853–56), signalled a new departure. First, Russia's resounding defeat in that war temporarily frustrated its aspirations in the Balkans and the Near East; but, because its dynastic and military ambitions were in no way diminished, its expansionist energies turned with increased vigour to its Asian frontiers. Second, the emancipation of the serfs (1861), which eased the feudal restrictions on the landless peasants, led to large waves of migration by Russians and Ukrainians—first to Siberia and later to Central Asia. Third, the surge of industrialization, foreign trade, and railway building in the post-Crimean War decades paved the way for the integration of Russian Asia, which formerly, for all practical purposes, had been composed of separate dependencies, and for a new type of subjugation for many of these areas, especially in Central Asia, in which the conquered societies were "colonized" to suit the political and economic needs of the conqueror.

This process of acquisition and consolidation in Asia spread out in four directions: Siberia, the Far East, the Caucasus, and Central Asia. This pursuit of tsarist ambitions for empire and for warm-water ports involved numerous clashes and conflicts along the way. Russian expansion was ultimately limited not by the fierce opposition of the native population, which was at times a stumbling block, but by the counterpressure of competitive empire builders, such as Great Britain and Japan. Great Britain and Russia were mutually alarmed as the distances between the expanding frontiers of Russia and India shortened. One point of conflict was finally resolved when both powers agreed on the delimitation of the northern border of Afghanistan. A second major area of conflict in Central Asia was settled by an Anglo-Russian treaty (1907) to divide Persia into two separate spheres of influence, leaving a nominally independent Persian nation.

Penetration of China

As in the case of Afghanistan and Persia, penetration of Chinese territory produced clashes with both the native government and other imperialist powers. At times China's preoccupation with its struggle against other invading powers eased the way for Russia's penetration. Thus, in 1860, when Anglo-French soldiers had entered Peking, Russia was able to wrest from China the Amur Province and special privileges in Manchuria (Northeast Provinces) south of the Amur River. With this as a stepping-stone, Russia took over the seacoast north of Korea and founded the town of Vladivostok. But, because the Vladivostok harbour is icebound for some four months of the year, the Russians began to pay more attention to getting control of the Korean coastline, where many good year-round harbours could be found. Attempts to acquire a share of Korea, as well as all of Manchuria, met with the resistance of Britain and Japan. Further thrusts into China beyond the Amur and maritime provinces were finally thwarted by defeat in 1905 in the Russo-Japanese War.

The partitioning of China. The evolution of the penetration of Asia was naturally influenced by a multiplicity of factors—economic and political conditions in the expanding nations, the strategy of the military officials of the latter nations, the problems facing colonial rulers in each locality, pressures arising from white settlers and businessmen in the colonies, as well as the constraints imposed by the always limited economic and military resources of the imperialist powers. All these elements were present to a greater or lesser extent at each stage of the forward push of the colonial frontiers by the Dutch in Indonesia, the French in Indochina (Vietnam, Laos, Cambodia), and the British in Malaya, Burma, and Borneo.

Yet, despite the variety of influences at work, three general types of penetration stand out. One of these is expansion designed to overcome resistance to foreign rule. Resistance, which assumed many forms ranging from outright rebellion to sabotage of colonial political and economic domination, was often strongest in the border areas farthest removed from the centres of colonial power. The consequent extension of military control to the border regions tended to arouse the fears and opposition of neighbouring states or tribal societies and thus led to the further extension of control. Hence, attempts to achieve military security prompted the addition of border areas and neighbouring nations to the original colony.

A second type of expansion was a response to the economic opportunities offered by exploitation of the colonial interiors. Traditional trade and the free play of market forces in Asia did not produce huge supplies of raw materials and food or the enlarged export markets sought by the industrializing colonial powers. For this, entrepreneurs and capital from abroad were needed, mines and plantations had to be organized, labour supplies mobilized, and money economies created. All these alien intrusions functioned best under the firm security of an accommodating alien law and order.

The third type of expansion was the result of rivalry among colonial powers. When possible, new territory was acquired or old possessions extended in order either to preclude occupation by rivals or to serve as buffers for military security against the expansions of nearby colonial powers. Where the crosscurrents of these rivalries prevented any one power from obtaining exclusive control, various substitute arrangements were arrived at: parts of a country were chipped off and occupied by one or

more of the powers; spheres of influence were partitioned; unequal commerical treaties were imposed—while the countries subjected to such treatment remained nominally independent.

The penetration of China is the outstanding example of this type of expansion. In the early 19th century the middle part of eastern Asia (Japan, Korea, and China), containing about half the Asian population, was still little affected by Western penetration. By the end of the century, Korea was on the way to becoming annexed by Japan, which had itself become a leading imperialist power. China remained independent politically, though it was already extensively dominated by outside powers. Undoubtedly, the intense rivalry of the foreign powers helped save China from being taken over outright (as India had been). China was pressed on all sides by competing powers anxious for its trade and territory: Russia from the north, Great Britain (via India and Burma) from the south and west, France (via Indochina) from the south, and Japan and the United States (in part, via the Philippines) from the east.

Rivalry over China

The Opium Wars. The first phase of the forceful penetration of China by western Europe came in the two Opium Wars. Great Britain had been buying increasing quantities of tea from China, but it had few products that China was interested in buying by way of exchange. A resulting steady drain of British silver to pay for the tea was eventually stopped by Great Britain's ascendancy in India. With British merchants in control of India's foreign trade and with the financing of this trade centred in London, a three-way exchange developed: the tea Britain bought in China was paid for by India's exports of opium and cotton to China. And because of a rapidly increasing demand for tea in England, British merchants actively fostered the profitable exports of opium and cotton from India.

An increasing Chinese addiction to opium fed a boom in imports of the drug and led to an unfavourable trade balance paid for by a steady loss of China's silver reserves. In light of the economic effect of the opium trade plus the physical and mental deterioration of opium users, Chinese authorities banned the opium trade. At first this posed few obstacles to British merchants, who resorted to smuggling. But enforcement of the ban became stringent toward the end of the 1830s; stores of opium were confiscated, and warehouses were closed down. British merchants had an additional and longstanding grievance because the Chinese limited all trade by foreigners to the port of Canton.

In June 1840 the British fleet arrived at the mouth of the Canton River to begin the Opium War. The Chinese capitulated in 1842 after the fleet reached the Yangtze, Shanghai fell, and Nanking was under British guns. The resulting Treaty of Nanking—the first in a series of commercial treaties China was forced to sign over the years—provided for: (1) cession of Hong Kong to the British crown; (2) the opening of five treaty ports, where the British would have residence and trade rights; (3) the right of British nationals in China who were accused of criminal acts to be tried in British courts; and (4) the limitation of duties on imports and exports to a modest rate. Other countries soon took advantage of this forcible opening of China; in a few years similar treaties were signed by China with the United States, France, and Russia.

Opening of China

The Chinese, however, tried to retain some independence by preventing foreigners from entering the interior of China. With the country's economic and social institutions still intact, markets for Western goods, such as cotton textiles and machinery, remained disappointing: the self-sufficient communities of China were not disrupted as those in India had been under direct British rule, and opium smuggling by British merchants continued as a major component of China's foreign trade. Western merchants sought further concessions to improve markets. But meanwhile China's weakness, along with the stresses induced by foreign intervention, was further intensified by an upsurge of peasant rebellions, especially the massive 14-year Taiping Rebellion (1850–64).

The Western powers took advantage of the increasing difficulties by pressing for even more favourable trade treaties, culminating in a second war against China (1856–60), this time by France and England. Characteristically, the Western powers invading China played a double role: in addition to forcing a new trade treaty, they also helped to sustain the Chinese ruling establishment by participating in the suppression of the Taiping Rebellion; they believed that a Taiping victory would result in a reformed and centralized China, more resistant to Western penetration. China's defeat in the second war with the West produced a series of treaties, signed at Tientsin with Britain, France, Russia, and the United States, which brought the Western world deeper into China's affairs. The Tientsin treaties provided, among other things, for the right of foreign nationals to travel in the interior, the right of foreign ships to trade and patrol on the Yangtze River, the opening up of more treaty ports, and additional exclusive legal jurisdiction by foreign powers over their nationals residing in China.

Foreign privileges in China. Treaties of this general nature were extended over the years to grant further privileges to foreigners. Furthermore, more and more Western nations—including Germany, Italy, Denmark, The Netherlands, Spain, Belgium, and Austria-Hungary—took advantage of the new opportunities by signing such treaties. By the beginning of the 20th century, some 90 Chinese ports had been opened to foreign control. While the Chinese government retained nominal sovereignty in these ports, de facto rule was exercised by one or more of the powers: in Shanghai, for example, Great Britain and the United States coalesced their interests to form the Shanghai International Settlement. In most of the treaty ports, China leased substantial areas of land at low rates to foreign governments. The consulates in these concessions exercised legal jurisdiction over their nationals, who thereby escaped China's laws and tax collections. The foreign settlements had their own police forces and tax systems and ran their own affairs independently of nominally sovereign China.

These settlements were not the only intrusion on China's sovereignty. In addition, the opium trade was finally legalized, customs duties were forced downward to facilitate competition of imported Western goods, foreign gunboats patrolled China's rivers, and aliens were placed on customs-collection staffs to ensure that China would pay the indemnities imposed by various treaties. In response to these indignities and amid growing antiforeign sentiment, the Chinese government attempted reforms to modernize and develop sufficient strength to resist foreign intrusions. Steps were taken to master Western science and technology, erect shipyards and arsenals, and build a more effective army and navy. The reforms, however, did not get very far: they did not tackle the roots of China's vulnerability, its social and political structure; and they were undertaken quite late, after foreign nations had already established a strong foothold. Also, it is likely that the reforms were not wholehearted because two opposing tendencies were at play: on the one hand, a wish to seek independence and, on the other hand, a basic reliance on foreign support by a weak Manchu government beset with rebellion and internal opposition.

Chinese attempts at modernization

The Open Door Policy. In any event, preliminary attempts to Westernize Chinese society from within did not deter further foreign penetration; nor did the subsequent revolution (1911) succeed in freeing China from Western domination. Toward the end of the 19th century, under the impact of the new imperialism, the spread of foreign penetration accelerated. Germany entered a vigorous bid for its sphere of influence; Japan and Russia pushed forward their territorial claims; and U.S. commercial and financial penetration of the Pacific, with naval vessels patrolling Chinese rivers, was growing rapidly. But at the same time this mounting foreign interest also inhibited the outright partition of China. Any step by one of the powers toward outright partition or sizable enlargement of its sphere of influence met with strong opposition from other powers. This led eventually to the Open Door Policy, advocated by the United States, which limited or restricted exclusive privileges of any one power vis-à-vis the others. It became generally accepted after the anti-foreign Boxer Rebellion (1900) in China. With the foreign armies that had been brought in to suppress the rebellion now stationed in

North China, the danger to the continued existence of the Chinese government and the danger of war among the imperialist powers for their share of the country seemed greater than ever. Agreement on the Open Door Policy helped to retain both a compliant native government and equal opportunity for commerce, finance, and investment by the more advanced nations.

Japanese resistance to colonization

Japan's rise as a colonial power. Japan was the only Asian country to escape colonization from the West. European nations and the United States tried to "open the door," and to some extent they succeeded; but Japan was able to shake off the kind of subjugation, informal or formal, to which the rest of Asia succumbed. Even more important, it moved onto the same road of industrialization as did Europe and the United States. And instead of being colonized it became one of the colonial powers.

Japan had traditionally sought to avoid foreign intrusion. For many years, only the Dutch and the Chinese were allowed trading depots, each having access to only one port. No other foreigners were permitted to land in Japan, though Russia, France, and England tried, but with little success. The first significant crack in Japan's trade and travel barriers was forced by the United States in an effort to guarantee and strengthen its shipping interests in the Far East. Japan's guns and ships were no match for those of Commodore Perry in his two U.S. naval expeditions to Japan (1853, 1854).

The Japanese, well aware of the implications of foreign penetration through observing what was happening to China, tried to limit Western trade to two ports. In 1858, however, Japan agreed to a full commercial treaty with the United States, followed by similar treaties with the Low Countries, Russia, France, and Britain. The treaty pattern was familiar: more ports were opened; resident foreigners were granted extraterritorial rights, as in China; import and export duties were predetermined, thus removing control that Japan might otherwise exercise over its foreign trade.

Many attempts have been made to explain why a weak Japan was not taken over as a colony or, at least, did not follow in China's footsteps. Despite the absence of a commonly accepted theory, two factors were undoubtedly crucial. On the one hand, the Western nations did not pursue their attempts to control Japan as aggressively as they did elsewhere. In Asia the interests of the more aggressively expanding powers had centred on India, China, and the immediately surrounding areas. When greater interest developed in a possible breakthrough in Japan in the 1850s and 1860s, the leading powers were occupied with other pressing affairs, such as thhe 1857 Indian mutiny, the Taiping Rebellion, the Crimean War, French intervention in Mexico, and the U.S. Civil War. International jealousy may also have played a role in deterring any one power from trying to gain exclusive control over the country. On the other hand, in Japan itself, the danger of foreign military intervention, a crisis in its traditional feudal society, the rise of commerce, and a disaffected peasantry led to an intense internal power struggle and finally to a revolutionary change in the country's society and a thoroughgoing modernization program, one that brought Japan the economic and military strength to resist foreign nations.

The opposing forces in Japan's civil war were lined up between the supporters of the ruling Tokugawa family, which headed a rigid hierarchical feudal society, and the supporters of the emperor Meiji, whose court had been isolated from any significant government role. The civil war culminated in 1868 in the overthrow of the Tokugawa government and the restoration of the rule of the Emperor. The Meiji Restoration also brought new interest groups to the centre of political power and instigated a radical redirection of Japan's economic development. The nub of the changeover was the destruction of the traditional feudal social system and the building of a political, social, and economic framework conducive to capitalist industrialization. The new state actively participated in the turnabout by various forms of grants and guarantees to enterprising industrialists and by direct investment in basic industries such as railways, shipbuilding, communications, and machinery. The concentration of resources in the industrial sector was matched by social reforms that eliminated feudal restrictions, accelerated mass education, and encouraged acquisition of skills in the use of Western technology. The ensuing industrialized economy provided the means for Japan to hold its own in modern warfare and to withstand foreign economic competition.

The Meiji Restoration

Soon Japan not only followed the Western path of internal industrialization, but it also began an outward aggression resembling that of the European nations. First came the acquisition and colonization of neighbouring islands: Ryukyu Islands (including Okinawa), the Kuril Islands, Bonin Islands, and Hokkaido. Next in Japan's expansion program was Korea, but the opposition of other powers postponed the transformation of Korea into a Japanese colony. The pursuit of influence in Korea involved Japan in war with China (1894–95), at the end of which China recognized Japan's interest in Korea and ceded to Japan Taiwan, the Pescadores, and southern Manchuria. At this point rival powers interceded to force Japan to forgo taking over the southern Manchuria peninsula. While France, Britain, and Germany were involved in seeking to frustrate Japan's imperial ambitions, the most direct clash was with Russia over Korea and Manchuria. Japan's defeat of Russia in the war of 1904–05 procured for Japan the lease of the Liaotung Peninsula, the southern part of the island of Sakhalin, and recognition of its "paramount interest" in Korea. Still, pressure by Britain and the United States kept Japan from fulfillment of its plan to possess Manchuria outright. By the early 20th century, however, Japan had, by means of economic and political penetration, attained a privileged position in that part of China, as well as colonies in Korea and Taiwan and neighbouring islands.

PARTITION OF AFRICA

By the turn of the 20th century, the map of Africa looked like a huge jigsaw puzzle, with most of the boundary lines having been drawn in a sort of game of give-and-take played in the foreign offices of the leading European powers. The division of Africa, the last continent to be so carved up, was essentially a product of the new imperialism, vividly highlighting its essential features. In this respect, the timing and the pace of the scramble for Africa are especially noteworthy. Before 1880 colonial possessions in Africa were relatively few and limited to coastal areas, with large sections of the coastline and almost all the interior still independent. By 1900 Africa was almost entirely divided into separate territories that were under the administration of European nations. The only exceptions were Liberia, generally regarded as being under the special protection of the United States; Morocco, conquered by France a few years later; Libya, later taken over by Italy; and Ethiopia.

The second feature of the new imperialism was also strongly evident. It was in Africa that Germany made its first major bid for membership in the club of colonial powers: between May 1884 and February 1885, Germany announced its claims to territory in South West Africa (now South West Africa/Namibia), Togoland, Cameroon, and part of the East African coast opposite Zanzibar. Two smaller nations, Belgium and Italy, also entered the ranks, and even Portugal and Spain once again became active in bidding for African territory. The increasing number of participants in itself sped up the race for conquest. And with the heightened rivalry came more intense concern for preclusive occupation, increased attention to military arguments for additional buffer zones, and, in a period when free trade was giving way to protective tariffs and discriminatory practices in colonies as well as at home, a growing urgency for protected overseas markets. Not only the wish but also the means were at hand for this carving up of the African pie. Repeating rifles, machine guns, and other advances in weaponry gave the small armies of the conquering nations the effective power to defeat the much larger armies of the peoples of Africa. Rapid railroad construction provided the means for military, political, and economic consolidation of continental interiors. With the new steamships, settlers and materials could be moved to Africa with greater dispatch, and bulk shipments of raw

materials and food from Africa, prohibitively costly for some products in the days of the sailing ship, became economically feasible and profitable.

Penetration of Islāmic North Africa was complicated, on the one hand, by the struggle among European powers for control of the Mediterranean Sea and, on the other hand, by the suzerainty that the Ottoman Empire exercised to a greater or lesser extent over large sections of the region. Developments in both respects contributed to the wave of partition toward the end of the 19th century. First, Ottoman power was perceptibly waning: the military balance had tipped decisively in favour of the European nations, and Turkey was becoming increasingly dependent on loans from European centres of capital (in the late 1870s Turkey needed half of its government income just to service its foreign debt). Second, the importance of domination of the Mediterranean increased significantly after the Suez Canal was opened in 1869.

French penetration of North Africa

France was the one European nation that had established a major beachhead in Islāmic North Africa before the 1880s. At a time when Great Britain was too preoccupied to interfere, the French captured the fortress of Algiers in 1830. Frequent revolts kept the French Army busy in the Algerian interior for another 50 years before all Algeria was under full French rule. While Tunisia and Egypt had been areas of great interest to European powers during the long period of France's Algerian takeover, the penetration of these countries had been informal, confined to diplomatic and financial manoeuvres. Italy, as well as France and England, had loaned large sums to the ruling *beys* of Tunisia to help loosen that country's ties with Turkey. The inability of the *beys* to service the foreign debt in the 1870s led to the installation of debt commissioners by the lenders. Tunisia's revenues were pledged to pay the interest due on outstanding bonds; in fact, the debt charges had first call on the government's income. With this came increased pressure on the people for larger tax payments and a growing popular dissatisfaction with a government that had "sold out" to foreigners. The weakness of the ruling group, intensified by the danger of popular revolt or a military coup, opened the door further for formal occupation by one of the interested foreign powers. When Italy's actions showed that it might be preparing for outright possession, France jumped the gun by invading Tunisia in 1881 and then completed its conquest by defeating the rebellions precipitated by this occupation.

The Europeans in North Africa. The course of Egypt's loss of sovereignty resembled somewhat the same process in Tunisia: easy credit extended by Europeans, bankruptcy, increasing control by foreign-debt commissioners, mulct-

The European partition of Africa.

ing of the peasants to raise revenue for servicing the debt, growing independence movements, and finally military conquest by a foreign power. In Egypt, inter-imperialist rivalry, mainly between Great Britain and France, reached back to the early 19th century but was intensified under the circumstances of the new imperialism and the construction of the Suez Canal. By building the Suez Canal and financing Egypt's ruling group, France had gained a prominent position in Egypt. But Britain's interests were perhaps even more pressing because the Suez Canal was a strategic link to its empire and its other Eastern trade and colonial interests. The successful nationalist revolt headed by the Egyptian army imminently threatened in the 1880s the interests of both powers. France, occupied with war in Tunisia and with internal political problems, did not participate in the military intervention to suppress the revolt. Great Britain bombarded Alexandria in 1882, landed troops, and thus obtained control of Egypt. Unable to find a stable collaborationist government that would also pay Egypt's debts and concerned with suppressing not only the rebellion but also a powerful anti-Egyptian Mahdist revolt in the Sudan, Britain completely took over the reins of government in Egypt.

The rest of North Africa was carved up in the early 20th century. France, manoeuvring for possession of Morocco, which bordered on her Algerian colony, tried to obtain the acquiescence of the other powers by both secret and open treaties granting Italy a free hand in Libya, allotting to Spain a sphere of influence, and acknowledging Britain's paramountcy in Egypt. France had, however, overlooked Germany's ambitions, now backed by an increasingly effective army and navy. The tension created by Germany led to an international conference at Algeciras (1906), which produced a short-lived compromise, including recognition of France's paramount interest, Spanish participation in policing Morocco, and an open door for the country's economic penetration by other nations. But France's vigorous pursuit of her claims, reinforced by the occupation of Casablanca and surrounding territory, precipitated critical confrontations, which reached their peak in 1911 when French troops were suppressing a Moroccan revolt and a German cruiser appeared before Agadir in a show of force. The resulting settlements completed the European partition of North Africa: France obtained the lion's share of Morocco; in return, Germany received a large part of the French Congo; Italy was given the green light for its war with Turkey over control of Tripoli, the first step in its eventual acquisition of Libya; and Spain was enabled to extend its Río de Oro protectorate to the southern frontier of Morocco. The more or less peaceful trade-offs by the occupying powers differed sharply from the long, bitter, and expensive wars they waged against the indigenous peoples and rulers of Islāmic North Africa to solidify European rule.

The race for colonies in sub-Saharan Africa. The partition of Africa below the Sahara took place at two levels: (1) on paper—in deals made among colonial powers who were seeking colonies partly for the sake of the colonies themselves and partly as pawns in the power play of European nations struggling for world dominance—and (2) in the field—in battles of conquest against African states and tribes and in military confrontations among the rival powers themselves. This process produced, over and above the ravages of colonialism, a wasp's nest of problems that was to plague African nations long after they achieved independence. Boundary lines between colonies were often drawn arbitrarily, with little or no attention to ethnic unity, regional economic ties, tribal migratory patterns, or even natural boundaries.

Colonies in West Africa

Before the race for partition, only three European powers—France, Portugal, and Britain—had territory in tropical Africa, located mainly in West Africa. Only France had moved into the interior along the Sénégal River. The other French colonies or spheres of influence were located along the Ivory Coast and in Dahomey (now Benin) and Gabon. Portugal held on to some coastal points in Angola, Mozambique (Moçambique), and Portuguese Guinea (now Guinea-Bissau). While Great Britain had a virtual protectorate over Zanzibar in East Africa, its actual possessions were on the west coast in the Gambia, the Gold Coast, the Sierra Leone, all of them surrounded by African states that had enough organization and military strength to make the British hesitate about further expansion. Meanwhile, the ground for eventual occupation of the interior of tropical Africa was being prepared by explorers, missionaries, and traders. But such penetration remained tenuous until the construction of railroads and the arrival of steamships on navigable waterways made it feasible for European merchants to dominate the trade of the interior and for European governments to consolidate conquests.

Once conditions were ripe for the introduction of railroads and steamships in West Africa, tensions between the English and French increased as each country tried to extend its sphere of influence. As customs duties, the prime source of colonial revenue, could be evaded in uncontrolled ports, both powers began to stretch their coastal frontiers, and overlapping claims and disputes soon arose. The commercial penetration of the interior created additional rivalry and set off a chain reaction. The drive for exclusive control over interior areas intensified in response to both economic competition and the need for protection from African states resisting foreign intrusion. This drive for African possessions was intensified by the new entrants to the colonial race who felt menaced by the possibility of being completely locked out.

Perhaps the most important stimulants to the scramble for colonies south of the Sahara were the opening up of the Congo Basin by Belgium's king Leopold II and Germany's energetic annexationist activities on both the east and west coasts. As the dash for territory began to accelerate, 15 nations convened in Berlin in 1884 for the West African Conference, which, however, merely set ground rules for the ensuing intensified scramble for colonies. It also recognized the Congo Free State ruled by King Leopold, while insisting that the rivers in the Congo Basin be open to free trade. From his base in the Congo, the King subsequently took over mineral-rich Katanga, transferring both territories to Belgium in 1908.

In West Africa, Germany concentrated on consolidating its possessions of Togoland and Cameroon (Kamerun), while England and France pushed northward and eastward from their bases: England concentrated on the Niger region, the centre of its commercial activity, while France aimed at joining its possessions at Lake Chad within a grand design for an empire of contiguous territories from Algeria to the Congo. Final boundaries were arrived at after the British had defeated, among others, the Ashanti, the Fanti Confederation, the Opobo kingdom, and the Fulani; and the French won wars against the Fon kingdom, the Tuareg, the Mandingo, and other resisting tribes. The boundaries determined by conquest and agreement between the conquerors gave France the lion's share: in addition to the extension of its former coastal possessions, France acquired French West Africa and French Equatorial Africa, while Britain carved out its Nigerian colony.

In southern Africa, the intercolonial rivalries chiefly involved the British, the Portuguese, the South African Republic of the Transvaal, the British-backed Cape Colony, and the Germans. The acquisitive drive was enormously stimulated by dreams of wealth generated by the discovery of diamonds in Griqualand West and gold in Matabeleland. Encouraged by these discoveries, Cecil Rhodes (heading the British South Africa Company) and other entrepreneurs expected to find gold, copper, and diamonds in the regions surrounding the Transvaal, among them Bechuanaland, Matabeleland, Mashonaland, and Trans-Zambezia. In the ensuing struggle, which involved the conquest of the Nbele and Shona peoples, Britain obtained control over Bechuanaland and, through the British South Africa Company, over the areas later designated as the Rhodesias and Nyasaland. At the same time, Portugal moved inland to seize control over the colony of Mozambique. It was clearly the rivalries of stronger powers, especially the concern of Germany and France over the extension of British rule in southern Africa, that enabled a weak Portugal to have its way in Angola and Mozambique.

Rivalry in East Africa

The boundary lines in East Africa were arrived at largely in settlements between Britain and Germany, the two chief rivals in that region. Zanzibar and the future Tanganyika were divided in the Anglo-German treaty of 1890: Britain obtained the future Uganda and recognition of its paramount interest in Zanzibar and Pemba in exchange for ceding the strategic North Sea island of Heligoland (Helgoland) and noninterference in Germany's acquisitions in Tanganyika, Rwanda, and Urundi. Britain began to build an East African railroad to the coast, establishing the East African Protectorate (later Kenya) over the area where the railroad was to be built.

Rivalry in northeastern Africa between the French and British was based on domination of the upper end of the Nile. Italy had established itself at two ends of Ethiopia, in an area on the Red Sea that the Italians called Eritrea and in Italian Somaliland along the Indian Ocean. Italy's inland thrust led to war with Ethiopia and defeat at the hands of the Ethiopians at Adowa (1896). Ethiopia, surrounded by Italian and British armies, had turned to French advisers. The unique victory by an African state over a European army strengthened French influence in Ethiopia and enabled France to stage military expeditions from Ethiopia as well as from the Congo in order to establish footholds on the Upper Nile. The resulting race between British and French armies ended in a confrontation at Fashoda in 1898, with the British army in the stronger position. War was narrowly avoided in a settlement that completed the partition of the region: eastern Sudan was to be ruled jointly by Britain and Egypt, while France was to have the remaining Sudan from the Congo and Lake Chad to Darfur.

Germany's entrance into southern Africa through occupation and conquest of South West Africa touched off an upsurge of British colonial activity in that area, notably the separation of Basutoland (Lesotho) as a crown colony from the Cape Colony and the annexation of Zululand. As a consequence of the South African (Boer) War (1899–1902) Britain obtained sovereignty over the Transvaal and the Afrikaner Orange Free State. (Ha.Ma.)

WORLD WAR I AND THE INTERWAR PERIOD (1914–39)

Postwar redistribution of colonies. After World War I the Allied powers partitioned among themselves both the German overseas colonial holdings and the vast Arab provinces of the Ottoman Empire. They carried out this operation through the League of Nations, which awarded mandates under varying conditions. Great Britain received as mandates Iraq and Palestine (which it promptly split into Transjordan and Palestine proper); the Palestine mandate obligated Britain to respect its contradictory wartime commitments to both Jews and Arabs. France assumed a mandate over both Syria and Lebanon. In Africa the two powers divided Togo and Cameroon between them, Britain acquired Tanganyika (with a few thousand German settlers), Belgium took Rwanda–Urundi, and South Africa received German South West Africa. Italy, as compensation for not sharing in the award of mandates, obtained from Britain the Juba (Giuba) Valley on the Kenya–Somali frontier, and France eventually ceded to Italy a desert area that rounded out Libya's southern frontiers.

League mandates

The interwar years marked the apex of colonial empires throughout the world, and indirect forms of colonial penetration grew with the development of the petroleum industry. Nevertheless, most colonial systems began to show clear signs of strain and even revolt. The Russian Revolution, the Nationalist and Communist successes in China during the 1920s and '30s, the radical nationalism of Kemal Atatürk, all contributed to the rise of political movements opposed to colonialism. The very process of economic modernization, however—with the rise of factories, coordination with the world market, and mass urbanization—did more than any political or cultural factor, taken in itself, to undermine the paternal-militaristic forms of direct colonial domination.

The British Empire. Britain tended toward a decentralized and empirical type of colonial administration, in which some degree of partial decolonization could prepare the way for eventual self-rule. Realizing that direct rule over ancient civilized lands could not last indefinitely, Britain worked for a continued British presence in areas where the empire conferred self-government.

Middle East. At the outset of World War I, Britain had proclaimed a protectorate over Egypt, annulling Ottoman sovereignty; afterward, Egyptian nationalist leaders finally brought the British to recognize Egypt as an independent kingdom in 1922. In 1936–37 Egypt received control over its own economic development, and British military forces were confined to the Suez Canal area. Britain granted Iraq independence in 1932 but retained a military power base in the new kingdom. Both the world strategic balance and the British petroleum industry ruled out any possibility of a real British withdrawal from either of these Middle Eastern states.

Egypt

In Palestine the political claims of Arabs and Jews proved to be irreconcilable, and insurrection, terrorism, and occasional guerrilla warfare marked the whole period of British rule. Finally, in 1939, with war looming, the British decided to limit and eventually terminate the flow of Jewish refugees into Palestine, though not proposing to force the more than 500,000 Jewish inhabitants to live under an Arab national regime. Transjordan, detached from Palestine, became a British protectorate.

India. In India Britain faced a powerful adversary, the Indian National Congress, uniting businessmen and working classes, Hindus of high and low caste, in a common drive toward independence. The Congress never, however, succeeded in bridging the gap that separated the country's Hindu and Sikh majority from its 90,000,000 Muslims. The British met the Indian anticolonial movement half way. In 1919–23 a series of measures gave the Indians a certain degree of self-rule in a "dyarchy" in which elected Indian ministers governed together with British administrators. These constitutional reforms, however, failed to bring the princely states into line with the new trend toward self-rule. Though Mahatma Gandhi denounced the new system as a "whited sepulchre," Congress in fact began to participate in the governmental process. Under the constitution granted in 1935–37, the British maintained separate voting rolls for the Muslim minority, in order to ensure its proportional representation; in 1939 relations between Britain and the Congress Party were tense, but India was clearly headed for independence in some form.

Indian dyarchy

In 1937 the British gave a separate constitution to Burma. Ceylon (renamed Sri Lanka in 1972) had been separate and self-governing from 1931.

Africa. In British Africa decolonization progressed more slowly, but London began to accept it as an ultimate outcome. In Kenya, for example, the British government refused to grant the 20,000 European settlers in the "white highlands" any kind of direct political power over the mass of tribal blacks who constituted the colony's overwhelming majority. In British West Africa the passage from direct colonial government to self-rule by a black elite had started by 1939, there being no white settlers or Indian merchants (as there were in East Africa) to complicate matters. Only in the mining areas of Northern Rhodesia (the Copperbelt) and in Southern Rhodesia, where white farmer settlers enjoyed self-government and caste privileges over a disenfranchised black majority, did decolonization make no headway at all.

Overseas France. France, in contrast to Britain, preferred centralized and assimilative methods in an effort to integrate its colonies into a greater Overseas France. It made no progress in colonial devolution and refused even to grant independence to Syria and Lebanon. In North Africa the French energetically implanted large agrarian capitalist enterprises as well as some industries connected with the area's mineral wealth. These modern production centres and infrastructures were directed and financed by metropolitan French business and were staffed and operated by a large, politically aggressive European settler population. The Muslim majority was subordinate both politically and economically; North African peasants struggled to subsist on the margins. Overt resistance was strongest in Morocco, where a rural Muslim rebellion endangered both the French and the Spanish protectorates. Abd el-Krim, a Berber Moroccan leader who combined tradition with

Abd el-Krim

modern nationalism, waged a brilliant five-year campaign till a combined French and Spanish force finally defeated him in 1926. After 1934, resistance to France revived in Morocco, this time in the cities. In Tunisia resistance was centred in Habib Bourguiba's constitutional party; in Algeria the urban Muslim middle classes merely asked for true civil rights and integration. The French Communist Party did not move to mobilize the peasant masses in an anticolonial struggle, and, in consequence, future rebellion in the Maghrib was to be Arab nationalist and not Marxist in its leadership and doctrines.

Matters were different in French Indochina, where the growth of a modern, French-directed agricultural economy had thrown masses of peasants into debt slavery. The circumstances favoured the formation of an independence movement much influenced by both the Chinese Kuomintang (Nationalist Party) and the Chinese Communist Party; the movement in the 1930s took the form of a Communist party under the leadership of Ho Chi Minh.

French sub-Saharan Africa attracted no European settler population. The French colonial authorities promoted a shift from subsistence to market economies, and their methods, including labour conscription for public works, led to protest and questions in the French parliament. The results, guaranteed by a protective tariff linking the colonies to France, were solid but unspectacular.

Axis Powers. In the 1930s an aggressive new colonialism devoloped on the part of the Axis Powers, which developed a new colonial doctrine ("living space" in German geopolitics, the "empire" in Italian Fascist ideology, the "co-prosperity sphere" in Japan) aiming at the repartition of the world's colonial areas, justified by the supposed racial superiority, higher birth rates, and greater productivity that the Axis Powers enjoyed as against the "decadent" West. To this the Japanese added a slogan of their own, "Asia for the Asians." In fact, the three powers aimed at carving out for themselves vast, self-sufficient empires. Though intent on a new colonialism of their own, they had to use anticolonialism as a political instrument before and during World War II; in doing so, they helped in the process of world decolonization.

Fascist Italy's first colonial war was a long, bloody campaign in Cyrenaica that lasted until the early 1930s, when Italy began developing Libya as a place of settlement for Italian peasants. Then a dispute over the border between Italian Somaliland and Ethiopia (1934) gave the Italian dictator, Benito Mussolini, the opportunity to move against the African power that had routed Italian armies at Adowa. In October 1935 Italian troops from Eritrea moved into the Tigre province of northern Ethiopia, although war was never declared. Ethiopia, underequipped and feudal, could not long hold out in open combat, especially against Italian air attacks. In May 1936 Italian motorized columns reached Addis Ababa, and the Emperor went into exile. Mussolini proclaimed the Italian "empire" in East Africa. In reality, however, Ethiopian feudal chiefs continued violent resistance, even in the environs of the capital, while the Italians massacred hundreds of nobles, clergy, and commoners in an effort to repress Ethiopia by terror. In this their success was limited. The Italians built roads and kept control over all principal communication lines, but they never subdued the mountainous hinterland.

Italy in Ethiopia

The Greater East Asia Co-prosperity Sphere, Japan's new order, amounted to a self-contained empire from Manchuria to the Dutch East Indies, including China, Indochina, Thailand, and Malaya as satellite states. Japan intended to exclude both European imperialism and Communist influence from the entire Far East, while ensuring Japanese political and industrial hegemony.

The United States and the Soviet Union. During World War I the United States purchased the Virgin Islands from Denmark (1917), but it acquired no new colonies thereafter. In the 1920s the United States agreed to leave unfortified its possessions beyond Hawaii, in exchange for Japan's accepting naval limitations. The Philippines, by the Tydings–McDuffie Act of 1934, were to become independent on July 4, 1946. Until U.S.–Japanese relations began to worsen, in 1939, U.S. possessions in the Pacific counted for little in world affairs. On the other hand, the United States established or continued virtual protectorates in Cuba, Haiti, the Dominican Republic, Nicaragua, and Panama during the Harding and Coolidge administrations (1921–29), a trend reversed under Hoover and Roosevelt, particularly under the latter's Good Neighbor Policy toward Latin America.

Roosevelt's Good Neighbor Policy

The new Soviet Russian regime succeeded, after years of civil and foreign war, in regaining the Asian possessions of its tsarist predecessor. The Caucasus was repossessed step by step between 1919 and 1921; after the mountain areas and Azerbaijan were brought back under Soviet control, Armenia was partitioned between Russia and Turkey. Then Georgia, an independent parliamentary republic, was overrun by the Red Army. Russian Turkistan was subdued by 1922, and the khanates of Khiva and Bukhara were suppressed. By 1922, Outer Mongolia was also solidly linked to the Soviet state. Nevertheless, the Russian revolutionary government was ideologically opposed to colonialism, especially where it had no colonial interests that it cared to defend. In general, the Soviet authorities hesitated during the interwar period between the alternatives of backing liberation movements of "national bourgeoisies" and supporting peasant revolutionary parties.

In Central Asia the Soviet authorities followed a moderate line up to 1928, but with the advent of Stalin a new policy, consisting in purges of national leaders, increasing industrialization, and forced settlement of nomad populations, led to a great increase in the proportion of European settlers, mostly Russians and Ukrainians, to native Muslims. During the 1930s the Kazakhs declined sharply in absolute numbers as well as in ratio to the Europeans in their areas. Other Muslim nationalities, especially the Uzbeks, stemmed the Slavic tide of settlement only by virtue of their birth rates, which greatly exceeded those of the Russians and Ukrainians.

WORLD WAR II (1939–45)

Although the Axis Powers failed in their global strategy, they crippled European colonial rule in Asia.

Asia. Japan conquered its Greater East Asia Co-prosperity Sphere and arrived at the gates of India, displacing British, Dutch, and French colonial rulers as well as the Americans in Guam and the Philippines. The Japanese had to allow some margin of freedom to their satellite regimes in Burma and Indonesia in both of which preexisting local parties proved capable of creating sovereign states after the war. On August 17, 1945, Sukarno declared Indonesia independent. Indonesia had had a long history of Muslim, nationalist, and Communist agitation against the Dutch; with captured Japanese arms, Indonesia could resist reimposition of Dutch authority.

Indonesian independence

In India the Congress Party, though totally unsympathetic to the Axis, tried to take advantage of Britain's wartime extremity in order to secure immediate independence. The Muslim League supported the British administration during the war but demanded a sovereign Muslim homeland (Pakistan) as a postwar objective. By 1945 direct British rule in India was coming to an end, but the contest between Britain, the Congress Party, and the Muslim League clouded any final settlement.

Middle East. In the Middle East, Britain returned to forms of direct colonial control as Axis forces drew near, and in June–July 1941 it occupied Syria and Lebanon, under the guise of Free French administration. With Beirut and Damascus secured, the British supported Syrian and Lebanese independence from France; the two states were incorporated into the sterling area. Only U.S. and Soviet support guaranteed the independence of the two republics (1944) and their subsequent admission to the United Nations.

In Egypt, when Axis forces in 1941 and 1942 came within striking distance of Alexandria, both the king, Farouk, and groups of dissident army officers were ready to welcome them and turn against the British. In February 1942 the British minister forced the King to appoint a government willing to cooperate with the Anglo-Americans; the defeat of the Germans in the Egyptian desert later that year put Egypt firmly in the Allied camp. Nevertheless much anti-

British and anticolonial bitterness remained in Egypt, with postwar consequences.

Iran

At the outset of World War II Iran was pro-German, and in August 1941 the Soviet Union and Britain jointly occupied the country, which then became the main supply line connecting the Soviet Union with the Western Allies. In 1942, in a three-power treaty, both Britain and the Soviet Union promised to leave Iran six months after the end of the war. Notwithstanding such commitments, the Soviet Union began to build spheres of influence in northern Iran; in 1944 the Soviet Union brought pressure to bear on Iran for an oil concession.

During the final years of World War II the United States became vitally interested in the Middle East because of United States petroleum ventures in Saudi Arabia and because of strategic considerations. By the end of the war it was clear to both the Soviet Union and Britain that the United States, as a world power, would support no imposition of direct colonial controls in the postwar Middle East.

Africa. During World War II Italy lost its entire colonial domain. Ethiopia was restored as an independent empire, and the other colonies eventually came under UN jurisdiction, in the first step toward decolonization in the African continent.

DECOLONIZATION FROM 1945

In the first postwar years there were some prospects that (except in the case of the Indian subcontinent) decolonization might come gradually and on terms favourable to the continued world power positions of the western European colonial nations. After the French defeat at Dien Bien Phu (Vietnam) in 1954 and the abortive Anglo-French Suez expedition of 1956, however, decolonization took on an irresistible momentum, so that by the mid-1970s only scattered vestiges of Europe's colonial territories remained.

The reasons for this accelerated decolonization were threefold. First, the two postwar superpowers, the United States and the Soviet Union, preferred to exert their might by indirect means of penetration—ideological, economic, and military—often supplanting previous colonial rulers; both the United States and the Soviet Union took up positions opposed to colonialism. Second, the mass revolutionary movements of the colonial world fought colonial wars that were expensive and bloody. Third, the war-weary public of western Europe eventually refused any further sacrifices to maintain overseas colonies.

In general, those colonies that offered neither concentrated resources nor strategic advantages and that harboured no European settlers won easy separation from their overlords. Armed struggle against colonialism centred in a few areas, which mark the real milestones in the history of postwar decolonization.

British decolonization, 1945–56. General elections in India in 1946 strengthened the Muslim League. In subsequent negotiations, punctuated by mass violence, the Congress Party leaders finally accepted partition as preferable to civil war, and in 1947 the British evacuated the subcontinent, leaving India and a territorially divided Pakistan to contend with problems of communal strife.

Far more damaging to Britain's world position as a great power was the end of the Palestine mandate. The British would have favoured an Arab state in Palestine, tied to the British system in the Middle East, with Jews as a permanent minority. The Jewish national movement, however, succeeded in making this policy both costly and unpopular; in particular, the U.S. and Soviet governments began to see a Jewish state in Palestine as a necessary solution to the problem of Europe's surviving Jewry. All Arab spokesmen expressed intransigent opposition to any two-nation solution. Britain, isolated internationally, threw the problem into the lap of the United Nations; in November 1947 the General Assembly voted for partition. Britain, exhausted both politically and financially, decided to leave by May 15, 1948. The Jewish national movement's military branch succeeded in defeating the Palestine Arab terrorist and guerrilla bands step by step, and after British evacuation, and the declaration of Israel's independence, the Arab states in turn suffered a series of military defeats.

End of the Palestine mandate

The new Jewish state, recognized by the United States, the Soviet Union, and France, reached an uneasy armistice with the Arabs in 1949, and Britain's position in the Middle East began to crumble.

The Arab chain reaction against Britain started in Egypt, where in July 1952 a group of army officers seized power. By the end of 1954, Gamal Abdel Nasser had induced Britain to accept total withdrawal by June 1956 and set to work to undermine Britain's position in Iraq and Jordan. In June 1956 the British troops quit Suez on schedule. At that point Britain's Middle Eastern position, which depended on a chain of bases and friendly governments, was imperilled. Iran had moved close to the United States, warding off Soviet penetration and expropriating British oil holdings. Now Cyprus and the Persian Gulf oil ports remained the last outposts under British control in the Middle East. Nasser's next move was to cut the link between them. On July 26, 1956, he nationalized the Suez Canal Company, ending the last vestiges of European authority over that vital waterway and precipitating the most serious international crisis of the postwar era.

Wars in overseas France, 1945–56. The constitution of the French Fourth Republic provided for token decentralization of colonial rule, and cycles of revolt and repression marked French history for 15 years after the end of World War II. The first colonial war was in Indochina, where a power vacuum, caused by Japan's removal after wartime occupation, gave a unique opportunity to the Communist Viet Minh. When in 1946 the French Army tried to regain the colony, the Communists, proclaiming a republic, resorted to the political and military strategies of Mao Tse-tung to wear down and eventually defeat France. All chances for maintaining a semicolonial administration in Indochina ended when the Communists won the civil war in China (1949). Eventually, in 1954, when the French engaged the Communist armies in a pitched battle at Dien Bien Phu, the Communists won with the help of new heavy guns supplied by the Chinese. The Fourth Republic left Indochina under the terms of the Geneva Accords (1954), which set up two independent regimes.

Indochina War

By 1954 French North Africa was beginning to stir; guerrilla warfare occurred in both Morocco (where the French had deposed and exiled Sultan Muḥammad V) and Tunisia. On November 1, 1954, Algerian rebels began a revolt against France in which for the first time urban Muslims and Muslim peasants joined forces. In March 1956 France accorded complete independence to Morocco and Tunisia, while the army concentrated on a "revolutionary" counterinsurgent war in order to hold Algeria, where French rule had solid local support from about a million European settlers. The Muslim rebels depended on help from the Arab world, especially Egypt. Hence the French took the initiative, in October 1956, in forming an alliance with Nasser's principal adversaries, Britain and Israel, to reclaim the Suez Canal for the West and overthrow the pan-Arab regime in Cairo.

The Sinai–Suez campaign (October–November 1956). On October 29, 1956, Israel's army attacked Egypt in the Sinai Peninsula, and within 48 hours the British and French were fighting Egypt for control of the Suez area. But the Western allies found Egyptian resistance more determined than they had anticipated. Before they could turn their invasion into a real occupation, U.S. and Soviet pressure forced them to desist (November 7). The Suez campaign was thus a political disaster for the two colonial powers. The events of November 1956 showed the decline of European colonialism to be irreversible.

Algeria and French decolonization, from 1956. Between 1956 and 1958 French army commanders in Algeria, politically radicalized, tried to promote a new Franco-Muslim society in preparation for Algeria's total integration into France. Hundreds of thousands of rural Muslims were resettled under French military control, Algiers was successfully cleared of all guerrilla cells, French investments in Saharan petroleum grew, and, in a dramatic climax, a coalition of European settlers, colonial troops, and armed forces commanders in May 1958 refused further obedience to the Fourth Republic.

Charles de Gaulle, first president of the Fifth Republic,

De Gaulle and decolonization

thought that the effort of fighting colonial wars had prevented France from developing nuclear weapons and also came to realize that Algerian Muslims could not be converted to a French identity. He began to negotiate with the rebels; the negotiations culminated in a plebiscite, French evacuation, and proclamation of the independence of Muslim Algeria (July 1962). De Gaulle then proceeded to develop a nuclear striking force as the new foundation of France's status as a great power. The Fifth Republic moved rapidly toward freeing the colonies of sub-Saharan Africa, and France's colonial realm became vestigial and insular.

British decolonization after 1956. During the 15 years after the Suez disaster, Britain divested itself of most colonial holdings and abandoned most power positions in Africa and Asia. In 1958 the pro-British monarchy in Iraq fell; during the 1960s Cyprus and Malta became independent; and in 1971 Britain left the Persian Gulf. Of the imperial lifelines, only Gibraltar remains. After 1956 Britain moved rapidly to grant independence to its black African colonies. One British colony, Southern Rhodesia (now Zimbabwe), broke away unilaterally in 1965.

In Malaya the British fought a successful counterinsurgent war against a predominantly Chinese guerrilla movement and then turned over sovereignty to a federal Malaysian government (1957). In 1971 the Royal Navy left Singapore (an independent state since 1965), thus ending British presence in the Far East except at Hong Kong and (until 1983) at Brunei.

Britain's world position shrank, in effect, to membership in the North Atlantic Treaty Organization and the European Economic Community, with the postcolonial Commonwealth decreasing in importance.

Dutch, Belgian, and Portuguese decolonization. After World War II the Dutch tried to regain some of their lost control in Indonesia. The Sukarno regime held fast through three years of intermittent war, however, and the Dutch found no allies and no international support. In 1950 Indonesia became a centralized, independent republic.

The Belgian Congo

The Belgian administration in the Congo had never trained even a small number of Africans much beyond the grade-school level. When Britain and France began to divest themselves of their colonies, Belgium was in no position to impose on the Congo a schedule of its own for gradual withdrawal. The abrupt granting of independence to the Belgian Congo in the summer of 1960 led to a series of civil wars, with intervention by the UN, European business interests employing white mercenaries, and other outside forces. In 1965, Joseph Mobutu (later Mobutu Sese Seko) gained control over the central government and created an independent African state, renamed Zaire in 1971.

Portugal, in the 20th century the poorest and least developed of the western European powers, was the first nation (with Spain) to establish itself as a colonial power and the last to give up its colonial possessions. In Portuguese Africa during the authoritarian regime of António de Oliveira Salazar, the settler population had grown to about 400,000. After 1961 pan-African pressures grew, and Portugal found itself mired in a series of colonial wars, while the development of mining in Angola and Mozambique revealed hitherto unknown economic assets. In 1974 the armed forces overthrew the successors to Salazar, and in the unstable political situation it became clear that Portugal would cut its colonial ties to Africa. Portuguese Guinea (Guinea-Bissau) became independent in 1974. In June 1975 Mozambique achieved independence as a people's republic; in July 1975 São Tomé and Príncipe became an independent republic; and in November of the same year Angola, involved in a civil war between three rival liberation movements, also received sovereignty.

Conclusion. Historians will long debate the heritage of economic development, mass bitterness, and cultural cleavage that colonialism has left to the world, but the political problems of decolonization are grave and immediate. The international community is laden with minute states unable to secure either sovereignty or solvency and with large states erected without a common ethnic base. The world's postcolonial areas often have been scenes of protracted and violent conflicts: ethnic, as in Nigeria's Biafran war (1967–70); national–religious, as in the Arab–Israeli conflicts, the civil wars in Cyprus, and the continual clashes between India and Pakistan; or purely political, as in the confrontation between Communist and Nationalist regimes in the divided Korean Peninsula. Most ominously, the fading away of colonialism has created power vacuums, notably in the Indian Ocean area, into which the two superpowers have rushed. The end of colonialism has not brought with it the spread of new, neatly divided nation-states throughout the world, nor has it abated or eased rivalry between the great powers.

Post-colonial conflict

(1598–1600)—a useful and accessible edition has been edited by JOHN MASEFIELD (1927–28); J.C. BEAGLEHOLE, *The Exploration of the Pacific,* 3rd ed. (1966); *The Journals of Captain James Cook on His Voyages of Discovery,* 3 vol. (1955–67); MARGERY PERHAM and JACK SIMMONS (eds.), *African Discovery,* 2nd ed. (1957); ERNEST SCOTT (ed.), *Australian Discovery,* 2 vol. (1929, reprinted 1966), a wide selection of passages from the journals of African and Australian explorers, with comment; CLEMENTS MARKHAM, *The Lands of Silence* (1921); ROBERT HUXLEY (ed.), *Scott's Last Expedition,* 2nd enl. ed. (1964).

European colonization (European expansion before 1763): OTTO BERKELBACH VAN DER SPRENKEL, *Die überseeische Welt und ihre Erschliessung* (1959), is a collaborative work by specialists covering all areas and subjects included here. ROMOLA and ROGER C. ANDERSON, *The Sailing-Ship,* 2nd ed. (1980), offers a concise account of sailing until the advent of steam. WILBUR CORTEZ ABBOTT, *The Expansion of Europe,* 2nd rev. ed., 2 vol. (1938), covers colonialism to 1815, with much attention to European backgrounds. JOHN H. PARRY, *The Age of Reconnaissance,* 2nd ed. (1966), is a history of discovery and conquest to 1650, offering a good scientific and maritime survey. EDGAR PRESTAGE, *The Portuguese Pioneers* (1933, reprinted 1967), is the best work in English on Portuguese voyages. CHARLES R. BOXER, *The Portuguese Seaborne Empire, 1415–1825* (1969), covers the older Portuguese empire by topics. ROGER B. MERRIMAN, *The Rise of the Spanish Empire in the Old World and the New,* 4 vol. (1918–34, reprinted 1962), follows Spain in America to the death of Philip II; LOUIS A. HARTZ (ed.), *The Founding of New Societies* (1964), presents a highly original series of essays on the colonization of Spanish America, Canada, South Africa, and the 13 colonies. *The Cambridge Economic History of Europe,* 2nd ed., vol. 4 (1967), covers the economies of the early Dutch, French, and English empires. SHEPARD B. CLOUGH and RICHARD T. RAPP, *European*

Economic History, 3rd ed. (1975), are especially good for the effects of the discoveries on Europe. GEORGE MASSELMAN, *The Cradle of Colonialism* (1963), describes the Dutch early activities in the East, providing a good European background. CHARLES R. BOXER, *The Dutch Seaborne Empire, 1600–1800* (1965), is a major work on the great age of Dutch imperialism. HERBERT I. PRIESTLEY, *France Overseas* (1938, reprinted 1966), presents a fairly good, if somewhat disjointed, account of early French overseas activity. ELI HECKSCHER, *Der Merkantilismus,* 2 vol. (1932; Eng. trans., *Mercantilism,* 2nd ed., 2 vol., 1955), is the acknowledged standard work on theoretical and historical mercantilism. ERIC WILLIAMS, *Capitalism and Slavery* (1944, reprinted 1966); and FRANK J. KLINGBERG, *The Anti-Slavery Movement in England* (1926, reprinted 1968), have chapters on the early slave trade. ALFRED T. MAHAN, *The Influence of Sea Power upon History, 1660–1783* (1890, many later editions); and LAWRENCE H. GIPSON, *The British Empire Before the American Revolution,* 15 vol. (1936–70; rev. ed., 1958–), describe the colonial wars in detail.

European expansion since 1763: DAVID K. FIELDHOUSE, *The Colonial Empires* (1966), and *Colonialism, 1870–1945* (1980), are useful general surveys of the growth and decline of empires from the 18th and 19th centuries. On the British Empire the best source is *The Cambridge History of the British Empire,* especially vol. 2, *The Growth of the New Empire, 1783–1870,* 2nd ed. (1963) and vol. 3, *The Empire Commonwealth, 1870–1919,* 2nd ed. (1967). HENRI BRUNSCHWIG, *Mythes et réalités de l'impérialisme colonial français (1871–1914)* (1960; Eng. trans., *French Colonialism, 1871–1914,* 1966), presents the case against the economic interpretation of French colonialism. A sociological study of how French colonialism operated will be found in JEAN SURET-CANALE, *L'Afrique noire: occidentale et centrale,* vol. 2, *L'Ère coloniale, 1900–1945* (1964; Eng. trans., *French Colonialism in Tropical Africa, 1900–1945,* 1971). PROSSER GIFFORD and WILLIAM R. LOUIS (eds.), *Britain and Germany in Africa* (1967), and *France and Britain in Africa* (1971), contain useful collections of essays on British, German, and French colonialism. The scramble for Africa viewed as part of Britain's striving for security in the Mediterranean and the East is forcefully argued in RONALD ROBINSON and JOHN GALLAGHER with ALICE DENNY, *Africa and the Victorians* (1961). On the growth of empire in the Far East, MICHAEL EDWARDES, *Asia in the European Age, 1498–1955* (1962), should be consulted; but see also this history as examined by an Asian in K.M. PANIKKAR, *Asia and Western Dominance,* new ed. (1959, reprinted 1969). An illuminating comparative study of colonial policies is contained in JOHN S. FURNIVALL, *Colonial Policy and Practice: A Comparative Study of Burma and Netherlands India* (1956). For a Marxist view of the impact of colonialism as related to the problems of economic development of the former colonies, see PAUL A. BARAN, *The Political Economy of Growth,* 2nd ed. (1962). U.S. expansion from the Civil War to the Spanish–American War is explored by WALTER LAFEBER in *The New Empire* (1963); and the economic aspects of U.S. expansionism are discussed by HARRY MAGDOFF in *The Age of Imperialism* (1969), and *Imperialism: From the Colonial Age to the Present* (1978). HERBERT FEIS, *Europe, the World's Banker, 1870–1914* (1930, reprinted 1964), is a useful reference work on the connection between world finance and diplomacy before World War I. A standard and detailed diplomatic history of the new imperialism is found in WILLIAM L. LANGER, *The Diplomacy of Imperialism, 1890–1902,* 2nd ed. (1950, reprinted 1965). The psychological impact of colonialism, viewed from an African perspective, is explored in FRANTZ FANON, *Les Damnés de la terre* (1961; Eng. trans., *The Wretched of the Earth,* also as *The Damned,* 1963). The case against the continuation of Western domination in the period of decolonization is found in KWAME NKRUMAH, *Neo-Colonialism: The Last Stage of Imperialism* (1965, reprinted 1981). Theories of imperialism are discussed in JOHN A. HOBSON, *Imperialism,* rev. ed. (1938, reprinted 1975); LENIN, *Imperialism, the Highest Stage of Capitalism* (1939; originally published in Russian, 1917); JOSEPH SCHUMPETER, *Imperialism and Social Classes,* ed. by PAUL M. SWEEZY (1951); ARCHIBALD P. THORNTON, *Imperialism in the Twentieth Century* (1978); and WOLFGANG J. MOMMSEN, *Imperialismustheorien,* 2nd ed. (1979; Eng. trans., *Theories of Imperialism,* (1980).

Ancient European Religions

For roughly 20,000 years, from the Upper Paleolithic period to the beginning of the Bronze Age (*c.* 3000 BC), the continent of Europe was home to a matrifocal, pre-agrarian culture, sedentary and peaceful, extending from the eastern shores of the Black and Mediterranean seas to the Aegean and Adriatic seas. To denote this period prior to the 3rd millennium BC, by which time Indo-European invaders from the steppe region north of the Black Sea had imposed their language and their patriarchal, violent culture across the continent, archaeologists use the term "Old Europe." (The term has also been used to describe a late phase in the development of Indo-European languages.)

According to archaeological evidence, the Old Europeans worshiped a goddess represented either as a corpulent woman similar to the Paleolithic "Venus" or as a waterbird or snake-woman. The latter type, having an elongated neck and prominent buttocks, sometimes strikingly suggests the form of a phallus. An incomplete list of the goddess' companions would include the bear, the bee, the bull, the deer, the dog, the hare, the hedgehog, the hegoat, the turtle, and the toad (the last associated with the iconography of the goddess in childbirth). After the Indo-European invasions, which began in about the mid-5th millennium BC and continued for some 2,000 years, the goddess cult survived in ancient Greece and western Anatolia in the worship of such deities as Hecate, Artemis, and Kubaba. There is no consensus of interpretation among scholars regarding the iconography of the goddess, yet her absolute predominance over male representations is unmistakable. Some scholars believe that the builders of such western European megalithic monuments as Stonehenge in southwestern England, whose chronology roughly coincides with that of Old Europe, were also goddess worshipers.

Scholars have long hypothesized an underlying relationship among ancient Western languages. In 1786, in his presidential address to the Royal Asiatic Society of Bengal, the British Orientalist Sir William Jones postulated the common ancestry of Latin, Greek, and Sanskrit. The first linguist to undertake the study of this relationship was the German Franz Bopp in the 19th century. Thomas Young, the 19th-century physician and Egyptologist who helped decipher the Rosetta Stone, in 1814 coined the term "Indo-European" to encompass the ancient languages Sanskrit, Old Iranian, Hittite, Greek, and Latin, together with the Slavic, Romance, Germanic, and Celtic language groups of modern Europe. In 1819 the German philosopher Friedrich von Schlegel adopted the word "Aryan" (which properly is the name of a people who in prehistoric times settled in what is now Iran and northern India) to designate the newly discovered "race"; four years later the German Orientalist Heinrich Julius Klaproth invented the term "Indo-German," which is no more legitimate than "Indo-Slav" or "Indo-Roman," but which was adopted out of national pride. Although 19th-century philologists took quite seriously the reconstruction of the Proto-Indo-European language—which was supposed to be the common ancestor of all Indo-European languages—to the point that they conducted correspondence with one another in this artificial idiom, it has remained debatable whether or not actual linguistic unity ever existed among Indo-European peoples.

As to the existence of a Proto-Indo-European homeland, the difficult interpretation of linguistic and archaeological data has led to a proliferation of theories, most of which, however, overlap. The American archaeologist Marija Gimbutas devised the theory of the Kurgan (Turkic and Russian: "barrow," or "artificial mound") culture of seminomadic Proto-Indo-European herdsmen whose original territory encompassed the lower Volga River basin. According to Gimbutas, these patriarchal pastoralists worshiped celestial and warlike gods associated with horses, cattle, and weapons.

About 4500 BC, these people embarked on a series of broad waves of expansion, and after the second wave (*c.* 3500 BC) a secondary homeland was established in the Danube River basin, roughly coinciding with what many linguists consider to be the Proto-Indo-European homeland. Although this designation has often been restricted to the Balkan Peninsula and the northern coast of the Black Sea, it can be said to extend from southern Scandinavia to the Balkans and from the Black Sea to the Rhine River, a region that also corresponds with the diffusion of so-called corded-ware pottery. The main linguistic argument for this larger designation is based on what scholars call "macrohydronymy," *i.e.*, the names of rivers longer than 300 miles (500 kilometres) within the above-mentioned territory. Twenty-six such rivers have Indo-European names derived from roots meaning "water," "river," "marsh," and the like; and the first non-Indo-European hydronyms are Kama and Ural in the east and Liger (Loire) and Garumna (Garonne) in the west.

Thus, in the period between *c.* 3500 and *c.* 2500 BC the Indo-European languages became distributed in Europe over an area stretching from the Alps and the Rhine River in the west to the Don River in the east, and from the North and Baltic seas and the Western Dvina River in the north to the Balkan Peninsula and western Asia Minor (Anatolia) in the south.

In the late 20th century some scholars have used linguistic evidence (including hydronymy) to propose that the original homeland of the Indo-Europeans was in the Middle East and encompassed eastern Anatolia, the southern Caucasus region, and northern Mesopotamia. While this theory gained only a few adherents, it did point up the exceedingly complex and problematic nature of any such model.

If the description, or even the existence, of a common language and a common homeland of most Bronze Age Europeans (1600–1200 BC; the main exception being the Finns, a non-Indo-European, Uralic people) is open to question, all the more so does their religion elude reconstruction. Common religious themes and structures among Indo-European peoples have been emphasized since the emergence of comparative mythology in the mid-19th century. The French philologist Georges Dumézil in the mid-20th century proposed a tripartite model of Indo-European society, encompassing three groups distinguished by "social function": priests, warriors, and producers. Influenced by the French sociologist Émile Durkheim (1858–1917), who defined religion as a system of symbols encoding the rules of society, Dumézil envisioned an Indo-European religion reflecting the tripartite social order. This model, for which he found striking evidence in the major Indo-European pantheons, remained the principal focus of his work for almost 50 years. In the classic summary of his position (1958), Dumézil explicitly stated that only Indo-European societies exhibited tripartition and that its occurrence in other societies indicates Indo-European influence. Obviously, this assertion weakens his argument, but his structural scheme has opened new perspectives in the search for a common foundation among Indo-European religions. (I.P.C.)

This article treats the beliefs in and organized worship and service of gods or other supernatural powers by the various cultural groups that flourished on the continent of Europe before or concurrently with the advent of the Christian religion. For coverage of related topics in the *Macropædia* and *Micropædia*, see the *Propædia*, section 822, and the *Index*.

The article is divided into the following sections:

Celtic religion

The Celts, an ancient Indo-European people, reached the apogee of their influence and territorial expansion during the 4th century BC, extending across the length of Europe from Britain to Asia Minor. From the 3rd century BC onward their history is one of decline and disintegration, and with Julius Caesar's conquest of Gaul (58–51 BC) Celtic independence came to an end on the European continent. In Britain and Ireland this decline moved more slowly, but traditional culture was gradually eroded through the pressures of political subjugation; today the Celtic languages are spoken only on the western periphery of Europe, in restricted areas of Ireland, Scotland, Wales, and Brittany (in this last instance largely as a result of immigration from Britain from the 4th to the 7th century AD). It is not surprising, therefore, that the unsettled and uneven history of the Celts has affected the documentation of their culture and religion.

SOURCES

Two main types of sources provide information on Celtic religion: the sculptural monuments associated with the Celts of continental Europe and of Roman Britain, and the insular Celtic literatures that have survived in writing from medieval times. Both pose problems of interpretation. Most of the monuments, and their accompanying inscriptions, belong to the Roman period and reflect a considerable degree of syncretism between Celtic and Roman gods; even where figures and motifs appear to derive from pre-Roman tradition, they are difficult to interpret in the absence of a preserved literature on mythology. Only after the lapse of many centuries—beginning in the 7th century in Ireland, even later in Wales—was the mythological tradition consigned to writing, but by then Ireland and Wales had been Christianized and the scribes and redactors were monastic scholars. The resulting literature is abundant and varied, but it is much removed in both time and location from its epigraphic and iconographic correlatives on the

Problems of interpretation

Continent and inevitably reflects the redactors' selectivity and something of their Christian learning. Given these circumstances it is remarkable that there are so many points of agreement between the insular literatures and the continental evidence. This is particularly notable in the case of the Classical commentators from Poseidonius (*c.* 135–*c.* 51 BC) onward who recorded their own or others' observations on the Celts.

THE CELTIC GODS

The locus classicus for the Celtic gods of Gaul is the passage in Caesar's *Commentarii de bello Gallico* (52–51 BC; *The Gallic War*) in which he names five of them together with their functions. Mercury was the most honoured of all the gods and many images of him were to be found. Mercury was regarded as the inventor of all the arts, the patron of travelers and of merchants, and the most powerful god in matters of commerce and gain. After him the Gauls honoured Apollo, Mars, Jupiter, and Minerva. Of these gods they held almost the same opinions as other peoples did: Apollo drives away diseases, Minerva promotes handicrafts, Jupiter rules the heavens, and Mars controls wars.

In characteristic Roman fashion, however, Caesar does not refer to these figures by their native names but by the names of the Roman gods with which he equated them, a procedure that greatly complicates the task of identifying his Gaulish deities with their counterparts in the insular literatures. He also presents a neat schematic equation of god and function that is quite foreign to the vernacular literary testimony. Yet, given its limitations, his brief catalog is a valuable and essentially accurate witness. In comparing his account with the vernacular literatures, or even with the continental iconography, it is well to recall their disparate contexts and motivations. As has been noted, Caesar's commentary and the iconography refer to quite different stages in the history of Gaulish religion; the iconography of the Roman period belongs to an environment of profound cultural and political change, and the religion it represents may in fact have been less clearly structured than that maintained by the druids (the priestly order) in the time of Gaulish independence. On the other hand, the lack of structure is sometimes more apparent than real. It has, for instance, been noted that of the several hundred names containing a Celtic element attested in Gaul the majority occur only once, which has led some scholars to conclude that the Celtic gods and their cults were local and tribal rather than national. Supporters of this view cite Lucan's mention of a god Teutates, which they interpret as "god of the tribe" (it is thought that *teutā* meant "tribe" in Celtic). The seeming multiplicity of deity names may, however, be explained otherwise—for example, many are simply epithets applied to major deities by widely extended cults. The notion of the Celtic pantheon as merely a proliferation of local gods is contradicted by the several well-attested deities whose cults were observed virtually throughout the areas of Celtic settlement.

According to Caesar the god most honoured by the Gauls was "Mercury," and this is confirmed by numerous images and inscriptions. His Celtic name is not explicitly stated, but it is clearly implied in the place-name Lugudunon ("the fort or dwelling of the god Lugus") by which his numerous cult centres were known and from which the modern Lyon, Laon, and Loudun in France, Leiden in The Netherlands, and Legnica in Poland derive. The Irish and Welsh cognates of Lugus are Lugh and Lleu, respectively, and the traditions concerning these figures mesh neatly with those of the Gaulish god. Caesar's description of the latter as "the inventor of all the arts" might almost have been a paraphrase of Lugh's conventional epithet *sam ildánach* ("possessed of many talents"). An episode in the Irish tale of the Battle of Magh Tuiredh is a dramatic exposition of Lugh's claim to be master of all the arts and crafts, and dedicatory inscriptions in Spain and Switzerland, one of them from a guild of shoemakers, commemorate Lugus, or Lugoves, the plural perhaps referring to the god conceived in triple form. An episode in the Middle Welsh collection of tales called the *Mabinogion,* (or *Mabinogi*), seems to echo the connection with shoemaking, for it represents Lleu as working briefly as a skilled exponent of the craft. In Ireland Lugh was the youthful victor over the demonic Balar "of the venomous eye." He was the divine exemplar of sacral kingship, and his other common epithet, *lámhfhada* ("of the long arm"), perpetuates an old Indo-European metaphor for a great king extending his rule and sovereignty far afield. His proper festival, called Lughnasadh ("Festival of Lugh") in Ireland, was celebrated—and still is at several locations—in August; at least two of the early festival sites, Carmun and Tailtiu, were the reputed burial places of goddesses associated with the fertility of the earth (as was, evidently, the consort Maia—or Rosmerta ["the Provider"]—who accompanies "Mercury" on many Gaulish monuments).

The god Lugus

The Gaulish god "Mars" illustrates vividly the difficulty of equating individual Roman and Celtic deities. A famous passage in Lucan's *Bellum civile* mentions the bloody sacrifices offered to the three Celtic gods Teutates, Esus, and Taranis; of two later commentators on Lucan's text, one identifies Teutates with Mercury, the other with Mars. The probable explanation of this apparent confusion, which is paralleled elsewhere, is that the Celtic gods are not rigidly compartmentalized in terms of function. Thus "Mercury" as the god of sovereignty may function as a warrior, while "Mars" may function as protector of the tribe, so that either one may plausibly be equated with Teutates.

The problem of identification is still more pronounced in the case of the Gaulish "Apollo," for some of his 15 or more epithets may refer to separate deities. The solar connotations of Belenus (from Celtic: *bel,* "shining" or "brilliant") would have supported the identification with the Greco-Roman Apollo. Several of his epithets, such as Grannus and Borvo (which are associated etymologically with the notions of "boiling" and "heat," respectively), connect him with healing and especially with the therapeutic powers of thermal and other springs, an area of religious belief that retained much of its ancient vigour in Celtic lands throughout the Middle Ages and even to the present time. Maponos ("Divine Son" or "Divine Youth") is attested in Gaul but occurs mainly in northern Britain. He appears in medieval Welsh literature as Mabon, son of Modron (that is, of Matrona, "Divine Mother"), and he evidently figured in a myth of the infant god carried off from his mother when three nights old. His name survives in Arthurian romance under the forms Mabon, Mabuz, and Mabonagrain. His Irish equivalent was Mac ind Óg ("Young Son" or "Young Lad"), known also as Oenghus, who dwelt in Bruigh na Bóinne, the great Neolithic, and therefore pre-Celtic, passage grave of Newgrange (or Newgrange House). He was the son of Dagda (or Daghda), chief god of the Irish, and of Boann, the personified sacred river of Irish tradition. In the literature the Divine Son tends to figure in the role of trickster and lover.

The "Divine Son"

There are dedications to "Minerva" in Britain and throughout the Celtic areas of the Continent. At Bath she was identified with the goddess Sulis, whose cult there centred on the thermal springs. Through the plural form Suleviae, found at Bath and elsewhere, she is also related to the numerous and important mother goddesses—who often occur in duplicate or, more commonly, triadic form. Her nearest equivalent in insular tradition is the Irish goddess Brighid, daughter of the chief god, Dagda. Like Minerva she was concerned with healing and craftsmanship, but she was also the patron of poetry and traditional learning. Her name is cognate with that of Brigantī, Latin Brigantia, tutelary goddess of the Brigantes of Britain, and there is some onomastic evidence that her cult was known on the Continent, whence the Brigantes had migrated.

The Gaulish Sucellos (or Sucellus), possibly meaning "the Good Striker," appears on a number of reliefs and statuettes with a mallet as his attribute. He has been equated with the Irish Dagda, "the Good God," also called Eochaidh Ollathair ("Eochaidh the Great Father"), whose attributes are his club and his caldron of plenty. But, whereas Ireland had its god of the sea, Manannán mac Lir ("Manannán, son of the Ocean"), and a more shadowy predecessor called Tethra, there is no clear evidence for a Gaulish sea-god, perhaps because the original central European homeland of the Celts had been landlocked.

The "Great Father"

The insular literatures show that certain deities were associated with particular crafts. Caesar makes no mention of a Gaulish Vulcan, though insular sources reveal that there was one and that he enjoyed high status. His name in Irish, Goibhniu, and Welsh, Gofannon, derived from the Celtic word for smith. The weapons that Goibhniu forged with his fellow craft gods, the wright Luchta and the metalworker Creidhne, were unerringly accurate and lethal. He was also known for his power of healing, and as Gobbán the Wright, a popular or hypocoristic form of his name, he was renowned as a wondrous builder. Medieval Welsh also mentions Amaethon, evidently a god of agriculture, of whom little is known.

GODDESSES AND DIVINE CONSORTS

One notable feature of Celtic sculpture is the frequent conjunction of male deity and female consort, such as "Mercury" and Rosmerta, or Sucellos and Nantosvelta. Essentially these reflect the coupling of the protecting god of tribe or nation with the mother-goddess who ensured the fertility of the land. It is in fact impossible to distinguish clearly between the individual goddesses and these mother-goddesses, *matres* or *matronae,* who figure so frequently in Celtic iconography, often, as in Irish tradition, in triadic form. Both types of goddesses are concerned with fertility and with the seasonal cycle of nature, and, on the evidence of insular tradition, both drew much of their power from the old concept of a great goddess who, like the Indian Aditi, was mother of all the gods. Welsh and Irish tradition also bring out the multifaceted character of the goddess, who in her various epiphanies or avatars assumes quite different and sometimes wholly contrasting forms and personalities. She may be the embodiment of sovereignty, youthful and beautiful in union with her rightful king, or aged and hideously ugly when lacking a fitting mate. She may be the spirit of war, like the fearsome Morrígan or the Badhbh Chatha ("Raven of Battle"), whose name is attested in its Gaulish form, Cathubodua, in Haute-Savoie, or the lovely otherworld visitor who invites the chosen hero to accompany her to the land of eternal youth. As the life-giving force she is often identified with rivers, such as the Seine (Sequana) and the Marne (Matrona) in Gaul or the Boyne (Boann) in Ireland; many rivers were called simply Devona, "the Divine."

The goddess is the Celtic reflex of the primordial mother who creates life and fruitfulness through her union with the universal father-god. Welsh and Irish tradition preserve many variations on a basic triadic relationship of divine mother, father, and son. The goddess appears, for example, in Welsh as Modron (from Matrona, "Divine Mother") and Rhiannon ("Divine Queen") and in Irish as Boann and Macha. Her partner is represented by the Gaulish father-figure Sucellos, his Irish counterpart Dagda, and the Welsh Teyrnon ("Divine Lord"), and her son by the Welsh Mabon (from Maponos, "Divine Son") and Pryderi and the Irish Oenghus and Mac ind Óg, among others.

The "Divine Mother"

ZOOMORPHIC DEITIES

The rich abundance of animal imagery in Celto-Roman iconography, representing the deities in combinations of animal and human forms, finds frequent echoes in the insular literary tradition. Perhaps the most familiar instance is the deity, or deity type, known as Cernunnos, "Horned One" or "Peaked One," even though the name is attested only once, on a Paris relief. The interior relief of the Gundestrup Caldron, a 1st-century-BC vessel found in Denmark, provides a striking depiction of the antlered Cernunnos as "Lord of the Animals," seated in the yogic lotus position and accompanied by a ram-headed serpent; in this role he closely resembles the Hindu god Śiva in the guise of Paśupati, Lord of Beasts. Another prominent zoomorphic deity type is the divine bull, the Donn Cuailnge ("Brown Bull of Cooley"), which has a central role in the great Irish hero-tale *Táin Bó Cuailnge* ("The Cattle Raid of Cooley") and which recalls the Tarvos Trigaranus ("The Bull of the Three Cranes") pictured on reliefs from the cathedral at Trier, W.Ger., and at Nôtre-Dame de Paris and presumably the subject of a lost Gaulish narrative. Other animals that figure particularly prominently in association with the pantheon in Celto-Roman art as well as in insular literature are boars, dogs, bears, and horses. The horse, an instrument of Indo-European expansion, has always had a special place in the affections of the Celtic peoples. The goddess Epona, whose name, meaning "Divine Horse" or "Horse Goddess," epitomizes the religious dimension of this relationship, was a pan-Celtic deity, and her cult was adopted by the Roman cavalry and spread throughout much of Europe, even to Rome itself. She has insular analogues in the Welsh Rhiannon and in the Irish Édaín Echraidhe (*echraidhe,* "horse riding") and Macha, who outran the fastest steeds.

BELIEFS, PRACTICES, AND INSTITUTIONS

Cosmology and eschatology. Little is known about the religious beliefs of the Celts of Gaul. They believed in a life after death, for they buried food, weapons, and ornaments with the dead. The druids, the early Celtic priesthood, taught the doctrine of transmigration of souls and discussed the nature and power of the gods. The Irish believed in an otherworld, imagined sometimes as underground and sometimes as islands in the sea. The otherworld was variously called "the Land of the Living," "Delightful Plain," and "Land of the Young" and was believed to be a country where there was no sickness, old age, or death, where happiness lasted forever, and a hundred years was as one day. It was similar to the Elysium of the Greeks and may have belonged to ancient Indo-European tradition. In Celtic eschatology, as noted in Irish vision or voyage tales, a beautiful girl approaches the hero and sings to him of this happy land. He follows her, and they sail away in a boat of glass and are seen no more; or else he returns after a short time to find that all his companions are dead, for he has really been away for hundreds of years. Sometimes the hero sets out on a quest, and a magic mist descends upon him. He finds himself before a palace and enters to find a warrior and a beautiful girl who make him welcome. The warrior may be Manannán, or Lugh himself may be the one who receives him, and after strange adventures the hero returns successfully. These Irish tales, some of which date from the 8th century, are infused with the magic quality

Life after death

that is found 400 years later in the Arthurian romances. Something of this quality is preserved, too, in the Welsh story of Branwen, daughter of Llŷr, which ends with the survivors of the great battle feasting in the presence of the severed head of Bran the Blessed, having forgotten all their suffering and sorrow. But this "delightful plain" was not accessible to all. Donn, god of the dead and ancestor of all the Irish, reigned over Tech Duinn, which was imagined as on or under Bull Island off the Beare Peninsula, and to him all men returned except the happy few.

Worship. According to Poseidonius and later classical authors Gaulish religion and culture were the concern of three professional classes—the druids, the bards, and between them an order closely associated with the druids that seems to have been best known by the Gaulish term *vates,* cognate with the Latin *vates* ("seers"). This threefold hierarchy had its reflex among the two main branches of Celts in Ireland and Wales but is best represented in early Irish tradition with its druids, *filidh* (singular *fili*), and bards; the *filidh* evidently correspond to the Gaulish *vates.*

The druids

The name druid means "knowing the oak tree" and may derive from druidic ritual, which seems in the early period to have been performed in the forest. Caesar stated that the druids avoided manual labour and paid no taxes, so that many were attracted by these privileges to join the order. They learned great numbers of verses by heart, and some studied for as long as 20 years; they thought it wrong to commit their learning to writing but used the Greek alphabet for other purposes.

As far as is known, the Celts had no temples before the Gallo-Roman period; their ceremonies took place in forest sanctuaries. In the Gallo-Roman period temples were erected, and many of them have been discovered by archaeologists in Britain as well as in Gaul.

Human sacrifice was practiced in Gaul: Cicero, Caesar, Suetonius, and Lucan all refer to it, and Pliny the Elder says that it occurred in Britain, too. It was forbidden under Tiberius and Claudius. There is some evidence that human sacrifice was known in Ireland and was forbidden by St. Patrick.

Festivals. Insular sources provide important information about Celtic religious festivals. In Ireland the year was divided into two periods of six months by the feasts

Beltine and Samhain

of Beltine (May 1) and Samhain (Samain; November 1), and each of these periods was equally divided by the feasts of Imbolc (February 1), and Lughnasadh (August 1). Samhain seems originally to have meant "summer," but by the early Irish period it had come to mark summer's end. Beltine is also called Cetśamain ("First Samhain"). Imbolc has been compared by the French scholar Joseph Vendryes to the Roman lustrations and apparently was a feast of purification for the farmers. It was sometimes called *oímelc* ("sheep milk") with reference to the lambing season. Beltine ("Fire of Bel") was the summer festival, and there is a tradition that on that day the druids drove cattle between two fires as a protection against disease. Lughnasadh was the feast of the god Lugh.

The impact of Christianity. The conversion to Christianity had inevitably a profound effect on this socio-religious system from the 5th century onward, though its character can only be extrapolated from documents of considerably later date. By the early 7th century the church had succeeded in relegating the druids to ignominious irrelevancy, while the *filidh,* masters of traditional learning, operated in easy harmony with their clerical counterparts, contriving at the same time to retain a considerable part of their pre-Christian tradition, social status, and privilege. But virtually all the vast corpus of early vernacular literature that has survived was written down in monastic scriptoria, and it is part of the task of modern scholarship to identify the relative roles of traditional continuity and ecclesiastical innovation as reflected in the written texts. Cormac's Glossary (*c.* 900) recounts that St. Patrick banished those mantic rites of the *filidh* that involved offerings to demons, and it seems probable that the church took particular pains to stamp out animal sacrifice and other rituals grossly repugnant to Christian teaching. What survived of ancient ritual practice tended to be related to *filidhecht,* the traditional repertoire of the *filidh,* or to the central institution of sacral kingship. A good example is the pervasive and persistent concept of the hierogamy (sacred marriage) of the king with the goddess of sovereignty: the sexual union, or *banais ríghi* ("wedding of kingship"), that constituted the core of the royal inauguration seems to have been purged from the ritual at an early date through ecclesiastical influence, but it remains at least implicit, and often quite explicit, for many centuries in the literary tradition. (M.D./P.Mac C.)

Germanic religion

Germanic religion comprises the mythology, religious beliefs, and cults of the Germanic-speaking peoples before their conversion to Christianity. Germanic culture extended, at various times, from the Black Sea to Greenland, or even the North American continent. Germanic religion played an important role in shaping the civilization of Europe. But since the Germanic peoples of the Continent and of England were converted to Christianity in comparatively early times, it is not surprising that less is known about the gods whom they used to worship and the forms of their religious cults than about those of Scandinavia, where Germanic religion survived until relatively late in the Middle Ages.

SOURCES

Classical and early medieval sources. The works of classical authors, written mostly in Latin and occasionally in Greek, throw some light on the religion of Germanic peoples; however, their interest in the religious practices of Germanic tribes remains limited to its direct relevance to their narrative, as when Strabo describes the gory sacrifice of Roman prisoners by the Cimbri at the end of the 2nd century BC.

For all his knowledge of the Celts, Caesar had no more than a superficial knowledge of Germans. He made some judicious observations in *Commentarii de bello Gallico* about their social and political organization, but his remarks on their religion were rather perfunctory. Contrasting Germans with the Celts of Gaul, Caesar claimed that the Germans had no druids (*i.e.,* organized priesthood), nor zeal for sacrifice, and counted as gods only the Sun, the fire god (Vulcan or *Vulcanus*), and the Moon. His limited information accounts for Caesar's assumption of the poverty of the Germanic religion and the partial inaccuracy and incompleteness of his statement.

Tacitus, on the contrary, provided a lucid picture of customs and religious practices of continental Germanic tribes in his *Germania,* written *c.* AD 98. He describes some of their rituals and occasionally names a god or goddess. While Tacitus presumably never visited Germany, his information was partly based on direct sources; he also used older works, now lost.

Early medieval records. As the power of Rome declined, records grew poorer, and nothing of great importance survives before the *Getica,* a history of the Goths written by the Gothic historian Jordanes *c.* 550; it was based on a larger (lost) work of Cassiodorus, which also incorporated the earlier work of Ablavius. The *Getica* incorporates valuable records of Gothic tradition, the origin of the Goths, and some important remarks about the gods whom the Goths worshipped and the forms of their sacrifices, human and otherwise.

Origin of the Lombards

A story about the origin of the Lombards is given in a tract, *Origo gentis Langobardorum* ("Origin of the Nation of Lombards"), of the late 7th century. It relates how the goddess Frea, wife of Godan (Wodan), tricked her husband into granting the Lombards victory over the Vandals. The story shows that the divine pair, recognizable from Scandinavian sources as Odin and Frigg, was known to the Lombards at this early time. A rather similar story about this pair is told in a Scandinavian source. The Lombard Paul the Deacon, working late in the 8th or early in the 9th century, repeated the tale just mentioned in his fairly comprehensive *Historia Langobardorum* ("History of the Lombards"). Paul used written sources available to him and seemed also to draw upon Lombard tradition in prose and verse.

The Venerable Bede, writing his *Historia ecclesiastica gentis Anglorum* ("Ecclesiastical History of the English People") early in the 8th century, showed much interest in the conversion of the English and some in their earlier religion. The lives of Irish and Anglo-Saxon missionaries who worked among Germanic peoples on the Continent (*e.g.*, Columbanus, Willibrord, and Boniface) provide some information about pagan customs and sacrifices.

The first detailed document touching upon the early religion of Scandinavia is the biography by St. Rembert (or Rimbert) of St. Ansgar (or Anskar), a 9th-century missionary and now patron saint of Scandinavia, who twice visited the royal seat, Björkö, in eastern Sweden, and noticed some religious practices, among them the worship of a dead king. Ansgar was well received by the Swedes, but it was much later that they adopted Christianity.

Some two centuries later, *c.* 1072, Adam of Bremen compiled his *Gesta Hammaburgensis ecclesiae pontificum* (*History of the Archbishops of Hamburg-Bremen*), which included a description of the lands in the north, then part of the ecclesiastical province of Hamburg. Adam's work is particularly rich in descriptions of the festivals and sacrifices of the Swedes, who were still largely pagan in his day.

German and English vernacular sources. Learned sources, such as those just mentioned, may be supplemented by a few written in vernacular in continental Germany and England. Among the most interesting are two charms, the so-called Merseburg Charms, found in a manuscript of *c.* 900, in alliterating verse. The charms appear to be of great antiquity, and the second, intended to cure sprains, contains the names of seven deities. Four of these are known from Scandinavian sources, *viz.*, Wodan (Odin), Friia (Frigg), Volla (Fulla), and Balder, but *balder* could merely designate the lord and apply to Wodan's companion Phol, an otherwise unidentified god. Sinthgunt (Sinhtgunt in the manuscript), the sister of Sunna ("Sun"), could be a name for the Moon.

A manuscript of the 9th century contains a baptismal vow in the Saxon dialect, probably dating from the 8th century. The postulant is made to renounce the Devil and all his works, as well as three gods, Thunaer (Donar/Thor), Wôden (Wodan/Odin), and Saxnôt, whose name has been associated with Seaxneat, who appears as the son of Wôden in the genealogy of the kings of Essex. Saxnôt is undoubtedly a Saxon tribal god, but it is not clear whether the second element of his name means "companion" or refers to "(sacrificial) cattle."

Old English sources

Vernacular sources in Old English are rich, but reveal little about the pre-Christian religion. The poem *Beowulf* is based upon heroic traditions, ultimately of Scandinavian origin, but in spite of its rather thorough Christianization, it retains a number of striking Germanic elements in its symbolism and contents. The fight of Beowulf against the monsters from the dark is paralleled by the struggle of Scandinavian heroes against trolls. The same heroism and defiance of death that characterize Germanic warrior ethics are found in minor historical poems, such as the *Battle of Brunanburh* and the *Battle of Maldon.* Old English literature also includes numerous charms intended as safeguards against illnesses and misfortunes, but these can hardly be called religious. In the 9th century *Runic Poem,* an old tradition about the god Ing has clearly been retained. Wôden (Odin) is also mentioned repeatedly in Old English sources; he is frequently named among ancestors of the royal houses.

Scandinavian literary sources. The greater part of scholarly knowledge of Germanic religion comes from literary sources written in Scandinavia. These sources are mostly written in the Old Norse language, and they are nearly all preserved in manuscripts written in Iceland from the 12th to 14th century or in later copies of manuscripts written at that period. This implies a surviving tradition and an antiquarian revival in that distant outpost of Scandinavian culture.

The oldest of the sources found in the Icelandic manuscripts are in verse. Although remembered and written down in Iceland, some of these verses originated elsewhere, some in Norway and a few in Denmark and Sweden. Some of them may well be older than the settlement of Iceland, which took place toward the end of the 9th century. The Icelanders remained pagan until the year 999 or 1000.

The Icelandic manuscripts are written either in Eddic or in skaldic verse. The Eddic poetry is mostly composed in free alliterative measures, much like that of the Old English *Beowulf.* Much of it is preserved in a manuscript now called the *Elder Edda,* or *Poetic Edda,* written in Iceland *c.* 1270 and containing material centuries older. The meaning of the name *Edda* is disputed; it was not originally applied to this book but to another mentioned below.

The *Elder Edda* consists of a number of lays, which may be divided into two classes, the mythological and the heroic. The mythological poems contain stories about the northern Germanic gods; words of wisdom; a cosmogony, depicting the beginning of the world; and an apocalyptic description of the Ragnarök, the end of the ancient Scandinavian world. There is much controversy among scholars about the date and place of origin of several of the lays preserved in the *Edda* and minor collections. The first lay is the "Völuspá" ("Prophecy of the Seeress") which, in about 65 short stanzas, covers the history of the world of gods from the beginning to the Ragnarök. In spite of its clearly pagan theme, the poem reveals Christian influence in its imagery. The scenery described is that of Iceland, and it is commonly thought that it was composed in Iceland about the year 1000, when Icelanders perceived the fall of their ancient gods and the approach of Christianity.

"Hávamál"

The "Hávamál" ("Words of the High One") is a heterogeneous collection of aphorisms, homely wisdom, and counsels, as well as magic charms, ascribed to Odin. It contains at least five separate sections, some of which definitely point to their origin in Norway in the Viking age (9th–10th century) by their scenery and view of life. Of interest are the myths about Odin's erotic affairs, illustrating his cynical remarks about man's relation to woman, especially his amorous adventure leading to the theft of the precious mead. Particularly important is the account of Odin's hanging himself on the world tree, Yggdrasill, a name apparently meaning "Odin's Horse."

In another poem Odin engages in a contest of wits with an immensely wise giant (Vafthrúdnir). The poem, in the form of question and answer, tells of the cosmos, gods, giants, the beginning of the world, and its end. The other lays of the first section of the *Elder Edda* deal essentially with the adventures of the gods, especially Thor's relations with the giants, such as when he goes fetching the brewing kettle, fishing for the Midgard-Serpent, and recovering his hammer Mjölnir. The "Lokasenna" ("The Flyting of Loki"), which sharply criticizes the behaviour of the major Scandinavian gods and goddesses, perhaps on the model of Lucian's *Assembly of the Gods,* is presumably a late addition, written *c.* 1200. Similarly, the political implications in the "Rígsthula" suggest that this poem about the divine origin of social stratification dates at least to the 13th century.

The second section of the *Elder Edda* tells of traditional Germanic heroes, such as Sigurd (Siegfried) or Völundr (Wayland the Smith). Many of the stories told there are also known from continental Germany and England, but the Norse sources preserve them in an older and purer form. They are of some interest for the study of religion because the gods often intervene in the lives of heroes.

The Icelandic and, to a lesser extent, the Norwegian manuscripts of the 13th and 14th centuries contain a great bulk of poetry of a quite different kind. This is commonly, if unjustifiably, called skaldic poetry. The skaldic verse forms were perhaps devised in Norway in the 9th century. They differ fundamentally from the traditional Germanic and Eddic forms in that the syllables are strictly counted and the lines must end in a given form. The skalds also used a complicated system of alliteration, as well as internal rhyme and consonance. With all these constraints, their short, eight-line strophes, falling neatly into four-line half strophes, are often difficult to understand because of the complexity of the syntax and of an abstruse diction, making a very extensive use of periphrastic metaphors called kennings. These phrases, *e.g.*, "Sif's hair" or "the

otter's ransom" for "gold," allude to specific myths, and their testimony is most reliable to assess pagan worship. Skaldic poetry is often composed in praise of chieftains of Norway and other Scandinavian lands. Its authors are frequently named, and their approximate date is known.

After the Icelanders were converted to Christianity, much of their ancient poetry survived this religious change, as did traditions about pagan gods and their worship. Icelanders of the 12th century traveled widely and were among the most lettered people in Europe, studying and translating homilies, saints' lives, and other learned literature of Europe. During the 13th century there was a revival of the Icelanders' interest in the practices of their pagan ancestors, as well as in those of their kinsfolk in Norway and, to a lesser extent, in Sweden.

The *Edda* and other writings of Snorri Sturluson

The name chiefly associated with this revival is that of Snorri Sturluson (1179–1241). Snorri acquired great wealth and received the best education available. He became a powerful man in Icelandic politics, and political intrigue led to his assassination in 1241. The first of Snorri's works and one of the most memorable was his *Prose Edda,* written *c.* 1220. It is to this book that the title *Edda,* whatever its meaning, originally belonged.

It is likely that Snorri wrote the various sections of this book in an order opposite to that which they now have. He began with a poem exemplifying 102 different forms of verse, addressed to Haakon, the young king of Norway, and his uncle Earl Skúli Baardson. He then furnished a section entitled "Skáldskaparmál" ("Poetic Diction"), explaining and illustrating the abstruse allusions to gods and ancient heroes in the poetry of the skalds. After this, he wrote an introduction to the mythology of the north in the "Gylfaginning" ("Beguiling of Gylfi"), a section describing all of the major gods and their functions. Snorri worked partly from Eddic and skaldic poetry still extant, but partly from sources that are now lost. He presents a clear, if not altogether reliable, account of the gods, the creation of the world, and Ragnarök.

Another important work ascribed to Snorri is the *Heimskringla* ("Orb of the World"), a history of the kings of Norway from the beginning to the mid-12th century. The first section of this book, the "Ynglinga saga," is of particular interest, for in it, Snorri described the descent of the kings of Norway from the royal house of Sweden, the Ynglingar, who, in their turn, were said to descend from gods. Snorri used such written sources as were available; he also relied on skaldic poems, some of which were very old. Snorri visited Norway twice and Sweden once, and he probably used popular traditions that he heard in both countries.

About the beginning of the 13th century Icelanders began to write so-called family sagas, or Icelanders' sagas; *i.e.,* lives of their ancestors who had settled in Iceland in the late 9th century, and lived through the 10th and 11th centuries. A good deal had already been written about these people in summary form by Ari the Learned (*c.* 1067–1148) and other scholars of the early 12th century, but much more had been preserved in tradition handed down in verse and prose.

The reliability of family sagas as sources of history has long been debated and no simple answer can be given. Each saga has to be studied separately, with a view not only to the author's sources but also to his aims. Some of the authors were antiquarians and tried to relate faithfully the history of a district, a family, or a hero; others simply entertained by writing historical fiction.

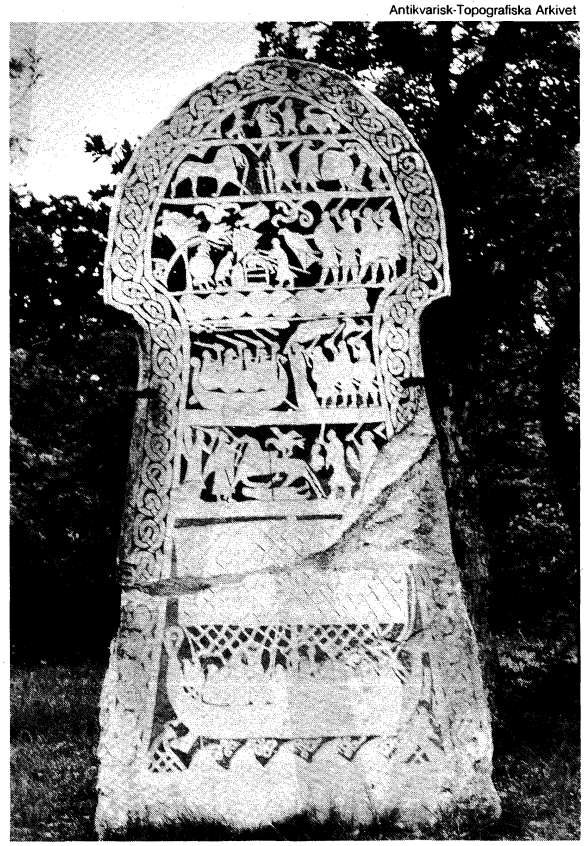
Saxo Grammaticus

About the time when the first family sagas were written, the Dane Saxo Grammaticus, secretary of Absalon, archbishop of Lund, was compiling in Latin his great history of the Danes (*Gesta Danorum*). The first nine books of this work deal with the prehistory of the Danes and are actually a history of the ancient gods and heroes. Interpreting the old religion euhemeristically (*i.e.,* by reducing the gods to the level of distinguished men), Saxo regarded the pagan gods chiefly as crafty men of old. Some of his sources may have been Danish traditions and poetry now lost, but he derived much of his information from vagrant Icelanders, of whom he speaks with some respect.

Material such as Saxo used was also used by Icelanders some generations later in the so-called heroic sagas (*Fornaldar Sögur*). Sagas of this kind describe the adventures of heroes who lived, or were supposed to have lived, in Scandinavia or on the Continent before Iceland was peopled. The gods, and particularly Odin, are frequently said to take part in the affairs of men, but since few of the heroic sagas were written before the 14th century, and the aim of their authors was often entertainment rather than instruction, these sagas can be used as sources only with utmost discrimination.

Other sources. *Archaeology.* The archaeological finds of Scandinavia are rich, and information about religious beliefs may be drawn especially from the grave goods and forms of burial. It may, in fact, be possible to trace continuity of belief from the Bronze Age to the Viking age in the 9th and 10th centuries. Archaeological finds, however, are difficult to interpret from a religious point of view. The numerous petroglyphs of southern Scandinavia, dating to the 2nd millennium BC, attest to an extensive sun cult and prevalent fertility rites. Other early Bronze Age finds such as the Trundholm chariot of the sun confirm these religious practices. Ship or boat graves were initially meant to carry the buried or cremated remains of those put in them to the otherworld, but such practices could later have become purely conventional.

Antikvarisk-Topografiska Arkivet



Memorial stone from Gotland, Sweden, showing battle scenes and ships. In the third panel from the top, a warrior is being hanged in a tree as a sacrifice to Odin, whose cult is represented by an eagle and a twisted knot. Late 8th century.

A number of small images in silver or bronze, dating from the Viking age, have also been found in various parts of Scandinavia. They show Thor with his hammer or a fertility god with full erection, perhaps Freyr; frequently found is a silver hammer, the symbol of Thor, often worn as an amulet, like the hundreds of gold medals or bracteates, representing Germanic deities worshiped on the Continent and in Scandinavia in the 5th–6th century.

Runic inscriptions. The runic alphabet was used throughout the Germanic world beginning in about the 1st century AD. The runes had magical and sacral significance. Occasionally one god or another is named; the god Thor may be called upon to hallow a grave.

Place-names. Theophoric place-names (derived from or

compounded with the name of a god) are found in all Germanic lands. Such names supplement the limited information available concerning pagan religion in Continental Germany and England. The theophoric place-names of Norway and Sweden are richer and have been carefully sifted. The evidence drawn from them must, however, be handled with caution. A name such as Thorslundr ("Thor's Grove") does not necessarily imply that Thor was worshiped there, for names are often transferred by settlers from one place to another, as from England to America and, in the Viking age, from the Scandinavian mainland to Iceland. Groups of theophoric place-names may, however, provide evidence of the cult of one god or another.

MYTHOLOGY

The beginning of the world of giants, gods, and men. The story of the beginning is told, with much variation, in three poems of the *Elder Edda,* and a synthesis of these is given by Snorri Sturluson in his *Prose Edda.* Snorri adds certain details that he must have taken from sources now lost.

"Völuspá" Defective as it is, the account of the "Völuspá" appears to be the most rational description of the cosmogony. The story is told by an age-old seeress who was reared by primeval giants. In the beginning there was nothing but Ginnungagap, a void charged with magic force. Three gods, Odin and his brothers, raised up the earth, presumably from the sea into which it will ultimately sink back. The sun shone on the barren rocks and the earth was overgrown with green herbage.

Later, Odin and two other gods came upon two lifeless tree trunks, Askr and Embla, on the shore. They endowed them with breath, reason, hair, and fair countenance, thus creating the first human couple.

A quite different story is told in the didactic poem "Vafthrúdnismál" ("The Lay of Vafthrúdnir"). The poet ascribes his ancestry to a primal giant, Aurgelmir, who sometimes goes by the name Ymir. The giant grew out of the venom-cold drops spurted by the stormy rivers called Élivágar. One of the giant's legs begat a six-headed son with the other leg, and under his arms grew a maid and a youth. The earth was formed from the body of the giant Ymir who, according to Snorri, was slaughtered by Odin and his brothers. Ymir's bones were the rocks, his skull the sky, and his blood the sea. Another didactic poem, "Grímnismál" ("The Lay of Grímnir [Odin]"), adds further details. The trees were the giant's hair and his brains the clouds. Snorri quotes the three poetic sources just mentioned, giving a more coherent account and adding some details. One of the most interesting is the reference to the primeval cow Audhumla (Auðumla), formed from drops of melting rime. She was nourished by licking salty, rime-covered stones. Four rivers of milk flowed from her udders and thus she fed the giant Ymir. The cow licked the stones into the shape of a man; this was Buri (Búri), who was to be grandfather of Odin and his brothers. The theme of the creation of the world from parts of the body of a primeval being is also found in Indo-Iranian tradition and may belong to the Indo-European heritage in Germanic religion.

A central point in the cosmos is the evergreen ash, Yggdrasill, whose three roots stretch to the worlds of death, frost-giants, and men. A hart (stag) is biting its foliage, its trunk is rotting, and a cruel dragon is gnawing its roots. When Ragnarök approaches, the tree will shiver and, presumably, fall. Beneath the tree stands a well, the fount of wisdom. Odin got a drink from this well and had to leave one of his eyes as a pledge.

The gods. Old Norse sources name a great number of deities. The evidence of place-names suggests that one cult succeeded another. Names, especially those in southeastern Norway and southern Sweden, suggest that there was once widespread worship of a god Ull (Ullr). Indeed, an early poem reports an oath on the ring of Ull, suggesting that he was once one of the highest gods, at least in some areas. Beyond that, little is known about Ull; he was god of the bow and snowshoes, and, according to Saxo Grammaticus, who calls him Ollerus, he temporarily replaced Odin when the latter was banned from his throne.

The gods can be divided roughly into two tribes, Aesir and Vanir. At one time, according to fairly reliable sources, there was war between the Aesir and the Vanir, but when neither side could score a decisive victory they made peace and exchanged hostages. In this way, the specialized fertility gods, the Vanir, Njörd (Njörðr), his son Freyr, and presumably his daughter, Freyja, came to dwell among the Aesir and to be accepted in their hierarchy. Two tribes of gods: Aesir and Vanir

Odin (*Óðinn*). According to literary sources, Odin was the foremost of the Aesir, but the limited occurrence of his name in place-names seems to indicate that his worship was not widespread. He appears, however, to have been the god of kings and nobility more than the deity to whom the common man would turn for support. His name defines him as the god of inspired mental activity and strong emotional stress, as it is related to Icelandic *óðr,* which applies to the movements of the mind, and to German *Wut,* meaning "rage," or "fury." This qualifies him as the god of poetic inspiration and the stories about the origin of poetry narrate how Odin brought the sacred mead of poetry to the world of the gods. This beverage was first brewed from the blood of a wise god, Kvasir, who was murdered by dwarfs. It later came into the hands of a giant and was stolen by Odin, who flew from the giant's stronghold in the shape of an eagle, carrying the sacred mead in his crop to regurgitate it in the dwelling of the gods. Therefore, the early skalds designate poetry as "Kvasir's blood" or "Odin's theft."

There is also a darker side to Odin's personality: he incites kinsmen to fight and turns against his own favourites, because he needs heroes in the otherworld to join him in the final battle against the forces of destruction at the time of Ragnarök. Therefore, the fallen warriors on the battlefield are said to go to his castle Valhalla (Valhöll), the "Hall of the Slain," where they live in bliss, training for the ultimate combat. He is also a necromancer and a powerful magician who can make hanged men talk. He is the god of the hanged, because he hanged himself on the cosmic tree Yggdrasill to acquire his occult wisdom. As the "Hávamál" tells us, he hung there for nine nights, pierced with a spear, sacrificed to himself, nearly dead, to gain the mastery of the runes and the knowledge of the magic spells that blunt a foe's weapons or free a friend from fetters. Valhalla

Odin could change his shape at will, and, with his body in cataleptic sleep, he traveled to other worlds, like a shaman. As god of the dead, he was accompanied by carrion beasts, two wolves and two ravens. These birds kept him informed of what happened in the world, adding to the knowledge he had acquired by relinquishing his one eye in the well of Mímir under the tree Yggdrasill.

Untrustworthy, Odin may break the most sacred oath on the holy ring. As "spear-thruster," he opens the hostilities, and in the bellicose period of the Viking expeditions his cult appeared to gain momentum. Odin, like Wôden or Wotan, is, however, essentially the sovereign god, whom the Germanic dynasties, in England as well as in Scandinavia, originally regarded as their divine founder. He thus maintains the prominent position of Wōðan[az] in classical antiquity, to whom, according to Tacitus, human sacrifice was offered. Latin writers identified Wōðan[az] with Mercury, as the name of the day, Wednesday, (*i.e.,* "day of Wôden"), for *Mercurii dies* (French *mercredi*), indicates. It is possible that the tribal god of the Semnones, described by Tacitus as *regnator omnium deus* ("the god governing all"), could be identified with Wōðan[az]. They would indeed sacrifice a man to him in a sacred grove in what the ancient author describes as a "horrendous ritual."

Thor (*þórr*). Thor is a god of very different stamp. Place-names, personal names, poetry, and prose show that he was worshiped widely, especially toward the end of the pagan period. Thor is described as Odin's son, but his name derives from the Germanic term for "thunder." Like Indra and other Indo-European thunder-gods, he is essentially the champion of the gods, being constantly involved in struggles with the giants. His main weapon is a short-handled hammer, Mjölnir, with which he smashes the skull of his antagonists. One of his best-known adventures describes his pulling the cosmic serpent Jörmungand (Jörmungandr), which surrounds the world, out of the

ocean. As he fails to kill the monster then, he will have to face it again in a combat to the finish in which they both die, in the Ragnarök.

Thor is the god of the common man. As place-names in eastern Scandinavia and in England indicate, peasants worshiped him because he brought the rains that ensured good crops. Warriors trusted him, and he seems to have been popular with them everywhere. He was well known as Thunor in the Saxon and Jutish areas in England; the Saxons on the mainland venerated him as Thunær. When the Vikings conquered Normandy and the Varangians settled in Russia, they called upon Thor to help them in their military enterprises.

On account of his association with thunder, the Germanic god *þunraz* (Thor) was equated with Jupiter by the Romans; hence, the name of the day, Thursday (German *Donnerstag*), for *Jovis dies* (Italian *giovedì*). Thor traveled in a chariot drawn by goats, and later evidence suggested that thunder was thought of as the sound of his chariot.

Balder (*Baldr*). The west Norse sources name another son of Odin, Balder, the immaculate, patient god. When Balder had dreams foreboding his death, his mother, Frigg, took oaths from all creatures, as well as from fire, water, metals, trees, stones, and illnesses, not to harm Balder. Only the mistletoe was thought too young and slender to take the oath. The guileful Loki tore up the mistletoe and, under his guidance, the blind god Höd (Höðr) hurled it as a shaft through Balder's body. The gods sent an emissary to Hel, goddess of death; she would release Balder if all things would weep for him. All did, except a giantess, who appears to be none other than Loki in disguise. There is another version of this story, to which allusion is made in a west Norse poem (*Baldrs draumar*). According to this Loki does not seem to be directly responsible for Balder's death but Höd alone. Balder's name occurs rarely in place-names, and it does not appear that his worship was widespread.

The Danish historian Saxo gives an entirely different picture of Balder: he is not the innocent figure of the west Norse sources but a vicious and lustful demigod. He and Höd were rivals for the hand of Nanna, said in west Norse sources to be Balder's wife. After many adventures, Höd pierced Balder with a sword. In order to secure vengeance, Odin raped a princess, Rinda (Rindr), who bore a son, Bous, who killed Höd.

Saxo's story has many details in common with the west Norse sources, but his views of Balder were so different that he may have been following a Danish rather than a west Norse tradition. Much of Saxo's story is placed in Denmark.

There has been much dispute among scholars about the symbolic significance of Balder's myth. He has been described as a dying spring god; some have stressed his Christ-like features in the west Norse version. The major protagonists in the drama have warrior names, and the game in which the gods hurl missiles at the almost invulnerable Balder is reminiscent of an initiatory test.

Loki. There is no more baffling figure in Norse mythology than Loki. He is counted among the Aesir but is not one of them. His father was a giant (Fárbauti; "Dangerous Striker"). Loki begat a female, Angrboda (Angrboða; "Boder of Sorrow"), and produced three evil progeny—the goddess of death, Hel, the monstrous serpent surrounding the world, Jörmungand, and the wolf Fenrir (Fenrisúlfr), who lies chained until he will break loose in the Ragnarök. Loki himself lies bound but will break his bonds in the Ragnarök to join the giants in battle against the gods.

Loki deceived the gods and cheated them, but sometimes he got them out of trouble. He is seen in company with Odin and an obscure god Hœnir, and he is called the friend of Thor. He is essentially a "trickster" figure who can change sex and shape at will. Thus, he can give birth as well as beget offspring. The eight-legged horse of Odin, Sleipnir, was born of Loki in the shape of a mare. According to an Eddic lay, Loki ate the heart of an evil woman and grew pregnant. He fights with Heimdall in the shape of a seal for the possession of the Brísingamen necklace, and later, he sneaks into Freyja's residence in the form of a fly to steal the same precious object for Odin. According to an early poem, Odin and Loki had mixed their blood as foster brothers. It has been suggested that Loki was a hypostasis of Odin, or at least that he represents Odin's darkest side. He seems to symbolize "impulsive intelligence," together with an irrepressible urge to act and an unpredictable maliciousness.

Origin of monsters

Minor Aesir. A number of minor deities are also ranked among the Aesir. The god Heimdall (Heimdal[l]r) is particularly interesting, but rather enigmatic. His antagonism with Loki, with whom he struggles for the possession of the Brísingamen necklace, results in their killing each other in the Ragnarök, according to Snorri. Heimdall is of mysterious origin: he is the son of nine mothers, said to be sisters, all of whom bear names of giantesses, though they are mostly identified with the storm waves. Heimdall lives in Himinbjörg ("Heavenly Fells"), at the edge of the world of the Aesir, which he guards against the giants. He is endowed with a wonderful hearing, detecting anything in the world, but he is blamed with drinking too much mead. When the Ragnarök draws near, he will blow his ringing horn (Gjallarhorn).

Another myth in which he appears as Rigr (Rígr), a name probably derived from the Irish *rí* ("king"), makes Heimdall the father of mankind. He consorted with three women, from whom descend the three classes of men—serf (*thrall*), freeman (*karl*), and nobleman (*jarl*).

Information about the Scandinavian gods is based chiefly on poetry composed late in the pagan period and on the remarks of outside observers, who generally had little interest in what they considered to be heathendom. Many gods were nearly forgotten when these authors mentioned them, as is the case with Ull, described above. Similarly, memories had apparently faded about Tyr (Týr), who must have been a major god in early times. His name, derived from Germanic *Tîwaz* (Old English *Tīw*) and related to the Greek god Zeus, suggests that he was originally a sky-god, but in Roman times, he was equated with Mars, and hence *dies Martis* (Mars's day; French *mardi*) became Tuesday (Icelandic *Týs dagr*). Tyr is the one-handed god, because one of his hands had been bitten off by the wolf Fenrir. He is brave and warlike; in the Ragnarök he will face the hellhound Garm (Garmr), and they will kill each other. Like other gods, Tyr is said to be a son of Odin, but, according to one early poem, he was the son of a giant. Tyr's cult is remembered in place-names, particularly those of Denmark.

Bragi. Bragi appears in later sources as the god of poetry and eloquence. It is remarkable that the first recorded skald, living in the 9th century, was also called Bragi. Since there is no record of a cult of the god Bragi, some have suspected that the god and the poet are identical.

Frigg. Frigg is the wife of Odin. In the southern Germanic sources she appears as Friia (Second Merseburg Charm) or Frea (Langobardic), the spouse of Wodan. Snorri depicted her as the weeping mother of Balder, but Saxo described her as unchaste and makes her misconduct responsible for the temporary banishment of Odin. In the "Ynglinga saga," Odin's brothers Vili and Vé share her during his absence in a polyandric relationship similar to that of Draupadī in Hindu myth. She has been equated with Venus, and her name survives in Friday (Old English *Frīgedæg*) from *dies Veneris,* Venus' day.

Idun (*Iðunn*). According to an early skaldic poem (*c.*

900), Idun, the wife of Bragi, was entrusted with the apples that prevent the gods from growing old. She was abducted by the giant Thjazi, but Loki brought her back with the precious apples. This myth has many parallels such as Heracles' obtaining the golden apples of the Hesperides.

Jörd (Jörðr). The name Jörd means "earth," but this goddess who is described as the mother of Thor, and consequently Odin's lover, is also known under different names, such as Fjörgyn ("Earth"), perhaps originally a goddess of the furrow, and Hlódyn (Hlóðyn). A *dea Hludana* is also remembered in votive inscriptions of lower Germany and Holland.

The Vanir. The Vanir represent a distinct group of gods associated with wealth, health, and fertility. Although they would also fight, the Vanir were not essentially gods of battle, like the Aesir. The best known Vanir—Njörd, Freyr, and probably Freyja—came as hostages to the Aesir. Njörd was the father of the god Freyr and the goddess Freyja.

In his *Germania,* Tacitus described the worship of a goddess, Nerthus, on an island, probably in the Baltic Sea. Whatever symbol represented her was kept hidden in a grove and taken around once a year in a covered chariot. During her pageant, there was rejoicing and peace, and all weapons were laid aside. Afterward, she was bathed in a lake and returned to her grove, but those who participated in her lustration were drowned in the lake as a sacrifice to thank her for her blessings.

Njörd

Nerthus is described as Terra Mater ("Earth Mother"), but her name corresponds to that of the god Njörd (from Germanic *Nerthuz*). Scholars have attempted various explanations of this puzzling change of sex, assuming that the original deity was androgynous or claiming that the loss of feminine nouns of the type *Njörd* represents triggered the reinterpretation of the goddess as a male god. As Njörd is essentially a god of the sea and its riches, it may be preferable to consider Nerthus and Njörd as originally separate gods altogether, whose relationship might be similar to that of Poseidon ("Husband of the Earth-Goddess") and Demeter ("Earth Mother") in Arcadia. Etymologically, the name *Njörd* could then be related to that of the Greek "Old Man of the Sea," Nereus. Before coming to the Aesir, Njörd was supposed to have begotten his two children with his (unnamed) sister. Since such incestuous unions were not allowed among the Aesir, Njörd afterward married Skadi (Skaði), daughter of the giant Thjazi. Evidence from place-names shows that Njörd was worshiped widely in Sweden and Norway, and he was one of the gods whom Icelanders invoked when they swore their most sacred oaths.

Freyr. Much more is told of Freyr, the son of Njörd. His name means "Lord" (compare Old English *Frea*), but Freyr had other names as well; he was called Yngvi or Yngvi-Freyr, and this name suggests that he was the eponymous father of the north Germans whom Tacitus calls Ingvæones (Ingævones). The Old English *Runic Poem* indicates that the god Ing was seen first among the eastern Danes; he departed eastward over a wave and his chariot went after him. It is remarkable how the chariot persists in the cult of the Vanir, Nerthus, Ing, and Freyr. A comparatively late source tells how the idol of Freyr was carried in a chariot to bring fertility to the crops in Sweden. In an early saga of Iceland, where crops were little cultivated, Freyr still appears as the guardian of the sacred wheatfield. Freyr's name often is found as the first element of a place-name, especially in eastern Sweden; the second element often means "wheatfield," or "meadow."

The Eddic poem *Skírnismál* ("The Lay of Skírnir") relates the wooing of Freyr's bride, Gerd (Gerðr), a giant-maiden. This story has often been considered as a fertility myth. Gerdr (from *garðr,* "field") is held fast in the clutches of the frost-giants of winter. Thus, Freyr, as sun-god, would free her. However, this interpretation rests entirely on disputable etymologies. The narrative indicates that Freyr's bride belongs to the otherworld, and her wooing may rather symbolize the affinities of the fertility god with the chthonian powers, dominating the cycle of life and death. Several animals were sacred to Freyr, particularly the horse and, because of his great fertility, the boar.

The centre of Freyr's cult was Uppsala, and he was once said to be king of the Swedes. His reign was one of peace and plenty. While Freyr reigned in Sweden, a certain Frodi ruled the Danes, and the Danes attributed this age of prosperity to him. Frodi (Fróði) was also conveyed ceremoniously in a chariot, and some have seen him as no other than a doublet of Freyr. Freyr was said to be ancestor of the Ynglingar, the Swedish royal family. Such myths are connected with the concept of "divine kingship" in the Germanic world, but earlier views on "sacral royalty" are now being challenged.

Freyja. Freyr's sister, Freyja, shares several features with her brother. She was the goddess of love, wealth, and fertility. She owned precious jewels such as the famous Brísingamen necklace, forged by dwarfs. She is said to be weeping tears of gold for her absent husband, but she is also blamed for being promiscuous. She practiced a disreputable kind of magic, called *seiðr,* which she taught Odin. She was known under various names, some obscure such as Mardöll, and others, such as Sýr ("Sow"), referring to her association with animals. Taking half of those who fall in battle, Freyja had some affinity with the chthonian deities of death.

This relation of fertility goddesses with the otherworld is already illustrated by the Germanic mother goddesses or *matronae,* whose cult was widespread along the lower Rhine in Roman imperial times. They are often represented with chthonian symbols such as the dog, the snake, or baskets of fruit. The same applies to the goddess Nehalennia, worshiped near the mouth of the Scheldt River. Her name may be related to Greek *nekués,* "spirits of the dead."

Guardian spirits. Besides gods and goddesses, medieval writers frequently allude to female guardian spirits called *dísir* and *fylgjur.* The conceptions underlying these two certainly differed originally, although some of the later writers used the words interchangeably.

Dísir and *fylgjur*

Reference is made several times to sacrifice to the *dísir,* held at the beginning of winter. The ritual involved a festive meal and seems to have been a private ceremony, suggesting that the *dísir* belonged to one house, one district, or one family. In an Eddic poem the *dísir* are described as "dead women," and in actuality they may have been dead female ancestors, assuring the prosperity of their descendants.

There is no record of a cult of the *fylgja* (plural *fylgjur*), a word best translated as "fetch," or "wraith." The *fylgja* may take the form of a woman or an animal that is rarely seen except in dreams or at the time of death. It may be the companion of one man or of a family and is transferred at death from father to son.

The elves (*álfar*) also stood in fairly close relationship to men. An Icelandic Christian poet of the 11th century described a sacrifice to the elves early in winter among the pagan Swedes. The elves lived in mounds or rocks. An old saga tells how the blood of a bull was smeared on a mound inhabited by elves.

A good deal is told of land spirits (*landvættir*). According to the pre-Christian law of Iceland, no one must approach the land in a ship bearing a dragonhead, lest he frighten the land spirits. An Icelandic poet, cursing the king and queen of Norway, enjoined the *landvættir* to drive them from the land.

Dwarfs. Dwarfs (*dvergar*) play a part in Norse mythology. They were very wise and expert craftsmen who forged practically all of the treasures of the gods, in particular Thor's hammer. Snorri said that they originated as maggots in the flesh of the slaughtered giant Ymir. Four of them are supporting the sky, made of the skull of this primeval giant. They may have been originally nature spirits or demonic beings, living in mountain caves, but they generally were friendly to man.

BELIEFS, PRACTICES, AND INSTITUTIONS

Worship. Sacrifice often was conducted in the open or in groves and forests. The human sacrifice to the tribal god of the Semnones, described by Tacitus, took place in a sacred grove; other examples of sacred groves include the one in which Nerthus usually resides. Tacitus does,

however, mention temples in Germany, though they were probably few. Old English laws mention fenced places around a stone, tree, or other object of worship. In Scandinavia, men brought sacrifice to groves and waterfalls.

A common word for a holy place in Old English is *hearg* and in Old High German *harug,* occasionally glossed as *lucus* ("grove") or *nemus* ("forest"). The corresponding Old Norse word, *hörgr,* denotes a cairn, a pile of stones used as an altar; the word was also used occasionally for roofed temples. Another term applied to sacred places in Scandinavia was *vé* (compare with *vígja,* "to consecrate"), which appears in many place-names; *e.g.,* Odense (older Óðinsvé).

Temples

Although worship was originally conducted in the open, temples also developed with the art of building. Bede claims that some temples in England were built well enough to be used as churches and mentions a great one that burned.

The word *hof,* commonly applied to temples in the literature of Iceland, seems to belong to the later rather than to the earlier period. A detailed description of a *hof* is given in one of the sagas. The temple consisted of two compartments, perhaps analogous to the chancel and the nave of a church. The images of the gods were kept in the chancel. This does not imply, however, that Icelandic temples of the 10th century were modeled on churches; rather they resembled large Icelandic farmhouses. A building believed to be a temple has been excavated in northern Iceland, and its outline agrees closely with that described in the saga.

Temples on the mainland of Scandinavia were probably built of wood, of which nothing survives, although an influence of pagan temples may be discernible in the so-called stave churches. At the close of the pagan period, the most splendid temple of all was at Uppsala. It was richly described by Adam of Bremen, whose report is based on statements of eyewitnesses, though he may have been influenced by the biblical description of Solomon's temple. Statues of Thor, Wodan, and Fricco (Freyr) stood together within it; the whole building was covered with gold, which could be seen glittering from afar. There were also famous temples in Norway, but no detailed descriptions are given of them.

Sacrifice took different forms. Roman authors repeatedly mention the sacrifice of prisoners of war to the gods of victory. The *thralls* who bathed the numen of Nerthus paid for the revelation of her secret identity with their lives. A detailed description of a sacrificial feast is given in a saga about a king of Norway. All kinds of cattle were slaughtered, and blood was sprinkled inside and out; the meat was consumed and toasts were drunk to Odin, Njörd, and Freyr. The most detailed description of a sacrifice is that given by Adam of Bremen. Every nine years a great festival was held at Uppsala, and sacrifice was conducted in a sacred grove that stood beside the temple. The victims, human and animal, were hung on trees. One of the trees in this grove was holier than all the others and beneath it lay a well into which a living man would be plunged.

There also were sacrifices of a more private kind. A man might sacrifice an ox to a god or smear an elf mound with bull's blood.

Eschatology and death customs. No unified conception of the afterlife is known. Some may have believed that fallen warriors would go to Valhalla to live happily with Odin until the Ragnarök, but it is unlikely that this belief was widespread. Others seemed to believe that there was no afterlife. According to the "Hávamál," any misfortune was better than to be burnt on a funeral pyre, for a corpse was a useless object.

More often people believed that life went on for a time after death but was inseparable from the body. If men had been evil in life, they could persecute the living when dead; they might have to be killed a second time or even a third before they were finished.

The presence of ships or boats in graves, and occasionally of chariots and horses, may suggest that the dead were thought to go on a journey to the otherworld, but this is questionable; such accoutrements more likely reflected a person's earthly occupation. Some records imply that the dead needed company; a wife, mistress, or servant would be placed in the grave with them. The famous Oseberg grave contained the bones of two women, probably a queen and her servant. Some stories suggest the existence of an ancient belief in rebirth, but a medieval writer labels the notion an old wives' tale. On the whole, beliefs in afterlife seem rather gloomy. The dead pass, perhaps by slow stages, to a dark, misty world called Niflheim (Niflheimr).

The end of the world is designated by two terms. The older is Ragnarök, meaning "Fate of the Gods"; the later form, used by Snorri and some others, is Ragnarøkkr, "Twilight of the Gods." Allusions to the impending disaster are made by several skalds of the 10th and 11th centuries, but fuller descriptions are given chiefly in the "Völuspá" and the didactic poems of the *Poetic Edda,* which form the basis of Snorri's description in his *Edda.*

Cosmic destruction: Twilight of the Gods

Only a brief summary of this rich subject can be attempted here. Through their own work, and especially because of the strength of Thor, gods have kept the demons of destruction at bay. The savage wolf Fenrir is chained, as is the guileful Loki, but they will break loose. Giants and other monsters will attack the world of gods and humans from various directions. Odin will fight the wolf and lose his life, to be avenged by his son Vidar (Víðarr), who will pierce the beast to the heart. Thor will face the World Serpent, and they will kill each other. The sun will turn black, the stars vanish, and fire will play against the firmament. The earth will sink into the sea but will rise again, purified and renewed. Unsown fields will bear wheat. Balder and his innocent slayer, Höd, will return to inhabit the dwellings of gods. Worthy people will live forever in a shining hall thatched with gold.

Although the cosmic cataclysm portrayed by the poet of the "Völuspá" reflects the apocalyptic imagery of the Book of Revelation, it is essentially a symbolic reflection of the waning Germanic world, ineluctably moving to its destruction because of the outrages committed by its divine and human representatives. According to another Eddic poem, the wolf will swallow Odin and, in revenge, his son will tear the jaws of the beast asunder. Several more details are given in other sources, generally cruder than those of the "Völuspá."

THE END OF PAGANISM

The Germanic peoples were converted to Christianity in different periods: many of the Goths in the 4th century, the English in the 6th and 7th centuries, the Saxons, under force of Frankish arms, in the late 8th century, and the Danes, under German pressure, in the course of the 10th century. The pagan religion held out longest in the most northerly lands, Iceland, Norway, and Sweden.

The story of the conversion of Iceland is known best because of the wealth of historical documents written in that country during the Middle Ages. Icelanders were, in many ways, the most international of northern Scandinavians. Among those who settled in Iceland in the late 9th century were men and women partly of Norse stock from Christian Ireland. Some of these were Christians; some were mixed in their beliefs, worshiping Christ and Thor at once. There were others who believed in no gods at all. Lack of faith in the heathen gods seems to have grown during the 10th century. Influence of Christian thought on some Icelandic poets is noticeable. Occasional missions to Iceland in the later 10th century are recorded, but little progress was made until Olaf I Tryggvason, king of Norway, sent out the German priest Thangbrand *c.* 997. Thangbrand was a ruthless, brutal man; he was outlawed and returned to Norway *c.* 999. But in the year after Thangbrand left (*c.* 1000), the Icelandic parliament (Althingi) resolved, at the instigation of King Olaf, that all should be baptized, although concessions were made to those who wished to practice heathen rites in private. Many of those who had been hereditary pagan chieftains became leaders of the church and, largely for this reason, tradition survived in Iceland as in no other Scandinavian land.

Conversions to Christianity

The conversion of Norway was far less peaceful. Much is known about it, chiefly from highly colourful Icelandic records. Olaf Tryggvason, who had come to Norway from England *c.* 995, quickly overcame the arch-pagan ruler Haakon Sigurdsson. Paganism was deeply rooted in the

minds of hereditary landowners, as the whole social system was largely founded upon its principles. Using fire and sword rather than persuasion, Olaf converted the whole of Norway in his short reign of five years. When he died in a naval battle, *c.* 1000, many of Olaf's subjects were Christians in name only. By the time Olaf II Haraldsson (later Saint Olaf) came to the throne about 15 years later, some of the Norwegians were baptized and some not, and everyone believed whatever he chose. Olaf II set out to complete the work of his predecessor, resorting to the same methods. He was such a tyrant that his own subjects, Christian though they were, drove him into exile in Russia. When he returned with a motley army, *c.* 1030, he met his death and was soon regarded as a saint. For all his faults, Olaf had established Christianity firmly in Norway.

Very little is known about the conversion of Sweden. It was a slow and complicated process. The people of West Gautland were, apparently, converted earlier than the rest, but public pagan sacrifice persisted in the temple of Uppsala until late in the 11th century. Kings who professed to be Christian were driven out, presumably because of their religious activities. Sweden was hardly a Christian country before *c.* 1100.

The picture that Scandinavian sources provide of Germanic religion is to a large extent lopsided, since many of the documents date to the period when waning paganism was threatened with doom by the growing impact of Christianity. This may account for the pessimistic worldview that pervades some aspects of Eddic poetry, as well as for some rather derogatory descriptions of the behaviour of the gods. The rigorous ethics of early Germanic society, based on trust, loyalty, and courage, and the perhaps somewhat idealized picture of the moral code given by Tacitus, had a divine sanction, but when Christianity arrived in the north, the message had apparently been dimmed by the gods' disrespect of their most solemn oaths. Paganism no longer had the stamina and inner drive to resist the pressure of Christianity, with its strong, well-organized church and its positive monotheistic creed, encompassing faith and ethics. (E.O.G.T.-P./E.C.Po.)

Finno-Ugric religion

The religion of the Finno-Ugric peoples, who inhabit regions of northern Scandinavia, Siberia, the Baltic area, and central Europe, is an admixture of agrarian and nomadic primitive religion and of Christianity and Islām. This treatment is concerned primarily with the pre-Christian and pre-Islāmic elements of Finno-Ugric religion.

GEOGRAPHIC AND CULTURAL BACKGROUND

The Finno-Ugric peoples. The area inhabited by the Finno-Ugric peoples is extensive: from Norway to the region of the Ob River in Siberia and southward into the Carpathian Basin in central Europe and the Ukraine. The history of their geographic dispersion is based almost entirely on linguistic criteria, since historical knowledge is recent and archaeological finds are scanty and interpreted variously.

Geographic distribution

The Finno-Ugric languages and the Samoyed languages together form the Uralic family of languages, which began to split up about 4000–5000 BC. The original Uralic people are thought to have lived in the region between the Ural Mountains and the middle reaches of the Volga River. Their descendants in the north are the Nenets, who live on the shores of the Arctic Ocean between the Taymyr and the Kanin peninsulas. In the south, the original speakers of the parent Finno-Ugric language probably began to disperse by 3000 BC, when the Ugrians formed their own group. One branch moved northeast, behind the Ural Mountains: the Ostyak (who in their own language call themselves Khanty), living east of the Ob River, and the Vogul (who call themselves Mansi), living west of the Ob River. The other branch spread southward and made contact with the Bulgar Turks and the Khazars; in the year 895 this branch (the Magyars [Hungarians]), together with certain Turkish tribes, conquered what is now Hungary. In this way, the largest, but at the same time linguistically the most isolated, Finno-Ugric nation came into existence. Other Magyars live in the countries of Romania and Czechoslovakia.

The Permian branch of the Finno-Ugric populations living in central Russia split from the other groups between 2500 and 2000 BC; the linguistic differentiation is not very great between the present-day Permians, who are divided into Votyaks (called Udmurts, living between the Kama and Vyatka rivers) and Zyryan (called Komi, living in the region between the upper reaches of the Western Dvina River, Kama, and Pechora)—the differentiation only occurred a little over 1,000 years ago. An intermediary group between the two branches are the Permyaks, whose language is sometimes considered a dialect of Zyryan.

Farther to the south, the differentiation of the Volga Finns into separate groups probably began about 1200 BC. The Volga Finns consist today of the Mordvins (including the Moksha in the southeast and the Erzya in the northwest), living in a rather large region near the middle reaches of the Volga River, and the Cheremis (the Mari), living in the vicinity of the confluence of the Volga and the Kama.

When the Baltic Finns came to the regions bordering on the Baltic Sea is not certain. The latest possible date would be *c.* 1500 BC (the evidence being the Baltic loan words in proto-Finnic), when the "proto-Finns" still maintained contact with the Mordvins and the Lapps. A much earlier date is possible, however, as there must have been many and repeated migrations by the Finno-Ugric populations westward from the Ural Mountains toward the Baltic regions. Initially, settlement was sparse, as is always the case with hunting cultures, but language differentiation sped up with the change to sedentary agriculture. The Lapps (called the Sāpmi) have been the slowest of the Finno-Ugric peoples to relinquish the hunting and nomadic culture—which has withdrawn slowly toward the north—and they themselves have moved from the direction of Lakes Ladoga and Onega (northeast of Leningrad) to the northern parts of Fennoscandia and the Kola Peninsula (northwestern Soviet Union).

After separating from early proto-Finnic about 3,000 years ago, the Lapp language became divided into a number of very different dialects. The oldest population settlements of the Baltic Finns were to the south of the Gulf of Finland and to the south of Lake Ladoga. The most westerly group, the Livonians (in the north of Courland, now part of the Latvian S.S.R.), is disappearing. The Estonians (living in the Estonian S.S.R.) are one of the three most advanced of the Finno-Ugric peoples, the others being the Finns and the Hungarians. Small but interesting cultures are represented by the Greek Orthodox Votes and Izhora Ingrians, both nearly extinct groups living near the head of the Gulf of Finland in an area once called Ingria, the Veps (living near Lake Onega), and the Karelians (living in central Russian S.F.S.R., the Karelian A.S.S.R., and Finland), as well as the Ludes in Olonets, who speak a transition dialect. The population moved into Finland from the south and southeast.

Ecological and intercultural factors. To attain a proper understanding of the history and phenomenology of the religion of the Finno-Ugric peoples, two basic influences must be borne in mind: the ecological factors and the pressure of alien cultures on the original religious tradition. The result of both factors has been a great variation in the religious atmosphere in different places.

Influences on Finno-Ugric religion

The Lapps, Nenets, Vogul, and Ostyak—who all have been associated with a nomadic and hunting culture in Arctic regions—retain a religious life that has many ancient elements. The Finns, Karelians, and Zyryans have practiced hunting up to the present, but they have been familiar with agriculture for thousands of years. The peoples on the south side of the Gulf of Finland, such as the Estonians, have long practiced agriculture and cattle breeding as well as fishing, but hunting has not been as important to them. The Finno-Ugric peoples of the southeast, like the Votyaks and the Cheremis, have practiced agriculture and cattle breeding only. The agrarian economy of the Hungarians, with its seminomadic features, is the outcome of a complicated history.

Habitat, climate, and other ecological factors have had

an important influence on economy and social organization and on traditional religion. Some of the differences between the various Finno-Ugric peoples, however, can be traced to outside cultural influences. The southeastern Finno-Ugric peoples have been marked by Turko-Tatar influence. In the 8th century the Votyaks and the Cheremis came under Bulgar domination; the conversion of the Bulgars to Islām in 922 and the subsequent Tatar domination in eastern Russia (1236–1552) gave added significance to the Arab–Islāmic tradition. In the 16th and 17th centuries, the Volga Finns, the Permians, the Ob Ugrians, and the Nenets finally came under the domination of Moscow; before this, Orthodox missionaries had worked, for example, among the Zyryans (St. Stephen, 14th century) and the Baltic Finns.

The influence of Slavic tradition on the Finno-Ugric peoples has been considerable—from the point of view of both folk religion and the more institutionalized Orthodox faith, though some of this influence in many places is late and superficial. There are also Finno-Ugric substrates in the Russian tradition in the north and northwest of Russia. Pre-Christian practices were still alive in the early 20th century, and among the Votyaks, the Ob Ugrians, and the Nenets there were still people who were unbaptized. Roman (Catholic) and Byzantine (Orthodox) traditions met one another in Finland and Estonia, but the Orthodox groups remain established only in the eastern regions. Most of Finland was converted to Christianity by way of Sweden, beginning in the 12th century, and the country remained Roman Catholic until Lutheranism was established in the 16th century. The position of the Hungarians, who formed a pocket surrounded by alien cultures, resulted in an extremely mixed array of contacts at different levels.

Thus, each of the Finno-Ugric peoples has its own cultural history, habitat, and level of civilization. In considering their religion, all this must be borne in mind. The Hungarians, Finns, and Estonians have the longest literary traditions, while a number of the other peoples are only now developing written literature in their own language. Ancient popular belief, preserved in oral tradition, has for the most part developed more persistently on the periphery, but near centres of culture it has become a minor growth alongside institutional religions.

Difficulties involved in the study of Finno-Ugric religion

The problem of the concept of a Finno-Ugric religion. Since it is not possible to find a single formula to cover Finno-Ugric cultures and religions and since the relationship between the peoples is often distant both geographically and historically, it may well be asked whether there is any utility in attempting, by means of comparative methods, to discover some common or basic substratum in Finno-Ugric religion. Many earlier scholars attempted this enthusiastically, but today there is general agreement that a hypothetical reconstruction representing the "original religion" of a single language family is virtually impossible. That ancient tradition may have been preserved in different regions, although fragmented and adapted to new conditions, is, of course, possible, and indeed seemingly trustworthy discoveries have been made that substantiate this view. One must, however, be extremely circumspect in projecting hypotheses applying to the entire linguistic group. Genetic-historical considerations are of great importance when dealing with those areas of the language family where a cultural connection has subsisted long and late.

The search for a common historical tradition is not, however, the most rewarding aspect of the study of Finno-Ugric religions. The religio-phenomenological approach is equally interesting and significant. In the course of conducting nonhistorical studies of similarities and differences in Finno-Ugric religious material, scholars have uncovered a spectrum of basic religious forms running from Arctic hunting and fishing cultures to southern cattle breeding and agriculture.

MYTHOLOGY

Creation, cosmography, and cosmology. The most widespread account of the creation among the Finno-Ugric peoples is the earth-diver myth. In the north it is known in an area extending from eastern Finland to the Ob River, and in the south it is found, for example, among the Mordvins. This myth, which is well known in North America and Siberia, is fairly constant in form among the Finno-Ugric peoples. In the Mordvin variant, God sits on a rock in the middle of the primeval sea and spits into the water; the saliva begins to grow and God strikes it with a staff, whereupon the Devil comes out of it (sometimes in the form of a goose). God orders the Devil to dive into the sea for earth from the bottom; at the third attempt, he succeeds but tries to hide some of the earth in his mouth. While God scatters sand, the earth begins to grow and the Devil's deceit is unmasked, and the earth found in his cheek becomes mountains and hills. The eastern Finnish myth contains an interesting detail; God stands on the top of a golden statue and orders his reflection on the water to rise, and this becomes the Devil.

Etiological (explanatory and expanding) continuations of the basic myth are common; the Devil demands for himself a piece of earth the size of the end of a stick, and from the hole that results vermin emerge—mice, fleas, mosquitoes, flies, and other such living things. Indo-Iranian influence has been seen in the dualism of the myth—setting God against the Devil—since religious dualism is most significant in Indo-Iranian religion. A water bird may be older than the Devil; it also occurs, however, without the dualistic emphasis. Thus, in an account by the Yenisey Ostyak, the great shaman (a medicine man with psychic abilities) Doh glides above the primeval sea among the water birds, asks the red-throated loon to dive for earth from the bottom of the sea, and with the earth makes an island. A rarer, but apparently ancient, myth is found among the Vogul: the god of the skies lets earth come down from heaven and places it on the surface of the great primeval sea.

Cosmic egg myth

The world made from an egg is a myth best known in equatorial regions, though the most northerly points of its distribution are in Finland and Estonia. A water bird or an eagle makes its nest on the knee of the creator (Väinämöinen), who is floating in the water; it lays an egg, which rolls into the water, and pieces of it become the earth, the sky, the moon, and the stars. Myths concerning the creation of man are found in the north among the Vogul and in the south among the Volga Finns. The common element among all such myths is that man, on the brink of achieving perfection, had his hairy covering transferred to the dog by the Devil, whose spit blighted man and made him subject to disease and death. In Finland the variant of yet another anthropogonic (origin of man) myth has been found: a hummock rises from the sea, a tree stump thereon splits open, and the first human couple steps forth.

Finno-Ugric cosmographic (world-describing) concepts include the following well-known mythological themes: a stream or sea encircling the round world; a canopy of the heavens, the central point of which is the North Star (a kind of nail on which the sky rotates); a world pole supporting the sky; a world mountain and a world tree rising in the middle of the earth; animals carrying the earth; and the nub of the earth and the nub of the sea (an abyss that swallows ships). From these and from other materials more or less coherent cosmographies have been formed in different places; the central components are the sky, the earth, and the underworld. Among the Ob Ugrians and the Nenets is found a myth of the seven- or nine-storied heaven.

The cosmogonic (concerning the origin of the world) and cosmographic myths have had important ritual functions and have provided the basis for cosmology (the ordering of the world). When, in incantations and prayers, numerous natural, cultural, and social phenomena derive from these basic myths, it is not a matter of giving an explanation but of finding the connection with the decisive primeval events that gave the world its lasting order. A pillar representing the world pole has been worshiped by the Lapps and the Ob Ugrians, especially as a symbol of the world order.

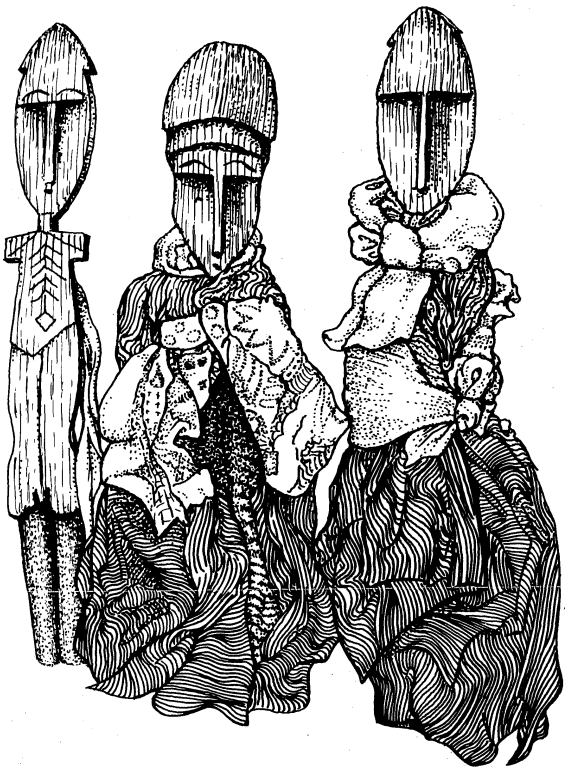
High gods. The semantic elements "sky" and "god of the sky" are found to be so close in the terminology of certain of the Finno-Ugric peoples (for example,

Cheremis Jumo, Finnish Jumala, Votyak Inmar, Zyryan Jen, Nenets Num) that the association cannot be a recent phenomenon. The tradition of the god of the sky is many-layered, and the influence of monotheism, especially of Christianity and Islām, is widely exhibited. This influence was evidently preceded by that of ancient southern high cultures. Thus the Cheremis Jumo has a real court with servants in his heaven, and these servants act as intermediaries between humans and the god of the sky. This indicates a Turko-Tatar influence, which can also be seen in the Votyak Inmar; Christian elements, however, are also found (Inmar's mother is related to the Virgin Mary). "Great," the most common epithet for Inmar and Jumo, reminds one of Allāh. The Mordvin god of the sky (Škaj, "creator" or "birth giver," among the Moksha people, and also Ńiškė-pas, "the great inseminating god") is the chief of the gods, all-knowing and all-seeing, who is not approached for trivial things. He appears, however, very concretely in a festival connected with the beginning of the spring plowing. In this festival an old man represents the god of the sky and from an attic or a tree answers questions put to him by people who pray about health, the grain harvest, the weather, and other matters. The gods of the sky of the Arctic Finno-Ugric peoples (Nenets Num; Ostyak Num-Turom and Sängke; Vogul Num-Tarom; Lappish Tiermes, Horagalles, and Radien) are the high gods of hunting and nomadic cultures, who sometimes appear in myths as creator gods and culture heroes (often as *dei otiosi,* or "inactive gods," without a cult) and sometimes as venerated gods of the economy (as the promoters of fishing, hunting, and reindeer herding), especially as weather gods. Originally the Finno-Ugric peoples probably had no concept of a hierarchic family of gods with a supreme god at its head; the attribute found in many places, "lofty" or "high," merely means "being above"—that is to say, a god appearing in the sky.

The concept of a begetting sky is stressed in southern agricultural cultures, in which an increasing importance of the Earth Mother may be observed; it is no longer a mere local field spirit but rather has the role of a great birth giver. "The god of the sky is our father, and the Earth Mother is our mother," say the Mordvins. The Earth Mother's function is not limited to field sacrifices, but also includes child giving; she is the begetter par excellence.

System of spirits. The high gods are usually encountered in connection with a rite; they are distant, invisible, and do not make surprise visits. With the guardian spirits, however, matters are different. They are first and foremost supranormal beings that appear in definite visions, auditory experiences, and other such occurrences. They appear especially when a social norm involving a guardian-spirit sanction is broken. The guardian spirits—along with the spirits of the dead—are significant as regulating factors in daily behaviour and normally are solitary local spirits, believed to "govern" and "own" a particular area: a cultural locality (*e.g.,* household spirits), a natural region (*e.g.,* guardian spirits of forest or water), or a natural element or phenomenon (*e.g.,* fire spirits or wind spirits). There are also special guardians (of man or of treasure) and various demonic beings that—though similar to the guardian spirits—are not worshiped.

The names of guardian spirits are normally compounds of words, the first element of which indicates the sphere of action and the second being a name such as "man" or "master," as in Votyak Korka-murt ("House-man") or Vu-murt ("Water-man"); "old man" or "old woman," as in Cheremis Pört-kuguza ("the Old Man of the House") or Pört-kuwa ("the Old Woman of the House"); or "father" or "mother" as in Mordvin Jurt-at'a or Jurt-ava. The system of social values is revealed by the system of guardian spirits: The house spirit protects the luck of the home; the cattle spirit watches over the cattle during the winter (in the summer the cattle come under the forest spirit); and the barn spirit looks after threshing luck. In representing these values the spirit may appear in a number of roles. Thus, the Ingrian house spirit appears as "owner," the original owner of the plot on which a house is built; "moralist," punisher of crimes against norms that may endanger the luck of the house; and "sympathizer,"



Wooden images of Ostyak house spirits.

From K.F. Karjalainen, *Die Religion der Jugra-Volker;* reproduced with permission from the Finnish Academy of Science and Letters

one who warns in advance of catastrophes threatening house or family. With some peoples—the Mordvins, for example—the guardian-spirit system is very specific and there are a very large number of spirits; with others, such as the Lapps, the Nenets, and the Ob Ugrians, there are fewer of them, and Herr der Tiere ("Master of Animals") game spirits predominate.

Sacred ancestors. The oldest form of Finno-Ugric religion is thought to be ancestor worship. Some of the main terms (*e.g.,* "grave," "hades," and "soul") go back several millennia. The cult concerned only dead members of the family; other dead beings were experienced as restless haunters, and aggressive expelling rites were used to dispel them. The worship of ancestors must be understood as a family institution in which intercourse between the living and the dead is the internal activity of a social primary group. The dead belong to the family, and they have both rights and duties; they protect the happiness of the family, assist it in its means of livelihood, and receive their share of the produce; they are also considered to be counselors, moralists, and judges. The cult of the dead can be divided in the following manner: (1) rites at the moment of death; (2) funeral preparations (washing the corpse, attiring it, and watching by it; making the coffin); (3) the committal; (4) celebrations in memory of a single dead person; (5) annual memorial ceremonies for the dead; (6) offerings and prayers to the dead in connection with earning the means of subsistence; and (7) occasional rites (*e.g.,* when moving to a new place or during illness).

The most important of the ritual ceremonies for a dead person are those that take place during the transition period, which may last for six weeks and may include addressing the departed euphemistically and in dirges. The departed person remains in the dwelling place, separated from his body; agreements are made with him about the distribution of property; he is given advice about how to live on the other side; he is invited to return for the celebration of his anniversary; and so on. The most important matter is the ensurance of harmony between the newly departed and his relations in the graveyard. Of central importance in the collective worship of the dead is the visit of the departed members to their old home; among the Eastern Finno-Ugric peoples this approximates with the Chris-

tian feast of Easter, and among the Western it is in late autumn (*e.g.,* the Finnish Kekri, November 1, an ancient festival to celebrate the seasonal change). Living members of the family also visit the graves on the anniversary days of the departed. Customs among the Lapps, the Nenets, and the northern Ostyak differ somewhat from the above; among the Lapps, the departed person is represented by a clothed log and among the Ostyak and the Nenets by a doll-effigy that is kept for as long as three years.

The otherworld is viewed as two-storied and consists of first, a graveyard hades, or underground village of the dead in a holy forest near the village; and second, a distant hades, far in the north behind the burning stream (with an admixture of paradise concepts). Name-giving rites suggest continuity and reincarnation; a child is given the name of a dead relative, and the child thereby is believed to receive the personality of the deceased relation. If the result is unsuccessful, a name-changing rite can be performed.

Divine heroes. Hero worship in Finno-Ugric religion does not point to culture heroes who are described in myth and whose actions are located in cosmogonic contexts. In general, culture heroes are not worshiped. The matter is otherwise when dealing with divinized historical figures, the cults of which are found among several of the Finno-Ugric peoples. Mardan of the Yelabuga Votyak is viewed as the progenitor of 11 villages and the one who led the dwellers therein from the north to their present habitations. There is a sacrificial ceremony in his honour every year. Also, there are signs of the worship of tribal chiefs, for example, in the forest sanctuary worship of the Votyak (*lud*) and the Volga Finns (*keremet*). The best-known of the Cheremis princes, called "the old man of the Nemda Mountain," is a great ancient warrior under whose rule the people were strong and united. According to this myth, he promised to return when war threatened; once he was called for unnecessarily and, after discovering the betrayal, he ordered the annual propitiation sacrifice of a foal. The Ob Ugrians have a large number of "local gods" of whom pictures have been made and who are sometimes associated with ancient mighty men or Christian heroes and saints. A death doll made by a shaman may also have been the origin of a hero cult; the Nenets have been known to cherish and feed such a doll for as long as 50 years.

Sacred animals. In the "hunters' religion" preserved among the northern Finno-Ugric peoples, bear ceremonies are central. The Ostyak, Vogul, Nenets, Lapps, Finns, and Karelians have all been acquainted with myths and rites connected with the bear. The myths recount that the bear is of heavenly origin and is the son of the god of the sky; it descends from heaven and, when it dies, returns there. There is also a story about a marriage between a bear and a woman from which a tribe of the Skolt Lapps (in Finland) is said to be descended. The bear-killing ceremony is divided into two acts—the killing itself and the feast afterward. Killing a bear that was protected by a forest guardian spirit involved a complicated ritual, which ended with bringing the bear home. Women believed that they had to keep at a distance so that the bear would not make them pregnant. The feast to celebrate the killing of the bear lasted two days and was full of marriage symbolism. The bear was addressed euphemistically, and a young man or woman was chosen to be its mate. A large meal made of the meat of the bear was consumed. Finally, the skull of the bear was carried in procession to the branch of a pine tree on the top of a mountain. This was the custom in Karelia. A number of miniature dramas were connected with Ob Ugrian bear rites. Masked participants tell the bear that members of a strange tribe have killed it. There seems to be a historical connection among the bear ceremonies of Ob Ugrians, Karelians, Finns, and Lapps. Nowhere else in the wide Arctic sphere have the bear songs and dramas taken such a prominent place as in this hunting ritual.

Bear ceremonies

The exogamic patrilineal clans (involving marriage outside a particular group) of the Ob Ugrians are often known by animal names—"bear," "falcon," "frog," or "dog." The animal is regarded as the manifestation of the family guardian spirit and is not allowed to be killed or eaten. Evidence of totemistic systems, in which animals are associated with blood-related groups, has been found among the Lapps and the Nenets. Some scholars consider the names of relations (animal names) found among other Finno-Ugric peoples, such as the Hungarians and Karelians, as evidence of a lost totemism.

INSTITUTIONS AND PRACTICES

Cult authorities. The male head of the family has long had a central role in leading different home and family cults. In the *lud* sanctuaries of the Votyak, for example, worship was performed by members of the family; the head of the family had the responsibility of organizing the cult and the task was hereditary. Women also were able to supervise certain minor home rituals—such as those performed in connection with cattle breeding (offerings to the guardian spirit of the cattle shed and the forest). In hunting and nomadic cultures, the head man (*e.g.,* the oldest of the hunting party or the reindeer chief) supervised the rites. The official authorities of the rites (*i.e.,* the religious specialists) among the Finno-Ugric peoples were of the following types: shamans (among the Nenets and the Lapps); seers (the counterparts of the shaman among southern peoples); sacrificing priests (the leaders of the annual rites, especially in cattle-breeding cultures and agricultural communities); guardians of the sanctuary (the protectors of holy groves, buildings, and other places and the controller of the rites); professional weeping women (the "vocalists," especially of the cult of the dead but also of weddings, who were the verbal expressers of the content of the ritual); and the masters of ceremonies at weddings. The shaman had many and various tasks in Arctic regions, but further south particular tasks were undertaken by various cult authorities: the seer (healing and counseling) and the weeping woman, or psychopomp (*i.e.,* "conductor of souls"), guiding the soul to the other world. The two last-mentioned are verbal ecstatics; the task of the seer, especially in solving critical problems, was of the utmost importance. The task of the sacrificing priest was more of a routine affair, but among the Volga Finns and the Permians for example, the long and skillful prayers as well as the complex ceremonies performed by the priests required great professional competence.

Cult centres. The home sanctuary of the Votyak is a *kuala,* a primitive log cabin near the dwelling house. In a corner at one end of the *kuala* is a shelf, at the height of a man, on which there are branches of deciduous trees and conifers, and on top of them a *voršud* (a box with a lid). A weekly offering is made here. Another Votyak sanctuary is the *lud*—a fenced-off area in an isolated place in the forest. In the middle is a primitive table for sacrificial gifts. In the *lud* regular animal sacrifices are offered and occasional crisis rites performed (sacrifices to dispel accidents or disease). The cult group in both *kuala* and *lud* is the family; the office of the sacrificing priest of the *lud* is hereditary, and in the principal house of the family there is a great *kuala,* which is visited three times a year in addition to the offerings made in the small *kuala* at home. The small *kuala* is built on a foundation of earth and ashes brought from the big *kuala.* The system is exogamous—the woman visiting the *kuala* of her own father and not that of her husband's father. The Votyak also have large groves near a spring or a brook in the vicinity of a village, where common sacrifices for the whole village are made. There are, in addition, larger sacrificing groups, which may include dozens of villages and which meet every third year for a festival lasting many weeks. The Volga Finns also have fenced-in *keremet* groves for the family cult and places of worship common to the whole village. Evidence also exists concerning sacrificial groves among the Baltic Finns and from group villages in Karelia and Ingria. In the thinly populated parts of Finland, the family cult took place either at cup stones (sacrifice stones with shallow cuplike depressions) or at holy trees. Among the nomadic Lapps (those involved in reindeer herding and fishing) *seita* ("sacrificial stone") places for worship arose near a reindeer migration route or a good fishing place, and for such a place an outstanding stone generally was chosen. The Ob Ugrians had a kind of "mobile temple"

Home and forest sanctuaries

for the wooden idols (normally kept in the corner of the house) that were placed on special sledges.

Cult practices. All the main categories of rites are found among the Finno-Ugric peoples: cyclic or calendric rites (concerning the means of livelihood), rites of passage (the transition of the individual from one status to another), and crisis rites (concerning threats of disaster). The character of these rites varies considerably, depending on ecological factors and cultural contacts. Generally, an agrarian culture produces a cult system that is more stable and formal than that produced by a mobile hunting culture or a nomadic way of life. In the latter, sacrifice rites tend to be more improvised and the cult group smaller. An example of a formal system is the distinction "upward" and "downward" in worship found among the Votyaks and the Cheremis; sacrifices of white animals are made in deciduous groves to the god of the sky and to certain nature gods, the direction of prayer being to the south; sacrifices of black animals are made to the departed and to the guardian spirits of the earth near conifers, the direction of prayer being to the north.

CONCLUSION

Two phenomena may be consistently observed with regard to the religious customs of the Finno-Ugric peoples. These are the ecological adaptation of religion and the stratification of tradition in connection with acculturation. A number of examples of the former have already been given. As far as acculturation is concerned, it may be said that the "syncretism" it produces does not result in any conflict in the religious field, except perhaps for short periods of adjustment. Old and new elements of different origins are molded into an active system, and choice and adaptation take place according to practical religious need. Christianity and Islām have in many places provided a religious superstructure, but they have not been accepted as such; certain elements from them have been adapted to the depth structure of a primitive religion. The best example of this is the preservation of folk religion in Hungary, Finland, and Estonia, where Christianity, supported by a literate culture, is ancient. Popular belief has become intertwined with the religious tradition because it has always had a function that no Christian practice has replaced. Only mass media and urbanization have jeopardized the ancient belief tradition. (L.O.H.)

Baltic religion

The term Baltic religion covers the religious beliefs and practices of the Balts, ancient inhabitants of the Baltic region of eastern Europe, who spoke languages belonging to the Baltic family of languages.

THE STUDY OF BALTIC RELIGION

Problems. The study of Baltic religion has developed as an offshoot of the study of Baltic languages—Old Prussian, Latvian, and Lithuanian (see LANGUAGES OF THE WORLD: *Indo-European languages: Baltic languages*). These form a separate group—the oldest one—of the Indo-European languages, which are closely related to the ancient Indian language Sanskrit.

Although the study of Baltic languages is important in the study of Indo-European linguistics, the study of Baltic religion has not assumed a similar level of importance in the study of comparative religion. In 1875 it was shown that the religious concepts of the Balts, when compared with those of other European peoples, are found to be marked by many older features that agree with Vedic (ancient Indian) and Iranian ideas. At least one scholarly reconstruction of ancient Indo-European religion depended mainly on Baltic religious traditions. International research in Baltic religion has, however, been greatly hindered by the fact that the languages of these small Baltic countries (Latvia and Lithuania) are but little known and because Baltic scholars have been able to work in this field only relatively recently. Thus, a comprehensive review of Baltic religion is possible only on the express understanding that many findings are only hypothetical and require further research. But, as will be seen below, even under these circumstances Baltic religious concepts help greatly in understanding the formation and structure of the oldest phases of Indo-European religion.

Age of religious concepts

Sources of data. There are four main sources of data, each with its own relevance and each requiring its own specific methodology: archaeological material, historical documents, linguistics, including toponymy (the study of the place-names of a region or language), and folklore. Since the last half of the 19th century, archaeological material has furnished much information about burial and sacrificial rites. The remains of sacred buildings have also been found. This material is of special interest in that it corroborates old religious traditions preserved by folklore, which gives added reliability to both of these sources. But archaeological material can at best furnish only a partial and incomplete picture, even though it is meaningful in some respects. Historical documents, already partially compiled and published, could be expected to yield much more information. Their value, however, is made problematic by the fact that all such documents were written by foreigners, mainly Germans who, in the course of their centuries-long eastward expansion, subjugated the Baltic peoples and exterminated some of them. Since the conquerors did not understand the Baltic languages, many documents contain the names of gods and other divinities that are without basis in fact. Baltic religion was viewed dogmatically and negatively in the light of Christian interpretations. Linguistic source material, also compiled by foreigners, shows fewer signs of interpretation, especially in regard to toponymy. Baltic folklore—one of the most extensive folklores of all European peoples—contains the greatest amount of material, especially in the form of *dainas* (short folk songs of four lines each) and folktales. Folklore is especially valuable because it contains many concepts that elsewhere have been lost under the influence of Christianity. Old religious beliefs have persisted because the Germans, after conquering the Baltic lands in the 13th and 14th centuries, made practically no attempt at Christianization and contented themselves with only economic gains. The positive result of this policy is the preservation of old traditions and religious beliefs; some researchers have also noted the similarity between the metrical structure of the *dainas* and that of the Old Indian short verses in the Rigveda (a Hindu sacred scripture).

The student of Baltic religion still encounters two difficulties. First, as has been noted, since written documents were established in Christian times, Christian influences in them are inescapable. Such influences cause difficulties and make a critical approach mandatory. Second, after the establishment of political independence of the Baltic countries following World War I, there arose a certain national romanticism that has attempted to identify Baltic culture with that of the ancient Indo-Europeans. Thus, an uncritical approach has led even to the introduction of "gods" that are actually only etymological derivations from the names of Christian saints. On the other hand, those western European scholars who are unfamiliar with the special historical and social circumstances of the Balts have assumed Baltic folklore to be on a level with the thoroughly Christianized western European folklore and thus have underestimated its importance.

MYTHOLOGY

Cosmology. In the traditions of the Baltic peoples, there are no epic myths about the creation of the world and its structure. This fact is explained by the historical and social circumstances mentioned above, which either have hindered the formation of these types of myths or, more likely, have simply made their preservation impossible. Furthermore, there has been no significant research concerning Baltic myths and their interrelationships. Fragmentary evidence found exclusively in folklore indicates only two complexes of ideas with any certainty: the first concerns the structure of the world, the second the enmity between Saule ("Sun") and Mēness (Latvian; Lithuanian Mėnulis; "Moon").

The two-region hypothesis

There is disagreement as to whether the Balts pictured the world as consisting of two regions or of three. The two-region hypothesis seems to be more plausible and is

supported by a dualism found frequently in the *dainas*: *šī saule* (literally "this sun") and *viņa saule* (literally "the other sun"). The metaphor *šī saule* symbolizes ordinary everyday human life, while *viņa saule* indicates the invisible world where the sun goes at night, which is also the abode of the dead.

The evidence does not show conclusively whether this world is located in the direction of the setting sun or under the earth, beneath which the sun travels back to the east. The sky is considered to be a mountain, sometimes of stone, and is the residence of the sky gods. Saule rides over the sky in a chariot drawn by a varying number of horses, Mēness rides to be married, and Pērkons (Latvian; Lithuanian Perkūnas; "Thunderer") makes weapons and jewelry in the sky.

The concept that Saule, unseen during the night, makes her way from west to east under the earth so that she can start her course anew over the sky mountain is also familiar. It is also possible to see here the ancient idea of a world ocean on which the earth, as a round plate, swims, an idea that has disappeared under the influence of Christianity.

The notion of a sun tree, or world tree, is one of the most important concepts regarding the cosmos. This tree grows at the edge of the path of Saule, and the setting sun (Saule) hangs her belt on the tree in preparation for rest. It is usually considered to be an oak but is also described as a linden or some other kind of tree. The tree is said to be located in the middle of the world ocean or generally to the west.

The gods. *Dievs.* The Baltic words Latvian *dievs,* Lithuanian *dievas,* and Old Prussian *deivas* are etymologically related to the Indo-European *deiu̯os;* among others, the Greek Zeus is derived from the same root. It originally meant the physical sky, but already in Old Indian and other religions the sky became personified as an anthropomorphic deity. Dievs, the pre-Christian Baltic name for God, was used by Christian missionaries (and still is) to denote the Christian God. The etymology of the word indicates that the Balts preserved its oldest forms, which is also true of the functions and attributes of the personified Baltic sky god Dievs, who lives on his farmstead on the sky mountain but does not participate in the work of the farm. Importantly, Dievs is a bridegroom who rides together with the other gods to a sky wedding in which his bride is Saule. Dievs' family is a later development; in the family, Dieva dēli ("God's Sons") play the primary role. Thus Dievs is pictured as the father of a family of sky gods. Besides such anthropomorphic characteristics, another characteristic that gives Dievs a universal significance may be observed: he appears as the creator of order in the world on the one hand, and as the judge and guardian of moral law on the other. From time to time he leaves the sky mountain and actively takes part in the everyday life of the farmers below. His participation in various yearly festivals is vividly described. In spite of this, the Baltic Dievs is similar to the Old Indian Dyaus, the Greek Zeus, and other personifications of the sky. Such divinities have a tendency, in comparison with other gods of their religions, to recede into a secondary role.

The sky god

Pērkons. In Baltic, as in other Indo-European religions, there is, in addition to Dievs, the Thunderer (Latvian Pērkons, Lithuanian Perkūnas) with quite specific functions. Pērkons is described in the oldest chronicles and in poetic and epic folklore, but, though he is a primary divinity, there is no reason to believe that he is the main god. His abode is in the sky, and, like Dievs, he sometimes descends from the sky mountain. He has two main characteristics. First, he is a mighty warrior, metaphorically described as the sky smith, and the scourge of evil. His role as adversary of the Devil and other evil spirits is of secondary importance and has been formed to a great extent under the influence of Christian syncretism. Second, he is a fertility god, and he controls the rain, an important event in the life of farmers. Various sacrifices were made to him in periods of drought as well as in times of sickness and plague. No other god occupied a place of such importance at the farmer's table during festivals, especially in the fall at harvest time. Like the other sky gods, he also has a family. Even though his daughters are mentioned occasionally, originally he had only sons, and myths depicting sky weddings portray his role vividly, as a bridegroom and as the father in his sons' weddings.

Saule. The Sun, Saule, occupies the central place in the pantheon of Baltic gods. The divinity of the sun has been recognized throughout the world, and the Balts were no exception. The Baltic description of Saule is so complete and specific that it was one of the first to be studied by scholars. Of greatest importance is the similarity in both functions and attributes of Saule and the ancient Indian god Sūrya. Similarities between the two deities are so great that, were not the two peoples separated by several thousand miles and several millennia, direct contact between them would be indicated instead of only a common origin.

The sun goddess

The representation of Saule is dualistic in that she is depicted as a mother on one hand, and a daughter on the other. Her attributes are described according to the role she plays. As a daughter she is mentioned only when she is a bride to the other sky gods. But as her daughters frequently are in the same role, it is difficult to differentiate between them. As a mother, however, she is depicted much more extensively and completely. Her farmstead on the sky mountain borders that of Dievs, and both Dieva dēli and Saules meitas ("Daughters of the Sun") play and work together. Sometimes Dievs and Saule become enraged at each other because of their respective children, as, for example, when Dieva dēli break the rings of Saules meitas or when Saules meitas shatter the swords of Dieva dēli. Their enmity lasts three days, which some scholars explain through natural phenomena; *i.e.,* the three days before the new moon when Dievs, a substitute for the moon, is not visible.

That Saule, richly described in mythology, also had a cult devoted to her is suggested by the many hymns in her honour. They contain either expressions of thanks for her bounty or prayers seeking her aid, not only in relation to agriculture but to life in general. In agriculture Saule is a sanctifier of the fertility of the fields; in the life of the individual she is a typical sky goddess, interfering in her omniscience. She has human moral characteristics and punishes the immoral and aids the suffering. Though the question of where Saule's places of worship were located is not solved, the occasions for rituals pertaining to Saule have been definitely established, the most important of which was the summer solstice. Besides song, recitative, and dance, a central place in the ceremonies was occupied by a ritual meal, at which cheese and a drink brewed with honey (later beer) were consumed.

Mēness. The Moon, Mēness, also belongs to the sky pantheon. Detailed analysis only recently has shown that he has a role as a war god in Baltic religion. Such a role is indicated not only by his dress and accoutrements but especially by his weapons and expressions used in times of war. The influence of syncretism, however, has erased the outlines of his characteristics so far as to make a description of his role and any cult he may have had very difficult. The sky wedding myths furnish a somewhat more complete picture in which he is represented as a conflict-creating rival suitor of Auseklis ("Morning Star").

The moon god

Auseklis, his sons, Dieva dēli, and Saules meitas form a separate group of divinities. Although they are mentioned in the sky myths, they have remained only as personifications of natural phenomena, characterized by the most beautiful metaphors. It is notable that a common characteristic of the sky gods, and, in fact, of all Baltic divinities, is the express tendency for each to have a family.

All of the divinities mentioned above are closely associated with horses: they either ride or are drawn in chariots across the sky mountain and arrive on earth in the same fashion. The number of horses is indeterminate but usually varies from two to five or more. This trait also confirms the close ties between Baltic and Indo-Iranian religions.

Although males form the majority of the sky gods, the chthonic (underworld) divinities are mostly female. In both Latvian and Lithuanian religions the earth is personified and called Earth Mother (Latvian Zemes māte, Lithuanian Žemyna). But the Lithuanians also have Earth Master (Žemėpatis). Latvians in general refer to mothers,

Lithuanians to masters. Zemes māte is the only deity in addition to Dievs who is originally responsible for human welfare. Based on the writings of the Roman historian Tacitus, it has been asserted that she is the mother of the other gods, but there is no support for this view in other sources. Under the influence of Christian–pagan syncretism, the Virgin Mary has assumed some of the functions of Zemes māte. Furthermore, some of these functions have been acquired and differentiated by various other later divinities, who, however, have not lost their original chthonic character. Thus, a deity of the dead has developed from Zemes māte, called in Latvian Smilšu māte ("Mother of the Sands"), Kapu māte ("Mother of the Graves"), and Veļu māte ("Mother of the Ghosts"). Libations and sacrifices were offered to Zemes māte. Such rituals were also performed in connection with the other divinities at a later stage of development. The fertility of the fields is also guaranteed by Jumis, who is symbolized by a double head of grain, and by various mothers, such as Lauka māte ("Mother of the Fields"), Linu māte ("Mother of the Flax"), and Mieža māte ("Mother of the Barley").

Forest and agricultural deities. A forest divinity, common to all Baltic peoples, is called in Latvian Meža māte and in Lithuanian Medeinė ("Mother of the Forest"). She again has been further differentiated into other divinities, or rather she was given metaphorical appellations with no mythological significance, such as Krūmu māte ("Mother of the Bushes"), Lazdu māte ("Mother of the Hazels"), Lapu māte ("Mother of the Leaves"), Ziedu māte ("Mother of the Blossoms"), and even Sēņu māte ("Mother of the Mushrooms"). Forest animals are ruled by the Lithuanian Žvėrinė opposed to the Latvian Meža māte.

The safety and welfare of the farmer's house is cared for by the Latvian Mājas gars ("Spirit of the House"; Lithuanian Kaukas), which lives in the hearth. Similarly, other farm buildings have their own patrons—Latvian Pirts māte ("Mother of the Bathhouse") and Rijas māte ("Mother of the Threshing House"); Lithuanian Gabjauja.

Gods of natural phenomena

Because natural phenomena and processes have often been raised to the level of divinities, there are a large number of beautifully described lesser mythological beings whose functions are either very limited or completely denoted by their names. Water deities are Latvian Jūras māte ("Mother of the Sea"), Ūdens māte ("Mother of the Waters"), Upes māte ("Mother of the Rivers"), and Bangu māte ("Mother of the Waves"; Lithuanian Bangpūtys), while atmospheric deities are Latvian Vēja māte ("Mother of the Wind"), Lithuanian Vėjopatis ("Master of the Wind"), Latvian Lietus māte ("Mother of the Rain"), Miglas māte ("Mother of the Fog"), and Sniega māte ("Mother of the Snow"). Even greater is the number of those beings related to human activities, but only their names are still to be found, for example Miega māte ("Mother of Sleep") and Tirgus māte ("Mother of the Market").

Goddess of destiny. Because of peculiarities of the source materials, it is difficult to determine whether the goddess of destiny, Laima (from the root word *laime,* meaning "happiness" and "luck"), originally had the same importance in Baltic religion as later, or whether her eminence is due to the specific historical circumstances of each of the Baltic peoples. In any case, a wide collection of material concerning Laima is available. The real ruler of human fate, she is mentioned frequently together with Dievs in connection with the process of creation. Although Laima determines a man's unchangeable destiny at the moment of his birth, he can still lead his life well or badly within the limits prescribed by her. She also determines the moment of a person's death, sometimes even arguing about it with Dievs.

The Devil. The Devil, Velns (Lithuanian Velnias), has a well-defined role, which is rarely documented so well in the folklore of other peoples. Besides the usual outer features, several characteristics are especially emphasized. Velns, for instance, is a stupid devil. In addition, the Balts are the only colonialized people in Europe who have preserved a large amount of folklore that in different variations and situations portrays the Devil as a German landlord. Another evil being is the Latvian Vilkacis, Lithuanian Vilkatas, who corresponds to the werewolf in the traditions of other peoples. The belief that the dead do not leave this world completely is the basis for both good and evil spirits. As good spirits the dead return to the living as invisible beings (Latvian *velis,* Lithuanian *vėlė*), but as evil ones they return as persecutors and misleaders (Latvian *vadātājs,* Lithuanian *vaidilas*).

PRACTICES, CULTS, AND INSTITUTIONS

Temples and other holy places. Archaeological excavations in the 20th century have indicated the existence of temples made of wood. The only remains of these temples are postholes. Such temples were circular, approximately 15 feet (five metres) in diameter, in the centre of which a statue of a god may have been erected. At present, however, the existence of such temples must be regarded only as conjecture within the realm of probability. On the other hand, the existence of open-air holy places or sites of worship among the Balts is confirmed by both the earliest historical documents and folklore. Such places were holy groves, called *alka* in Lithuanian. Later the word came to mean any holy place or site of worship (Lithuanian *alkvietė*). Considerable research has shown that the usual sites were little hills, where the populace gathered and sacrificed during holy festivals, all of which supports the idea that wooden buildings could have been built at these sites.

Sites of worship

Other holy places were also recognized. The most important of these appear to be bathhouses, whose function some researchers have compared to that of churches in Christianity. A large amount of evidence indicates that religious–magical rites, from birth ceremonies to funerals, were performed in such bathhouses. There are various opinions as to whether the so-called holy corner (*heilige Hinterecke*)—*i.e.,* the dark corner of a peasant's house in which a deity or patron lives—belongs to pre-Christian concepts or not. On the other hand, various places in the house proper, such as the hearth and the doorstep, were considered to be abodes of spirits. In general, the more important work sites each had its own guardian spirit. Sacrifices were performed at each spot to assure successful completion of work. Because they supplied the farmstead with water, streams and rivers were also especially important.

Religious personages. There is no reliable information that the Balts had a priestly class, let alone religious hierarchy. The 11th-century German historian Adam of Bremen, in describing conflicts between Christian missionaries and Latvians, said that "every house is filled with seers, augurers, and necromancers," which indicates that the Balts had sacral persons, probably the patriarchs of large extended families or heads of clans. As even 18th-century church inspection records show, the Christian church had great difficulty in curbing their influence, especially within their clans. Their religious functions were twofold. First, they were responsible for the welfare and means of existence of the people through the performance of appropriate rites both at work sites and during the holy festivals. Second, they assured that the proper procedure would be followed in rituals connected with the important occasions of human life, such as birth, marriage, and death. In the syncretistic amalgam of Christianity and the religion of the Balts, those persons were called sorcerers (*Zauberer*) and, according to church records, were treated by the Balts with the same reverence as bishops were treated by Christians.

Sacred times. Special rites evolved for the festivals of the summer solstice and the harvest, while other rites were used specifically for beginning various kinds of spring work. Such spring work included sending farm animals to pasture or horses to forage for the first time, plowing the first furrow, and starting the first spring planting. The birth of a child was especially noted; it usually took place in the bathhouse or some other quiet spot. Laima was responsible for both mother and child. One birth rite, called *pirtīžas,* was a special sacral meal in which only women took part. Marriage rites were quite extensive and corresponded closely to similar Old Indian ceremonies. Fire and bread had special importance and were taken along to the house of the newly married couple. These

rites persisted until quite late and were to be seen even at the end of the 19th century, though in many cases only as games. In this connection, fire in general occupied a central place in Baltic religion. Considered holy, it was worshiped, and sacrifices were offered to it.

Death rites and customs

It seems unbelievable that even as late as 1377 and 1382, respectively, the Lithuanian king Algirdas and his brother Kęstutis could still be buried according to the old traditions in a Christian Europe; dressed in silver and gold, they were burned in funeral pyres together with their best possessions, horses, hunting dogs, birds, and weapons. In spite of a ban by the church and subsequent persecution, this rite still persisted in the 15th century. The tenacious preservation of this ancient Indo-European ritual casts light on other features of Baltic religion. Chronicles relate that Lithuanians, after losing a battle, joyfully committed suicide; this was also true of the widows of soldiers killed in battle. Such voluntary immolation and the articles buried with the dead are evidence of a belief in life after death. It is said that at the funeral of a nobleman his companions threw lynx and bear claws into the fire to aid his climb up the mountain to God, an indication of Christian influence. Archaeological excavations have also yielded evidence of fire funeral rites: the bones of humans and animals, metal jewelry, and weapons found at the sites of the funeral pyres.

Decorated horse skull used in Baltic funeral rites. In the Kaunas State Historical Museum, Lithuania.

In funeral rites several different phases are discernible during the period between death and burning. The deceased was laid out in his house for a longer or shorter period depending on his social position and the size of his estate. During this time a meal lasting several days was held for the deceased's relatives and friends. In the course of the festivities the participants conducted fights on horseback. Lamentations, leave-takings, and praises of the deceased, as well as wishes for a safe journey to the world of the dead, accompanied the corpse on the way to the funeral pyre. In spite of persecution by the church, the tradition of lamentation has lasted until modern times, though in a somewhat modified form. One of the peculiarities of Baltic funeral rites was their similarity to wedding ceremonies. The corpse and a partner selected from the living were dressed in elaborate wedding costumes, wedding songs were sung, and dancing took place. The basis of these ceremonies was the belief that the dead anticipate a new companion with the same joy as the living do a new in-law. The corpse's living partner was a symbolical substitute for the new comrade awaited by the dead.

The use of living people to represent symbolically the companions of the dead in funerary practices suggests a dominant concept in Baltic religious thought, namely, that the boundary between the worlds of the dead and the living was not real. The dead continued to live invisibly and were present at all important occasions. A place was set for them at the festival table and no one else might sit there. The extensive practice of feeding the dead was a consequence of the concept that the living were responsible for their welfare. Originally, their food must have been placed at the hearth. In later development, meals for the dead were also placed in other buildings, such as the threshing house or the bathhouse. Under the influence of Christianity, these living dead (Latvian *velis,* Lithuanian *vėlė*) have been confused with the Devil. A widespread view was that the souls of the dead dwell in the *zalktis* (Latvian; Lithuanian *žaltys;* "green snake"); thus special care was taken in its feeding. But the *zalktis* was also closely associated with fertility and sexual symbolism.

CONCLUSION

Three main characteristics

Three main characteristics are discernible in Baltic religion. First, it is a typical astral religion in which the personified sky and main heavenly bodies play a major role. Saule, Mēness, Auseklis, and other gods have their own traits, frequently based on counterparts in nature. Although they are all related as one family, their roles within the family are varied. Depending on the cult or the plot of the myth, each divinity can assume various functions; a religious person, in general, does not experience such fluctuations as a contradiction. The second main characteristic is the personification of happiness, luck, and fate in Laima, who has assumed the role of a goddess of destiny. Because happiness is not an external, datable event, other gods besides Laima can help determine happiness in human life. The differentiation of Laima's functions has led to the establishment of some of her functions as independent entities with sometimes a poetic, sometimes a religious, meaning. The concept of destiny in Baltic religion has not, however, resulted in passive resignation or quietism but rather full exploitation of opportunities within the limits set by it. The third characteristic is the fertility cult. Here the primary force is the personified earth, called Mother, with all her functions and characteristics. It must be understood that the concept of a fertility cult entails a wider meaning, that of the assurance of human welfare in general.

These three main typological traits hardly describe Baltic religion in all of its details and nuances. The religion can also be analyzed as having two strata: one, expressed in the above three features, can be called the stable surface layer; the second, visible below the first, contains only the outlines of undifferentiated, fluid mythological and religious beings that, because of their vague character, appear in various guises and have no stable role. They are the countless house, field, and wood spirits of the nature myths.

Baltic religion, typologically, is an agricultural religion, and it is useless to speculate whether any other basis—such as nomadism, hunting, or fishing—can be found for it, because no information regarding such possibilities can be derived from any source. The amorphous agricultural clan defines the nature of Baltic religion. The farmer's gods are also farmers, though they live in great glory on their farmsteads on the sky mountain, from which they descend to help their lesser image—man. If necessary, Dievs, Saule, and Laima dress themselves in farmer's clothes and walk his fields with him. This religion does not recognize contemplation or mysticism but rather exhibits a healthy rationalism. Just as the gods are part of the cosmic order and are responsible for its maintenance, so humans obey it and become part of the divine rhythm of life set by the gods. In this way, humans cross the boundary that otherwise separates them from the world of the gods. Various specific historical circumstances explain why the Balts, in their language as well as in their religion, have preserved many elements undoubtedly belonging to the oldest phase of Indo-European religion. (H.Bi.)

Slavic religion

Slavic religion is understood here to include only the relevant beliefs and practices of the ancient Slavic peoples of eastern Europe. Slavs are usually subdivided into East Slavs (Russians, Ukrainians, and Belorussians), West Slavs (Poles, Czechs, Slovaks, and Lusatians [Sorbs]), and South Slavs (Serbs, Croats, Slovenes, Macedonians, and Bulgars).

In antiquity the Slavs were perhaps the most numerous branch of the Indo-European family of peoples. The very late date at which they came into the light of recorded history (even their name does not appear before the 6th century AD) and the scarcity of relics of their culture make serious study of them a difficult task. Sources of information about their religious beliefs are all late and by Christian hands.

SLAVIC WORLDVIEW

Socially the Slavs were organized as exogamous clans (based on marriages outside blood relationship) or, more properly, as sibs (groups of lineages with common ancestry) since marriage did not cancel membership in the clan of one's birth—a type of organization unique among Indo-European peoples. The elected chief did not have executive powers. The world had been created, in the Slavic view, once and for all, and no new law ought to modify the way of life transmitted by their ancestors. Since the social group was not homogeneous, validity and executive power were attributed only to decisions taken unanimously in an assembly, and the deliberations in each instance concerned only the question of conformity to tradition. Ancient Slavic civilization was one of the most conservative known on earth.

According to a primitive Slavic belief, a forest spirit, *leshy,* regulates and assigns prey to hunters. Its food-distributing function may be related to an archaic divinity. Though in early times the *leshy* was the protector of wild animals, in later ages it became the protector of flocks and herds. In early 20th-century Russia, if a cow or a herdsman did not come back from pasture, the spirit was offered bran and eggs to obtain a safe return.

arieties f pirits

Equally ancient is the belief in a tree spirit that enters buildings through the trunks of trees used in their construction. Every structure is thus inhabited by its particular spirit: the *domovoy* in the house, the *ovinnik* in the drying-house, the *gumenik* in the storehouse, and so on. The belief that either harmful or beneficial spirits dwell in the posts and beams of houses is still alive in the historic regions of Bosnia and Slovenia and the Poznań area of west central Poland. Old trees with fences around them are objects of veneration in Serbia and Russia and among the Slavs on the Elbe River. In 19th-century Russia a chicken was slaughtered in the drying house as a sacrifice to the *ovinnik.* This vegetal spirit is also present in the sheaf of grain kept in the "sacred corner" of the dwelling under the icon and venerated along with it, and also in noncultivated plant species that are kept in the house for propitiation or protection, such as branches of the birch tree and bunches of thistle. Such practices evidence the preagrarian origin of these beliefs. Similar to the *leshy* are the field spirit (*polevoy*), and, perhaps, the water spirit (*vodyanoy*). Akin to the *domovoy* are the spirits of the auxiliary buildings of the homestead.

MYTHOLOGY

Cosmogony. A myth known to all Slavs tells how God ordered a handful of sand to be brought up from the bottom of the sea and created the land from it. Usually, it is the Devil who brings up the sand; in only one case, in Slovenia, is it God himself. This earth-diver myth is diffused throughout practically all of Eurasia and is found in ancient India as well.

The 12th-century German missionary Helmold of Bosau recorded in *Chronica Slavorum* (*Chronicle of the Slavs*) his surprise in encountering among the Slavs on the Baltic a belief in a single heavenly God, who ignored the affairs of this world, having delegated the governance of it to certain spirits begotten by him. This is the only instance in which the sources allude to a hierarchy of divinities, but its centre is empty. The divinity mentioned by Helmold is a *deus otiosus; i.e.,* an inactive god, unique in the mythology of the Indo-European peoples. Such a deity is, however, also found among the Volga Finns, the Ugrians, and the Uralians.

Helmold's *deus otiosus*

Principal divine beings. Common to this Eurasian area is another divinity, called by Helmold and in the *Knytlinga saga* (a Danish legend that recounts the conquest of Arkona through the efforts of King Valdemar I of Denmark against the pagan and pirate Slavs) Zcerneboch (or Chernobog), the Black God, and Tiarnoglofi, the Black Head (Mind or Brain). The Black God survives in numerous Slavic curses and in a White God, whose aid is sought to obtain protection or mercy in Bulgaria, Serbia, and Pomerania. This religious dualism of white and black gods is common to practically all the peoples of Eurasia.

The Kiev Chronicle (*Povest vremennykh let*)—a 12th- to 13th-century account of events and life in the Kievan state—enumerates seven Russian pagan divinities: Perun, Volos, Khors, Dazhbog, Stribog, Simargl, and Mokosh. A Russian glossary to the 6th-century Byzantine writer John Malalas' *Chronographia* mentions a Svarog, apparently the son of Dazhbog. Of all these figures only two, Perun and Svarog, are at all likely to have been common to all the Slavs. In Polish, *piorun,* the lightning, is derived from the name of Perun, and not vice versa. In the province of Wielkopolska the expression *do pierona*—meaning "go to the Devil"—has been recorded. In the expression, *pieron/piorun* is no longer the lightning but the being who launches it. Uncertain or indirect traces of Perun are also encountered among the Carpathians and in Slovenia and Serbia. The lightning-wielding Perun cannot be considered the supreme god of the Slavs but is rather a spirit to whom was given the governance of the lightning.

In Estonia the prophet Elijah is considered to be the successor to Ukko, the ancient spirit of lightning. Similarly, the prophet Elijah replaces Elwa in Georgia and Zeus in Greece. It is therefore probable that, among the Slavs also, Elijah is to be considered a successor of Perun. According to a popular Serbian tradition, God gave the lightning to Elijah when he decided to retire from governing the world. The Serbian story agrees with Helmold's description of the distribution of offices by an inactive God. Elijah is a severe and peevish saint. It is rare that his feast day passes without some ill fortune. Fires—even spontaneous combustion—are blamed on him.

A similar complex may be seen if the Slavic Perun is equated with Perkūnas, the lightning deity of the Lithuanians. In Latvia, creatures with black fur or plumage were sacrificed to Pērkons, as they were to the fire god Agni in ancient India. Such deities are therefore generic deities of fire, not specifically celestial and even less to be regarded as supreme. Scholarly efforts to place Perun at the centre of Slavic religion and to create around him a pantheon of deities of the Greco-Roman type cannot yield appreciable results. Russian sources treat Svarog, present as Zuarasici among the Liutici of Rethra (an ancient locality in eastern Germany), as a god of the drying-house fire. But the Belorussians of Chernigov, when lighting the drying-house fire, invoke Perun and not Svarog, as if Svarog (apparently from *svar,* "litigation" or "dispute," perhaps referring to the friction between the pieces of wood used to produce ignition) were an appellation of Perun.

Folk conceptions. In a series of Belorussian songs a divine figure enters the homes of the peasants in four forms in order to bring them abundance. These forms are: *bog* ("god"); *sporysh,* anciently an edible herb, today a stalk of grain with two ears, a symbol of abundance; *ray* ("paradise"); and *dobro* ("the good"). The word *bog* is an Indo-Iranian word signifying riches, abundance, and good fortune. *Sporysh* symbolizes the same concept. In Iranian *ray* has a similar meaning, which it probably also had in Slavic languages before it acquired the Christian meaning of paradise. *Bog,* meaning "riches," connotes grain. The same concept is also present in Mordvinian *pa* and *riz*—where their provenance is certainly Iranian. Among the Mordvins, Paz, like the Slavic Bog, enters into the homes bringing abundance. The adoption of the foreign word *bog* probably displaced from the Slavic languages the Indo-

European name of the celestial God, Deivos (Ancient Indian Deva, Latin Deus, Old High German Ziu, etc.), which Lithuanian, on the other hand, has conserved as Dievas.

Worship of celestial bodies

Among the heavenly bodies the primary object of Slavic veneration was the moon. The name of the moon is of masculine gender in Slavic languages (Russian *mesyats;* compare to Latin *mensis*). The word for sun (Russian *solntse*), on the other hand, is a neuter diminutive that may derive from an ancient feminine form. In many Russian folk songs a verb having the sun as its subject is put in the feminine form, and the sun is almost always thought of as a bride or a maiden.

It is to the moon that recourse is had to obtain abundance and health. The moon is saluted with round dances and is prayed to for the health of children. During lunar eclipses, weapons are discharged at the monsters who are said to be devouring the moon, and weeping and wailing express the sharing of the moon's sufferings. In Serbia the people have always envisioned the moon as a human being. Such appellations as father and grandfather are customarily applied to the moon in Russian, Serbo-Croatian, and Bulgarian folk songs. At Risano (modern-day Risan, Yugos.) in the days of the 19th-century writer Vuk Karadžić—the father of modern Serbian literature—it was said of a baby four months old that he had four grandfathers. In Bulgaria the old people teach small children to call the moon Dedo Bozhe, Dedo Gospod ("Uncle God, Uncle Lord"). Ukrainian peasants in the Carpathians openly affirm that the moon is their god and that no other being could fulfill such functions if they were to be deprived of the moon. In two Great Russian supplications the sickle moon is invoked as "Adam"—the final phase of a fully developed moon worship in which the moon becomes the progenitor of the human family.

PRACTICES, CULTS, AND INSTITUTIONS

Places of worship. Though the idols of which the Russian chronicles speak appear to have been erected out-of-doors, the German chronicles provide detailed descriptions of enclosed sacred places and temples among the Baltic Slavs. Such enclosures were walled and did not differ from profane fortifications—areas usually of triangular shape at the confluence of two rivers, fortified with earthwork and palisades, especially on the access side. The fortifications intended for religious purposes contained wooden structures including a cell for the statue of a god, also made of wood and sometimes covered in metal. These representations, all anthropomorphic, very often had supernumerary bodily parts: seven arms, three or five heads (Trigelavus, Suantevitus, and Porenutius). The temples were in the custody of priests, who enjoyed prestige and authority even in the eyes of the chiefs and received tribute and shares of military booty. Human sacrifices, including eviscerations, decapitations, and trepanning, had a propitiatory role in securing abundance and victory. One enclosure might contain up to four temples; those at Szczecin (Stettin), in northwestern Poland, were erected in close proximity to each other. They were visited annually by the whole population of the surrounding district, who brought with them oxen and sheep destined to be butchered. The boiled meat of the animals was distributed to all the participants without regard to sex or age. Dances and plays, sometimes humorous, enlivened the festival.

Temple ceremonies

Communal banquets and related practices. The custom of communal banquets has been preserved into modern times in Russia in the *bratchina* (from *brat,* "brother"), in the *mol'ba* ("entreaty" or "supplication"), and in the *kanun* (a short religious service); in the Serbian *slava* ("glorification"); and in the *sobor* ("assembly") and *kurban* ("victim" or "prey") of Bulgaria. Formerly, communal banquets were also held by the Poles and the Polabs (Elbe Slavs) of Hannover. In Russia the love feasts are dedicated to the memory of a deceased person or to the patron saint of the village and in Serbia to the protecting saint from whom the *rod* or *pleme* ("clan") took its name. Scholars no longer have any doubts of the pre-Christian nature of these banquets. The Serbian *slava* is clearly dedicated to a saint held to be the founder of the clan. These saints are patrons or founders and are all men who have died. When the Serbs celebrate the *slava* of the prophet Elijah or of the archangel Michael they do not set out the "dead man's plate" (the *koljivo,* boiled wheat), because Elijah and Michael are not dead. In certain localities in Serbia even the women given in marriage to another clan, the so-called *odive,* have to be present at the *slava.* They return with their children (according to the ancient matrilineal conception of the offspring), but not with their husbands, who belong to another clan and celebrate another *slava.* More akin to the ancient pagan feasts of the Baltic is the Serbian *seoska slava,* or "*slava* of the village," in which the whole population of the place takes part and consumes in common the flesh of the victims prepared in the open air. Such feasts are votive. In Russia sometimes the animals (or their flesh) are first brought into the church and perfumed with incense. Even at the beginning of the 20th century there were small villages in Russia where cattle were butchered only on the occasion of these festivities, three or four times a year. *The Homily of Opatoviz* (attributed to Herman, bishop of Prague) of the 10th–11th century emphatically condemns the love feasts as well as the veneration of statues and Slavic worship of the dead and veneration of saints as if they were gods. As in the Christian era the saints entered the line of ancestors, so perhaps in pagan antiquity ancient divinities (Perun, Svarog) were taken over as tribal progenitors. The Slavs did not record genealogies, and the founders of their clans were mainly legendary. The social unit sought to assure for itself the favour of powerful figures of the past, even of more than one, representing them in several forms on the same pillar or giving to their statues supernumerary bodily parts that would express their superhuman powers. A hollow bronze idol, probably ancient Russian, was found at Ryazan, Russian S.F.S.R. The idol has four faces with a fifth face on its breast.

The eastern Finns and the Ugrians venerated their dead in the same way, similarly representing them as polycephalic (multiple-headed), and also held communal banquets in their honour. Wooden buildings (the so-called *continae*) in which the faithful Baltic Slavs used to assemble for amusement, to deliberate, or to cook food have been observed in the 20th century among the Votyaks, the Cheremis, and the Mordvins, but especially among the Votyaks. Such wooden buildings also existed sparsely in Slavic territory in the 19th century, in Russia, particularly in the Ukraine, as well as here and there among the South Slavs.

If it is supposed that, as among the Finns and the Ugrians, each clan venerated its own divine ancestor in a separate building, this would explain why many sacred enclosures would contain more than one *contina*—three at Carentia (the island of Garz at the mouth of the Oder River) and four at Szczecin.

The system of idolatry of the Baltic area was essentially manistic (pertaining to worship of ancestors). It is not irrelevant that until the 19th century there survived here and there throughout the Danubian-Balkan region the custom of reopening graves three, five, or seven years after interment, taking out the bones of the corpses, washing them, wrapping them in new linen, and reinterring them. Detailed descriptions of this procedure have come particularly from Macedonia and Slovenia. Among East and West Slavs only faint echoes of the custom of a second interment survive in folk songs. In the former *guberniya* (province) of Vladimir, east of Moscow, as late as 1914, when a grave was to be dug, a piece of cloth was taken along with which to wrap the bones of any earlier corpse that might be unearthed in the process of digging. Such corpses would then be reinterred with the newly deceased. In protohistoric times the tumuli (mounds) of the mortuaries of the Krivichi, a populous tribe of the East Slavs of the northwest, the so-called long kurgans (burial mounds), contained cinerary urns buried in the tumulus together and all at one time. Such a practice could occur only as the consequence of collective and simultaneous cremation. There must, therefore, have existed a periodic cremation season or date, as for the opening of the tombs in Macedonia and as has been verified elsewhere in comparing the South Asian areas of second interment, in preparation for which the corpses are temporarily ex-

The custom of second interment

humed. The cremations by the Krivichi are of exhumed bones. In the Volga region today the Mordvins still burn the disinterred bones of the dead in the flames of a "living fire" ignited by friction.

Considering the religious past of the Slavs, it is not surprising that manism was strong enough to epitomize and overwhelm all or practically all of their religious views. The seasonal festivals of the Slavs turn out to be almost entirely dedicated to the dead, very often without the participants realizing it, as in the case of the Koljada (Latin Kalendae)—the annual visit made by the spirits of the dead, under the disguise of beggars, to all the houses in the village. It is possible that the bones of the disinterred were kept for a long period inside the dwellings, as is still sometimes done in the Tyrol of Austria, and that the sacred corner—now occupied by the icon—was the place where they were kept.

The spirits of the departed are not only venerated but also feared, especially the spirits of those who were prematurely deprived of life and its joys. It is believed that such spirits are greedy for the good things thus lost and that they make attempts to return to life—to the peril of the living. They are the prematurely dead, the so-called unclean dead. Particularly feared are maidens who died before marriage and are believed to be addicted to the kidnapping of bridegrooms and babies. One annual festival in particular, the Semik (seventh Thursday after Easter) was dedicated to the expulsion of these spirits. They are called *rusalki* in Russia, *vile* or *samovile* in Serbo-Croatia and Bulgaria.

The dead person who does not decompose in the grave becomes a vampire, a word and concept of Slavic origin. To save the living from a vampire's evil deeds, it is necessary to plant a stake in the grave so that it passes through the heart of the corpse or else to exhume the corpse and burn it. Since the classes of unclean dead are believed to have been constantly increasing (in Macedonia, for example, it is believed that all those born in the three months between Christmas and Lady Day are unclean), then all of the dead—once objects of veneration and piety—will at some point be in danger of rancor, fear, and eventual disregard. A Christian clergy that has lent its presence at the exhumation and destruction of vampires has thereby contributed unwittingly to the preservation of this last phase of Slavic paganism into modern times.

There are other rites associated with second interment of which the Slavs have forgotten the purpose, such as the cemetery pyres—fires lit on top of the tombs—or the assiduous watering of graves. In Polynesia and South America where second interment is practiced, these same acts have the purpose of fostering decomposition of the corpses in order to hasten exhumation.

Numerous other ritual acts are performed by the Slavs, for the most part related to this complex of beliefs. In 19th-century Russia, if a man encountered the procession of naked women who were plowing a furrow around the village at night in order to protect it from an epidemic, he was inevitably killed. It was a chthonic (underworld) being to which, in those same times, human sacrifices were offered in Russia (more rarely in Poland and Bulgaria), since the victims were often buried alive. In most cases they were either voluntary victims or chosen by lot from among the devotees. Since such acts were punished by the law of the state, the sacrifices were performed in secrecy and are difficult to document. (E.G.)

Greek religion

Greek religion, comprising the beliefs of the ancient Hellenes about gods and their relationship with humanity, lasted in its developed form for more than a thousand years, from the time of Homer (probably 9th or 8th century BC) to the reign of the emperor Julian (4th century AD), though its origins may be traced to the remotest eras. During that period its influence spread as far west as Spain, east to the Indus River, and throughout the Mediterranean world. Its effect was most marked on the Romans, who identified their deities with the Greek. Under Christianity, Greek heroes and even deities survived as saints, while the rival madonnas of southern European communities reflected the independence of local cults. The rediscovery of Greek literature during the Renaissance and, above all, the novel perfection of classical sculpture produced a revolution in taste that had far-reaching effects on Christian religious art. The most striking characteristic of Greek religion was the belief in a multiplicity of anthropomorphic deities, coupled with a minimum of dogmatism.

The student of Greek religion is naturally concerned to know what the Greeks believed about their gods. They had numerous beliefs, but the sole requirement was to believe that the gods existed and to perform ritual and sacrifice, through which the gods received their due. To deny the existence of a deity was to risk reprisals, from the deity or from other mortals. The list of avowed atheists is brief. But if a Greek went through the motions of piety, he risked little, since no attempt was made to enforce orthodoxy, a religious concept almost incomprehensible to the Greeks. The Greeks had no word for religion itself, the closest approximations being *eusebeia* ("piety") and *threskeia* ("cult"). The large corpus of myths concerned with gods, heroes, and rituals embodied the worldview of Greek religion and remains its legacy. It should be noted that the myths varied over time and that, within limits, a writer—*e.g.*, a Greek tragedian—could vary a myth in order to change not only the role played by the gods in it but also the evaluation of the gods' actions. From the later 6th century BC onward, myths and gods were subject to rational criticism on ethical or other grounds. In these circumstances it is easy to overlook the fact that most Greeks "believed" in their gods in roughly the modern sense of the term and that they prayed in a time of crisis not merely to the "relevant" deity but to any deity on whose aid they had established a claim by sacrifice. To this end, each Greek polis had a series of public festivals throughout the year that were intended to ensure the aid of all the gods who were thus honoured. They reminded the gods of services rendered and asked for a quid pro quo. In crises in particular the Greeks, like the Romans, were often willing to add deities borrowed from other cultures.

It is frequently difficult to obtain evidence of Greek religious practice, not only within the mystery cults but also more generally. In the latter case, the reason is not one of secrecy; the Greeks simply did not anticipate a posterity that would be different from themselves. Religious practices were universally known—as were such everyday activities as sailing triremes and holding assemblies—and it was not deemed necessary to record these things. It should be remembered that Pausanias, the most important source for a number of topics, was writing in the 2nd century AD, and that even by the 5th century BC the meaning and origins of some of the practices he described were evidently unknown.

HISTORY

The roots of Greek religion. The study of a religion's history includes the study of the history of those who espoused it, together with their spiritual, ethical, political, and intellectual experiences. Greek religion as it is currently understood probably resulted from the mingling of religious beliefs and practices between the incoming Greek-speaking peoples who arrived from the north during the 2nd millennium BC and the indigenous inhabitants whom they called "Pelasgi." The incomers' pantheon was headed by the Indo-European sky god variously known as Zeus (Greek), Dyaus (Indian), or Jupiter (Roman Diespater). But there was also a Cretan sky god, whose birth and death were celebrated in rituals and myths quite different from those of the incomers. The incomers applied the name of Zeus to his Cretan counterpart. In addition, there was a tendency, fostered but not necessarily originated by Homer and Hesiod, for major Greek deities to be given a home on Mount Olympus. Once established there in a conspicuous position, the Olympians came to be identified with local deities and to be assigned as consorts to the local god or goddess. An unintended consequence (since the Greeks were monogamous) was that Zeus in particular became markedly polygamous. (Zeus already had a consort when he arrived in the Greek world and

Greek and Pelasgian deities

took Hera, herself a major goddess in Argos, as another.) Hesiod used—or sometimes invented—the family links among the deities, traced out over several generations, to explain the origin and present condition of the universe. At some date, Zeus and other deities were identified locally with heroes and heroines from the Homeric poems and called by such names as Zeus Agamemnon. The Pelasgian and the Greek strands of the religion of the Greeks can sometimes be disentangled, but the view held by some scholars that any belief related to fertility must be Pelasgian, on the grounds that the Pelasgi were agriculturalists while the Greeks were nomadic pastoralists and warriors, seems somewhat simplistic. Pastoralists and warriors certainly require fertility in their herds—not to mention in their own number. In cult, Athena, a warrior goddess and patron of the arts and crafts and a prominent Olympian, presided also over fertility festivals. The citizens prayed to her for all good things; the fertility of field, flock, and citizen was as essential to the well-being of the polis as its victory in war.

The Archaic period. Sometime before the Homeric poems took their present form, the orgiastic cult of the nature divinity Dionysus reached Greece, traditionally from Thrace and Phrygia. Because the god's name is Greek, it has been suggested that his worship represents not a novelty but a reversion to Mycenaean religion. His devotees, armed with *thyrsoi* (wands tipped with a pine cone and wreathed with vine or ivy) and known as maenads (literally "mad women"), were reputed to wander in *thiasoi* (revel bands) about mountain slopes, such as Cithaeron or Parnassus; the practice persisted into Roman imperial times. They were also supposed, in their ecstasy, to practice the *sparagmos,* the tearing of living victims to pieces and feasting on their raw flesh (*ōmophagia*). While such behaviour continued in the wild, in the cities—in Athens, at any rate—the cult of Dionysus was tamed before 500 BC. Tragedy developed from the choral song of Dionysus.

The cult of Dionysus

In the 7th and 6th centuries BC "tyrants" (monarchs whose position was not derived from heredity) seized power in many poleis. Some of them, such as Peisistratus in Athens, were nobles themselves and rose to power by offering the poor defense against the rest of the nobility. Once established, Peisistratus built temples and founded or revived festivals. At this time, too, the earliest references to the Eleusinian Mysteries appear. The Mysteries offered a more personal, less distant relationship with the divine than did most of the Olympians. There was no Eleusinian way of life. On one or two occasions (depending on the grade they wished to attain) the initiates went to Eleusis; what they saw there in the place of initiation sufficed to ensure them a life after death that was much more "real" than the Olympian belief that the dead were witless ghosts.

The Classical period. During the 6th century BC the rationalist thinking of Ionian philosophers had offered a serious challenge to traditional religion. At the beginning of the 5th century, Heracleitus of Ephesus and Xenophanes of Colophon heaped scorn on cult and gods alike.

The Sophists, with their relentless probing of accepted values, continued the process. Little is known of the general success of these attacks in society as a whole. The Parthenon and other Athenian temples of the late 5th century proclaim the taste and power of the Athenians rather than their awe of the gods; but it is said that after the completion of Phidias' chryselephantine Athena on the Acropolis, the old olive-wood statue of Athena, aesthetically no match for Phidias' work, continued to receive the worship of most of the citizens. Antiquity evoked awe; some of the most revered objects in Greece were antique and aniconic figures that bore the name of an Olympian deity.

Festivals were expressive of religion's social aspect and attracted large gatherings (*panēgyreis*). Mainly agrarian in origin, they were seasonal in character, held often at full moon and on the 7th of the month in the case of Apollo, and always with a sacrifice in view. Many were older than the deity they honoured, like the Hyacinthia and Carneia in Laconia, which were transferred from local heroes to Apollo. The games were a special festival, sometimes part of other religious events. Some festivals of Athens were performed on behalf of the polis and all its members. Many of these seem to have been originally the cults of individual noble families who came together at the *synoikismos,* the creation of the polis of Athens from its small towns and villages. The nobles continued to furnish the priests for these cults, but there was, and could be, no priestly class. There were no "priests of the gods," or even priests of an individual god; one became a priest of one god at one temple. Except for these public festivals, anyone might perform a sacrifice at any time. The priest's role was to keep the temple clean; he was usually guaranteed some part of the animal sacrificed. A priesthood offered a reasonably secure living to its incumbent.

Popular religion flourished alongside the civic cults. Peasants worshiped the omnipresent deities of the countryside, such as the Arcadian goat-god Pan, who prospered the flocks, and the nymphs (who, like Eileithyia, aided women in childbirth) inhabiting caves, springs (Naiads), trees (Dryads and Hamadryads), and the sea (Nereids). They also believed in nature spirits such as Satyrs and Sileni and equine Centaurs. Among the more popular festivals were the rural Dionysia, which included a phallus pole; the Anthesteria, when new wine was broached and offerings were made to the dead; the Thalysia, a harvest celebration; the Thargelia, when a scapegoat (*pharmakos*) assumed the communal guilt; and the Pyanepsia, a bean feast in which boys collected offerings to hang on the *eiresiōne* ("wool pole"). Women celebrated the Thesmophoria in honour of Demeter and commemorated the passing of Adonis with laments and miniature gardens, while images were swung from trees at the Aiora to get rid of an ancient hanging curse. Magic was widespread. Spells were inscribed on lead tablets. Statues of Hecate, goddess of witchcraft, stood outside dwellings, while Pan's image was beaten with herbs in time of meat shortage.

The Hellenistic period. Greek religion, having no creed, did not proselytize. In the heyday of the polis, the Greek religion was spread by the founding of new poleis, whose colonists took with them part of the sacred fire from the hearth of the mother city and the cults of the city's gods. ("Heroes," being essentially bound to the territory in which they were buried, had to be left behind.) There was a tendency for Greeks to identify the gods of others with their own, often at a superficial level. So the virgin Artemis was identified with the chief goddess of Ephesus, a fertility deity. After Alexander the Great had created a political world in which the poleis were engulfed by large kingdoms, those deities who were not too closely linked with a particular place became more prominent. Mystery cults, which offered a personal value to the individual in a large and indifferent world, also flourished. The Cabeiri of Samothrace were patronized by both the Ptolemies and the Romans, while the Egyptian cults of Isis and Sarapis, in a Hellenized form, spread widely. Rulers sometimes officially invited new gods to settle in times of crisis, in the hope that they would strive on their new worshipers' behalf against their mortal foes: a mode of religious thought that flourished at least until the days of the Roman emperor Constantine. Those novel cults that seemed likely to pose a threat to public order, on the other hand, were suppressed by the Romans. The Senate destroyed the Bacchic cult in Italy in 186 BC for the same reasons as Trajan gave to Pliny for his treatment of the Christians: Any cult in which men and women, bond and free, could participate and meet together—a most unusual circumstance in the ancient world—had dangerous political implications.

BELIEFS, PRACTICES, AND INSTITUTIONS

The gods. The early Greeks personalized every aspect of their world, natural and cultural, and their experiences in it. The earth, the sea, the mountains, the rivers, custom-law (*themis*), and one's share in society and its goods were all seen in personal as well as naturalistic terms. When Achilles fights with the River in the *Iliad,* the River speaks to Achilles but uses against him only such weapons as are appropriate to a stream of water. In Hesiod, what could be distinguished as anthropomorphic deities and personalizations of natural or cultural phenomena both beget and are begotten by each other. Hera is of the first type—god-

dess of marriage but not identified with marriage. Earth is evidently of the second type, as are, in a somewhat different sense, Eros and Aphrodite (god and goddess of sexual desire) and Ares (god of war). These latter are personalized and anthropomorphized, but their worshipers may be "filled" with them. Some deities have epithets that express a particular aspect of their activities. Zeus is known as Zeus Xenios in his role as guarantor of guests. It is possible that Xenios was originally an independent deity, absorbed by Zeus as a result of the Olympocentric tendencies of Greek religion encouraged by the poems of Homer and Hesiod.

In Homer the gods constitute essentially a super-aristocracy. The worshipers of these gods do not believe in reward or punishment after death; one's due must come in this life. Every success shows that the gods are well disposed, for the time being at least; every failure shows that some god is angry, usually as a result of a slight, intended or unintended, rather than from the just or unjust behaviour of one mortal to another. The Greeks knew what angered their mortal aristocracy and extrapolated from there. Prayer and sacrifice, however abundant, could not guarantee that the gods would grant success. The gods might prefer peace on Olympus to helping their worshipers. These are not merely literary fictions; they reflect the beliefs of people who knew that though it might be necessary to offer prayer and sacrifice to the gods, it was not sufficient. Greek and Trojans sacrificed to their gods to ensure divine support in war and at other times of crisis. It was believed that Zeus, the strongest of the gods, had favoured the Trojans, while Hera had favoured the Greeks. Yet Troy fell, like many another city. The Homeric poems here offer an explanation for something that the Greek audience might at any time experience themselves.

There is no universal determinism in Homer or in other early writers. *Moira* ("share") denotes one's earthly portion, all the attributes, possessions, goods, or ills that together define one's position in society. Homeric society is stratified, from Zeus to the meanest beggar. To behave in accordance with one's share is to behave in accordance with one's status; and even a beggar may go beyond his share, though he is likely to be punished for it. Zeus, the most powerful entity in Homer's universe, certainly has the power to go beyond his share; but if he does so, the other gods "will not approve." And Zeus may be restrained, unless he feels that his "excellence," his ability to perform the action, is being called into question. Then he may insist on displaying his excellence, as do Achilles and Agamemnon, whose values coincide with those of Zeus in such matters.

tratifica-
ion of
ociety

In Homer, *hērōs* denotes the greatest of the living warriors. The cults of these mighty men developed later around their tombs. Heroes were worshiped as the most powerful of the dead, who were able, if they wished, to help the inhabitants of the polis in which their bones were buried. Thus, the Spartans brought back the bones of Orestes from Tegea. Historical characters might be elevated to the status of heroes at their deaths. During the Peloponnesian War, the inhabitants of Amphipolis heroized the Spartan general Brasidas, who had fought so well and bravely and died in their defense. It is power, not righteousness, that distinguishes the hero; it is the feeling of awe before the old, blind Oedipus that stimulates the Thebans and the Athenians to quarrel over his place of burial. Since they are the mightiest of the dead, heroes receive offerings suitable for chthonic deities.

Cosmogony. Of several competing cosmogonies in archaic Greece, Hesiod's *Theogony* is the only one that has survived in more than fragments. It records the generations of the gods from Chaos (literally, "Yawning Gap") through Zeus and his contemporaries to the gods who had two divine parents (*e.g.,* Apollo and Artemis, born of Zeus and Leto) and the mortals who had one divine parent (*e.g.,* Heracles, born of Zeus and Alcmene). Hesiod uses the relationships of the deities, by birth, marriage, or treaty, to explain why the world is as it is and why Zeus, the third supreme deity of the Greeks, has succeeded in maintaining his supremacy—thus far—where his predecessors failed. Essentially, Zeus is a better politician and has the balance of power, practical wisdom, and good counsel on his side. (Whether Hesiod or some earlier thinker produced this complex nexus of relationships, with which Hesiod could account for virtually anything that had occurred or might occur in the future, the grandeur of this intellectual achievement should not be overlooked.)

Man. In the period in Greece between Homer and about 450 BC the language of relationships between god and god, man and god, and human beings of lower status with human beings of higher status was the same. The deities remained a super-aristocracy. There was a scale of "power-and-excellence" on which the position of every human being and every deity could be plotted. Both god and man were likely to resent any attempt of an inferior to move higher on the scale. It constituted *hubris* ("overweening pride") for a Greek *heros* to claim that he would have a safe voyage whether or not the gods were willing; it was likewise *hubris* for Electra to presume to criticize the behaviour of her mother Clytemnestra.

A further reason for Olympian disapproval, only marginally present in Homer, was the pollution caused by certain actions and experiences, such as childbirth, death, or having a bad dream. The divine world of the Greeks was bisected by a horizontal line. Above that line were the Olympians, gods of life, daylight, and the bright sky; below it were the chthonic (underworld) gods of the dead and of the mysterious fertility of the earth. The Olympians kept aloof from the underworld gods and from those who should be in their realm: Creon is punished in Sophocles' *Antigone* by the Olympians for burying Antigone alive, for she is still "theirs," and for failing to bury the dead Polyneices, gobbets of whose flesh are polluting their altars; Hippolytus is abandoned by Artemis, her most ardent worshiper, as his death approaches, for all corpses pollute. Pollution was not a moral concept; and it further complicated relationships between the Greeks and their gods.

Eschatology. In Homer only the gods were by nature immortal, but Elysium was reserved for their favoured sons-in-law, who they exempted from death. Heracles alone gained a place on Olympus by his own efforts. The ordinary hero hated death, for the dead were regarded as strengthless doubles who had to be revived with drafts of blood, mead, wine, and water in order to enable them to speak. They were conducted, it was believed, to the realm of Hades by Hermes; but the way was barred, according to popular accounts, by the marshy river Styx. Across this, Charon ferried all who had received at least token burial, and coins were placed in the mouths of corpses to pay the fare. Originally only great sinners like Ixion, Sisyphus, and Tityus, who had offended the gods personally, were punished in Tartarus. But the doctrines of the Orphics influenced Pindar, Empedocles, and, above all, Plato. According to the latter, the dead were judged in a meadow by Aeacus, Minos, and Rhadamanthus and were consigned either to Tartarus or to the Isles of the Blest. Long periods of purgation were required before the wicked could regain their celestial state, while some were condemned forever. The dead were permitted to choose lots for their next incarnation. Subsequently they drank from the stream of Lethe, the river of oblivion, and forgot all of their previous experiences.

Immortality and death

Sacred writings. Greek religion was not based on a written creed or body of dogma. Nevertheless, certain sacred writings survive in the form of hymns, oracles, inscriptions, and instructions to the dead. Most elaborate are the Homeric Hymns, some of which may have been composed for religious festivals, though their subject matter is almost entirely mythological. Delphic inscriptions include hymns to Apollo but, like the Epidaurian hymn by Isyllus to Asclepius, they are not concerned with liturgy. Delphic oracles are quoted from literary sources but appear, on the whole, to be retrospective concoctions, like the Hebraic–Hellenistic collection of Sibylline prophecies. Questions scratched on folded lead tablets have been found at Dodona, and detailed instructions to the dead, inscribed on gold leaf and possibly of Orphic inspiration, have been found in Greek graves in southern Italy. Papyrus fragments of similar character have been recovered from graves in Macedonia and Thessaly.

Shrines and temples. In the earliest times deities were worshiped in awesome places such as groves, caves, or mountain tops. Mycenaean deities shared the king's palace. Fundamental was the precinct (temenos) allotted to the deity, containing the altar, temple (if any), and other sacral or natural features, such as the sacred olive in the temenos of Pandrosos on the Athenian Acropolis. *Naoi* (temples—literally "dwellings"—that housed the god's image) were already known in Homeric times and, like models discovered at Perachora, were of wood and simple design. Poros and marble replaced wood by the end of the 7th century BC, when temples became large and were constructed with rows of columns on all sides. The image, crude and wooden at first, was placed in the central chamber (cella), which was open at the eastern end. No ritual was associated with the image itself, though it was sometimes paraded. Hero shrines were far less elaborate and had pits for offerings. Miniature shrines also were known.

Oracles and divination

Most oracular shrines included a subterranean chamber, but no trace of such has been found at Delphi, though the Pythia was always said to "descend." At the oracle of Trophonius, discovered in 1967 at Levádhia, incubation was practiced in a hole. The most famous centre of incubation was that of Asclepius at Epidaurus. His temple was furnished with a hall where the sick were advised by the demigod in dreams. Divination was also widely practiced in Greece. Augurs interpreted the flight of birds, while dreams, and even sneezes, were regarded as ominous. Seers also divined from the shape of altar smoke and the conformation of victims' entrails.

Priesthood. Even in the state cults, priesthoods were frequently ancestral prerogatives. Eteobutads organized the cult of the hero-king Erechtheus at Athens; Praxiergids superintended the washing of Athena's robes at the Plynteria; Clytiads and Iamids officiated at the altar of Zeus at Olympia. Although there was no official clergy, since the religious and secular spheres were not sharply divided, professional assistance was available at sacrifices. There was no necessary correspondence between the sex of deities and that of priests. Hera and Athena favoured priestesses, but Isis and Cybele favoured priests. Apollo again inspired the Pythia (priestess) at Delphi but a priest at Ptoon. The mysteries at Eleusis were administered by the Eumolpids and Kerykes. The latter assembled the initiates (*mystae*), while the former provided the Hierophant, who revealed the mysteries in the torchlit Anaktoron (king's shrine) within the great Telesterion, or entrance hall.

Festivals. The precise details of many festivals are obscure. Among the more elaborate was the Panathenaea, which was celebrated at high summer, and every fourth year (the Great Panathenaea) on a more splendid scale. Its purpose, besides offering sacrifice, was to provide the ancient wooden image of Athena, housed in the "Old Temple," with a new robe woven by the wives of Athenian citizens. The Great Panathenaea included a procession, a torch race, athletic contests, mock fights, and bardic recitations. The Great Dionysia was celebrated at Athens in spring. At the end of the ritual the god's image was escorted to the theatre of Dionysus, where it presided over the dramatic contests. It, like its rural counterpart, included phallic features.

Olympic Games

The Olympic Games formed part of the great festival of Zeus held every fourth summer in the god's sacred precinct—the Altis beside the river Alpheius in the western Peloponnese. A truce was proclaimed in order to permit any warring Greeks to compete, and the celebrations lasted five days. Sacrifice and libation were made at the altar of Zeus, where omens were taken and oracles proclaimed, and at the tomb of Pelops and the altar of Hestia. Competitors and judges took the oath to observe the rules, processions were held, bards recited, and winners were honoured at state banquets. The richer and more famous were immortalized by lyric poets, such as Simonides, Bacchylides, and Pindar. Though women were banned, girls competed at the festival of Hera. The games held in honour of Zeus at Nemea, Apollo at Delphi, and Poseidon at the Isthmus followed the Olympian pattern.

Rites. Sacrifice was offered to the Olympian deities at dawn at the altar in the temenos, which normally stood east of the temple. Representing as it did a gift to the gods, sacrifice constituted the principal proof of piety. The gods were content with the burnt portion of the offering, while the priests and worshipers shared the remainder of the meat. Different animals were sacred to different deities—*e.g.,* heifers to Athena, cows to Hera, pigs to Demeter, bulls to Zeus and Dionysus, dogs to Hecate, game and heifers to Artemis, horses to Poseidon, and asses to Priapus—though the distinctions were not rigorously observed. The practices of ritual washing before sacrifice, sprinkling barley grains, and making token offerings of hair are described by Homer. Victims were required to be free of blemish, or they were likely to offend the deity. Sacrifice also was made to chthonian powers in the evening. Black victims were offered, placed in pits, and the meat was entirely consumed. Sacrifice preceded battles, treaties, or similar events. Human sacrifice appears, if it was practiced at all, to have been the exception. Bloodless sacrifices were made to some deities and heroes.

Prayers and processions

Prayers normally began with compliments to the deity, followed by discreet references to the petitioner's piety, and ended with his special plea. In addressing a prayer to an Olympian, the suppliant stood with his arms raised palm upward. Processions formed part of most gatherings (*panēgyreis*) and festivals. The Panathenaic procession set out from the Pompeion (sacred storehouse) at dawn, headed by maiden basket-bearers (*kanēphoroi*), who carried the sacred panoply. Elders bore boughs (*thallophoroi*) while youths (*ephēboi*) conducted the victims for sacrifice, and cavalry brought up the rear. The robe was spread on the mast of a wheeled ship.

The procession to Eleusis to restore the sacred objects, brought by the *ephēboi* to the Eleusinium some time previously, followed the wooden image of Iacchus (a personification of the ritual cry), which was escorted by its own priest, the *iacchagogos,* and officials. The *mystae* wore myrtle crowns and carried sheaves of grain. Whatever the nature of the mysteries, those initiated returned in a mood of exaltation. Adepts (*epoptai*) were later admitted to more solemn rites (to see an ear of wheat, scoffers said).

Religious art and iconography. Art often portrays incidents relevant to the study of Greek religion, but frequently essential information is missing. On a well-known sarcophagus from Ayías Triádhos in Crete, for example, a priestess dressed in a skin skirt assists at a sacrifice, flanked by wreathed axes on which squat birds. The significance of the scene has been much discussed. The birds have been regarded as epiphanies of deities, giving sacral meaning to the transformations in Homer. Again, since goddesses appear to preponderate in Minoan–Mycenaean art, while male deities are represented on an inferior scale, this has been thought to reflect the general superiority of goddesses in many parts of Greece. In the earliest period, terra-cotta statuettes of deities were small and crude, while the old cult images were made of wood and commonly attributed to Daedalus. When artists turned to bronze and marble,

Gad Borel—Boissonnas

they depicted the anthropomorphic deities as idealized human beings. The skill of the Greek sculptor reached an almost unparalleled height in the new temples on the Acropolis of Athens; but while high attainment in the visual arts indicates the presence of a high level of aesthetic consciousness, it would be hazardous to conclude that it necessarily accompanied a profound religious experience. The human form idealized was still used for portraying the gods, but only a brief step was needed to produce an art in which the human form was idealized for its own sake. The growth and decline of religions may be matched by the growth and decline of their art, and works of high artistic quality may inspire, and be inspired by, profound religious emotions; but, as the continued worship of the old wooden aniconic statue of Athena, mentioned above, indicates, it is often the antiquity of a cult object that inspires the awe that surrounds it.

Apart from cult statues and dedications like the Acropolis *korai* ("maidens"), the gods frequently were represented on the pediments, metopes, and friezes of temples, usually in mythological scenes. For the details of ritual, vase painting has proved a fruitful source of information. Dionysiac subjects are common, though usually imaginary, but cult scenes and fertility customs also appear.

If "Greek religion" is understood to denote the beliefs about the Greek gods and their relationships with humanity as recorded in surviving writings from the Homeric poems onward, Greek religion was always evolving. Cultic activity, however, was conservative, as it is in most cultures. Practices continued to be observed that were no longer understood by the worshipers. High claims have been made, and continue to be made, for the quality of Greek religion as a religion, with ethical deities and strong tendencies toward monotheism. Indeed, this is probably the orthodox view. Those who contest it hold that it is incautious to extrapolate from a few scattered passages in a Greek author to produce a systematic theology that can then be used to interpret the rest of the work under discussion. The debate shows no sign of coming to an end; but the heterodox are wont to observe that Xenophanes, Pindar, and Plato evidently read Greek literature in the same way as the heterodox propose that it should be read. Plato's strictures in Books II and III of *The Republic* and elsewhere on Greek religion as he knew it bear eloquent testimony to this.

MYTHOLOGY

mpor-
ance of
Greek
nythology
n the
Vestern
vorld

Although people of all countries, eras, and stages of civilization have developed myths that explain the existence and workings of natural phenomena, recount the deeds of gods or heroes, or seek to justify social or political institutions, the myths of the Greeks have remained unrivaled in the Western world as sources of imaginative and appealing ideas. Poets and artists from ancient times to the present have derived inspiration from Greek mythology and have discovered contemporary significance and relevance in classical mythological themes.

Sources of myths: literary and archaeological. *The Homeric poems: the Iliad and the Odyssey.* Herodotus remarked that Homer and Hesiod gave to the Olympian gods their familiar characteristics. Few today would accept this literally. In the first book of the *Iliad,* the son of Zeus and Leto (Apollo, line 9) is as instantly identifiable by his patronymic as are the sons of Atreus (Agamemnon and Menelaus, line 16). In both cases, the audience is expected to have knowledge of the myths that preceded their literary rendering. Most scholars hold that Homer's tone is light and humorous and that the audience is not expected to take the gods seriously. Others reply that little is known to suggest that the Greeks treated Homer, or any other source of Greek myths, as mere entertainment, whereas there are prominent Greeks from Pindar to the later Stoa for whom myths, and those from Homer in particular, are so serious as to warrant bowdlerization or allegorization.

Assumption of prior knowledge

The works of Hesiod: Theogony and Works and Days. The fullest and most important source of myths about the origin of the gods is the *Theogony* of Hesiod. The elaborate genealogies mentioned above are accompanied by folktales and etiological myths. The *Works and Days* shares some of these in the context of a farmer's calendar and an extensive harangue on the subject of justice addressed to Hesiod's possibly fictitious brother Perses. The orthodox view treats the two poems as quite different in theme and treats the *Works and Days* as a theodicy (a natural theology). It is possible, however, to treat the two poems as a diptych, each part dependent on the other. The *Theogony* declares the identities and alliances of the gods, while the *Works and Days* gives advice on the best way to succeed in a dangerous world rendered yet more dangerous by its gods; and Hesiod urges that the most reliable—though by no means certain—way is to be just.

Other literary works. Fragmentary post-Homeric epics, of varying date and authorship, filled the gaps in the accounts of the Trojan War recorded in the *Iliad* and *Odyssey;* the so-called Homeric Hymns (shorter surviving poems) are the source of several important religious myths. Many of the lyric poets preserved various myths, but the odes of Pindar of Thebes (flourished 6th–5th century BC) are particularly rich in myth and legend. The works of the three tragedians—Aeschylus, Sophocles, and Euripides, all of the 5th century BC—are remarkable for the variety of the traditions they preserve. In Hellenistic times (323–30 BC) Callimachus, a 3rd-century-BC poet and scholar in Alexandria, recorded many obscure myths; his contemporary, the mythographer Euhemerus, suggested that the gods were originally human, a view known as Euhemerism. Apollonius of Rhodes, another scholar of the 3rd century BC, preserved the fullest account of the Argonauts in search of the Golden Fleece. In the period of the Roman Empire, the *Library* of the pseudo-Apollodorus (attributed to a 2nd-century-AD scholar), the antiquarian writings of the Greek biographer Plutarch, and the works of Pausanias, a 2nd-century-AD geographer, as well as the *Genealogies* of Hyginus, a 2nd-century-AD mythographer, have provided valuable sources in Latin of later Greek mythology.

Archaeological discoveries. The discovery of the Mycenaean civilization by Heinrich Schliemann, a 19th-century German amateur archaeologist, and the discovery of the Minoan civilization in Crete (from which the Mycenaean ultimately derived) by Sir Arthur Evans, a 20th-century English archaeologist, helped to explain many of the ques-

Significance of Mycenaean and Minoan archaeological discoveries

tions about Homer's epics and provided archaeological proofs of many of the mythological details about gods and heroes. Unfortunately, the evidence about myth and ritual at Mycenaean and Minoan sites is entirely monumental, because the Linear B script (an ancient form of Greek found in both Crete and Greece) was mainly used to record inventories, though the names of gods and heroes have been doubtfully revealed.

Geometric designs on pottery of the 8th century BC depict scenes from the Trojan cycle, as well as the adventures of Heracles. The extreme formality of the style, however, renders much of the identification difficult, and there is no inscriptional evidence accompanying the designs to assist scholars in identification and interpretation. In the succeeding Archaic (*c.* 750–*c.* 500 BC), Classical (*c.* 480–323 BC), and Hellenistic periods, Homeric and various other mythological scenes appear to supplement the existing literary evidence.

Forms of myth in Greek culture. To distinguish among myth, legend, and folktale can be useful, provided it is remembered that the Greeks themselves did not do so.

Religious myths. Greek religious myths are concerned with gods or heroes in their more serious aspects or are connected with ritual. They include cosmogonical tales of the genesis of the gods and the world out of Chaos, the successions of divine rulers, and the internecine struggles that culminated in the supremacy of Zeus, the ruling god of Olympus. They also include the long tale of Zeus's amours with goddesses and mortal women, which usually resulted in the births of younger deities and heroes. The goddess Athena's unique status is implicit in the story of her motherless birth (she was born directly from Zeus); and the myths of Apollo explain that god's sacral associations, describe his remarkable victories over monsters and giants, and stress his jealousy and the dangers inherent in immortal alliances.

Myths of Dionysus, on the other hand, demonstrate the hostility aroused by a novel faith. Some myths are closely associated with rituals, such as the account of the drowning of the infant Zeus's cries by the Curetes, attendants of Zeus, clashing their weapons, or Hera's annual restoration of her virginity by bathing in the spring Canathus. Some myths about heroes and heroines also had a religious basis. The tale of man's creation and moral decline forms part of the myth of the Four Ages (see below). His subsequent destruction by flood and regeneration from stones is partly based on folktale.

Themes of legends and folktales

Legends. Myths were viewed as embodying divine or timeless truths, whereas legends (or sagas) were quasihistorical. Hence, famous events in epics, such as the Trojan War, were generally regarded as having really happened, and heroes and heroines were believed to have actually lived. Earlier sagas, such as the voyage of the Argonauts, were accepted in a similar fashion. Most Greek legends were embellished with folktales and fiction, but some certainly contain a historical substratum. Such are the tales of more than one sack of Troy, which are supported by archaeological evidence, and the labours of Heracles, which suggest Mycenaean feudalism. Again, the legend of the Minotaur (a being part human, part bull) could have arisen from exaggerated accounts of bull leaping in ancient Crete.

In another class of legends, heinous offenses, such as attempting to make love to a goddess against her will, deceiving the gods grossly by inculpating them in crime, or assuming their prerogatives, were punished by everlasting torture in the underworld. The consequences of social crimes, such as murder or incest, were also described in legend (*e.g.,* the story of Oedipus, who killed his father and married his mother). Legends were also sometimes employed to justify existing political systems or to bolster territorial claims.

Folktales. Folktales, consisting of popular recurring themes and told for amusement, inevitably found their way into Greek myth. Such is the theme of lost persons—whether husband, wife, or child (*e.g.,* Odysseus, Helen of Troy, or Paris of Troy)—found or recovered after long and exciting adventures. Journeys to the land of the dead were made by Orpheus (a hero who went to Hades to restore his dead wife, Eurydice, to the realm of the living), Heracles, Odysseus, and Theseus (the slayer of the Minotaur). The victory of the little man by means of cunning against impossible odds, the exploits of the superman (*e.g.,* Heracles), or the long-delayed victory over enemies are still as popular with modern writers as they were with the Greeks. The successful countering of the machinations of cruel sires and stepmothers (who are often witches), rescues of princesses from monsters, or temporary forgetfulness at a crucial moment are also familiar themes in Greek myth. Recognition by tokens, such as Odysseus' scar or peculiarities of dress, is another common folktale motif. The babes-in-the-wood theme of the exposure of children and their subsequent recovery is also found in Greek myth. The Greeks, however, also knew of the exposure of children as a common practice.

Types of myths in Greek culture. *Myths of origin.* Myths of origin represent an attempt to render the universe comprehensible in human terms. Greek creation myths (cosmogonies) and views of the universe (cosmologies) were more systematic and specific than those of other ancient peoples. Yet their very artistry serves as an impediment to interpretation, since the Greeks embellished the myths with folktale and fiction told for its own sake. Thus, though the aim of Hesiod's *Theogony* is to describe the ascendancy of Zeus (and, incidentally, the rise of the other gods), the inclusion of such familiar themes as the hostility between the generations, the enigma of woman (Pandora), the exploits of the friendly trickster (Prometheus), or struggles against powerful beings or monsters like the Titans (and, in later tradition, the Giants) enhances the interest of an epic account.

According to Hesiod, four primary divine beings first came into existence: the Gap (Chaos), Earth (Gaea), the Abyss (Tartarus), and Love (Eros). The creative process began with the forcible separation of Gaea from her doting consort Heaven (Uranus) in order to allow her progeny to be born. The means of separation employed, the cutting off of Uranus' genitals by his son Cronus, bears a certain resemblance to a similar story recorded in Babylonian epic. The crudity is relieved, however, in characteristic Greek fashion by the friendly collaboration of Uranus and Gaea, after their divorce, in a plan to save Zeus from the same Cronus, his cannibalistic sire.

According to Greek cosmological concepts, the Earth was viewed as a flat disk afloat on the river of Ocean. The Sun (Helios) traversed the heavens like a charioteer and sailed around the Earth in a golden bowl at night. Natural fissures were popularly regarded as entrances to the subterranean house of Hades, home of the dead.

Myths of the ages of the world. From a very early period, Greek myths seem open to criticism and alteration on grounds of morality or of misrepresentation of known facts. In the *Works and Days,* Hesiod makes use of a scheme of Four Ages (or Races): Golden, Silver, Bronze, and Iron. "Race" is the more accurate translation, but "Golden Age" has become so established in English that both terms should be mentioned. These races or ages are separate creations of the gods, the Golden Age belonging to the reign of Cronus, the subsequent races the creation

The Four Ages of Hesiod

of Zeus. Those of the Golden Age never grew old, were free from toil, and passed their time in jollity and feasting. When they died, they became guardian spirits on Earth.

Why the Golden Age came to an end Hesiod failed to explain, but it was succeeded by the Silver Age. After an inordinately prolonged childhood, the men of the Silver Age began to act presumptuously and neglected the gods. Consequently, Zeus hid them in the Earth, where they became spirits among the dead.

Zeus next created the men of the Bronze Age, men of violence who perished by mutual destruction. At this point the poet intercalates the Age (or Race) of Heroes. He thereby destroys the symmetry of the myth, in the interests of history: what is now known as the Minoan–Mycenaean period was generally believed in antiquity to have been a good time to live. (This subjection of myth to history is not universal in Greece, but it is found in writers such as Hesiod, Xenophanes, Pindar, Aeschylus, and Plato.) Of these heroes the more favoured (who were related to the gods) reverted to a kind of restored Golden Age existence under the rule of Cronus (forced into honourable exile by his son Zeus) in the Isles of the Blessed.

The final age, the antithesis of the Golden Age, was the Iron Age, during which the poet himself had the misfortune to live. But even that was not the worst, for he believed that a time would come when infants would be born old, and there would be no recourse left against the universal moral decline. The presence of evil was explained by Pandora's rash action in opening the fatal urn.

Elsewhere in Greek and Roman literature, the belief in successive periods or races is found with the belief that by some means, when the worst is reached, the system gradually (Plato, *Politikos*) or quickly (Virgil, *Fourth Eclogue*) returns to the Golden Age. Hesiod may have known this version; he wishes to have been born either earlier or later. There is also a myth of progress, associated with Prometheus, god of craftsmen; but the progress is limited, for the 19th-century concept of eternal advancement is absent from Greek thought.

Myths of the gods. Myths about the gods described their births, victories over monsters or rivals, love affairs, special powers, or connections with a cultic site or ritual. As these powers tended to be wide, the myths of many gods were correspondingly complex. Thus, the Homeric Hymns to Demeter, a goddess of agriculture, and to the Delian and Pythian Apollo describe how these deities came to be associated with sites at Eleusis, Delos, and Delphi, respectively. Similarly, myths about Athena, the patroness of Athens, tend to emphasize the goddess' love of war and her affection for heroes and the city of Athens; and those concerning Hermes (the messenger of the gods), Aphrodite (goddess of love), or Dionysus describe Hermes' proclivities as a god of thieves, Aphrodite's lovemaking, and Dionysus' association with wine, frenzy, miracles, and even ritual death. Poseidon (god of the sea) was unusually atavistic, in that his union with Earth and his equine adventures appear to hark back to his pre-marine status as a horse or earthquake god. Many myths are treated as trivial and lighthearted; but, as was said above, this judgment rests on the suppressed premise that any divine behaviour that seems inappropriate for a major religion must have seemed absurd and fictitious to the Greeks. It is uncertain whether Homer knew of the judgment of Paris; but he knew the far from trivial consequences for Troy of the favour of Aphrodite and the bitter enmity of Hera and Athena, which the judgment of Paris was composed to explain.

Combinations of myths, legends, and folktales

As time went on, an accretion of minor myths continued to supplement the older and more authentic ones. Thus, the loves of Apollo, virtually ignored by Homer and Hesiod, explained why the bay (or laurel) became Apollo's sacred tree and how he came to father Asclepius, a healing god. Similarly, the presence of the cuckoo on Hera's sceptre at Hermione or the invention of the panpipe were explained by fables. Such etiological myths proliferated during the Hellenistic era, though in the earlier periods genuine examples are harder to detect.

Of folk deities, the nymphs (nature goddesses) personified nature or the life in water or trees and were said to punish unfaithful lovers. Water nymphs (Naiads) were reputed to drown those with whom they fell in love, such as Hylas, a companion of Heracles. Even the gentle Muses (goddesses of the arts and sciences) blinded their human rivals, such as the bard Thamyris. Satyrs (youthful folk deities with bestial features) and Sileni (old and drunken folk deities) were the nymphs' male counterparts. Like sea deities, Sileni possessed secret knowledge that they would reveal only under duress. Charon, the grisly ferryman of the dead, was also a popular figure of folktale.

Myths of heroes. Hero myths included elements from tradition, folktale, and fiction. The saga of the Argonauts, for example, is highly complex and includes elements from folktale and fiction, but the information that the fleet mustered at Colchis may be regarded as genuine legend. Episodes in the Trojan cycle, such as the departure of the Greek fleet from Aulis or Theseus' Cretan expedition and death on Scyros, may belong to traditions dating from the Minoan–Mycenaean world. On the other hand, events described in the *Iliad* probably owe far more to Homer's creative ability than to genuine tradition. Even heroes like Achilles, Hector, or Diomedes are largely fictional, though doubtlessly based on legendary prototypes. The *Odyssey* is the prime example of the wholesale importation of folktales into epic. All the best-known Greek hero myths, such as the labours of Heracles and the adventures of Perseus, Cadmus, Pelops, or Oedipus, depend more for their interest on folktales than legend. Certain heroes—Heracles, the Dioscuri (the twins Castor and Pollux), Amphiaraus (one of the Argonauts), or Hyacinthus (a youth loved by Apollo and accidentally killed)—may be regarded as partly legend and partly religious myth. Thus, whereas Heracles, a man of Tiryns, may originally have been a historical character, the myth of his demise on Oeta and subsequent elevation to full divinity is closely linked with a cult. In time, Heracles' popularity was responsible for connecting his story with the Argonauts, an earlier attack on Troy, and with Theban myth. Similarly, the exploits of the Dioscuri are those of typical heroes: fighting, carrying off women, and cattle rustling. After their death they passed six months alternately beneath the Earth and in the world above, which suggests that their worship, like that of Persephone (the daughter of Zeus and Demeter), was connected with fertility or seasonal change.

Myths of seasonal renewal. Certain myths, in which goddesses or heroes were temporarily incarcerated in the underworld, were allegories of seasonal renewal. Perhaps the best-known myth of this type is the one telling how Hades (Latin Pluto), the god of the underworld, carried Persephone off to be his consort, causing her mother Demeter, the goddess of grain, to allow the earth to grow barren out of grief. Because of her mother's grief, Zeus permitted Persephone to spend four months of the year in the house of Hades and eight in the light of day. In less benign climates, she was said to spend six months of the year in each. Some scholars hold that Persephone's time below ground represents the summer months, when Greek fields are parched and bare; but the *Hymn to Demeter,* the earliest source, states explicitly that Persephone returns when the spring flowers are flourishing (line 401). Myths of seasonal renewal, in which the deity dies and returns to life at particular times of the year, are plentiful. An important Greek example is the Cretan Zeus, mentioned above.

Myths involving theriolatry. Many Greek myths involve animal transformations, though there is no proof that theriolatry (animal worship) was ever practiced by the Greeks. Gods sometimes assumed the form of beasts in order to deceive goddesses or women. Zeus, for example, assumed the form of a bull when he carried off Europa, a Phoenician princess, and appeared in the guise of a swan in order to attract Leda, wife of a king of Sparta. Poseidon took the shape of a stallion to beget the wonder horses Arion and Pegasus.

Deities appearing in nonhuman form

These myths do not suggest theriolatry. No worship is offered to the deity concerned. The animals serve other purposes in the narratives. Bulls were the most powerful animals known to the Greeks and may have been worshiped in the remote past. But for the Greeks in even the earliest sources, there is no indication that Zeus or

Heracles fighting with the Amazons, detail from a volute crater attributed to Euphronius, *c.* 500 BC. In the Museo Archeologico, Arezzo, Italy.

Alinari—Art Resource/EB Inc.

Poseidon were once bulls or horses, or that Hera was ever "ox-eyed" other than metaphorically, or that "gray-eyed" Athena was ever "owl-faced."

Deities appearing in human form

Other types. Other types of myth exemplified the belief that the gods sometimes appeared on Earth disguised as men and women and rewarded any help or hospitality offered them. Baucis, an old Phrygian woman, and Philemon, her husband, for example, were saved from the flood by offering hospitality to Zeus and Hermes, both of whom were in human form. The punishment of men's presumption in claiming to be the gods' superiors, whether in musical skill or even the number of their children, is described in several myths. The gods' jealousy of their musical talents appears in the beating and flaying of the flute-playing Satyr, Marsyas, by Athena and Apollo, as well as in the attaching of ass's ears to King Midas for failing to appreciate the superiority of Apollo's music to that of the god Pan. Jealousy was the motive for the slaying of Niobe's many children, because of Niobe's flaunting her fecundity to the goddess Leto, who had only two offspring. Similar to such stories are the moral tales about the fate of Icarus, who flew too high on homemade wings, or the myth about Phaethon, the son of Helios, who failed to perform a task too great for him (controlling the horses of the Sun).

Transformation into flowers or trees, whether to escape a god's embraces (such as Daphne, a nymph transformed into a laurel tree), as the result of an accident (such as Hyacinthus, a friend of Apollo, who was changed into a flower), or because of pride (*e.g.,* the beautiful youth Narcissus who fell in love with his own reflection and was changed into a flower), were familiar themes in Greek myth.

Also popular were myths of fairylands, such as the Garden of the Hesperides (in the far west) or the land of the Hyperboreans (in the far north), or encounters with monstrous or outlandish people, such as the Centaurs or Amazons.

Greek mythological characters and motifs in art and literature. People of all eras have been moved and baffled by the deceptive simplicity of Greek myths, and Greek mythology has had a profound effect on the development of Western civilization.

The earliest visual representations of mythological characters and motifs occur in late Mycenaean and sub-Mycenaean art. Though identification is controversial, Centaurs, a Siren, and even Zeus's lover Europa have been recognized. Mythological and epic themes are also found in Geometric art of the 8th century BC, but not until the 7th century did such themes become popular in both ceramic and sculptured works. During the Classical and subsequent periods, they became commonplace. The birth of Athena was the subject of the east pediment of the Parthenon in Athens, and the legend of Pelops and the labours of Heracles was the subject of the corresponding pediment and the metopes (a space on a Doric frieze) of the Temple of Zeus at Olympia. The battles of gods with Giants and of Lapiths (a wild race in northern Greece) with Centaurs were also favourite motifs. Pompeian frescoes reveal realistic representations of Theseus and Ariadne, Perseus, the fall of Icarus, and the death of Pyramus.

Resurgence of Greek mythological motifs

The great Renaissance masters added a new dimension to Greek mythology. Among the best-known subjects of Italian artists are Botticelli's "Birth of Venus," the Ledas of Leonardo da Vinci and Michelangelo, and Raphael's "Galatea."

Through the medium of Latin and, above all, the works of Ovid, Greek myth influenced medieval poets such as Petrarch and Boccaccio in Italy and Chaucer in England; Dante in Italy during the Renaissance; and, later, the English Elizabethans and John Milton. Racine in France and Goethe in Germany revived Greek drama, and nearly all the major English poets from Shakespeare to Robert Bridges turned for inspiration to Greek mythology. In more recent times, classical themes have been reinterpreted by such major dramatists as Jean Anouilh, Jean Cocteau, and Jean Giraudoux in France, Eugene O'Neill in America, and T.S. Eliot in England and by great novelists such as James Joyce (Irish) and André Gide (French). The German composers Christoph Gluck (18th century) and Richard Strauss (20th century), the German-French composer Jacques Offenbach (19th century), and many others have set Greek mythological themes to music.

Roman religion

This section deals with the beliefs and practices of the inhabitants of the Italian peninsula from ancient times until the ascendancy of Christianity in the 4th century AD.

NATURE AND SIGNIFICANCE

The Romans, according to the orator and politician Cicero, excelled all other peoples in the unique wisdom that made them realize that everything is subordinate to the rule and direction of the gods. Yet Roman religion was based not on divine grace but instead on mutual trust (*fides*) between god and man. The object of Roman religion was to secure the cooperation, benevolence, and "peace" of the gods (*pax deorum*). The Romans believed that this divine help would make it possible for them to master the unknown forces around them that inspired awe and anxiety (*religio*), and thus they would be able to live successfully. Consequently, there arose a body of rules,

Object of Roman religion

the *jus divinum* ("divine law"), ordaining what had to be done or avoided.

These precepts for many centuries contained scarcely any moral element; they consisted of directions for the correct performance of ritual. Roman religion laid almost exclusive emphasis on cult acts, endowing them with all the sanctity of patriotic tradition. Roman ceremonial was so obsessively meticulous and conservative that, if the various partisan accretions that grew upon it throughout the years can be eliminated, remnants of very early thought can be detected near the surface.

This demonstrates one of the many differences between Roman religion and Greek religion, in which such remnants tend to be deeply concealed. The Greeks, when they first began to document themselves, had already gone quite a long way toward sophisticated, abstract, and sometimes daring conceptions of divinity and its relation to man. But the orderly, legalistic, and relatively inarticulate Romans never quite gave up their old practices. Moreover, until the vivid pictorial imagination of the Greeks began to influence them, they lacked the Greek taste for seeing their deities in personalized human form and endowing them with mythology. In a sense, there is no Roman mythology, or scarcely any. Although discoveries in the 20th century, notably in the ancient region of Etruria (between the Tiber and Arno rivers, west and south of the Apennines), confirm that Italians were not entirely unmythological, their mythology is sparse. What is found at Rome is chiefly only a pseudomythology (which, in due course, clothed their own nationalistic or family legends in mythical dress borrowed from the Greeks). Nor did Roman religion have a creed; provided that a Roman performed the right religious actions, he was free to think what he liked about the gods. And, having no creed, he usually deprecated emotion as out of place in acts of worship.

In spite, however, of the antique features not far from the surface, it is difficult to reconstruct the history and evolution of Roman religion. The principal literary sources, antiquarians such as the 1st-century-BC Roman scholars Varro and Verrius Flaccus, and the poets who were their contemporaries (under the late Republic and Augustus), wrote 700 and 800 years after the beginnings of Rome. They wrote at a time when the introduction of Greek methods and myths had made erroneous (and flattering) interpretations of the distant Roman past unavoidable. In order to supplement such conjectures or facts as they may provide, scholars rely on surviving copies of the religious calendar and on other inscriptions. There is also a rich, though frequently cryptic, treasure-house of material in coins and medallions and in works of art.

HISTORY

Early Roman religion. For the earliest times, there are the various finds and findings of archaeology. But they are not sufficient to enable scholars to reconstruct archaic Roman religion. They do, however, suggest that early in the 1st millennium BC, though not necessarily at the time of the traditional date for the founding of Rome (753 BC), Latin and Sabine shepherds and farmers with light plows came from the Alban Hills and the Sabine Hills, and that they proceeded to establish villages at Rome, the Latins on the Palatine Hill and the Sabines (though this is uncertain) on the Quirinal and Esquiline hills. About 620 the communities merged, and *c.* 575 the Forum Romanum between them became the town's meeting place and market.

Deification of functions. From such evidence it appears that the early Romans, like many other Italians, sometimes saw divine force, or divinity, operating in pure function and act, such as in human activities like opening doors or giving birth to children, and in nonhuman phenomena such as the movements of the sun and seasons of the soil. They directed this feeling of veneration both toward happenings that affected human beings regularly and, sometimes, toward single, unique manifestations, such as a mysterious voice that once spoke and saved them in a crisis (Aius Locutius). They multiplied functional deities of this kind to an extraordinary degree of "religious atomism," in which countless powers or forces were identified with one phase of life or another. Their functions were sharply defined; and in approaching them it was important to use their right names and titles. If one knew the name, one could secure a hearing. Failing that, it was often best to cover every contingency by admitting that the divinity was "unknown" or adding the precautionary phrase "or whatever name you want to be called" or "if it be a god or goddess."

Veneration of objects. The same sort of anxious awe was extended not only to functions and acts but also to certain objects that inspired a similar belief that they were in some way more than natural. This feeling was aroused, for example, by springs and woods, objects of gratitude in the torrid summer, or by stones that were often believed to be meteorites—*i.e.,* had apparently reached the earth in an uncanny fashion. To these were added products of human action, such as burial places and boundary stones, and inexplicable things, such as Neolithic implements (probably the mysterious meteorites were often these) or bronze shields (artifacts that had strayed in from more advanced cultures).

To describe the powers in these objects and functions that inspired the *horror,* or sacred thrill, the Romans eventually employed the word *numen,* suggestive of a god's nod, *nutus;* though so far there is no evidence that this usage was earlier than the 2nd century BC. The application of the word spirit to *numen* is anachronistic in regard to early epochs because it presupposes a society capable of greater abstraction. Nor must the term mana, used by Melanesians to describe their own concept of superhuman forces, be introduced too readily. The two societies are not necessarily analogous and, besides, the deduction from such comparisons that the Romans experienced an impersonal, pre-deistic, primordial stage of religion that neatly preceded the personal stage cannot be regarded as correct. On the contrary, from the very earliest times, the supernatural forces that they envisaged included a number of deities in analogous human forms; among them were certain "high gods." Foremost among these was a divinity of the sky, Jupiter, akin to the sky gods of other early Indo-European-speaking peoples, the Sanskrit Dyaus and Greek Zeus. Not yet, probably, a Supreme Being, though superior in some sense to other divine powers, this god of the heavens was easily linked with the forces of function and object, with lightning and weather, or with the uncanny stone that came from on high and was called Jupiter Lapis. High gods

Purpose of sacrifice and magic. These gods and sacred functions and objects seemed charged with power because they were mysterious and alarming. In order to secure their food supply, physical protection, and growth in numbers, the early Romans believed that such forces had to be propitiated and made allies. Sacrifice was necessary. The product sacrificed would revitalize the divinity, which was seen as a power of action and therefore likely to run down unless so revitalized. By this nourishment he or it would become able and ready to fulfill requests. And so the sacrifice was accompanied by the phrase *macte esto!* ("be you increased!").

Prayer was a normal accompaniment of sacrifice, and as a conception of the divine powers gradually developed, it contained varying ingredients of flattery, cajolery, and attempted justification; but it also was compounded by magic—the attempt not to persuade nature, but to coerce it. Though the authorities (*e.g., c.* 451–450 BC, Law of the Twelve Tables) sought to limit its noxious aspects, magic continued to abound throughout the ancient world. Even official rites remained full of its survivals, notably the annual festival of the Lupercalia and the ritual dances of the Salii in honour of Mars. Romans in historical times regarded magic as an oriental intrusion, but Italian tribes, such as the Marsi and Paeligni, were famous for such practices. Among them curses figured prominently, and curse inscriptions from *c.* 500 BC onward have been found in large numbers. There were also numerous survivals of taboo, a negative branch of magic: people were admonished to have no dealings with strangers, corpses, newborn children, spots struck by lightning, etc., lest harm would befall them.

Religion in the Etruscan period. The apparent amalgamation of the Latin and Sabine villages of Rome coincided with, or more probably was soon followed by, a period in which Rome was under the control of at least one dynasty (the Tarquins) from Etruria, north of the Tiber (*c.* 575–510 BC, though some scholars would extend this domination to *c.* 450).

Importance of ritual. The Etruscans felt profound religious anxieties and were more devoted to ritual than any other people of the ancient Western world. Though sources are, again, late and unsatisfactory, it appears that they possessed a comprehensive collection of rules regulating these rites. Etruscan culture was heavily based on influences from Greece in its orientalizing period, conveyed mainly through Greek centres (such as Cumae) in Campania, colonized by Euboeans, who were also prominent in Syrian markets. But the religion of Etruria proclaims a very un-Greek view of the abasement and nonentity of man before the gods and their will.

Divination and views of the afterlife

To the Etruscans the whole fanatical effort of life was directed toward forcing their deities, led by Tinia or Tin (Jupiter), to yield up their secrets by divination. They saw an intimate link existing between heaven and earth, which seemed to echo one another within a unitary system, and they were more ambitious than either Greeks or Romans in their claims to foretell the future. They also formed an exceptionally complex, rich, and imaginative picture of the afterlife. The living were perpetually obsessed by their care for the dead, expressed in elaborate, magnificently equipped and decorated tombs and lavish sacrifices. For, in spite of beliefs in an underworld, or Hades, there was also a conviction that the individuality of the dead somehow continued in their mortal remains; and it was therefore imperative that they take pleasure in their graves or tombs and not return to haunt the living. From the 4th century BC onward, after the Etruscans had lost their political power to Rome, their art depicts horrors indicating an increasing fear of what death might bring.

Influence on Roman religion. The Roman religion continued to display certain obvious debts to the period when the city had been under Etruscan control. It is true that the Roman shades (Di Manes) were much less substantial than the fantastic Etruscan conceptions and, although Etruscan divination by the liver and entrails survived and later became increasingly fashionable in Rome, Roman diviners in general, products of a more realistic and prosaic society, never aspired to such precise information about the future as the Etruscans had hoped to gain. Yet, it was the Etruscans who first gave a vigorous definition to Italian religious forms. Indeed, many of the religious features that patriotic historians preferred to ascribe to the mythical King Numa Pompilius (who was supposed to have been Romulus' Sabine successor in the 8th century BC—the man of peace following the man of war) date, in fact, from the period of Etruscan domination two centuries later. Nevertheless, Romans acknowledged a debt to Etruria that included much ceremony and ritual and the plan, appearance, and decoration of a number of temples, notably the great shrine of the Capitoline Triad, Jupiter, Juno, and Minerva. The Romans also were indebted to the Etruscans for their first statues of gods, including the cult image of Jupiter commissioned from an Etruscan for the Capitoline temple. Such statuary, showing the gods in human shape, encouraged the Romans to think of their gods in this way, with the consequent possibility of investing them with myths, which thereafter gradually accumulated around them in the form of Hellenic stories often infused with a native patriotic element.

The calendar

Above all, Rome owed to its Etruscan kings its religious calendar. In addition to poetical works discussing the calendar in antiquarian fashion, such as the *Fasti* of Ovid, there are extant fragments of about 40 copies of the calendar itself, in a revised shape established by Julius Caesar. Besides the Julian revision, there is an incomplete pre-Caesarian, Republican calendar, the Fasti Antiates, discovered at Antium (Anzio); it dates from after 100 BC. It is possible to detect in these calendars much that is very ancient, including a pre-Etruscan 10-month solar year. However, the basis of the calendars, in their surviving form, is later, since it consists of an attempt to reconcile the solar and lunar year, in accordance with Babylonian calculations. This endeavour belongs to the period of Etruscan domination of Rome—for example, the names of the months April and June (in their Roman form) come from Etruria. Moreover, the presence or absence of certain festivals permits a dating approximating to the time of Etruscan domination in the later 6th century BC. Additional modifications were introduced in the following century and again when the calendar was subsequently published (30 BC).

The festivals it records, of which the earliest are indicated in large letters, reflect a period of transition between country and town life. Though local cult continued to remain active, many forms of worship hitherto maintained by families and farms had now been taken over by the comparatively mature Roman state. The state management blocked any tendency toward spiritualization and removed the need for any vigorous individual participation; however, by ensuring that the gods were conciliated by a schedule corresponding to the regular process of nature, it made the individual citizens feel for centuries that relations with the supernatural were being maintained safely.

Religion in the early Republic. Even if, as tradition records, a coup d'état dislodged the Etruscan kings before 500 BC, in the first half of the 5th century there was no weakening of trade relations with Etruria. Its southern cities, such as Caere (Cerveteri) and Veii close to Rome, had long used the Greek city of Cumae as a commercial outlet, converting it into an important grain supplier. And now Rome, faced with a shortage of grain, arranged for it to be imported from Cumae. The same city also influenced the foundation of Roman temples in the Greek style. Rome, which had already become accustomed to Greek religious customs in the Etruscan epoch, now showed a willingness to absorb them. This forms a strange contrast to its deeply ingrained religious conservatism. Moreover, at some quite early stage (though there is no positive evidence of the practice until the 3rd century), Romans borrowed from elsewhere in Italy a special ritual (*evocatio*) for inviting the patron deities of captured towns to abandon their homes and migrate to Rome.

Influence of Greek religion

In an emergency in 399 BC, during a difficult siege of Veii, Rome carried Hellenization further by importing a Greek rite in which, as an appeal to emotional feeling, images of pairs of gods were exhibited on couches before tables spread with food and drink; this rite (*lectisternium*) was designed to make them Rome's welcome guests. From the same century onward, if not earlier, pestilences were averted by another ritual (*supplicatio*), in which the whole populace went around the temples and prostrated themselves in Greek fashion. Later the custom was extended to the celebration of victories.

Religion in the later Republic: crises and new trends. The *lectisternium* was repeated, with increased elaboration and pomp, in 217 BC during a period in which emotional religion was running rampant because of Hannibal's invasion of Italy in the Second Punic War. Faced with a flood of fears and anxieties and reports of many alarming and extraordinary events, Rome took precautions to secure the favour of all manner of gods. Among them, as a desperate attempt at novelty when appeals to the usual deities seemed stale, was the introduction of the Great Mother of Asia Minor, Cybele (204 BC). Eighteen years later, the equally orgiastic worship of Dionysus (Bacchus) was coming in so rapidly and violently, by way of southern Italy, that the Senate, scenting subversion, repressed its practitioners. But these and other mystery religions, promising initiation, afterlife, and an excitement that Roman national cults could not provide, had come to stay and, although there were long periods of official disapproval before acclimatization was completed, they gradually played an immense part upon the religious scene. Eastern astrology, too, became extremely popular. It was based on the conviction that, since there is cosmic sympathy between the earth and other heavenly bodies, and since, therefore, the emanations of these bodies influence the earth, men must learn how to foresee their dictates—and outwit them.

Influence of Stoicism

Astrological practices received encouragement from Stoic philosophy, which was introduced to Rome in the 2nd and early 1st centuries BC, notably by Panaetius and Poseidonius. The Stoics saw this pseudoscience as proof of the Platonic unity of the universe. Stoicism affected Roman religious thinking in at least three other ways. First, it had a deterministic effect, encouraging a widespread belief in Fate and also, somewhat illogically, in Fortune, both of which were revered in other parts of the Mediterranean and Middle Eastern world. Second, Stoicism infused a new spirituality into religious thinking by its insistence that the human soul is part of the universal spirit and shares its divinity. Third, the moral implication of this, as the Stoics pointed out, was that all men are brothers and must treat each other accordingly. This demonstration struck a chord in the psychology of the Romans, who possessed strongly ethical inclinations and now, at last, saw this trend supported and justified by a philosophical sanction that their formalistic religion had not provided. In changing times of imperialism, materialism, and widespread heart-searching, the state religion had failed to fill the vacuum, and philosophy stepped in instead. At the same time the negative approach of Roman religion to the afterlife was counteracted by an influx of speculations that blended theology, mysticism, and magic and claimed the mythical Orpheus and the part historical, part legendary Pythagoras as prophets.

While their national poet Ennius helped to diffuse such beliefs, he and the comic dramatist Plautus ridiculed the traditional Roman gods on the stage. The upper-class attitude of the times was expressed by the historian Polybius, the priestly lawyer Scaevola, the scholarly Varro, and the orator and philosopher Cicero, who maintained that the importance of religion was political, residing in its power to keep the multitude under control, to prevent social chaos, and to promote patriotic feeling.

The imperial epoch: the final forms of Roman paganism. After the prolonged horrors of civil war had ended (30 BC), the victorious Octavian, the adoptive son of the dictator Caesar and founder of the imperial regime or principate, decided, correctly, that the ancient religion was far from dead and that the restoration of all its forms would respond to a strong popular, instinctive belief that the disasters of the past generations had been due to the neglect of religious duties.

Deification of Caesar and Augustus

The imperial cult. Octavian himself took the name Augustus, a term indicating a claim to reverence. This did not make him a god in his lifetime, but, combined with the insertion of his *numen* and his *genius* (originally the procreative power that enables a family to be carried on) into certain cults, it prepared the way for his posthumous deification, just as Caesar had been deified before him. Both were deified by the state because they seemed to have given Rome gifts worthy of a god. From earliest times in Greece there had been an idea that, if someone saved you, you should pay him the honours you would offer to a god. Alexander the Great and his successors had demanded reverence as divine saviours, and Ptolemy II Philadelphus of Egypt introduced a cult of his own living person. The Stoic belief that the human soul was part of the world soul was a corollary of the view that great men possessed a larger share of this divine element. Moreover, the 3rd-century-BC mythographer Euhemerus had elaborated a theory that the gods themselves had once been human; this idea was readily adapted to the supposed careers of Heracles (Hercules) and the Dioscuri (Castor and Polydeuces [Pollux]); and the Romans applied it to their own gods Saturn and Quirinus, the latter identified with the national founder, Romulus, risen to heaven. And so it became customary—if emperors (and empresses) were approved of in their lives—to raise them to divinity after their deaths. They were called *divi,* not *dei* like the Olympian gods; the latter were prayed to, but the former were regarded with veneration and gratitude.

As the empire proceeded and the old religion seemed more and more irrelevant to people's personal preoccupations and successive national emergencies, the cult of the *divi,* subsequently grouped together in a single Hall of Fame, remained foremost among the patriotic cults that were increasingly encouraged as unifying forces. Concentrating on the protectors of the emperor and the nation, they included the worship of Rome herself, and of the *genius* of the Roman people; for the army a number of special military celebrations are recorded on the Calendar of Doura-Europus in Mesopotamia (Feriale Duranum, *c.* AD 225–27). As for the ruling emperors, they were more and more frequently treated as divine, with varying degrees of formality, and officially they often were compared with gods. As monotheistic tendencies grew, however, this custom led not so much to their identification with the gods as to the doctrine that they were the elect of the divine powers, who were defined as their companions (*comites*). In pursuance of this way of thinking, as official paganism approached its last days, the emperors Diocletian and Maximian took the names Jovius and Herculius, respectively, after their Companions and Patrons Jupiter and Hercules.

Apotheosis of Faustina, wife of Marcus Aurelius, ancient bas-relief. In the Capitoline Museum, Rome.

Introduction of Christianity and Mithraism. By now, however, the humanistic idea that men could become gods had ceased to have any plausibility. Plotinus and his Neoplatonism, the dominant philosophy of the pagan world from the mid-3rd century AD, had given powerful, mystical shape to the Platonic and Stoic conception that the universe is governed by a single force. On the other hand, the greatest religious figure of the century, the Iranian Mani, who had started to preach in Mesopotamia *c.* 240, dramatically preached the opposing dualistic idea that the world is the creation not only of a good power but of an evil one as well. Mani's church, which alarmed Diocletian and for a time attracted the great Christian theologian St. Augustine, absorbed many of the innumerable cults of Gnostics who claimed special knowledge (*gnōsis*) by illumination and revelation and taught how people can purge the nonspiritual from within themselves and escape their earthly prison. More impressively, the cult of the Persian Mithra blended the dualism of Mani with the emotional initiations of the mystery religions (corrected by a much sterner tone of moral endeavour) and became a strong link between the cult of the Sun (which appealed to contemporary monotheists) and the fashionable revulsion from the senses that was shortly to lead to Christian monasticism. Like Christianity, Mithraism had its sacraments; but the life of Mithra exercised a less far-reaching appeal than the life of Christ, and Mithra's cult excluded women.

Speculative religious thought

Christianity, unique in its universal charity and unique

also in its demand for a noble effort of faith in Jesus' blend of divinity and humanity, was the religion that prevailed in the Roman world. It satisfied the emperor Constantine's impulsive need for divine support, and from AD 312 onward, by a complex and gradual process, it became the official religion of the empire.

The survival of Roman religion. For a time, coins and other monuments continued to link Christian doctrines with the worship of the Sun, to which Constantine had been addicted previously. But even when this phase came to an end, Roman paganism continued to exert other, permanent influences, great and small. The emperors passed on to the popes the title of chief priest, *pontifex maximus.* The saints, with their distribution of functions, often seemed to perpetuate the many *numina* of ancient tradition. The ecclesiastical calendar retains numerous remnants of pre-Christian festivals—notably Christmas, which blends elements including both the feast of the Saturnalia and the birthday of Mithra. But, most of all, the mainstream of Western Christianity owed ancient Rome the firm discipline that gave it stability and shape, combining insistence on established forms with the possibility of recognizing that novelties need not be excluded, since they were implicit from the start.

BELIEFS, PRACTICES, AND INSTITUTIONS

The earliest divinities. The early Romans, like other Italians, worshiped not only purely functional and local forces but also certain high gods. Chief among them was the sky god Jupiter, whose cult, at first limited to the communities around the Alban Hills, later gained Rome as an adherent. The Romans gave Jupiter his own priest (*flamen*), and the fact that there were two other senior *flamines,* devoted to Mars and Quirinus, confirms other indications that the cults of these three deities, envisaged perhaps in some sort of association, belonged to a very early stratum (though the theory of their correspondence to the three-class social division of the early Indo-European-speaking peoples is generally unacceptable). Mars, whose name may or may not be Indo-European, was a high god of many Italian peoples, as liturgical bronze tablets found at Iguvium (Gubbio), the Tabulae Iguvinae (*c.* 200–*c.* 80 BC), confirm, protecting them in war and defending their agriculture and animals against disease. Later, he was identified with the Greek god of war, Ares, and also was regarded as the father of Romulus. Mars Gradivus presided over the beginning of a war and Mars Quirinus over its end, but earlier Quirinus had apparently, as a separate deity, been the patron of the Quirinal village before its amalgamation with the Palatine; subsequently he was believed to have been the god that Romulus became when he ascended into heaven.

Jupiter, Mars, and Quirinus

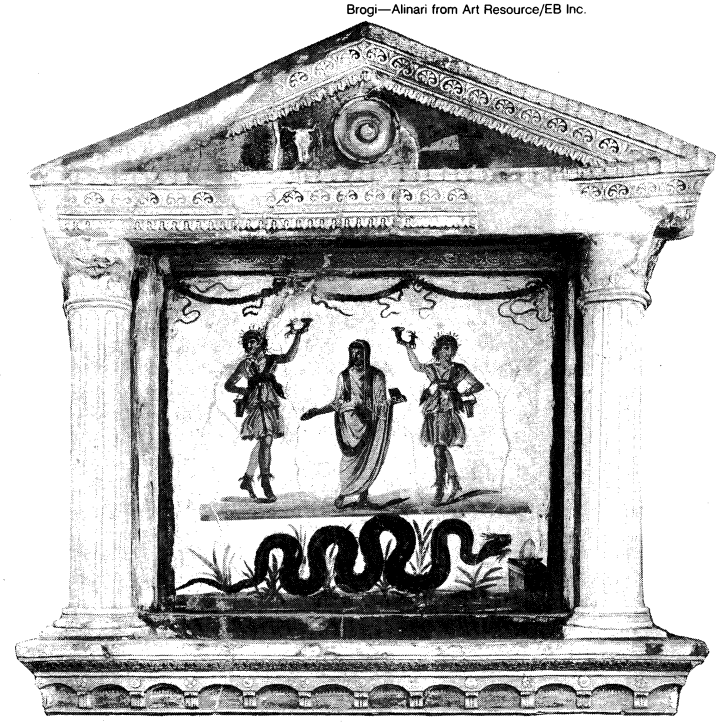
Janus and Vesta

Two other forces that belong to an early phase were Janus and Vesta, the powers of the door and hearth, respectively. Janus, who had no Greek equivalent, was worshiped beside the Forum in a small shrine with double doors at either end and originated either from a divine power that regulated the passage over running water or rather, perhaps, from sacred doorways like those found on the art of Bronze Age Mycenae. Janus originally stood for the magic of the door of a private house or hut and later became a part of the state religion. The gates of his temple were formally closed when the state was at peace, a custom going back to the primitive war magic that required armies to march out to battle by this properly sanctified route. Vesta, too, passed from the home to the state, always retaining a circular temple reminiscent of the primitive huts whose form can be reconstructed from traces left in the earth and from surviving funerary urns. Vesta's shrine contained the eternal fire, but the absence of a statue indicates that it preceded the anthropomorphic period; its correspondence with the Indian *garhapatya,* "house-father's fire," suggest an origin prior to the time of the differentiation of the Indo-European-speaking peoples. The cultic site just outside the area of the primitive Palatine settlement indicates that there had been a form of fire worship even earlier than Vesta's (dedicated to the deity Caca) on the Palatine itself. The cult of Vesta, tended by her Virgins, continued to flourish until the end of antiquity, endowed with an important role in the sacred protectorship of Rome.

Manes, Indigetes, Lares, and Penates

The Di Manes, collective powers (later "spirits") of the dead, may mean "the good people," an anxious euphemism like the Greek name of "the kindly ones" for the Furies. As a member of the family or clan, however, the dead man or woman would, more specifically, be one of the Di Parentes; reverence for ancestors was the core of Roman religious and social life. Di Indigetes was a name given collectively to these forebears, as well as to other deified powers or spirits who likewise controlled the destiny of Rome. For example, the name Indiges is applied to Aeneas, whose mythical immigration from Troy led to the eventual foundation of the city. According to an inscription of the 4th century BC (found at Tor Tignosa, 15 miles south of Rome), Aeneas is also called Lar, which indicates that the Lares, too, were originally regarded as divine ancestors and not as deities who presided over the farmland. The Lares were worshiped wherever properties adjoined, and inside every home their statuettes were placed in the domestic shrine (*lararium*). Under state control they moved from boundaries of properties to crossroads (where Augustus eventually associated his own *genius* with the cult) and were worshiped as the guardian spirits of the whole community (Lares Praestites). The cult of the Di Penates likewise moved from house to state. From very early times the Penates, the powers that ensured that there was enough to eat, were worshiped in every home. They also came to be regarded as national protectors, the Penates Publici. Originally they were synonymous with the Dioscuri. The legend that they had been brought to Italy by Aeneas with his followers from Troy was imported from Lavinium (Pratica di Mare) when the early Romans incorporated that town into their own state.

Brogi—Alinari from Art Resource/EB Inc.



Altar of the Lares, depicting two Lares on either side of the Genius, AD 69–72. In the House of the Vettii, Pompei.

The divinities of the later Regal period. Two other deities whose Roman cults tradition attributed to the period of the kings were Diana and Fors Fortuna. Diana, an Italian wood goddess worshiped at Aricia (Ariccia) in Latium and prayed to by women who wanted children, was in due course identified with the Greek Artemis. Her temple on the Aventine Hill (*c.* 540 BC) with its statue, an imitation of a Greek model from Massilia (Marseille), was based on the Temple of Artemis of Ephesus. By establishing such a sanctuary, the Roman monarch Servius Tullius hoped to emulate the Pan-Ionian League among the Latin peoples. Fors Fortuna, whose temple across the

Tiber from the city was one of the few that slaves could attend, was similar to the oracular shrines of Fortuna at Antium (Anzio) and Praeneste (Palestrina). Originally a farming deity, she eventually represented luck. She came to be identified with Tyche, the patroness of cities and goddess of Fortune among the Hellenistic Greeks.

In Roman tradition, Servius Tullius reigned between two Etruscan kings, Tarquinius Priscus and Tarquinius Superbus. The Etruscan kings began and perhaps finished the most important Roman temple, devoted to the cult of the Capitoline Triad, Jupiter, Juno, and Minerva (the dedication was believed to have taken place in 509 or 507 BC after the expulsion of the Etruscans). Such triads, housed in temples with three chambers (*cellae*), were an Etruscan institution. But the grouping of these three Roman deities seems to be owed to Greek anthropomorphic ideas, since Hera and Athena, with whom Juno and Minerva were identified, were respectively the wife and daughter of Zeus (Jupiter). In Italy, Juno (Uni in Etruscan) was sometimes the warlike high goddess of a town (*e.g.*, Lanuvium [Lanuvio] in Latium), but her chief function was to supervise the life of women, and particularly their sexual life. The functions of Minerva concerned craftsmen and reflected the growing industrial life of Rome. Two gods with Etruscan names, both worshiped at open altars before they had temples in Rome, were Vulcan and Saturn, the former a fire god identified with the Greek blacksmiths' deity Hephaestus, and the latter an agricultural god identified with Cronus, the father of Zeus. Saturn was worshiped in Greek fashion, with head uncovered.

Capitoline Triad

The focal point of the cult of Hercules was the Great Altar (Ara Maxima) in the cattle market, just inside the boundaries of the primitive Palatine settlement. The altar may be traced to a shrine of Melkart established by traders from Phoenicia in the 7th century BC. The name of the god, however, was derived from the Greek Heracles, whose worship spread northward from southern Italy, brought by traders who venerated his journeys, his labours, and his power to avert evil. In a market frequented by strangers, a widely recognized divinity of this type was needed to keep the peace. The Greek cult, at first private, perhaps dates from the 5th century BC.

The divinities of the Republic. An important series of temples was founded early in the 5th century BC. The completion of the temple of the Etruscan Saturn was attributed to this time (497). A shrine honouring the twin horsemen, the Dioscuri (Castor and Pollux), was also built in this period. An inscription from Lavinium describing them by the Greek term *kouroi* indicates a Greek origin (from southern Italy) without Etruscan mediation. In legend, the Dioscuri had helped Rome to victory in a battle against the Latins at Lake Regillus, and in historic times, on anniversaries of that engagement, they continued to preside over the annual parade of knights (*equites*). From southern Italy, too, came the cult of Ceres, whose temple traditionally was vowed in 496 and dedicated in 493. Ceres was an old Italian deity who presided over the generative powers of nature and came to be identified with Demeter, the Greek goddess of grain. She owed her installation in Rome to the influence of the Greek colony of Cumae, from which the Romans imported grain during a threatened famine. The association of Ceres at this temple with two other deities, Liber (a fertility god identified with Dionysus) and Libera (his female counterpart), was based on the triad at Eleusis in Greece. The Roman temple, built in the Etruscan style but with Greek ornamentation, stood beside a Greek trading centre on the Aventine Hill and became a rallying ground for the plebeians, the humbler section of the community who were hard hit by the grain shortage at this time and who were pressing for their rights against the patricians.

Ceres, Apollo, and Venus

Cumae also played a part in the introduction of Apollo. The Sibylline oracles housed in Apollo's shrine at Cumae allegedly were brought to Rome by the last Etruscan kings. The importation of the cult (431 BC) was prescribed by the Sibylline Books at a time when Rome, as on earlier occasions, had requested Cumae for help with grain. The Cumaean Apollo, however, was primarily prophetic, whereas the Roman cult, introduced at a time of epidemic, was concerned principally with his gifts as a healer. This role may possibly have been derived from the Etruscans, whose Apollo is known from a superb statue of *c.* 500 BC from Veii, Etruria's nearest city to Rome. In 82 BC the Sibylline Books were destroyed and replaced by a collection assembled from various sources. Later, Augustus elevated Apollo as the patron of himself and his regime, intending thereby to convert the brilliant Hellenic god of peace and civilization to the glory of Rome.

Unlike Apollo, Aphrodite did not keep her name when she became identified with an Italian deity. Instead, she took on the name Venus, derived, without complete certainty, from the idea of *venus,* "blooming nature" (the derivation from *venia,* "grace," seems less likely). She gained greatly in significance because of the legend that she was the mother of Aeneas, the ancestor of Rome, whom statuettes of the 5th century BC from Veii show escaping from Troy with his father and son. From the time of the Punic Wars 200 years later the Trojan legend grew, for long before the 1st-century-BC dictators Sulla and Caesar claimed Venus as their ancestor, the story was interpreted as the preface to the Carthaginian struggle.

A number of gods were spoken of as possessing accompaniments, often in the feminine gender; *e.g.,* Lua Saturni and Moles Martis. These attachments, sometimes spoken of as cult partners, were not the wives of the male divinities but rather expressed a special aspect of their power or will. A similar origin could be ascribed to the worship of divine powers representing "qualities." Fides ("Faith" or "Loyalty"), for example, may at first have been an attribute or aspect of a Latin-Sabine god of oaths, Semo Sanctus Dius Fidius; and in the same way Victoria may come from Jupiter Victor. Some of these concepts were worshiped very early, such as Ops ("Plenty," later associated with Saturn and equated with Hebe), and Juventas (who watched over the men of military age). The first of these qualities to receive a temple, as far as is known, is Concordia (367), in celebration of the end of civil strife. Salus (health or well-being) followed in *c.* 302, Victoria in *c.* 300, Pietas (dutifulness to family and gods, later exalted by Virgil as the whole basis of Roman religion) in 191. The Greeks, too, from the earliest days, had clothed such qualities in words; *e.g.,* Shame, Peace, Justice, and Fortune. In the Hellenic world they had a wide variety of signification, ranging from full-fledged divinity to nothing more than abstractions. But in early Rome and Italy they were in no sense abstractions or allegories and were likewise not thought of as possessing the anthropomorphic shape that the term personification might imply. They were things, objects of worship, like many other functions that were venerated. They were external divine forces working upon humans and affecting them with the qualities that their names described. Later on, under philosophical (particularly Stoic) influences that flooded into ethically minded Rome, they duly took their place as moral concepts, the Virtues and Blessings which abounded for centuries and were depicted in human form on Roman coinage as part of the imperial propaganda.

Divine qualities

The Sun and stars. Little or no contribution to cosmology was made in the Roman world, and the demonstration of Aristarchus of Samos (*c.* 270 BC) that the Earth revolves around the Sun received virtually no support. The complicated geocentric interpretation that held sway in Rome was summed up in Cicero's *Dream of Scipio.* It formed the basis for the concept of the solar system on which the popular pseudoscience of astrology was founded, the Sun being regarded as the centre of the concentric planetary spheres encircling the Earth—not the centre of the cosmos in the sense of Aristarchus but its heart. From the 5th century BC onward this solar god was identified with Apollo in his role as the supreme dispenser of agricultural wealth. Possessor of a sacred grove at Lavinium, Sol Indiges was regarded as one of the divine ancestors of Rome. During the last centuries before the Christian era, worship of the Sun spread throughout the Mediterranean world and formed the principal rallying point of paganism's last years. Closely associated with the sun cult was that of Mithra, the Sun's ally and agent who was elevated to partake of communion and the love feast as

Sol

the god's companion. Sun worship was popular in the army, and particularly on the Danube. Aurelian, one of the great military emperors produced by that area in the 3rd century, built a magnificent temple of Sol Invictus (the "Unconquered Sun") at Rome (274). Constantine the Great declared the Sun his Comrade on empire-wide coinages and devoted himself to the cult until he adopted Christianity in its stead.

The *rex sacrorum, flamines,* and colleges of priests

Priests. Precedence among Roman priests belonged to the *rex sacrorum* ("king of the sacred rites"), who, after the expulsion of the kings, took over the residue of their religious powers and duties that had not been assumed by the Republican officers of state. Nevertheless, the hold exercised by the *rex sacrorum* and his colleagues was weakened by the Law of the Twelve Tables (*c.* 451–450 BC), which displayed the secular arm exercising some control over sacral law. As late as *c.* 275 BC the religious calendar was still dated by the *rex sacrorum,* but by this time he was already fading into the background.

Very early origins can also be attributed to some of the *flamines,* the priests of certain specific cults, and particularly to the three major *flamines* of Jupiter, Mars, and Quirinus. Jupiter's priest, the *flamen dialis,* was encompassed by an extraordinary series of taboos, some dating to the Bronze Age, which made it difficult to fill the office in historic times.

Except for the *rex sacrorum* and *flamen dialis,* whose duties were unusually professional and technical, almost all Roman priesthoods were held by men prominent in public life. The social distinction and political prestige carried by these part-time posts caused them to be keenly fought for.

There were four chief colleges, or boards, of priests: the *pontifices, augures, quindecimviri sacris faciundis,* and *epulones.* Originally three, and finally 16 in number, the *pontifices* (whose name may recall antique tasks and magic rites in connection with bridges) had assumed control of the religious system by the 3rd century BC. The chief priest, the *pontifex maximus* (the head of the state clergy), was an elected official and not chosen from the existing *pontifices.* The *augures,* whose name may have been derived from the practice of magic in fertility rites and perhaps meant "increasers," had the task of discovering whether or not the gods approved of an action. This they performed mainly by interpreting divine signs in the movements of birds (*auspicia*). Such divination was elevated, perhaps under Etruscan influence, into an indispensable preliminary to state acts, though the responsibility for the decision rested not with the priests but with the presiding state officials, who were said to "possess the auspices." In private life too, even as late as Cicero and Horace in the 1st century BC, important courses of action were often preceded by consultation of the heavens. The Etruscan method of divining from the liver and entrails of animals (*haruspicina*) became popular in the Second Punic War, though its practitioners (who numbered 60 under the empire) never attained an official priesthood.

Of the other two major colleges, the *quindecimviri* ("Board of Fifteen," who earlier had been 10 in number) *sacris faciundis* looked after foreign rites, and the members of the other body, the *epulones,* supervised religious feasts. There were also *fetiales,* priestly officials who were concerned with various aspects of international relationships, such as treaties and declarations of war. Also six Vestal Virgins, chosen as young girls from the old patrician families, tended the shrine and fire of Vesta and lived in the House of Vestals nearby, amid a formidable array of prehistoric taboos.

Annual festivals

Shrines and temples. The Roman calendar, as introduced or modified in the period of the Etruscan kings, contained 58 regular festivals. These included 45 Feriae Publicae, celebrated on the same fixed day every year, as well as the Ides of each month, which were sacred to Jupiter, and the Kalends of March, which belonged to Mars. Famous examples of Feriae Publicae were the Lupercalia (February 15) and Saturnalia (December 17, later extended). There were also the Feriae Conceptivae, the dates of which were fixed each year by the proper authority, and which included the Feriae Latinae ("Latin Festival") celebrated in the Alban Hills, usually at the end of April.

Templum is a term derived from Etruscan divination. First of all, it meant an area of the sky defined by the priest for his collection and interpretation of the omens. Later, by a projection of this area onto the earth, it came to signify a piece of ground set aside and consecrated to the gods. At first such areas did not contain sacred buildings, but there often were altars on such sites, and later shrines. In Rome, temples have been identified from *c.* 575 BC onward, including not only the round shrine of Vesta but also a group in a sacred area (S. Omobono), close to the river Tiber beside the cattle market (Forum Boarium). The great Etruscan temples, made of wood with terra-cotta ornaments, were constructed later and culminated in the temple of the Capitoline Triad. Subsequently, more solid materials, such as tuff (tufa), travertine, marble, cement, and brick, gradually came into use. Temple archives, now vanished, play a large part in the historical tradition, and the anniversaries of the vows to build the temples and their dedication were scrupulously remembered and celebrated on numerous coins.

Sacrifice and burial rites. The characteristic offering of the Romans was a sacrifice accompanied by a prayer or vow. (The Triumph, associated with Jupiter, was regarded as a thanksgiving in discharge of a vow.) Animal sacrifices were regarded as more effective than anything else, the pig being the commonest victim, with sheep and ox added on important occasions. Considered best of all were the basic elements of life: heart, liver, and kidneys. Human sacrifice, on the whole, was extraneous to Roman custom, though its practice among the Etruscans may have contributed to the institution of gladiatorial funeral games in both Etruria and Rome, and it was resorted to in major crises, notably during the Second Punic War (216 BC). Earlier in the century, and perhaps once before, a member of the family of the Decii had given up his life by self-sacrifice (*devotio*) in a critical battle.

Although ancestors were meticulously revered, there was nothing resembling the comprehensive Etruscan attention to the dead. In spite of elaborate philosophizing by Cicero and Virgil about the possibility of some sort of survival of the soul (especially for the deserving), most Romans' ideas of the afterlife, unless they believed in the promises of the mystery religions, were vague. Such ideas often amounted to a cautious hope or fear that the spirit in some sense lived on, and this was sometimes combined with an anxiety that the ghosts of the dead, especially the young dead who bore the living a grudge, might return and cause harm. Graves and tombs were inviolable, protected by supernatural powers and by taboos. In the earliest days of Rome both cremation and inhumation were practiced simultaneously, but by the 2nd century BC the former had prevailed. Some 300 years later, however, there was a massive reversion to inhumation, probably because of an inarticulate revival of the feeling that the future welfare of the soul depended on comfortable repose of the body—a feeling that, as sarcophagi show, was fully shared by the adherents of the mystery cults, though, on the rational level, it contradicted their assurance of an afterlife in some spiritual sphere. The designs on these tombs reflect the soul's survival as a personal entity that has won its right to paradise.

Cremation and inhumation

Religious art. A vast gallery of architecture, sculpture, numismatics, painting, and mosaics illustrates Roman religion and helps to fill the gaps left by the fragmentary, though extensive, literary and epigraphic record. Starting with primitive statuettes and terra-cotta temple decorations, this array eventually included masterpieces such as the Apollo of Veii. Other works of art, more than 400 years later, include paintings illustrating Dionysiac mysteries at Boscoreale near Pompeii, and the reliefs of Augustus' Ara Pacis at Rome; and with the Christian emblems of Constantinian sarcophagi and coinage a thousand years of ancient Roman religious art comes to an end.

CONCLUSION

Though Roman religion never produced a comprehensive code of conduct, its early rituals of house and farm engen-

dered a feeling of duty and unity. Its idea of reciprocal understanding between man and god not only imparted the sense of security that Romans needed in order to achieve their successes but stimulated, by analogy, the concept of mutual obligations and binding agreements between one person and another. Except for rare aberrations, such as human sacrifice, Roman religion was unspoiled by orgiastic rites and savage practices. Moreover—unlike ancient philosophy—it was neither sectarian nor exclusive. It was a tolerant religion, and it would be difficult to think of any other whose adherents committed fewer crimes and atrocities in its name. (M.Gr.)

Hellenistic religions

The period of Hellenistic influence (which extended roughly from 300 BC to AD 300), when taken as a whole, constitutes one of the most creative periods in the history of religions. It was a time of spiritual revolution in the Greek and Roman empires, when old cults died or were fundamentally transformed and when new religious movements came into being.

NATURE AND SIGNIFICANCE

The historical Hellenistic Age is defined as the period from the death of the Greco-Macedonian conqueror Alexander the Great (323 BC) to the conquest of Egypt by Rome (30 BC), but the influence of the Hellenistic religions extended to the time of Constantine, the first Christian Roman emperor (d. AD 337); these religions are confined to those that were active within the Mediterranean world. The empire of Alexander and his successors created a great world community which, whether in Macedonian, Greco-Roman, or its later Christian form, established a cultural unity that was destined to be broken only 1,000 years later with the advent of Muslim imperialism (beginning in 7th century AD). This empire was so vast as truly to stagger the imagination. Extending from the Strait of Gibraltar to the Indus River, from the forests of Germany and the steppes of Russia to the Sahara Desert and the Indian Ocean, it took in an area of some 1.5 million square miles (3.9 million square kilometres; most of Europe, the Mediterranean, the Middle East, Africa, Persia, and the borderlands of India) and had a total population of more than 54 million.

The study of Hellenistic religions is a study of the dynamics of religious persistence and change in this vast and culturally varied area. Almost every religion in this period occurred in both its homeland and in diasporic centres—the foreign cities in which its adherents lived as minority groups. For example, Isis (Egypt), Baal (Syria), the Great Mother (Phrygia), Yahweh (Palestine), and Mithra (Kurdistan) were worshiped in their native lands as well as in Rome and other cosmopolitan centres. With few exceptions, each of these religions, originally tied to a specific geographic area and people, had traditions extending back centuries before the Hellenistic period. In their homeland they were inextricably tied to local loyalties and ambitions. Each persisted in its native land with little perceptible change save for its becoming linked to nationalistic or messianic movements (centring on a deliverer figure) seeking to overthrow Greco-Roman political and cultural domination. Indeed, many of these native religions underwent a conscious archaism during this period, attempting to recover earlier forms and practices. Old texts in native languages (especially those related to relevant themes such as kingship) were recopied, national temples were restored, and old, mythic traditions were revived. From Palestine to Persia one may trace the rise of Wisdom literature (the teachings of a sage concerning the hidden purposes of the deity) and apocalyptic traditions (referring to a belief in the dramatic intervention of a god in human and natural events) that represent these central concerns—*i.e.,* national destiny, the importance of traditional lore, the saving power of kingship, and the revival of mythic images. Each of these native traditions likewise underwent hellenization (modifications based on Greek cultural ideas), but in a manner frequently different from their diasporic counterparts.

The dispersion of local and area cults and the resultant changes

Each of these native religions also had diasporic centres that exhibited marked change during the Hellenistic period. There was a noticeable lessening of concern on the part of the members of the dispersed religious group for the destiny and fortunes of the native land and also a relative severing of the traditional ties between religion and the land. Certain cult centres remained sites of pilgrimage or objects of sentimental attachment; but the old beliefs in national deities and the inextricable relationship of the deity to certain sacred places was weakened. Rather than a god who dwelt in his temple, the diasporic traditions evolved complicated techniques for achieving visions, epiphanies (manifestations of a god), or heavenly journeys to a transcendent god. This led to a change from concern for a religion of national prosperity to one for individual salvation, from focus on a particular ethnic group to concern for every human. The prophet or saviour replaced the priest and king as the chief religious figure. In the diasporic centres, as is generally characteristic of immigrant groups, there were two circles. The first (or inner circle) was composed of devout, full-time adherents of the cult for whom the deity retained a separate and decisive identity (*e.g.,* those of Yahweh, Zeus Sarapis, and Isis). Its membership was drawn from the ethnic group for whom the deity was indigenous, and the group tended to continue to speak the native language. The second (or outer circle) was composed of either second- and third-generation immigrants or converts from groups for whom the religion was not native. These individuals tended to speak Greek, and this began the lengthy process of reinterpretation of the archaic religion. Ancient sacred books were translated or paraphrased into Greek—*e.g.,* the 4th–3rd-century-BC Babylonian priest Berosus' version of Babylonian materials, the 4th–3rd-century-BC Egyptian priest Manetho's Egyptian accounts, the Jewish Septuagint (Greek version of the Old Testament), or the 1st-century-AD Jewish historian Josephus' *Antiquities of the Jews,* and the ethnic histories of the 1st-century-BC Greek writer Alexander Polyhistor. In each case the material was reinterpreted both in light of common Hellenistic ideals and in accord with the special traditions and needs of the diasporic community. Both the inner and outer circles fostered esotericism (secrets to be known only by initiates)—the former by its use of native language and its oral recollection of traditions from the homeland; the latter by its use of allegory and other similar methods to radically reinterpret the sacred texts. The difference between these groups was responsible for many shifts in the character of the religion. Most notable was the shift from elements characteristic of native religion in its definition of religion (*e.g.,* local tradition and custom, informal knowledge orally transmitted, and birth) to formulated dogma, creeds, law codes, and rules for conversion and admission that were characteristic of diasporic religion. It was a shift from "birthright" to "convinced" religion.

The history of Hellenistic religions is rarely the history of genuinely new religions. Rather it is best understood as the study of archaic Mediterranean religions in their Hellenistic phase within both their native and diasporic settings. It is usually by concentrating on the diaspora that the Hellenistic character of a cult has been described.

HISTORY

Religion from the death of Alexander to the reformation of Augustus: 323–27 BC. The conquests of Alexander opened the way for religious interchange between East and West; the political structures left behind by Alexander and continued by his successors provided strong incentives for the hellenization of native religions. Characteristic of this first period of Hellenistic religious history were the following developments: (1) the introduction of Oriental cults into the West, especially those associated with female deities who were either worshiped in frenzied rites of self-mutilation (*e.g.,* the Phrygian Cybele, brought to Rome in 204 BC; the Syrian Atargatis; or the Cappadocian Ma-Bellona) or in adoring contemplation of their beneficence and gentle rites of divine rebirth (*e.g.,* the Egyptian Isis, whose cult was widespread in the Greco-Roman world by the middle of the 2nd century BC); (2) the hellenization

Religious interchange between East and West

of native cults (most famously that of the archaic Egyptian god Sarapis whose Greek form was promulgated by Ptolemy I, the founder of the Egyptian Ptolemaic dynasty in 305 BC); (3) the development of the ideology of divine kingship based on Oriental kingship traditions; and (4) the rise of nationalistic and messianic movements directed against internal and external hellenization; *e.g.*, the Maccabean rebellion led by Judas Maccabeus against Jewish hellenizing parties and the Syrian overlords in 167–165 BC, and the numerous Egyptian rebellions, especially that led by the Egyptian independence leader Harmakhis in Thebais in 207/6 BC.

Religion from the Augustan reformation to the death of Marcus Aurelius: 27 BC–AD 180. Oriental cults underwent their most significant expansion westward during this period. Particularly noticeable was the success of a variety of prophets, magicians, and healers—*e.g.*, John the Baptist, Jesus, Simon Magus, Apollonius of Tyana, Alexander the Paphlagonian, and the cult of the healer Asclepius—whose preaching corresponded to the activities of various Greek and Roman philosophic missionaries. A developing tension between these "new" Eastern religions and the archaic Greco-Roman traditions was expressed internally in the attempt by the emperor Augustus to revive traditional Roman religious practices. Attempts were made to expel foreigners or to suppress foreign worship—*e.g.*, the suppression of the Bacchic mysteries (salvation cults devoted to the god Dionysus, or Bacchus) in Rome in 186 BC, or the numerous attempts to prohibit the worship of the Egyptian goddess Isis in Rome, beginning in 59 BC. The Augustan reformation also restored Roman sacred books and Greek temples.

Developing tensions between the Greco-Roman and the Eastern religions

Externally, the developing tension was expressed in wars, riots, and persecutions, such as the Jewish–pagan riots in Alexandria in AD 38 and 115–116, the Jewish–Roman wars of AD 66–70 and 132–135, and the beginning of the persecution of Christians under the Roman emperor Nero in AD 64. Another cause of tension was the elaboration of a full-blown cult of "emperor worship," beginning with the deification of Augustus (Sept. 17, AD 14) shortly after his death.

Religion from Commodus to Theodosius I: AD 180–395. After the death of the "philosopher-king" Marcus Aurelius in AD 180, his son Commodus became emperor, and a period of political instability began. The dominant feature of the concluding period of Hellenistic influence—and shortly thereafter—was the rapid growth of Christianity throughout the Roman Empire, culminating in the conversion to Christianity of the emperor Constantine in 313 and the religious legislation of the emperor Theodosius affirming in 380 the dogmas of the Christian Council of Nicaea—which had been convened in 325 under the auspices of Constantine—and prohibiting paganism in a decree of 392. In this period the various Hellenistic cults were victims of active hostilities, which were expressed through prohibition, acts of violence, and theological polemics between "pagans" and Christians (*e.g.*, the pagan philosophers Maximus of Tyre and Celsus, and the Christian philosophical theologians Irenaeus, Tertullian, and St. Clement of Alexandria, all of the 2nd century); but there were also brief periods of Hellenistic revitalization. The Neoplatonic school (based on a complicated system of levels of reality) of the 3rd-century philosophers Plotinus and Porphyry represented the culmination of Hellenistic religious philosophy. The Syrian solar cults of Sol Invictus (the "Unconquered Sun") and Jupiter Dolichenus played an important role under the emperors Antoninus Pius, the Severans—Septimius, and Alexander—and Elagabalus and these were hailed as the supreme deities of Rome under Aurelian, whose Sun temple was dedicated in 274. From Parthia, the dualistic and spiritual teachings of the 2nd-century Iranian prophet Mani were widely disseminated throughout the Empire. The Persian cult of the ancient Iranian god of light, Mithra, spread rapidly throughout the western and northern Empire during the 3rd through 5th centuries. Although these various traditions enjoyed brief imperial patronage under Julian, they eventually were subsumed under the political and religious hegemony of Christianity (see below).

BELIEFS, PRACTICES, AND INSTITUTIONS

The archaic religions of the Mediterranean world were primarily religions of etiquette. At the centre of these religions were complex systems governing the interrelationships between gods and humans, individuals and the state, and living people and their ancestors. The entire cosmos was conceived as a vast network of relationships, each component of which, whether divine or human, must know its place and fulfill its appointed role. The model for this all-encompassing system was the divine society of the gods, and the map of this system was the order of the planets and stars. Through astrology, divination, and oracles, people discerned the unalterable patterns of destiny and sought to bring their world (the microcosm) into harmony with the divine cosmos (the macrocosm; see also OCCULTISM: *Divination: astrology*).

The centrality of the relationship between the gods and men

Cincinnati Art Museum, Museum Purchase

Limestone relief of the goddess Tyche in a zodiac, 2nd century AD. In the Cincinnati Art Museum.

This archaic pattern of affirming and celebrating the order of the cosmos was expressed in the typical creation myth of the Middle Eastern and Mediterranean world, which consisted of a creation by combat between the forces of order and chaos. Order was understood to be something won in the beginning by the gods, and it was this primordial act of salvation that was renewed and reexperienced in the cult.

In the Hellenistic period a new religious world was experienced that required new religious expressions. The old religions of conformity and place no longer spoke to this new religious situation and its questions. What if the law and order of the cosmos was no longer seen as the creative expression of limits and the delineation of roles, but rather as an evil, perverse, confining structure from which man and the cosmos must escape? Rather than the archaic structures of celebration and conformity to place, the new religious mood spoke of escape and liberation from place and of salvation from an evil, imprisoned world. The characteristic religion of the Hellenistic period was dualistic. People sought to escape from the despotism of this world and its rulers (exemplified by the seven planetary spheres) and to ascend to another world of freedom. Hellenistic people saw themselves as exiles from their true home, the Beyond, and they sought for ways to return. They strove to regain their place in the world beyond this world where they truly belonged, to encounter the god beyond the god of this world who was the true god, and to awaken that part of themselves (their souls or spirits) that had descended from the heavenly realm by stripping off their bodies, which belonged to this world. The questions that the religions of the Hellenistic period sought to answer may be seen in a fragment from the 2nd-century Anatolian Gnostic teacher Theodotus: "What liberates is the

Salvation as liberation through knowledge of one's origin, identity, and destiny

knowledge of who we were [before our earthly existence] and what we have become [on earth]; where we were [the Beyond] and the place to which we have been thrown [the world]; where we are going and from what are we redeemed; what is birth and what is rebirth" (preserved in Clement of Alexandria, *Excerpta ex Theodoto,* 78.2).

The gods. In the Greco-Roman world during the Hellenistic period, archaic deities were transformed in part because of the new spirit of the age and in part by foreign influences. A number of the old chthonic (underworld) and agricultural (fertility) gods and the old agricultural mysteries (corporate renewal religions related to fertility concepts) fundamentally altered their character. Rather than an expression of the alternation of life and death, of fertility and sterility, and a celebration of the promise of renewal for the land and the people, the seasonal drama was homologized to a soteriology (salvation concept) concerning the destiny, fortune, and salvation of the individual after death. The collective agricultural rite became a mystery, a salvific experience reserved for the elect (such as the Greek mystery religion of Eleusis). Other traditions even more radically reinterpreted the ancient figures. The cosmic or seasonal drama was interiorized to refer to the divine soul within man that must be liberated. Such cults were dualistic mysteries distinguishing sharply between the body and soul. They taught that it is the soul alone that was initiated by passing through death or the Underworld, or by being dismembered so that it might be freed from the body and regain its rightful mode of spiritual existence (such as the Orphic—mystical—reinterpretation of the role of the agricultural god Dionysus). In the gnostic mysteries (the esoteric dualistic cults that viewed matter as evil and the spirit as good), this process was carried further through the identification of the experiences of the soul that was to be saved with the vicissitudes of a divine but fallen soul, which had to be redeemed by cultic activity and divine intervention. This view is illustrated in the concept of the paradoxical figure of the saved saviour, *salvator salvandus.*

Other deities, who had previously been associated with national destiny (*e.g.,* Zeus, Yahweh, and Isis), were raised to the status of transcendent, supreme deities whose power and ontological status (relating to being or existence) far surpassed the other gods, who were understood as their servants or antagonists. The religious person sought to make contact with, or to stand before, this one, true god of the Beyond. The piety of the individual was directed either toward preparing himself to ascend up through the planetary spheres to the realm of the transcendent god or toward calling the transcendent god down that he might appear to him in an epiphany or vision. These techniques for achieving ascent or a divine epiphany make up the bulk of the material that has usually been termed magical, theurgic (referring to the art of persuading a god to reveal himself and grant salvation, healing, and other requests), or astrological and that represents the characteristic expression of Hellenistic religiosity.

Individual piety

Cosmogony and cosmology. The cosmogonies (dealing with the origins of the world) and cosmologies (dealing with the ordering of the world) of the Hellenistic period centred around the problem of accounting for the distance between this world and the Beyond, or on accounting for the evil nature of this world and its gods. Many mythic schema were employed regarding the origin and ordering of this world. It was viewed as being: the result of the conscious or unconscious emanation from the transcendent realm; the result of the fall of a deity from the Beyond; the creation of a hostile, ignorant, or evil deity; or a joke or mistake. The purpose of this speculation was both pragmatic and soteriological: if one could determine how this creation came into being, one could reverse it or overcome it and be saved.

Religious organization. The temples and cult institutions of the various Hellenistic religions were repositories of the knowledge and techniques necessary for salvation and were the agents of the public worship of a particular deity. In addition, they served an important sociological role. In the new, cosmopolitan ideology that followed Alexander's conquests, the old nationalistic and ethnic boundaries had broken down and the problem of religious and social identity had become acute. The Hellenistic Age was characterized by the rapid growth of private religious societies (*thiasoi*). Though some were organized according to national origin or trade, the majority were dedicated to the worship of a particular deity. In many instances these groups began as immigrant associations (*e.g.,* an Egyptian association of devotees of Amon was chartered in Athens at the beginning of the 3rd century BC); but they often transcended these origins and became a new form of religious organization in which citizens of various countries, freemen and slaves, could be united by their common devotion and share in a common religious heritage. Admission to such groups was voluntary (in contradistinction to the archaic national or familial religious organizations) and demanded the payment of dues, submission to collective authority, and the acceptance of strict codes of morality. Most of these groups had regular meetings for a communal meal that served the dual role of sacramental participation (referring to the use of material elements believed to convey spiritual benefits among the members and with their deity) and the social function of fellowship; *i.e.,* the security of membership in a group and a shared sense of identity.

Hellenistic religions as voluntary associations

THE INFLUENCE OF HELLENISTIC RELIGIONS

The archaic gods worshiped during the Hellenistic period possessed a remarkable longevity. The Eleusinian Mysteries, founded in the 15th century BC, ceased in the 4th century AD; Dionysus, whose name first appears on tablets dated to *c.* 1400 BC, was last celebrated in the beginning of the 6th century AD; the last temple of Isis, whose cult extended back to the 2nd millennium BC in Egypt, was closed in AD 560. Yet even after these ceased as objects of devotion in the post-Constantinian period, they continued to exercise their influence. Hellenistic philosophy (Stoicism, Cynicism, Neo-Aristotelianism, Neo-Pythagoreanism, and Neoplatonism) provided key formulations for Jewish, Christian, and Muslim philosophy, theology, and mysticism through the 18th century. Hellenistic magic, theurgy, astrology, and alchemy remained influential until modern times in both East and West. Theosophy and other forms of the occult, especially since the Renaissance, drew their inspiration from the Hellenistic mystery cults, Hermeticism (Greco-Egyptian astrological, magical, and occultic movement), and Gnosticism. Various Jewish, Christian, and Muslim sectarian groups continued the theologies of many of the Hellenistic religions (especially dualistic modes of thought). Hellenistic sacred art and architecture has remained a basis of Christian and Jewish iconography and architecture to the present day. Figures such as Alexander the Great inspired a vast body of religious literature, especially in the Middle Ages. Many of the symbols and legends associated with Hellenistic deities persisted in folk literature and hagiography (stories of saints and "holy" persons). The basic forms of worship of both the Jewish and Christian communities were heavily influenced in their formative period by Hellenistic practices, and this remains fundamentally unchanged to the present time. Finally, the central religious literature of both traditions—the Jewish Talmud (an authoritative compendium of law, lore, and interpretation), the New Testament, and the later patristic literature of the early Church Fathers—are characteristic Hellenistic documents both in form and content. (J.Z.S.)

BIBLIOGRAPHY

General: Scholarly articles in English on the topics discussed below, with bibliographies, may be found in *The Encyclopedia of Religion,* ed. by MIRCEA ELIADE, 14 vol. (1987). The classic work on old European religion is MARIJA GIMBUTAS, *The Goddesses and Gods of Old Europe, 6500–3500 BC: Myths and Cult Images,* new and updated ed. (1982). Her theory is also condensed in two of her articles in *The Encyclopedia of Religion*: "Prehistoric Religions: Old Europe," vol. 11, pp. 506–515, and "Megalithic Religion: Prehistoric Evidence," vol. 9, pp. 336–344. For Gimbutas' updated bio-bibliography, see SUSAN NACEV SKOMAL and EDGAR C. POLOMÉ (eds.), *Proto-Indo-European: The Archaeology of a Linguistic Problem* (1987). The problem of the Indo-European homeland is discussed in, among others, PEDRO BOSCH GIMPERA, *El problema indoeuropeo*

(1960); GIACOMO DEVOTO, *Origini indeuropee* (1962); VLADIMIR I. GEORGIEV, *Introduction to the History of the Indo-European Languages,* trans. from Bulgarian (1981); and EDGAR C. POLOMÉ (ed.), *The Indo-Europeans in the Fourth and Third Millennia* (1982). The theories of the scholars T.V. Gamkrelidze and V.V. Ivanov, together with critical reactions from I.M. Diakonov and Marija Gimbutas, were made available by EDGAR C. POLOMÉ, "Recent Russian Papers on the Indo-European Problem and on the Ethnogenesis and Original Homeland of the Slavs," a special issue of *The Journal of Indo-European Studies,* 13(1–2) (Spring-Summer 1985).

A fine survey of scholarly theories on Indo-European religion is given by C. SCOTT LITTLETON, "Indo-European Religions: History of Study," in *The Encyclopedia of Religion,* vol. 7, pp. 204–213, but one should also keep in mind the nationalistic and racist theories connected with the names "Aryans" and "Indo-Germans," as discussed in LÉON POLIAKOV, *The Aryan Myth: A History of Racist and Nationalistic Ideas in Europe* (1974; originally published in French, 1971). The most comprehensive statement of the "tripartite ideology" is GEORGES DUMÉZIL, *L'idéologie tripartie des Indo-Européens* (1958). An analysis of Dumézil's work and theories can be found in C. SCOTT LITTLETON, *The New Comparative Mythology,* 3rd ed. (1982). On the "Dumézilian school," see especially two collections of essays: EDGAR C. POLOMÉ (ed.), *Homage to Georges Dumézil* (1982); and FRANÇOISE DESBORDES *et al., Pour un temps: Georges Dumézil* (1981), with contributions by many French and American scholars. (I.P.C.)

Celtic religion: JOHN RHYS, *Lectures on the Origin and Growth of Religion as Illustrated by Celtic Heathendom,* 3rd ed. (1898, reprinted 1979), although the classic work in English, is now out-of-date. Useful accounts include JOSEPH VENDRYÈS, ERNEST TONNELAT, and B.-O. UNBEGAUN, *Les Religions des Celtes, des Germains et des anciens Slaves* (1948); and PAUL-MARIE DUVAL, *Les Dieux de la Gaule,* new ed. updated and enlarged (1976). JOHN MACNEILL, *Celtic Religion* (1911?), provides a brief outline for an overview of the subject. THOMAS F. O'RAHILLY, *Early Irish History and Mythology* (1946, reissued 1971), contains massive learning based on a great wealth of material, including some fanciful conclusions. MARIE-LOUISE SJOESTEDT, *Gods and Heroes of the Celts* (1949, reissued 1982; originally published in French, 1940), is an extremely perceptive reading of the heroic function in Celtic mythological tradition. JAN DE VRIES, *Keltische Religion* (1961), is a comprehensive survey, useful as a reference work. PROINSIAS MAC CANA, *Celtic Mythology* (1970), contains a concise presentation and evaluation of the evidence, with copious illustrations. CLAUDE STERCKS, *Éléments de cosmogonie celtique* (1986), contains a fine interpretive essay on the goddess Epona and related deities. (P.Mac.C.)

Germanic religion: JACOB GRIMM, *Teutonic Mythology,* 4 vol. (1883–88, reprinted 1976; originally published in German, 4th ed., 3 vol., 1875–78), is still a most valuable source. JAN DE VRIES, *Altgermanische Religionsgeschichte,* 2nd ed., 2 vol. (1956–57, reprinted 1970), is a thorough account of Germanic heathendom in Scandinavia, Germany, and England. GEORGES DUMÉZIL, *Gods of the Ancient Northmen* (1973; originally published in French, 1959), offers a short account of German mythology based on the author's view of the Indo-European heritage in Germanic religion. R.L.M. DEROLEZ, *De godsdienst der Germanen* (1959), surveys the gods and myths, with special attention to runic inscriptions; there is also a French translation, *Les Dieux et la religion des Germains* (1962), and a German translation, *Götter und Mythen der Germanen* (1963, reissued 1976). GABRIEL TURVILLE-PETRE, *Myth and Religion of the North: The Religion of Ancient Scandinavia* (1964, reprinted 1975), gives a comprehensive account of Norse myth and religious practice. A.V. STRÖM and HARALDS BIEZAIS, *Germanische und baltische Religion* (1975), encompasses the whole development from prehistoric times to the conversion to Christianity, with somewhat controversial interpretations. RÉGIS BOYER, *La Religion des anciens Scandinaves: Yggdrasill* (1981), an original survey, covers the topic from the Bronze Age petroglyphs to the saga religion but is somewhat marred by inaccuracies. RUDOLF SIMEK, *Lexikon der germanischen Mythologie* (1984), is well documented and contains reliable information. JOHN LINDOW, *Scandinavian Mythology: An Annotated Bibliography* (1988), is excellent.

ROBERT J. GLENDINNING and HARALDUR BESSASON (eds.), *Edda: A Collection of Essays* (1983), provides valuable insight. The best English version remains LEE M. HOLLANDER (trans.), *The Poetic Edda,* 2nd ed. rev. (1962, reprinted 1986). For Snorri's presentation of Scandinavian mythology, the major source is SNORRI STURLUSON, *Gylfaginning,* ed. by GOTTFRIED LORENZ (1984), with a substantial commentary in German. The best edition of the *Germania* by CORNELIUS TACITUS is the annotated German translation by ALLAN A. LUND (1988); for an English edition, see the translation by M. HUTTON (1970) in the *Loeb Classical Library, Latin Authors* series. An essay on early Germanic religion in the context of ancient Germanic culture can be found in EDGAR C. POLOMÉ, "Germantum und religiose Vorstellungen," in HEINRICH BECK (ed.), *Germanenprobleme in heutiger Sicht* (1986), pp. 267–297. (E.C.Po.)

Finno-Ugric religion: A comprehensive presentation can be found in LOUIS HERBERT GRAY, GEORGE FOOT MORE, and J.A. MACCULLOCH (eds.), *The Mythology of All Races,* vol. 4, *Finno-Ugric, Siberian,* by UNO HOLMBERG (1927, reprinted 1964). More recent surveys with extensive bibliographies include IVAR PAULSON, "Die Religionen der finnischen Völker," in IVAR PAULSON, ÅKE HULTKRANTZ, and KARL JETTMAR (eds.), *Die Religionen Nordeurasiens und der amerikanischen Arktis* (1962), pp. 145–303; and LAURI HONKO, "Religionen der finnisch-ugrischen Völker," in JES PETER ASMUSSEN, JØRGEN LAESSØE, and CARSTEN COLPE (eds.), *Handbuch der Religionsgeschichte,* vol. 1, trans. from Danish (1971), pp. 173–224. (L.O.H.)

Baltic religion: MARIJA GIMBUTAS, *The Balts* (1963), pp. 179–204, gives a concise summary. HANS BERTULEIT, "Das Religionswesen der alten Preussen mit litauisch-lettischen Parallelen," *Prussia,* vol. 25 (1924), is still the only complete review of the Old Prussian religion. A critical examination of sources and research may be found in HARALDS BIEZAIS, *Die Religionsquellen der baltischen Völker und die Ergebnisse der bisherigen Forschungen* (1954). For a comprehensive collection of historic records of the Prussian, Lithuanian, and Lettish religion, see WILHELM MANNHARDT, *Letto-preussische Götterlehre* (1936, reissued 1971). HARALDS BIEZAIS, *Die Hauptgöttinnen der alten Letten* (1955), *Die Gottesgestalt der lettischen Volksreligion* (1961), *Die himmlische Götterfamilie der alten Letten* (1972), *Lichtgott der alten Letten* (1976), and *Die baltische Ikonographie* (1985), are devoted to central problems of Baltic religion, with exhaustive bibliographies. (H.Bi.)

Slavic religion: Slavic mythology is outlined by JAN MÁCHAL, "Slavic," in LOUIS HERBERT GRAY, GEORGE FOOT MOORE, and J.A. MACCULLOCH (eds.), *The Mythology of All Races,* vol. 3 (1918, reissued 1964); and MYROSLAVA T. ZNAYENKO, *The Gods of the Ancient Slavs: Tatishchev and the Beginnings of Slavic Mythology* (1980). ALEKSANDER BRÜCKNER, *Mitologia słowiańska i polska,* 2nd ed. (1985), represents an attempt to furnish an Indo-European interpretation of Slavic paganism; for the critical side of the problem this work remains indispensable. For the archaeological aspects, see KARL SCHUCHHARDT, *Arkona, Rethra, Vineta: Ortsuntersuchungen und ausgrabungen,* 2nd rev. and enlarged ed. (1926). A descriptive exposition can be found in B.-O. UNBEGAUN, *Les Religions des Celtes, des Germains et des Slaves* (1948). An attempt to find in the folklore traces of a more ancient mythology was made by W.R.S. RALSTON, *The Songs of the Russian People, as Illustrative of Slavonic Mythology and Russian Social Life,* 2nd ed. (1872, reprinted 1970). A collection of materials and provocative suggestions in the same field is found in V.J. MANSIKKA, *Die Religion der Ostslaven* (1922, reissued 1967). For ethnography, see DMITRIJ ZELENIN, *Russische (ostslavische) Volkskunde* (1927); EDMUND SCHNEEWEIS, *Grundriss des Volksglaubens und Volksbrauchs der Serbokroaten* (1935); and PIERRE BOGATYREV, *Actes magiques, rites et croyances en Russie subcarpathique* (1929).

(E.G./Ed.)

Greek religion: General works include MARTIN P. NILSSON, *Greek Popular Religion* (1940, reissued as *Greek Folk Religion,* 1972), a sound and detailed survey, *Greek Piety* (1948, reissued 1969; originally published in Swedish, 1946), a general survey, *The Minoan-Mycenaean Religion and Its Survival in Greek Religion,* 2nd rev. ed. (1950, reprinted 1971), the best account of origins, and *Geschichte der griechischen Religion* (1941–50), the standard history; H.J. ROSE, *Ancient Greek Religion* (1928, reissued 1948), a brief but masterly sketch; W.K.C. GUTHRIE, *The Greeks and Their Gods* (1950, reprinted 1985), the best general account, and *The Religion and Mythology of the Greeks* (1961), a brief sound sketch of origins; and JOHN POLLARD, *Seers, Shrines, and Sirens: The Greek Religious Revolution in the Sixth Century B.C.* (1965). JANE ELLEN HARRISON, *Themis: A Study of the Social Origins of Greek Religion,* 2nd ed. (1927, reissued 1974), *Prolegomena to the Study of Greek Religion,* 3rd ed. (1922, reprinted 1973), and a sequel, *Epilegomena to the Study of Greek Religion* (1921, reissued 1962); and GILBERT MURRAY, *Five Stages of Greek Religion* (1925), are dependent on an anthropology that has gone out of favour, but much may still be learned from them and much has been borrowed from them without acknowledgement. WALTER BURKERT, *Homo Necans: The Anthropology of Ancient Greek Sacrificial Ritual and Myth* (1983; originally published in German, 1972), and *Greek Religion* (1985; originally published in German, 1977), have broken much new ground in discussing the origins of Greek religion. A.W.H. ADKINS, *Merit and Responsibility: A Study in Greek Values* (1960, reprinted 1975), and *Moral Values and Political Behaviour in Ancient Greece: From Homer to the End of the Fifth Century* (1972), include studies of the religious vocabulary of the Greeks.

The copious works of the "Paris school" together constitute an account of Greek religion that combines the structuralism of the French social anthropologist Claude Lévi-Strauss with a detailed attention to the phenomena furnished by the evidence of Greek religion, literature, philosophy, and art. A few examples include JEAN-PIERRE VERNANT, *Myth and Thought Among the Greeks* (1983; originally published in French, 1965), and *Myth and Society in Ancient Greece* (1980; originally published in French, 1974); MARCEL DETIENNE, *The Gardens of Adonis: Spices in Greek Mythology* (1977; originally published in French, 1972), and *Dionysus at Large* (1989; originally published in French, 1986); MARCEL DETIENNE and JEAN-PIERRE VERNANT, *Cunning Intelligence in Greek Culture and Society* (1978; originally published in French, 1974); PIERRE VIDAL-NAQUET, *The Black Hunter: Forms of Thought and Forms of Society in the Greek World* (1986; originally published in French, 1981); and JEAN-PIERRE VERNANT and PIERRE VIDAL-NAQUET, *Myth and Tragedy in Ancient Greece* (1988; originally published in French, 2 vol., 1972–86).

Works on oracles and divination include the authoritative W.R. HALLIDAY, *Greek Divination: A Study of Its Methods and Principles* (1913, reissued 1967); PIERRE AMANDRY, *La Mantique apollinienne à Delphes: essai sur le fonctionnement de l'oracle* (1950, reprinted 1975); H.W. PARKE and D.E.W. WORMELL, *The Delphic Oracle,* 2 vol. (1956); ROBERT FLACELIÈRE, *Greek Oracles,* 2nd ed. (1976; originally published in French, 1961); and H.W. PARKE, *Greek Oracles* (1967), and *The Oracles of Zeus: Dodona, Olympia, Ammon* (1967). Mysteries and eschatology are treated in ERWIN ROHDE, *Psyche: The Cult of Souls and Belief in Immortality Among the Greeks* (1925, reprinted 1987; originally published in German, 8th ed., 2 vol., 1921), the fundamental work; W.K.C. GUTHRIE, *Orpheus and Greek Religion: A Study of the Orphic Movement,* 2nd rev. ed. (1952, reissued 1967), the best work on Orphism; IVAN M. LINFORTH, *The Arts of Orpheus* (1941, reprinted 1973), a hypercritical account; E.R. DODDS, *The Greeks and the Irrational* (1951, reissued 1973), the best account since Rohde; GEORGE E. MYLONAS, *Eleusis and the Eleusinian Mysteries* (1961, reissued 1974), a good general survey; C. KERÉNYI, *Eleusis: Archetypal Image of Mother and Daughter* (1967, reprinted 1977), a psychological account; and W.F. JACKSON KNIGHT, *Elysion: On Ancient Greek and Roman Beliefs Concerning a Life After Death* (1970). Works on cults and festivals include LEWIS RICHARD FARNELL, *The Cults of the Greek States,* 5 vol. (1896–1909, reissued 1969), the best critical survey in English, and *Greek Hero Cults and Ideas of Immortality* (1921, reprinted 1970), a formal and critical account; MARTIN P. NILSSON, *Griechische Feste von religiösen Bedeutung* (1906, reprinted 1975), the standard work on non-Attic festivals; ARTHUR BERNARD COOK, *Zeus: A Study in Ancient Religion,* 3 vol. (1914–40, vol. 1–2 reprinted in 3 vol., 1964–65), a monumental compendium of all the evidence; LUDWIG DEUBNER, *Attische Feste* (1932, reissued 1969), the standard work on Attic festivals; EMMA J. EDELSTEIN and LUDWIG EDELSTEIN, *Asclepius: A Collection and Interpretation of the Testimonies,* 2 vol. (1945–46, reprinted in 1 vol., 1988), the best account in English; C. KERÉNYI, *Asklepios: Archetypal Image of the Physician's Existence* (1959; originally published in German, 1956), a psychological account; and LUDWIG DREES, *Olympia: Gods, Artists, and Athletes* (1968; originally published in German, 1967), a full, popular account of the festival. The art and architecture of Greek religion are treated in VINCENT SCULLY, *The Earth, the Temple, and the Gods: Greek Sacred Architecture,* rev. ed. (1979), a full if somewhat fanciful account of temple siting; HELMUT BERVE and GOTTFRIED GRUBEN, *Greek Temples, Theatres, and Shrines* (1963), a detailed survey of the chief buildings; and BIRGITTA BERGQUIST, *The Archaic Greek Temenos: A Study of Structure and Function* (1967), a scholarly survey.

W.H. ROSCHER, *Ausführliches Lexikon der griechischen und römischen Mythologie,* 6 vol. in 9 (1884–1937, reprinted 7 vol. in 10, 1977–78), is the authoritative encyclopaedia of Greek mythology. Other works on the subject include MARTIN P. NILSSON, *The Mycenean Origin of Greek Mythology* (1932, reissued 1983), a pioneer work, and *Cults, Myths, Oracles, and Politics in Ancient Greece* (1951, reprinted 1986), an excellent survey; C. KERÉNYI, *The Gods of the Greeks* (1951, reissued 1982; originally published in German, 1951), containing detailed data, and *The Heroes of the Greeks* (1959, reissued 1981; originally published in German, 1958), a dictionary of saga; H.J. ROSE, *A Handbook of Greek Mythology, Including Its Extension to Rome,* 6th ed. (1958, reissued 1972), the most comprehensive handbook in English; RHYS CARPENTER, *Folktale, Fiction, and Saga in the Homeric Epics* (1946, reissued 1974), a lively comparative account; JOSEPH FONTENROSE, *Python: A Study of Delphic Myth and Its Origins* (1959, reprinted 1980), a massive comparative account with full bibliography; MICHAEL GRANT, *Myths of the Greeks and Romans* (1962, reprinted 1986), discussion of chief myths and their subsequent history; ROBERT GRAVES, *The Greek Myths,* 2 vol. (1955, reissued 2 vol. in 1, 1988), a comprehensive account; JOHN POLLARD, *Helen of Troy* (1965), a popular account of the Trojan saga; PETER WALCOT, *Hesiod and the Near East* (1966), a discussion of Oriental origins of Greek myth; G.S. KIRK, *Myth: Its Meaning and Functions in Ancient and Other Cultures* (1970), a comprehensive critical account; and ANNE G. WARD *et al., The Quest for Theseus* (1970), a full, illustrated account. (A.W.H.A.)

Roman religion: General works include R.M. OGILVIE, *The Romans and Their Gods in the Age of Augustus* (1969), a short account; H.J. ROSE, *Ancient Roman Religion* (1948), a standard work; W. WARDE FOWLER, *The Religious Experience of the Roman People, from the Earliest Times to the Age of Augustus* (1911, reprinted 1971); KURT LATTE, *Römische Religionsgeschichte* (1960, reissued 1976); MARTIN P. NILSSON, *Geschichte der griechischen Religion,* vol. 2, *Die hellenistische und römische Zeit,* 3rd ed. (1974), with a rich bibliography; GEORG WISSOWA, *Religion und Kultus der Römer,* 2nd ed. (1912, reprinted 1971), a basic collection of material; ROBERT E.A. PALMER, *Roman Religion and Roman Empire* (1974); and RAMSAY MACMULLEN, *Paganism in the Roman Empire* (1981). Special periods and subjects are treated in RAYMOND BLOCH, *The Origins of Rome* (1960); MICHAEL GRANT, *Roman Myths* (1971, reissued 1984); H. WAGENVOORT, *Roman Dynamism: Studies in Ancient Roman Thought, Language, and Custom* (1947, reprinted 1976; originally published in Dutch, 1941); MAURO CRISTOFANI (ed.), *Dizionario della civiltà etrusca* (1985); AGNES KIRSOPP MICHELS, *The Calendar of the Roman Republic* (1967, reprinted 1978); W. WARDE FOWLER, *The Roman Festivals of the Period of the Republic: An Introduction to the Study of the Religion of the Romans* (1899, reissued 1969); INEZ SCOTT RYBERG, *Rites of the State Religion in Roman Art* (1955); ALAN WARDMAN, *Religion and Statecraft Among the Romans* (1982); DUNCAN FISHWICK, *The Imperial Cult in the Latin West: Studies in the Ruler Cult of the Western Provinces of the Roman Empire,* vol. 1 in 2 parts (1988); FRANZ CUMONT, *The Oriental Religions in Roman Paganism* (1911, reprinted 1956; originally published in French, 1906); LILY ROSS TAYLOR, *The Divinity of the Roman Emperor* (1931, reprinted 1981); JOHN FERGUSON, *The Religions of the Roman Empire* (1970, reissued 1985); A.D. NOCK, *Conversion: The Old and the New in Religion from Alexander the Great to Augustine of Hippo* (1933, reprinted 1988); MICHAEL GRANT, *The Climax of Rome: The Final Achievements of the Ancient World, A.D. 161–337* (1968); E.R. DODDS, *Pagan and Christian in an Age of Anxiety: Some Aspects of Religious Experience from Marcus Aurelius to Constantine* (1965); ROBERT C. SMITH and JOHN LOUNIBOS, *Pagan and Christian Anxiety: A Response to E.R. Dodds* (1984); and ARNALDO MOMIGLIANO (ed.), *The Conflict Between Paganism and Christianity in the Fourth Century* (1963). Hellenistic religions: The most useful cultural and political history containing valuable discussions of controversial issues with full bibliography is ROBERT COHEN, *La Grèce et l'hellénisation du monde antique,* new ed. (1948). W.W. TARN, *Hellenistic Civilisation,* 3rd ed. rev. by TARN and G.T. GRIFFITH (1952, reissued 1975); and M. ROSTOVTZEFF, *The Social & Economic History of the Hellenistic World,* 3 vol. (1941, reissued 1986), remain the standard English works. KARL PRÜMM, *Religionsgeschichtliches Handbuch für den Raum der altchristlichen Umwelt: Hellenistisch-römisch Geistesströmungen und Kulte mit Beachtung des Eigenlebens der Provinzen* (1943, reissued 1954), is indispensable for its rich bibliography. The magnificent encyclopaedia now in progress, *Reallexikon für Antike und Christentum* (1950–), will be, when completed, the best single resource for the study of Hellenistic and early Christian religion.

Important general interpretations include PAUL WENDLAND, *Die hellenistisch-römische Kultur in ihren Beziehungen zu Judentum und Christentum,* 4th enlarged ed. (1972); HAROLD R. WILLOUGHBY, *Pagan Regeneration: A Study of Mystery Initiations in the Graeco-Roman World* (1929, reprinted 1974); A.J. FESTUGIÈRE, *L'Idéal religieux des Grècs et l'Évangile* (1932, reissued 1981), and *Personal Religion Among the Greeks* (1954, reprinted 1984); ERWIN R. GOODENOUGH, *Jewish Symbols in the Greco-Roman Period,* 13 vol. (1953–68); SAMUEL K. EDDY, *The King Is Dead: Studies in the Near Eastern Resistance to Hellenism, 334–31 B.C.* (1961); ARNOLD TOYNBEE (ed.), *The Crucible of Christianity: Judaism, Hellenism, and the Historical Background to the Christian Faith* (1969); and LUTHER H. MARTIN, *Hellenistic Religions: An Introduction* (1987). In addition to these works (all of which contain full bibliographies), see the individual volumes in the important series, *Études préliminaires aux religions orientales dans l'Empire romain.* (J.Z.S.)

Human Evolution

Human beings, extant and extinct, comprise the zoological family Hominidae; and the single living human species, *Homo sapiens,* is one of some 200 species of the order Primates, in turn one of 20 orders constituting the vertebrate class Mammalia. Among the past and present diversity of primates, hominids have long been recognized as having the closest resemblances, and hence affinities, to the African great apes (pongids); thus, in 1863 the British biologist T.H. Huxley noted in *The Evidence as to Man's Place in Nature* that "whatever system of organs be studied . . . the structural differences which separate Man from the Gorilla and the Chimpanzee are not so great as those which separate the Gorilla from the lower apes [monkeys]." Various methods for the comparative evaluation of genetic character states have both repeatedly confirmed and measured in some detail the very close proximity of the extant African apes and modern *Homo sapiens.* All such findings are congruent with a common origin of apes and Hominidae, within the African continent, which took place some five to six million years ago.

Three major areas are generally recognized within the subject of human evolution: primatology, which has as its major focus the biological and behavioral aspects of nonhuman primates; human paleontology, which is concerned with the recovery, description, and evaluation of the fossil evidence for hominid evolution; and paleoanthropology, which encompasses interrelated investigations into the biological and behavioral evolution of Hominidae. In addition, five major areas of research can be identified in human evolutionary studies: the origins of Hominidae, adaptation and diversification of the genus *Australopithecus,* the origins of the genus *Homo,* the emergence of *Homo erectus* and subsequent hominid occupation of Eurasia, and the origins and dispersals of premodern and modern *Homo sapiens.*

Investigations of hominid origins are variously concerned with diverse comparative studies of extant higher primates and humans, as well as the search for ancestors in the fossil record. Pongids and hominids show a diversity of contrasting adaptations that evidently reflect their evolutionary divergences and which thus require explanation. Moreover, although markedly different from the Asian pongid (orangutan), the African pongids (gorilla and chimpanzee) differ from one another both structurally and behaviorally. The roots of Hominidae have been traced to at least four million years ago, and possibly to some five million years ago. The rarity and fragmentary condition of the few oldest known specimens, however, do not reveal critical aspects of hominid adaptation, such as modifications in trunk and lower-limb structure. Hence, the details of hominid origins remain unknown and the subject of lively debate and substantial speculation. The ancestral stock of extant African apes and of hominids also remains unknown, in large part a reflection of the paucity of fossil-bearing localities in the five- to 10-million-year time span. In the absence of a fossil record, structural and other adaptations have been projected back as an ancestral condition from living descendant species; but this is a very risky procedure that dismisses morphological transformation and adaptation and assumes stasis without complementary confirmation.

The oldest definitely known hominids are attributed to the extinct genus *Australopithecus.* The genus speciated substantially, producing distinct and, in some cases, possibly convergent lineages. At least four species (*afarensis, africanus, robustus, boisei*) are commonly accepted, and two more (*aethiopicus, crassidens*) are recognized by some workers on morphological grounds. All species of the genus originated in the Pliocene epoch (5.3 to 1.6 million years ago), and the genus apparently became extinct in the Early Pleistocene (about 1.6 million to 900,000 years ago); its distribution is unknown outside the African continent. The oldest and most primitive species is *A. afarensis,* and most workers believe it to be ancestral to succedent species. Although they exhibited some fundamental hominid adaptations (bipedalism, reduction of anterior dentition, exploitation of nonforested habitats), most or all australopithecine species remained primitive in terms of growth and maturation, brain size and proportions, dietary adjustments, and complexity of cultural behaviour. *Homo* coexisted with the later, so-called "robust," australopithecines—*robustus* (and possibly *crassidens*) in southern Africa and *boisei* in East Africa—although the adaptations enabling such coexistence are scarcely understood, and it is generally thought that an australopithecine species was ancestral to *Homo.*

The recognition and suitable definition of the genus *Homo* and its initial representatives has been a persistently troublesome problem. There have been no formal diagnoses, and the few characterizations offered suffer from both lack of definitive character states and inclusiveness. The problem has been exacerbated as the hominid fossil record has expanded, particularly in respect to specimens dated to the end of the Pliocene epoch that lack distinctively *Australopithecus*-like characteristics. The first such specimens, found in the early 1960s in the Olduvai Gorge of Tanzania, were designated *Homo habilis.* Further remains of both comparable and greater age were subsequently recovered from northern Kenya and southwestern Ethiopia. Although a single initial *Homo* species (*H. habilis*) was originally proposed, this perspective has been criticized by some workers as simplistic because of the substantial variability of the fossil finds; accordingly, it is entirely possible that two contemporaneous and even sympatric species may have existed in the Late Pliocene. Coincident with the appearance and subsequent presence of such hominid(s) are various traces of associated culturally patterned behaviours. These include evidence of natural but transported and accumulated stone, flaked-stone artifacts, and occasional associated mammal (and other) skeletal parts, all of which indicate the exploitation and utilization of animal resources; the repeated utilization and occupation of particular locales; and the expanded employment of natural resources in conjunction with technological capabilities and requirements. Such biological and behavioral adaptations are believed by many workers to reflect major transformations and reorganizations in hominid phylogeny, perhaps consequent upon the initial appearance of genus *Homo.*

The fossil record in sub-Saharan Africa affords evidence of the appearance of another, more derived (*i.e.,* more evolved) species of *Homo—Homo erectus*—at the beginning of the Pleistocene epoch. At several localities in East and southern Africa, the species occurs sympatrically with the "robust" australopithecines. Less ancient occurrences are also known from northwestern Africa. The initial occupation of Eurasia by hominids appears to postdate such an antiquity, and it is generally inferred that the first Eurasian hominids were dispersals from an African source, perhaps between 1.5 and one million years ago. *Homo erectus* was first and, for a long time, best known from fossil finds in Southeast and East Asia. The fossil occurrences there range in age from approximately 1.6 million to 250,000 years. Although initial hominid occupation in Europe was probably at least as early, no human skeletal remains are known from the most ancient times, and those that have been found—dated to between 500,000 and 300,000 years ago—do not represent *H. erectus* but rather a form of *H. sapiens* that has been labeled "archaic." The initial and subsequent penetration of hominids from the lower to middle latitudes occurred as the amplitude and intensity

of glacial–interglacial climatic cycles was increasing. The extent to which there were attendant, and perhaps correlative, changes in human biology and in behaviour have remained the subjects of substantial research and much controversy.

Traditionally, the tendency among students of hominid evolution was to attribute premodern human fossil finds to one or more extinct species, and sometimes even distinct genera, but as efforts increasingly have been directed at seeking congruence between developments in evolutionary biology and in the state of the hominid fossil record, substantial revisions in the classification of Hominidae have emerged. A variety of premodern human finds of both late Middle Pleistocene and early Late Pleistocene ages came to be subsumed within the species *H. sapiens* and were only further distinguished below the species level. This varied and increasingly large sample of post-*erectus* hominids came to be regarded as archaic *H. sapiens,* as distinguished from anatomically modern humans. This is largely a consequence of the mosaic of morphological features represented in the substantial variations among such materials, which exhibit primitive versus advanced, or derived, features.

If early African *H. erectus* constituted the source of subsequent hominids, then it would appear that evolution proceeded quite differently in major geographic areas. For example, *H. erectus* is characteristic of the Asian Middle Pleistocene, where it is also long persistent and distinguished by its own group of singular, derived features. In Africa derivatives of early *H. erectus* are known, as are some transitional examples linking *H. erectus* to archaic *H. sapiens.* Skeletal parts of the earliest hominid occupants of western Eurasia are not known. The first examples from this area occur well into the Middle Pleistocene, and there is a range of variation in the specimens from strongly and partially *erectus*-like to incipiently Neanderthal-like, passing ultimately into the well-known and widely distributed Neanderthal peoples. The Neanderthals were for many years treated as a distinct species (*Homo neanderthalensis*), but they were subsequently subsumed as an archaic subspecies of *H. sapiens.* An increasingly substantial body of evidence has been accumulated, however, which suggests that a return to the older position is probably warranted. In western Europe, at least, there is increasing evidence of the contemporaneity of the last Neanderthal peoples with those early modern populations that have come to be known as Cro-Magnons. For these reasons, and in order to recognize and express differing degrees of derivation, further taxonomic evaluation and distinction of these archaic *H. sapiens* specimens is required, which will doubtless include the recognition of additional subspecies of both the *H. erectus* and *H. neanderthalensis* groups in western Eurasia and also corresponding taxonomic reassessment of various African Middle Pleistocene samples. In East Asia the existence and morphology of archaic *H. sapiens* has been well established, but the extent to which this form was a contemporaneous or a succedent replacement for the late *H. erectus* populations has not been firmly resolved.

The roots of anatomically modern humans have long been a puzzle to students of human evolution and hence the source of much speculation and debate. Nonetheless, several developments have caused renewed interest in the problem from different perspectives. First, there has been the recognition of substantially greater relative and absolute ages for the archaeological industries of the African Middle Stone Age (about 200,000 to 40,000 years ago) and, correspondingly, some associated modernlike human skeletal parts. A series of such sub-Saharan occurrences has been identified within earlier and later segments of this time span. Second, there has been the recognition and broad acceptance of early modern human (often called "Cro-Magnoid") populations in western Asia that were distinct from, and considerably older than (*i.e.,* 90,000–100,000 years ago), the known Neanderthals from that area and also much older than the European Cro-Magnon peoples who were widespread in Europe by some 30,000–35,000 years ago. Third, there has been the increasing availability of comparative genetic data on degrees of affinities of modern human populations. The biochemical systems of Asian and European populations appear to be more similar to each other than those of either group are to African populations; thus, Asians and Europeans may have shared a common ancestry some 40,000 years ago and a common ancestry with African populations almost three times as long ago. Moreover, investigations of human mitochondrial DNA reveal two facts: that the variation among modern human populations is small compared, for example, with that between apes and monkeys, which points to the recency of human origin; and that there is a distinction between African and other human mitochondrial DNA types, suggesting the substantial antiquity of the African peoples and the relative recency of other human populations. (F.C.H.)

The major focus of this article is on the physical evidence—both fossil and lithic—for human evolution and on the interpretation of this evidence. For a detailed discussion of evolutionary theory, see EVOLUTION, THE THEORY OF; for a detailed discussion of the evolution of human behaviour and culture, see PREHISTORIC PEOPLES AND CULTURES. For coverage of related topics in the *Macropædia* and *Micropædia,* see the *Propædia,* sections 411 and 412, and the *Index.*

The article is divided into the following sections:

GENERAL BACKGROUND TO HUMAN EVOLUTION

Evolutionary process in man

Evolution may be defined as change in the genetic composition of a population through time (see also GENETICS AND HEREDITY, THE PRINCIPLES OF). It may be thought of as progressing on two levels: the production of variation and the selection of those gene combinations most fit in a particular environment. It would be wrong to consider that evolution is "caused" by any one factor. Indeed, the error of many earlier theories of evolution was neither intrinsic nor factual but lay in the consideration of evolutionary change solely in the light of a single process. While the modern theory of evolution relies heavily on the Darwinian concept of natural selection, many other factors unknown in Darwin's day have enlarged and enhanced the knowledge of evolutionary process. The modern synthesis of evolutionary theory is a composite approach that views evolutionary process in the light of different scientific disciplines such as paleontology, biology, biochemistry, ecology, and many others, all of which have made significant contributions. The synthesis of fact and theory from these various fields has been the major contribution of evolutionary biology to 20th-century science.

GENERAL CONSIDERATIONS

Darwinian evolution

With the publication of *On the Origin of Species by Means of Natural Selection,* Charles Darwin in 1859 showed conclusively that species evolved and were not immutable over time. This revolutionary idea permitted an explanation of the fossil record that did not need to invoke the biblical story of the Flood or the view that all extinct animals and plants had perished as a result of this one global catastrophe. It became possible to compare modern and fossil animals and to construct lineages through time that documented the changes that had occurred, and the distribution of fossil forms began to take on new significance. It became apparent that assemblages of fossils betray climatic preferences at any given time and climatic change through time. Another 12 years elapsed before Darwin applied his theory of evolution—and its mechanism, natural selection acting upon a pool of normal biological variation—to the case of man; the delay more likely was because of lack of fossil evidence than lack of courage.

The so-called Darwinian tautology, "The survival of the fittest is the survival of those best fitted to survive," gives an insight into the adaptations of living organisms that lead to an increase in their chances of survival and of leaving more offspring than their rivals. The closer the adaptation to the environment, the greater the chances of survival. This pathway leads to specialization: fish need water in which to swim, birds need wings with which to fly, koalas need eucalyptus leaves to eat—nothing else will do.

This approach to survival has its advantages but also its drawbacks. Should the environment change suddenly, those who have gambled on specialization may lose, while those who have retained a generalized form and remained adaptable can adjust to the new situation and survive. On the whole, the order Primates, which contains humans and their ancestors, has retained this approach, an evolutionary flexibility that has enabled primates to respond to change when it has arisen.

Dating fossils. The period of time involved in human evolution is at least three to four million years and probably much longer. During this time the world has undergone a number of climatic changes, including glaciations and warm periods, which can be detected by studying the geologic record. The variety of dating methods that are available to paleontologists makes it possible to place fossils in time and succession. The fossils can also be assembled into faunal groups that provide ecological information; from such information, coupled with the analysis of skulls, bones, and teeth, a picture begins to emerge of the creatures in their world or, as evolving lineages are sampled, in successive worlds. No such opportunity was granted to Darwin.

Two general categories of dating methods exist: relative and absolute dating.

Relative dating. Before the age of a fossil can be determined, it is first necessary to establish that it is contemporary with the deposit in which it was found and not a more recent, intrusive burial in an older deposit. Often, contemporaneity can be determined by the fossil's association with other fossils or rock strata of known age from the same or other sites. This will establish what is called a fossil site's biostratigraphy. Chemical tests for fluorine and nitrogen in fossilized bone should show equivalent amounts throughout an assemblage (if it is contemporaneous), and the newer technique of X-ray microanalysis may establish an elemental "fingerprint" that is typical of a given location or stratum. An absolute method employing the decay of uranium also is useful for establishing contemporaneity.

Absolute dating. Once contemporaneity has been determined, the age of a fossil in years can be approached using several methods that collectively are called absolute, or chronological, dating. These methods rely on the fact that a number of radioactive isotopes (such as uranium) are known to decay into daughter products at known constant rates. Measuring the amount of uranium that has decayed into thorium, for example, can be used to determine the age of some rocks if uranium was laid down with the original deposit.

Carbon-14 dating

Probably the most popular and best-known radiometric method is called carbon-14 (radiocarbon) dating. Carbon-14, a naturally occurring isotope of carbon-12, is absorbed by living organisms at a known rate. Absorption ceases when an organism dies, and its age can be determined by measuring the ratio of carbon-14 to carbon-12; the method is effective up to about 60,000 years ago and perhaps up to 100,000 years ago using a modern particle accelerator. Another highly effective method is called potassium–argon dating. Radioactive potassium decays into argon gas, which becomes trapped in volcanic rocks as they cool. The amount of argon relative to radioactive potassium can be measured to yield reasonably accurate dates on volcanic-rock samples that are more than 250,000 years old.

Other dating techniques include the fission-track method, in which the tracks made by uranium atoms undergoing spontaneous fission can be measured; this method is useful in bridging the gap between the carbon-14 and potassium–argon methods. Changes in the Earth's magnetic polarity that are preserved in rock strata also provide an accurate dating method. An even more recent dating method employs the principle of electron paramagnetic (or spin) resonance, a form of microwave absorption spectroscopy in which the magnetic moment induced by the self-rotation of negatively charged electrons can be detected.

Mosaic evolution. Evolution has been defined as change in the modal human phenotype, a genetic idea that suggests a shift in the makeup of the average man or woman through time and through successive generations. It is a process that is continuous but at varying rates in response to environmental pressure and natural selection. The idea that not only do differing populations evolve at differential rates but also that individual parts of the body may evolve differentially is called mosaic evolution; recognizing and applying this phenomenon has greatly expanded the understanding of human evolution. The makeup of individuals is determined by their genetic endowment, so that the very wellspring of evolution will be found in that variability that defines all humans as individuals.

GENETICS AND MAN

The ultimate source of all new genetic variation is change in the genetic material itself. Genetic information is passed from parent to offspring through the complicated protein molecule known as deoxyribonucleic acid (DNA). The DNA is carried on long strands called chromosomes. Each species has a characteristic number of these strands—in humans the number is 46. These 46 chromosomes com-

prise 23 pairs. The DNA molecules in similar positions along paired strands will code for the same feature, and, in the chemical relationships between these positions (or genes), one gene of each pair will generally be dominant, and the other will be recessive. It is usual for the activity of a gene on one strand to be masked or inhibited by its counterpart on the other strand. An important exception to this is in the determination of coloration patterns, in which the genes may appear to blend, producing colour patterns different from those of the parents.

Types of mutation

Mutation. Alteration of the genetic material is called mutation and can be of two types: point mutations, in which the molecular composition of a discrete location on the chromosome strand can be changed by a chemical process or the physical interaction of a particle (perhaps resulting from radioactivity) with the DNA molecules that make up the chromosome at that point, and mechanical mutations, in which the gross structure of the chromosome is altered, often in the process of cell reproduction. Point mutation is well documented in human populations; for example, normal hemoglobin is formed of a long chain of amino acids; if the genetic code for one of these amino acids, glutamic acid, is changed, the amino acid is replaced by another amino acid, valine, and the abnormal hemoglobin responsible for sickle-cell anemia results. This disease is of considerable importance in some human populations and will be discussed in more detail below. Mechanical mutations do not involve chemical changes in the DNA but are physical alterations involving the body of the chromosome itself; these abnormalities usually occur during cell reproduction. One such process involves the exchange (called crossing-over) of material between two adjacent paired chromosomes. Other types of chromosomal mutations can be due to the inversion or translocation of chromosomal material, its loss or deletion, or the nondisjunction of chromosome pairs.

While the ultimate source of all intrinsic genetic change must occur through mutation, the vast majority of these alterations result in the death of the individual or so reduce his fitness that he suffers "genetic death" (*i.e.,* fails to reproduce) even though he may live to great age. The greatest source of variability is simply a change in the frequency of existing genes under various environmental and, in some cases, social stimuli. The genes themselves contain a vast reservoir of variability, only part of which can be realized in any single population. Here an important distinction must be made between the genotype—the chemical composition of the genes—and the phenotype—the external appearance—of the individual. Similar genotypes can in certain situations give quite different phenotypes, presumably because only part of the genes' activity occurs at any one time. This phenotypic flexibility may be of considerable importance in the origin of certain racial variations in living groups, but its long-term significance in evolutionary process is not yet understood.

Most variability arises, then, as existing genetic material is recombined or reshuffled into new patterns via sexual reproduction. Alterations in gene frequencies will occur mainly under pressure of selection. Besides the reservoir or variability that any sexually reproducing local population contains, another important source of genetic potential can be derived from interbreeding with nonlocal groups. This is sometimes called gene flow, and, although there may be a temporary disruption of the genetic equilibrium, once a balance is again obtained the hybrid population may be more fit than the parent generation. Heterosis, or hybrid vigour (the phenomenon whereby an organism that is the result of crossbreeding between parents of different genetic populations shows increased fitness and general vitality), is well documented for some human groups, most notably the people of Pitcairn Island, who are ultimately derived from crosses between Tahitian women and the British sailors from the HMS *Bounty,* groups whose ancestors were genetically separated by distance for thousands of years.

Hybrid vigour

Observations on the occurrence of genetically derived traits in fossil hominids can be used to suggest earlier patterns of gene flow. Such observations have been made with regard to *Homo erectus,* and the suggestion has been made that genetic exchange was occurring between widely spaced members of this group during the Middle Pleistocene (about 900,000 to 130,000 years ago). It has been pointed out by a number of workers that the approximately contemporaneous mandibles (lower jawbones) found at the Ternifine site in Algeria and the mandibles found near Peking show extreme similarities; the great similarities between the Peking femurs (thighbones) and that of Olduvai Hominid 28 found in the Olduvai Gorge of northern Tanzania have also been noted, as have the similarities between the pelvis of OH 28, the hominid pelvis designated KNM-ER 3228 from the Koobi Fora site in northern Kenya, and the Arago XLIV hominid pelvis from Tautavel in southern France. A reasonable explanation of this similarity is that migratory hunting patterns had brought many groups of *H. erectus* into contact and that exogamous (marrying outside the tribal group) breeding patterns had resulted in the widespread occurrence of certain traits. These similarities are very likely too great and consistent to have resulted from separate evolution along parallel lines in isolation; and, indeed, the degree of similarity seen in the available material makes it extremely unlikely that long-term isolation was a factor in human evolution after the early Middle Pleistocene.

Natural selection. Genetic variation derives from several sources and provides only the raw materials of evolution; random variation can only have a disrupting effect on genetic equilibrium unless deleterious combinations of genes are eliminated and advantageous ones are preserved. The process by which this occurs is called natural selection. Although Darwin is credited with the first full statement of the theory of evolution through natural selection, the origins of the concept are deeply rooted in European thought and may be traced to the early 17th century. Indeed, the practices of artificial selection of domesticated plants and animals, which so influenced Darwin, can be traced at least as far as the Romans and perhaps even to Neolithic (New Stone Age) times. The theory of natural selection can be stated as follows: All living things vary and reproduce themselves many times, yet the number of a given group tends to remain constant. Therefore there is a competition for survival, and only those most adapted to external conditions survive. In essence, the idea of natural selection is statistical; those members of a population who are most evolutionarily fit are those who will leave the greatest number of offspring. These will not be the only members of the population to leave offspring, but it is probable, in a statistical sense, that they will leave more living descendants in the long run than the less well adapted members of the population. Fitness therefore refers to a population's ability to cope successfully with a particular environment at a particular time; it is tied to time and place in an absolute way. The factors that help determine the course and direction of evolution are many: predation and disease, migration and conflict, behaviour and temperament, competition for breeding space and mates, and competition for living space and food. Purely physical factors in the environment are no less important: stability or instability of the climate; solar radiation; natural disaster; pollution of the soil, water, and air—all will have their effect and take their toll on living groups. Evolution is not, therefore, something that has occurred and been completed. Any population is constantly evolving, assimilating changes and variations in its gene pool in response to stimuli from a large number of sources—some that are recognized and some that are not.

Evolutionary fitness

ADAPTATION AND GENETIC CHANGE

There are a number of ways in which a population can adapt to the changing world in which it lives; under the heading of natural selection, it is possible to define several mechanisms that help maintain a viable relationship between that population and the environment of which it is a part. In a seeming paradox, natural selection can work to maintain the status quo in a changing environment while at the same time drawing on new or existing material in the gene pool to meet the demands of the environment in a new way. Natural selection is then both conservative and dynamic, with both mechanisms work-

ing to achieve the same end result, that of adaptation to the environment. Conservative, or stabilizing, natural selection basically works to eliminate detrimental genetic effects or genes harmful in a particular situation; it tends to reduce variation in the gene pool. It would appear that this aspect of natural selection has become less effective in man with the development of modern medical research and practice. Chronic and often lethal diseases caused by genetic conditions, such as diabetes mellitus, hemophilia, and phenylketonuria, are certainly more common now than several decades ago because of modern medical care, since persons with these diseases live and produce children with the disease, although they would have died or failed to reproduce under less advanced medical techniques. These individuals, however, are not less fit in a Darwinian sense than the "normal" members of the population as long as their environment includes this medical care; it is only in the absence of this care that they are less fit.

Homeostatic change. A nongenetic correlate of conservative natural selection is homeostasis. This term refers to adaptive physiological cultural flexibility that is genetically based, and it means the retention and preservation in a population of its internal equilibrium in the face of disruptive external environmental conditions. By drawing on this source of variation, a population may adapt its physiology or behaviour in response to new environmental demands without actual changes in the gene pool; because it is an immediate response, it may enhance a group's survival potential. One type of homeostatic response has been called acclimatization; the efficiency and scope of this process are genetically based, yet the full range of responses is seldom, if ever, activated. Because man occupies a wider range of habitats and is therefore exposed to more extreme conditions than any other species, the necessity for broad responsive ability to changes in environmental conditions such as climate is obvious. Homeostatic responses merge undetectably with both dynamic and conservative natural selection and cannot, indeed perhaps need not, be separated from them for most purposes. The extent of homeostatic response is unique in man, not only in the diversity of the physiological responses that deal with the extremes of the environment but also because of the added dimension of culture as an adaptive mechanism. It is this aspect, culture, that allows humans not only to fully inhabit and utilize a wide range of environments but also to alter these environments to their own ends. The diversity of the ways in which humans deal with environmental extremes can be seen in the various mechanisms (skeletal, physiological, and cultural) used by people in cold climates.

Acclimatization

Blood types, abnormal hemoglobin, and disease. Diversifying, or dynamic, natural selection is one of the important and basic processes by which evolutionary changes occur. Under conditions of changing environmental pressure, advantageous genotypes will be assimilated into the gene pool, and those individuals within the population who have superior fitness will leave more numerous offspring than those without. One such adaptation is the maintenance of a potentially lethal gene for an abnormal hemoglobin (hemoglobin S) in populations that are exposed to malaria. Sickle-cell anemia and several related anemias are genetically based blood disorders that can kill an individual who inherits a gene for the condition from both parents (homozygous condition); those with only a single abnormal gene (heterozygous condition) will demonstrate the disease under certain conditions but are less affected and usually do not die of it. In certain areas of tropical Africa, however, as well as around the Mediterranean and in regions of East Asia, individuals without one gene for the abnormal hemoglobin can die or become seriously ill from malaria before they have the chance to reproduce. The presence of the abnormal hemoglobin therefore confers protection in certain environments, while outside these areas the abnormal gene has no adaptive significance and will be selected against. The abnormal hemoglobin is virtually absent in nonmalarial areas except in the descendants of people from such areas.

Lethal genetic disorders

Other examples of diversifying selection are to be found in the distribution patterns of the ABO blood group system (see BLOOD: *Blood groups*). Although the data is incomplete, it would appear that individuals with certain blood types are more susceptible to certain diseases and that, therefore, in areas where these diseases are common, these blood groups will be selected against. Suggestions have been made that blood group O individuals are less susceptible to syphilis, group A to plague, and group B to streptococcal infections; fieldwork seems to support statistical correlations between certain types of disorders of the gastrointestinal tract and some ABO blood groups. For example, a higher frequency of duodenal and gastric ulcers in group O and a higher incidence of cancer of the stomach of group A have been demonstrated.

Random genetic drift. Genetic drift is another mechanism by which evolutionary changes may occur. Drift can be defined as the apparently random variation of certain gene frequencies under special conditions of small population size or of isolation or both. Also called the Sewall Wright effect and non-Darwinian evolution, it has been the subject of considerable controversy. From these discussions it emerges that many of the features previously thought caused by drift are now known to have been the result of previously unrecognized natural selection. Central to the definition of genetic drift is the assumption that genes can be neutral and without effect in terms of evolutionary adaptation, and it is this assumption that has led to the greatest controversy. Some workers have argued that 5 to 10 percent of all mutations are selectively neutral and may be maintained in the gene pool without effect. Others have asserted that, because genetic systems have complex chemical interrelationships, with each gene contributing something to the finished product, it is unlikely that a single gene or group of genes could be totally without effect. This latter position recognizes that, while certain observable features may have little apparent effect on fitness, the genes responsible may be inextricably associated with other genetic features that do have important fitness correlations.

The near absence of blood group B in the American Indian has been attributed to genetic drift. However, B-type blood reaches its highest frequency in some Mongoloid groups thought to be ancestral to the early inhabitants of the New World. This and the probability that many incursions from Asia must have occurred in the Late Pleistocene epoch (35,000–10,000 years ago) make drift a somewhat untenable explanation of the lack. A more likely explanation is that holders of B blood were faced with some as yet undefined environmental hazard in the New World that made blood type B a genetic liability and it was subsequently lost through selection.

CULTURALLY PATTERNED BEHAVIOUR AND EVOLUTION

Biological or organic evolution takes place as a result of the process of natural selection affecting a pool of normal variability within a living population. This genetically based variability principally involves the physical characteristics of the individuals who make up the population, such as size, shape, coloration, or susceptibility to disease. For many years these alone were thought to be the only mechanisms of evolutionary change. Animal behaviour was studied as a discipline on its own, and human behaviour and human cultures were studied similarly in relative isolation. It has come to be realized, however, that behavioral traits in animals and in humans may under certain circumstances have profound effects on breeding patterns, mate selection, and the survival of offspring. If this is the case, then these behavioral and, in man, cultural attributes will affect the course of organic evolution through their modification of the selective processes operating on the gene pool. The study of these behavioural and cultural effects in relation to evolution has been termed sociobiology.

Natural selection can be shown to operate at a number of levels within populations, but the ultimate level of selection may be at the molecular level—that of the genes themselves. Perfect replication occurs over millions of years so that while individuals and groups of individuals may come and go, the genes march on forever as seemingly immortal. They have been termed "selfish genes" or "survival machines" that are concerned only with their

own survival and are spread, as it were, by driving the bodies that carry them to increase and multiply. Given a stable environment and gene pool, this strategy is said to be evolutionarily stable; a new gene entering the pool that could influence the behavioral strategy would be selected against.

Most animal behaviour is directed toward the reproductive advantage of the individual. Occasionally among social insects such as ants or bees, however, workers are seen not to take part in reproduction, a behaviour called altruistic with respect to the colony and its future. In other species, different forms of altruistic behaviour can be observed, such as "aunts" sharing the rearing of young; in all cases, such behaviour is paradoxical from the viewpoint of individual selection. It may be, however, that the donor and the recipient of this type of behaviour share a larger number of genes or gene types than previously had been believed, so that the "sacrifice" may help the genes held in common with the recipient to survive and multiply. If this is true, then the altruism of close relatives is given purpose and kin selection is an effective strategy.

Altruistic behaviour

There are those who believe that these ideas can be transferred from animal behavioral studies to the more complex realm of human behaviour and culture, but the study of sociobiology is not without controversy. For example, the relationships between mothers and infants are strong in all mammals; in some mammals and birds pair-bonding is lifelong, but in others, including primates, are found males with harem groups and altruistic behaviour by "aunts" and "uncles" toward "nephews" and "nieces." If comparisons are made with human kinship systems—the stuff of social anthropology—the typical pattern is that of monogamy (single pair-bond), with less frequency of polygyny (multiple-female, single-male groups) and, occasionally, even polyandry (multiple-male, single-female groups). Unlike the animal system, however, the basis of the human system may be cultural or even economic, and there appears to be no correlation between cultural kinship (*i.e.,* shared behaviour) and genetic kinship (shared genes).

The relationship between organic evolution and cultural evolution is complicated, since each form appears to have differing mechanisms. Culture as a uniquely human attribute seems bound to affect the totality of humanity and through this totality the patterns and results of human reproductive behaviour; this, in turn, must affect the human gene pool and the selective processes that act upon it, which is the essence of human evolution.

MAN'S CONTINUING EVOLUTION

The question of man's continuing evolution may be posed on two levels, because it is possible to define two distinct yet interrelated levels of evolutionary change: the first can be called phyletic evolution and the second, phenetic evolution.

Phyletic evolution. This term refers to cumulative and important changes in the population gene pool that lead eventually to speciation (separation into new species) and the higher levels of taxonomic differentiation. It is phyletic evolution that is usually identified in the fossil record. Phenetic evolution is more subtle, and, while it is identifiable in living populations, it is less easy to see in fossil groups. It involves changes of a lower magnitude than phyletic evolution and may be called ecotypic evolution. As with all evolutionary changes, phenetic changes occur in response to environmental stimuli, but it is the consistency of these stimuli through time that determines whether the changes will become permanently impressed on a group's phyletic record or if they will be lost within a relatively short period due to changing pressures on the gene pool. Phenetic evolution is the mechanism underlying the formation of subspecies, races, or varieties.

Levels of evolutionary change

It is difficult to identify any unequivocal evidence of phyletic evolution in man for perhaps the last 250,000 years, and the reasons for this difficulty are not hard to find. Human adaptations to the environment have been as broad and generalized as the ecological niche that humans occupy. As a species man inhabits and uses possibly more of the Earth's surface than does any other species, and the breadth of this niche demands considerable flexibility in the human gene pool. An additional factor in man's at least temporarily arrested phyletic evolution is the intervention of culture between man and his environment. With culture, first in the form of crude tools and perhaps skin clothing and now with a variety of sophisticated technologies interposed between humans and the natural environment, the environment cannot exert pressures on the human species in the same way that it has in the past. A third factor must certainly be the size of the gene pool itself and the relatively extended length of a human generation. Evolutionary changes can occur with considerable rapidity in small populations and in populations that mature and reproduce quickly; but the flow of favourable genotypes, however advantageous, must be extremely slow in man's particular circumstances. In terms of man's total morphological pattern and its component parts, then, no important changes are preserved in the fossil record since late Middle Pleistocene times. The last known evidence of human phyletic evolution concerns the *H. erectus–H. sapiens* transition; this period of transition occupied a considerable period of time, and, because of the incompleteness of the fossil record, scholars can only guess at many of its details. Certainly, *H. sapiens* did not spring fully formed from their *H. erectus* ancestors but, through the process of mosaic evolution, crossed the sapient threshold at varying times in the development of different functional complexes. The resultant combination of *H. erectus* and *H. sapiens* features is well demonstrated in a number of specimens, notably Omo II, Steinheim, and Vértesszőllős (see below *Homo sapiens*).

Phenetic evolution. The apparent arrest of man's phyletic evolution should not suggest that the environment will never affect human development again; the observed fact of continuing human phenetic evolution clearly demonstrates the possibility of further phyletic evolution. Some of the clearest evidence that man is still responding to environmental stimuli comes from studies on the distributions of ABO blood groups; this and the importance of sickle-cell anemia in this context have already been described. Further evidence for phenetic evolution is to be found in the analysis of certain general morphological patterns, such as Bergmann's rule, which states that within a polytypic warm-blooded species the body size of a subspecies usually increases with decreasing temperature of its habitat, and Allen's rule, which states that in warm-blooded species there tends to be an increase in the relative size of protruding organs such as the ears and tail with increasing temperature of the habitat.

Disease is an especially acute natural selective agent, and it is well recognized that many diseases recur in cyclic patterns when their virulence is increased. This may be associated with conditions in the environment favourable to the disease-producing organism (pathogen) or by changes in the organism that suffers the disease (host); plague, tuberculosis, and scarlet fever may demonstrate this sort of pattern. In addition, populations that do not have natural immunity may be decimated by a disease that is relatively mild in nonsusceptible groups. Many Polynesian peoples, for example, have been virtually annihilated by measles. It is possible, therefore, that highly lethal worldwide epidemics could act as potent selective forces; such selection could be caused by some new or previously unrecognized disease or by a new episode of high lethality in an existing one.

Disease as a selection factor

The effects of disease are one example of how further evolution in man may occur. Although clear conclusions with regard to human populations are not yet available, experiments with laboratory animals indicate further possibilities. A number of pathologies, both social and physical, have been induced in laboratory animals under conditions of crowding: infertility, cannibalism, mental aberration, and early death have all been observed. Environmental pollution is also known to seriously damage laboratory animals, but again the application of these results to human populations is not yet defined. Clearly, in order to obtain an understanding of the course of human evolution in a modern context, it is necessary for information to be combined from a wider range of disciplines than was formerly the case. The facts of organic evolution as the overall

mechanism by which man has evolved are no longer in serious dispute; undisputed too is his continuing need for reactive and progressive changes, whether evolutionary or cultural, in response to a changing world.

Man's evolutionary relationships

THE LIVING PRIMATES

Taxonomic classification includes man as a member of the order Primates, which is a part of the class Mammalia. Within the Primates are included such divergent creatures as the Southeast Asian tarsiers, the Madagascan lemurs, the South American monkeys, the African monkeys, the great apes (gibbons, orangutans, chimpanzees, gorillas), and finally, humans themselves (see Table 1). The primates that exist today comprise a remarkable gradational series that links *Homo* anatomically with small mammals of very primitive types. The most lowly representatives of the living primates are the tree shrews, small squirrellike creatures that have a wide distribution in Southeast Asia. So primitive are the tree shrews that many authorities refuse to include them among the primates. But even these authorities would agree that tree shrews must at least be very closely related to the ancestral stock from which the primates in general have derived. In a number of their anatomic characters, the tree shrews show such a close resemblance to undoubted primates (*e.g.*, some of the lemurs) as to amount in certain details to an identity of structure. The lemurs in their more advanced anatomic structure show a mixture of characters that indicate an intermediate position between tree shrews and monkeys. The curious little tarsier (which inhabits Borneo, Sumatra, the Celebes, and the Philippines) is in some respects even more monkeylike. The various types of tailed monkeys represent a still higher grade of organization and through the gibbon, smallest of the apes, are linked with the larger tailless anthropoid apes: the chimpanzee, orangutan, and gorilla.

Table 1: Classification of Man Within the Order Primates

Order	Primates	contained forms: prosimians, monkeys, apes, ape-men, and humans
Suborder	Anthropoidea	monkeys, apes, ape-men, and humans
Superfamily	Hominoidea	apes, ape-men, and humans
Family	Hominidae	ape-men and humans
Subfamily	Homininae	humans
Genus	*Homo*	archaic and modern humans
Species	*erectus* *sapiens*	

The manlike apes

As their name implies, the anthropoid apes are manlike in their anatomic structure. Their brains, although much smaller than a modern human brain, are relatively well developed as compared with lower primates and have the same patterns of convolutions as the human brain has (though in a simplified form); the similarities in many details of the intrinsic structure of the brain of the anthropoid ape are astonishingly precise. These anatomic resemblances in the brain have been found to be correlated with physiological similarities. Thus, the sensory and motor mechanisms fulfill functions so closely reproducing those of the human brain that for experimental studies anthropoid apes have been found to be far more reliable than any other nonhuman mammal in their application to problems of cerebral function in man. Many features of the skull and skeleton of the large apes approximate very closely those of the Hominidae (the taxonomic family that includes living and fossil humans), particularly if account is taken of certain extinct primitive hominids. Some of the structural similarities in the skeleton of the trunk and limbs are in part related to posture, for the chimpanzee and gorilla are capable, at times, of balancing themselves on their hind limbs in a manner that suggests, albeit distantly, the erect posture characteristic of the Hominidae. In their dentition, particularly in the molar teeth, anthropoid apes also show a close resemblance to the Hominidae. Indeed, it is sometimes difficult to determine whether isolated fossil molar teeth belong to apes or hominids, for the distinctions that exist between the teeth of apes and those of humans are in general far less obtrusive when fossil specimens are considered. Many of the muscles of the human body have the same disposition and attachments as those of the anthropoid apes. In the sole of the human foot, for example, are found the same muscles that are used for the mobile functions of the ape foot, even though in man the mobility is not present. The disposition of the abdominal organs in apes corresponds quite closely with that of man, and even in their microscopic details some of the organs of the body show a remarkable resemblance. These examples of anatomic and physiological similarities between the large anthropoid apes and the Hominidae could well be multiplied. Their implications for a real phylogenetic relationship are further supported by reference to similarities in serum protein patterns, immunologic responses, some of the blood groups, parasitic infestation, and susceptibility to certain diseases.

Trends of primate evolutionary development. As diversified as the primates are in terms of appearance, ecological adaptations, and behaviour, through their common ancestry they share a number of distinctive characteristics. Fundamentally they have avoided extreme anatomic specializations and have, for the most part, preserved a generalized morphology, which confers on them a considerable degree of functional plasticity. The order can be defined on the basis of the prevailing trends that have dominated its evolutionary development: a generalized structure of the limbs with the replacement of sharp claws by flattened nails resulting in a grasping hand, the elaboration of the visual sense and a corresponding reduction in the sense of smell, and the progressive development of a large and complicated brain. In the Hominidae these same tendencies have manifested themselves and have progressed further than among other groups of primates. The Hominidae show also a unique specialization of the lower limb; the pelvis and leg have become adapted for support and bipedal propulsion of the body in the erect position, while the foot and toes have lost the prehensility characteristic of the primates in general.

Primate generalized morphology

In examining the development of the primates over a period of perhaps 70 million years, the evolutionary trends that have emerged form a pattern of progressive adaptational changes largely related to arboreal life. Although a number of separate trends can be traced individually, they are largely grouped around several functional and behavioral centres. The very existence of evolutionary trends has

been questioned, and some workers have suggested that they existed only in the mind of the paleontologist. But, if it is true that directed, straight-line, orthogenetic trends do not exist in nature, it is also true that within a single evolutionary lineage only certain types of variation can be accepted in a viable, reproductively successful population and that these variations, when observed in the context of geologic time, will show up as evolutionary trends. While these trends in the primates are primarily related to increasing success in utilizing the arboreal environment, they have at the same time provided essential preadaptations for ground life in some primates and man.

Primate limb development. The first group of trends relates to the development of the limbs. Although some primates show a certain amount of specialization in their degree of adaptation to a specific niche, the primates have as a rule maintained a very generalized limb and hand structure. The basic pattern of pentadactylism (five digits on each hand and foot) of the early vertebrates has been retained, as have the fibula (one of two bones in the lower leg) and the radius (one of two bones in the lower arm), bones that are reduced to vestiges or are absent in some mammalian groups. The nonspecialized primate hands and feet are mobile and prehensile; the thumb and big toe remain flexible in most groups with true opposability of the thumb possible in some. Sharp claws have been replaced by flattened nails, which improve the use of the hand as a grasping instrument. The flexible, grasping hand of the primates allows use of the forelimb for nonlocomotor activities, including important primate activities such as grooming, one-handed feeding, and infant carriage. Freeing the hands from locomotion means that the body can be held upright, and this progressive development of an erect posture is another important trend in primate evolution.

Non-specialized appendages

Primate sensory development. A further major trend in primate evolution concerns the way in which primates perceive their environment. In most land mammals the sense of smell is the one most highly developed, as is demonstrated not only in the organization of the brain but in the more obvious development of the snout. In even the most primitive primates, however, the sense of smell has lost importance, and the visual sense has become paramount. Stereoscopic vision has been achieved by moving the eyes from the sides of the head to the front of the face, thereby allowing the visual fields to overlap and producing the ability to perceive in depth. Anatomically, these changes are easy to trace in the fossil record. The importance of the eyes is demonstrated by the additional protection of a bony bar or a bony partition at the side of the head, resulting in a completely enclosed bony socket (the orbit) for the eye. This complete enclosure is absent in the closely related insectivores and in some of the most primitive living primates. The loss of importance of the olfactory sense and hence the diminution of the nose is demonstrated in the increasing orthognathism (straightness of the face) seen in the evolutionary line leading to man.

Primate dentition. Dentition has remained nonspecialized, and the occlusal (closing or biting) pattern of the molars is a simple arrangement of four or five small pointed projections (cusps). Primate dentition is composed of four distinct types of teeth: incisors (the front teeth), canines (the eyeteeth), premolars, and molars (the chewing teeth). While some groups may show specializations of certain tooth groups (an incisor "comb" in the lemurs and enlarged canines in the baboons, for example), no group demonstrates pronounced specializations involving the entire dentition as is commonly seen in other groups of mammals.

Evolutionary trends of primate behaviour. Evolutionary trends involving behaviour are obviously difficult if not impossible to document, but observations on living primate groups suggest that certain behavioral responses are more appropriate than others to the primate way of life. From such observations workers have extrapolated that certain behavioral patterns have arisen during the course of primate evolution. Virtually all living primates demonstrate a social hierarchical structure that enables them to live together in social groups of variable composition. This social structure allows—indeed demands—prolongation of infant dependency and thereby intensifies the mother–offspring relationship. It is within the primate social structure that the roots of human behaviour are to be found.

Underlying and reinforcing all of these trends is the crucial development, both qualitatively and quantitatively, of the brain. The size of the brain has, during primate evolution, increased in absolute size and in size relative to body weight. That it has also increased in complexity is demonstrated by the deeper and more varied convolutions on its surface. Those areas of the brain concerned with vision, muscular coordination, memory, learning, and communication have especially shown development.

The primate brain

As varied as these trends may seem, none developed in isolation from the others. They form a tightly interlocking feedback system whereby advances in one area are reinforced by, and in turn necessitate changes in, another area. For example, in the development of a successful adaptation to an arboreal environment, the ability to see well and to see in depth was obviously more crucial than the ability to smell acutely. The grasping hand with flat nails instead of claws is an important advantage when moving rapidly through the trees. A superior brain, stereoscopic vision, and a supremely flexible hand, along with a tendency for upright posture, were the important preadaptations (adaptations to one set of conditions that later prove to be useful or helpful under different conditions) that the ancestors of man carried with them when they left the trees for the savanna.

FOSSIL PRIMATES

Paleontology, or the study of fossils, provides the really crucial evidence concerning the evolution of the Hominidae in the past. However extensive and compelling it may be, the evidence for evolution based on the study of creatures living today can be only indirect. Further evidence of evolutionary change can be seen in the persistence of certain anatomic structures such as the vermiform appendix, which remains only as a vestige and appears to have reduced functional significance. Direct evidence of evolution must depend on actual demonstration from the fossil record of a succession of stages representing the transformation of an ancestral into a descendant type. The comparative anatomy of living forms, together with the geographic distribution of local species and varieties that exist today, suggests that evolution might have occurred. Study of the process of natural selection, experimental genetics, population statistics, and so forth establishes quite clearly how evolution could have occurred. But that evolution did occur can be scientifically established only by fossilized representative samples of those intermediate types that have been postulated on the basis of indirect evidence. Broadly speaking, the main features of the evolutionary succession of the primates are now known from the fossil record, and they conform in a remarkable way with inferences already reached by a consideration of living primates.

Primate development in the early Tertiary period. At the beginning of the geologic phase now called the Tertiary period—about 66.4 million years ago—there were in existence the most primitive of the primates. So primitive are their anatomic characters as shown by fossils that it might be impossible to determine that they were primates but for the fact that they mark a gradation toward more highly organized creatures that definitely come within the category of primates.

The climate of the early Tertiary period was warm, with wide tropical and subtropical zones extending from the equator up to the higher latitudes in both the Old and the New World. During the Paleocene epoch, which lasted for about 8.6 million years (*c.* 66.4 million–*c.* 57.8 million years ago), there were many primates in existence; 60 genera have been recognized and grouped into eight families. Three of these families had long chisel-shaped teeth that resembled those of the rodents with which they competed for a similar ecological niche, or habitat. It is likely that this confrontation was won by the rodents, for all of the early primate families with rodentlike teeth became

extinct. It is possible that this early rodent competition was one of the factors that led the primates to occupy an arboreal habitat, but a number of groups of primates, such as the baboons, the great apes, and the hominids, later returned to the ground during the evolution of the primate order.

Early Tertiary primates

Early in the Tertiary period, during the Paleocene and Eocene epochs (from about 66.4 million to about 36.6 million years ago), more advanced primates appeared that belong to the same zoological groups as the modern lemurs and tarsiers. The Lemuriformes are represented in the fossil record by a widespread family, the Adapidae, divided into two subfamilies, the Adapinae and the Notharctinae. The Tarsiiformes are known from one family, the Omomyidae, containing four subfamilies: the Anaptomorphidae, the Omomyinae, the Ekgmowechashalinae, and the Microchoerinae. It would appear that the characteristic tarsioid (tarsier-like) specialization of the skull and hind limb were already well advanced in the fossil forms that are known, but some of the European genera have some structures that indicate relationships with the early monkeys. Generally speaking, however, little is known of the Eocene ancestors of the Old World monkeys and apes; thus the Eocene epoch terminated after about 30 million years of primate evolution with lemurlike forms and tarsier-like forms but little or no evidence of anything else.

Later, in the Oligocene epoch (36.6 to 23.7 million years ago), which followed, there came into existence primitive monkeys and exceedingly primitive anthropoid apes. Excavations into the Fayum deposits of Egypt, of Oligocene age, have disclosed a deltaic shoreline bounded by tropical bush country that supported an extensive fauna including rodents, hyraxes, pigs, small elephants, and primates. One of the earliest fossil primates from the Fayum is *Parapithecus,* known from some lower jaws; *Apidium,* which is included in the same family, the Parapithecidae, is also found there. These may be the forerunners of African monkeys. Also derived from the Egyptian Oligocene are several fossil apes of primitive type; these include *Aeolopithecus,* which may be an ancestral gibbon, and *Aegyptopithecus,* which may be ancestral to the modern great apes. One other fossil ape from the Fayum that deserves special mention is *Propliopithecus,* formerly believed to be an ancestral gibbon. It has been suggested, primarily on the basis of its generalized dentition, that *Propliopithecus* is possibly ancestral to the hominids. This, however, is a speculation that requires much more evidence before it can be generally accepted.

Primate development in the Miocene epoch. The Miocene epoch began about 23.7 million years ago and lasted about 18.4 million years. It was a remarkable phase in primate evolution in which there appears to have been an increase in the numbers of larger primates that were widely spread throughout the Old World, including Europe, Asia, and Africa. The large number of specimens recovered from widely separated sites over a long period of time has led to taxonomic confusion, and more than 50 species have been described and classified in 20 genera; this number has been considerably reduced by an overdue taxonomic revision. The large Miocene hominoids appear to belong to three groups, the *Sivapithecus,* the *Dryopithecus,* and the *Proconsul* groups. Within these groups are some 24 species from Europe, Africa, and Asia.

The three Miocene hominoid groups

The *Sivapithecus* group is recognized from fossils first found in the Siwalik Hills of Pakistan and includes specimens from that region formerly known as *Ramapithecus;* other examples are known from the Çandir sites and Paşalar in Turkey, Lu-feng (Lufeng) in China, as well as from Kenya. The most remarkable specimen, with almost a complete face, comes from the Potwar Plateau of Pakistan and shows many similarities to the face of the modern orangutan. The *Dryopithecus* group includes the first specimen, found in 1856 in Saint-Gaudens, Fr. (*D. fontani*), whose molar cusp and fissure pattern, known as the Y-5 arrangement, is typical of the dryopithecines. Other examples are now known from Hungary (*Rudapithecus*), Spain (*D. laietanus*), and China (*D. keiyuanensis*).

The *Proconsul* group derives from Africa from the earlier part of the Miocene period. It includes three species—*P. africanus, P. nyanzae,* and *P. major*—as well as *Rangwapithecus gordoni* and several other smaller-bodied apes. The second group of African and Middle Miocene apes are the Oreopithecidae, which includes *Nyanzapithecus,* the large *Afropithecus,* and two species of *Kenyapithecus,* all from East Africa.

The relationships of the modern apes of Africa and East Asia to this radiation of Miocene hominoids is of prime interest, but it is complicated. It is now fairly well established that the modern orangutan is derived from Late Miocene *Sivapithecus,* based on dental and facial similarities. The date of the separation of this lineage from that which led to the African apes and to man is uncertain but seems likely to be earlier than 13 million years ago. The ancestry of the modern great apes is poorly known other than to say that the *Proconsul* group radiated early but seems too primitive in a number of respects to be linked directly with modern forms. The divergence of the modern apes may have occurred from six to 10 million years ago. The evidence obtained by molecular biologists seems to concur reasonably well on both the date of divergence of the orangutan line and that of the African great apes.

The early hominids seem certain to have originated from a Miocene ape, but it is unclear which one it might be of those that are known. It may very well be that the ancestor that is sought has not yet been discovered. The earlier view held that *Ramapithecus* was the best candidate, based on dental and palatal evidence, but such specific characteristics as thick enamel, broad, low-crowned molars, and robust jaws are shared not only with later hominids but also with several of the Middle and Late Miocene apes. (M.H.D.)

Hominidae as a zoological family

Hominidae (superfamily Hominoidea, infraorder Anthropoidea, order Primates) is the taxonomic family that includes modern humans (*Homo sapiens*) and their direct extinct ancestors. *Homo sapiens* is the only species in the genus *Homo* of the family Hominidae that is living today, and extinct populations ancestral to man are known only from fossil bones and teeth. Earlier, extinct species of the genus *Homo—H. erectus* and *H. habilis,* dating from the Pleistocene epoch (about 1.6 million to 10,000 years ago)—clearly must be included in the Hominidae; and the genus *Australopithecus*—which dates from the earlier Pliocene epoch (about 5.3 to 1.6 million years ago) and includes species such as *A. africanus, A. robustus, A. boisei,* and *A. afarensis*—is also generally included in the family.

CONTRASTING ADAPTATIONS OF HOMINIDAE AND PONGIDAE

Hominidae are distinguished from Pongidae (anthropoid apes) by evolutionary trends that illustrate the adaptations of each for different environmental situations.

Modifications of the skeleton and musculature. Obvious morphological contrasts in skeleton and musculature between living pongids and hominids suggest the functional significance of similar features observed in fossil representatives of the two families. The contrasts are particularly evident in progressive skeletal modifications in adapting to erect bipedalism. Most significant in hominids are changes in the proportions and morphological details of the pelvis, femur, and foot skeleton—all related to the mechanical requirements of erect posture and bipedal gait. Associated soft tissues also are modified, especially the hamstring and gluteal muscles and the iliopsoas muscle that flexes the trunk and thigh. The hominids preserve a well-developed pollex (thumb) and have lost opposability of the hallux (big toe).

Pongid skeletal modifications have been interpreted as deriving from hind limb reduction from a rather small ape (presumably one of the dryopithecine fossils of the Miocene epoch) whose limb proportions were those of a semi-brachiator (one that swung by the arms part of the time). The pongid pollex is reduced, and there is a strong and opposable hallux. The forelimb and hand of some pongid genera seem to be adaptations to knuckle or fist walking. Increase in size and mass of some individuals

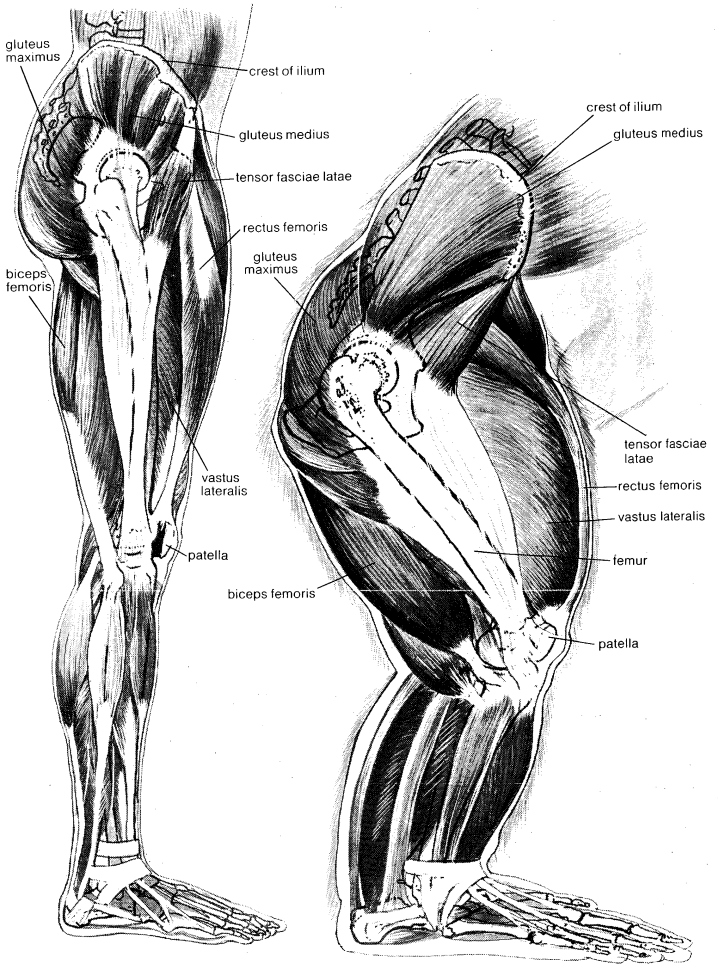

Figure 1: Right leg of (left) man and (right) gorilla.
From J. Buettner-Janusch, *The Origins of Man* (1966); John Wiley & Sons, Inc.

in the pongid lineage (including the large, extinct genus *Gigantopithecus*) probably made a shift from arboreal or terrestrial quadrupedal locomotion to the knuckle-walking gait a distinct advantage.

The pongid hand is still normally involved in locomotion, although in exceptional circumstances a few bipedal steps can be taken. In no pongid, however, does bipedalism form a significant part of its locomotor repertoire. In young pongids, acrobatic climbing and a form of brachiation (arm swinging) are common, but, with increase in size and weight, the African apes spend more and more time on the ground, using a pronograde (horizontal) quadrupedal stance and a gait that includes taking the weight of the upper part of the body on the knuckles or the closed fist. This specialized form of locomotion leaves a recognizable mark on the skeleton of the hand and the elbow.

The pongid pelvis retains the main proportions characteristic of all quadrupedal mammals. Although to some scholars the anatomy of the pectoral girdle (bones supporting the forelimbs) of pongids suggests a brachiating ancestor, all Miocene Hominoidea (Hominidae and Pongidae) recovered and described have failed to show specific adaptations for brachiation. At least, the Miocene hominoids do not resemble modern gibbons (*Hylobates*), whose arboreal acrobatics led to the definition of brachiation. Detailed analyses of both living and extinct pongid forms strongly suggest that the basic hominoid adaptation is dominated by forelimb locomotor and feeding behaviour, knuckle walking distinguishing pongids from their Oligocene or Early Miocene ancestors.

Skull and dentition. The hominid skull bears marks of a way of life that contrasts strongly with that of pongids. In fossil skulls of australopithecines the occipital condyles (protuberances on the base of the skull that articulate with the vertebral column) are more anterior than in pongids. Their position is associated with increased flexion of the basicranial axis, leading to upward displacement of the braincase relative to the face, with resultant increase in cranial height. These changes often are cited as serving to maintain the balance of the head, consequent to development of erect posture and bipedal gait. They are also a result of the expansion of the braincase.

The pongid skull is that of a quadrupedal pronograde primate. There is marked prognathism and, in larger species, massive jaws associated with strong muscular ridges on the skull. The extensive nuchal (nape) area of the occiput, the relatively high inion (occipital protuberance), the position of the occipital condyles well behind the level of the auditory apertures, and the limited degree of flexion of the basicranial axis are all features consistent with pongid posture. These characteristics of the skull are found in Miocene Pongidae as well.

Hominid teeth

Hominid and pongid dentitions differ significantly in form because they are adapted to different diets. Important hominid features include the reduction of the incisors and canines, the appearance of bicuspid premolars, and changes in the occlusal relationship of the jaws. The canines have diminished to a spatulate form and interlock slightly or not at all. There is no pronounced sexual dimorphism of the canines, and the spaces between these teeth (diastemata) largely have vanished. First premolars, in pongids adapted for cutting, are bicuspid in hominids, with secondary reduction of the inner (lingual) cusp in later hominid forms. Occlusal alterations tend to promote wear in all teeth to a flat, even surface at an early stage of attrition and lead to the later development of a helicoidal plane of wear. The dental arcade is even and rounded, and there is a marked tendency in later stages of the fossil record, as in modern humans, toward a reduction in molar size. Deciduous teeth appear to be replaced earlier, relative to eruption of permanent molars, and there is progressive molarization of the first deciduous premolar. This is the dentition of a terrestrial animal whose forelimbs were not primarily used in locomotion and whose dietary adaptations were for eating seeds, fruits, grasses, and meat obtained in an open savanna environment.

Pongid dentition is clearly established in the fossil record of the Miocene epoch and probably originated earlier. There appears to be progressive increase in the size of the incisors and widening of the symphysial region of the mandible with eventual formation of the simian shelf (a distinctive bony buttress of the anthropoid ape mandible). Strong, conical, sexually dimorphic canines that interlock are found throughout the pongids. The cutting function of the first lower premolar is accentuated by the development of a strong anterior root. Postcanine teeth preserve parallel or slightly divergent alignment in relatively straight rows, as opposed to the rounded hominid dental arcade. First deciduous molars remain predominantly unicuspid, and there is no apparent acceleration in the eruption of permanent canines. Pongid dentition belongs to an animal that feeds on large stalks of vegetation and fruit—tearing with its incisors, crushing with its large molar teeth, and chiseling with its enormous canines.

Skeletal, especially cranial, comparisons of living and fossil Hominidae and Pongidae once led to widely varying conclusions. Relatively few cranial characteristics of the fossils provide evidence for obviously differing evolutionary directions for the two families. For example, the cranial capacity of *Australopithecus* is relatively small, ranging from about 410 cubic centimetres (25 cubic inches) to more than 600 cubic centimetres; some skulls have strongly built supraorbital tori; and among larger early hominids a low sagittal crest occurs at the vertex of the skull (the frontoparietal area). When hominid adaptation became better understood, these features were no longer held to indicate necessarily pongid affinities. Yet it is understandable that early in the 20th-century some authorities were reluctant to classify australopithecines as Hominidae. As long as notions of what constitutes an early hominid prompt a search for a miniature version of *Homo sapiens,* most fossil hominids will be rejected. Nevertheless, hominid adaptations are clearly manifest in *Australopithecus.*

PHYSIOLOGICAL AND BIOLOGICAL CHARACTERISTICS

The locomotor system of hominids is adapted for erect posture, bipedal gait, and manual prehensility. The hand is a highly specialized appendage adapted for a variety of grips, including a power grip for strength of grasp and a precision grip for fine manipulation. The feet are the base, in both standing and walking, through which weight and propulsive efforts are transmitted to the ground. The foot and the rest of the lower limb together form a system of levers that enables a variety of activities such as walking, running, jumping, and climbing.

Upright posture. Erection of the trunk is part of the locomotor repertoire of all primates, although many are normally quadrupedal in their resting postures and gaits. Humans and their hominid ancestors are the only primates who are, or were, habitual erect bipeds in whom the vertebral column is normally held vertically in both stance and gait.

By the late 1980s the earliest known fossil evidence of hominids came from the Middle Awash region of Ethiopia, and dated from about four million years ago. These primitive australopithecines, *Australopithecus afarensis*, were essentially erect and apparently capable of bipedal locomotion. A specimen (AL 288-1) from the Hadar site, just to the north, commonly called "Lucy," was the most complete early hominid skeleton yet recovered and showed postcranial features that permitted reliable judgments about early hominid locomotion to be made.

The Lucy skeleton and Laetoli footprints

Bipedal locomotion. The earliest known evidence of bipedal locomotion is not that of fossil hominid remains but of several trails of bipedal footprints found remarkably preserved in consolidated volcanic ash at the Laetoli site in northern Tanzania and dated to 3.6 million years ago by radiometric analysis. These footprints, when analyzed by a contouring method, disclosed that the mechanism of weight and force transference through the early hominid

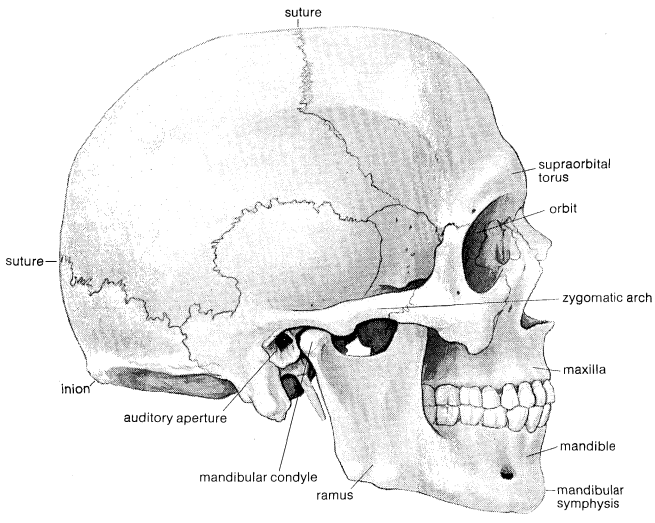

Figure 4: Right side of hominid (human) skull.
From J. Buettner-Janusch, *The Origins of Man* (1966), John Wiley & Sons, Inc.

foot was virtually identical to that of modern humans (see Figure 6). This indirect evidence of the existence and locomotor pattern of the hominids at this early date can give no indication of which group of hominids was responsible for the bipedal footprints, but other fossil evidence from Laetoli and Hadar indicates that they were made by australopithecines of an early type.

Hominid locomotor adaptations include modifications of the vertebral column, pelvis, femur, knee, ankle, and foot (for a detailed description of these, see SUPPORTIVE AND CONNECTIVE TISSUES). All of these are related to the mechanical requirements of bipedal locomotion. The vertebral column, when erect as in a biped, acquires two new secondary curves—one the cervical curve that brings the head and eyes into position for forward vision, the other a lumbar curve that permits the pelvis and lower limbs to remain in position while the trunk is erected. The lumbar curve is produced by the "wedging" of the vertebral bodies and discs, as in modern humans. This wedging is also known in australopithecine vertebrae from the Sterkfontein and Swartkrans sites in South Africa.

The hominid pelvis. The form of the hominid pelvis is regarded as a functional compromise between the needs of efficient upright stance and bipedal gait and the imperative of a female pelvis large enough to transmit a large-brained, full-term fetus.

Australopithecus and *Homo* differences

Australopithecine pelvic and limb bones differ from those of *Homo* in several anatomic features, including forward prolongation in the region of the anterior superior spine of the ilium and a relatively small sacroiliac surface. The australopithecine ischial tuberosity is usually low, and there is a marked forward prolongation of the intercondylar notch of the femur (see Figure 10).

Analysis of australopithecine and modern human pelvises allows the postulation of evolutionary changes that led to bipedalism: the ilium became shortened and bent back on the ischium; the angle between ilium and ischium grew smaller. Such bony changes seem to have been part of a process that brought the gluteus maximus muscle behind the hip joint and made it a powerful extensor of the leg.

Efforts to trace the evolution of gait and posture among the Hominidae face the critical question of whether the australopithecine pelvis is that of a hominid or more like that of a pongid. At least one characteristic of australopithecine pelvic remains is clearly hominid: the ilium is bent back, shortened, and broadened so that the iliac blade has the characteristics expected of a pelvis that is part of the bipedal complex. Investigators who favour the view that the earliest known hominid pelvis is that of the australopithecines are well aware that it is not exactly like that of the contemporary hominid pelvis in other respects. It is the major functional change, however, that assumes significance in attempts to reconstruct the past.

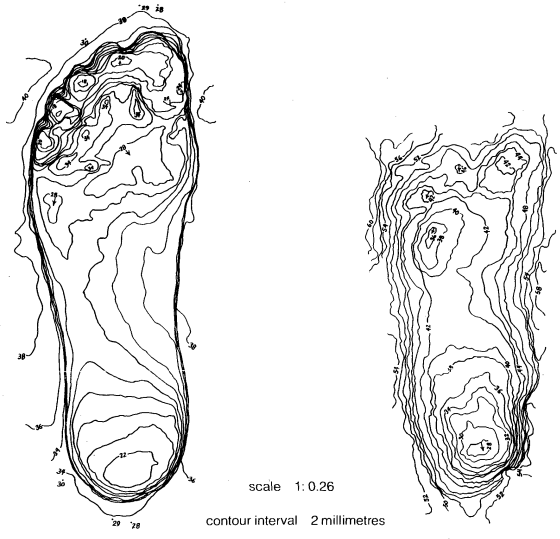

Figure 6: Comparative photogrammetric contours of (left) the left footprint of a modern human female and (right) the left footprint of a fossil hominid from Laetoli (Site G).

The femurs of modern human bipeds are obliquely placed within the thigh because of the width of the pelvis and the need for the knees to be close together during walking. This reduces the width of the walking base and avoids an inefficient, broad-based rolling gait. This requirement produces angulated femurs and knees that can be matched many times from the hominid fossil record from a variety of African sites such as Hadar and Sterkfontein, as well as Koobi Fora and West Turkana in Kenya.

The plantigrade foot

The hominid foot. Essential to the locomotor adaptation of the Hominidae is the plantigrade foot—one in which both sole and heel touch the ground—that was produced by structural modifications of the ancestral prehensile primate foot. The foot of erect bipedal man must completely support the body and be strong enough to lift the load by its lever action. Specializations that make these effects possible include the shape of the arch and the position and robustness of the big toe. Bones associated with the lever action of the foot are in such proportion that they provide support adequate to man's unique walk; humans stride. In striding, the repeated sequence in which the foot bears the weight is heel, lateral edge of the foot, ball of foot, big toe. The big toe transmits both weight and propulsive force at the end of each stride; thus the metatarsal and phalangeal bones of man's big toe are more robust than are those of the other toes.

A foot skeleton has been reconstructed from a dozen bones recovered from deposits at Olduvai Gorge that are about 1.7 million years old. While many of the proportions

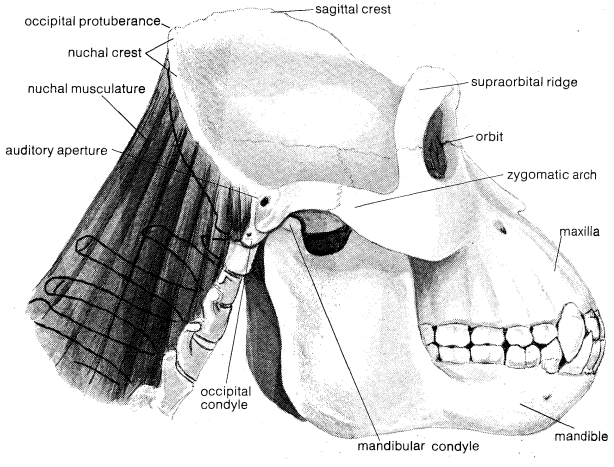

Figure 5: Right side of gorilla skull, with the massive neck muscles typical of pongids.

and articulations among the bones are typically hominid, certain bones—the first metatarsal and the skeleton of the big toe—of the Olduvai australopithecine resemble those of modern humans. The terminal phalanx of the big toe in man is specially adapted for the role that it plays in locomotion; it is unique in its form among the higher primates and contrasts strongly with that of the great apes. In line with the robustness of the first metatarsal, the skeleton of the big toe, in particular the terminal phalanx, is very stout. The terminal phalanx of modern man is broad, is flattened from above downward, and bears large collateral tubercles for the attachment of strong ligaments that support the interphalangeal joint. The bone also bears a corona that supports the large, flat big toenail that in turn supports the pad of the big toe. In addition, the terminal phalanx tilts to the outside of the foot and displays a twist in its length, both of which features are related to its function in bipedalism. The Olduvai toe bone faithfully duplicates these features and provides strong comparative anatomic evidence for bipedalism in the early hominids from Olduvai.

Forelimb structure and manipulation. The human hand is an impressive organ that distinguishes man from all other living primates, which rely on their forelimbs and hands as major organs of locomotion. Humans alone have freed their hands for manipulation by specializing for erect posture and bipedal locomotion.

The hominid hand

Fossil evidence for the evolution of the hands of hominids other than modern man is meagre. A reconstructed hand from Olduvai Gorge appears to have more similarity to those of juvenile pongids and of adult *Homo sapiens* than to the hands of adult great apes. An important feature of this hand is a truly opposable thumb—one that rotates at the carpometacarpal joint so that it opposes the other four fingers. Other significant features of this hand are the stoutness of the phalanges and their muscle markings, which indicate the presence of powerful flexor muscles; a broad, flat terminal phalanx to the thumb, which indicates a broad thumbnail supporting a substantial thumb pad; and a strong muscle marking for a long flexor tendon on the thumb terminal phalanx. This combination of features is good anatomic evidence of the strength of the grip and also of the type of grip that this creature could perform. The two main grips that are recognized in man are the power grip and the precision grip. The former is used when grasping something, such as the handle of a hammer, the latter when using a fine instrument, such as a pen or a pair of forceps.

The fossil hand from Olduvai meets the anatomic requirements of the power grip and those of the precision grip in terms of the opposability of the thumb. On this basis, it has been suggested that the Olduvai stone tools found in abundance at the Olduvai site could have been fashioned by the owner of the Olduvai hand. Hand bones recovered from the Hadar site in Ethiopia and attributed to *Australopithecus afarensis* date to about three million years ago (twice as old as the Olduvai hand) and show some signs of what may be arboreal adaption. The digits appear to be somewhat curved and thus adapted for climbing. It is uncertain, however, whether these features are signs of an active tree-living life for *A. afarensis* or of a vestigial feature from a former arboreal phase of hominid evolution.

Dentition and diet. The advent of hominid dental features in the form of the reduction of the anterior teeth (canines and incisors) seems likely to indicate a dietary shift of real significance. The amount of wear and tear on fossil teeth has always provided a clue to diet, but work with scanning electron microscopes has revealed tiny pits and scratches on the surfaces of tooth enamel—called microwear patterns—that provide further evidence of dietary conditions. It has been observed that grasses leave linear scratches on the teeth, leaves produce a polished effect, and the bone crunching of carnivores gouges out tiny pits in the enamel.

Microwear patterns on the teeth of early australopithecines seem to indicate that their diet did not consist of the tough plant material consumed by some pongids, but that the australopithecine diet had more in common with that of modern fruit-eating forms such as chimpanzees. The robust australopithecines show dental specializations of a high order in that there is gross disproportion between anterior and posterior dentition. The incisors and canines are small, while the premolars and molars are extremely large. The specialization of these molar and premolar teeth is for crushing; at first it was thought that this was an indication of increasing dietary specialization from the early to the later robust forms such as *Australopithecus boisei,* which became extinct about one million years ago. The discovery of a robust australopithecine skull from West Turkana, dated at about 2.5 million years ago, has changed that viewpoint, however, since it has the largest australopithecine molar and premolar dentition found so far as well as huge crests on the skull to permit the attachment of very large masticatory muscles. The dietary specialization of the large australopithecines, therefore, spans at least 1.5 million years.

The teeth of the early members of the genus *Homo,* such as *Homo habilis,* show changes related to both shape and proportion. The incisors become more spatulate and the molars smaller in both size and proportion, perhaps indicating another dietary shift. The teeth of *Homo erectus* show heavy wear patterns that include pits, scratches, and polish, all of which indicate an unspecialized, omnivorous dietary preference. Fossil food remains are usually the remains from meat eating, since fossil food bones are preserved more frequently than vegetable matter.

Brain and nervous system. Because brain tissue does not fossilize, the modern human brain is the only hominid brain that can be known in any detail. From the remains of fossil hominid skulls from Africa, Indonesia, China, and Europe, however, the shape and size of the hominid brain can be determined for some groups. It is clear that during hominid evolution there was an increase in brain volume and a likely increase in the ratio of brain weight to body weight. In particular, the cerebral cortex expanded in size to become a highly complex organ for the receipt, integration, and discrimination of sensory information, as well as for the initiation and coordination of motor activity. For extinct hominids, the interior of the braincase is often all that is available for studies of the volume and shape of the brain and, despite valiant efforts, the amount of reliable functional information that arises from these studies is small.

The hominid brain

Traits such as the possession of speech, the level of manipulative skills, and the level of visual and auditory abilities of early hominids cannot be judged with certainty, although some generalizations from modern man may be justified. The complexity of human behaviour is related to the human ability to interpret symbols, to appreciate abstract ideas, and to communicate them to others, particularly the young. Neuroanatomical studies show that these abilities reside primarily in the cortex of the brain, an area that has expanded rapidly in hominid evolution. Yet volume alone is not enough, and the level of differentiation and organization of brain tissue may also be of crucial importance. The fossil record can yield only endocranial casts and, from them, possible brain volumes, but the firm association of stone tools with such remains must indicate a level of intellectual attainment that can foresee a use for a tool, envisage it within a stone, and then shape it to a set and repeatable pattern.

Biomolecular characteristics. Chromosomes, hemoglobins, blood groups, many serum proteins, and red-cell enzymes, among other genetically controlled traits, have been studied extensively in contemporary *Homo sapiens* and the modern pongids. No reliable information on homologous traits of any extinct hominid exists, since chromosomes and proteins do not fossilize. Data available for man and living pongids, however, are compatible with modern notions of the close affinity between hominids and pongids. Precise immunologic and biochemical comparisons, representing efforts to refine views of the phylogenetic relationship of pongids and hominids, have been inconclusive at best. Use of these data to specify the time of divergence of the hominids and the pongids has produced dates at variance with paleontological opinion based on the fossil record. The theory of late divergence—from five

to four million years ago—favoured by evolutionary biochemists, however, has become more favourably viewed by some paleontologists than it was in the past.

BEHAVIORAL CHARACTERISTICS OF HOMINIDAE

Homo sapiens is biologically close to the other higher primates, but it is behavioral characteristics that predominantly set the species apart. The most significant features of hominid behavioral evolution are the development of toolmaking capabilities, conceptual thought, and symbolic language. These features are relatively simple to examine in *Homo sapiens,* but in extinct hominids they can only be inferred indirectly from fossil remains.

Toolmaking capabilities. The ability to use tools is not unique to the Hominidae; vultures are reported to use rocks to crack open ostrich eggs, and sea otters use stones to open clam or oyster shells. It was long claimed that only hominids actually made tools, but in 1960 chimpanzees were observed in the wild breaking off twigs from trees, stripping away the leaves, and using the twigs to extract termites from their nests. Since the twig had to be modified by removing its leaves, this activity constituted toolmaking, even though at a crude level. Repeated observations of such behaviour resulted in hominids being defined not only as toolmakers but also as skilled toolmakers; they are the only animals able to use one tool to make another and to manufacture standardized precision tools.

Tool use obviously preceded toolmaking in hominid development, but—because the earliest tools were probably made from perishable materials, such as wood—it is not known when either of these activities became a regular feature of hominid behaviour. The first recognizable tools of hominids were made of stone, which, fortunately for archaeologists, is extremely durable. When a fine-grained stone without cleavage planes is hit with another, it will always break in a distinctive fashion, called a conchoidal fracture. Characteristic of this fracture pattern are a bruised striking platform at the point of impact with shock waves radiating from it and, on the resultant flake, a bulb of percussion and bulbar scar. When these features are present, it is possible to distinguish human workmanship from natural breakage caused by heat or frost. Stone tools first appear in the archaeological record as crude pebble choppers with no more than a few flakes removed from one side; they have been found at sites with fossils that date to at least two million years ago. By the Middle Pleistocene the tools had developed into finely made, symmetrical, ovate hand axes that were flaked on both sides and carefully trimmed or retouched to produce straight edges. These are the first standardized artifacts (*i.e.,* objects made systematically to conform to a pattern preconceived in the maker's mind) and are the first to show that the toolmakers' considerations were aesthetic as well as functional. With the development of the soft-hammer technique and the use of pressure as well as percussion flaking, stone tool technology continued to be refined, and hafting was introduced to produce composite tools with wooden handles. The delicate blades and arrowheads of the Upper Paleolithic (*c.* 40,000 to *c.* 10,000 years ago) represent the pinnacle of stone technology, when functional considerations were sometimes overshadowed by aesthetic or symbolic values. Modern man has, of course, superseded stone tools with those made of metals.

Toolmaking from stone

No tools have been found in association with the hominid fossils from Laetoli and Hadar attributed to *Australopithecus afarensis.* The earliest tools, from sites such as Koobi Fora and Olduvai Gorge, have been found in stratigraphic levels that have yielded robust australopithecines, *Homo habilis,* and—in the case of Koobi Fora—*Homo erectus.* Under these circumstances it is not possible to decide which of the hominid species was the first stone toolmaker.

Language and symbolic behaviour. Toolmaking at least leaves behind some tangible evidence, but it is much more difficult to trace the origins of spoken language in the Hominidae. Inferences about the anatomy and position of the larynx can be made from cranial form, but otherwise fossil bones tell us nothing about speech capabilities. Archaeological finds of standardized tools and evidence of the cooperative hunting of large animals may well indicate some kind of communication among early hominids, but not necessarily in the form of modern human language. All primates, including man, use visual communications such as facial expressions, body language, and nonlinguistic vocalizations such as screams and cries to transmit information to other members of their group. These communications are largely instinctive, and the signs are very limited in meaning. Spoken language, however, allows human beings to name things with "open" symbols—*i.e.,* symbols that, in countless combinations, can be made to relay different messages. Not only can human communication cover immediate situations and feelings but also discussions at abstract or hypothetical levels. Humans thus can store and transmit knowledge gained by past experiences as well as discuss plans for the future.

From J. Buettner-Janusch, *The Origins of Man* (1966); John Wiley & Sons, Inc.

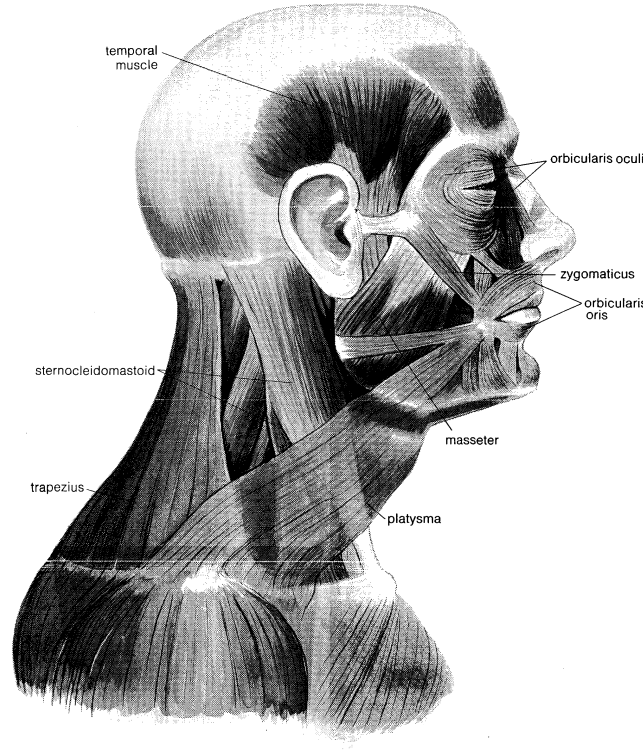

Figure 7: Muscles of human head and neck.

The principal difference in the vocal apparatus of hominids and pongids is the position of the larynx relative to the rest of the respiratory tract. Man's larynx is lower in the throat and farther from the soft palate than in other primates, directly reflecting development of erect posture and expansion of the braincase. The position of the larynx changed as the foramen magnum (the skull's aperture for the spinal cord), in turn, moved in response to the way the head is balanced on the neck and to the expansion of the posterior portion of the base of the skull. The consequent descent of the larynx created a long, tubular resonating cavity that permits the low-pitched speech of man.

Possible origin of hominid language

While no evidence exists to show how hominid language first developed, it has been suggested that the vowel sounds had their origins in nonlinguistic vocalizations and that consonants were added as the hominids developed more control over their airways by manipulating tongues, lips, and teeth. Coupled with the ability to make the sounds necessary for speech would be changes in the brain that allow vocabulary to be stored and retrieved and changes in the auditory apparatus that allow language to be understood when spoken by others with slightly different intonation or pitch. The ability to learn language is inherited, as all children learn very quickly, but the actual language, be it English or Chinese or any other, must be learned. Written language is clearly a much more recent human acquisition, with no good evidence for it before 5,500 years ago.

Because the fossils reveal so little, studies of the develop-

ment of hominid speech have centred around experiments with one of man's closest living relatives, the chimpanzee. The structure of the chimpanzee larynx does not allow it to make many of the sounds needed for human speech, and so experimenters have concentrated on teaching chimpanzees sign languages designed for deaf people. One female chimpanzee, Washoe, was taught to make signs for more than 100 words and showed that she could understand more than 300 signs. She was eventually able to put two or three signs together to make rudimentary sentences, usually demands for food, but did not make signs spontaneously in order to communicate ideas.

Social organization. The shift to terrestrial life in an open savanna environment would mean that a small, upright biped without the benefit of large, powerful jaws would be vulnerable to attack from predators. Opposing views have been proposed to explain why the early hominids not only survived but also prospered. One view is the "hunting hypothesis," which suggests that keen eyesight, cunning, and the development of weapons necessary to hunt large animals channeled the natural aggression of humans and enabled them to defend themselves against predators. The other view stresses the significance of hunting as a stimulus toward social cooperation and food sharing.

Also important to the second view is the fact that human infants are much more helpless than other primate babies and require constant care for a relatively long period of time. With the formation of kinship groups a division of labour could occur, with the men doing the hunting and the women staying behind to gather plant foods and care for the children. Pair-bonding within groups may have been established among the early hominids when the females became sexually receptive at all times, unlike other primate females who have an estrus cycle. Members of a group who perform different economic tasks during the day must operate within a limited territory and have a place where the entire group reassembles to distribute the food and spend the night. The concept of a home base has been confirmed in the archaeological record from early sites at Koobi Fora, where concentrations of stones and bones indicate places that were continuously or periodically occupied by groups for the purposes of butchering and eating animals and making tools. (J.B.-J./M.H.D.)

THE EVOLUTION OF HOMINIDAE

Australopithecus

Australopithecus (literally "Southern Ape") was the generic name given to the first-discovered member of a series of fossils of creatures closely related, if not ancestral, to modern human beings. Since the first discovery—of a child's skull in a cave at Taung, S.Af., in 1924—similar hominid remains have been found at numerous sites in East and southern Africa. The term australopithecine is often used to refer to all the fossil hominid material that dates between the last half of the Late Miocene epoch (about eight to 5.3 million years ago) and the beginning of the Pleistocene epoch (around 1.6 million years ago). Fossil remains that date from before eight million years ago are widely regarded as those of fossil apes, while evidence of *Homo erectus* ("Upright Man") dates to about the beginning of the Pleistocene. The remains of *Homo habilis* ("Handy Man") have been recovered from sites between 2.5 and 1.5 million years old. These are more easily confused with those of *Australopithecus,* and the final allocation of some of this material is still being debated.

The fossil evidence of the australopithecines has been

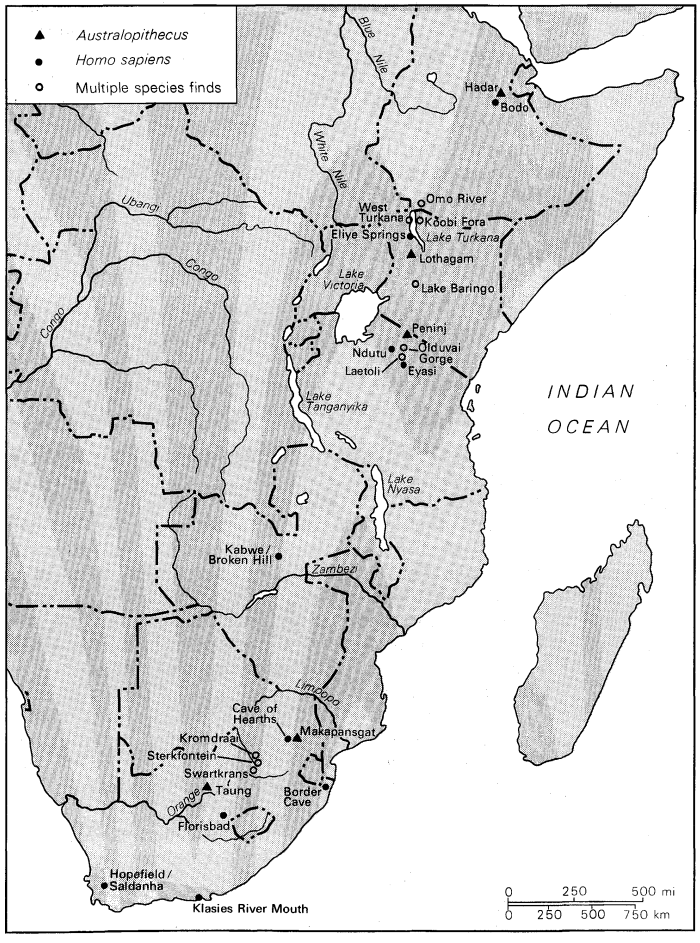

Figure 8: Major sites of hominid fossil finds in sub-Saharan Africa.

seen by some scholars as merely representing temporal stages within a single evolving hominid lineage leading to *Homo erectus* and thence to *Homo sapiens.* Others have stressed the extent of the adaptive differences between the various fossils and have suggested that there may have been two, or even three, lineages evolving in parallel, only one of which led to the later species of *Homo.* Whatever the details of their interpretations, however, most hominid paleontologists are agreed that the australopithecines represent a link—direct or indirect—between the fossil apes and human beings. Thus, the study of the australopithecines is regarded as the study of one of the most important stages in the emergence of modern *H. sapiens.*

FOSSIL EVIDENCE

The South African australopithecines. More than a decade was to elapse between the recognition of the importance of the Taung child's skull by Raymond Dart in 1924 and the next series of discoveries of australopithecines in southern Africa. These latter discoveries were made by Robert Broom in 1936 and 1938 as the direct result of mining operations at the caves of Sterkfontein and Kromdraai, several hundred miles northeast of Taung, in the Transvaal. When research activities resumed in earnest in South Africa after World War II, two additional cave sites were discovered at Swartkrans and Makapansgat. After the early discoveries the rate of recovery of fossils from these hard, breccia-filled cave deposits diminished. During the 1970s, however, there was renewed activity at these sites, and the total number of hominid remains recovered from southern African caves is well in excess of 1,000.

As each series of discoveries was announced, it was usually marked by the suggestion of a new species, if not genus, for the newly found fossils. Scientists are now agreed, however, that the evidence does not justify the multiplicity of taxa that resulted. It is generally accepted that the australopithecine fossils recovered from these cave sites belong to either *Australopithecus africanus,* the species usually referred to as the "gracile" australopithecine, or *A. robustus,* the species called the "robust" australopithecine. (Some workers support the recognition of a second species of robust australopithecine found at Swartkrans, called *A. crassidens,* but this is a minority view.) The classification into two main species within one genus won the support of Dart and Sir Wilfred Le Gros Clark, and, with minor modifications, it is the scheme that has come to be supported by the majority of scholars. The labels gracile and robust are useful because they are widely understood, but they also are dangerous in that such a simple classification is misleading. An increasing number of workers have argued that the generic name *Paranthropus* ("Next to Man"), coined by Broom in 1938, should be revived to distinguish the robust australopithecines.

Two main species

The skull of *Australopithecus africanus* has a braincase that is roughly spherical in shape, with the greatest width across the base of the skull. The cranial capacity of the species depends upon which estimates are used; the average value is probably between 430 and 450 cubic centimetres (26 and 27 cubic inches), a capacity just within the range of that of living apes. Brain size is best judged in relation to body size, however, and on this count the gracile australopithecines have a relative brain size intermediate between that of modern apes and that of modern human beings. The area of attachment on the skull for the neck muscles is reduced when compared to that of equivalent-sized apes. Although bony crests mark the attachment of the jaw muscles onto the skull, these are not obvious features and, in particular, do not form large midline, or sagittal, crests. The foramen magnum (the area of the skull through which the spinal cord passes) lies nearer the centre of the skull in these fossil hominids than it does in the apes. The face is projecting, but it does not form the marked muzzle that is a feature of most modern and fossil ape skulls.

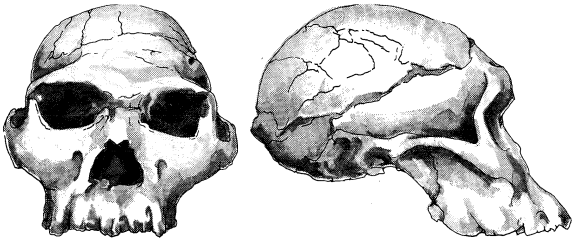

Figure 9: Skull of *Australopithecus africanus,* specimen STS 5, found at Sterkfontein, S.Af.

The teeth of the gracile australopithecines are not arranged in the characteristic U-shaped fashion of the apes but instead lie in a more rounded arcade. The incisor teeth are set vertically in the jaw, and the canines are small and do not project above the other teeth, which is always the case in the apes. There is no gap, or diastema, between the canines and the premolars, and the upper canines do not form a shearing unit with the first lower premolars. The milk teeth resemble those of the later hominids, but the order of eruption and the rate of maturation of the teeth follow the ape pattern more closely than they do that of modern humans.

There are fewer limb-bone fossils than skull remains. Upper-limb bones are particularly poorly represented and provide little or no information about manipulative ability, but there are indications from remains of the shoulder that this region of the gracile australopithecine was well adapted for climbing. The remains of the lower limbs and vertebral column provide good evidence for a more or less upright posture and suggest that these creatures walked bipedally in a way that was more efficient than the occasional bipedal walking observed in apes. An important aspect of this evidence is the low, posteriorly expanded blade of the ilium with the characteristic sciatic notch. The greatly increased width of the pelvic cavity, when compared to that of the apes, allowed for the birth of infants with larger heads and is additional evidence of the increase in relative brain size (see Figure 10). Estimates of stature and body weight are necessarily imprecise, but they suggest that the height of the gracile australopithecines was about 150 centimetres (five feet) and that they weighed between 35 and 60 kilograms (about 75 and 130 pounds).

Evidence of upright posture

The robust australopithecines found at sites in southern Africa share many of the basic features of the gracile group, the main points of difference being in the skull and the teeth and jaws. The average brain size of the robust australopithecines is a little larger than that of the gracile form and averages about 500 cubic centimetres. Because estimates of the robust form's body weight are between 10 and 25 percent greater than those of the gracile form's weight, however, the relative brain size of the two species is of the same order. The skulls of the robust australopithecines are more rugged than those of the graciles; crests that mark the attachment of the jaw and neck muscles are better developed, and the face is flatter and broader.

The dental arcade of the robust sample differs from that of the gracile remains in several ways. The molars of the robust form are larger, and the premolars of the lower jaw tend to develop extra cusps and so appear more like molar teeth. The anterior teeth of the robust form show no corresponding increase in size; in fact, their average size is smaller than in the graciles. The canines of the robust dentition are conical and more like those of later hominids, while the canines of the graciles are unusually asymmetrical. All of these features, taken with microscopic evidence of tooth wear, suggest that the face of the robust australopithecines had become specialized to increase the tooth area devoted to chewing, concentrating the power of the jaw muscles on the molar and premolar teeth.

The extent and functional significance of the differences between the pelvic and hip regions of the two types of australopithecines has been vigorously debated. John Talbot Robinson has contended that the robust australopithecine pelvis is adapted more for activities that emphasize power, such as climbing, than for length of stride and is thus significantly different from that of the gracile form. He and others have also maintained that the shape of the top end of the femur is distinctive. Many other scholars, however, interpret the fossil evidence as indicating no major differences in the gait of the two types of australopithecines, contending that there is still too little well-preserved ma-

terial to justify claims for substantial differences in locomotor habit.

The East African australopithecines. The first major discovery of australopithecine remains in this region was made at the Olduvai Gorge in Tanzania by Mary and L.S.B. Leakey. In 1959 they discovered a well-preserved cranium—designated Olduvai Hominid (OH) 5—that showed, in an exaggerated form, many of the features of the robust australopithecines from Swartkrans and Kromdraai. Although the cranium was initially attributed to a new genus and species—*Zinjanthropus boisei*—it was later suggested that the fossil be included as a separate species in *Australopithecus*. The discovery in 1964 of a massive robust australopithecine jaw at the Peninj site near Lake Natron in Tanzania confirmed the presence of this species in East Africa. Remains of a larger-brained, smaller-toothed hominid were also found at Olduvai from the early 1960s onward, and some have believed that these represented *A. africanus*. More recent analyses, however, have provided support for classifying the remains as *Homo habilis* (see below *Homo habilis*).

Olduvai Gorge discoveries

Since then, the major contributions to knowledge of the australopithecines have come from research at sites on the Omo River in Ethiopia; at Koobi Fora (formerly East Rudolf), on the northeastern shore of Lake Turkana (Lake Rudolf); and at West Turkana, on the northwestern shore of Lake Turkana. At the first two sites there is evidence of both gracile and robust hominids. The more robust remains clearly belong to *Australopithecus boisei,* the East African variety of the robust australopithecines. There is a good deal of size variation among the skulls, jaws, and teeth belonging to *A. boisei.* This suggests that the males and females of this taxon may have been markedly different in body size, which has implications for any attempts to reconstruct the social organization of these creatures. The remains of a nearly complete cranium from West Turkana (designated KNM-WT 17000 and popularly called the "black skull") also have been attributed to *A. boisei,* but they may exemplify a different and less-specialized taxon called *A. aethiopicus* (see below).

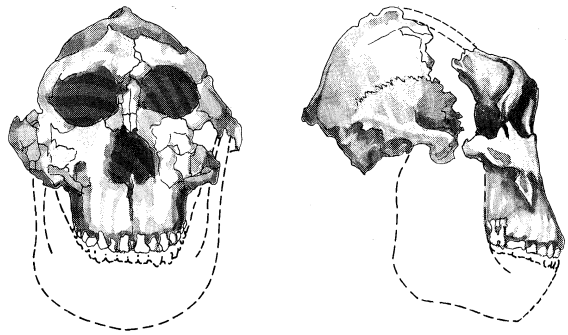

Figure 11: Skull of Olduvai Hominid (OH) 5 from Bed 1, Olduvai Gorge, Tanz.

The interpretation of the more gracile, smaller-toothed remains is more problematic. Evidence from the earliest fossil-bearing strata at Omo and Koobi Fora consists mainly of isolated teeth, and they most closely match teeth belonging to *A. africanus.* The gracile fossils from slightly younger strata at both sites are more difficult to interpret and resemble in many ways the *H. habilis* material recovered from Olduvai Gorge. Some of the cranial remains (*e.g.,* specimens KNM-ER 1470 and ER 3732 from Koobi Fora) suggest that the brains of these creatures were significantly larger than those of *A. africanus,* yet other gracile crania (*e.g.,* KNM-ER 1813) have brain capacities between 500 and 600 cubic centimetres, clearly within the accepted range for gracile australopithecines. Jaws and teeth show a mixture of australopithecine and later *Homo* features, and some of the limb bones suggest affinities with later *Homo erectus* remains. The result of this mosaic of features is that opinions differ about how this material should be classified. Some scholars regard it as strengthening the case for *H. habilis,* yet others consider it to be a geographic variant of *A. africanus.*

The Koobi Fora skulls

Fossil evidence of australopithecines from Laetoli in Tanzania and from Hadar and Middle Awash in Ethiopia represents hominids in the 4.5- to 2.5-million-year time period. In the 1930s the site at Laetoli (then called Garusi) yielded fragmentary remains of two upper jaws. The site was reexplored in the mid-1970s by Mary Leakey, resulting in a series of fossil hominid discoveries that included trails of hominid footprints (see below). Fieldwork carried out in 1972–77 by an international expedition led by Donald Johanson, Maurice Taieb, and Yves Coppens at Hadar, an extensive fossil site located in the Afar Triangle of Ethiopia, resulted in a remarkable collection of several hundred fossil hominid remains. Two discoveries were particularly notable. One is an individual specimen (AL 288-1, popularly called "Lucy") that includes nearly half of the bones of the preserved skeleton; the other is a series of fossils, popularly called the "First Family," from locality AL 333 that includes remains from at least 13 individuals.

The initial assessment of the material from Laetoli suggested that the remains most closely resembled the allegedly early *Homo* fossils from Koobi Fora, and thus the Laetoli evidence was also tentatively referred to the genus *Homo.* Similar inferences were made about part of the Hadar sample, while the remaining material from Hadar was considered to show affinities with the gracile and the robust australopithecines. More-detailed examination, however, resulted in a new interpretation that links the remains at the two sites in an entirely new australopithecine species, *Australopithecus afarensis.* The authors of this proposal, Johanson and Timothy White, listed a series of features that they consider as differentiating *A. afarensis* from *A. africanus,* the existing taxon that it most closely resembles. The features they find important include a more projecting face; a long, narrow, straight-sided dental arcade, with relatively and absolutely large anterior teeth (canines and incisors); and the shape of the canine and premolar teeth.

Proposal of *Australopithecus afarensis*

The distinctiveness of these features that, together with aspects of the mandible and cranium, make up the diagnosis of *A. afarensis* has been challenged by other researchers. In their view the features cited either overlap with the known samples of *A. africanus* or are features that are common to all australopithecines. Such shared features, these researchers argue, are of no value in defining a single species within the same group of fossil taxa. Some researchers have also pointed to the large range in size

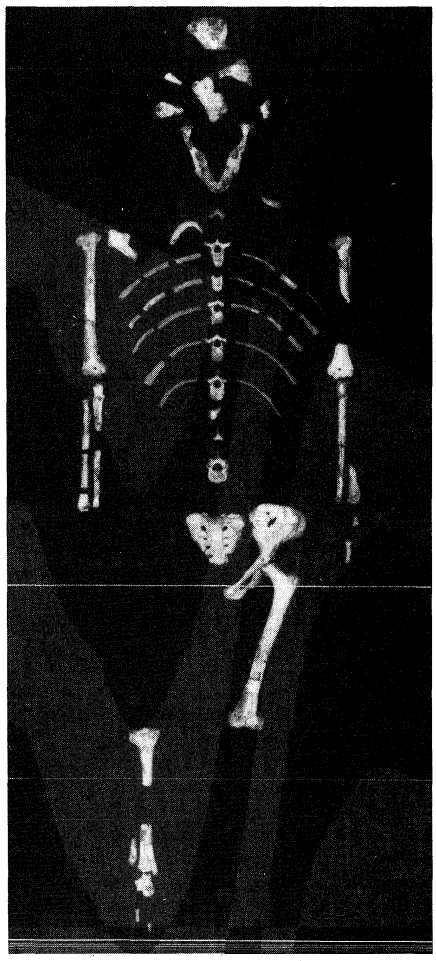

Figure 12: The AL 288-1 ("Lucy") skeleton, found at Hadar, Eth., and attributed to *Australopithecus afarensis*.
Cleveland Museum of Natural History

of mandibles and teeth in the Hadar collection and have questioned whether such variability can be accommodated within a single taxon. Subsequent research reports, however, have consistently lent support to the interpretation that the specimens from Laetoli and Hadar represent a single species that is distinct from *A. africanus*.

DATING THE FOSSILS

The most useful absolute-dating methods for australopithecine finds have been through potassium–argon and uranium-series dating. The record of the Earth's magnetism preserved in strata has also been widely used to date fossil hominid sites. The most common method of relative dating (*i.e.*, finding links between the strata of one site and those of another, well-dated locality that is used as a reference) uses fossils of ubiquitous species, such as fossil elephants and pigs, to provide relative dates for australopithecine-bearing hominid sites.

Dating the South African caves. The cave sites in South Africa have proved difficult to date by absolute methods because the sediments they contain lack most of the useful dating isotopes and the cave fillings seldom preserve a sufficiently strong or reliable record of the direction of the Earth's magnetic axis. Another problem is that the stratification within the caves is complex, with interposition of the strata. The estimated ages of the australopithecine-bearing strata at these cave sites are given in Figure 13. The oldest is probably Makapansgat, its dating being one of the few for the cave sites that combined absolute and relative methods. The vast majority of the australopithecine remains from Sterkfontein come from the stratum called Member 4 and are dated to three to 2.5 million years ago. Kromdraai is usually considered to be younger, though a slightly older date for these hominids is possible.

Dating the East African sites. Attempts to date hominid sites in East Africa have not been without problems. Nonetheless, it is widely accepted that, because the region's isotope-rich layers of volcanic ash, called tuffs, have provided good samples for absolute dating methods, the dates for East Africa are more reliable than those for the cave sites in South Africa. Each tuff has its own chemical profile, and tuff "fingerprinting" has enabled ash layers from sites hundreds of miles apart to be linked to the same eruptive event.

Uncertainties about the classification of the gracile fossils from Olduvai, Koobi Fora, and Omo mean that the attributions of taxa to sites shown in Figure 13 are necessarily simplified. Two observations are important, however. First, in both East and southern Africa the gracile australopithecines, *A. africanus* and *A. afarensis*, antedate the robust australopithecines. Second, the emergence of the robust australopithecines at the East African sites seems to coincide with the appearance of the so-called advanced gracile hominids attributed to *Homo habilis*.

ARCHAEOLOGICAL EVIDENCE

The relative richness of the archaeological record at the principal East African australopithecine sites contrasts with the lesser amount of evidence recovered from the cave sites of southern Africa. The probable explanation for this has come from careful studies of the animal bones found together with the hominid remains in the South African caves. The results of these studies suggest that the australopithecines were not living in the caves but were simply part of the bone refuse accumulated by a predator, most likely a leopard-sized creature. Even if these gracile and robust australopithecines had been making stone artifacts, it is most unlikely that their tools would have found their way into a carnivore's lair.

Bone "tools" from Makapansgat. Perhaps the best-known so-called archaeological evidence from the South African cave sites came from Makapansgat. Two discoveries there were thought to be particularly significant. The first was an unusual abundance of the jaws and forelimb bones of fossil antelopes, and the second was a series of baboon skulls that had been extensively fractured. The evidence of the antelope bones led Dart to propose the existence of what he called the osteodontokeratic ("bone-tooth-horn") culture, speculations that later were to foster the idea that the early australopithecines were "killer apes." Research on the way predators and scavengers deal with animal skeletons, however, has cast considerable doubt on this interpretation. These findings suggest that the natural breakup of antelope skeletons leads to the differential survival of particular bony parts, and that this,

The killer-ape theory

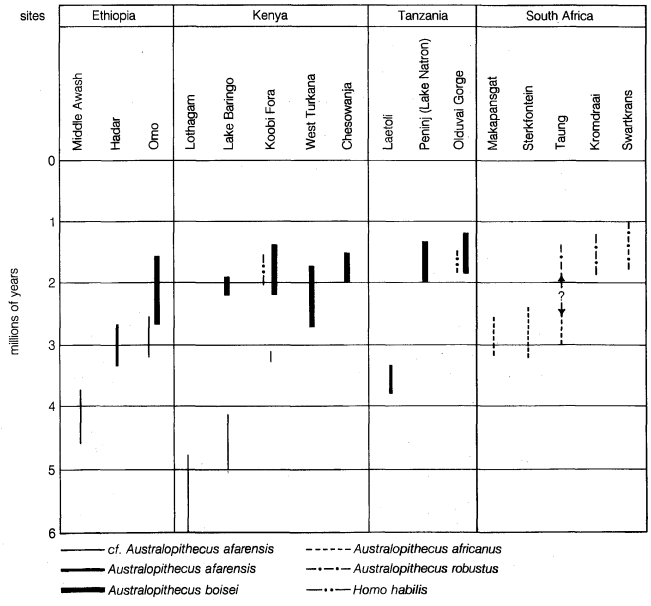

Figure 13: Approximate time ranges of sites yielding *Australopithecus* and *Homo habilis* fossils.

along with the preferences of predators and damage to the bones by stones falling from the cave roof, would be sufficient to account for the bone accumulations and the pattern of breakage found at Makapansgat. These studies do not exclude the use of bone tools at Makapansgat, but they do suggest that the present evidence for it is, at the very least, ambiguous.

Stone artifacts. No stone artifacts have been found at Makapansgat, but small collections of such artifacts have been recovered in the later robust-australopithecine-bearing layers at Swartkrans and in strata of similar age at Sterkfontein. The Swartkrans artifacts are mainly relatively crude stone chopper cores, flakes, and scrapers made of quartzite and quartz, and some bone tools. The artifacts at Sterkfontein, also made of quartzite, are technologically more advanced and include small scrapers and primitive hand axes. Subsequent analysis of the hand bones from Swartkrans—which are presumed to be australopithecine—has demonstrated that they are compatible with tool use.

Although artifacts have been recovered from older levels at Hadar, the earliest substantial and comprehensive archaeological evidence from East Africa occurs in strata dating from around two million years ago. The earliest of this series of occurrences is at the Omo River in Ethiopia, where collections of small quartz flakes have been found. It is, however, the sites at Olduvai Gorge and Koobi Fora that have provided the richest evidence of early hominid technology and behaviour. At both sites there is evidence that by about 1,750,000 years ago hominids had developed sufficient manipulative skills and cognitive ability to fashion a range of stone tools. The best known of these early industries is the Oldowan, first described from sites in Bed I of Olduvai. The artifacts range from choppers to small flakes, and variants (and perhaps developments) of this basic tool kit have since been described in later strata at Olduvai and other East African sites.

The Oldowan industry

The lack of good lithic tool evidence at early australopithecine sites and the contemporaneous appearance in the fossil record of *Homo* and stone artifacts led most workers to presume that *Homo habilis* manufactured the artifacts. There is, however, nothing other than circumstantial evidence to substantiate this association, and the most recent finds from Swartkrans suggest that the behavioral contrast between *Homo* and *Australopithecus* may be related to the different ways in which the two forms used stone tools.

HABITAT

Since the 1960s scientists have paid particular attention to reconstructing the paleoenvironment of the australopithecines. Information about the strata, fauna, and flora (from pollen analysis) of the period have been combined to provide reliable assessments of the habitat of the early hominids.

The evidence from both East and southern Africa suggests a similar pattern of climatic change. Bovids, which include the antelopes and bucks, are especially sensitive to environmental change. Their distribution in the southern cave sites suggests that the deposits in the earlier sites of Makapansgat and Sterkfontein (Member 4) accumulated under more wooded conditions than those of the later sites of Swartkrans and Sterkfontein (Member 5), where the types of bovids found indicate a drier climate with more open grassland. Evidence from the early sites in East Africa seems to indicate an open woodland environment, but the results from studies at Omo, Olduvai, and Koobi Fora suggests that a marked change in climate and vegetation occurred throughout East Africa about 2.3 million years ago. The evidence, ranging from oxygen isotope analysis of lake sediments to the detailed examination of microfauna, all points to a shift at that time to a drier climate and a more open, relatively treeless, scrub-type savanna environment.

BEHAVIORAL INFERENCES AND EVOLUTIONARY IMPLICATIONS

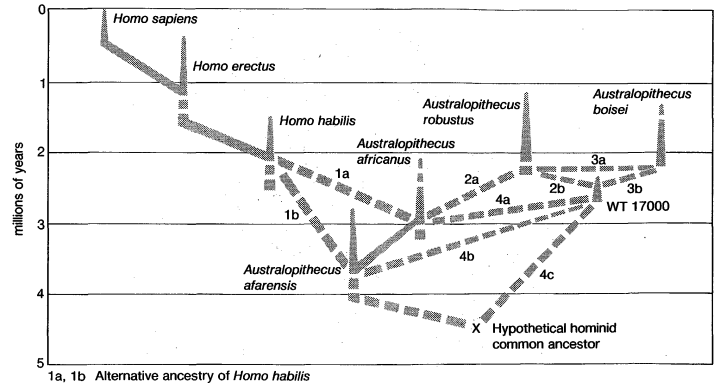
Fossil and paleoenvironmental evidence from the Miocene epoch, the finds at Hadar and West Turkana, and the bipedal footprints and other remains from Laetoli have led paleontologists to revise their theories about the emergence and adaptations of the australopithecines and of their evolutionary relationships.

Emergence and adaptation. The paleoenvironment at most of the fossil-ape-bearing Miocene sites included open woodland, similar to the habitats reconstructed for the early australopithecine sites. The footprints at Laetoli are unambiguous evidence for bipedal walking, and the pelvic remains from Hadar confirm that modifications for upright posture were well established by three million years ago. There is, however, increasing evidence from studies of the limb bones of the australopithecines that the skeletal adaptations for climbing and bipedal walking are similar. That the skeletal changes necessary for climbing may be preadaptive for bipedal running and walking suggests that the early gracile australopithecines from East and southern Africa may have used both these modes of locomotion and may well have spent more time resting and feeding in trees than has hitherto been believed. The dental remains of the gracile australopithecines do not suggest any particular dietary adaptation, and researchers have suggested that they subsisted mainly on a plant diet consisting of fruits, berries, and tubers. The most reasonable hypothesis to account for the appearance of the gracile australopithecines prior to about four million years ago is that their appearance coincided with a climatic change about five million years ago to a generally drier climate; that shift marked the beginning of the desertification of the Sahara.

Bipedal locomotion

A second climatic shift, the one noted above that is associated with further expansion of the savanna environment, coincided with the emergence of the robust australopithecines as well as with the appearance of the more advanced hominids attributed to *Homo habilis* and perhaps to other species of *Homo.* Studies of the molar teeth belonging to robust australopithecines have suggested that they would have been well adapted to crushing hard objects, such as the casings and husks of fruits. Thus, it may be that the drier climate forced the robust australopithecines to occupy a specialized—and ultimately limited—niche in the sparsely wooded savanna grasslands. During the same period it seems most likely that the dentally less specialized australopithecines were adapting in a different direction, and it is natural to link them with the quickening pace of cultural advance and the emergence of *Homo habilis* and, later, *Homo erectus.*

Evolutionary relationships. The various phylogenetic hypotheses, or trees, that have been put forward to explain the relationships between australopithecine taxa are summarized in Figure 14. *A. afarensis* has consistently been recognized as the ancestor of *A. africanus,* but views vary about whether its connections with *Homo* are direct (path 1b in the figure) or indirect—*i.e.,* via *A. africanus* (path 1a). *A. africanus* was once regarded as the ancestral hominid, but few contemporary researchers would subscribe to this hypothesis. Studies which have taken characters and compared their expression, one by one, with those in other



1a, 1b Alternative ancestry of *Homo habilis*
2a, 2b Alternative ancestry of *Australopithecus robustus*
3a, 3b Alternative ancestry of *Australopithecus boisei*
4a, 4b, 4c Alternative ancestry of "robust" australopithecine clade

Figure 14: Tentative phylogenetic scheme for early hominid evolution. A solid line between species indicates general agreement on a single evolutionary pathway; dotted lines signify that more than one pathway has been proposed.

taxa have demonstrated that *A. africanus* has affinities with both *Homo* and the robust australopithecines. This mixture of traits has suggested to some workers that *A. africanus* is the common ancestor of both *Homo* and *A. robustus* (paths 1a and 2a), but others see a preponderance of either *Homo* (path 1a) or robust australopithecine (path 2a or paths 4a, 2b, and 3b) traits. The discovery in the mid-1980s of the KNM-WT 17000 cranium at the West Turkana site has further sharpened the debate. If, as is generally believed, the robust australopithecines (*A. robustus* and *A. boisei*) represent a separate branch, or clade, of the evolutionary tree, then the evidence gathered from the study of KNM-WT 17000 reduces the probability that *A. africanus* can be included in that grouping. Conversely, if *A. africanus* is judged to show robust australopithecine specializations, then the hypothesis must seriously be entertained that the East and southern African forms of robust australopithecine are similar because of convergence and not because of shared ancestry (paths 2a and 3b).

The KNM-WT 17000 cranium

The surest way to adjudicate on the claims of these rival hypotheses lies in the exploration of the detailed morphology that underlies the various characters alleged to link australopithecine taxa. Whereas characters inherited from a common ancestor are likely to be similar in most details, it is predictable that phylogenetically misleading, or convergent, characters will not show such detailed similarities. (B.Wo.)

Homo habilis

The extinct species of the genus *Homo* called *Homo habilis* inhabited parts of sub-Saharan Africa at least two million years ago. In 1959 and 1960 the first *H. habilis* fossils were discovered at Olduvai Gorge in northern Tanzania. These consisted of several teeth and a lower jaw associated with fragments of a cranium and some hand bones. As more specimens were unearthed workers began to realize that the hominids they represented were anatomically different from *Australopithecus.* Formal announcement of this and other discoveries was made by L.S.B. Leakey, Phillip Tobias, and John Napier in 1964. They described increased cranial capacity and comparatively smaller premolar and molar teeth as factors leading to the designation of the fossils as *H. habilis* and also suggested that the hand was capable of fine manipulation; *Homo habilis* thus seemed to foreshadow conditions seen in *Homo erectus* and in later humans.

FOSSIL EVIDENCE

Apart from the jaw, cranial bones, and hand thought to represent a juvenile individual (Olduvai Hominid, or OH, 7) and recovered from Bed I deposits, several additional fossils from Olduvai have been ascribed to *Homo habilis.* At Bed II, at a site somewhat higher in the deposits than Bed I, pieces of another thin-walled cranium along with upper and lower jaws and teeth came to light in 1963. Just a month later a third skull was found in Bed II, but these bones had been trampled by cattle after being washed into a gully. Some of the teeth survived, but the cranium was broken into many small fragments; only the top of the braincase has been pieced back together. The two skulls from Bed II are numbered OH 13 and OH 16, and both are mentioned in the report prepared by Leakey, Tobias, and Napier in 1964.

The Olduvai and Koobi Fora finds

G. Philip Rightmire

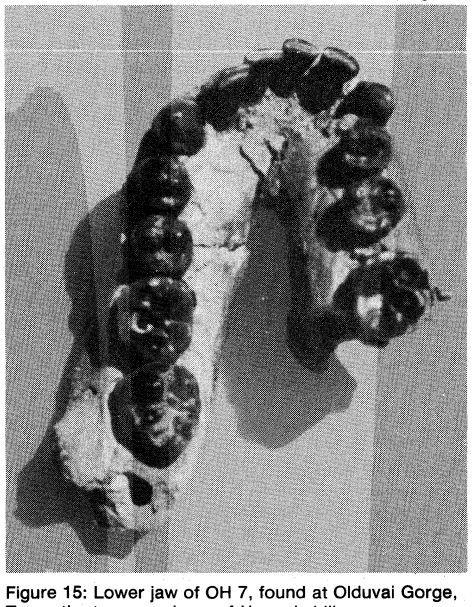


Figure 15: Lower jaw of OH 7, found at Olduvai Gorge, Tanz.; the type specimen of *Homo habilis.*

Since 1964 more material has been discovered, not only at Olduvai but at other African localities as well. One intriguing specimen is OH 24. This cranium is more complete than others from Olduvai ascribed to *H. habilis.* Because some of the bones are crushed and distorted, however, the face and braincase are warped and provide less anatomical information than they otherwise would. OH 24 is said to differ from *Australopithecus* in brain size and dental characteristics, but there are resemblances to the australopithecines of southern Africa in other features, such as face form. Partly because the fossil is damaged, complete agreement concerning its significance has not been reached.

Important discoveries made in the Koobi Fora region of northern Kenya include the famous cranium numbered KNM-ER 1470. As in the case of OH 16, this specimen had been broken into many fragments, which could be collected only after extensive sieving of the deposits. Some of the pieces were then fitted into the reconstruction of a face and much of a large cranial vault. Brain volume can be measured rather accurately and is about 750 cubic centimetres (cc; 46 cubic inches). This evidence prompted Richard Leakey to describe KNM-ER 1470 as one of the oldest undoubted representatives of the genus *Homo* to be unearthed in East Africa. Some other features of the braincase are *Homo*-like, and many workers have accepted this opinion. At the same time, it is apparent that the facial skeleton is relatively large and flattened in its lower parts. In this respect, the Koobi Fora specimen resembles *Australopithecus* anatomically.

Among other key finds from the Koobi Fora region are KNM-ER 1813 and ER 1805. The former, which is most of a cranium, is smaller than ER 1470 and resembles OH 13 from Olduvai in many details, including tooth size and morphology. The latter skull exhibits some peculiar features. Although the braincase of ER 1805 is close to 600 cc in volume and is thus expanded moderately beyond the size expected in *Australopithecus,* a bony crest is formed along the top of the vault. This sagittal crest is coupled with another, more massive crest, oriented transversely across the rear of the skull. These ridges indicate that the temporal muscles (which function in chewing) and also the neck muscles were powerfully developed. A similar if more exaggerated pattern of cresting appears in what are referred to as robust australopithecines but not in *Homo.* Other features of ER 1805, however, are *Homo*-like. As a result, there has been disagreement among anatomists regarding the hominid species to which this individual should be assigned. Despite its anomalies, ER 1805 is probably best discussed along with other specimens grouped as *Homo habilis.*

Several mandibles resembling that of OH 7 have been recovered from the Koobi Fora area, and teeth that may belong to *H. habilis* have been found further to the north, in the Omo River valley of Ethiopia. Some additional materials, including a badly broken cranium, are known from the cave at Swartkrans in South Africa. At Swartkrans the fossils are mixed in the Member 1 deposits with many other bones of robust australopithecines. An early species of *Homo* may also be present in the Member 5 breccias at Sterkfontein, not far from Swartkrans. Here again the remains are fragmentary and not particularly informative.

Finds at other sites

A more recent and valuable discovery has been reported from Olduvai Gorge: in 1986 a jaw with teeth, cranial parts, and pieces of a right arm and both legs were located low in Bed I. The bones seem to represent one individual,

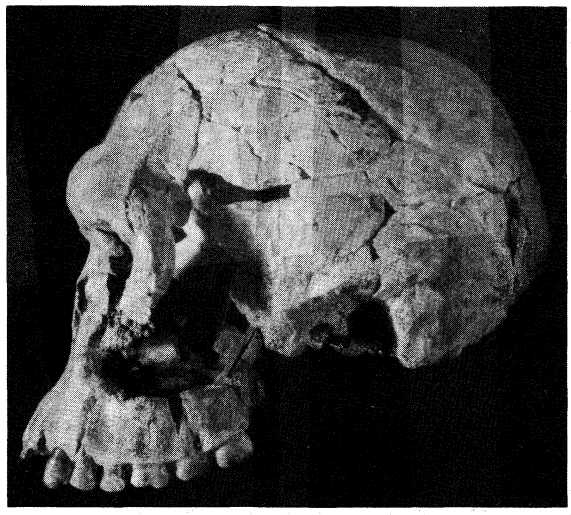

Figure 16: Left side view of the KNM-ER 1813 cranium, found at Koobi Fora, Kenya.
G. Philip Rightmire

called OH 62. Although the skull is shattered, enough of the face is preserved to suggest similarities to early *Homo*. The find is especially important because of the associated limbs, which show that OH 62 is a very small hominid indeed. The arm is long relative to leg length so that this individual has body proportions which differ dramatically from those of more modern hominids.

DATING THE FOSSILS

Fossils from Olduvai that are attributed to *Homo habilis* come from Beds I and II. Several approaches have been used to obtain dates for these stratigraphic levels. One of the most tested and most reliable techniques, potassium–argon dating, measures the amount of argon relative to radioactive potassium in samples of volcanic rock or minerals. Volcanic materials suitable for dating often occur as tuffs deposited along with other sediments in the Olduvai sequence. Other methods, such as magnetic stratigraphy and measurement of sediment thicknesses, also yield clues to the age of deposits. These approaches are subject to uncertainty, but a reasonably secure time scale for Olduvai has been developed. The oldest remains, including OH 24, were found just below a tuff that is about 1,850,000 years old. Other individuals from Bed I such as OH 7 and OH 62 are not quite so ancient. The youngest Olduvai skull that is representative of early *Homo* is OH 13, from Middle Bed II. No radiometric date for this level is available, but OH 13 is probably about 1.5 million years in age.

In the Koobi Fora region a number of the important fossils have been located near a level of volcanic ash that also contains stone tools. This ash bed, known as the KBS tuff, was sampled and dated initially by potassium–argon to about 2.6 million years. When ER 1470 was found several metres below this tuff in 1972, it was thought that the new cranium must document *Homo* in the record at a time well before the Olduvai deposits had accumulated. This assumption was soon questioned on the basis of other evidence, however, and before 1980 it was clear that the age of the KBS tuff had been overestimated. A series of potassium–argon determinations done subsequently has yielded a date of 1,880,000 years. ER 1470 and other *H. habilis* specimens recovered below this ash layer, therefore, must be close to two million years old. Remains collected above the tuff are somewhat younger, but probably none of the Koobi Fora fossils is as recent as OH 13. Dating evidence from East Africa thus suggests that *H. habilis* lived for half a million years or so before giving way to later *Homo* species.

BODILY STRUCTURE OF HOMO HABILIS

Olduvai and Koobi Fora fossils have allowed researchers to make some determinations about the anatomy of early *Homo*. It is clear that the braincase of *H. habilis* is larger than that of *Australopithecus*. The original finds from Olduvai Gorge include two parietal bones from OH 7. An incomplete brain cast that was molded when the parietals were put together to form a partial cranium has been used to estimate total brain volume, and the result, after correction for the juvenile status of OH 7, is about 680 cc. Less-direct methods can also be employed to assess the endocranial volume of OH 7, and most give figures close to 700 cc. A brain cast from ER 1470, which has a more complete cranium, can be measured directly from water displacement; its volume, as mentioned above, is about 750 cc. One or two additional skulls from the East Turkana (Koobi Fora) region that are fragmentary appear to be about the same size as ER 1470. Other individuals—such as ER 1813, which has a cranial capacity of only about 510 cc—are much smaller. Thus, brain sizes ranging from slightly more than 500 cc to nearly 800 cc seem to characterize *H. habilis*.

Increase in brain size

The craniums by and large have thin walls and a rounded, rather than low and flattened, vault; they do not have the heavy crests and projecting browridges characteristic of later *H. erectus*. As with *Australopithecus* and archaic *Homo* the occipital of these specimens is flexed, but unlike these others the transverse torus does not protrude. The area of the lower occiput covered by the nuchal (neck) muscles is much smaller than that of *H. erectus*. The underside of the cranium is shortened from the back of the palate to the occipital bone, as in all later *Homo* species. This is an important contrast to the condition exhibited by the gracile australopithecines, where the cranial base is relatively narrow and elongated.

The facial bones of several specimens are at least partly preserved, and facial proportions vary considerably. One of the Olduvai hominids, OH 24, seems similar anatomically to *Australopithecus*, having prominent cheekbones and a flattened nasal region. This gives the central region of the face a depressed, or "dished," appearance, and the upper part of the nasal profile is obscured by the cheek when the specimen is viewed from the side. Such hollowing of the face is characteristic of some South African australopithecines but is not seen in later *Homo*. The facial skeleton of ER 1470 is large relative to the braincase and shows flattening below the nose, again *Australopithecus*-like features. The walls of the nasal opening, however, are slightly everted, and there is at least an indication that the nose stands out in more relief than would be expected in australopithecines. The face of ER 1813 is still more modern in form: the edge of the nasal opening is thin and flared outward, and this region is prominent relative to the cheeks on either side.

The anterior teeth of *H. habilis* are not much different in size from those of *Australopithecus*, but the premolar and molar crowns—particularly in the mandible—are narrower. The jaw itself may be quite heavily constructed and overlap in size with mandibles of gracile australopithecines. This is the case for OH 7 from Olduvai and also for at least one specimen from Koobi Fora. Other jaws are smaller but still robust, in the sense of being thick relative to height. For example, the mandible of OH 13 is similar in many respects to that of *H. erectus*, and this individual might have been called *H. erectus* if its jaw had not been found with the small, thin vault bones that mark it as different from that species.

Only a few postcranial parts have been discovered. Some limb bones from Olduvai and Koobi Fora have been grouped tentatively with *H. habilis* on the strength of general anatomic similarity to later humans. These fossils, however, are not associated with teeth or skulls, and it is probably not appropriate to use them as the basis for describing early *Homo*. One individual for which body parts are more fully represented is OH 62 from Olduvai. Arm and leg bones of OH 62 are fragmentary and must be studied in greater detail, but a preliminary report by the discoverers suggests that the arm is relatively long. The skeleton may be similar in its proportions to small species of *Australopithecus*. Probably OH 62 walked bipedally as efficiently as other early hominids, but this diminutive individual was unlike later humans in many respects.

Another important specimen is the immature hand of OH 7. These bones found with the parietals are still ape-

like in some features, but it is almost certain that the individual from which they came could manipulate objects with precision. Stone artifacts and early *Homo* fossils have been found in the same levels at Olduvai and other sites. These tools are called the Oldowan industry, and though they are crude they do indicate that *H. habilis* could shape stone.

Use of tools

BEHAVIORAL INFERENCES

The stone tools and unused waste materials (mainly crude chopping tools and sharp flakes) left by *H. habilis* provide important clues about the behaviour of these early humans. Olduvai Gorge has been a rich source of Oldowan tools, where they are found in several levels of Bed I, often in association with animal fossils. Originally, the occurrence of artifacts with bones was interpreted to mean that *H. habilis* hunted animals, brought them to their living sites, and butchered the carcasses with the Oldowan implements, but through other studies it is now known that the situation is more complicated than this. Assemblages such as those found at Olduvai can be created through various means, not all of which are related to hominid activities.

Further study of the Olduvai material has indicated that *H. habilis* did use animal products. With the aid of a scanning electron microscope it has been shown that cut marks on some of the Bed I bones must have been made by stone tools, but this does not prove that animals were hunted. Analysis of Olduvai animal fossils shows that marks were made by either rodent or carnivore teeth and by cutting, the indication being that at least some of the animals were killed by nonhominid predators. In all likelihood, the hominids at Olduvai could obtain larger carcasses only after the animals had been killed and partially eaten by other predators. *H. habilis* may have hunted small prey, such as antelopes, but they were also scavengers.

It is debatable whether or not the Olduvai sites were home bases. Nothing recovered indicates that people lived where the animal bones accumulated, and presumably such areas were dangerous since they undoubtedly attracted numerous predators. These sites may have been caches of stone tools and raw materials that were established in areas convenient for the rapid processing of animal parts. Thus, where the hominids lived or whether their social structure was prototypical of later hunter-gatherers remains unknown, although *H. habilis* must have engaged in cultural activities.

Language ability

Whether or not early *Homo* had acquired language is another fundamental question, and the indirect evidence on this issue has been variously interpreted. It is the belief of some anatomists that endocranial casts of *H. habilis* fossils indicate that the regions associated in modern humans with speech are enlarged. Other workers have disagreed with this assessment, particularly since the number of braincases preserved well enough to make detailed casts is small. Anthropologists have based their interpretations on the archaeological record. According to some, the crude Oldowan artifacts indicate the ability to use language. Critics of this view assert that the Oldowan industry represents only opportunistic stonework and that the later Acheulean tools of *H. erectus*—because they are more carefully formed and are often highly symmetrical—indicate this later hominid species to have been the first to use symbols and language. One of the problems with this theory is that no clear link between technological and linguistic behaviour has been established; even the more sophisticated tools could have been made by nonspeaking hominids. Thus, it is not certain when *Homo* developed the linguistic skills that characterize modern humans.

EVOLUTIONARY IMPLICATIONS

The general interpretation of the fossil evidence is that *Homo habilis* is anatomically different from *Australopithecus* and that it represents the beginning of the trends which characterize human evolutionary history. One of the hallmarks is the expansion of the brain. Some of the Olduvai and Koobi Fora hominids clearly have a larger cranial capacity than that of *Australopithecus* specimens, and the capacity increases progressively with *H. erectus*, archaic *H. sapiens*, and modern humans. *H. habilis* is also thought to exhibit the origins of such other trends as smaller dentition and changes in facial structure, especially of the nasal region. In addition, the argument has been made that *H. habilis* could fashion simple tools and could communicate verbally. It is fairly certain that these early hominids had the technological skills to make the Oldowan artifacts, but it is not clear that this stoneworking ability alone meant that they could speak; there is simply too little evidence to make such an inference.

The theory that *H. habilis* is intermediate between relatively primitive Pliocene *Australopithecus* and more advanced *Homo* of the Pleistocene appears to be generally accurate, but several aspects of this view can be challenged. Although *Homo habilis* is still a rather poorly known species, it is becoming clear that there are anatomic differences within the East African assemblages. Some of the newer discoveries, such as ER 1470 from Koobi Fora, have confirmed the expectation that early *Homo* crania should be relatively large, with rounded occiputs and shortened bases. Other fossils have proved less easy to assign to *H. habilis*, and there has been considerable controversy over OH 24 from Olduvai and ER 1805 and ER 1813 from Koobi Fora. These braincases are considerably smaller, and it is frequently suggested that this variation may be due to sex: OH 7 and ER 1470 are said to be male, while OH 24 and ER 1813, with their smaller craniums, female. But there are also differences in shape as well as size, and several of the smaller skulls depart from the morphology of large-brained *H. habilis* in ways that are not obviously related to sex. The facial affinities between OH 24 and *Australopithecus* have been mentioned above, and ER 1805 exhibits cranial cresting patterns that are unlike those seen in other *Homo*. There is the possibility that two taxa, rather than one sexually dimorphic group, are actually represented by the fossils.

Anatomic differences

Placing the specimens in two groups, however, means that both must be fitted into a scheme of hominid phylogeny. One interpretation assigns specimens with smaller craniums (including OH 24) to a "gracile" species of *Australopithecus*. According to this scenario, only the larger skulls (including OH 7 and ER 1470) represent early *Homo* evolution. Others believe that early human populations were more diverse than had been recognized, questioning the notion that all species of *Homo* form a simple linear progression; although these workers recognize two separate taxa, they prefer to lump both in the genus *Homo*. In this view, two species may have lived contemporaneously two to 1.5 million years ago, but only one was the direct ancestor of *H. erectus*. Perhaps it was the large-brained form that evolved further, while the smaller hominid became extinct. What is certain is that getting a clearer understanding of the history of these first humans requires further paleoanthropological research. (G.P.Ri.)

Homo erectus

Homo erectus, the first generally recognized human species, most likely originated in Africa, and it quite possibly evolved from *Homo habilis*. *H. erectus* seems to have been restricted to the African tropics for several hundred thousand years, but eventually these people gradually migrated into Asia and probably into parts of Europe. This history can be documented directly from the many sites that have yielded fossil remains of *H. erectus*. Other localities from which animal bones and stone tools have been recovered indicate that this species was present, although there is no evidence of the people themselves. *H. erectus* seems to have flourished until sometime in the Middle Pleistocene—perhaps 300,000 years ago—before giving way to early representatives of *Homo sapiens*.

FOSSIL EVIDENCE

The first fossils that came to be attributed to the species were discovered by a Dutch army surgeon, Eugène Dubois, who began his search for ancient human bones in Java (now part of Indonesia) in 1890. Dubois found his first specimen in that year, and in 1891 a fine skullcap was unearthed at Trinil on the Solo River. Considering its prominent browridges, retreating forehead, and flexed oc-

The Java finds

ciput, Dubois concluded that the Trinil cranium showed anatomic features intermediate between those of humans—as they were then understood—and those of apes. Several years later, near where the skull was discovered, he found a remarkably complete and modern-looking femur (thighbone). Since this long, straight bone was so much like a modern human femur, Dubois decided that its owner must have walked erect. He adopted the name *Pithecanthropus,* which had been coined earlier by the German zoologist Ernst Haeckel, calling his discoveries *Pithecanthropus erectus,* or "Upright Ape-Man." Only a few other limb fragments turned up in the Trinil excavations, and it would be some three decades before more substantial evidence of these archaic people appeared. Most paleontologists now regard all of this material as *Homo erectus,* and the name *Pithecanthropus* has been dropped.

Asian fossils. Subsequent discoveries gradually established the case for a new and separate species of fossil hominid. At first, these discoveries were centred largely in Asia. At several different places in Java, essentially similar fossils were found: the sites other than Trinil are Kedung Brubus, Modjokerto (Mojokerto), Sangiran, Sambungmatjan (Sambungmachan), and Ngandong. Another series of finds was made in China, especially in the caves of Chouk'ou-tien (Zhoukoudian) near Peking, although virtually all of the remains from there subsequently were lost during the Sino-Japanese War late in 1941. Newer discoveries have since been made in the caves, while three new Chinese sites—at Kung-wang-ling (Gongwangling) and Ch'en-chia-wo (Chenjiawo) in the Lan-t'ien (Lantian) district of Shensi province, and at Ho-hsien (Hexian) in Anhwei province—have yielded remains attributable to *H. erectus.*

By the end of World War II the pattern of early discovery had given rise to an idea that *H. erectus* was a peculiarly Asian expression of early humans. Subsequent discoveries in Africa served to change this view, and it came to be realized that Europe, too, may have harboured *H. erectus.*

African fossils. In Africa in 1954–55, excavations at Ternifine, east of Mascara, Alg., yielded remains whose nearest affinities seemed to be with the Chinese form of *H. erectus.* Other hominid fragments from northwestern Africa—parts of a skull found in 1933 near Rabat in Morocco and jaws and teeth from Sīdī ʿAbd ar-Raḥmān (Sidi Abderrahman; 1954) in Morocco—show features reminiscent of *H. erectus,* though they are rather more advanced in structure than those of Ternifine and of Asia. Another fossil probably related to *H. erectus* is a cranium found in 1971 at Salé, Mor. Although nearly all of the face and part of the frontal bone have been broken away, it is an important specimen.

Finds at Olduvai Gorge

Some of the more convincing evidence for the existence of *H. erectus* in Africa came with the discovery in 1960 of a partial braincase at Olduvai Gorge in Tanzania. This fossil, called OH 9, was picked up by L.S.B. Leakey in deposits of Bed II, the second of four numbered beds (or layers) identified in the Olduvai stratigraphic sequence, beginning with Bed I (the oldest) and ending with Bed IV (consisting of more recent sediments). Additional cranial remains, jaws, and limb bones of *H. erectus* were later discovered in Beds III and IV and the overlying Masek levels.

Much of the Olduvai material is fragmentary, but gaps in the knowledge of *H. erectus* in East Africa have been filled to some extent through finds made by Richard Leakey. Since 1970 a number of valuable fossils have been unearthed at localities on the eastern shore of Lake Turkana (Lake Rudolf) in northwestern Kenya, now com-

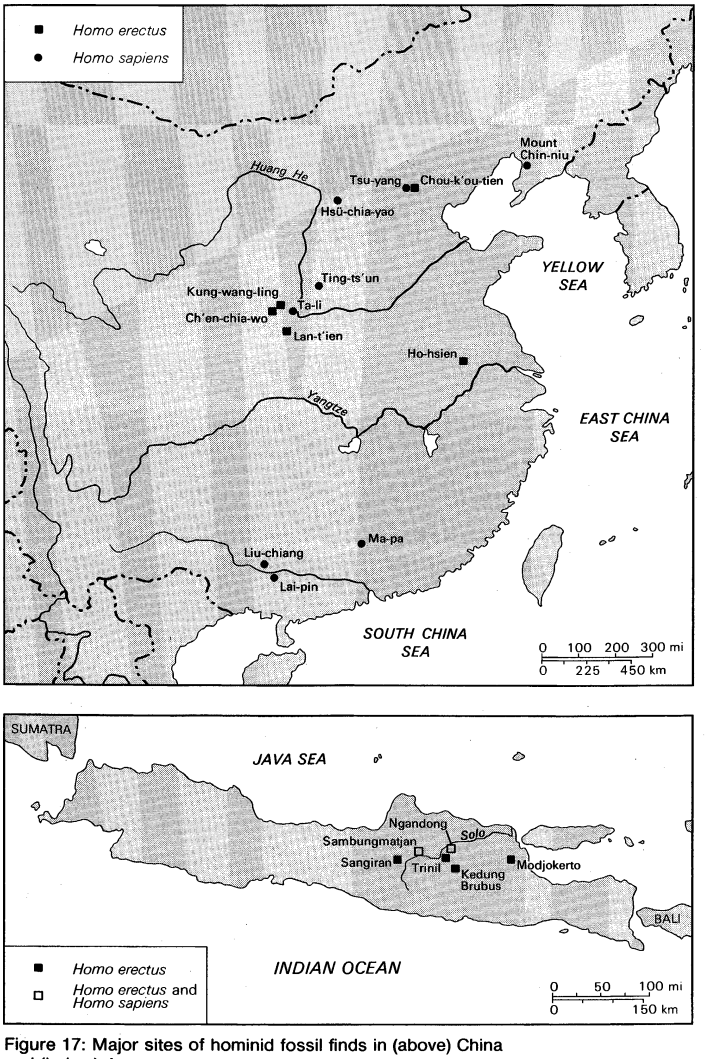

Figure 17: Major sites of hominid fossil finds in (above) China and (below) Java.

monly referred to as the Koobi Fora sites. Included in these assemblages are the remains of *Australopithecus* and probably some representatives of the species *H. habilis.* Of several specimens that clearly do belong to *H. erectus,* one cranium from Koobi Fora (KNM-ER 3733) is quite complete and well preserved; it is likely to be one of the most ancient *H. erectus* fossils discovered anywhere in Africa. Other significant finds at Koobi Fora include a nearly intact skeleton (ER 1808), although it has been shown to have come from a diseased individual. Another nearly complete skeleton (designated KNM-WT 15000) found at Nariokotome (West Turkana), a site on the northwestern shore of Lake Turkana, is of an adolescent male.

European fossils. The realization that Africa as well as Asia was apparently peopled by a form of mankind classifiable as *H. erectus* led to a reexamination of some of the earliest hominid fossils from Europe. An isolated mandible (lower jawbone) had been found in a sandpit just north of Mauer, close to Heidelberg, Ger., in 1907. Although it had been given a variety of names over the years, its exact affinities to other fossils remained uncertain, because no associated cranium was found. Since then, a number of investigators have come to regard the Mauer mandible as representing a member of the species *H. erectus.* Although its geologic age is perhaps comparable with that of the Chou-k'ou-tien hominids in China, this skeletal fragment from Europe shows more modern structural features than do the Asian and African jaws of *H. erectus.* The exact significance of these features in the Mauer jaw is still being debated; they could be the mark of an individual variant, highlighting the fact that it is not yet known how variable in bony structure *H. erectus* was. Alternatively, the Mauer specimen could represent a subspecies or race of *H. erectus* that is slightly more advanced in anatomic structure than are the African and Asian populations; or it is possible that the Mauer individual could have been a member of a very early population of *H. sapiens.* Evidence for the latter view has been provided by fossils discovered in Hungary.

The Mauer mandible

In 1965, remains of two individuals—a child and an adult—were found in a travertine quarry at Vértesszőllős, Hung., about 30 miles (50 kilometres) west of Budapest. The remains of the child are milk teeth, and enough of them are preserved to show affinities with the Chinese *Homo erectus* of Chou-k'ou-tien. The adult is represented by a large part of an occipital bone (at the back of the head) from a large-brained skull. While showing some features reminiscent of *H. erectus,* the general form and the capacity of the Hungarian cranium also suggest an affinity with an early branch of *H. sapiens.* In fact, it appears to be related to somewhat later Middle Pleistocene skulls (perhaps 200,000 years old) from Europe, such as those of Swanscombe and Steinheim, which are accepted as early members of *H. sapiens.* Since such twofold affinities are exhibited by the Vértesszőllős group of remains, authorities differ as to whether to call the population they represent *H. erectus* or *H. sapiens.* The same uncertainty applies to some of the fossils found in North Africa; the Sīdī ʿAbd ar-Raḥmān and Rabat remains are regarded by some experts as late surviving members of *H. erectus* and by others as forms transitional between *H. erectus* and *H. sapiens.*

The European fossils that are of equivalent age to those of Chou-k'ou-tien and the later northwestern African localities—including the jaw from Mauer; the teeth and occipital bone from Vértesszőllős; and some skull parts, teeth, and postcranial remains discovered more recently at Arago cave (near the village of Tautavel in southwestern France)—appear to have more structural features in common with early *Homo sapiens* than do their Asian and African contemporaries. This is also true of several other European finds that are somewhat younger (that is, of later Middle Pleistocene antiquity). Pieces of braincase and an upper molar tooth from travertine deposits at Bilzingsleben, E.Ger., show some resemblances to *H. erectus,* but the skull fragments are more comparable to those of a remarkably complete hominid recovered in 1960 from a limestone cave near Petralona, Greece. Detailed study of the anatomy of this latter hominid suggests that it shares with *H. sapiens* some traits that are not characteristic of

The Petralona skeleton

H. erectus. There is still no firm consensus regarding the classification of these later Middle Pleistocene populations of Europe. It may be safest to conclude that the case has not yet been convincingly established for the existence in Europe of *H. erectus* as known from Asia and Africa.

DATING THE FOSSILS

To reconstruct the position of *Homo erectus* in hominid evolution, it is essential to define his place in time as precisely as possible. Modern developments in such disciplines as physics have placed at the disposal of the paleoanthropologist a variety of techniques that permit increasingly accurate assessments of the absolute age of fossils. Many of these methods are based upon the effectively constant (or absolute) rate at which radioactive isotopes of such elements as potassium and argon decay. When the newer methods cannot be applied, investigators may still ascribe a relative age to a fossil. This can be done by noting the contents of the layer of rock or the deposit in which the fossil was found; a layer containing, for instance, evidence of the remains primarily of extinct animals is probably older than one containing signs of predominantly recent or still living forms.

Such lines of evidence have led to the tentative conclusion that the species *Homo erectus* flourished over a long interval of Pleistocene time. The fossils recovered at the Koobi Fora sites may be about 1.6 million years old if radiometric dates obtained from associated volcanic materials are correct. Some of the remains from Olduvai Gorge are also ancient, and OH 9 is probably about 1.2 million years old. Many of the other older-appearing fossil hominids unfortunately lack absolute dates; but, by relative dating from several approaches, it would seem probable that the specimens from Sangiran and Modjokerto in Java (more especially the fossils from deposits of the Putjangan [Pucangan] beds) and perhaps from one of the Lan-t'ien localities in China are among the earlier representatives of *H. erectus.* On the other hand, the youngest hominids accepted unequivocally as *H. erectus* would seem to be the group from Ternifine in Algeria, Chou-k'ou-tien in China, and Trinil in Java.

Until more complete evidence is available it is reasonable to suggest 1.6 million to perhaps 250,000 years ago as a time range for *Homo erectus.* For the most part, fossils dated earlier than this are the remains of *H. habilis.* This species is best known from Olduvai Gorge and Koobi Fora in Africa, and the oldest specimens from there seem to be about 1.8 to two million years old. On the other hand, there is a group of later specimens that show some features of *H. erectus* but are commonly regarded as transitional forms or as members of *H. sapiens;* these include later Middle Pleistocene specimens from Europe (discovered at sites such as Bilzingsleben, Petralona, and

Transitional forms

Montmaurin), from northwestern Africa (Salé, Sīdī 'Abd ar-Raḥmān, and Rabat), and from Asia (the Ta-li find of 1978). Other later forms suggest that *H. erectus* had given rise to several regionally distinct forms, or subspecies, of archaic *H. sapiens,* represented by late Middle Pleistocene or early Late Pleistocene fossils from Africa (Kabwe/Broken Hill, Elandsfontein [Hopefield/Saldanha], Cave of Hearths, Lake Ndutu, Omo, Bodo) and Europe (Swanscombe, Steinheim, Biache, Ehringsdorf, La Chaise). Thus, the problem of recognizing populations as belonging to *H. erectus* becomes more difficult; the boundaries of the species become blurred. These are the transitional zones in which a predecessor species seems to have been grading imperceptibly into its evolutionary product, *H. erectus,* and in which *H. erectus* apparently was undergoing further evolutionary change into its descendant species, *H. sapiens,* to which modern humans belong.

BODILY STRUCTURE OF HOMO ERECTUS

Much of the fossil material discovered in Java and China consists of cranial bones, mandibles, and teeth. The few broken limb bones found at Chou-k'ou-tien have provided little information. It is possible that the complete femur excavated by Dubois at Trinil is more recent in age than the other fossils found there and not attributable to *Homo erectus.* It comes as no surprise, therefore, that the greatest descriptive emphasis has been on the shape of the skull and not on the postcranial finds. The continuing discoveries in Africa—particularly at the Olduvai and Lake Turkana sites—have yielded a more complete picture of *H. erectus* anatomy.

The cranium of *H. erectus*—with its low profile and average endocranial (interior) capacity of less than 1,000 cc (60 cubic inches)—is distinctly different from that of other humans. The average endocranial capacity of modern *H. sapiens,* for example, is 1,450 cc, although the range for recent humans is appreciable, perhaps 1,000 to 2,000 cc. The upper part of the range for *H. erectus,* extending to more than 1,200 cc, overlaps with the lower values expected for *Homo sapiens.*

Table 2: Average Capacity of the Braincase in Fossil Hominids

hominid	number of fossil examples	average capacity of the braincase (cc)
"Gracile" *Australopithecus*	6	440
"Robust" *Australopithecus*	4	519
Homo habilis	4	640
Javanese *Homo erectus*	7	883
Chinese (Peking) *Homo erectus*	5	1,043
Homo sapiens	7	1,450

Some difference in estimated brain size is apparent between the Javanese and the Chou-k'ou-tien populations of *Homo erectus.* Thus, for seven Javanese craniums, the average is 883 cc, with a range from 750 to 1,030 cc; while for five Chou-k'ou-tien craniums, the capacity ranges from 915 to 1,225 cc and averages about 1,043 cc. That is, the mean capacity in the Peking fossils of *H. erectus* exceeds that of the Javanese by about 160 cc. Investigators note with interest that the cranium from Kung-wangling (also Chinese), which comes from an earlier period than do those of Chou-k'ou-tien and is an approximate contemporary of the earlier fossils from Java, shares with the Javanese group a smaller cranial capacity (780 cc).

Differences in brain size

Theoretically, the difference in brain size between the two groups of Asian fossils of *H. erectus* may be the consequence of further evolutionary increase in brain size in later populations of *H. erectus.* Alternatively, it may simply be interpreted as representing differences in average features between two different "races" or subspecies of *H. erectus.* Several African values are available, and in the case of the Koobi Fora and Olduvai individuals, these range from about 850 cc (ER 3733) to 1,067 cc (OH 9).

While the cranial capacity of *H. erectus* falls short of that of *H. sapiens* by about 570 cc on the average for the Javanese group and about 400 cc for the Peking group, *H. erectus,* in turn, exceeds the australopithecine capacities by an average of about 440 cc in the case of the Javanese fossils and about 600 cc for the Peking group. Thus, the cerebral gap between *Australopithecus* and *H. erectus* is slightly greater than that between *H. erectus* and *H. sapiens.* Into the former gap fit the cranial capacities of the group of fossils known as *Homo habilis.* Clearly, the last word has not been written on their affinities. The possible evolutionary place of the cranial capacity of *H. erectus* can be seen in Table 2 (above), but it perhaps emerges more clearly in Figure 19.

From W. Howells, *Evolution of Genus Homo* (Benjamin/Cummings Pub. Co., copyright © 1973), p. 47; reproduced by permission of Benjamin/Cummings Pub. Co.

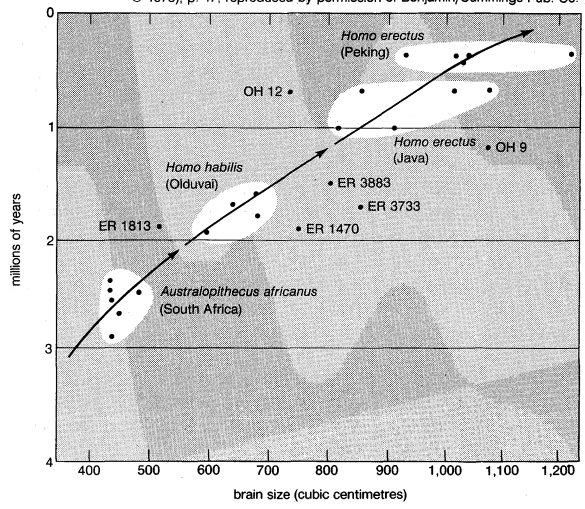

Figure 19: The increase in hominid cranial capacity over time.

Apart from their characteristically small capacity, the skulls of *H. erectus* show a number of distinctive features. The face, which is preserved in only a few specimens, is massively constructed and projecting in its lower parts. The bone forming the wall of the nose is thinner and more everted than in earlier *Homo* or *Australopithecus,* and the nasal profile is not too different from that seen in modern humans. The braincase is low, with sides that taper upward, and the bones of the cranial vault are thick. Over the eye sockets is a strongly jutting browridge, called a supraorbital torus. There is a flattened forehead, and the front part of the cranium immediately behind the supraorbital torus is appreciably constricted from side to side. A low ridge or keel of bone may extend from the frontal bone onto the parietals (side walls) along the midline, and there tend to be strongly developed crests in the mastoid region. The broad-based skull has a sharply curved occiput and a markedly thickened shelf of bone (occipital torus) that divides the upper and lower occipital surfaces. The area of neck-muscle attachment below the occipital torus is much larger than in *H. habilis* or *H. sapiens.* Other distinguishing features in *H. erectus* can be found on the underside of the cranium, especially at the joint of the mandible. The mandible itself is deep and robust and lacks chin development. The teeth are on the whole larger than those of *H. sapiens.*

Postcranial fossils

The femur is the most commonly recovered postcranial fossil. Apart from the Trinil specimen, the affinities of which are open to doubt, a number of femurs have been found at Chou-k'ou-tien, and more have been recovered from sites in Africa. Several notable characteristics have been observed in the *H. erectus* femur. The form of these bones resembles that of modern humans, and *H. erectus* must have walked upright efficiently. On the other hand, the construction of the bones is robust, a condition also seen in other skeletal members. This robusticity suggests that the life-style of *Homo erectus* was physically demanding.

Limb bones also supply information about the size of *H. erectus.* Size is important to any hominoid species, since it influences behaviour and various aspects of anatomy, including bodily proportions. One measure of size is stature,

or height. The femurs found at Chou-k'ou-tien and Koobi Fora are too broken to yield a good estimate of the height of these individuals, but accurate measurements of the skeleton numbered KNM-WT 15000 from Nariokotome have been made. Although he was not fully grown, it is thought that the Nariokotome boy would have reached about 160 centimetres in height, which is close to the stature expected for modern adult males.

The total pattern of the bodily structure of *H. erectus,* as preserved in the bones, is rather different from that of *H. sapiens.* Parts of the postcranial skeleton are robust but otherwise generally comparable to those of modern humans. The brain is relatively small, though not so small as that of *Australopithecus* and *H. habilis.* In addition, in this hominid's thick skull bones and extraordinarily developed eyebrow ridges and occipital torus, some investigators say they see unique, specialized features, not characteristic either of its presumed ancestors or of apes and not pointing to *H. sapiens* as the direction of subsequent evolution.

Some scientists even infer that these last traits show *Homo erectus* to have specialized so far off the modern human line that it could not have been ancestral to *Homo sapiens.* It is notable that the more ancient *Australopithecus* had thin skull bones and only modest protuberances on the cranium; while the later *H. sapiens* also tends to have thin skull bones with a marked diminution in the size of crests and ridges sculpted on the surface of the cranium. It is often said that only two choices are open in interpreting this situation: either *H. erectus,* with a thick cranium and large adornments on the skull, could not have been on any direct evolutionary line from *Australopithecus* to *H. sapiens;* or else *H. erectus* evolved specialized features from *Australopithecus* and then lost them again (or underwent a type of evolutionary reversal) to produce the thin, smooth cranium of modern *H. sapiens.*

Yet, the two choices offered for solving the problem are judged by some authorities to be oversimplified. It has been observed that the exponents of either view probably fail to take into account that there is very little evidence about the variability of these features—cranial thickness and external embellishments of the skull—among members of even one population of *H. erectus,* let alone among different populations of *H. erectus* dispersed through two or three large continents. Then, too, practically nothing is known about the climatic or ecological conditions under which cranial thickening occurred, or of the effect on skull growth of the brain enlargement that was so striking a feature of the evolutionary advance of earliest Pleistocene humans to the people of the later Middle Pleistocene and of the Late Pleistocene. These and many other questions need answers before *H. erectus* can be written off as an ancestor of *H. sapiens.* In the meantime, another hypothesis that meets most of the available evidence is that *H. erectus* was in the process of evolving from pre-*Homo erectus*—probably *Australopithecus* and *Homo habilis*—to post-*Homo erectus;* that is, to *Homo sapiens.* In most details, the bodily structure of *H. erectus* fulfills what might have been predicted for an intermediate between *Australopithecus* and *H. sapiens.*

Unanswered questions

BEHAVIORAL INFERENCES

To understand this species of fossil humans more completely requires looking past their bones and beyond their dispersal in time and space. What evidence is there that bears upon the behavioral or cultural pattern of their daily existence?

First, the discovery sites themselves may throw light on this question. At Chou-k'ou-tien, the remains of *H. erectus* were found in cave deposits; this in itself does not prove that these hominids were consistent cave dwellers. But the additional evidence of associated remains of stone and bone that seem to have been accumulated by these creatures—charred animal bones, collections of seeds, and what could be ancient hearths and charcoal—all point to *H. erectus* as having spent appreciable periods of time as a troglodyte (cave dweller) at Chou-k'ou-tien. The remains of Lan-t'ien, Trinil, Sangiran, and Modjokerto, as well as Ternifine and Olduvai, were all found in open sites, sometimes in stream gravels and clays, sometimes in river sandstones, in conglomerate and volcanic rocks, or in lake beds. These suggest that *H. erectus* also lived in open encampments along the banks of streams or on the shores of lakes; proximity to water was crucial to human survival. The remains of the Vértesszőllős individual showed that he occupied mud flats deposited along with minerals around springs in a tributary of the Danube River. These open presumed campsites revealed by excavation contain abundant stone implements and stone chips that seem to have resulted from manufacture, fractured and partly burnt bones of animals that could have been hunted for food, and traces of what appears to have been a hearth.

Thus, both Chou-k'ou-tien and Vértesszőllős have shown signs that Middle Pleistocene humans had a controlled mastery of fire. Indeed, outside a cave at Chou k'ou-tien, charcoal was found along with traces of a stone toolmaking industry in an open gully deposit that seems to be slightly older than the cave deposit itself (containing the bones of *H. erectus*). In this region of China, therefore, it has been observed that the earliest convincing indication of the use of fire by humans immediately precedes the earliest example of a cave being occupied by them. This supports the notion that successful cave dwelling by human creatures depended on their first having mastered fire.

Mastery of fire

It was not only cave dwelling that mastery of fire seems to have made possible. Able to keep warm, man was apparently able to move into colder climes; indeed, this factor may have speeded the migrations of ancient humans into the chilly, often glaciated regions of prehistoric Europe. Sooner or later, too, humans started cooking their food, thus reducing the work demanded of their teeth. This, in turn, may have played an important part in minimizing the evolutionary advantage of big teeth—cooked food needs far less cutting, tearing, and grinding than does raw food. This relaxation of the evolutionary selective pressure that favoured the survival of people with strong, big teeth may, in turn, have led directly to a diminution in the size of the teeth—one of the features that has come to distinguish *H. sapiens* from *H. erectus.*

Other signs of the culture of *Homo erectus* are the implements found in the same deposits as their bones. Chopping tools made from split pebbles characterize both the Chou-k'ou-tien and Vértesszőllős deposits; both are members of a so-called chopper–chopping-tool family of industries. At Ternifine, in northwestern Africa, *H. erectus* was found in association with totally different kinds of stone implements; these comprise bifacial hand axes and scrapers that have been characterized as representing what archaeologists call an early Acheulean industry. This is part of the great Acheulean hand-ax complex of human industry, remnants of which are found widely spread over large parts of Europe and Africa. An Acheulean industry is known also from Olduvai Gorge, as is a local, more ancient form of stone chopper manufacture known as the Oldowan industry; but the exact cultural associations of these stone tools with African *H. erectus* (as exemplified by OH 9) are uncertain.

Hence, *Homo erectus* has been found associated in some parts of the world with a chopper–chopping-tool tradition and in other places with an Acheulean bifaced hand-ax industrial complex. Numerous nonhominid animal bones occur also with the remains of *H. erectus;* sometimes these bones seem to have been broken deliberately or burned. From this evidence, it seems that *H. erectus* was a hunter. His bodily (including cerebral) endowment and manufactured equipment were so much superior to those of *Australopithecus* and *H. habilis* that it is highly probable that his food-collecting techniques, including hunting, also were better. Many scientists hold that *Australopithecus* and *H. habilis* were more scavengers than hunters, perhaps at best opportunistic hunters who seized their chance when a weak, young, sick, or aged animal crossed their paths. Indeed, many of the animal bones found in australopithecine deposits are of juvenile and aged creatures; and, although larger animal bones have been recovered from *H. habilis* deposits, these have exhibited tooth marks of nonhominid predators as well as cut marks. *H. erectus,* on the other hand, seems to have been a confirmed hunter, and his prey included animals of all age groups.

Diet

It can credibly be supposed that, as with present-day hunters such as the Kalahari San (Bushmen) and the Australian Aborigines, meat from the hunt formed only a part of the diet of *Homo erectus*. Other juicy morsels may have been furnished by snakes, birds and their eggs, locusts, scorpions, centipedes, tortoises, mice and other rodents, hedgehogs, fish, crustaceans, and numerous other edible forms of life. Even children could have caught many of these—as they do in the Kalahari today, before they are allowed to accompany the older men on the hunt. Vegetable food also must have played a big part in the diet of *H. erectus,* in the form of fleshy leaves, fruits, nuts, and roots. Accumulations of hackberry seeds, for example, were found in the Chou-k'ou-tien cave deposits.

There seems little doubt that *H. erectus* must have been omnivorous (as *H. sapiens* is today), for such a diet is the most opportunistic of all, and modern humans are the most opportunistic of all living primates. Emancipated from too narrow an environmental dependence, from too restricted a dietary regimen, humans have come to live off many diets, in many surroundings. *H. erectus* was probably one of the earliest of the great opportunists; and it is likely that his very opportunism endowed the species with evolutionary flexibility, with adaptability, and with a very plastic survival kit.

Another question that may be asked about *Homo erectus* culture is whether there is any evidence of ritual among these extinct people. There is no sign that they buried their dead; no complete burials have been found, no graves, no grave goods, no red ochre (a mineral used as a paint by later forms of hominids) on or around the bones. That cannibalism was practiced was once inferred from the Chou-k'ou-tien finds, but little evidence remains to support such a hypothesis.

EVOLUTIONARY IMPLICATIONS

Erectus as a possible direct ancestor of sapiens. A few workers have generally opposed the view that *H. erectus* was the direct ancestor of *H. sapiens.* L.S.B. Leakey argued energetically that *H. erectus* populations, particularly in Africa, overlap in time with more advanced *H. sapiens* and therefore cannot be ancestral to the latter. His arguments were based primarily on stratigraphic considerations and chronology, but some support for Leakey's point of view has come from the analysis of anatomical characteristics exhibited by the fossils. By emphasizing the distinction between "primitive" and "derived" traits in the reconstruction of relationships between species, several paleontologists have attempted to show that *H. erectus* does not make a suitable morphological ancestor for *H. sapiens.* Because the braincase is long and low, is thick-walled, and presents a strong supraorbital torus, they claim *H. erectus* to show derived (or specialized) characters not shared with more modern humans. At the same time, it is noted that *H. sapiens* does share some features—such as a rounded, lightly built cranium—with earlier hominids (*e.g.,* the smaller, or "gracile," *Australopithecus* species or *H. habilis*). It is clear that these paleontologists consider the early, gracile Plio-Pleistocene *H. habilis* to be more closely related to *H. sapiens* than is *H. erectus* (a conclusion with which Leakey would have agreed).

Leakey's argument against ancestry

These findings have not been widely accepted. Stratigraphic arguments concerning the overlap of (late) *H. erectus* and (early) *H. sapiens* are no longer compelling, and it is difficult to reject hypotheses of continuity between Middle and Late Pleistocene *Homo* populations on morphological grounds. When the effects of body size on scaling of the brain are taken into account, for example, it is apparent that gracile australopithecines (and *H. habilis*) have relatively rounded skulls because they are small-bodied creatures. General resemblances between these earlier hominids—with their more spherical, lightly constructed craniums—and *H. sapiens* therefore cannot be used to demonstrate a direct relationship. Instead, studies of size and scaling in human evolution have emphasized that representatives of *Homo* can be grouped into a reasonable ancestor–descendant sequence showing increases in body size through time. Despite having a heavier, more flattened braincase, *H. erectus* is not out of place in this sequence, and there is no reason to expect that hominid craniums should have remained subspherical in form as bodies grew larger in the Middle Pleistocene.

If this much is agreed, there is still uncertainty as to how and where populations of *H. erectus* evolved into early *H. sapiens.* This is a major question in the study of human evolution, and one that resists resolution even when hominid fossils from throughout the Old World are surveyed in detail. Several general hypotheses have been advanced, but there is still no firm consensus regarding models of gradual change (local evolution in different geographic regions) as opposed to scenarios of rapid evolution in one region followed by migration of the new populations into other areas.

Gradualistic views of the transition to Homo sapiens. A traditional view held by many paleontologists is that a species may be transformed gradually into a succeeding species in the same lineage. Such successive species in the evolutionary sequence are called chronospecies. The boundaries between chronospecies seem almost impossible to determine by any objective anatomic or functional criteria; what is left is the guesswork of "ruling off" at a moment in time to draw the boundary. Thus, competent authorities have seriously suggested that, in the last analysis, such a chronological boundary may have to be drawn arbitrarily between the last survivors of *H. erectus* and the earliest members of *H. sapiens.* The problem of defining the limits of chronospecies is not peculiar to *H. erectus;* it is one of the most vexing questions in paleontology.

Such gradual change with continuity between successive forms has been postulated particularly for North Africa (where *H. erectus* at Ternifine is seen as ancestral to later populations at Rabat, Temara, Jebel Irhoud, and elsewhere) and for Southeast Asia (where *H. erectus* at Sangiran may have progressed toward populations such as those at Ngandong and at Kow Swamp in Australia). Some workers have suggested that similar developments could have occurred in other parts of the world. Certainly the most thoroughly documented statement of this view has been provided by the American anthropologist Carleton S. Coon in *The Origin of Races* (1962). Coon departed from traditional gradualist theory when he postulated the

Coon's *The Origin of Races*

Painting by Zdenek Burian; reproduced with permission

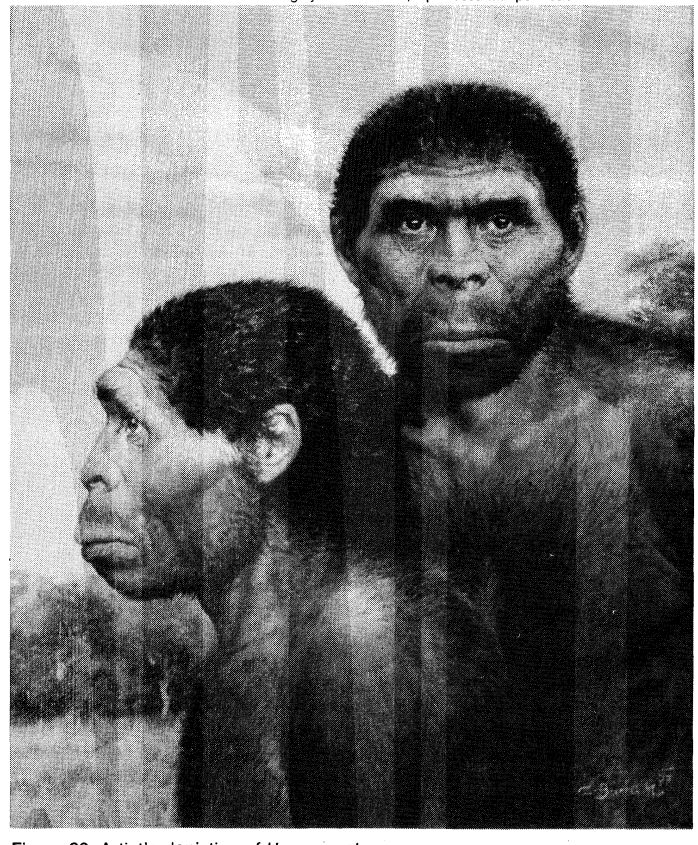

Figure 20: Artist's depiction of *Homo erectus.*

transition from *H. erectus* to *H. sapiens* as a crossing of a kind of evolutionary Rubicon—that is, a clear-cut boundary, or threshold, marked not only by bodily changes but also by striking cultural changes.

This supposed interrelation of cultural achievement and the shape and size of teeth, jaws, and brain is a theorized state of affairs with which many students of fossil hominids strongly disagree. Throughout the human fossil record, there are examples of dissociation between skull shape and size, on the one hand, and cultural achievement, on the other. A smaller-brained *H. erectus* from China seems to have been among the first humans to tame fire, while much bigger-brained people in other regions of the world, living later in time, have yielded no evidence that they knew how to handle fire. (Differences in inferred cultural activities between the African and Asian members of *H. erectus* have been emphasized above.)

The core of Coon's thesis is that *H. erectus* evolved into *H. sapiens* not once but five times, as each subspecies of *H. erectus,* living in its own territory, passed the postulated critical threshold. Since this part of Coon's theory depends on accepting his supposed *erectus–sapiens* threshold as correct, it is opposed by those who find the threshold concept at variance with the modern genetic theory of evolutionary change.

A corollary of this concept was Coon's suggestion that different subspecies (or "races") of man evolved at different rates and, hence, crossed the *erectus–sapiens* threshold at different times. In particular, Coon has suggested that "the step from the ancestral *H. erectus* to the modern *H. sapiens* was taken by Caucasoid man in Europe no less than 200,000 years before the same step was taken by Negro man in Africa." Not only was this part of Coon's reasoning based on a concept that is at odds with modern evolutionary theory, but some of the assumed "facts" on which it was based are highly problematic. He claimed that the races of today had already appeared before the *erectus–sapiens* transition. Apparently by allocating two very early fossil human skulls from Europe (Swanscombe from England and Steinheim from Germany) to the European, or Caucasoid, "race," although they lived 250,000 years ago, he concluded that the supposed *erectus–sapiens* transition had occurred among Europeans, or Caucasoids, as long as 250,000 years ago. Few if any paleoanthropologists would agree with Coon that these early skulls are to be recognized as those of members of the Caucasoid, or European, "racial" group, as generally understood.

Turning to Africa, Coon claimed that "Rhodesian man" (represented by parts of several skeletons found in Zambia [formerly Northern Rhodesia] in 1921) belonged to *H. erectus.* Coon, who thought that Rhodesian man lived only 30,000 or 40,000 years ago, thus argued that *H. erectus* was still present in Africa long after he had disappeared from the European scene. This argument hinges on controversial judgments of the species to which Rhodesian man is to be assigned and on dating of the fossil remains. In contrast to Coon, most paleoanthropologists regard Rhodesian man as a member of an African subspecies of *H. sapiens,* commonly dubbed *H. sapiens rhodesiensis.* Also, it is now thought that the bones are of later Middle Pleistocene age. The evidence for the late survival of *H. erectus* in Africa is questionable at best.

Alternative modes of species change. That phyletic gradualism marks the transition from *H. erectus* to *H. sapiens* is one interpretation of the fossil record, but the available evidence can also be read differently. Some workers who do not hold Coon's ideas of body change tied to cultural achievement have come to accept what can be termed a punctuational view of human evolution. In their view, species are seen as more stable entities, not simply as arbitrarily defined segments of a lineage. It has been suggested that species such as *H. erectus* may be expected to exhibit evolutionary stasis (*i.e.,* little or no morphological change) over long periods of time. The transition from one species to a descendant form may occur relatively rapidly in geologic terms and in a restricted geographic area rather than on a worldwide basis. Whether this may be a correct interpretation of the situation involving *H. erectus* and *H. sapiens* is unclear; that is, whether *H. sapiens* evolved from populations of more archaic *H. erectus* gradually, or rapidly during a short "pulse" of evolution late in the Middle Pleistocene, has not been settled, although a good deal of attention has been given to the problem.

Punctuational view of evolution

The continuation of the argument underlines the need for more fossils to establish the range of physical variation of *H. erectus* and for more discoveries in good archaeological contexts that permit increasingly precise dating. Additions to these two bodies of data may settle remaining questions and bring the unsolved problems of phylogeny and classification of *H. erectus* nearer to resolution.

(P.V.T./G.P.Ri.)

Homo sapiens

ORIGIN AND EARLY EVOLUTION

Homo sapiens, the hominid species that includes modern humans, emerged during the Pleistocene epoch. The date of the transition from the Pliocene to the Pleistocene is an arbitrary point in time, and geologists have not found it easy to agree on its definition; for years the generally accepted date was about 2.5 million years ago, but more recently a date of 1.6 million years ago has been adopted. Broadly speaking, it was marked by the gradual onset of a cooler climate in many parts of the world about 2.5 million years ago and by a general lowering of temperature that finally led to the great Ice Ages, during which, in modern temperate zones, ice caps and glaciers originating at high altitude and latitude spread out for considerable distances over lowlands. This process of glaciation was recurrent and extended throughout most of the Pleistocene epoch; it is now generally agreed that there were four main glacial periods, of varying duration and severity, separated by interglacial periods during which the climate became warmer and in some cases (even in Europe) almost subtropical. Evidence of the successive glaciations can be detected in the characteristic geologic deposits left by melting ice and also in the fossil remains of Arctic or subarctic animals and plants from the glaciated regions. By the determination of the rhythmic succession of glacial and interglacial phases during the Pleistocene, geologists have provided a time scale for inferring the relative antiquity of fossil hominids and the implements they left behind.

The Ice Ages

Even in those parts of the world where there was no actual glaciation, such as the equatorial regions, there was a succession of alternating rainy and dry periods, but there is no evidence that these pluvial and interpluvial phases were closely correlated with the glacial and interglacial periods in the Northern and Southern hemispheres. The recurrent glaciations were accompanied by considerable falls in sea level, which had a profound effect on the formation of river valleys and caused the opening of land bridges that permitted migration of hominid populations and, consequently, encouraged gene flow and mixture between such populations. Similarly, the rise in sea levels during the interglacials cut these routes and produced isolation of hominid populations. With a fall in sea level, the erosive power of the rivers increased, and they cut their valleys more deeply. With the rise in sea level during the interglacial periods, the rivers flowed more sluggishly and laid down such stratified deposits as gravel and sand over their alluvial plains. As a result, series of terraces were formed along the riverbanks, and it is in these terraces that some of the oldest remains of Paleolithic (Old Stone Age) humans and their stone implements have been found. The time relationship of the terraces to the glaciations has been worked out in some detail by geologists, and largely on this basis the relative antiquity of the fossils can be established.

Since the mid-20th century, new chemical and physical methods that have been developed have assisted greatly in establishing a chronology for *Homo sapiens* that enables paleontologists to set their materials in a proper phylogenetic context. Relative dating (the assessment of contemporaneity of a fossil and its layer) has been aided by the fluorine and uranium methods, while absolute dating (or age in years) has often established the sequence of fossils in the deposits.

The antiquity of Homo sapiens. It is a curious fact that,

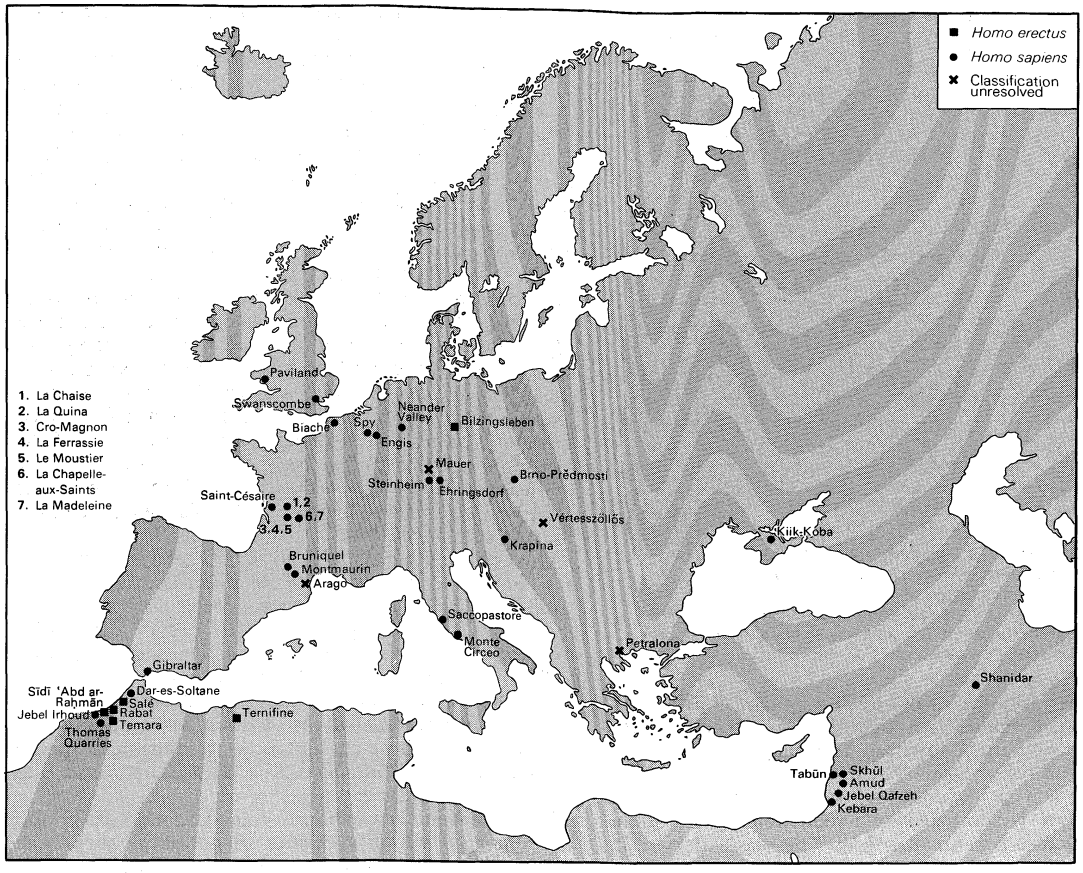

Figure 21: Major sites of hominid fossil finds in Europe, North Africa, and the Middle East.

Defining *H. sapiens*

although evidence for the evolution of man is extensive, direct fossil evidence of the earliest members of the species *Homo sapiens* is relatively scarce. The species *H. sapiens* (of which the modern human races comprise a number of different geographic varieties) may be defined in terms of the anatomic characters shared by its members. The definition for prehistoric representatives of the species must be limited to skeletal characters, the only remains to be found, and includes such features as a mean cranial capacity of about 1,350 cubic centimetres (82 cubic inches), an approximately vertical forehead, a rounded occipital (back) part of the skull with a relatively small area for the attachment of the neck musculature, jaws and teeth of reduced size, small canine teeth of spatulate form, the presence of a pointed or projecting chin, and limb bones adapted to a fully erect posture and gait. Any skeletal remains that conform to this pattern to an extent that precludes classification in other groups of higher primates must be assumed to belong to anatomically modern *H. sapiens.* In the past there was a tendency to create entirely new species of *Homo* on the basis of fragments of prehistoric human skeletons, even though the remains showed no significant differences from modern man. This tendency was prompted by the supposed antiquity of the remains or by a failure to realize how variable some features are even in modern man. The species of the genus *Homo* that immediately preceded *H. sapiens* was *H. erectus,* and it is most likely that sapient humans (*H. sapiens*) evolved from *H. erectus.*

Bodily structure of Homo sapiens. Fossil remains of early *Homo sapiens* are known from sites in Africa, the Middle East, and Europe, but later examples come from a wide range of sites in the Old World as a whole. It is of particular interest to look at the skulls of some of the early specimens, for it is in their functional morphology that the combination of features that results in attribution to *Homo sapiens* is often found.

Evolution of the human skull. The human skull is composed of both cranial and facial portions. The cranium consists of the skull vault and base, while the facial skeleton consists of the region of the eye sockets, nose, cheekbones, upper jaw (orbital and maxillary region), and the region of the lower jaw (mandibular region). During the evolution of the hominid skull from its apelike precursors, there are a number of general trends that can readily be discerned. The principal trends are the gradual increase in brain size (as measured by cranial capacity), the rounding of the cranial vault, and the gradual reduction of the size of the whole masticatory complex, including both the upper and lower jaws and the teeth. These trends lead to an overall change in skull shape and proportions, so that, while the vault expands, the "muzzle" tends to retract from a protruding (prognathic) form to a straighter-faced (orthognathic) appearance. At the same time, the whole skull tends to become lighter and more delicate in its structures. If this process is examined a little more closely, it can be at least partly explained in mechanical terms. A comparison of the skull of *H. erectus* and a modern *H. sapiens* skull illustrates the point (Figure 22).

The skull of *H. erectus* has a low skull vault, a sharply receding forehead, a lower cranial capacity (averaging less than 1,000 cubic centimetres), a large face with big teeth and jaws, and a jutting occipital region (the back of the head). Muscles in the occipital region relate principally to the balance of the head on the vertebral column (spine); those of the temporal region (at the sides of the head) relate to the working of the jaw apparatus. In a skull with a large face and a heavy jaw, the muscles of the occipital region, which balance the head on the neck (nuchal musculature), must be strong in order to counterbalance the heavy face and jaw. This results in marked occipital ridges in *H. erectus.* Similarly, large jaws and teeth demand well-developed muscles of mastication with strong attachments to the cranium. In order to dissipate the considerable forces produced by these muscles when the teeth meet during chewing, there is in *H. erectus* a stout maxilla (upper jaw) and a heavy supraorbital ridge, or torus (browridge), extending the whole width of the cranium, a ridge rendered even more necessary because *H. erectus* had a skull of lower cranial capacity and therefore lacked a well-developed forehead. Such skulls are found in the examples of *H. erectus* known from both China and Java.

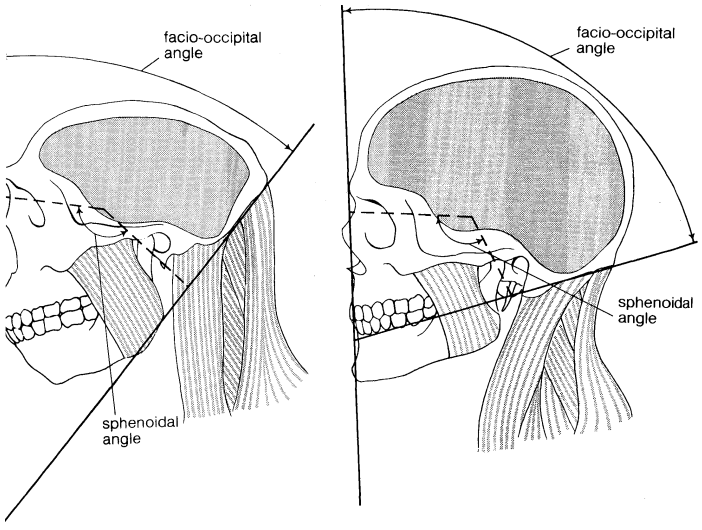

Figure 22: *Comparison of Homo erectus and Homo sapiens skulls, showing differences in cranial capacity, sphenoidal angle, and facio-occipital angle.*
(Left) Small brain, large muscles, and flattened skull vault of *H. erectus* skull. (Right) Large brain, small muscles, and rounded skull vault of *H. sapiens* skull.

The skull of *H. sapiens*

By comparison, the skulls of *H. sapiens* show an expanded cranial vault with a high maximum breadth and a well-developed vertical forehead, resulting from expansion of the frontal region of the brain, so that the supraorbital ridge is, as it were, "overgrown" and buried. At the same time, the face is shortened by a reduction in size of the jaws, which also bear smaller teeth. The masticatory muscles therefore need not be so large; and the forces that they produce are less, so that the need to neutralize them through the face is reduced. Thus, the facial structure can be more delicate, and the need for a heavy supraorbital ridge is removed. Finally, the lighter face does not require such powerful muscles behind the point of balance of the skull; as a result, the neck muscles can be reduced in size and their areas of attachment to the skull brought more underneath the back of the head.

The decrease in the size of the teeth of *H. sapiens* tends to leave the nose and point of the jaw as prominent features of the face. Thus, the presence of a mental protuberance (chin) is an obvious character of the jaw of *H. sapiens* and provides external support for the symphysial region (the point at which the two sides of the jaw have grown together).

Dental characteristics. The dental characteristics of *H. sapiens* revolve around the basic fact of reduction of the masticatory apparatus. Thus, the dentition as a whole shows tooth crowding (dento-alveolar disproportion), accompanied by smallness of the individual teeth and marked reduction in size of the third molar. In modern populations the third molars tend to be genetically unstable; *i.e.,* they are frequently absent or malpositioned (impacted wisdom teeth). Similarly, but less frequently, the lateral incisors (the cutting teeth on either side of the front teeth) may be absent. In other respects the dentition of *H. sapiens* is best contrasted with that of *H. erectus* in that it lacks some of the special features known from this species. For example, the teeth of *H. sapiens* are less likely to show secondary enamel wrinkling of the occlusal (chewing) surface of the teeth and less taurodontism (pulp space enlargement), although this is still well known from Neanderthals. The eruption sequence of teeth seems to be an unreliable criterion because variability is common in modern populations and may have been so in the past.

Postcranial skeleton. The form of the skeleton of the trunk and limbs of *Homo sapiens* (postcranial skeleton) is characterized by its adaptation for a fully upright posture and a striding bipedal gait. This remarkable locomotor capability is the final expression of an evolutionary process that has taken at least four million years to achieve, and so some aspects of the process are well known from earlier members of the genus *Homo* and also from the genus *Australopithecus.*

Bipedal posture and gait

In terms of posture, the bipedal vertebral column is held upright and shows two secondarily developed curves when viewed from the side, one in the lumbar region of the back (small of the back) and the other in the neck region. From the front the column should appear straight. These curves allow the weight to be evenly disposed about the line of gravity, which passes vertically through the second sacral vertebra (at the base of the spine) and behind the rotation centres of the two hip joints. This permits the pelvis to tip backward just beyond the vertical and rest upon a straplike ligament across the front of the hip joint, a sophisticated effort-saving mechanism that allows most of the muscles around the hip to relax so that the upright stance is an economical posture. Associated with this is the ability to lock the knees back, which also relaxes some surrounding muscles. To rise from the squatting or seated position requires considerable power of extension of the hip joints, and this is provided by the large buttock muscle (gluteus maximus) and a backward extension (posterior superior iliac spine) of the bony pelvic flange (blade of the ilium) for its attachment.

An alternating bipedal gait, to be fully efficient, must allow each leg to swing clear of the ground during walking; this is provided for by a pelvic-tilt mechanism that raises the side of the swinging leg. In addition, such a gait must avoid wild side-to-side movements of the centre of gravity, and this is achieved by inclining the thighbones toward the midline and thus bringing the feet closer together. Finally the bipedal adaptations of the modern human foot are such that both weight and force are transmitted to the ground through a propulsive system of short levers that permits a heel–toe stride.

The upper-limb adaptations to bipedalism are fewer and are concerned with the dynamic balance of the body while moving. Arm swinging is a normal part of bipedalism and compensates for the twist of the body toward the side opposite to the advancing foot. The selective advantages of bipedalism, in terms of the upper limb, are immense in that they free the hands for the carriage of infants, food, tools, or weapons, as well as permitting the development of the hands for a manipulative role such as toolmaking. Although hominids below the human level of evolutionary advance could make tools, the refinement and exploitation of tools demanded hands capable of both power and precision grips. The power grip involves primarily the inner, or ulnar, side of the hand and permits a firm grip on a branch, a rock, or hammer handle. The precision grip involves the outer, or radial, fingers and thumb, as in using a small stone for engraving, a small brush for painting, or a pen for writing (Figure 23). This requires the bringing together of the tips of the opposed thumb and the next two fingers in order to grip a small object, a grip that demands that the lengths of the index finger and thumb be proportionate and that the joint at the base of the thumb

Freeing the hands for tool use

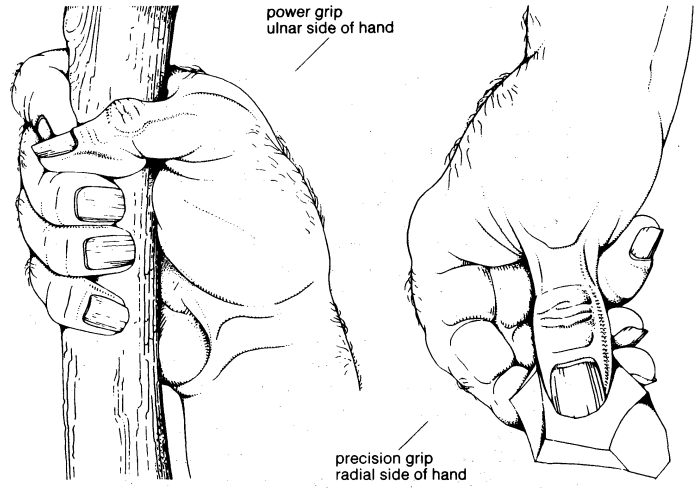

Figure 23: Hand grips.

be of a special saddle-shaped variety. It seems likely that the precision grip evolved later than the power grip and that its perfection may even have been a specialization in *Homo sapiens.* Only when human hands had evolved to this level, concomitantly with brain expansion, could manipulative skills give expression to the artistic impulse in terms of cave painting, bas-relief, and sculpture in the round, all of which are sophisticated behavioral correlates of a highly evolved individual, in terms of both locomotor and intellectual skills.

Fossil evidence. Having looked at the problems of the identification of human characteristics and also at the difficulties of interpreting the significance of these characteristics singly or in groups, it is appropriate to consider the early fossil materials that might provide reasonable candidates for attribution to *Homo sapiens.* These are likely to be found during the late Middle Pleistocene to Late Pleistocene (about 200,000 to about 15,000 years ago)—in archaeological terms, during the Paleolithic period, or Old Stone Age. Naturally, the quantity of fossil material recoverable tends to increase markedly as more recent periods are dealt with, so that the total number of human specimens amounts to some hundreds. On the other hand, toward the earlier end of this time range, the fossils available for study are far fewer in number. Advances in dating methods have eliminated a number of specimens formerly given an antiquity that they do not deserve, so that the picture has been somewhat clarified. A number of specimens remain that often in the past have been divided into the Neanderthals (or Neandertals) and the sapients (*i.e.,* members of *Homo sapiens sapiens,* the same subspecies as modern humans).

The problem of Neanderthal man. This group was originally recognized by a combination of cranial, dental, and postcranial features that were generally considered distinct enough to classify Neanderthals as a separate species. Thus *Homo neanderthalensis* was described on morphological grounds and regarded as a specialized group of the genus *Homo* that lived during the last glaciation (Würm glacial stage) in Eurasia. The sites from which examples of the Neanderthals were recovered have commonly produced tools of the Mousterian culture, a stone tool industry dating from about 90,000 to about 30,000 years ago. Quite suddenly these people disappeared from the fossil record, and various theories have been put forward to account for their disappearance. In addition to these "classic" Neanderthals—exemplified by remains from such sites as the Neander Valley (West Germany); La Chapelle-aux-Saints, Le Moustier, La Ferrassie, and La Quina (France); Gibraltar; Monte Circeo (Italy); Shanidar (Iraq); and Kiik-Koba (Soviet Union)—there are also remains from Krapina (Yugoslavia), Saccopastore (Italy), Ehringsdorf (East Germany), and Tabūn (on Mount Carmel), Amud, and Kebara (Israel).

Many have considered that the classic Neanderthals were a cold-adapted, specialized side branch from the human line that became isolated in Europe and then became extinct as the climate improved. Some Neanderthals are considered to have avoided this specialization and continued to give rise to the later modern sapient populations. This involves invoking the so-called catastrophic demise of classic Neanderthals. An alternative view placed classic Neanderthals in the modern human evolutionary line, their disappearance both anatomically and culturally being due to an absorption process involving some contribution of Neanderthal genes to the succeeding populations. Most modern systematists tend to include Neanderthals within the species *Homo sapiens* and only accord subspecific status to the combination of morphological characters that make up the anatomy of the classic Neanderthals of the Würm glaciation; they are thus named *Homo sapiens neanderthalensis* rather than *Homo neanderthalensis.* Some workers subsequently have advocated returning Neanderthal man to the status of a separate species.

Neanderthals' place in human evolution

In addition to the European and Middle Eastern evidence of Neanderthals, a number of specimens from Africa and Asia must be considered. Examples of this group could include Rhodesian man (Zambia, formerly Northern Rhodesia), Solo man (Java), and Saldanha man (South Africa), all from Late Pleistocene deposits (130,000 to 10,000 years ago). Their very presence shows that the whole problem of defining *Homo sapiens* must be considered in a wider context and cannot reasonably be considered in European terms alone. Clearly, the problem of the origin of *Homo sapiens* from his Middle Pleistocene forebears is complex; hence, it is valuable to examine in detail those specimens that come from the earliest well-dated sites, in order to try to discern the centre of sapient evolution (if such a centre exists) and to discover which are the earliest specimens that show incipient sapient characters. Bearing in mind the principle of mosaic evolution, which has been demonstrated as an important part of the evolutionary process, it is not reasonable to suppose that all of the features that have been mentioned as characteristic of *Homo sapiens* will appear together in these early specimens. Thus, a mixture of advanced and less advanced features may be expected in early forms, some perhaps relating to *Homo erectus,* to Neanderthals, or to modern humans as they are today.

The Omo hominids. In 1967 the Kenyan group of an international expedition to the Omo River in southern Ethiopia led by the paleoanthropologist Richard Leakey recovered large parts of two skulls and a large number of limb bones from two sites that have been dated to the East African late Middle Pleistocene or early Late Pleistocene (about 200,000 to 70,000 years ago). The most complete skull (Omo II) is long and narrow with a receding forehead, a rounded cranial vault, and a prominent occipital ridge, below which lies a flattened neck region. The bones of the skull vault are thick, and the maximum breadth of the skull is low in the temporal region, which is marked by the presence of large mastoid processes (bony projections below and behind the ears). The completeness of this skull has allowed accurate estimations of the cranial volume at about 1,430 cubic centimetres. Preliminary assessment of the taxonomic affinities of this skull has suggested that, while it shows a number of specialized features, some of which are reminiscent of the earlier *Homo erectus* skulls, it also has some advanced features, such as the rounding of the vault, the large mastoid processes, and the high cranial capacity. In view of this, it has been regarded as an early example of the African segment of evolving *Homo sapiens.*

Features of the Omo skulls

The other skull (Omo I) recovered from the same general area was accompanied by a large number of limb bones and is in many ways quite different from Omo II. Although the forehead still slopes from a prominent supraorbital (brow) ridge, the vault is very well rounded down to the occipital region. There is a prominent down-turned mastoid process. The vault of this skull is robust by modern standards, but it is less so than that of Omo II.

Viewed from the rear, the two skulls show striking differences—the Omo I skull is far more modern in outline. The limb bones of Omo I are rugged and well marked by muscle impressions, but in general they have few, if any, features that would distinguish them from the limb bones of *Homo sapiens.* A preliminary assessment of Omo I therefore suggests that, although it has some specialized features, they are far fewer than those of the Omo II skull; at the same time, its advanced features are perhaps more marked.

Perhaps the most striking feature of the whole Omo assemblage is once again the mixed character of each of the two principal specimens that are said to be of the same geologic age. The Omo II skull undeniably has features that can be paralleled in earlier forms of *Homo,* and at the same time the Omo I specimen seems to foreshadow the later morphology of modern *Homo sapiens,* particularly in the occipital region of the skull and in the limb bones. It is possible that the mosaic evolutionary process is seen here in microcosm. Not only is differential evolution occurring within individual representatives of contemporary populations but also between populations in one area of East Africa.

The Omo I remains were partly in situ in Member I of the Kibish Formation, a layer of undeformed Pleistocene lake and river sediments to the north of Lake Turkana (Lake Rudolf). The Kibish Formation consists of four members

(major strata), the lowest of which (Member I) is more than 40 metres (130 feet) thick and has seven stratigraphic subunits. It was from Member I that the Omo I skull was recovered, while the Omo II skull has been referred to the same level in an analogous stratigraphic sequence.

The dating of Omo

The relative dating of the site has been established by means of the fluorine, nitrogen, and uranium tests, and the fauna recovered is not inconsistent with the late Middle Pleistocene date (*c.* 200,000–100,000 years ago), but it cannot be positively dated to this time level. The stone flakes are also undiagnostic in terms of relative archaeological dating. Direct chronometric dating has been attempted on material from the deposit, making use of both the carbon-14 and the uranium–thorium radiometric methods. The carbon-14 test has shown that the upper part of Member III, Member II, and Member I are all too old to be dated by this method and, therefore, older than 40,000–35,000 years. Member I of the Kibish Formation has been dated to 130,000 years ago by the uranium–thorium method, and thus both Omo I and Omo II are regarded as being of this age because their sites are stratigraphically equivalent.

Ngaloba man. In 1976 a skull was found in the Ngaloba beds at the Laetoli site in Tanzania. These beds consist of deposits of sandstone and clay stone that are preserved in patches; these patches are made up of redeposited detritus that has been eroded from the underlying Ndolanya and Laetoli beds. In the upper Ngaloba beds, stone tools have been recovered that have been attributed to the African Middle Stone Age cultural complex, and they resemble tools recovered from the upper Ndutu beds at nearby Olduvai Gorge. The dating of the Ngaloba beds at Laetoli is based on correlation with a marker tuff in the lower unit of the Ndutu beds at Olduvai, and its age is estimated at about 120,000 years.

The Laetoli skull (LH 18) is nearly complete, including most of the cranium and much of the face. The forehead is recessed, the occiput is rounded, and the mastoid process is small. The supraorbital torus is divided. The skull clearly belongs to an archaic form of *H. sapiens;* its morphology is modern, although archaic features are retained. The skull differs considerably from those of *H. erectus* or of Neanderthal hominids. Its greatest resemblance is with the craniums of other archaic *H. sapiens* such as Kabwe (Rhodesian man) and Omo I. If the date of this skull is accepted it is one of the earliest examples of *H. sapiens* that is known from Africa and adds to the view that this species of human arose there.

Border Cave man. The Border Cave site lies on the boundary between the black state of KwaZulu in South Africa and Swaziland. It has been known for many years and has from time to time produced human remains and artifacts. The various levels in the cave have been dated by correlation, but more recent carbon-14 dating of the Middle Stone Age layers showed them to be more than 48,000 years old. Newer data has shown that the hominid finds 1, 2, and 3 from the Border Cave are between 110,000 and 90,000 years old. These estimates are based on the correlation of climatic and cultural evidence derived from other African sites.

The remains consist of fragments of a skull (Border Cave 1), a mandible (Border Cave 2), and parts of an infant's skeleton (Border Cave 3). The features of the skull are very close to those of anatomically modern man and are without doubt to be attributed to *H. sapiens.* If the dating is correct, Border Cave man is another example of early *H. sapiens* from the African continent, this time from the south rather than the east.

Jebel Qafzeh. Jebel Qafzeh, a cave site in Israel not far from Nazareth, has also been known for many years, and the remains of about a dozen individuals have been recovered from it. The cave is large, and 24 layers have been identified that contain human remains and stone tools of the Levalloiso-Mousterian type. Animal remains are extensive, including those of horses, rhinoceroses, fallow deer, wild oxen, and gazelles. The site has been dated on the basis of the fauna and by a technique called amino-acid racemization, as well as by archaeological appraisal. The earlier evidence suggested an age of between 78,000 and 39,000 years, but subsequent evidence has suggested that the skeletons should be dated to 115,000 to 90,000 years ago.

The most completely reconstructed skulls show that they have no resemblance to either *H. erectus* or to Neanderthals but rather a clear affinity to *H. sapiens.* The cranial vaults are high and well rounded with no exaggerated browridges, and one skull, Qafzeh 6, has a cranial capacity of about 1,570 cubic centimetres. The limb bones are similar to those of modern humans. Once again, if the dating is correct, these hominids represent early examples of *H. sapiens* from the Middle East, thus linking the African populations with those of Europe.

Vértesszőllős man. In 1965 some fossil remains were recovered from a site in Hungary at the foot of the Gerecse Mountains. In a quarry cut into the fourth terrace of the Danube River system, a number of occupation layers were recognized. The third of these layers contained some human remains as well as a tool culture and some fossil mammalian bones. The site is known as Vértesszőllős, and the first finds were some fragments of milk teeth from the mandible of a child (Vértesszőllős I). Rather more important was the second find (Vértesszőllős II), a fine adult occipital bone that was broken into two pieces. The bone is stoutly constructed, having thick walls in the ear region, whereas the floor of the depression for each cerebellar hemisphere (at the base of the skull) is relatively thin. When seen in profile, the bone is divided into two parts: an upper, curved occipital portion and a lower, flattened neck portion. The flattened area is incomplete and does not include the margin of the foramen magnum (the opening at the base of the skull through which the spinal cord passes as it merges with the medulla oblongata), the borders of which are broken away. The attachments of the neck muscles are well marked on the outer surface of the flattened area, which also has signs of an occipitomastoid crest (a crest of the occipital bone near the mastoid process), a primitive feature. The occipital ridge, or torus, that divides the upper, curved portion from the lower, flattened area is prominent and continuous across the bone; indeed, it is so prominent that in its central portion it is even undercut. On the inside of the skull, the cerebellar fossae (depressions in the skull where the lobes of the cerebellum lie) are rather small compared to the impressions above for the occipital lobes of the brain. The internal occipital protuberance lies well below the external occipital protuberance (inion), and there are distinct impressions for the venous sinuses (marks where blood vessels lie against the skull). The cranial volume of this individual has been estimated at about 1,400 cubic centimetres.

Features of cranial remains

The remains have been attributed to a male less than 30 years old. The thickness and the breadth of the bone and the undivided occipital ridge are relatively primitive features, but the height and curvatures of the upper segment are considered modern; the brain configuration is primitive in spite of its large size. The morphological comparisons and the statistical analysis of this specimen suggest that, although this population took its origin with *H. erectus,* it had differentiated from this group and perhaps ought to be classified as at the beginning of a progressive evolutionary line.

Perhaps the principal significance of this specimen, apart from its structure, is that it is dated to a warm phase within the second (Mindel) glaciation, 500,000 to 400,000 years ago. The specimen has been assigned to an unusual new category *Homo* (*erectus seu sapiens*) *palaeohungaricus;* whatever the precise taxonomic meaning of this name, it is clear that it is regarded as an intermediate form, the mixed *H. sapiens* and *H. erectus* features of which are the result of mosaic evolution.

Petralona man. In 1960 a cranium was recovered from a cave in Thessaloníki *nomós* (department) in eastern Greece. The cave is part of an extensive system in calcareous Mesozoic deposits containing a large quantity of fossil mammalian bones, including horse, cave bear, cave lion, and others. Three superimposed faunas have been identified, and the skull has been linked to the oldest of the three. This suggests that the skull is older than the later Middle Pleistocene. The date of the skull is disputed, but

Age of the Petralona skull

the general consensus is that it may be as old as 400,000 years. This still makes the skull one of the oldest human finds from Europe. The question of its relationships is also unclear. While the skull seems more advanced than *H. erectus,* it has some *H. erectus* features; on the other hand, it can also be distinguished from both Neanderthals and from modern *H. sapiens,* while possessing some features that are more advanced than *H. erectus.*

Tautavel man. The Arago cave near Tautavel, in southern France, has been excavated since 1964 and has yielded numerous fossils of mammals as well as stone tools attributed to the Tayacian industry. The dating of the site has been a matter of some doubt; at first it was given as about 200,000 years ago and subsequently as early as 400,000 years ago. In either case this is an early date for human remains in Europe. The Arago skull was found on a living floor (*i.e.,* layer of human occupation) and consists of a partially deformed face and part of a vault that has been reconstructed. The result is equivocal: in some ways the skull resembles *H. erectus* and in other ways Neanderthals. On this basis it has been termed a "pre-Neanderthal." There is no doubt, however, that it shows not only archaic *H. erectus* features but also advanced characteristics which may be related to adaptation to cold in an early and primitive example of *H. sapiens.*

Swanscombe man. A more widely known example of early *H. sapiens* is derived from the Thames Middle Gravels at Swanscombe in North Kent, Eng., which are gravels attributed to the Mindel–Riss interglacial stage, 400,000 to 200,000 years ago. Here, at a site well known for its Paleolithic tools, two parts of a human skull were recovered in 1935 and 1936. About 20 years later, a third piece was recovered that fits with the other two pieces to form the back half of a cranial vault. All three bones are virtually complete, and it is believed that they belonged to a young adult. Generally speaking, the bones are modern; the bones of the skull vault are rather thick, however, and the skull is broad at the back. The occipital bone shows no sign of the heavy occipital torus, or "chignon," characteristic of Neanderthals, and the occipital ridge is modest, although a little more prominent at its ends than in the middle. This bone is rounded both above and below the ridge, in contrast with the Vértesszőllős occipital. The position of the foramen magnum and the joints for the vertebral column are modern, so that the posture of the head does not appear to differ significantly from that of modern man. In the original report on these bones, it was stated that by measurements the Swanscombe skull could not be distinguished from that of *H. sapiens.* Despite this, several authorities have been less convinced by the sapient features of Swanscombe man and have emphasized the Neanderthal features of the bones. A more recent reappraisal of the Swanscombe material, making use of multivariate statistics, suggested that it is necessary to emphasize the interrelatedness of all the early forms of *Homo* and that it is no longer possible to maintain specific status for each form. It is preferred, rather, to regard them all as a spectrum of varieties within one species. It was suggested further that Swanscombe should be regarded as belonging to a "Neanderthaloid Intermediate" group that contains the Ehringsdorf, Skhūl V, Krapina, and Steinheim specimens.

Classifying Swanscombe man

Once again, as with Vértesszőllős, there is a mixture of features that, at this somewhat later date in Europe, combines sapient and Neanderthal characteristics in keeping with the concept of mosaic evolution.

Steinheim man. Another skull of approximately the same age as the Swanscombe skull is known from the Steinheim site, near Stuttgart, W.Ger. This skull was recovered in 1933 from a gravel pit cut into Pleistocene deposits that have been dated to the Mindel–Riss interglacial stage. This skull is more complete than either of those mentioned above but suffers from some distortion, perhaps due to the pressure of the deposits. It consists of the cranium and the right side of the face of a young adult; much of the base of the skull is missing, but there is a good deal of the palate and also some teeth present, including a premolar and all the molars of both sides. The face is straight, with little projection of the upper jaw, while the vault of the skull appears to be long and narrow but fairly well rounded in profile, and there is only moderate frontal flattening. The occipital region is marked by a very low occipital ridge, and it does not have a Neanderthal "bun." The frontal region has a pronounced but divided browridge. The cranial volume has been estimated variously between 1,070 and 1,175 cubic centimetres, but the distortion precludes accurate measurement.

The teeth are of particular importance because they are perhaps the earliest sapient teeth known. The premolar crown is symmetrical in shape but has a large outer and a smaller inner cusp. The molars decrease in size from front to back, but the third molar is markedly smaller than the other two. All of the teeth have some degree of taurodontism (enlarged pulp cavities).

Again, there is a mixture of primitive and advanced features in this skull, the principal resemblances of which are, with the Swanscombe skull, described above. The contour of the occipital region and the rounded vault are advanced sapient features, whereas the broad nasal opening and the browridge recall the Neanderthal shape. The teeth are small and sapient in both form and molar size, while the marked reduction of the size of the third molars is a distinctly modern feature. The enlarged pulp cavities are sometimes regarded as primitive since they are widely known from both *Homo erectus* and Neanderthal teeth. However, this trait is still frequently observed in the teeth of modern populations.

Taxonomic affiliations

Earlier opinions have suggested that Steinheim man represented an intermediate stage between *H. erectus* and the later forms of *Homo,* thus being ancestral to both Neanderthal and modern man. Another view does not accept the Steinheim fossil as being ancestral to the classic Neanderthal and modern man, suggesting instead that it represents a stage on a separate but parallel line leading to modern man. Both views now appear to be too simplistic and not in harmony with the findings of modern population genetics; the pattern of mixed characters that is becoming apparent follows the general trend of cranial enlargement and rounding, accompanied both by facial and dental reduction.

Behavioral inferences. While bones and teeth provide the most direct evidence of the form and locomotor capabilities of fossil man, there are other sources of information from which to obtain some concept of both his surroundings and his activities. This information comes from the careful excavation of the geologic deposits from which the fossil remains are taken. Modern methods in archaeology make use of an increasing number of scientific techniques, and through these studies it is sometimes possible to reconstruct both the environmental situation and the behavioral activities of fossil humans at a given site and time period.

Cultural remains preserved in the fossil record. In considering early *Homo sapiens* from a cultural standpoint, there are a few general considerations to be taken into account. The evidence that can be found must be inherently capable of preservation; thus, the types of materials most likely to be found are stone tools or stone structures and often fossilized animal bones and teeth. On the other hand, wood and plant remains are much rarer because such materials are more subject to decay. It must not be assumed, therefore, that the absence of wooden materials in the fossil record implies that they were not used by early man. Materials not normally preserved may be present in some situations and provide valuable clues; hence, fossil pollens, dealt with by the science of palynology, can give enormous insight into the vegetational structure and thus the climate of the time. Other general considerations relating to a fossil site include the likelihood of its location being close to a source of water for both humans and the animals that they may have hunted. Similarly, it is likely that sources of stone for the manufacture of tools will be found near living sites. Given these basic requirements, the living sites of early humans can clearly be in temporary structures in the open, in caves, or in rock shelters. In many circumstances it is likely early humans had little choice about where to shelter, but under glacial conditions the ability to find, acquire, and defend a cave or shelter

could have been crucial and might have overridden other considerations. During interglacial periods, when warmer conditions prevailed in summer in Europe and possibly all the year round nearer the equator, a temporary open-air site with a makeshift windbreak or skin tent may have sufficed.

Homo sapiens' early distribution

The known occupation sites of early *Homo sapiens* are so few that it is unlikely that any valid distribution pattern can be described at this stage. The principal early sites are from Europe and Africa, but they vary in age to such an extent that it would be unwise to draw conclusions as to possible migrations or to population density at any given time period.

Stone tools associated with Homo sapiens. Having considered the fossil remains of early *Homo sapiens* and the environmental and cultural situation of the group by means of the analysis of remains associated with the fossils, it is possible to look further by considering other sites that have provided tools but no human remains. Sites of this kind are very numerous and it is easy, but unwise, to speculate as to the kind of individuals that occupied them on the theory that human types and tool types will invariably go hand in hand. Experience has shown that such a correspondence cannot be safely inferred in most cases because overlap of both differing human populations and differing tool cultures is known to exist.

In general terms, the earliest known stone tool industry from the Early Pleistocene (about one million years ago) seems to have split into two basically parallel cultural systems, the hand ax and the flake tool industries (Figure 24). Within each of these types there is evidence of late diversification, so that the variety of tools increases; each presumably was used for more specific purposes.

Hand ax industries

The distribution of tool sites shows some general features, such as the restriction of hand ax industries to Africa, western Europe, Arabia, and the Indian subcontinent, whereas the flake industries overlap with the hand ax industries in western Europe but extend through the Balkans and into Southeast Asia. It seems clear that in Africa hand axes were developed from chopping tools, such as those found at Olduvai Gorge in Tanzania, by the gradual extension of the flaking process around the edges until the flaked areas met on the other side of the stone. The earlier stages of this process have been shown at Olduvai, but it is uncertain whether all hand ax cultures derived from a single African dispersal centre. The early Oldowan chopper tools led eventually to the principal group of hand axes known as the Acheulean industry and it seems very likely that early Acheulean hand axes were made by *Homo erectus.* This does not mean, however, that the later products of that industry must also be attributed to *H. erectus,* as has been shown by the fine Acheulean tools recovered from Swanscombe and many other sites of much later date.

Flake tool industries

The parallel, but not mutually exclusive, flake industries seem to have originated in the large chopper tool industries, such as those made by *H. erectus* at Peking (Choukoutienian industry). Similar early flake industries are known from Burma (Anyathian), Malaysia (Tampanian), and from the Indian Punjab (Soan). The early Buda industry of Vértesszőllős had no hand axes but many choppers and flake tools yet associated with *Homo sapiens.* The principal early development of the flake industry was the Clactonian industry, which is known from a number of European sites of the Mindel–Riss interglacial stage (400,000 to 200,000 years ago). In this industry the choppers and chopping tools were made from large flint nodules by striking off coarse but useful flakes. In its later and more evolved form, this tool industry has been termed Tayacian (it dates from *c.* 200,000 BC) and is known from sites in the Dordogne region of southwestern France. Beyond this, the flake and hand ax industries seem to merge into the Mousterian phase, while the more advanced Levallois technique leads on the Solutrean industry. (These are all stone tool industries of the Upper Paleolithic in Europe—*c.* 80,000–15,000 years ago.) All of the latter industries are well associated with *Homo sapiens* of the Late Pleistocene (after *c.* 100,000 years ago). (M.H.D.)

NEANDERTHALS

The human populations referred to as the Neanderthals inhabited much of Europe and western Asia during the time period of the earlier Late Pleistocene. They were the most recent archaic humans and represent the immediate predecessors of early modern humans. They lived in the region from Atlantic Europe eastward to Central Asia and from the latitude of Belgium southward to the Mediterranean and the Levant. The earliest of the Neanderthals emerged from more archaic humans between 200,000 and 100,000 years ago, and they were replaced by early modern humans between 50,000 and 30,000 years ago across the same region. Similar human populations lived at the same time in eastern Asia and Africa. As one of the more recent groups of archaic humanity, one that lived in a region of abundant limestone caves (which preserve bones well) and where there has been a long history of prehistoric research, the Neanderthals are better known than any other archaic human group. They have consequently become the archetypal cavemen, a role they play only reluctantly.

Early discoveries

Fossil finds. The name Neanderthal (or Neandertal) derives from the Neander Valley near Düsseldorf, W.Ger. In a cave in the valley in 1856 quarrymen unearthed portions of a human skeleton; 16 pieces of the skeleton were rescued and described shortly thereafter. Immediately, there was disagreement as to whether the bones represented an archaic and extinct human form or an abnormal modern human. The former view was shown to be correct in 1886, when two Neanderthal skeletons were discovered in a cave at Spy, Belg., associated with Middle Paleolithic stone tools and an extinct subarctic fauna. However, the view that the Neanderthals were somehow pathological still survives, despite abundant evidence to the contrary.

Shortly after the Spy discovery, up to about 1910, a series of Neanderthal skeletons were discovered in western and central Europe. Using those skeletons as a basis, scholars reconstructed the Neanderthals as semihuman, lacking a full upright posture and being somewhat less intelligent than modern humans. According to that view the

Table 3: Cultural Correlations in the Paleolithic Period

geologic period	years ago (000)	hand ax industry	flake industry	sapient site
Würm III glaciation		Magdalenian		Neanderthal and later sapient sites
Paudorf interstadial		Solutrean		
Würm II glaciation		Aurignacian		
Gottweiger interstadial		Perigordian		
Würm I glaciation		Mousterian	Tayacian	
Third interglacial	100			
(Riss–Würm)	130		Levalloisian	Omo
Riss II glaciation		Acheulean		
Inter-Riss interstadial				
Riss I glaciation			Clactonian	Steinheim Swanscombe
	250			
Second interglacial (Mindel–Riss)				
Mindel II glaciation			Buda	
Inter-Mindel interstadial	350?	Abbevillian		Vértesszőllős
Mindel I glaciation				
First interglacial (Günz–Mindel)				

Neanderthals were intermediate between modern humans and the apes (no older human forms were then generally recognized) but also too divergent to be the ancestors of modern humans. Only after World War II were the errors in the old Neanderthal postural reconstruction recognized, and the Neanderthals have since come to be viewed as quite close to modern humans evolutionarily. This view has been reflected in the frequent inclusion of the Neanderthals within the species *Homo sapiens,* usually as a distinct subspecies (*H. sapiens neanderthalensis*); some scholars maintain them in a different but closely related species, *H. neanderthalensis.* In the meantime a number of Neanderthal skeletons have been found in caves and shelters across Europe, the Middle East, and eastward to Uzbekistan in Central Asia, providing abundant skeletal remains and associated archaeological material for understanding these prehistoric humans. The Neanderthals are now known from several hundred individuals, represented by remains varying from isolated teeth to virtually complete skeletons.

Neanderthal origins and anatomy. The fossil evidence for the few hundred thousand years leading up to the time of the Neanderthals shows a gradual change from a *Homo erectus* form to one approaching the Neanderthals. Particularly in western Europe, the evidence shows a gradual decrease in the size and frequency of the anatomic characteristics of *H. erectus* and a gradual increase in features suggestive of the Neanderthals. From this a gradual emergence of the Neanderthals from earlier regional populations of archaic humans can be inferred, especially in western Europe and probably across their entire geographic range.

Figure 25: Side view of the La Ferrassie 1 skull, that of an adult male Neanderthal from western Europe.

The changes between Neanderthal ancestors and the Neanderthals highlight their characteristics. Brain size gradually increased to reach modern human volumes relative to body mass, even if Neanderthal brains and braincases tended to be somewhat longer and lower than those of modern humans. Neanderthal faces remained large and especially long, similar to those of their ancestors and retaining browridges, a projecting dentition and nose, and the absence of a full chin. Their premolars and molars were reduced to the size of early modern humans, and their chewing muscles and cheek regions were reduced accordingly; yet their incisors and canines remained large, like those of their ancestors, indicating continued use as a vise or third hand.

Characteristics

The postcranial skeletons of the Neanderthals changed little from those of their ancestors. They retained broad shoulders, extremely muscular upper limbs, large chests, strong and fatigue-resistant legs, and broad, strong feet. There is nothing in their limb anatomies to indicate less dexterity or an inability to walk bipedally. The details of their hand bones, however, suggest greater emphasis on power than precision grips. Furthermore, details of their pelvises, legs, and toes suggest that they engaged in more irregular, lateral movement during locomotion than do most modern humans. All of these features, however, appear to have been inherited and maintained from their ancestors.

© Erik Trinkaus

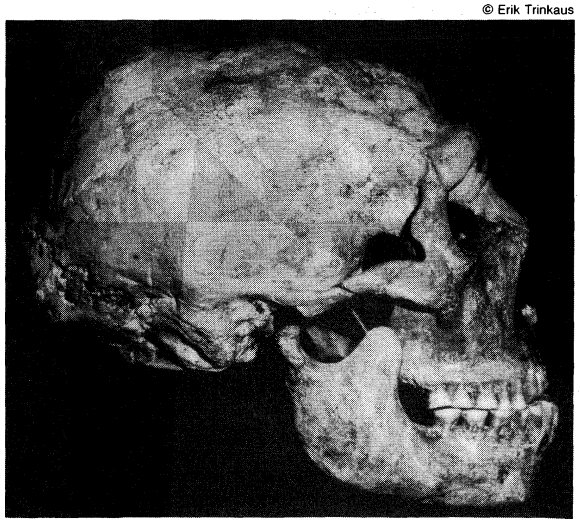

Figure 26: Side view of the Shanidar 1 Neanderthal skull, found at Shanidar Cave, Iraq.

The Neanderthals differed from their East Asian and African relatives (other late archaic humans) primarily in their retention of large incisors and canines and long faces to support those teeth. In Africa and East Asia front teeth and faces became smaller; at the same time, in both these and Neanderthal populations, the size of premolars and molars and facial massiveness were diminishing.

The fate of the Neanderthals. The evolutionary fate of the Neanderthals is closely related to the origins of modern humans. Over the years, the Neanderthals have been portrayed as everything from an evolutionary dead end to the direct lineal ancestors of modern European and western Asian populations. The evidence now indicates that modern humans first emerged in sub-Saharan Africa sometime prior to 50,000 years ago. Subsequently they spread northward, absorbing and occasionally displacing (through competition, not confrontation) local late archaic human populations. As a result the Middle Eastern, Central Asian, and central European Neanderthals were absorbed into those spreading modern human populations, contributing genetically to the subsequent early modern human populations across those regions. In western Europe—a culde-sac where the transition to modern humans took place relatively late—it is probable that the local Neanderthal populations died out largely without issue.

Emergence of modern humans

The anatomic changes between the Neanderthals and early modern humans involved largely a loss of the massiveness characteristic of all archaic humans. Limbs became more gracile, although they were still very muscular by modern human standards. The hand anatomy shifted to emphasize precision grips, and the frequency of lateral movement during walking was reduced. Front teeth became smaller and faces shortened, producing full chins and brows without ridges. Braincases became more elevated and rounded, but brains became no larger, nor, as far as is known, did humans become smarter.

Neanderthal behaviour. The behavioral patterns of the Neanderthals can be inferred from their anatomy in combination with the debris they left behind, their archaeological record. From their fossil remains and the hundreds of sites created by them—in cave entrances, rock shelters and the open air—an accurate view of their lifeways can be put together.

The Neanderthals appear to have lived in relatively small groups, moving frequently on the landscape but reusing the same locations often. This is indicated by the small sizes of their sites and by the considerable depth of debris at a number of sites. The materials left behind show only minor variations among sites, suggesting that there was little planned differential use of the landscape, one site serving as well as another for most purposes. In fact, combined with the evidence from their leg bones for high levels of irregular movement over the terrain, their sites suggest opportunistic use of resources and little forethought in their daily foraging activities.

Tool kits

Their tool kits, those subsumed by the Middle Paleolithic, or Mousterian, technological complex, included carefully made chipped stone tools or broad flakes and simple spears made of wood. Although much of their stone technology was simple and crude, they occasionally made high-quality stone tools by first preparing the block of raw material so as to strike off symmetrical and relatively uniform stone flakes. They rarely used bone as a raw material, however, despite its abundance in their sites as kitchen debris, and few of their tools were hafted. The predominance of hand-held thick flakes in their tool kits matches the strength of their arms and hands; such tools would have required great strength to carry out the same tasks that modern humans accomplish with more mechanically efficient implements and less strength. It also fits with their tendency to use their front teeth as a vise, augmenting their hands and tools.

Information about the Neanderthal diet—all of their food was gathered from the landscape—consists mostly of the animal bones that they left behind. There is rare evidence that they ate nuts, tubers, and other plant foods when available. The animal bones they abandoned indicate that they were able to hunt small and medium-sized animals (goats and small deer) but were able to obtain food from larger animals (*e.g.*, elk, horses, and cattle) only by scavenging from large carnivore kills. The species that were exploited closely reflected what was available in the surrounding countryside. Any use of small mammals, fish, birds, or shellfish as food must have been rare. There is simply no evidence for any systematic harvesting of wild plant or animal resources, a characteristic of modern hunter-gatherers in similar environments.

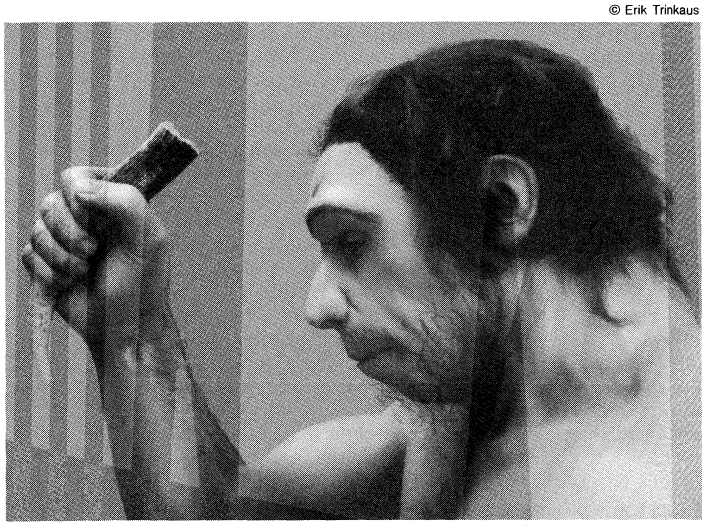

Figure 27: Reconstruction of the appearance of a Neanderthal man. Shown are the head and shoulders of a complete statue.

At the same time, the Neanderthals were the first human group to survive in northern latitudes during the cold (glacial) phases of the Pleistocene. They had domesticated fire, as indicated by concentrations of charcoal and reddened earth in their sites. Yet, their hearths were simple and shallow and must have cooled off quickly, giving little warmth through the night. Not surprisingly, they exhibit anatomic adaptations to cold, especially in Europe, such as large body cores and relatively short limbs, which maximize heat production and minimize heat loss.

The Neanderthals, despite their archaic anatomy and their less efficient foraging systems (compared to those of modern human hunter-gatherers), exhibited some uniquely modern features. They were the first humans to intentionally bury their dead, usually in simple graves. This indicates sufficiently elaborate social systems to make some kind of formal disposal of the dead desirable. They also occasionally created simple forms of personal decoration, such as pierced pendants.

The difficult existence of the Neanderthals is reflected in their high frequency of traumatic injury (the remains of all older individuals show signs of serious wounds, sprains, or breaks), abundant evidence of nutritional deprivation during growth (more than 75 percent have evidence of growth defects in their teeth), and low life expectancies (few lived past 40 years, and almost none lived past 50 years). Yet, they were able to keep severely injured individuals alive, in some cases for decades, again reflecting more advanced social organization.

Image of the Neanderthals

The image of the Neanderthals, therefore, is one of archaic humans who shared a number of important characteristics with modern humans, including their large brains, manual dexterity and walking abilities, and social sophistication. Like their archaic predecessors, however, their foraging systems were considerably less efficient at hunting and gathering than those of modern human hunter-gatherers, necessitating larger bodies, more-muscular limbs, greater endurance, and larger faces to hold their large front teeth. It was only with the emergence of modern humans that these archaic features disappeared, being superseded by more elaborate cultural behaviours and technologies.

(E.Tr.)

CRO-MAGNONS

Cro-Magnon is the name of a rock shelter near Les Eyzies-de-Tayac, Dordogne, Fr., where several prehistoric skeletons were found in 1868. Sent to the site, the French geologist Louis Lartet began excavations in which he established the existence of five archaeological layers covered with ash. The age of the human remains found in the topmost layer—along with worked flint and the bones of animals of species now extinct—is Upper Paleolithic (*c.* 35,000–10,000 years ago), but the attribution of these to a clearly defined Upper Paleolithic culture is less definite. Traditionally regarded as Aurignacian, since typically Aurignacian artifacts were found in the rock shelter, they could be more recent, and it has been suggested that they should be assigned to the Perigordian (a separate industry covering approximately the same time period as the Aurignacian), which would give an age of about 25,000 BC.

Examination and analysis of fossils. Although it appears that at the time of discovery the remains of more than 10 individuals existed at Cro-Magnon, only fragments from some five individuals were preserved and studied, among them the cranium and mandible of a male about 50 years old. Considered representative of the Cro-Magnon type, this specimen is known as the "Old Man of Cro-Magnon." Also preserved were skull fragments of about four other individuals, some bits of bone from a fetus or newborn child, and an assortment of bones attributed variously to the individuals mentioned above. The first subject men-

tioned, the Old Man of Cro-Magnon, has been regarded as typical of the Cro-Magnon peoples.

The skull is longheaded (dolichocephalic) and as seen from above has a pentagonal outline, with outward bulging of the parietal bones (at the sides of the skull). The forehead is straight, the browridges only slightly projecting, the cranial vault noticeably flattened, and the occipital bone (at the back of the head) projects backward. The cranial capacity is large, about 1,600 cubic centimetres (about 100 cubic inches). Although the skull is relatively long and narrow, the face appears quite short and wide. This combination is often regarded as a common feature of the Cro-Magnon race. The forward projection of the upper jaw (maxilla) is also distinctive. The eye sockets are low-set, wide, and rather square in shape; and the nasal aperture of the skull is narrow and strongly projecting. The mandible is robust, with massive ascending ramus (the upward projection of the lower jaw, where it attaches to the skull), strongly developed points of muscular attachment, and a quite prominent chin.

Typical skull features

The root of only one molar tooth remains in the jaw of the Old Man of Cro-Magnon, a fact that contributed to the idea of his advanced age. In fact, it is probable that the loss of the majority of his teeth occurred after death. The teeth of the other individuals found at Cro-Magnon, which are similar to the teeth of other fossil humans classed as Cro-Magnon, show that the dentition of Cro-Magnons was nearly identical to that of modern humans. Most of the teeth recovered, however, especially the last molars, are distinctly larger than those of most modern peoples. Dental caries is sometimes apparent, and tooth wear is often extreme.

The remainder of the Cro-Magnon skeleton is not fully known from the remains found at the original site, which are incomplete and poorly preserved. Skeletal material attributed to the Cro-Magnon race from other sites, however, affords the general impression of robustness, probably combined with powerful musculature. The forearm is relatively long, as is the thigh; the femur (thighbone) has a very prominent linea aspera (a bony ridge that runs lengthwise down the back of the femur), and the tibia is flattened from back to front (platycnemy). The hand skeleton is large with short fingers, and the foot has a prominent heel.

Early investigators were impressed by the stature of Cro-Magnon man, as some reconstructions suggest that the Old Man of Cro-Magnon may have been as much as 190 centimetres (six feet three inches) tall. A restudy, however, suggests that the stature of the original Cro-Magnon remains varied from 166 to 171 centimetres (five feet five inches to five feet seven inches). The stature of several skeletons from the Grimaldi Caves (in Italy, near the French frontier), which show clear affinities to those of Cro-Magnon, was noticeably greater, with an average height of 177 centimetres. It is thus reasonable to conclude that, on the whole, the Cro-Magnon peoples were relatively tall.

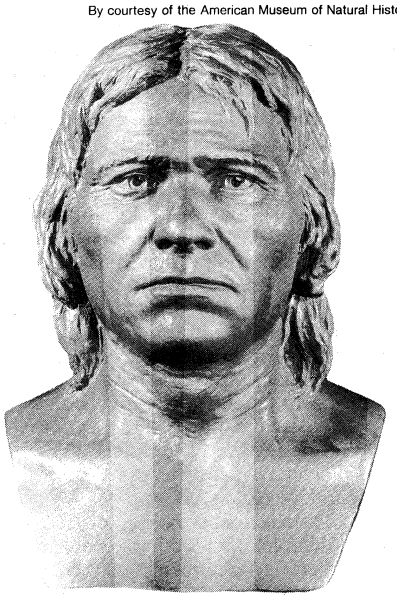

Figure 28: Reconstruction of the appearance of Cro-Magnon man.

Lesions noted in the Cro-Magnon skeletal remains have been attributed to wounds, but one analysis has suggested that these lesions are pathological in origin and may have resulted from the action of a toxic mushroom, *Actinomyces israeli.*

Two French prehistorians, A. de Quatrefages and Ernest Hamy, in 1882 took the Cro-Magnon fossils to be prototypes of a Cro-Magnon race. As opposed to the Neanderthal race—the first remains of which were found about 25 years earlier—the Cro-Magnons were then considered to be the most ancient form of *Homo sapiens.* To the Cro-Magnons were assigned other remains discovered before 1868 at La Madeleine and Bruniquel, in France; Engis, in Belgium; and Paviland, in Wales. Subsequently, further finds of human skeletal remains extended the geographic range of the Cro-Magnon peoples through much of Europe and into Asia and North Africa. Many of the central European fossils, however, belong to a type that differs from the Cro-Magnons called Brno-Předmosti, named for the area of central Czechoslovakia where they were discovered; like the Combe-Capelle remains, which they resemble, these individuals appear to have more primitive characteristics than typical for Cro-Magnons.

Variant Cro-Magnon finds

The place of Cro-Magnons in human evolution. The question of the relation of Cro-Magnons to the earliest forms of *Homo sapiens* is still unclear. It does appear, however, that Cro-Magnons (*H. sapiens sapiens*) and Neanderthals (*H. sapiens neanderthalensis*) are closer in affinity than was once believed. It long was thought that certain Cro-Magnon traits could be seen in human remains of Middle Pleistocene age (900,000–130,000 years old), but this argument no longer seems convincing. The tendency now is to locate the origin of the Cro-Magnon type in western Asia, as typified by the remains found at the Jebel Qafzeh and Skhūl sites in Israel.

Perhaps as complex as the question of origin is that of the duration of Cro-Magnons. It appears that they flourished during the Upper Paleolithic, and that there was a tendency toward more gracile individuals, as seen in the fossils from Saint-Germain-la-Rivière in France. Individuals with at least some Cro-Magnon characteristics—called Cro-Magnoids—are found in the Upper Paleolithic, the Mesolithic (in Europe, *c.* 8000–*c.* 5000 BC)—for example, at Muge, Port.—and in the Neolithic (in Europe, roughly from 5000 to about 2000 BC); at the same time, remains have been found for individuals who were quite different, often brachycephalic (broad-headed). Some modern human groups that are more or less homogeneous are thought to have retained a close relationship to Cro-Magnon types, at least in their cranial morphology. Particularly noteworthy are the Dal people from Dalecarlia (now Dalarna, Swed.) and the Guanches of the Canary Islands, the latter of which is said to represent a relatively pure Cro-Magnon stock.

The culture of the Cro-Magnons. The ties between *Homo sapiens sapiens,* and particularly Cro-Magnon peoples and the various Upper Paleolithic cultures (*e.g.,* Châtelperronian, Aurignacian, and Gravettian, which are classified on the basis of stone and bone tools), are relatively clear, although in 1979 Neanderthal fossils were found in Châtelperronian strata near Saint-Césaire, Fr. It is still difficult to establish precisely an outline of physical types and cultures for this period. Moreover, there are some detectable differences between populations and cultures of western Europe and roughly contemporaneous populations of central or eastern Europe.

Toolmaking. The Cro-Magnon peoples are generally associated with the Aurignacian culture tool industry, and perhaps with the Gravettian (also called Upper Perigordian). The Aurignacian tool industry is characterized by retouched blade tools, end scrapers and "nosed" scrapers, burins (chisellike tools), and fine bone tools, in particular long, flat points (spearheads) with cleft bases. Other bone and reindeer-horn implements are also seen: awls,

Cro-Magnon tool industries

tools for smoothing and scraping leather, and the so-called *bâtons de commandement*—bars of antler or bone with holes drilled in them, the use of which is still uncertain, although they may have been used for straightening arrow or spear shafts. The Gravettian industry differs from the Aurignacian industry in the use of an abrupt retouching technique to form what are called backed blades (*i.e.,* tools with one edge blunted). Modern knowledge of all of these industries has been advanced as the ability to trace how and why various implements were used by Paleolithic peoples has improved.

Dwellings. The dwellings of Cro-Magnons were most often caves and shelters made by rock overhangs, but it is apparent that huts were made also; sometimes these were simply lean-tos against rock walls, but foundation stones and "pavements" of stone in the shape of houses are evidence of complete huts. These houses are not a new development with the Cro-Magnons, however; both the Neanderthals and earlier peoples of the Middle Pleistocene are associated with similar remains. It seems probable that the Cro-Magnons lived fairly settled lives. Studies of occupation sites and the types and extent of remains found in these sites suggest that the rock shelters were inhabited throughout the year rather than seasonally, and it is likely that these Paleolithic hunters moved their homes only when hunting or environmental conditions forced them to do so.

Hunting techniques. The climate in the habitable parts of Europe in Cro-Magnon times was cool to cold. Plants and animals of types associated with tundra and steppe environments were usual. Bone remains found at Cro-Magnon occupation sites indicate that they were successful hunters of such animals as reindeer, bison, wild horse, and even mammoth. As yet, very little is known of Cro-Magnon hunting methods—for example, whether hunting was individual or collective or if bows or traps were used. It is obvious from the animal remains, however, that hunting techniques must have been efficacious.

Aesthetics and religion. Although earlier human groups certainly had religious practices of some sort—the Neanderthal people buried their dead, a practice merely continued and elaborated by Cro-Magnon and later peoples—and no doubt had some appreciation of aesthetics as well, the first examples of prehistoric art are Cro-Magnon. Small engravings, reliefs, and sculptures of animals have been found in Aurignacian and Gravettian sites, as well as a few later statuettes of ivory or stone and occasional engravings in stone of female figures. These figures are usually large-breasted, wide-hipped, and most often apparently pregnant; they are generally assumed to be some sort of fertility symbol, perhaps used in religious or magical rituals intended to promote the fertility of the group or, possibly, of the game.

"Venus" figurines and animal paintings

The Cro-Magnon people also appreciated the decorative aspects of art, as demonstrated by their use of animal pictures and (more often) simple geometric designs to ornament tools and weapons. It is believed that the people of the second half of the Upper Paleolithic—*i.e.,* of the Solutrean and even more so the Magdalenian culture—were of the Cro-Magnoid variety and that they were responsible for the many splendid paintings of animals found in caves in France and Spain; but such sculptures as that called the "Lady," or "Venus," found at Brassempouy, Fr., are thought to be the work of Cro-Magnon artists. (H.J.De.)

HOMO SAPIENS OF ASIA AND AUSTRALASIA

The extinct *Homo sapiens* populations from what was the eastern end of the human range during most of the Pleistocene epoch were once described as the eastern representatives of a "Neanderthal stage" of human evolution. With the realization that the Neanderthals were a unique European and western Asian race, the term archaic *Homo sapiens* has come to describe these earlier members of the species. As a group they are descendants of local *Homo erectus* populations, and many believe that they are the direct ancestors of the more recent and living peoples of East Asia and Australasia.

East Asia. The extinct populations of *H. sapiens* in East Asia evolved from local *H. erectus* populations and share numerous unique regional features with these earliest Asians. The latest remains of *H. erectus,* particularly the Chou-k'ou-tien (Zhoukoudian) H1 mandible and H3 cranium from Layer 3, are dated to 370,000 years ago by amino-acid racemization (a thermoluminescence date of about 300,000 years is reported for the underlying Layer 4). Several of these, particularly the above-mentioned Locus H Chou-k'ou-tien specimens and a vault recovered from the Narmada valley in central India, could conceivably be considered early *H. sapiens,* but the support for this classification is not universal.

Fossil finds in China

The early Asian *H. sapiens* remains are limited to China, where a fairly complete skeleton from Mount Chin-niu (Jinniu) in Liaoning province and a cranial vault from the Ta-li (Dali) site in Shansi are the best-preserved specimens from the late Middle Pleistocene. The Ta-li cranium, which may have been the older of the two, is from a young (less than 30 years old) adult male and combines a thick, massive cranial vault with a robust but short and markedly flattened face. The supraorbitals are vertically thick, curving to follow the orbital contours, and separated from the forehead by a sulcus (furrow). The face below reflects numerous regional distinctions in its transverse flattening, low nasal angle, anterior position of the cheeks, and markedly vertical orientation (involving the entire face from the nasal bones to the premaxilla). Cranial capacity is about 1,120 cubic centimetres (68 cubic inches).

Milford H. Wolpoff

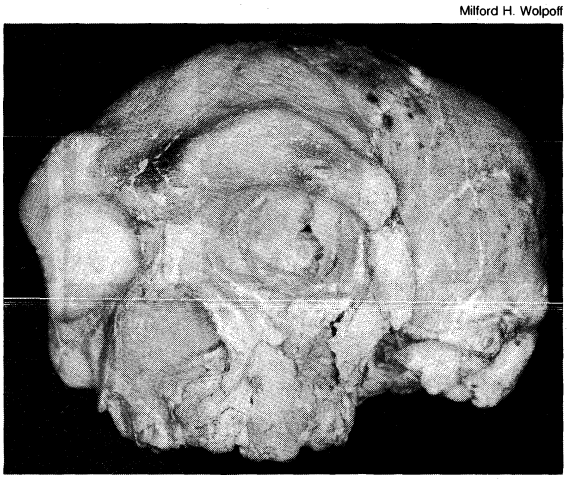

Figure 29: *Homo sapiens* skull found at the Ta-li site in Shansi, China.

Remarkably similar facial features characterize the female cranium (with associated skeleton) from Mount Chin-niu, but the vault is much thinner and about 25 percent larger (1,390 cubic centimetres) and could reflect a younger age. Uranium-thorium dates place the fossils between 200,000 and 100,000 years ago. With the more fragmentary female cranium from the Ma-pa (Maba) site in Kwangtung—which has gnaw marks on the face, suggesting that it was part of an interrupted meal—these two females differ dramatically in robustness from Ta-li while retaining similarities in features common to the region, such as transversely flat and vertically nonprojecting (orthognathic) faces, broad, low noses, arched supraorbitals following the orbital contours, and posterior dental reduction (especially compared with contemporaries to the south; see below). Details of the postcranial skeleton, said to be largely complete, remain unreported.

There are also some more fragmentary dental remains from several sites. The most important features of these remains centre on the unique size, morphology, and distribution of the marginal ridges and basal tubercles on the incisors (*i.e.,* the regionally specific complex of shovel shaping) that characterize these teeth as well as the dentition of many modern Asians.

Earlier Late Pleistocene discoveries of *H. sapiens* are much more fragmentary, and the best-established links for the Middle Pleistocene remains are with the latest Pleistocene finds from the Chou-k'ou-tien Upper Cave, Liuchiang (Liujiang) and Lai-pin (Laibin; Kwangsi), and Tsu-

yang (Ziyang; Szechwan). In addition to the continuation of the Mongoloid features common to the region, discussed above, there are specific resemblances, such as between the brow regions of the Ta-li female and the Chou-k'ou-tien Upper Cave male (specimen 101) and the moderate chignons (occipital buns) of the Chin-niu and Liu-chiang females. Of the earlier remains from the Late Pleistocene, the best-known are the Ch'ang-yang (Changyang; Hupeh) maxilla, teeth from Hsin-tung (Xindong; part of the Chou-k'ou-tien site) and Ting-ts'un (Dingcun; Shansi), and the numerous though fragmentary specimens from Hsü-chia-yao (Xujiayao; also Shansi). Lower facial flattening and orthognathism (Ch'ang-yang and the Hsü-chia-yao juvenile maxillae) and the complex of incisor shoveling are the most important characteristics of the sample.

Australasia. To the south a large sample of early Australasian *H. sapiens* from the Ngandong site in eastern Java (Indonesia)—commonly called Solo man—is clearly linked to much earlier Indonesian *H. erectus* ancestors by morphological comparisons and transitional specimens, such as the cranium from the Sambungmatjan (Sambungmachan) site in central Java. Some workers regard the Ngandong hominids as *H. erectus,* but the features that uniquely distinguish *H. erectus* from *H. sapiens* in Australasia have never been identified; and as the German anatomist and paleoanthropologist Franz Weidenreich (author of the most comprehensive study of these specimens) pointed out, their characteristics mostly fall within the known *H. sapiens* range. That the Ngandong remains are themselves unambiguously ancestral to at least some of the Late Pleistocene Australians is shown by fossil remains from the Willandra Lakes region (New South Wales) such as the specimen designated WLH 50. While their relative temporal sequence is clear, date determinations for all of the Australasian remains are very uncertain.

The Sambungmatjan cranium

The Sambungmatjan cranium, found on the Solo River west of Trinil, is Middle Pleistocene in age. The specimen has many of the special regional features foreshadowing those found in the geologically later sample from Ngandong, a site also on the Solo River but just east of Trinil. The specimen is the faceless vault of an adult male (the sex diagnosis being made on the basis of neck-muscle-related features of the occiput). With a cranial capacity of about 1,100 cubic centimetres, the vault is as large as the largest Chou-k'ou-tien *H. erectus* males and only slightly smaller than the (more recently dated) Ngandong males; it is otherwise similar to them in being long, low, and broadest above the base, with thick cranial bone and a particularly long, flat forehead beginning just behind the straight supraorbitals. Other diagnostic features shared with the Ngandong specimens include a unique thickening at the outer corner of the supraorbitals, which form a rearward-facing triangle, and a flattening at the back of the skull above the prominent nuchal torus.

Later in time, the Middle or early Late Pleistocene remains from Ngandong include two right tibiae and 14 faceless craniums or large cranial fragments that were found close to each other in 1931–33. Two additional fragmentary vaults were discovered nearby on the same high Solo River terrace in 1976, and several others have been recovered subsequently. The six best-preserved vaults (two females, four males) are within the modern range of Australasian size variation and share many regional features with Late Pleistocene and Holocene Australians. Most of the specimens have a supraorbital torus that can be described as a well-developed structure, positioned straight across the orbits except for an indentation at its middle, that is continuous with a long, flattened forehead. There are depressions at varying positions along the middle of the head, generally there is a sharp angulation on the occiput at the nuchal torus—which is prominently developed and separated from the flat surface above it by a pronounced transverse groove—and in many craniums the sphenoparietal articulation is lacking in the region of the temple (on the side of the head). Some of their features seem unusual, or even unique only to this sample. Included in these is the trigone at the corner of the supraorbitals described above and the positioning of the Glaserian fissure just at the roof of the narrow mandibular fossa. The length of the smaller tibia suggests a body height of about 162 centimetres (five feet four inches); the fragment of the larger tibia is from a much taller individual.

Milford H. Wolpoff

Figure 30: The Sambungmatjan cranium, found along the Solo River near Trinil, Java, Indon.

While the Ngandong specimens were not intentionally buried and there are no archaeological associations, some insights into their behaviour can be made. Healed cranial wounds are common and are found on more female craniums than on the males. It has been suggested that the accumulation of faceless skullcaps suggests that they were used as water bowls, and it is uncertain if the limited number of body parts represented is the result of ritual treatment of the dead, taphonomical factors, or the preferences of the collectors.

Links between populations

There are undisputable links between these Indonesian remains and the earliest Australians, populations of modern *Homo sapiens* who are perhaps the first from anywhere to have crossed a water barrier broad enough that one side was not visible from the other. These links can best be seen in the Australian cranium (WLH 50) from the Willandra Lakes region, New South Wales, known to be more than 30,000 years old and suspected of being much older. A direct descendant relationship for this male specimen is indicated by the dimensional and proportional similarities to the Ngandong males and the presence of numerous shared regional features. Many of these features are unique to Australasia and are not found in earlier or contemporary Late Pleistocene humans from other parts of the world. While these regional resemblances have been explained as pathologies, artificial deformations, or "primitive retentions" by some workers, there is no evidence to support any hypothesis of causality except that of ancestry. (M.H.Wo.)

HOMO SAPIENS OF AFRICA

Africa has long occupied centre stage in discussions of the evolution of early hominids. Yet, when considering the origins of the species *Homo sapiens* and in particular modern humans, debate has traditionally centred around Europe. This viewpoint was typified by the American anthropologist Carleton S. Coon, who in the 1960s asserted that Europe and Asia had been the main locations of modern human evolution. In the 1970s and '80s, however, such conceptions were abandoned. Numerous new hominid finds, new absolute datings, and a radical revision of the archaeochronological framework have increasingly placed Africa at the focal point of both *Homo sapiens* evolution and the origin of modern humans.

Fossil evidence. Based upon the fossil finds and dates available for Africa until the late 1960s, it was widely assumed that large areas of the African continent had been populated by very archaic Rhodesoids—named for the cranium found at Broken Hill, Northern Rhodesia (now Kabwe, Zambia)—up to about 30,000 years ago. Many researchers believed that the modern Africans had evolved from these Rhodesoids and had thus developed much later than their modern European counterparts (Cro-Magnons). Some workers even suggested that the modern Africans arose from modern Europeans who had emigrated out of Europe.

Figure 31: Side views of (top) the Kabwe/Broken Hill cranium, representative of early archaic *Homo sapiens;* (centre) the Laetoli LH 18 cranium, representative of late archaic *H. sapiens;* (bottom) the Omo I cranium, representative of early anatomically modern *H. sapiens.*

© Gunter Brauer

Toward the end of the 1960s several important finds were recovered: the remains of three individuals from the Kibish Formation of the Omo River in Ethiopia and the remains of a number of individuals at the Klasies River Mouth site, on the southern coast of South Africa. These specimens, most of which were anatomically modern, were determined to be some 130,000 to 80,000 years old, a finding that astonished the workers and did not fit well with the ideas of the period.

It was only after additional fossils were found during the 1970s, however, that conceptions about the evolution of *H. sapiens* in sub-Saharan Africa actually began to change. This shift was aided by the fact that the dates of many long-known finds were revised and determined to be significantly older than previously had been assumed. Based upon a new analysis of the total fossil evidence, the West German anthropologist Günter Bräuer was able to demonstrate a continuous evolutionary sequence in sub-Saharan Africa during the last 400,000 years. Three divisions have been differentiated in this sequence: early archaic *H. sapiens* (*c.* 400,000–200,000 years ago), late archaic *H. sapiens* (*c.* 200,000–100,000 years ago), and anatomically modern *H. sapiens* (*c.* 100,000 years ago–present). The course of *H. sapiens* evolution in North Africa is not as well known; for this reason, the fossil evidence from this area will be discussed after that from the sub-Sahara.

Three divisions of *H. sapiens* evolution

Sub-Saharan Africa. Early archaic *H. sapiens* from sub-Saharan Africa is represented particularly by the hominid finds at Bodo (Ethiopia), Ndutu and Eyasi (Tanzania), Kabwe/Broken Hill (Zambia), and Hopefield/Saldanha (South Africa). This division possesses some primitive *H. erectus*-like features along with derived features of *H. sapiens.* Cranial capacity is generally greater than 1,250 cubic centimetres (76 cubic inches), and the lateral walls of the cranial vault are more or less vertically oriented, similar to the modern type. The primary primitive features consist of a strongly developed supraorbital torus, an angular occipital, and a typically quite massive face. Even these features, however, also display clear trends in the modern direction. In spite of the considerable variability among these finds (thought, in part, to be the result of sexual dimorphism) and their relatively small number, it may be assumed that this division of *H. sapiens* was widely spread throughout Africa.

The late archaic *H. sapiens* of sub-Saharan Africa consists especially of the Omo II (Ethiopia), Ileret (Koobi Fora) KNM-ER 3884 and Eliye Springs ES 11693 (Kenya), Laetoli LH 18 (Tanzania), and Florisbad (South Africa) hominids. While these specimens display individually varying mosaics of primitive and derived features, they nevertheless possess a form that is distinctly more modern than that of early archaic *H. sapiens.* This is reflected in the increased cranial capacity (greater than 1,350 cubic centimetres) and the usually modern form of the face. Even where archaic traits are present, *e.g.,* in the supraorbital tori, these are considerably reduced in comparison to the early archaic condition. Obviously, such hominids as LH 18 or Florisbad stand very close to the threshold of anatomically modern humans.

The evolutionary transition to modern humans may be seen in both the morphology of the late archaic *H. sapiens* specimens as well as in certain archaic reminiscences among some of the earliest modern finds. Among the most important members of this division are the hominids Omo I and the remains from the Klasies River Mouth and Border Cave (South Africa) sites. The Omo I cranium, which is remarkably similar to the Cro-Magnoid craniums from North Africa and Europe, may certainly be classified as anatomically modern. In spite of their considerable variability, the cranial and mandibular remains from Klasies River Mouth are modern as well, although some of these fragments also appear to exhibit influences from late archaic populations. The cranium and the mandible from Border Cave (specimens 1 and 2) are also fundamentally anatomically modern. It must be noted, however, that these early moderns generally do not display any clear relationships to current human populations, and thus most likely represent a less differentiated, more pristine form of modern *H. sapiens.*

Transition to modern humans

North Africa. The fossil record in North Africa (nearly all of which has been found in Morocco) is less clear, and it is therefore difficult to connect the evolutionary sequence for this area with that of sub-Saharan Africa. There are several reasons for this: only a few finds, most of them jaw fragments, have been obtained from the Middle Pleistocene (Sīdī ʿAbd ar-Raḥmān [Sidi Abderrahman], Thomas Quarries, Rabat); there are uncertainties in the evaluation of the possibly pathological Salé hominid; the dates for the Jebel Irhoud hominids are uncertain; and the influences that the Eurasian Neanderthals may have had upon the Late Pleistocene North Africans are still the subject of debate. If the Jebel Irhoud hominids are indeed

found to be of early Late Pleistocene age (see below), then it is conceivable from a morphological point of view that there were indeed close connections to the sub-Saharan late archaic *Homo sapiens,* although this does not rule out the possibility that there may also have been some influence from the Neanderthals of the Mediterranean area. The most likely date for the appearance of early modern humans in North Africa is between 70,000 and 40,000 years ago, as represented by the finds at the Dar-es-Soltane II cave site (Morocco).

Revision of fossil dates

Dating the fossils. In the early 1970s a number of new carbon-14 datings gave rise to a radical revision in the then-accepted dating of the African Stone Age. The resulting picture has since been confirmed by a variety of newer methods. Accordingly, the African Middle Stone Age no longer is considered to have begun some 40,000 years ago and ended *c.* 10,000 years ago but instead to have begun *c.* 200,000 years ago and ended some 40,000 years ago. One result of this enormous expansion was that much greater ages began to be accepted for a number of hominids, including those found at Kabwe/Broken Hill, Hopefield/Saldanha, and the Cave of Hearths (South Africa). Beyond this, a number of important reexcavations helped to further clarify many dates that had long been uncertain.

After F.H. Smith and F. Spencer (eds.), *The Origins of Modern Humans: A World Survey of the Fossil Evidence,* copyright © 1984 Alan R. Liss, Inc.

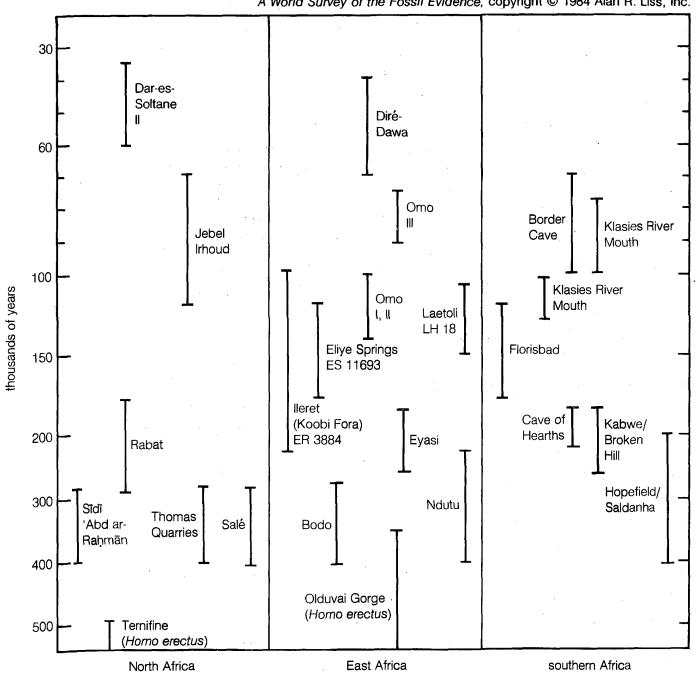

Figure 32: The age spans and chronological positions of the major African *Homo sapiens* fossil finds.

Referring to the representatives of early archaic *Homo sapiens,* the British prehistorian J. Desmond Clark has suggested that all of these finds most likely date from between 400,000 and *c.* 200,000 years ago. Reexcavations and new absolute dates have also yielded support for the ages now accepted for the late archaic specimens. A reinvestigation at Florisbad demonstrated that the hominid found there is between 200,000 and 100,000 years old. For LH 18 the uranium–thorium method has yielded dates ranging from about 130,000 to about 100,000 years. In addition, the stratigraphic provenance of the KNM-ER 3884 hominid indicates that this specimen is probably more than 100,000 years old.

Subsequent research also has provided confirmation for the greater ages of the early modern finds. Reexcavations and various redatings at Klasies River Mouth yielded an age from somewhat more than 100,000 to 80,000 years ago for the modern human remains associated with the African Middle Stone Age. On the basis of all of the available evidence, the German-born geographer and anthropologist Karl Butzer considered the *c.*-130,000-year age for the Omo I find (determined using the uranium–thorium method) to be quite likely. Because of the matrix present on the Border Cave 1 hominid, Butzer suggested that this specimen is associated with a level in the deposits that is about 90,000 years old.

While the dates for important finds representing all three divisions of sub-Saharan *Homo sapiens* are quite reliable, those for a number of North African finds are less certain. In contrast to earlier assumptions, which usually considered the Jebel Irhoud hominids to be between 60,000 and 40,000 years old, electron spin resonance dates now indicate that these specimens are at least 75,000 years old. Dates for the North African Aterian industry also vary widely, ranging from more than 70,000 to less than 40,000 years ago. The modern hominid from Dar-es-Soltane II, associated with the Aterian industry, may thus be between 70,000 and 50,000 years old.

Techno-logical changes

Behavioral inferences. The revision of the archaeochronological framework for sub-Saharan Africa during the 1970s demonstrated that great technological changes occurred in parallel both north and south of the Sahara and thus that the Middle Stone Age of Africa was broadly contemporaneous with the Middle Paleolithic of Eurasia. A comparison of the technologies of sub-Saharan Africa with the fossil record of the region indicates that early archaic *H. sapiens* were still generally associated with late Acheulean assemblages (*e.g.,* at Hopefield/Saldanha and Eyasi), while late archaic *H. sapiens* were associated with the Middle Stone Age (*e.g.,* at Laetoli). On the other hand, the transition to the early modern humans was not characterized by any recognizable technological innovation but took place during the Middle Stone Age. Precisely how the modern human form arose some 100,000 years ago and in what regard the behaviour of these early moderns may have differed from their predecessors is difficult to explain because of a lack of corresponding archaeological evidence. In all likelihood, changes were involved that would not have been preserved in either the fossil or the archaeological record. At least some of these changes may be attributable to the full development of human language and the associated increase in intellectual abilities. In addition, improved social systems and demographic changes probably also contributed to the success of the modern humans.

Evolutionary implications. Conceptions of the course of evolution of *Homo sapiens* have changed drastically since the 1960s. No longer is Africa considered an also-ran in the global context; instead, it has become the region in which the evolution of *H. sapiens* up to modern humans is best documented and where, moreover, modern humans appeared earlier than in any other part of the world. The implications that this changed view has for the origins of modern humans outside of Africa remain the subject of much controversy. Some researchers, such as the American anthropologist Milford H. Wolpoff, have interpreted the African lineage as a regional phenomenon, arguing that other lines of development were responsible for the rise of the modern humans elsewhere. As far as Europe and East Asia are concerned, however, others have expressed strong doubts about the evidence for such regional transitions to modern humans. The present discontinuities between archaic and modern humans in the fossil record outside of Africa and the later appearance of modern humans in those areas have instead led to the view that modern humans originated solely in Africa; subsequently, from there they radiated to the Middle East and then to Europe, supplanting the Neanderthals living in these regions. It can be assumed, however, that during this process some intermingling between these populations also took place.

Although the fossil record is less clear for East Asia, there are indications that the moderns from Africa also expanded into that region. Molecular biological studies by the New Zealand-born American Allan C. Wilson and his associates support the view that present-day human populations had their common origin in Africa, even though the extent of gene flow that may have occurred between the regional archaic populations and the radiating modern populations during the global expansion of modern humans remains a point of much debate. (G.Br.)

MODERN HUMAN POPULATIONS

General considerations

All living human populations belong to a single biological species (*Homo sapiens*) within a larger group or genus (*Homo*). Within the human species a large number of populations may be differentiated genetically through readily observable characteristics (*e.g.*, skin, hair, and face and body proportions) and through less obvious but more distinctive biological traits, such as blood type. These biological groupings within species are commonly called races, in humans as well as in other living forms.

RACE AND POPULATION

Definitions and terminology. The term race as applied to humans has been variously used—by politicians, military leaders, philologists, human biologists, demographers, and historians. Some "races" constitute language groups, often of peoples whose only kinship is that they speak a common language. Such was the original meaning of the so-called Aryan race. Some "races" are simply hypothetical, invented to embrace present distributions of such genetic (hereditary) characteristics as stature or hair colour—*e.g.*, the Nordics. (The word Nordic also has been given a political meaning, referring, despite their differences in physical characteristics, to peoples in northern Europe.) Race has been variously applied to national or cultural groupings, as in the days when English writers referred to an Irish race and to a Scottish race. As used in census and other applications, the designation race often groups different peoples for administrative convenience; thus, the category Hispanic may group people from Meso-America, the Caribbean, South America, and the Philippines who may differ considerably in their racial origins.

"Race" also has been applied to human groups inferred to have existed on the basis of archaeological discoveries; the Etruscan race is an example. Various religious groups who may or may not have common ancestry sometimes are called races—the Jewish race, for example. By extension of biblical thinking and in honour of Shem, son of Noah, a Semitic race was conceived in an effort to describe peoples who spoke Semitic tongues, some of whom may have learned their language more recently than others.

All of those uses of the term race are separate and distinct from its biological meaning in classification (taxonomy)—the natural divisions or groupings below the species level. As such, race differs from breed or line, which refer to artificially established groups maintained by intensive selection or by deliberate hybridization. Just as the term race is often too broadly applied to the entire species of man (as in the human race), particular race names invented to explain distributions of observable physical characteristics of human populations are not biologically meaningful.

The misuse of the word race—particularly the manner in which it was employed by Nazi Germany—had led workers to search for alternate terms. Some biological descriptions refer to human stocks, one intention for this being to avoid political overtones. Other writers have favoured the word division in lieu of race, again apparently to escape what may be perceived as offensive connotations. Other references to these human groupings include strain (without implying the equivalent of purebred strains of laboratory animals); variety (although the specific botanical meaning does not apply to human races as ordinarily constituted); and ethnic group, which, although generally meaning cultural or political groupings (*e.g.*, Macedonians, Croats, Magyars, or Slovenes), is at times used with exactly the same biological meaning as race. With the advent of population genetics, establishing gene frequencies in specific populations, many workers have come to prefer the word population for taxonomic purposes. Populations so defined, however—such as San (Bushman), Ainu, Lapp, Eskimo, Coloured (South Africa), or Micronesian—are often the same groupings that have been or can be called races. Still, population is a useful addition for such linguistically and genetically distinct groups as the Basques and is an easier concept to explain.

Other terminology

The term geographic, or continental, race is often used to describe populations that occupy a broad geographic range. Likewise, local race is used for populations in a more restricted area, and microrace may correspond to a single, extended breeding population. These natural groupings, which reflect geographic (and therefore reproductive) isolation, display a range of genetic differences that are the focus of much research. The ultimate questions are how long the races (or populations) have been distinguishable and what processes brought about the distinctions.

What the different geographic races are called is to some extent unimportant as long as the same terminology is employed by all; such traditional designations as white, yellow, and black, however, are clearly inappropriate. The designations for local races and microraces are similarly unimportant, except for communication and for the sensitivities of the people themselves. It has long been a practice on the part of some human taxonomists to convert placenames into taxonomic names by adding the suffix *-id* (*e.g.*, Pennsylvanid, Montanid) or the suffix *-oid* (Capoid for the Cape peoples of South Africa). Geographic terms, without suffixes, also suffice (hence, the Mediterranean race) or are used in conjunction with language groupings, where justified (*e.g.*, Azteco-Tanoan). Often reference is made to

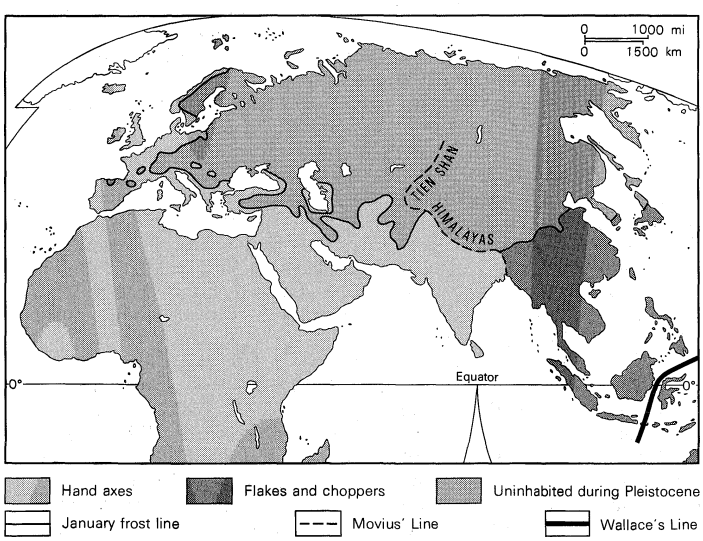

Figure 33: Distribution of human groups through habitable regions of the world in the Late Pleistocene.

particular national or cultural groupings, such as Finns, because available data are so arranged, or to artificial groupings (*e.g.,* Ghanaians or Vietnamese) until further information can establish more precisely the makeup of those groups. Even a designation as being from a city may not be enough, given demographic and genetic differentiation within cities, Tokyo being a typical example.

Geographic races. Naturally occurring (*i.e.,* produced by natural, usually geographic separation of human groups) races of the human species are by no means identical in number of members or degree of genetic differentiation. There are small groupings of a few hundred to a few thousand individuals, some slightly and only recently isolated reproductively from adjacent people. Other equally small groups may have been mating apart from the rest of mankind for centuries or even for thousands of years. Members of some human races number in the hundreds of millions (as the peoples of modern Europe) or in the billions (as in Asia).

It is both useful and meaningful to identify the very large human groupings that often correspond to continents or other major geographic areas as geographic races, a term extensively used with other life forms. Geographic races are numerically large, containing within them smaller groups of reproductive isolates (breeding populations).

Reasons for a geographic delineation

The reasons for the large groups' geographic delineation are usually clear. The Indians of the Americas were reproductively separated from the peoples of other geographic regions for many thousands of years. Thus, they have come to differ genetically from the rest of mankind and even from those Asians from whom they stemmed. The Australian Aborigines similarly constitute a geographically defined group of local races (see below) separated for millennia from the rest of the world, except for some slight contact, until the late 18th century.

Local races. Most geographic races include numerous local breeding populations. While such local races may have few members, others number in the hundreds of millions. Local populations (local races, usually with distinctive languages) dotted pre-Columbian America; there were hundreds in North America alone. In other parts of the world, where high population densities have built up, local races are also apparent, as in many parts of Africa. History provides a picture of ancient local races in much of the European continent, with numerous local groupings in the British Isles cataloged and categorized by Julius Caesar. In the course of the last two millennia, however, local races in Europe seem to have become less easily defined, except along such broad lines as northwestern Europe, the Alps, and the eastern Mediterranean. Such local races are the ones most easily identified and studied; they constitute population units that display continuing evolutionary change. Many of these units are allopatric in that they live in distinct places and their boundaries are easily defined. Others are sympatric—that is, they live in the same municipality or region but preserve their genetic identity. Hopi living in enclaves on Navajo lands or in government-assigned territories and their Navajo neighbours each constitute nearly allopatric populations, whereas enclaves of Korean nationals in Los Angeles or Algerians in Paris constitute distinct sympatric populations.

Microraces and smaller units. For much of the world, local races exist as reproductively isolated, culturally distinct, and genetically differentiated breeding populations. Indeed, barriers to gene flow (interbreeding) are prerequisites for the continuing existence of these populations. Culture and geography together tend to maintain such hereditary differences over time; thus, social or caste prohibitions on interbreeding serve to maintain local races in India. Elsewhere, religious regulations have maintained many local races for millennia. Rivers were efficient barriers to interbreeding in older days, and oceans remain major barriers to intermarriage. As populations have grown, however, as in Europe, geographic distance itself has become less of a barrier, and distance alone does not have the isolating influence it once had.

Yet sheer density of population is itself a restriction on gene flow and on the distance over which human mating is likely to occur. A man is less likely to venture far afield for marriage when there are many single women within the same apartment block in which he lives. Under such circumstances, the human male has the same effective mating range as the mosquito. Thus, even in heavily settled locations, genetic differentiation continues in its course. In a long-established city such as Tokyo genetic differences occur from district to district; this also holds for Rome and London and other large cities that have been studied. Some of these differences clearly represent older residence patterns of breeding that support the continuance of localized groups of people (microraces) long genetically distinct (as in the Limehouse district of London or in certain of the ghetto districts of Rome). In moving from one coast of England to the other, there are found systematic genetic differences, some related to earlier settlements and cultural patterns, still others apparently reflecting later differential directions of selection.

Causes of gene-flow restrictions

Associations with race. *Adaptations to environment.* Local genetic adaptations may well be expected for races long occupying the same habitat, accustomed to a distinctive way of life, and used to a particular climate. Long before the microscope made it possible to count melanin granules in skin sections, naturalists had come to appreciate the importance of differences in skin (and eye) pigmentation. They observed a direct relationship between sunlight levels and skin pigmentation, at least in Europe and Africa. Later it was determined that the pigment granules serve as a natural sunscreen, protecting the deeper layers of skin as harmful ultraviolet wavelengths in sunlight are absorbed, and that there is a correlation between higher melanin content and slightly lower sweating thresholds. Truly confirming experiments would be both unethical and impractical, but it has been demonstrated that the rate of skin cancer rises sharply as pigment densities go down; in Texas, for example, skin cancer is far more common among light-skinned and freckled individuals. Light-skinned people may generate considerable melanin with continued exposure to sunlight (and so tan), but this does not occur until after damage to the skin has been done. Those who have less melanin in their irises are also more likely to develop cataracts from long-term exposure to ultraviolet radiation. Conversely, low levels of melanin in the skin appear to be an advantage in parts of the world where cloudy conditions are common or where (as in the polar regions) there are prolonged periods of limited sunlight. Lighter-skinned individuals are more able to convert vitamin D precursors in the skin to usable vitamin D. This theoretical advantage has been confirmed: rickets and osteomalacia (progressive mineral loss from bones), both disorders caused by vitamin D deficiency, are more common among dark-skinned children living in northern Europe, with its generally cloudier climate and shortened hours of sunlight in winter.

Differences in body build or bodily proportions also interested early naturalists, and subsequently it has been shown that these differences are also adaptive at thermal extremes. At higher air temperatures a lanky build allows for greater heat loss—by convection, conduction, and radiation—and thus a large surface area relative to body mass makes for greater comfort. When air temperatures are low the trend is toward a small surface area relative to mass, which tends to conserve body heat. These adaptive traits have been demonstrated in environmental laboratories by measuring the threshold of shivering as temperatures are lowered and the increase of body temperature when the environment is heated. It is therefore of interest in population comparisons that the surface-to-mass ratio is lowest among some Asian and North American Eskimos and highest among such African groups as the Nilotes. The relative size of the extremities (hands and feet) also enters into consideration: short hands and pudgy fingers are less susceptible to frostbite than are long hands with thin fingers, especially if there is also increased vascular flow.

Foods

Potentially intolerable or toxic substances in foods constitute another area of influence by the environment. Lactose, the complex sugar in milk, is poorly absorbed by the adults from most populations because as they get older they lose the ability to produce sufficient lactase, the enzyme that breaks lactose down into simpler sugars.

Northern Europeans generally maintain high lactase levels into adulthood, but even among Europeans some infants do not have high enough lactase levels and are therefore intolerant even of their mothers' milk. This is a highly inadaptive circumstance, and such infants cannot thrive unless the genetic defect is recognized and appropriate substitutes are provided. Some infants lack the ability to metabolize other sugars, which is also a serious detriment. At the other end of the spectrum, wheat gluten and other glutens are poorly tolerated by some, particularly in western Europe (and especially Wales and western Ireland). Wheat has been a staple for thousands of years in Anatolia, the Middle East, and North Africa; it is a "late" food in northern Europe. The Windsor (fava, or broad) bean is a common staple food in southern Europe, but some individuals, particularly those of Mediterranean origin, develop hemolytic anemia (excessive destruction of red blood cells) if they eat them. The Egyptians were aware of this disorder, as were the Romans, and in modern times it has been identified as an inherited trait.

Many foods contain substances that are toxic—such as cyanide compounds—or substances that can render particular nutrients unusable, although the level of toxicity or unusability varies widely. The phytates in wheat can render zinc and iron biologically unavailable; this can result in growth failure and dwarfism, as has been observed in the Middle East. Oxylates in spinach and other greens can inhibit the absorption of calcium, and although the Cucurbitaceae (which includes cucumbers) are generally good sources of several vitamins and may help prevent cancer, some individuals are intolerant of them. The ability to metabolize ethanol also varies among populations and individuals, and these differences may be adaptive or inadaptive, depending upon social circumstances.

Diseases

Population differences in disease susceptibility and resistance to infectious diseases were long postulated, largely on anecdotal evidence. Africans were imported into the plantations of the New World, for example, on the assumption that they were more resistant to malaria. It is recognized that there was some truth in this belief, now that the sickle-cell gene and the red-cell enzyme "defects" have been identified. It is also known how such genes spread in Africa, the Middle East, some parts of Indonesia, and even into southern Europe (Italy). A wide variety of diseases, some of which have been around for a long time, are now being considered for their population implications. For example, the incidence of tuberculosis, which peaked in the mid-19th century, has declined since through improved sanitation and possibly because of improved nutrition; but it is also possible that the virulence of the responsible microorganism (the tubercle bacillus) diminished, the pool of genetically susceptible individuals was reduced, or these two factors worked in combination. Syphilis is another disease that seems to have changed in both virulence and symptomology over time. Similarly, there has been much speculation about the role of these factors in the outbreak and subsidence of the world's great epidemics. More recently, attention has focused on the human immunodeficiency virus (HIV-1), the causative agent of acquired immunodeficiency syndrome (AIDS). It has been suggested that the precurser to the HIV-1 virus was present in a relatively benign state in Africa for a long time and that it mutated into the more virulent form; also under exploration has been the possibility that individuals as well as populations may exhibit differing degrees of susceptibility to the virus.

Language and population. It was once conjectured that languages were originally influenced by hereditary configurations of the mouth, teeth, and tongue of their earliest speakers. Research, however, has failed to relate the characteristics of any spoken language to the genetically transmitted facial configurations of its speakers. English, for instance, seems to be no better learned by children of English ancestry than by those of German, Italian, Egyptian, Ethiopian, or Pakistani derivation. There is an increasingly popular theory, however, that all languages, like all races, have a common origin and that some words are understandable to all peoples, regardless of the language they speak. This hypothesis has been tested by asking children to match words and meanings in a cross-cultural and cross-language context. The results of these tests have been arguably positive, suggesting that vocabulary may have a neurological basis.

Correlation between language families and geographic races

Although language is learned and not genetically inherited, there is an obvious correspondence between the major language families and the geographic races, both of which are the result of initial differences, long maintained, intensified, and directed by thousands of years of geographic separation. Thus, linguists look to genetic differences between groups as an adjunct to linguistic studies, and human geneticists take an interest in comparative linguistics. The smaller or lesser divisions in each geographic area tend to speak related languages, as can be discerned in Denmark, Germany, The Netherlands, part of Belgium, and England. Language as well as gene frequencies identify the Navajo as being of Canadian origin, distinguish the Basques from the French-speaking and Spanish-speaking peoples surrounding them, and separate the Finns from their other Scandinavian neighbours. Conversely, there may be much diversity within a language grouping. Though written Arabic has spread over much of Africa and the Middle East, spoken Arabic still reflects older language and genetic distinctions. Likewise, the dialects of Chinese differ markedly between regions while the written language is mutually intelligible. English in Northumberland and across the Scottish border strongly reflects the language of the Gaelic speakers and follows differences in blood-group distributions.

In Europe there is a strong relationship between genetic distance and linguistic distance. Such groups as the Finns and the Basques are most distant from others, while Celtic speakers (in Ireland, Scotland, and Brittany) are less distant from English and Frisian speakers in their genetic makeup than in their languages. In addition, one language may supplant another as the result of political subjugation. This can be traced from both genetic and linguistic evidence, the latter in the form of loanwords and expressions. English, for example, is full of loanwords of French and Danish origin. Family names (surnames) also indicate previous periods of genetic and linguistic interchange as, for example, the Danish-derived names Anderson and Johnson in England; it is more difficult to trace how the French name Beauchamp became Beecham or how the Spanish name Henriques became Hendricks, but the historical and genetic evidence is there.

The languages and peoples of the Pacific Basin also provide collaborative evidence of population movements. Linguistically and genetically, the Polynesians preserve evidence of their origins in and relationships to the Indonesian archipelago. Some words, particularly those relating to specific cultivars, have spread so far and so rapidly from their places of origin that it is very difficult to trace their origins.

Race and "intelligence." People of one group traditionally have found reasons to disparage people of other groups on the basis of their behaviour, language, and other cultural attributes. Thus, the Arabs of the Middle Ages were highly critical of the Frankish (French) traders who did not bathe regularly, as were the Chinese of English mariners. The English took a dim view of many foods in India (although they did borrow chutney), and the Japanese were reluctant to accept beef until the keeping of cattle and the eating of beef was made acceptable by official edict. Commonly, people of one group have regarded people of another group as less trustworthy and, especially, less intelligent. Victors often described the vanquished as being of lower intellectual capacity, and colonizers considered the peoples they came to live among as inherently less capable, mentally inferior, and more childlike. There were learned theological arguments in the past as to whether the natives of North America even had souls, and equally learned discussions (in Europe) on whether or not these people had the capacity to read, write, and do sums.

Such notions were comforting to subjugators in the era of colonialism, and they were particularly congenial when slavery became economically important in the Americas. Yet subjugated peoples often had technological superiority over their new rulers, as shown by the metalworking,

weaving, and survival skills of Africans that were highly appropriate to their native habitats. The English-speaking settlers of North America were highly ethnocentric, according the highest intellectual capacities first to themselves, then to Scottish immigrants, and then (to a lesser extent) to those of German and Scandinavian origin who followed. Later immigrants from Ireland, eastern Europe and the Balkans, and Italy were accorded lesser abilities and capacities. Intelligence tests that were first put into use in the first two decades of the 20th century seemed to confirm earlier beliefs: people who spoke English as a native language scored highest, those who spoke other Germanic languages came next, and those recently arrived from eastern and southern Europe attained much lower test scores. It was later recognized that scores on these tests were language-dependent and also measured familiarity with the culture. For example, the descendants of people from Asia (who scored low on the tests in the early 20th century) have become some of the highest scorers. Another factor now realized is that long exposure to a culture of poverty depresses school-oriented test scores; Americans who have been impoverished for generations continue to score low on the tests.

Inaccuracy of intelligence tests

One may well ask whether people who have long lived in inhospitable deserts, in Arctic and subarctic climes, or in rain forests could have been of inferior mental capacity. Such conditions place a premium on survival skills, demanding a deep knowledge of botany, animal behaviour, and climatology.

GENETIC FACTORS AFFECTING HUMAN POPULATIONS

Admixture. Throughout human history, genetically different human populations have met and mixed. In many instances admixture (also called miscegenation, or gene flow) was accomplished through the friendly meeting of peoples, while in other instances it came as a consequence of invasion and conquest. Often treaties were sealed by an exchange of marriageable members, creating instant kinfolk on both sides of a political boundary. While warfare, invasion, and military occupation might suggest that gene flow was usually unidirectional—from the victor to the vanquished—reverse gene flow also took place. The Vikings contributed their genes to Ireland, England, and especially Scotland, but they also took captive brides home, altering their own gene pools in the process. American occupation forces in Japan after World War II fathered thousands of Japanese-American children, but they also took thousands of Japanese wives back to the United States; subsequent military excursions into Korea and Vietnam have also added genes in both directions.

England, of course, has long experienced gene flow, from the Romans and from Ireland (especially in the north) and Denmark. Spain experienced the advent of Roman legions and then occupation by the Arabic-speaking Moors. Sicily still shows the results of Arab occupation, and the Balkans still contain Muslims, the consequence of long Turkish domination.

The North American melting pot

The North American melting pot is perhaps the prime example of admixture potential, since so many of the world's genetic populations have been brought together in the United States; very few Americans can claim ancestry from fewer than three nations. There are, however, places in the world, such as Brazil and Hawaii, where admixture in relatively recent times is even more complicated. Quite often the ancestors of individuals from these areas came from two or even three continents. A typical Hawaiian, for example, may be an assemblage of Portuguese, Hawaiian, Japanese, and Irish genes. These examples, drawn from older history and more recent international excursions, mark instances of admixture for which there are good records. Earlier historical accounts, which may be less detailed, still reflect the opportunities for admixture over the centuries, such as in Europe from the Hun, Mongol, and other "barbarian" invasions. Few people can claim truly "pure" descent, even over a few centuries and even when travel was at a rate of only a few miles per day. Modern air transport now makes gene flow possible to any point on the globe in a matter of hours.

Isolation. Isolation, either geographic (in the form of oceans, mountain ranges, and deserts) or cultural (factors that favour gene exchange within groups) preserves racial differences and allows for genetic adaptation to climatic and disease factors over long periods of time. Geographic barriers are not perfect, of course, as individuals do cross them, and endogamy is rarely complete. Still, these barriers have remained effective in preserving particular sets of genes within populations. Pre-Columbian America is the classic case of genetic isolation by geography. Except for a small amount of gene flow across the Bering Strait, the peoples of the Americas were almost completely isolated from the genetic changes in Europe, Africa, and Asia and were thus maximally responsive to selective pressures in the New World; the severity of this responsiveness was best demonstrated in the indigenous Americans' lack of immunity to European diseases. Europe, on the other hand, is more of a case of cultural isolation. Geography was never as confining to the south or east. Nevertheless, vast expanses of desert and water and distance served as major impediments to gene flow when the rate of travel was only a few miles per day. As populations increased in size and territory, the possibilities of gene flow also increased, especially as previously separate groups newly came to have contiguous frontiers. But increased population densities and a nearly continuous distribution of humanity from the Baltic to the Adriatic actually tended to impede the flow of advantageous genes, since individuals did not have to travel far to find a mate.

Mutation. New genes in a given population arise by mutation and at a rate proportional to the level of penetrating radiation. Thus, the mutation rate is probably higher in Denver, Colo., than it is in Dubuque, Iowa (in this instance because Denver receives more solar radiation than Dubuque), in people who have been subject to medical X rays, and in those exposed to fallout from atomic weapons. Whether or not a mutant gene becomes established and spreads in a population depends on several factors. If it is both dominant and deleterious it is soon lost, though it may be first expressed as a spontaneous abortion or a developmental defect. If the mutant gene is recessive it can increase in frequency in the population, and if it is advantageous it will increase in frequency under the influence of natural selection. It has been possible to trace some mutant genes, the classic case being the gene for hemophilia that Queen Victoria passed through her descendants to other royal houses of Europe.

Tracing mutant genes

Mutant genes are the raw material upon which natural selection acts. Many of the differences between populations and races presumably arose as mutations were eliminated by selection in some cases and retained in other cases because of their degree of advantage at some place or period in time. For most of the morphological differences that can be seen and measured the advantages are often difficult to adduce, but differences in enzyme or hemoglobin levels are more accessible to investigation. It is clear that the mutant genes for the various atypical hemoglobins (*e.g.,* hemoglobin S and hemoglobin E) were immediately advantageous, since they conferred immunity to malaria, although they were disadvantageous where that disease was absent. The history of mutations culminating in lesser skin pigmentation, however, can only be guessed; it is clearly disadvantageous in areas of high solar radiation but more nearly neutral or possibly advantageous in cloudier climates.

Small-sample effects and human diversity. When populations are small and the number of breeding pairs smaller still, there can be large fluctuations in gene frequencies from generation to generation. Called small-sample effects, they are of particular interest because they provide one explanation for genetic differences among populations. Some genes may be lost from a small gene pool, and other genes may become fixed at a frequency of 1.0 simply by chance. This is the small-sample effect called genetic drift, which is of particular importance when the population size is 1,000 or less and the number of breeding pairs as small as 100. Most early preagricultural and incipient agricultural populations were of necessity that small or smaller; many modern hunter-gatherer groups are still no larger. It is likely that these early populations exhibited

wide fluctuations in gene frequencies from generation to generation, which may account for some of the geographic and local differences that are seen in modern populations.

Moreover, as populations enlarge and split into new populations, purely random allocation of genes rarely occurs. Historically, those who moved away and formed new groups tended to be related and so might differ genetically from those left behind. It is known from the genealogical records kept by the Polynesians that their migrant groups consisted of close relatives; and, when Amish groups in the United States split, the separate populations differed from the start. These are examples of what is called the founder effect. The effect taken to its extreme is evident on Pitcairn Island, where most of the living Pitcairners are descendants of Fletcher Christian, the leader of the HMS *Bounty* mutineers. Similarly, genealogical records kept by the Mormon church document the reproductive success of Joseph Smith and a few others. Family names and historical records also demonstrate how much reproductive success on the part of some of the founders can affect the genetic makeup of small towns and even some larger cities. Though family names usually are patronymic and therefore ignore the women in successive generations, they can be useful measures of microevolutionary change within defined populations in relatively recent times.

The founder effect

THE STUDY OF HUMAN POPULATIONS

Human populations are distinguished or classified in terms of genetically transmitted differences. They are studied (in terms of their hereditary origins and their biological relationships with other such races) for evidence of ongoing evolution and of continuing genetic change. Such studies help explain the origin and persistence of genetically determined diseases and serve to explore their long-term influence. For races that have been long resident in their present locations, research sheds light on the long-term genetic effects of such environmental factors as temperature and climate and of food type, source, and availability. For races that have been formed in the recent and historical past, the investigations can reveal the proportion of different groups that entered into genetic admixture. For particular groups with common racial ancestry that have moved from their original locations, evidence of genetic change also interests researchers.

For the most part, investigations of populations involve groups of individuals rather than individuals themselves. Differences and similarities between groups are expressed as trait frequencies, gene frequencies, and frequencies of different amino-acid sequences; from these frequencies, admixture—both ancient and recent—can be estimated.

Early methods of study. *Morphological comparisons.* For centuries, geographic and local races were identified by the most obvious physical differences, chief among them the colour of eyes, skin, and hair. From such observations came the simple notion of a few groupings based on the apparent colour of the skin alone. In the 19th century, attempts were made to create racial classifications based on the form of the hair: straight, curly, woolly. To some extent these classifications have validity; but hair form is affected by modes of hairdressing, and there is great individual variability in unmodified hair form within groups in many parts of the world. Other observations included those for eyelid form, nasal shape, and cranial shape. The assumption in all these cases was that agreement in trait frequencies was an indication of taxonomic affinity.

Anthropometry. The development of the technique of anthropometry (human bodily measurement) in the 19th century brought other approaches to the identification of races. Various groups of "pygmies" were identified by their extremely short stature. The proportions of leg and torso (trunk) were a distinguishing mark of short-legged groups such as the Eskimo and southern Asians and long-legged peoples such as the Nilotes.

Head measurements (craniometry) showed distinctively roundheaded (brachycephalic) populations like those of central Europe and longheaded (dolichocephalic) populations such as those typical of northern Europe. Cranial and facial bone measurements helped to distinguish differences in living people and in skeletons alike and clarified such features as the broad faces and jutting jaw angles of northern Asians and the broad-faced, narrower heads of some American Indian groups.

Body measurements do reflect a genetic component, but they only can be used with caution, since they are also affected by nutrition. Better-nourished people tend to grow larger in many dimensions because they have more fat and because a more ample diet enables them to build more muscle and bone. In regions in which the nutrition of the population is relatively uniform, however, anthropometry can be useful in comparing genetically isolated subgroups. Anthropometric comparisons are also useful in the study of the skeletal remains of ancient populations, and they are irreplaceable in archaeology for the study of fossil remains.

Modern methods of study. Since about 1940, workers in human taxonomy have studied factors that are genetically and simply determined, such as single-gene traits. While genetically complex differences as in the size and shape of the teeth can also be measured, their utility is limited by ignorance of their exact mode of inheritance. Thus, wisdom teeth never develop (third-molar agenesis) among an exceptionally high proportion of Eskimo and in many Asians, while, by contrast, third-molar agenesis is exceptionally rare in Australia, New Guinea, and in some parts of Africa. This genetically complex trait, however, is relatively little used in making racial comparisons. There are simply inherited skeletal traits, such as presence of a broad middle segment of the fifth, or little, finger (brachymesophalangia-5), that are common in some populations and extremely rare in others. Fusion of two of the wristbones occurs in up to 6 percent of individuals in some parts of Africa but in only the smallest fraction of the populations of Europe or Asia. Such skeletal differences can be studied readily with X rays but are not so easily detected in field studies through ordinary visual inspection. Significant racial differences in the size and thickness of the walls of longer bones also require X rays for their measurement.

Little-used particular traits

Single-gene traits. The greatest amount of information on simply inherited traits bearing on race has come from the study of the blood and from biochemical analysis of the urine. While the components of the blood are no more informative than are those of muscle or viscera, many millions of people throughout the world have had their blood typed, producing an accumulation of information on blood differences, their inheritance, and their geographic distribution. In similar fashion, modern medical interest in metabolic abnormalities ("biochemical lesions"), often diagnosed by measuring amounts of different amino acids in the urine, has revealed various biochemical polymorphisms (a variety of forms or types) that characterize families of close relatives, microraces, local races, and, in some cases, geographic races as well.

Some findings about race have been by-products of other kinds of study. It was discovered almost by accident that a chemical called phenylthiocarbamide tastes bitter to some people but seems tasteless to others. Only later did physical anthropologists and human geneticists discover that some racial groups are remarkably "taste-blind" to phenylthiocarbamide. Population differences in colour blindness were discovered in the course of routine, large-scale visual examinations for military purposes. Earwax polymorphism (dry-flaky and moist-sticky) was long known in Japan; this observation led European and African geneticists, who had assumed all earwax was sticky, to discover the polymorphism in their own lands. Discovery of the genetically determined deficiency of the enzyme glucose-6-phosphate dehydrogenase (G6PD) came about when new antimalarial drugs were introduced after World War II and occasionally caused dangerous side effects in persons of African and Middle Eastern origin.

Blood traits. The classic human blood groups are examples of traits produced in the individual by the action of a single set of genes within the set of chromosomes (the majority of genetically determined features of the individual come about through the interaction of many gene sets). The first blood groups to be elucidated were those of the ABO system. Because it is known how the A, B, and

The role of blood groups

O groups are inherited, the frequencies of their genes in any human population can be calculated from the results of blood tests. For blood group B, for example, the gene frequency is close to zero among American Indians and Australian Aborigines and occurs in as many as 40 percent of the people in parts of Africa and Asia; it is only a minor blood group in Europe, the observed frequency rarely exceeding 12 percent. Apparently, Australia became isolated reproductively from the rest of the world before B became frequent elsewhere. Most investigators assume either that the East Asian ancestors of American Indians crossed into the North American Arctic before blood group B had become established in Asia or that, having had it once, they lost blood group B in the process of evolution.

Other blood groups often used in racial comparisons include the MN series. The frequencies of M and N are about equal in most parts of Europe, and they do little to characterize local differences there. But since M is virtually missing in Aboriginal Australia and rare in the other lands of the Pacific Basin, and since N is absent or nearly so in American Indians, M and N have great value in comparing Pacific populations, in postulating their origins, and in assessing European or African admixture in various American groups.

Within the Diego blood group, the Diego positive gene (Di^a) is especially common among people of Asian origin. It also has been detected among people of Polish origin in the United States, perhaps as a residue of the Mongol invasions of Europe. Yet Di^a cannot be used to compare people within groups that lack the gene, nor is the question of origins easily resolved simply by comparing those who have it in the highest frequency. Not every genetically determined set of traits has equal value in comparing, differentiating, or searching for the origins of each race. Great differences within the same geographic race point to local selective factors and considerable blood-group diversity. Even within small and related villages, investigators do not use the same list of genetically determined traits for every set of people studied.

Other blood factors

Blood factors other than blood groups include abnormal red pigments, such as hemoglobin S (the variant hemoglobin that is the cause of sickle-cell anemia), which is rare in most parts of the world but found in as many as half the local residents in some parts of Africa. Inherited blood factors include blood substances called haptoglobins and transferrins and deficiency of the red-cell enzyme G6PD, mentioned above. Dozens of additional properties of red blood cells and of other blood fractions have become known through widespread medical use of blood transfusions. Among the best-known of these properties are the so-called Rh blood subtypes, first discovered in rhesus monkeys and later in humans. These became of medical importance in Europe when incompatibility between the Rh types of the mother and her unborn baby was found to damage or kill the fetus. The troublesome Rh-negative gene (r) is relatively common in Europe (especially among the Basques) but less frequent elsewhere; thus, its frequency can be used as one measure of European admixture in populations that once lacked it. Rare or absent in the rest of the world, R_0 (another distinctive gene in the Rh series) is relatively common in Africa. Thus, the occurrence of R_0 can provide a measure of the gene flow into the mixed population of Brazil or out from the "black" people of the port of Puerto Barrios in Guatemala. By its relative frequency, R_0 serves as one measure of the admixture of European and African genes in the United States.

Other genetic traits. Besides blood fractions and blood groups, there are genetically determined differences in the excretion of amino acids via the urine. While some people excrete much β-amino-isobutyric acid (BAIB), for example, the urine of most people shows very little of this substance even when all share the same diet. Genetically determined BAIB polymorphism and any metabolic advantages it may provide are incompletely understood. Nevertheless, people who do show high levels of BAIB excretion are Asians and some American Indians. If the trait is assumed to have come from Asia, it is an unexpected finding that many Indian groups living nearest to Asia (theoretically of more recent arrival) seem to excrete less BAIB than those living in South America.

Congenital defects

Through continuing natural selection, the frequency of congenital defects differs among populations. Phenylketonuria, a cause of mental deficiency that arises from an inherited enzyme disorder, is far less common in Africa and Asia, for instance, than it is in Europe. Jews from near Vilnius, Lithuanian S.S.R., tend to a relatively high frequency of Tay–Sachs disease (progressive blindness and mental defect in infants); people from England are particularly prone to develop a bone disorder called Paget's disease; and congenital hip dislocations are especially common in American Indians from the Southwest.

Certain types of cleft palate are remarkably common among Japanese, while abnormal narrowing of the body's largest artery, the aorta, is far less frequent in Americans of African origin than in their fellow citizens of other origins. Minor wristbone (carpal) fusions are much more common in people of African ancestry than in Mexican-Americans, who in turn show broad middle segments of the fifth finger much more frequently than black Americans. Women of African origin are comparatively unlikely to suffer the spontaneous fractures and low-back pains that come from adult bone loss (osteoporosis); yet men of African origin who are military pilots are unusually prone to suffer ejection-seat fractures of the lower lumbar vertebrae. Painfully impacted wisdom teeth are most common among Asians and Europeans who are genetically delayed in third-molar development.

Much of the increasing ability to calculate genetic distances and genetic similarities and to infer ancestral relationships is a serendipitous product of advances in medical knowledge. For example, the necessity of matching donors and recipients in organ and tissue transplants resulted in the discovery of the genetically determined human leukocyte group A (HLA), the main transplant antigens. Genetic mapping, involving amino-acid sequences, holds the greatest promise to human evolutionary research because so many different genes can be sampled. A product of genetic engineering, it can help explain how different human populations have been separated and how different lines have converged or combined.

The races of mankind

THE ANTIQUITY OF RACES

Homo sapiens is currently viewed by most systematists to be a single polytypic species derived directly from its predecessor species, *H. erectus,* through continual transformation directed by natural selection. As such, *H. sapiens* has a single origin, in terms of its single predecessor species, but with geographic differentiation arising well before the start of the Holocene epoch (about 10,000 years ago). At least some of the geographically delimited divisions of the species (*i.e.,* geographic, or continental, races) owe many of their distinctive features to differences present at an earlier time that were preserved. For other geographic races, intermediate status in morphological and skeletal features, consistent with their historic locations, may be due to admixture during the Pleistocene epoch or to competing directions of selection.

Modern dating methods support the belief that at least some of the geographic races have been in situ since at least the Late Pleistocene and possibly earlier than that. People resembling living Europeans appear to have lived in North Africa, in the Mediterranean, and even northward before the Holocene. Sub-Saharan Africa appears to have been inhabited by peoples resembling its current inhabitants since the Late Pleistocene. Australoids, or people much like them, may have been in residence in Australia for as long as 30,000 years. The evidence is convincing that the ancestors of the American Indians arrived via land bridges from Asia before the end of the last glaciation. Thus, it is probable that some of the geographic races actually antedate the emergence of pre-sapient hominids. The notion that some of the skeletal (and biochemical) differences between geographic races may antedate the *H. erectus–H. sapiens* boundary is both exciting and debatable. It contradicts the older assumption that *H. sapiens*

Possibility that races antedate *H. sapiens*

arose first, then migrated to different parts of the world, and then differentiated into the modern groupings.

The smaller groupings (local races and microraces) are for the most part of post-Pleistocene origin. Throughout the world, however, there are isolated populations of unique character. Unless these groups possessed extraordinary means of sea travel in prehistory, it must be assumed that they also originally migrated via the system of land bridges that connected continents during the last glaciation.

Human populations, such as American blacks, are of such recent formation that historical records and serological data can be used to trace their origins and to calculate the rate and degree of admixture with Europeans. Similar information has also been applied to the study of the racially complex populations of Brazil, many of the islands of the Caribbean, and Hawaii. In parts of the world where there are less complete historical records of migrations and invasions, serological data can be used to estimate, for example, the extent of Mongol influence in eastern Europe, Turkish influence in Greece and Yugoslavia, and Moorish influence in Spain and Sicily.

It is possible to justify a small number of geographic races if the number of defined populations is suitably restricted. Inclusion of more discrete populations raises the number of geographic races somewhat. It is also possible to identify both a very large number of local races, identical to the number of discrete populations, or to a smaller number placed in historical perspective. Not every population has been explored, and it is possible (but not probable) that additional geographic races will be described in the future. While new additions to technology, such as genetic mapping, will improve, alter, and amend the knowledge of human taxonomy and of relationships (*i.e.*, phylogeny), such additions are likely to be incremental.

THE GEOGRAPHIC RACES

The notion that there were but three primary races of mankind (Caucasoid, Negroid, and Mongoloid) became untenable during the European age of exploration, when new continents, new island chains, and new landmasses were discovered (along with new populations that did not fit into one of the three groupings mentioned above). American Indians, though resembling their Asian neighbours in some respects, were distinctly different in other respects. The Aborigines of Australia, called blacks by Europeans because of their dark skins, differed markedly from the peoples of equatorial Africa. So did the dark-skinned Melanesians, who were so named because of their skin pigmentation. The Polynesians, who resembled mainland Asians in some respects, were not exactly Mongoloid. Likewise, the peoples of the Indian subcontinent, though resembling their neighbours in Persia to the northwest, were not quite Caucasoid.

There are now thought to be between six and 10 major geographically delimited groupings, depending upon the assumptions made in defining them and the degree of attention given to their numbers. It is legitimate, for example, to separate American Indians and Asians because of the millennia that separate them in time, but it is also legitimate to group them (despite differences in blood-group frequencies and the absence of blood group B in American Indians). The same dichotomy exists between Australian Aborigines and Melanesians. Nonetheless, there is a broad consensus among workers for designating nine historical geographic races. They are (1) the African geographic race, which consists of sub-Saharan Africa; (2) the European geographic race, which includes Europe, North Africa, and the Middle East; (3) the Asiatic geographic race, which includes Central, East, and Southeast Asia and the Aleutian Islands and western Alaska; (4) the American Indian geographic race, which includes all of North and South America except western Alaska and the Aleutian Islands; (5) the Indian geographic race, which includes the Indian subcontinent to Nepal and the Iranian border; (6) the Australian geographic race, including Australia and (formerly) Tasmania; (7) the Polynesian geographic race, including the island arch defined by Easter Island, the Hawaiian Islands, and New Zealand; (8) the Micronesian geographic race, including the islands of Yap, Pohnpei, and Guam, and with continuities with the Polynesian group; and (9) the Melanesian geographic race, which includes the island of New Guinea with continuities with the Australian group (see Figure 34).

Number of geographic races

Even a listing of nine geographic races leaves a number of isolated local populations in taxonomic limbo. In Africa these include the Mbuti (Pygmies) of the Ituri Forest of Zaire and the San (Bushmen) of the Kalahari. In Asia the Ainu of northern Japan and groups in Taiwan and mainland China do not fit neatly into the category Asiatics. Eskimo in Asia and North America complicate any enumeration, for, although they are conveniently included under Asiatics, some are actually American Indians who have adapted an Eskimo way of life. Similarly, the Negritos of the Philippines are not easily included in either the Asiatic or Micronesian groups. In addition, there are numerous groupings of historically recent and hybrid origin throughout the Caribbean, in much of Central and South America, and in North America that complicate any attempt at a tidy taxonomy.

Of the nine geographic races, four have received more study than the others, both in morphological and genetic terms. These four are the African, European, American Indian, and Polynesian groupings. They are described in more detail below.

The African geographic race. Africa is geographically isolated from the rest of the world by oceans and seas around its perimeter. Only the narrow and inhospitable Sinai Desert connects the continent to the Middle East. Further isolation is provided by the Sahara, which separates much of Africa from its Mediterranean coast. Thus,

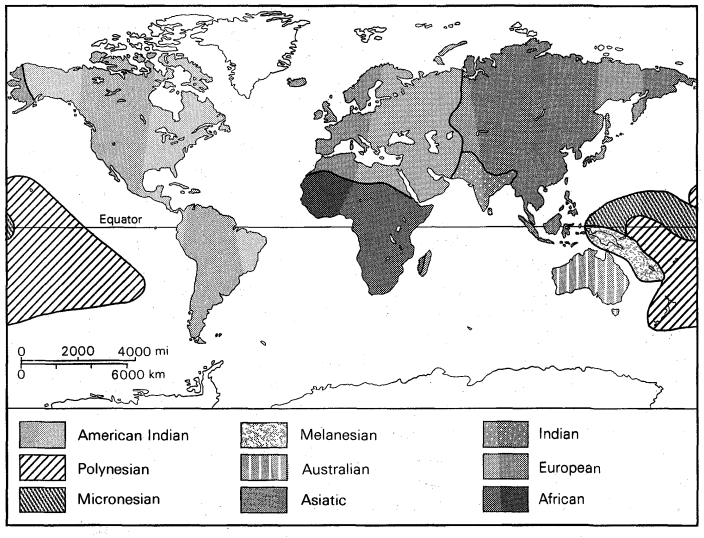

Figure 34: Historical locations of the major races of man.

most of the peoples of Africa constitute a single geographic race but with much local diversity, some of it extending to the last glaciation and before.

Africans south of the Sahara are characterized by heavy concentrations of melanin in the skin. Hair form in much of Africa is distinctive, growing in spiral tufts and with limitations on the attainable length. Tooth crown sizes tend to be large and third-molar agenesis rare. Both tooth formation and tooth eruption tend to be more rapid than in Europeans. Serologically, sub-Saharan Africans are characterized by a rather high incidence of blood group B, by some geographically limited variants in the Rh series, by the S blood group, especially around the Cape of Good Hope, and in the more malarial areas by hemoglobin S and a different constellation of red-cell enzymes. Most African peoples are low in adult lactase levels, except for those long habituated to the use of cow's milk. Geographic diversity is shown in various ways, including lighter pigmentation in the Cape area in the far south and in Ethiopia and Somalia nearest the Gulf of Aden. The present distribution of peoples in Africa has been much influenced by the introduction of such crops as corn (maize) and the potato, which has permitted more intensive agriculture and—by reducing the forest cover—more open areas and clearings, which have favoured the spread of malaria-carrying mosquitoes. Hemoglobin S, advantageous in the presence of malaria, has probably spread in relatively recent times.

Homeland of *Homo*

Africa, especially the area around Lake Tanganyika, now appears to be the homeland of *Homo,* in which case all humans must be of African ancestry. The greatest quantities of prehominid and australopithecine fossils have been found in Africa, and it is possible that the physical appearance and skeletal and serological makeup of present-day Africans is of very considerable antiquity. Thus, it raises the question of just what features were typical of the species before the migrations to Europe and Asia, and which features have come about—in Africa—after humans spread further to all parts of the globe. The Mbuti of the Ituri Forest are of particular interest as an ancient size adaptation with a distinctive variant of growth hormone. The San of the Kalahari are also a distinctive group, remnants of a much larger population, whose pictographs are found over a considerable area of the continent.

The movement of peoples out of Africa in historical times generally has been slow. In ancient times the Nile River served as a conduit for Africans from the Sudan to the cities of Egypt. The greatest outflow occurred between the 16th and 19th centuries, when several million equatorial Africans were captured and taken as slaves to the Americas. Millions were also taken, in servitude, to the Arabian Peninsula.

The European geographic race. Before Iceland, the Americas, Australia, and other places were colonized by Europeans, the European geographic race corresponded in its range to the European continent, North Africa, and the Middle East, with its outermost limit in Ireland to the west and Turkistan to the east. Except for Ireland, a relatively late settlement, these same borders were occupied by distinctively European-appearing peoples for millennia, extending back to the Upper Paleolithic.

Though differing in systematic fashion from north to south and from the northwest (Northern Ireland, the Scottish Highlands, and Denmark) to the southeast (including the Arabian Peninsula), the living peoples of this group are characterized by a rather high frequency of the Rh-negative blood type c, a low frequency of blood group B, nearly equal frequencies of groups M and N, and a variable incidence of relatively unpigmented hair and reduced skin pigmentation (which increases on a northwest–southeast axis). The ability to continue lactase production into adulthood is quite "European" but again declines on a northwest–southeast axis. In general, people from Europe, North Africa, and the Middle East tend to be later in tooth formation and eruption than are other groups.

There are enclaves in Europe that fall out of this description, notably the Lapps of Scandinavia and the Gypsies (who originated in India), and there are groups with linguistic origins outside of Europe proper (*e.g.,* the Finns). But despite population movements and migrations, both overland and by sea, people of European ancestry in many areas have retained skeletal similarities with their Neolithic and even Upper Paleolithic ancestors.

The American Indian geographic race. In facial form, tooth morphology, and minor peculiarities such as brachymesophalangia-5, the indigenous peoples of the Americas often resemble Asiatics, indicating a common ancestry. Some, in fact, have maintained affinities with the Asian mainland through the present, as is true for the Aleuts of the Aleutian Islands and the Eskimo of northern Alaska. Yet most of the "Indians" that Christopher Columbus met had been residents of the Americas for thousands of years, dating back to the existence of land bridges and a more salubrious climate in Alaska and Siberia. It is therefore appropriate to note the Asian origins and similarities, and the differences that have come about with time and isolation by distance and altered sea levels.

Asian origins

The absence of blood group B in American Indians is notable, suggesting that they came to America before blood group B had attained a high frequency in Asia. In the MNS series, American Indians are overwhelmingly M, again indicative of the long separation. Yet such genetically determined traits as shovel-shaped incisors and a relatively high frequency of third-molar agenesis again reaffirm Asian origins, as does eyelid morphology and (for most Indians) projecting malars (cheekbones). Hair form tends to be straight, hair shafts tend to be rather thick, and body hair and facial hair tend to be sparse. Bearded representations are virtually absent in graphic art from the northwest coast, Central America, and Peru. American Indians appear to share with Asiatics a low tolerance for alcohol, indicated by lower levels of the alcohol-degrading enzyme alcohol dehydrogenase.

Most American Indians do not look like "schoolbook" (Plains) Indians, and many do not look especially Asiatic, for variability is great over the range of two continents. Though some groups developed high civilizations and then disappeared, there also has been considerable continuity in many areas with living populations closely resembling those recovered from ancient burials. Many American Indian groups were eliminated as a result of disease, colonial expansion, and forced relocation; but others have come to exceed their pre-Columbian numbers, with varying degrees of admixture from Europe and Africa.

The Polynesian geographic race. The Polynesians were still expanding their territory when the British explorer James Cook first encountered them, and their overseas migrations extending from near New Zealand to Easter Island can be traced. Much of their social structure and their ability to navigate over thousand of miles of open waters is known, and museums preserve many of the resplendent feather cloaks and ceremonial objects they made. European mariners marveled at the Polynesians' body size and appearance. Though they had some Asiatic traits and a distinctively Asiatic appearance, they also appeared quite European.

It is possible to think of the Polynesians in terms of multiple origins—*i.e.,* Asiatic × Melanesian × "primitive" white. It is equally possible to think of the Polynesians as a purely distinctive group of their own. Over thousands of years (as suggested by ancient burials), many now-unoccupied Pacific islands were populated by Polynesians; this fact is reflected by the spread of their cultivars and by the depletion of indigenous animal and bird populations. It is a moot point whether the Polynesians ever reached coastal South America, though it is possible. It is certain, however, that their population numbers were once far larger, and that their language helps to identify their earliest origins.

LOCAL RACES AND MICRORACES

Besides the relatively few geographically delimited groupings just mentioned, there is also a very large number of genetically distinct populations that occupy a defined territory and often speak a language of their own. Many of these local races have been isolated for thousands of years and owe their unique genetic composition to reproductive isolation, selective forces peculiar to their climatic location, their mating practices, and the chance combination of genes that marked them at the start. The Ainu

of northern Japan are of particular interest because they represent the early preagricultural inhabitants who preceded the Neolithic invaders. Other groups—including the San of the Kalahari, the now-extinct Tasmanians, and the people of Tierra del Fuego at the southern tip of South America—are of interest, both genetically and culturally, because they exemplify the population dynamics of numerically small populations with limited mate selection, shortened life spans, and, often, changing gene frequencies from generation to generation.

Local races in larger populations

Local races are not limited to the most distant places and the most hostile environments (*e.g.,* Belgium has both Flemish-speaking and French-speaking populations), but distance and isolation have preserved such groupings over long periods of time. The Basques are of interest because of their unique language (unrelated to Indo-European languages) and their distinctive blood-group gene frequencies. The Berbers in North Africa, who speak a distinct language and who long antedate the spread of Arabic-speaking peoples, were in situ long before the spread of agriculturalists in that part of the world.

The great number of local races and their diversity complicates any attempt at simple listing, such as the numerous "Eskimo" groups, some of which are derived from American Indians and others of which are related culturally, linguistically, and genetically to the Eskimo now spread throughout the Arctic. American Indian groupings, many of which are valid local races, present a wide variety of language groupings and distinct gene frequencies, and it is often possible to re-create their migrations over time. It is known, for example, that the Navajo derive from northern Canada and that they are only relatively recent arrivals in the American Southwest, where they now encircle Hopi groupings that are the remnants of pueblo dwellers who long resided in that area.

In Europe with its hundreds of millions and Asia with its billions, it is often difficult to establish genetic boundaries for smaller populations. Marked average differences in many hereditary traits over the regions from northern to southern Europe, however, have been plotted like lines on a weather map; these clearly show enclaves of genetically distinct peoples. The Basques, and the Lapps of Scandinavia, represent such old enclaves. Gypsies, who still speak a language of Indian origin, are spread across Europe. In addition, European Jews preserve their Middle Eastern origins despite intermarriage with the local populations and their historical movements. Thus, the Sephardic Jews who left Spain during the Inquisition and the Ashkenazi Jews, especially those who live in enclaves in eastern Europe, preserve distinctions; and the Cochin Jews of India are distinct from these two groups and more closely resemble Jews from the Arabian Peninsula, who, in turn, share far more genes with Ethiopian Jews.

In Asia there are many geographically defined local races. Koreans remain distinct, as do the Japanese—although they are somewhat less uniform, especially if Okinawans are included. Differences between the Tibetans and the Han (Chinese) are considerable, and in China there are many local groupings that long have been distinct.

Local races often developed where agriculture, especially the cultivation of high-yielding cereal and tuber crops, was introduced at a late date. Groups that were wholly or largely dependent on hunting and the availability of game and that often lived in adverse climates could not maintain large populations. Even after the introduction of agriculture, yields often remained scanty: Scottish Highlanders considered themselves lucky to harvest four grains of rye for each seed planted, and before the introduction of the potato, agriculture did not support a large population in Ireland. That so many locally defined and genetically distinct populations have continued to exist in such a densely populated area as Europe can be understood in terms of the food supply. Although Britain profited much from industrialization after 1800, for example, its population expansion was fueled by relatively cheap imported grains and ameliorated by emigration to North America and Australia. Wick and Tyrie remain serologically distinct from East Anglia and Eastbourne, as they have for thousands of years.

THE EVER-CHANGING RACES

Population size and ongoing evolution. Population size is a critical factor in ongoing human evolution, ultimately determining whether any given population will continue to exist. If the number of breeding pairs of a population is too small and if many of them are infertile, it will disappear as a separate entity, even if it continues by merging with another. If, on the other hand, the number of breeding pairs becomes large and successful in reproduction, the number of mouths may exceed available resources. In the latter event the population must split and spread, forming at least two daughter populations and extending its territory as well.

Availability of mates

When populations are small, there may be little choice of mates and scant opportunity for selective mating. There may be large disparities in the ages of spouses, as is the case for some small Eskimo groups. Among the living Samaritans of Palestine, historical records reveal that preferential cousin marriage was not practiced when mate availability was low, but that it returned as the population increased. In addition, the smaller the size of a population, the less likely it is that any given mutation will appear, assuming a constant mutation rate over time. A given mutation is also more likely to be lost in a small population simply by accident, although at the other end of the probability curve a given mutation may also achieve a high gene frequency in a small population and even become fixed. These attributes are of interest to medical geneticists in particular, who search for clues to juvenile diabetes, hypercholesterolemia, and other chronic, genetically determined diseases.

Large populations with a thousand breeding pairs (and numbering in the tens of thousands) are also of interest because purely chance effects are less likely to affect gene frequencies from one generation to the next, thus allowing the classic mechanisms of natural selection to function unhindered. Also, large populations are likely to include a considerable socioeconomic range, so that the genetic effects of being poorer or being richer can be measured. In theory, a large population has built-in protection against the accidents of nature and of humans. The Aleuts of the Aleutian Islands were decimated after the arrival of the Russians in the late 18th century, but hundreds of them still survive (their numbers even increased somewhat after Alaska became part of the United States), while smaller groups on the Alaskan mainland now have few survivors. An originally large population size has helped to preserve the Armenians after their original lands were dispersed and despite the losses suffered in Turkey. Dispersion has also served to protect numerous other groups, including the Lapps and European Jews. In each such situation, localized groups have come to show genetic differences due to accidents of sampling and equally localized selective factors.

Large populations tend to acquire smaller, marginal groups, which may lose their identities unless they become localized within limits set by the larger group. Ultimately, the result is an increase in the gene pool, as is now seen in the United States. Often only names remain to identify the original contributors, as with the Scottish, German, Irish, and Polish surnames in a typical Midwestern industrial city—and many of these are Anglicizations and convenient misspellings. Numerically large populations, however, are not necessarily uniform genetic units; identifiable subgroups often suffer some form of discrimination, although it is often the case that those who are discriminated against may enjoy a reproductive advantage over the discriminators. Large class differences in fertility can therefore exist even in a "classless" society, which can give rise to important microevolutionary changes over time.

The ingredients of population evolution

Thus, ongoing evolution at the population level is a product of chance, geography, and natural selection. It also is affected by religion and local attitudes toward reproduction—*e.g.,* whether such attitudes support a norm of large or small families. Between populations, the rate of human evolution may be a question of technological advancement, of the availability of food, or of major medical advances that reduce the number of deaths. As countries develop improved food technology, more effective food

distribution, immunization, and other medical care, their populations tend to increase, thereby changing the genetic makeup of the world's population.

The future of races. The human species is in the process of accelerated evolutionary change, brought about by alterations in the relative size of different populations and by the breaching of geographic and social barriers to gene flow. When hundreds of thousands of individuals are transported from South Korea and Vietnam to the United States, from Pakistan and India to England, or (as guest workers) from Turkey to West Germany and Denmark, gene frequencies in the host countries can scarcely stay static. As China and most of Europe approach zero population growth while Central and South American numbers rapidly expand, it is evident that the human gene pool will be vastly different in a hundred years.

Changes in climate have affected population growth in the relatively recent past. The Little Ice Age in Europe, a cold period that ended about a century ago, had an adverse effect on agriculture. In the 20th century drought in eastern Africa and flooding in Bangladesh have had serious consequences for populations in those regions. The postulated greenhouse effect, which may increase global temperatures and lead to altered patterns of drought and rainfall, holds implications for the future of food production and the relative numbers of people in different geographic populations.

Until the 20th century, malaria was a potent selective force in much of the world, sparing those who lived at higher latitudes and altitudes and those who possessed atypical hemoglobins and red-cell enzyme defects; it continues to be a selective factor in some areas. The HIV-1 virus has become a major selective force in some parts of Africa. New diseases arise, often as mutant forms of less virulent maladies, and with increased international contact can rapidly sweep across the globe. At the same time, some old diseases, such as tuberculosis, seem to have lost their virulence, and thus their role as a possible selective factor is reduced.

Despite these actual or potential events, it is likely that the geographically defined human groupings that emerged from the Pleistocene will remain distinguishable for a long time to come, since these groups still have the advantages of relative geographic separation and vast numbers. It is also likely that many of the locally distinct populations will persist into the foreseeable future, although some do teeter on the brink of disappearance. Political events will determine, for example, whether the Kurds—who have been known since biblical times—survive and whether the San will be assimilated into the Bantu speakers or continue as a distinct group. (S.M.G.)

BIBLIOGRAPHY

General: CHARLES DARWIN, *The Descent of Man and Selection in Relation to Sex,* 2 vol. (1871), is historically the foundation reference. EDWARD O. WILSON, *Sociobiology: The New Synthesis* (1975); G.E. KENNEDY, *Paleoanthropology* (1980); and MILFORD H. WOLPOFF, *Paleoanthropology* (1980), are comprehensive general books.

Overviews of human evolution include JOHN BUETTNER-JANUSCH, *Origins of Man: Physical Anthropology* (1966); J.R. NAPIER, *The Roots of Mankind* (1970); W.E. Le GROS CLARK, *The Fossil Evidence for Human Evolution,* 3rd ed. rev. and enlarged by BERNARD G. CAMPBELL (1978); BERNARD WOOD, *Human Evolution* (1978); RICHARD E. LEAKEY, *The Making of Mankind* (1981); C.B. STRINGER (ed.), *Aspects of Human Evolution* (1981); BERNARD G. CAMPBELL, *Human Evolution: An Introduction to Man's Adaptations,* 3rd ed. (1985); ROGER LEWIN, *In the Age of Mankind: A Smithsonian Book of Human Evolution* (1988), and *Human Evolution: An Illustrated Introduction,* 2nd ed. (1989); D.R. PILBEAM, "Human Evolution," Part I of G.A. HARRISON *et al., Human Biology: An Introduction to Human Evolution, Variation, Growth, and Adaptability,* 3rd ed. (1988), pp. 1–143; JOHN READER, *Missing Links: The Hunt for Earliest Man,* 2nd ed. (1988); PAUL MELLARS, "Major Issues in the Emergence of Modern Humans," *Current Anthropology,* 30(3):349–385 (June 1989); and FRANK E. POIRIER, *Understanding Human Evolution,* 2nd ed. (1990).

IAN TATTERSALL, ERIC DELSON, and JOHN VAN COUVERING (eds.), *Encyclopedia of Human Evolution and Prehistory* (1988), is detailed and comprehensive and includes up-to-date bibliographies. A detailed, authoritative, and highly useful catalog of fossil finds is MICHAEL H. DAY, *Guide to Fossil Man,* 4th ed. (1986). MEAVE G. LEAKEY and RICHARD E. LEAKEY (eds.), *The Fossil Hominids and an Introduction to Their Context, 1968–1974* (1978), includes a lengthy catalog of the hominid finds at Koobi Fora. MICHAEL R. ZIMMERMAN and J. LAWRENCE ANGEL (eds.), *Dating and Age Determination of Biological Materials* (1986), includes discussion of dating human fossil remains. Two dated but still useful works are PHILLIP V. TOBIAS, *The Brain in Hominid Evolution* (1971), which contains data on endocranial capacity; and KENNETH P. OAKLEY, *Man the Tool-Maker,* 6th ed. (1972), an account of toolmaking development. PETER J. BOWLER, *Theories of Human Evolution: A Century of Debate, 1844–1944* (1986); and ROGER LEWIN, *Bones of Contention* (1987), discuss some of the major controversies in the field of paleoanthropology.

Good accounts of modern and fossil primates are found in J.R. NAPIER and P.H. NAPIER, *A Handbook of Living Primates: Morphology, Ecology, and Behaviour of Nonhuman Primates* (1967); W.E. Le GROS CLARK, *The Antecedents of Man: An Introduction to the Evolution of the Primates,* 3rd ed. (1971); ELWYN L. SIMONS, *Primate Evolution: An Introduction to Man's Place in Nature* (1972); ALISON JOLLY, *The Evolution of Primate Behavior,* 2nd ed. (1985); DARIS R. SWINDLER and J. ERWIN (eds.), *Comparative Primate Biology,* vol. 1, *Systematics, Evolution, and Anatomy* (1986); and JOHN G. FLEAGLE, *Primate Adaptation & Evolution* (1988). (F.C.H./M.H.D.)

Australopithecus: DONALD C. JOHANSON and MAITLAND A. EDEY, *Lucy: The Beginnings of Humankind* (1981), is a popular account of the discovery and interpretation of the Hadar hominids; and M.D. LEAKEY and J.M. HARRIS (eds.), *Laetoli: A Pliocene Site in Northern Tanzania* (1987), chronicles in detail the finds at this locality, including the tracks of hominid footprints. J.T. ROBINSON, *Early Hominid Posture and Locomotion* (1972), is also useful. FREDERICK E. GRINE, *The Evolutionary History of the "Robust" Australopithecines* (1989), is a comprehensive and specialized guide on the opinions about australopithecine variation. (B.Wo.)

Homo habilis: F.C. HOWELL, "Hominidae," in VINCENT J. MAGLIO and H.B.S. COOKE (eds.), *Evolution of African Mammals* (1978), pp. 154–248, provides thorough descriptions of the fossils assigned to *Homo habilis,* in addition to information about *Australopithecus.* RICHARD POTTS, *Early Hominid Activities at Olduvai* (1988), comments critically on hunting, scavenging, and social behaviour of the earliest humans, using the Olduvai archaeological evidence as a guide. P.V. TOBIAS, "The Brain of *Homo habilis:* A New Level of Organization in Cerebral Evolution," *Journal of Human Evolution,* 16(7–8):741–762 (1987), discusses the implications of brain anatomy for the use of language by the first representatives of *Homo.* C.B. STRINGER, "The Credibility of *Homo habilis,*" in BERNARD WOOD, LAWRENCE MARTIN, and PETER ANDREWS (eds.), *Major Topics in Primate and Human Evolution* (1986), pp. 266–294, advances the argument that fossils referred to as *Homo habilis* may actually document the presence of two distinct species in East Africa at about the same time.

Homo erectus: WILLIAM W. HOWELLS, "*Homo erectus*—Who, When, and Where: A Survey," *Yearbook of Physical Anthropology,* 23:1–23 (1980), is an excellent review. LARS-KÖNIG KÖNIGSSON (ed.), *Current Argument on Early Man* (1980), contains proceedings from a Nobel symposium that includes several papers on *H. erectus.* BECKY A. SIGMON and JEROME S. CYBULSKI (eds.), *Homo erectus* (1981), is a volume of essays by several authors who address history as well as current research on mid-Pleistocene humans. Useful works include RUKANG WU and SHENGLONG LIN, "Peking Man," *Scientific American,* 248(6):86–94 (June 1983), an account of excavations at Chou-k'ou-tien (Zhoukoudian), with information about the stone culture and hunting activities of Chinese *Homo erectus;* PETER ANDREWS and JENS LORENZ FRANZEN (eds.), *The Early Evolution of Man, with Special Emphasis on Southeast Asia and Africa* (1984), containing articles providing geologic background to the study of *Homo erectus* and discussion of anatomic features useful for defining the species; and G.P. RIGHTMIRE, "*Homo erectus* and Later Middle Pleistocene Humans," *Annual Review of Anthropology,* 17:239–260 (1988), a review emphasizing problems in the interpretation of the Middle Pleistocene fossil evidence. (G.P.Ri.)

Homo sapiens: (General): SEYMOUR W. ITZKOFF, *Triumph of the Intelligent: The Creation of Homo sapiens sapiens* (1985), which surveys the development of human intelligence and includes references to many classics in the field. FRED H. SMITH and FRANK SPENCER (eds.), *The Origins of Modern Humans: A World Survey of the Fossil Evidence* (1984), provides regional discussions of late archaic humans and the emergence of modern humans, with emphasis on the ancestor–descendant relationships between the regional groups. CAMERON D. OVEY (ed.), *The Swanscombe Skull: A Survey of Research on a Pleistocene Site* (1964), brings together the information that is available

concerning this fossil and its morphology, classification, dating, and site context. (M.H.D.)

(*Neanderthals*): ERIK TRINKAUS, "The Neandertals and Modern Human Origins," *Annual Review of Anthropology,* 15:193–218 (1986), provides an overview of behavioral contrasts between the Neanderthals and early modern humans, and his *The Shanidar Neandertals* (1983) explores the finds at Shanidar Cave in Iraq. GEORGE CONSTABLE, *The Neanderthals* (1973), is a useful introduction. ERIK TRINKAUS (ed.), *The Emergence of Modern Humans* (1990), discusses the human fossil and archaeological records as they relate to late archaic humans and the origin of modern humans. ERIK TRINKAUS and WILLIAM W. HOWELLS, "The Neanderthals," *Scientific American,* 241(6):118–133 (Dec. 1979), looks at the position of the Neanderthals in human ancestry and at their functional anatomy. (E.Tr.)

(*Cro-Magnons*): MARCELLIN BOULE and HENRI V. VALLOIS, *Fossil Men* (1957; originally published in French, 4th ed., 1952), is a well-illustrated general introduction to the field of fossil hominids, including an extended discussion of the Cro-Magnon peoples and the history of their discovery. *L'Homme de Cro-Magnon: anthropologie et archéologie* (1970), contains a series of papers by specialists in physical anthropology and prehistoric archaeology on the skeletal biology and culture of the Cro-Magnon peoples. ANDRÉ LEROI-GOURHAN, *Treasures of Prehistoric Art* (also published as *The Art of Prehistoric Man in Western Europe,* 1967; originally published in French, 1965), is a magnificently illustrated volume on the art of the Cro-Magnon peoples. HENRI V. VALLOIS and G. BILLY, "Nouvelles Recherches sur les hommes fossiles de l'abri de Cro-Magnon," *L'Anthropologie,* 69(1–2): 47–74 (1965) and 69(3–4): 249–272 (1965), is the most thorough study of the skeletal biology of the human remains from the Cro-Magnon shelter. E. GENET-VARCIN, *Les Hommes fossiles: découvertes et travaux depuis dix années* (1979), provides a descriptive inventory of Cro-Magnon discoveries throughout the world. (H.J.De.)

(*Asia and Australasia*): R.L. KIRK and A.G. THORNE (eds.), *The Origin of the Australians* (1976), contains essays on the nature and origins of the Aboriginal Australians and their relationship to both their nearest neighbours and the rest of the world. G.G. POPE, "Recent Advances in Far Eastern Paleoanthropology," *Annual Review of Anthropology,* 17:43–78 (1988); and RUKANG WU and JOHN W. OLSEN (eds.), *Palaeoanthropology and Palaeolithic Archaeology in the People's Republic of China* (1985), provide overviews of *H. sapiens* discoveries and research. *Atlas of Primitive Man in China* (1980), compiled by the Institute of Vertebrate Paleontology and Paleoanthropology, Chinese Academy of Science, contains maps of fossil finds. (M.H.Wo.)

(*Africa*): Two essays in PAUL MELLARS and CHRISTOPHER STRINGER (eds.), *The Human Revolution: Behavioural and Biological Perspectives on the Origins of Modern Humans* (1989), are especially useful: GÜNTER BRAÜER, "The Evolution of Modern Humans: A Comparison of the African and Non-African Evidence," pp. 123–154; and J. DESMOND CLARK, "The Origins and Spread of Modern Humans: A Broad Perspective on the African Evidence," pp. 565–588. Other essays include G.P. RIGHTMIRE, "Africa and the Origins of Modern Humans," in RONALD SINGER and JOHN K. LUNDY (eds.), *Variation, Culture, and Evolution in African Populations* (1986), pp. 209–220; and C.B. STRINGER and P. ANDREWS, "Genetic and Fossil Evidence for the Origin of Modern Humans," *Science,* 239(4845):1263–68 (Mar. 11, 1988). (G.Br.)

Modern human populations: STANLEY M. GARN, *Human Races,* 3rd ed. (1971), offers a brief, lucid account of the process of race formation with a study of microevolution into small, subracial populations. FREDERICK S. HULSE, *The Human Species: An Introduction to Physical Anthropology,* 2nd ed. (1971), provides a general survey of human evolution and racial distribution. WILLIAM W. HOWELLS, *Mankind in the Making: The Story of Human Evolution,* rev. ed. (1967), also presents original ideas about modern races and their geographic distribution. A.E. MOURANT, ADA C. KOPÉC, and KAZIMIERA DOMANIEWSKA-SOBCZAK, *The Distribution of the Human Blood Groups and Other Polymorphisms,* 2nd ed. (1976), and a supplement with the same title (1983), are the classic works on human blood groups, their distribution, and racial significance. WILLIAM Z. RIPLEY, *The Races of Europe: A Sociological Study* (1899, reissued 1965), contains his original and often-quoted division of the European geographic race into Nordics, Alpines, and Mediterraneans. PETER E. NUTE and GEORGE STAMATOYANNOPOULOS, "Estimating Mutation Rates Using Abnormal Human Hemoglobins," *Yearbook of Physical Anthropology,* 27:135–151 (1984), estimates the rate of mutation of selected conditions. Studies of racial variation, trait inheritance, and continuing evolution include MARGARET MEAD *et al.* (eds.), *Science and the Concept of Race* (1968); CARL JAY BAJEMA, *Natural Selection in Human Populations: The Measurement of Ongoing Genetic Evolution in Contemporary Societies* (1971); JANE H. UNDERWOOD, *Human Variation and Human Microevolution* (1979); and STEPHEN MOLNAR, *Human Variation: Races, Types, and Ethnic Groups,* 2nd ed. (1983). (S.M.G.)

The Theory of Evolution

The diversity of the living world is staggering. More than 2,000,000 existing species of plants and animals have been named and described; many more remain to be discovered—from 10,000,000 to 30,000,000 according to some estimates. What is impressive is not just the numbers but also the incredible heterogeneity in size, shape, and way of life: from lowly bacteria, measuring less than one-thousandth of a millimetre in diameter, to the stately sequoias of California, rising 300 feet (100 metres) above the ground and weighing several thousand tons; from bacteria living in the hot springs of Yellowstone National Park at temperatures near the boiling point of water to fungi and algae thriving on the ice masses of Antarctica and in saline pools at −9° F (−23° C); and from the strange wormlike creatures discovered in dark ocean depths at thousands of feet below the surface to spiders and larkspur plants existing on Mt. Everest more than 19,868 feet above sea level.

The virtually infinite variations on life are the fruit of the evolutionary process. All living creatures are related by descent from common ancestors. Humans and other mammals are descended from shrewlike creatures that lived more than 150,000,000 years ago; mammals, birds, reptiles, amphibians, and fishes share as ancestors aquatic worms that lived 600,000,000 years ago; all plants and animals are derived from bacteria-like microorganisms that originated more than 3,000,000,000 years ago. Biological evolution is a process of descent with modification. Lineages of organisms change through generations; diversity arises because the lineages that descend from common ancestors diverge through time.

The 19th-century English naturalist Charles Darwin argued that organisms come about by evolution, and he provided a scientific explanation, essentially correct but incomplete, of how evolution occurs and why it is that organisms have features—such as wings, eyes, and kidneys—clearly structured to serve specific functions. Natural selection was the fundamental concept in his explanation. Genetics, a science born in the 20th century, reveals in detail how natural selection works and led to the development of the modern theory of evolution. Since the 1960s a related scientific discipline, molecular biology, has advanced enormously knowledge of biological evolution and has made it possible to investigate detailed problems that seemed completely out of reach a few years earlier—for example, how similar the genes of humans and chimpanzees might be (they differ in about 1 or 2 percent of the units that make up the genes).

This article discusses evolution as it applies generally to living things. For a discussion of human evolution, see the article EVOLUTION, HUMAN. For a more complete treatment of a discipline that has proved essential to the study of evolution, see GENETICS AND HEREDITY, THE PRINCIPLES OF. Specific aspects of evolution are discussed in the articles COLORATION, BIOLOGICAL; and MIMICRY. Applications of evolutionary theory to plant and animal breeding are discussed in the article FARMING AND AGRICULTURAL TECHNOLOGY. A detailed discussion of the life and thought of Charles Darwin is found in the article DARWIN.

For coverage of related topics in the *Macropædia* and *Micropædia,* see the *Propædia,* section 312.

The article is divided into the following sections:

History of evolutionary theory

EARLY IDEAS

All human cultures have developed their own explanations for the origin of the world, man, and other creatures. Traditional Judaism and Christianity explain the origin of living beings and their adaptations to their environments—wings, gills, hands, flowers—as the handiwork of an omniscient God. The philosophers of ancient Greece had their own creation myths. Anaximander proposed that animals could be transformed from one kind into another, and Empedocles speculated that they could be made up of various combinations of preexisting parts. Closer to modern evolutionary ideas were the proposals of early Church Fathers like Gregory of Nazianzus and Augustine, who maintained that not all species of plants and animals were created by God; rather, some had developed in historical times from God's creations. Their motivation was not biological but religious: it would have been impossible to hold representatives of all species in a single vessel such as Noah's ark; hence, some species must have come into existence only after the Noachian Flood.

The notion that organisms may change by natural processes was not investigated as a biological subject by Christian theologians of the Middle Ages, but it was, usually incidentally, considered as a possibility by many, includ-

ing Albertus Magnus and his student Thomas Aquinas. Aquinas concluded, after detailed discussion, that the development of living creatures like maggots and flies from nonliving matter like decaying meat was not incompatible with Christian faith or philosophy. But he left it to scientists to decide whether this actually happened in fact.

The idea of progress, particularly the belief in unbounded human progress, was central to the Enlightenment of the 18th century, particularly in France among such philosophers as Condorcet and Diderot and such scientists as Buffon. But belief in progress did not necessarily lead to the development of a theory of evolution. Pierre-Louis Moreau de Maupertuis proposed the spontaneous generation and extinction of organisms as part of his theory of origins, but he advanced no theory of evolution—*i.e.*, the transformation of one species into another through knowable, natural causes. Georges-Louis Leclerc, comte de Buffon, one of the greatest naturalists of the time, explicitly considered—and rejected—the possible descent of several species from a common ancestor. He postulated that organisms arise from organic molecules by spontaneous generation, so that there could be as many kinds of animals and plants as there are viable combinations of organic molecules.

The physician Erasmus Darwin, grandfather of Charles Darwin, offered in his *Zoonomia or the Laws of Organic Life* some evolutionary speculations, but they were not further developed and had no real influence on subsequent theories. The Swedish botanist Carolus Linnaeus devised the hierarchical system of plant and animal classification that is still in use in a modernized form. Although he insisted on the fixity of species, his classification system eventually contributed much to the acceptance of the concept of common descent.

Lamarck's theory of evolution

The great French naturalist Jean-Baptiste Lamarck held the enlightened view of his age that living organisms represent a progression, with humans as the highest form. From this idea he proposed, in the early years of the 19th century, the first broad theory of evolution. Organisms evolve through eons of time from lower to higher forms, a process still going on, always culminating in man. As organisms become adapted to their environments through their habits, modifications occur. Use of an organ or structure reinforces it; disuse leads to obliteration. The characteristics acquired by use and disuse, according to this theory, would be inherited. This assumption, later called the inheritance of acquired characteristics, was thoroughly disproved in the 20th century. Although his theory did not stand up in the light of later knowledge, Lamarck made important contributions to the gradual acceptance of biological evolution and stimulated countless later studies.

CHARLES DARWIN

The founder of the modern theory of evolution was Charles Darwin. The son and grandson of physicians, he enrolled as a medical student at the University of Edinburgh. After two years, however, he left to study at Cambridge University and prepare to become a clergyman. He was not an exceptional student, but he was deeply interested in natural history. On Dec. 27, 1831, a few months after his graduation from Cambridge, he sailed as a naturalist aboard the HMS *Beagle* on a round-the-world trip that lasted until October 1836. Darwin was often able to disembark for extended trips ashore to collect natural specimens.

The discovery of fossil bones from large extinct mammals in Argentina and the observation of numerous species of finches in the Galápagos Islands were among the events credited with stimulating Darwin's interest in how species originate. In 1859 he published *On the Origin of Species by Means of Natural Selection,* a treatise establishing the theory of evolution and, most important, the role of natural selection in determining its course. He published many other books as well, notably *The Descent of Man and Selection in Relation to Sex* (1871), which extends the theory of natural selection to human evolution.

Darwin must be seen as a great intellectual revolutionary who inaugurated a new era in the cultural history of mankind, an era that was the second and final stage of the Copernican revolution that had begun in the 16th and 17th centuries under the leadership of men such as Copernicus, Galileo, and Newton. The Copernican revolution marked the beginnings of modern science. Discoveries in astronomy and physics overturned traditional conceptions of the universe. The Earth was no longer seen as the centre of the universe but as a small planet revolving around one of a myriad of stars; the seasons, the rains that make crops grow, destructive storms, and other vagaries of weather all became understood as aspects of natural processes; the circumvolutions of the planets were now explained by simple laws that also accounted for the motion of projectiles on the Earth.

The universe explained by natural laws

The significance of these and other discoveries was that they led to a conception of the universe as a system of matter in motion governed by laws of nature. The workings of the universe no longer needed to be attributed to the ineffable will of the Creator, but were brought into the realm of science—an explanation of phenomena through natural laws. Physical phenomena like tides, eclipses, and positions of the planets could now be predicted whenever the causes were adequately known. Darwin accumulated evidence showing that evolution had occurred, that diverse organisms share common ancestors, and that living beings have changed drastically over the course of the Earth's history. More importantly, however, he extended to the living world the idea of nature as a system of matter in motion governed by natural laws.

Before Darwin, the origin of the Earth's living things, with their marvelous contrivances for adaptation, had been attributed to the design of an omniscient God. He had created the fish in the waters, the birds in the air, and all sorts of animals and plants on the land. God had endowed these creatures with gills for breathing, wings for flying, and eyes for seeing, and he had coloured birds and flowers so that man could enjoy them and recognize his wisdom. Christian theologians, from Thomas Aquinas on, had argued that the presence of design, so evident in living beings, demonstrates the existence of a supreme creator; the argument from design was Aquinas' "fifth way" for proving the existence of God. In 19th-century England, the eight Bridgewater Treatises were commissioned so that eminent scientists and philosophers would expand on the marvels of the natural world and thereby set forth "the Power, wisdom, and goodness of God as manifested in the Creation."

The British theologian William Paley in his *Natural Theology* (1802) used natural history, physiology, and other contemporary knowledge to elaborate the argument from design. If a person should find a watch, even in an uninhabited desert, Paley contended, the harmony of its many parts would force him to conclude that it had been created by a skilled watchmaker; and, Paley went on, how much more intricate and perfect in design is the human eye, with its transparent lens, its retina placed at the precise distance for forming a distinct image, and its large nerve transmitting signals to the brain.

The argument from design seems to be forceful. A ladder is made for climbing, a knife for cutting, and a watch for telling time; their functional design leads to the conclusion that they have been fashioned by a carpenter, a smith, or a watchmaker. Similarly, the obvious functional design of animals and plants seems to denote the work of a Creator. It was Darwin's genius that he provided a natural explanation for the organization and functional design of living beings.

Darwin accepted the facts of adaptation: hands are for grasping, eyes for seeing, lungs for breathing. But he showed that the multiplicity of plants and animals, with their exquisite and varied adaptations, could be explained by a process of natural selection, without recourse to a Creator or any designer agent. He brought the living world into the realm of natural science, thereby completing the Copernican revolution. All natural phenomena were henceforth opened to explanation by natural causes and viewed as the result of physical processes governed by natural laws. This achievement of Darwin's had intellectual and cultural implications more profound and lasting than his multipronged evidence that convinced contemporaries of the fact of evolution.

Darwin's theory of natural selection

Darwin's theory of natural selection is summarized in the *Origin of Species* as follows:

> As many more individuals are produced than can possibly survive, there must in every case be a struggle for existence, either one individual with another of the same species, or with the individuals of distinct species, or with the physical conditions of life.... Can it, then, be thought improbable, seeing that variations useful to man have undoubtedly occurred, that other variations useful in some way to each being in the great and complex battle of life, should sometimes occur in the course of thousands of generations? If such do occur, can we doubt (remembering that many more individuals are born than can possibly survive) that individuals having any advantage, however slight, over others, would have the best chance of surviving and of procreating their kind? On the other hand, we may feel sure that any variation in the least degree injurious would be rigidly destroyed. This preservation of favourable variations and the rejection of injurious variations, I call Natural Selection.

Natural selection was proposed by Darwin primarily to account for the adaptive organization of living beings; it is a process that promotes or maintains adaptation. Evolutionary change through time and evolutionary diversification (multiplication of species) are not directly promoted by natural selection, but they often ensue as by-products of natural selection as it fosters adaptation to different environments. (See below *The process of evolution: The concept of natural selection.*)

MODERN CONCEPTIONS

The Darwinian aftermath. The publication of the *Origin of Species* produced considerable public excitement. Scientists, politicians, clergymen, and notables of all kinds read and discussed the book, defending or deriding Darwin's ideas. The most visible actor in the controversies immediately following publication was T.H. Huxley, known as "Darwin's bulldog," who defended the theory of evolution with articulate and sometimes mordant words on public occasions as well as in numerous writings. Evolution by natural selection was indeed a favourite topic in society salons during the 1860s and beyond. But serious scientific controversies also arose, first in Britain and then on the Continent and in the United States.

Collaboration of Darwin and Wallace

One occasional participant in the discussion was the naturalist Alfred Russel Wallace, who had hit upon the idea of natural selection independently and had sent a short manuscript to Darwin from the Malay archipelago. On July 1, 1858, one year before the publication of the *Origin,* a paper jointly written by Wallace and Darwin was presented, in the absence of both, to the Linnean Society in London—with apparently little notice. Greater credit is duly given to Darwin than to Wallace for the idea of evolution by natural selection; Darwin developed the theory in considerably more detail, provided far more evidence for it, and was primarily responsible for its acceptance. Wallace's views differed from Darwin's in several ways, most importantly in that Wallace did not think natural selection sufficient to account for the origin of man, which in his view required direct divine intervention.

A younger contemporary of Darwin, with considerable influence during the latter part of the 19th and early 20th centuries, was Herbert Spencer. He was a philosopher rather than a biologist, but he became an energetic proponent of evolutionary ideas, popularized a number of slogans, like "survival of the fittest" (which was taken up by Darwin in later editions of the *Origin*), and engaged in social and metaphysical speculations. His ideas considerably damaged proper understanding and acceptance of the theory of evolution by natural selection. Darwin wrote of Spencer's speculations:

> His deductive manner of treating any subject is wholly opposed to my frame of mind.... His fundamental generalizations (which have been compared in importance by some persons with Newton's laws!) which I dare say may be very valuable under a philosophical point of view, are of such a nature that they do not seem to me to be of any strictly scientific use.

Most pernicious was the crude extension of the notion of "struggle for existence" to human economic and social life that became known as social Darwinism.

The most serious difficulty facing Darwin's evolutionary theory was the lack of an adequate theory of inheritance that would account for the preservation through the generations of the variations on which natural selection was supposed to act. Current theories of "blending inheritance" proposed that offspring merely struck an average between the characteristics of their parents. As Darwin became aware, blending inheritance (including his own theory of "pangenesis") could not account for the conservation of variations, because differences among variant offspring would be halved each generation, rapidly reducing the original variation to the average of the preexisting characteristics.

The missing link in Darwin's argument was provided by Mendelian genetics. About the time the *Origin of Species* was published, the Augustinian monk Gregor Mendel was starting a long series of experiments with peas in the garden of his monastery in Brünn, Austria-Hungary (now Brno, Czech.). These experiments and the analysis of their results are by any standard an example of masterly scientific method. Mendel's paper, published in 1866 in the *Proceedings* of the Natural Science Society of Brünn, formulated the fundamental principles of the theory of heredity that is still current. His theory accounts for biological inheritance through particulate factors (genes) inherited one from each parent, which do not mix or blend but segregate in the formation of the sex cells, or gametes.

Mendel's principles of heredity

Mendel's discoveries, however, remained unknown to Darwin and, indeed, did not become generally known until 1900, when they were simultaneously rediscovered by a number of scientists on the Continent. In the meantime Darwinism, in the latter part of the 19th century, faced an alternative evolutionary theory known as neo-Lamarckism. This hypothesis shared with Lamarck's the importance of use and disuse in the development and obliteration of organs, and it added the notion that the environment acts directly on organic structures, which explained their adaptation to the way of life and environment of the organism. Adherents of this theory discarded natural selection as an explanation for adaptation to the environment.

Prominent among the defenders of natural selection was the German biologist August Weismann, who in the 1880s published his germ-plasm theory. He distinguished two substances that make up an organism: the soma, which comprises most body parts and organs, and the germ plasm, which contains the cells that give rise to the gametes and hence to progeny. Early in the development of an egg, the germ plasm becomes segregated from the soma; that is, from the cells that give rise to the rest of the body. This notion of a radical separation between germ and soma prompted Weismann to assert that inheritance of acquired characteristics was impossible, and it opened the way for his championship of natural selection as the only major process that would account for biological evolution. Weismann's ideas became known after 1896 as neo-Darwinism.

The synthetic theory. The rediscovery in 1900 of Mendel's theory of heredity, by Hugo de Vries of The Netherlands and others, led to an emphasis on the role of heredity in evolution. De Vries proposed a new theory of evolution known as mutationism, which essentially did away with natural selection as a major evolutionary process. According to de Vries (joined by other geneticists such as William Bateson in England), there are two kinds of variation that take place in organisms. One is the "ordinary" variability observed among individuals of a species, which is of no lasting consequence in evolution because, according to de Vries, it could not "lead to a transgression of the species border even under conditions of the most stringent and continued selection." The other consists of the changes brought about by mutations, spontaneous alterations of genes that yield large modifications of the organism and gave rise to new species: "The new species thus originates suddenly, it is produced by the existing one without any visible preparation and without transition."

Mutationists and biometricians

Mutationism was opposed by many naturalists, and in particular by the so-called biometricians, led by Karl Pearson, who defended Darwinian natural selection as the

major cause of evolution through the cumulative effects of small, continuous, individual variations (which the biometricians assumed passed from one generation to the next without being limited by Mendel's laws of inheritance).

The controversy between mutationists (also referred to at the time as Mendelians) and biometricians approached a resolution in the 1920s and '30s through the theoretical work of geneticists. They used mathematical arguments to show, first, that continuous variation (in such characteristics as size, number of eggs laid, and the like) could be explained by Mendel's laws; and second, that natural selection acting cumulatively on small variations could yield major evolutionary changes in form and function. Distinguished members of this group of theoretical geneticists were R.A. Fisher and J.B.S. Haldane in Britain and Sewall Wright in the United States. Their work contributed to the downfall of mutationism and, most importantly, provided a theoretical framework for the integration of genetics into Darwin's theory of natural selection. Yet their work had a limited impact on contemporary biologists because it was formulated in a mathematical language that most of them could not understand; because it was almost exclusively theoretical, with little empirical corroboration; and because it was limited in scope, largely omitting many issues, like speciation, that were of great importance to evolutionists.

A major breakthrough came in 1937 with the publication of *Genetics and the Origin of Species* by Theodosius Dobzhansky, a Russian-born American naturalist and experimental geneticist. Dobzhansky's book advanced a reasonably comprehensive account of the evolutionary process in genetic terms, laced with experimental evidence supporting the theoretical argument. *Genetics and the Origin of Species* may be considered the most important landmark in the formulation of what came to be known as the synthetic theory of evolution, effectively combining Darwinian natural selection and Mendelian genetics. It had an enormous impact on naturalists and experimental biologists, who rapidly embraced the new understanding of the evolutionary process as one of genetic change in populations. Interest in evolutionary studies was greatly stimulated, and contributions to the theory soon began to follow, extending the synthesis of genetics and natural selection to a variety of biological fields.

Influence of Dobzhansky

The main writers who, together with Dobzhansky, may be considered the architects of the synthetic theory were the zoologists Ernst Mayr and Sir Julian Huxley, the paleontologist George G. Simpson, and the botanist George Ledyard Stebbins. These researchers contributed to a burst of evolutionary studies in the traditional biological disciplines and in some emerging ones—notably population genetics and, later, evolutionary ecology. By 1950 acceptance of Darwin's theory of evolution by natural selection was universal among biologists, and the synthetic theory had become widely adopted.

Later developments. The most important line of investigation since 1950 has been the application of molecular biology to evolutionary studies. In 1953 James Watson and Francis Crick deduced the structure of DNA (deoxyribonucleic acid), the hereditary material contained in the chromosomes of every cell's nucleus. The genetic information is contained within the sequence of nucleotides that make up the chainlike DNA molecules. This information determines the sequence of amino acids in the proteins, including enzymes responsible for the organism's fundamental life processes. Genetic information contained in the DNA can thus be investigated by examining the sequences of amino acids in the proteins.

In the mid-1960s techniques like electrophoresis and selective assay of enzymes became available for the rapid and inexpensive study of differences among enzymes and other proteins. The application of these techniques to evolutionary problems made possible the pursuit of issues that earlier could not be investigated; for example, exploring the extent of genetic variation in natural populations (which sets bounds to their evolutionary potential) and determining the amount of genetic change that occurs during the formation of new species.

Comparisons of the amino acid sequences of proteins in different species provided quantitatively precise measures of species divergence, a considerable improvement over the typically qualitative evaluations obtained by comparative anatomy and other evolutionary subdisciplines. In 1968 the Japanese geneticist Motoo Kimura proposed the neutrality theory of molecular evolution, which assumes that at the level of DNA and protein sequence many changes are adaptively neutral and have little or no effect on the molecule's function. If the neutrality theory is correct, there should be a "molecular clock" of evolution; that is, the degree of divergence between species in amino acid or nucleotide sequence would provide a reliable estimate of the time since their divergence. This would make possible a reconstruction of evolutionary history that would reveal the order of branching of different lineages, such as those leading to humans, chimpanzees, and orangutans, as well as the time in the past when the lineages split from one another.

The "molecular clock"

During the 1970s and '80s it gradually became clear that the molecular clock is not exact; nevertheless, it has continued to provide the most reliable source of evidence for reconstructing a history of evolution. The techniques of DNA cloning and sequencing have provided a new and more powerful means of investigating evolution at the molecular level. The fruits of this new development began to accumulate during the 1980s.

The earth sciences have also experienced, in the second half of the 20th century, a conceptual revolution with considerable consequence to the study of evolution. The science of plate tectonics has shown that the configuration and position of the continents and oceans are dynamic, rather than static, features of the Earth. Oceans grow and shrink, while continents break into fragments or coalesce into larger masses. The continents move across the Earth's surface at rates of a few centimetres a year, and over millions of years of geologic history this profoundly alters the face of the Earth, causing major climatic changes along the way. These previously unsuspected massive modifications of the planet's environments have of necessity been reflected in the evolutionary history of life. Biogeography, the evolutionary study of plant and animal distribution, has been revolutionized by the knowledge, for example, that Africa and South America were part of a single landmass some 200,000,000 years ago and that the Indian subcontinent was not connected with Asia until recent geologic times.

Ecology, the study of the interactions of organisms with their environments, has evolved from descriptive studies—"natural history"—into a vigorous biological discipline with a strong mathematical component, both in the development of theoretical models and in the collection and analysis of quantitative data. Evolutionary ecology is an active field of evolutionary biology; another is evolutionary ethology, the study of animal behaviour. Sociobiology, the evolutionary study of social behaviour, is perhaps the most active subfield of ethology. It is also the most controversial, because of its extension to human societies.

IMPACT AND ACCEPTANCE OF EVOLUTIONARY THEORY

The theory of evolution makes statements about three different, though related, issues: (1) the fact of evolution; that is, that organisms are related by common descent; (2) evolutionary history—the details of when lineages split from one another and of the changes that occurred in each lineage; and (3) the mechanisms or processes by which evolutionary change occurs.

The first issue is the most fundamental and the one established with utmost certainty. Darwin gathered much evidence in its support, but the evidence has accumulated continuously ever since, derived from all biological disciplines. The evolutionary origin of organisms is today a scientific conclusion established with the kind of certainty attributable to such scientific concepts as the roundness of the Earth, the motions of the planets, and the molecular composition of matter. This degree of certainty beyond reasonable doubt is what is implied when biologists say that evolution is a "fact"; the evolutionary origin of organisms is accepted by virtually every biologist.

The scientific fact of evolution

But the theory of evolution goes much beyond this first

issue, the general affirmation that organisms evolve. The second and third issues involve seeking to ascertain the evolutionary relationships between particular organisms and the events of evolutionary history, as well as to explain how and why evolution takes place. These are matters of active scientific investigation. Some conclusions are well established; for example, that the chimpanzee and gorilla are more closely related to humans than is any of those three species to the baboon or other monkeys; or that natural selection, the process postulated by Darwin, explains the adaptive configuration of such features as the human eye and the wings of birds. Many matters are less certain, others are conjectural, and still others—such as the characteristics of the first living things and when they came about—remain completely unknown.

Since Darwin, the theory of evolution has gradually extended its influence to other biological disciplines, from physiology to ecology and from biochemistry to systematics. All biological knowledge now includes the phenomenon of evolution. In the words of Dobzhansky, "Nothing in biology makes sense except in the light of evolution."

The term evolution and the concept of change through time have also become incorporated into scientific language well beyond biology, and even into common language. Astrophysicists speak of the evolution of the solar system or of the universe; geologists, of the evolution of the Earth's mantle; psychologists, of the evolution of the mind; anthropologists, of the evolution of cultures; art historians, of the evolution of architectural styles; and couturiers, of the evolution of fashion. These and other disciplines share only the slightest commonality of meaning: the notion of gradual, and perhaps directional, change over the course of time.

Darwin's notion of natural selection has also been extended to other areas of human discourse, particularly in the fields of sociopolitical theory and economics. The extension can only be metaphorical, because in Darwin's intended meaning natural selection applies only to hereditary variations in entities endowed with biological reproduction, that is, to living organisms. That natural selection is a natural process in the living world has been taken by some as a justification for ruthless competition and for "survival of the fittest" in the struggle for economic advantage or for political hegemony. Social Darwinism was an influential social philosophy in some circles through the late 19th and early 20th centuries. At the other end of the political spectrum, Marxist theorists have resorted to evolution by natural selection as an explanation for mankind's political history.

These uses and abuses of the terms evolution and natural selection have in turn stimulated resistance against biological evolution and natural selection. In addition, the theory of evolution has been seen by some people as incompatible with religious beliefs, particularly those of Christianity.

Christianity and evolutionism

The first chapters of the book of Genesis describe God's creation of the world, the plants, the animals, and man. A literal interpretation of Genesis seems incompatible with the gradual evolution of humans and other organisms by natural processes. Independently of the biblical narrative, the Christian beliefs in the immortality of the soul and in man as "created in the image of God" have appeared to many as contrary to the evolutionary origin of man from nonhuman animals.

Religiously motivated attacks started during Darwin's lifetime. In 1874 Charles Hodge, an American Protestant theologian, published *What Is Darwinism?,* one of the most articulate assaults on evolutionism. Hodge perceived Darwin's theory as "the most thoroughly naturalistic that can be imagined and far more atheistic than that of his predecessor Lamarck." He argued that the design of the human eye evinces that "it has been planned by the Creator, like the design of a watch evinces a watchmaker." He concluded that "the denial of design in nature is actually the denial of God."

Other Protestant theologians saw a solution to the difficulty in the idea that God operates through intermediate causes. The origin and motion of the planets could be explained by the law of gravity and other natural processes without denying God's creation and providence. Similarly, evolution could be seen as the natural process through which God brought living beings into existence and developed them according to his plan. Thus, A.H. Strong, the president of Rochester (N.Y.) Theological Seminary, wrote in his *Systematic Theology* (1885): "We grant the principle of evolution, but we regard it as only the method of divine intelligence." The brutish ancestry of man was not incompatible with his excelling status as a creature in the image of God. Strong drew an analogy with Christ's miraculous conversion of water into wine: "The wine in the miracle was not water because water had been used in the making of it, nor is man a brute because the brute has made some contributions to its creation."

Arguments for and against Darwin's theory came from Roman Catholic theologians as well. Gradually, well into the 20th century, evolution by natural selection came to be accepted by the majority of Christian writers. Pope Pius XII in his encyclical *Humani Generis* (1950; "Of the Human Race") acknowledged that biological evolution was compatible with the Christian faith, although he argued that God's intervention was necessary for the creation of the human soul. In 1981 Pope John Paul II stated in an address to the Pontifical Academy of Sciences:

> The Bible itself speaks to us of the origin of the universe and its make-up, not in order to provide us with a scientific treatise but in order to state the correct relationships of man with God and with the universe. Sacred scripture wishes simply to declare that the world was created by God, and in order to teach this truth it expresses itself in the terms of the cosmology in use at the time of the writer.... Any other teaching about the origin and make-up of the universe is alien to the intentions of the Bible, which does not wish to teach how the heavens were made but how one goes to heaven.

The Pope's point was that it would be a blunder to mistake the Bible for an elementary book of astronomy, geology, and biology. The argument was clearly directed against Christian Fundamentalists who see in Genesis a literal description of how the world was created by God. Biblical Fundamentalists make up a minority of Christians, but they have periodically gained considerable public and political influence in the United States. During the decade of the 1920s, more than 20 state legislatures were influenced by them to debate antievolution laws, and four states—Arkansas, Mississippi, Oklahoma, and Tennessee—prohibited the teaching of evolution in their public schools. A spokesman for the antievolutionists was William Jennings Bryan, three times the unsuccessful Democratic candidate for the presidency, who said in 1922, "We will drive Darwinism from our schools." In 1925 Bryan took part in the prosecution of John T. Scopes, a high school teacher in Dayton, Tenn., who had admittedly violated the state's law forbidding the teaching of evolution.

The reaction of Christian Fundamentalists

In 1968 the Supreme Court of the United States declared unconstitutional any law banning the teaching of evolution in public schools. Since that time Christian Fundamentalists have introduced bills in a number of state legislatures ordering that the teaching of "evolution-science" be balanced by allocating equal time to "creation-science." Creation-science maintains that all kinds of organisms abruptly came into existence at the Creation, that the world is only a few thousand years old, and that the Noachian Flood was an actual event which only one pair of each animal species survived. In the 1980s Arkansas and Louisiana passed acts requiring the balanced treatment of evolution-science and creation-science in the schools, but opponents successfully challenged the acts as violations of the constitutionally mandated separation of church and state.

The evidence for evolution

Darwin and other 19th-century biologists found compelling evidence for biological evolution in the comparative study of living organisms, in their geographic distribution, and in the fossil remains of extinct organisms. In the 20th century the evidence from these sources has become considerably stronger and more comprehensive. New biological disciplines—genetics, biochemistry, phys-

Sources of information

iology, ecology—have supplied powerful additional evidence. Molecular biology, the most recent and successful of all biological disciplines, furnishes extensive, consistent, and detailed confirmation of evolution. The amount of information about evolutionary history stored in the DNA and proteins of living things is virtually unlimited. Only a want of resources now precludes the reconstruction of every detail of the phylogenetic history of life on Earth.

Evolutionists are no longer concerned with obtaining evidence to support the fact of evolution, but rather with what sorts of knowledge can be obtained from different sources of evidence. The following sections identify the most productive of these sources and illustrate the types of information they have provided.

THE FOSSIL RECORD

Paleontologists have recovered and studied the fossil remains of many thousands of organisms that lived in the past. The fossil record shows that many kinds of extinct organisms were very different in form from any now living. It also shows successions of organisms through time, manifesting the transition from one form to another.

When an organism dies, it is usually destroyed by other forms of life and by weathering processes. On rare occasions, some body parts—particularly hard ones like shells, teeth, or bones—are preserved by being buried in mud or protected in some other way from predators and weather. Eventually they may become petrified and preserved indefinitely with the rocks in which they are embedded. Methods such as measuring radioactive decay make it possible to estimate the time period when the rocks, and the fossils associated with them, were formed.

Radioactive dating indicates that the Earth was formed about 4,500,000,000 years ago. The earliest fossils resemble microorganisms such as bacteria and blue-green algae; the oldest ones appear in rocks 3,500,000,000 old. The oldest animal fossils, about 700,000,000 years old, come from small wormlike creatures with soft bodies. Numerous fossils belonging to many living phyla and exhibiting mineralized skeletons appear in rocks about 570,000,000 years old. These organisms are different from organisms living now and from those living at intervening times. Some are so radically different that paleontologists have created new phyla in order to classify them. The first vertebrates, animals with backbones, appeared about 400,000,000 years ago; the first mammals less than 200,000,000 years ago. The history of life recorded by fossils presents compelling evidence of evolution.

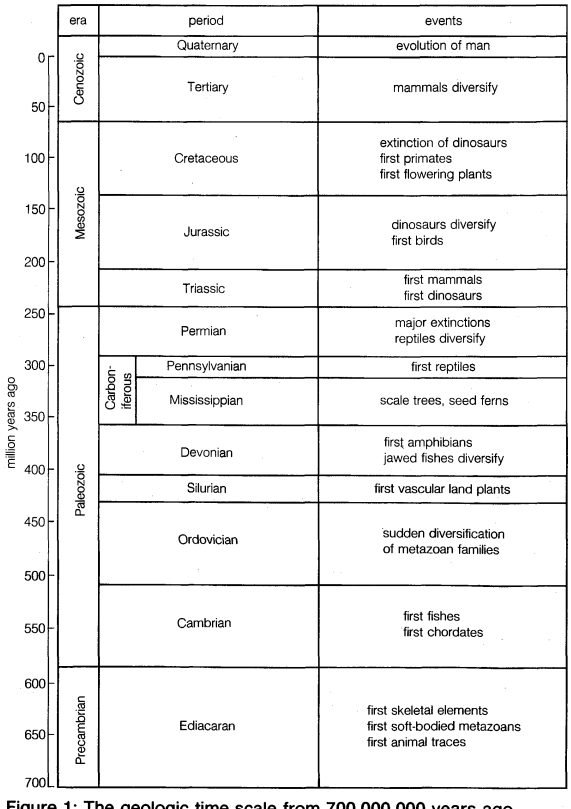

Figure 1: The geologic time scale from 700,000,000 years ago to the present, showing major evolutionary events.

The fossil record is incomplete. Of the small proportion of organisms preserved as fossils, only a tiny fraction have been recovered and studied by paleontologists. But the succession of forms over time has been in some cases reconstructed in detail. One example is the evolution of the horse (see Figure 2). It began with the dawn horse

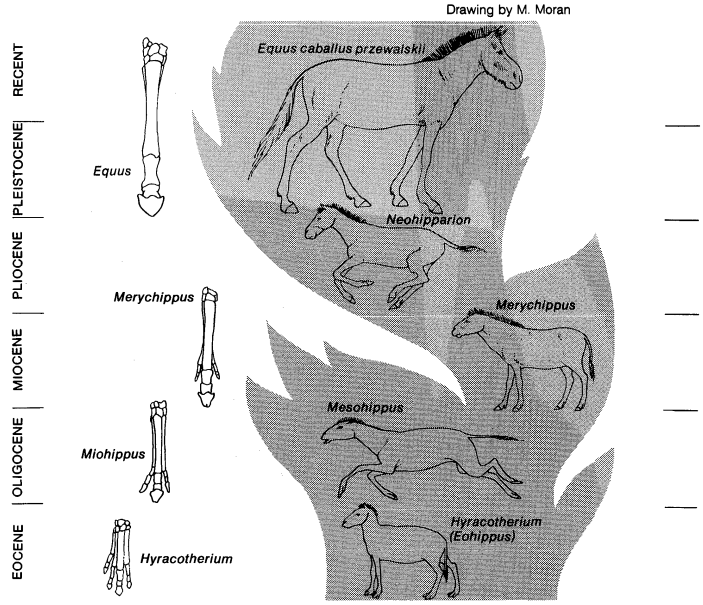

Figure 2: Evolution of the horse.

(genus *Hyracotherium*), an animal the size of a dog, with several toes on each foot and dentition appropriate for browsing, which evolved over 50,000,000 years ago; the most recent form is *Equus*, the modern horse, much larger in size, one-toed, and with teeth appropriate for grazing. The transitional forms are well preserved as fossils, as are many other kinds of extinct horses that evolved in different directions and left no living descendants.

Paleontologists have also been able to recover and reconstruct radical transitions in form and function. The lower jaw of reptiles contains several bones, that of mammals only one; the other bones in the reptile jaw evolved into bones now found in the mammalian ear. This would seem an unlikely transition. A bone being either in the jaw or in the ear, it is hard to imagine what function it could have during the intermediate stages. Yet paleontologists discovered two transitional forms of therapsids (mammal-like reptiles) with a double jaw joint—one joint consisting of the bones that persist in the mammalian jaw, the other composed of the quadrate and articular bones, which eventually became the hammer and anvil of the mammalian ear.

The "missing link"

For skeptical contemporaries of Darwin, the "missing link"—the absence of any transitional form between apes and humans—was a battle cry, as it remained for uninformed people afterward. Not one but many creatures intermediate between living apes and humans have since been found as fossils. *Australopithecus,* a hominid that lived 3,000,000 or 4,000,000 years ago, had an upright human stance but a cranial capacity of less than 500 cubic centimetres—comparable to that of a gorilla or chimpanzee and just about one-third that of humans. Its head displayed an odd mixture of ape and human characteristics: a low forehead and a long, ape-like face, but with teeth proportioned like those of humans. Along with increased cranial capacity, other human characteristics have been found in *Homo habilis,* which lived about 1,500,000 to 2,000,000 years ago and had a cranial capacity of more than 600 cubic centimetres, and *Homo erectus,* which lived between 500,000 and more than 1,000,000

years ago and had a cranial capacity of 800 to 1,100 cubic centimetres.

STRUCTURAL SIMILARITIES

The skeletons of turtles, horses, humans, birds, and bats are strikingly similar, in spite of the different ways of life of these animals and the diversity of their environments. The correspondence, bone by bone, can easily be seen in the limbs (Figure 3), but also in every other part of the body. From a purely practical point of view, it is incomprehensible that a turtle should swim, a horse run, a person write, and a bird or bat fly with structures built of the same bones. An engineer could design better limbs in each case. But if it is accepted that all of these skeletons inherited their structures from a common ancestor and became modified only as they adapted to different ways of life, the similarity of their structures makes sense.

Comparative anatomy investigates the homologies, or inherited similarities, among organisms in bone structure and in other parts of the body. The correspondence of structures is typically very close among some organisms—the different varieties of songbirds, for instance—but becomes less so as the organisms compared are less closely related in their evolutionary history. The similarities are less detailed between mammals and birds than they are among mammals, and less yet between mammals and fishes. Similarities in structure, therefore, not only manifest evolution but also help to reconstruct the phylogeny, or evolutionary history, of organisms.

An explanation of why most organismic structures are not perfect is also revealed by comparative anatomy. Like the forelimbs of turtles, horses, humans, birds, and bats, an organism's body parts are less than perfectly adapted because they are modified from an inherited structure rather than designed from completely "raw" materials for a specific purpose. The imperfection of structures is evidence for evolution and against design.

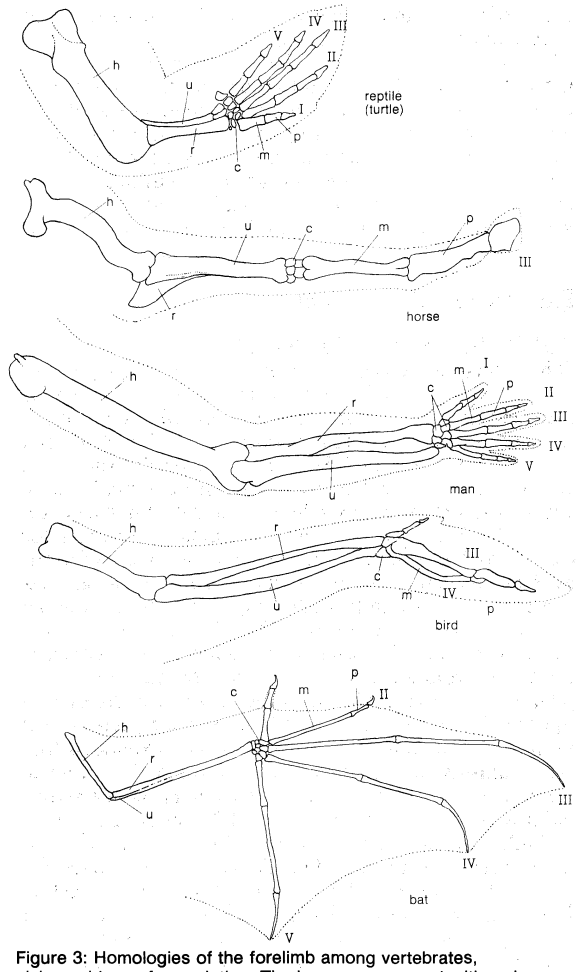

Figure 3: Homologies of the forelimb among vertebrates, giving evidence for evolution. The bones correspond, although they are adapted to the specific mode of life of the animal. The abbreviations are: h, humerus; r, radius; u, ulna; c, carpals; m, metacarpal; p, phalanx. The Roman numerals indicate corresponding digits.

EMBRYONIC DEVELOPMENT AND VESTIGES

Darwin and his followers found support for evolution in the comparative study of embryology—the science that investigates the development of organisms from fertilized egg to time of birth or hatching. Vertebrates, from fishes through lizards to humans, develop in ways that are remarkably similar during early stages, but they become more and more differentiated as the embryos approach maturity. The similarities persist longer between organisms that are more closely related (man and monkey) than between those less closely related (man and shark). Common developmental patterns reflect evolutionary kinship. Lizards and humans share developmental patterns inherited from their remote common ancestor; the inherited pattern was modified only as the separate descendant lineages evolved in different directions. The common embryonic stages of the two creatures reflect the constraints imposed by this common inheritance, which prevents changes that have not been necessitated by their diverging environment and way of life.

Similarity of vertebrate embryos

Human and other nonaquatic embryos exhibit gill slits even though they never breathe through gills. These slits are found in the embryos of all vertebrates because they share as common ancestors the fish in which these structures first evolved. Human embryos also exhibit by the fourth week of development a well-defined tail, which reaches maximum length when the embryo is six weeks old. Similar embryonic tails are found in other mammals, such as dogs, horses, and monkeys; in humans, however, the tail eventually shortens, persisting only as a rudiment in the adult coccyx.

A close evolutionary relationship between organisms that appear drastically different as adults can sometimes be recognized by their embryonic homologies. Barnacles are sedentary crustaceans with little apparent likeness to such crustaceans as lobsters, shrimps, or copepods. Yet barnacles pass through a free-swimming larval stage, the nauplius, which is unmistakably similar to other crustacean larvae.

Embryonic rudiments that never fully develop, such as the gill slits in humans, are common in all sorts of animals. Some, however, like the tail rudiment in humans, persist as adult vestiges reflecting evolutionary ancestry. The most familiar rudimentary organ in humans is the vermiform appendix. This wormlike structure attaches to a short section of intestine called the cecum, which is located at the point where the large and small intestines join. The human vermiform appendix is a functionless vestige of a fully developed organ present in other mammals, such as the rabbit and other herbivores, where a large cecum and appendix store vegetable cellulose to enable its digestion with the help of bacteria. Vestiges are instances of imperfections that argue against creation by design but are fully understandable as a result of evolution.

BIOGEOGRAPHY

Darwin also saw a confirmation of evolution in the geographic distribution of plants and animals, and later knowledge has reinforced his observations. For example, there are about 1,500 species of *Drosophila* vinegar flies in the world; nearly one-third of them live in Hawaii and nowhere else, although the total area of the archipelago is less than one-twentieth the area of California. There are also in Hawaii more than 1,000 species of snails and other land mollusks that exist nowhere else. This unusual diversity is easily explained by evolution. The Hawaiian Islands are extremely isolated and have had few colonizers; those species that arrived there found many unoccupied ecological niches, or local environments suited to sustain them and lacking predators that would prevent them from multiplying. In response, they rapidly diversified; this process of diversifying in order to fill in ecological niches is called adaptive radiation.

Evolutionary significance of species distribution

The continents of the world have their own distinc-

tive fauna and flora. In Africa there are rhinoceroses, hippopotamuses, lions, hyenas, giraffes, zebras, lemurs, monkeys with narrow noses and nonprehensile tails, chimpanzees, and gorillas. South America, which extends over much the same latitudes as Africa, has none of these animals but has different ones: pumas, jaguars, tapirs, llamas, raccoons, opossums, armadillos, and monkeys with broad noses and large prehensile tails.

These vagaries of biogeography are not due solely to the suitability of the different environments. There is no reason to believe that South American animals are not well suited to live in Africa or those of Africa to live in South America. The Hawaiian Islands are no better suited than other Pacific islands for *Drosophila* flies, nor are they less hospitable than other parts of the world for many absent organisms. In fact, although no large mammals are native to the islands, pigs and goats have multiplied there as wild animals since being introduced by humans. This absence of many species from a hospitable environment in which an extraordinary variety of other species flourishes can be explained by the theory of evolution, which holds that species can exist and evolve only in geographic areas that were colonized by their ancestors.

MOLECULAR BIOLOGY

The field of molecular biology has emerged during the mid-20th century. This new discipline has unveiled the nature of hereditary material and the workings of organisms at the level of enzymes and other molecules. Molecular biology provides the most detailed and convincing evidence available for biological evolution.

It is now known that the hereditary material, DNA, and the enzymes that govern all life processes hold information about an organism's ancestry. This information has made it possible to reconstruct evolutionary events that were previously unknown and to confirm and adjust the view of events that already were known. The precision with which events of evolution can be reconstructed is one reason the evidence from molecular biology is so compelling. Another reason is that molecular evolution has shown all living organisms, from bacteria to humans, to be related by descent from common ancestors.

Molecular uniformity of all organisms

A remarkable uniformity exists in the molecular components of organisms—in the nature of the components as well as in the ways in which they are assembled and used. In all bacteria, plants, animals, and humans, the DNA comprises a different sequence of the same four component nucleotides, and all of the various proteins are synthesized from different combinations and sequences of the same 20 amino acids, although several hundred other amino acids do exist. The genetic "code" by which the information contained in the nuclear DNA is passed on to proteins is everywhere the same. Similar metabolic pathways are used by the most diverse organisms to produce energy and to make up the cell components.

This unity reveals the genetic continuity and common ancestry of all organisms. There is no other rational way to account for their molecular uniformity when numerous alternative structures are equally likely. The genetic code may serve as an example. Each particular sequence of three nucleotides in the nuclear DNA acts as a pattern, or code, for the production of exactly the same amino acid in all organisms. This is no more necessary than it is for a language to use a particular combination of letters to represent a particular reality. If it is found that certain sequences of letters—*planet, tree, woman*—are used with identical meanings in a number of different books, one can be sure that the languages used in those books are of common origin.

Genes and proteins are long molecules that contain information in the sequence of their components in much the same way as sentences of the English language contain information in the sequence of their letters and words. The sequences that make up the genes are passed on from parents to offspring, identical except for occasional changes introduced by mutations. To illustrate, assume that two books are being compared; both books are 200 pages long and contain the same number of chapters. Closer examination reveals that the two books are identical page for page and word for word, except that an occasional word—say one in 100—is different. The two books cannot have been written independently; either one has been copied from the other or both have been copied, directly or indirectly, from the same original book. Similarly, if each nucleotide is represented by one letter, the complete sequence of nucleotides in the DNA of a higher organism would require several hundred books of hundreds of pages, with several thousand letters on each page. When the "pages" (or sequence of nucleotides) in these "books" (organisms) are examined one by one, the correspondence in the "letters" (nucleotides) gives unmistakable evidence of common origin.

The arguments presented above are based on different grounds, although both attest to evolution. Using the alphabet analogy, the first argument says that languages that use the same dictionary—the same genetic code and the same 20 amino acids—cannot be of independent origin. The second argument, concerning similarity in the sequence of nucleotides in the DNA or the sequence of amino acids in the proteins, says that books with very similar texts cannot be of independent origin.

The evidence of evolution revealed by molecular biology goes one step further. The degree of similarity in the sequence of nucleotides or of amino acids can be precisely quantified. For example, cytochrome c (a protein molecule) of humans and chimpanzees consists of the same 104 amino acids in exactly the same order; but differs from that of rhesus monkeys by one amino acid, that of horses by 11 additional amino acids, and that of tuna by 21 additional amino acids. The degree of similarity reflects the recency of common ancestry. Thus, the inferences from comparative anatomy and other disciplines concerning evolutionary history can be tested in molecular studies of DNA and proteins by examining their sequences of nucleotides and amino acids.

Molecular clues to evolutionary history

The authority of this kind of test is overwhelming; each of the thousands of genes and thousands of proteins contained in an organism provides an independent test of that organism's evolutionary history. Not all possible tests have been performed, but many hundreds have been done, and not one has given evidence contrary to evolution. There is probably no other notion in any field of science that has been as extensively tested and as thoroughly corroborated as the evolutionary origin of living organisms.

The process of evolution

EVOLUTION AS A GENETIC FUNCTION

The concept of natural selection. The central argument of Darwin's theory of evolution starts from the existence of hereditary variation. Experience with animal and plant breeding demonstrates that variations can be developed that are "useful to man." So, reasoned Darwin, variations must occur in nature that are favourable or useful in some way to the organism itself in the struggle for existence. Favourable variations are ones that increase chances for survival and procreation. Those advantageous variations are preserved and multiplied from generation to generation at the expense of less advantageous ones. This is the process known as natural selection. The outcome of the process is an organism that is well adapted to its environment, and evolution often occurs as a consequence.

Natural selection, then, can be defined as the differential reproduction of alternative hereditary variants, determined by the fact that some variants increase the likelihood that the organisms having them will survive and reproduce more successfully than will organisms carrying alternative variants. Selection may be due to differences in survival, in fertility, in rate of development, in mating success, or in any other aspect of the life cycle. All of these differences can be incorporated under the term "differential reproduction" because all result in natural selection to the extent that they affect the number of progeny an organism leaves.

Darwin maintained that competition for limited resources results in the survival of the most effective competitors. But natural selection may occur not only as a result of competition but also as a result of some aspect of the physical environment, such as inclement weather. Moreover,

natural selection would occur even if all the members of a population died at the same age, simply because some of them would have produced more offspring than others.

Darwinian fitness

Natural selection is quantified by a measure called Darwinian fitness, or relative fitness. Fitness in this sense is the relative probability that a hereditary characteristic will be reproduced; that is, the degree of fitness is a measure of the reproductive efficiency of the characteristic.

Biological evolution is the process of change and diversification of living things over time, and it affects all aspects of their lives—morphology, physiology, behaviour, and ecology. Underlying these changes are changes in the hereditary materials. Hence, in genetic terms, evolution consists of changes in the organism's hereditary makeup.

Evolution can be seen as a two-step process. First, hereditary variation takes place; second, selection is made of those genetic variants that will be passed on most effectively to the following generations. Hereditary variation also entails two mechanisms: the spontaneous mutation of one variant to another, and the sexual process that recombines those variants to form a multitude of variations. The variants that arise by mutation or recombination are not transmitted equally from one generation to another. Some may appear more frequently because they are favourable to the organism; the frequency of others may be determined by accidents of chance, called genetic drift.

Genetic variation in populations. *The gene pool.* The gene pool is the sum total of all of the genes and combinations of genes that occur in a population of organisms of the same species. It can be described by citing the frequencies of the alternative genetic constitutions. Consider, for example, a particular gene (which geneticists call a locus), such as the one determining the MN blood groups in humans. One form of the gene codes for the M blood group, while the other form codes for the N blood group; different forms of the same gene are called alleles. The gene pool of a particular population is specified by giving the frequencies of the alleles *M* and *N*. Thus, in the United States the *M* allele in Caucasoids occurs with a frequency of 0.539 and the *N* allele with a frequency of 0.461. In other populations, these frequencies are different; the frequency of the *M* allele is 0.917 in Navajo Indians and 0.178 in Australian Aborigines.

The necessity of hereditary variation for evolutionary change to occur can be understood in terms of the gene pool. Assume, for instance, that at the gene locus that codes for the MN blood groups there is no variation; only the *M* allele exists in all individuals. Evolution of the MN blood groups cannot take place in such a population, since the allelic frequencies have no opportunity to change from generation to generation. On the other hand, in populations in which both alleles *M* and *N* are present, evolutionary change is possible.

Genetic variation and rate of evolution. The more genetic variation that exists in a population, the greater the opportunity for evolution to occur. As the number of gene loci that are variable increases and as the number of alleles at each locus becomes greater, the likelihood that some alleles will change in frequency at the expense of their alternates grows. The British geneticist R.A. Fisher mathematically demonstrated a direct correlation between the amount of genetic variation in a population and the rate of evolutionary change by natural selection. This demonstration is embodied in his fundamental theorem of natural selection (1930): "The rate of increase in fitness of any organism at any time is equal to its genetic variance in fitness at that time."

Experimental vinegar fly populations

This theorem has been confirmed experimentally. One study employed different strains of *Drosophila serrata,* a species of vinegar fly from eastern Australia and New Guinea. Evolution in vinegar flies can be investigated by using "population cages" and finding out how a population changes over many generations. Experimental populations were set up, with the flies living and reproducing in isolated microcosms. Single-strain populations descended from flies collected either in Popondetta, New Guinea, or in Sydney, Australia; and a mixed population was established by crossing these two strains of flies. The mixed population had the greater initial genetic variation, since it was started by combining two different single-strain populations. To encourage rapid evolutionary change, the populations were manipulated in such a way that there was intense competition among the flies for food and space. Adaptation to the experimental environment was measured by periodically counting the number of individuals in the populations.

Two results deserve notice. First, the mixed population had, at the end of the experiment, more flies than the single-strain populations. Second, and more relevant, the number of flies increased at a faster rate in the mixed population than in the single-strain populations. Evolutionary adaptation to the environment occurred in both types of population; both were able to maintain higher numbers as the generations progressed. But the rate of evolution was more rapid in the mixed group than in the single-strain groups. The greater initial amount of genetic variation made possible a faster rate of evolution.

Measuring gene variability. Because a population's potential for evolving is determined by its genetic variation, evolutionists are interested in discovering the extent of such variation in natural populations. It is readily apparent that plant and animal species are heterogeneous in all sorts of ways; in the flower colours and growth habits of plants, for instance, or the shell shapes and banding patterns of snails. Differences are more readily noticed among humans—in facial features, hair and skin colour, height and weight—but morphological differences are present in all groups of organisms. One problem with morphological variation is that it is not known how much is due to genetic factors and how much may result from environmental influences.

Animal and plant breeders select for their experiments individuals or seeds that excel in desired attributes—in the protein content of corn, for example, or the milk yield of cows. The selection is repeated generation after generation. If the population changes in the direction favoured by the breeder, it becomes clear that the original stock possessed genetic variation with respect to the selected trait. The results of artificial selection are impressive. Selection for high oil content in corn (maize) increased the oil content from less than 5 percent to more than 19 percent in 76 generations, while selection for low oil content reduced it to below 1 percent. Thirty years of selection for increased egg production in a flock of White Leghorn chickens increased the average yearly output of a hen from 125.6 to 249.6 eggs. Artificial selection has produced an endless variety of dog, cat, and horse breeds. The plants that humans grow for food and fibre and the animals they breed for food and transportation are all products of age-old or modern-day artificial selection.

Artificial selection

The success of artificial selection for virtually every trait and every organism in which it has been tried suggests that genetic variation is pervasive throughout natural populations. But evolutionists like to go one step further and obtain quantitative estimates. Only since the 1960s, with the advances of molecular biology, have geneticists developed methods for measuring the extent of genetic variation in populations or among species of organisms. These methods consist essentially of taking a sample of genes and finding out how many are variable and how variable each one is. One simple way of measuring the variability of a gene locus is to ascertain what proportion of the individuals in a population are "heterozygotes" at that locus. In a heterozygous individual, the two genes for a trait, one received from the mother and the other from the father, are different. The proportion of heterozygotes in the population is, therefore, the same as the probability that two genes taken at random from the gene pool are different.

Techniques for determining heterozygosity have been used to investigate numerous species of plants and animals. Typically, insects and other invertebrates are more varied genetically than mammals and other vertebrates; and plants bred by outcrossing exhibit more variation than those bred by self-pollination. But the amount of genetic variation is in any case astounding. Consider as an example humans, whose level of variation is about the same as that of other mammals. The human heterozy-

gosity value is stated as $H = 0.067$, which means that an individual is heterozygous at 6.7 percent of his genes. It is not known how many gene loci there are in humans, but estimates range from 30,000 to 100,000. Assuming the lower estimate, a person would be heterozygous at $30{,}000 \times 0.067 = 2{,}010$ gene loci. An individual heterozygous at one locus (*Aa*) can produce two different kinds of sex cells, or gametes, one with each allele (*A* and *a*); an individual heterozygous at two loci (*AaBb*) can produce four kinds of gametes (*AB, Ab, aB,* and *ab*); an individual heterozygous at *n* loci can potentially produce 2^n different gametes. Therefore, a typical human individual has the potential to produce $2^{2{,}010}$, or approximately 10^{605} (1 with 605 zeros following), different kinds of gametes. But that number is much larger than the estimated number of atoms in the universe, 10^{76}, which is trivial by comparison.

Genetic uniqueness of individuals

It is clear, then, that every sex cell produced by a human being is genetically different from every other sex cell and, therefore, that no two persons who ever existed or will ever exist are likely to be genetically identical—with the exception of identical twins, which develop from a single fertilized ovum. The same conclusion applies to all organisms that reproduce sexually; every individual represents a unique genetic configuration that will never be repeated again. This enormous reservoir of genetic variation in natural populations provides virtually unlimited opportunities for evolutionary change in response to the environmental constraints and the needs of the organisms.

The origin of genetic variation: mutations. Life originated about 3,500,000,000 years ago in the form of primordial organisms that were very simple and very small. All living things have evolved from these lowly beginnings. At present there are more than 2,000,000 known species, which are widely diverse in size, shape, and way of life, as well as in the DNA sequences that contain their genetic information. What has produced the pervasive genetic variation within natural populations and the genetic differences among species? There must be some evolutionary means by which existing DNA sequences are changed and new sequences are incorporated into the gene pools of species.

The information encoded in the nucleotide sequence of DNA is, as a rule, faithfully reproduced during replication, so that each replication results in two DNA molecules that are identical to each other and to the parent molecule. But heredity is not a perfectly conservative process; otherwise, evolution could not have taken place. Occasionally "mistakes," or mutations, occur in the DNA molecule during replication, so that daughter cells differ from the parent cells in the sequence or in the amount of DNA. A mutation first appears on a single cell of an organism, but it is passed on to all cells descended from the first. Mutations can be classified into two categories: gene, or point, mutations, which affect only a few nucleotides within a gene; and chromosomal mutations, which either change the number of chromosomes or change the number or arrangement of genes on a chromosome.

Gene mutations. A gene mutation occurs when the nucleotide sequence of the DNA is altered and a new sequence is passed on to the offspring. The change may be either a substitution of one or a few nucleotides for others or an insertion or deletion of one or a few pairs of nucleotides.

The four nucleotide bases of DNA are represented by the letters A, C, G, and T. A gene that bears the code for constructing a protein molecule consists of a sequence of several thousand nucleotides, so that each segment of three nucleotides—called a codon—codes for one particular amino acid in the protein. The nucleotide sequence in the DNA is first transcribed onto a molecule of messenger RNA (ribonucleic acid). The RNA, with a slightly different code (represented by the letters A, C, G, and U), bears the message that determines which amino acid will be inserted into the protein's chain. Substitutions in the nucleotide sequence of a structural gene may result in changes in the amino acid sequence of the protein, although this is not always the case. The genetic code is redundant in that different triplets may hold the code for the same amino acid. Consider the triplet UUA in the messenger RNA, which codes for the amino acid leucine. If the first U is replaced by C, the triplet will still code for leucine; but if it is replaced by G, it will code for valine instead.

Changing the genetic instruction

A nucleotide substitution in the DNA that results in an amino acid substitution in the corresponding protein may or may not severely affect the biological function of the protein. Some nucleotide substitutions change a codon for an amino acid into a stop signal, and those mutations are likely to have harmful effects. If, for instance, the second U in the UUA triplet is replaced by A, the triplet becomes UAA, a "terminator" codon; the result is that the following triplets in the DNA sequence are not translated into amino acids.

Additions or deletions of nucleotide pairs within the DNA sequence of a structural gene often result in a greatly altered sequence of amino acids in the coded protein. The addition or deletion of one or two nucleotide pairs shifts the "reading frame" of the nucleotide sequence all along the way from the point of the insertion or deletion to the end of the molecule. To illustrate, assume that a DNA segment is read as . . . CAT-CAT-CAT-CAT-CAT. . . . If a nucleotide base, say T, is inserted after the C of the first triplet, the segment will then be read as . . . CTA-TCA-TCA-TCA-TCA. . . . From the point of the insertion onward, the sequence of encoded amino acids is altered. If, however, a total of three nucleotide pairs is either added or deleted, the original reading frame will be restored in the rest of the sequence. Additions or deletions of nucleotide pairs in numbers other than three or multiples of three are called frameshift mutations.

Gene mutations can occur spontaneously; that is, without being intentionally caused by humans. They can also be induced by ultraviolet light, X rays, and other high-frequency radiations, as well as by exposure to certain mutagenic chemicals, such as mustard gas. The consequences of gene mutations may range from negligible to lethal. Mutations that change one or even several amino acids may have a small or undetectable effect on the organism's ability to survive and reproduce if the essential biological function of the coded protein is not hindered. But where an amino acid substitution affects the active site of an enzyme or modifies in some other way an essential function of a protein, the impact may be severe.

Newly arisen mutations are more likely to be harmful than beneficial to their carriers, because mutations are random events with respect to adaptation; that is, their occurrence is independent of any possible consequences. The allelic variants present in an existing population have already been subject to natural selection. They are present in the population because they improve the adaptation of their carriers, and their alternative alleles have been eliminated or kept at low frequencies by natural selection. A newly arisen mutant is likely to have been preceded by an identical mutation in the previous history of a population; if the previous mutant no longer exists in the population, that will be a sign that the new mutant is not beneficial to the organism and is likely to be eliminated also.

This proposition can be illustrated with an analogy. Consider an English sentence, whose words have been chosen because together they express a certain idea. If single letters or words are replaced with others at random, most changes will be unlikely to improve the meaning of the sentence; very likely they will destroy it. The nucleotide sequence of a gene has been "edited" into its present form by natural selection because it "makes sense." If the sequence is changed at random, the "meaning" rarely will be improved and often will be hampered or destroyed.

Occasionally, however, a new mutation may increase the organism's adaptation. The probability of such an event's happening is greater when organisms colonize a new territory or when environmental changes confront a population with new challenges. In these cases, the established adaptation of a population is less than optimal, and there is greater opportunity for new mutations to be better adaptive. The consequences of mutations depend on the environment. Increased melanin pigmentation may be advantageous to inhabitants of tropical Africa, where dark skin protects them from the Sun's ultraviolet radiation; but it is not beneficial in Scandinavia, where the intensity

Adaptation to environmental challenges

of sunlight is low and light skin facilitates the synthesis of vitamin D.

Mutation rates have been measured in a great variety of organisms, mostly for mutants that exhibit conspicuous effects. Mutation rates are generally lower in bacteria and other microorganisms than in more complex species. In humans and other multicellular organisms, the rate typically ranges from about one per 100,000 to one per 1,000,000 gametes. There is, however, considerable variation from gene to gene as well as from organism to organism.

Although mutation rates are low, new mutants appear continuously in nature, because there are many individuals in every species and many gene loci in every individual. The process of mutation provides each generation with many new genetic variations. Thus, it is not surprising to see that when new environmental challenges arise, species are able to adapt to them. More than 200 insect and rodent species, for example, have developed resistance to the pesticide DDT in different parts of the world where spraying has been intense. Although the insects had never before encountered this synthetic compound, they adapted to it rapidly by means of mutations that allowed them to survive in its presence. Similarly, many species of moths and butterflies in industrialized regions have shown an increase in the frequency of individuals with dark wings in response to environmental pollution, an adaptation known as industrial melanism.

Chromosomal mutations. The chromosomes, which carry the hereditary material, or DNA, are contained in the nucleus of each cell. Chromosomes come in pairs, with one member of each pair inherited from each parent. The two members of a pair are called homologous chromosomes. Each cell of an organism and all individuals of the same species have, as a rule, the same number of chromosomes. The reproductive cells (gametes) are an exception; they have only half as many chromosomes as the body (somatic) cells. But the number, size, and organization of chromosomes varies among species. The parasitic nematode *Parascaris univalens* has only one pair of chromosomes, whereas many species of butterflies have more than 100 pairs and some ferns more than 600. Even closely related organisms may vary considerably in the number of chromosomes; species of spiny rats of the South American genus *Proechimys* range from 12 to 31 chromosome pairs. Changes in the number, size, or organization of chromosomes are termed chromosomal mutations, chromosomal abnormalities, or chromosomal aberrations.

Changes in the number and structure of chromosomes

Changes in the number of chromosomes may occur by fusion of two chromosomes into one, by fission of one chromosome into two, or by addition or subtraction of one or more whole chromosomes or sets of chromosomes (polyploidy). Changes in the structure of chromosomes may occur by inversion, when a chromosomal segment rotates 180° within the same location; by duplication, when a segment is added; by deletion, when a segment is lost; or by translocation, when a segment changes from one location to another in the same or a different chromosome. These are the processes by which chromosomes evolve. Inversions, translocations, fusions, and fissions do not change the amount of DNA. The importance of these mutations in evolution is that they change the linkage relationships between genes. Genes that were closely linked to each other become separated and vice versa.

DYNAMICS OF GENETIC CHANGE

Genetic equilibrium: the Hardy–Weinberg law. Genetic variation is present throughout natural populations of organisms. This variation is sorted out in new ways in each generation by the process of sexual reproduction, which recombines the chromosomes inherited from the two parents during the formation of the gametes that produce the following generation. But heredity by itself does not change gene frequencies. This principle is stated by the Hardy–Weinberg law, so called because it was independently discovered in 1908 by the English mathematician G.H. Hardy and the German physician Wilhelm Weinberg.

The Hardy–Weinberg law describes the genetic equilibrium in a population by means of an algebraic equation. It states that genotypes (the genetic constitution of individual organisms) exist in certain frequencies that are a simple function of the allelic frequencies; namely, the square expansion of the sum of the allelic frequencies.

If there are two alleles, A and a, at a gene locus, three genotypes will be possible, AA, Aa, and aa. If the frequencies of the two alleles are p and q, respectively, the equilibrium frequencies of the three genotypes will be given by $(p+q)^2 = p^2 + 2pq + q^2$, for AA, Aa, and aa, respectively. The genotype equilibrium frequencies for any number of alleles are derived in the same way. If there are three alleles, A_1, A_2, and A_3, with frequencies p, q, and r, the equilibrium frequencies corresponding to the six possible genotypes (shown in parentheses) will be calculated as follows:

$$(p+q+r)^2 = p^2(A_1A_1) + q^2(A_2A_2) + r^2(A_3A_3) + 2pq(A_1A_2) + 2pr(A_1A_3) + 2qr(A_2A_3).$$

Table 1 shows how the law operates in a situation with just two alleles. At the top and to the left are the frequencies in the parental generation of the two alleles, p for A and q for a. As shown at the lower right, the probabilities of the three possible genotypes in the following generation are products of the probabilities of the corresponding alleles in the parents. The probability of genotype AA among the progeny is the probability p that allele A will be present in the paternal gamete multiplied by the probability p that allele A will be present in the maternal gamete, or p^2. Similarly, the probability of the genotype aa is q^2. The genotype Aa can arise by getting A from the father and a from the mother, which will occur with a frequency pq, or by getting a from the father and A from the mother, which also has a probability of pq; this gives a total probability of $2pq$ for the frequency of the Aa genotype in the progeny.

Genotype probabilities

Table 1: The Hardy–Weinberg Law Applied to Two Alleles

paternal gametic frequencies	maternal gametic frequencies	
	$p(A)$	$q(a)$
$p(A)$	$p^2(AA)$	$pq(Aa)$
$q(a)$	$pq(Aa)$	$q^2(aa)$

There is no change in the allele equilibrium frequencies from one generation to the next. The frequency of the A allele among the offspring is the frequency of the AA genotype (because all alleles in these individuals are A alleles) plus half the frequency of the Aa genotype (because half the alleles in these individuals are A alleles), or $p^2 + pq = p(p+q) = p$ (because $p+q=1$). Similarly, the frequency of the a allele among the offspring is given by $q^2 + pq = q(q+p) = q$. These are precisely the frequencies of the alleles in the parents.

The genotype equilibrium frequencies are obtained by the Hardy–Weinberg law on the assumption that there is random mating; that is, the probability of a particular kind of mating is the same as the frequency of the genotypes of the two mating individuals. For example, the probability of an AA female mating with an aa male must be p^2 (the frequency of AA) times q^2 (the frequency of aa). Random mating can occur with respect to most gene loci even though mates may be chosen according to particular characteristics. People, for example, choose their spouses according to all sorts of preferences concerning looks, personality, and the like. But concerning the majority of genes, people's marriages are essentially random.

Assortative, or selective, mating takes place when the choice of mates is not random. Marriages in the United States, for example, are assortative with respect to racial features, so that Negroes, Asians, and Caucasoids marry members of their own racial group more often, and people from a different racial group less often, than would be expected from random mating. Consider a community in which 80 percent of the population are white and 20 percent are black. With random mating, 32 percent ($2 \times 0.80 \times 0.20 = 0.32$) of all marriages would be interracial, whereas only 4 percent ($0.20 \times 0.20 = 0.04$) would be marriages between two blacks. These expectations depart from typical observations. The most extreme form of as-

sortative mating is self-fertilization, which occurs rarely in animals but is a common form of reproduction in many plant groups.

Assumptions of the Hardy–Weinberg law

The Hardy–Weinberg law assumes that gene frequencies remain constant from generation to generation—that there is no gene mutation or natural selection and that populations are very large. But these assumptions are not correct; indeed, if they were, evolution could not occur. Why, then, is the Hardy–Weinberg law significant if its assumptions do not hold true in nature? The answer is that the Hardy–Weinberg law plays in evolutionary studies a role similar to that of Newton's first law of motion in mechanics. Newton's first law says that a body not acted upon by a net external force remains at rest or maintains a constant velocity. In fact, there are always external forces acting upon physical objects, but the first law provides the starting point for the application of other laws. Similarly, organisms are subject to mutation, selection, and other processes that change gene frequencies, but the effects of these processes can be calculated by using the Hardy–Weinberg law as the starting point.

Processes of gene frequency change. *Mutation.* The allelic variations that make evolution possible are generated by the process of mutation; but new mutations change gene frequencies very slowly, since mutation rates are low. Assume that the gene allele A_1 mutates to allele A_2 at a rate m per generation, and that at a given time the frequency of A_1 is p. In the next generation, a fraction m of all A_1 alleles become A_2 alleles. The frequency of A_1 in the next generation will then be reduced by the fraction of mutated alleles (pm), or $p_1 = p - pm = p(1 - m)$. After t generations, the frequency of A_1 will be $p_t = p(1 - m)^t$.

If the mutations continue, the frequency of A_1 alleles will gradually decrease, because a fraction of them change every generation to A_2. If the process continues indefinitely, the A_1 allele will eventually disappear, although the process is slow. If the mutation rate is 10^{-5} (1 in 100,000) per gene per generation, about 2,000 generations will be required to change the frequency of A_1 from 0.50 to 0.49 and about 10,000 generations to change it from 0.10 to 0.09.

Moreover, gene mutations are reversible: the allele A_2 may also mutate to A_1. Assume that A_1 mutates to A_2 at a rate m, as before, and that A_2 mutates to A_1 at a rate n per generation. If at a certain time the frequencies of A_1 and A_2 are p and q, respectively, after one generation the frequency of A_1 will be $p_1 = p - pm + qn$. A fraction pm of allele A_1 changes to A_2, but a fraction qn of the A_2 alleles changes to A_1. The conditions for equilibrium occur when $pm = qn$, or $p = m/(m + n)$. Suppose that the mutation rates are $m = 10^{-6}$ and $n = 10^{-5}$; then, at equilibrium, $p = 10^{-6}/(10^{-6} + 10^{-5}) = 1/(1 + 10) = 0.09$, and $q = 0.91$.

Changes in gene frequencies due to mutation occur, therefore, at even slower rates than was suggested above, because forward and backward mutations counteract each other. In any case, allelic frequencies usually are not in mutational equilibrium, because some alleles are favoured over others by natural selection. The equilibrium frequencies are then decided by the interaction between mutation and selection, with selection usually having the greater consequence.

Migration. Gene flow, or gene migration, takes place when individuals migrate from one population to another and interbreed with its members. Gene frequencies are not changed for the species as a whole, but they change locally whenever different populations have different allele frequencies. In general, the greater the difference in allele frequencies between the resident and the migrant individuals, and the larger the number of migrants, the greater effect the migrants have in changing the genetic constitution of the resident population.

Effect of migrants on a resident population

Suppose that a proportion of all reproducing individuals in a population are migrants and that the frequency of allele A_1 is p in the population but p_m among the migrants. The change in gene frequency, Δp, in the next generation will be $\Delta p = m(p_m - p)$. If the migration rate persists for a number t of generations, the frequency of A_1 will be given by $p_t = (1 - m)^t(p - p_m) + p_m$.

Genetic drift. Gene frequencies can change from one generation to another by a process of pure chance known as genetic drift. This occurs because populations are finite in numbers, and thus the frequency of a gene may change in the following generation by accidents of sampling, just as it is possible to get more or less than 50 "heads" in 100 throws of a coin simply by chance.

The magnitude of the gene frequency changes due to genetic drift is inversely related to the size of the population; the larger the number of reproducing individuals, the smaller the effects of genetic drift. This inverse relationship between sample size and magnitude of sampling errors can be illustrated by referring again to tossing a coin. When a penny is tossed twice, two heads are not surprising. But it will be surprising, and suspicious, if 20 tosses all yield heads. The proportion of heads obtained in a series of throws approaches closer to 0.5 as the number of throws grows larger.

The relationship is the same in populations, although the important value here is not the actual number of individuals in the population but the "effective" population size. This means the number of individuals that produce offspring, because only reproducing individuals transmit their genes to the following generation. It is not unusual, in plants as well as animals, for some individuals to have large numbers of progeny while others have none. In marine seals, antelopes, baboons, and many other mammals, for example, a dominant male may keep a large harem of females at the expense of many other males who can find no mates. It often happens that the effective population size is substantially smaller than the number of individuals in any one generation.

The effects of genetic drift in changing gene frequencies from one generation to the next are quite small in most natural populations, which generally consist of thousands of reproducing individuals. The effects over many generations are more important. Indeed, in the absence of other processes of change (such as natural selection and mutation), populations would eventually become fixed, having one allele at each locus after the gradual elimination of all others. With genetic drift as the only force in operation, the probability of a given allele eventually reaching a frequency of 1 would be precisely the frequency of the allele; that is, an allele with a frequency of 0.8 would have an 80 percent chance of ultimately becoming the only allele present in the population. The process would, however, take a long time, because increases and decreases are likely to alternate with equal probability. More important, natural selection and other processes change gene frequencies in deterministic ways, so that no allele has an opportunity to become fixed as a consequence of genetic drift alone.

Genetic drift can have important evolutionary consequences when a new population becomes established by only a few individuals—a phenomenon known as the founder principle. Islands, lakes, and other isolated ecological sites are often colonized by one or very few seeds or animals of a species, which are transported there passively by wind, in the fur of larger animals, or in some other way. The allelic frequencies present in these few colonizers are likely to differ at many loci from those in the population they came from, thus having a lasting impact on the evolution of the new population. The founder principle is one reason that species in neighbouring islands, such as those in the Hawaiian archipelago, are often more heterogeneous than species in comparable continental areas adjacent to one another.

The founder principle

Climatic or other conditions, if unfavourable, may on occasion drastically reduce the number of individuals in a population and even threaten it with extinction. Such occasional reductions are called population bottlenecks. The populations may later recover their typical size, but the allelic frequencies may have been considerably altered, thereby affecting the future evolution of the species. Bottlenecks are more likely in relatively large animals and plants than in smaller ones, because populations of large organisms typically consist of fewer individuals. Primitive human populations of the past were subdivided into many small tribes that were time and again decimated by disease, war, and other disasters. Differences among current human populations in the allele frequencies of many genes—such as those determining the ABO and

other blood groups—may have arisen at least in part as a consequence of bottlenecks in ancestral populations. Persistent population bottlenecks may reduce the overall genetic variation so greatly as to alter future evolution and endanger the survival of the species. A well-authenticated case is that of the cheetah, where no allelic variation whatsoever has been found among the many scores of gene loci studied.

THE OPERATION OF NATURAL SELECTION IN POPULATIONS

Natural selection as a process of genetic change. Natural selection refers to any reproductive bias favouring some genes or genotypes over others. Natural selection promotes the adaptation of organisms to the environments in which they live; any hereditary variant that improves the ability to survive and reproduce in an environment will increase in frequency over the generations, precisely because the organisms carrying such a variant will leave more descendants than those lacking it. Hereditary variants, favourable or not to the organisms, arise by mutation. Unfavourable ones are eventually eliminated by natural selection; their carriers leave no descendants or leave fewer than those carrying alternative variants. Favourable mutations accumulate over the generations. The process continues indefinitely because the environments that organisms live in are forever changing. Environments change physically—in their climate, physical configuration, and so on—but also biologically, because the predators, parasites, and competitors with which an organism interacts are themselves evolving.

The ever-changing environment

Mutation, migration, and drift are random processes with respect to adaptation; they change gene frequencies without regard for the consequences that such changes may have in the ability of the organisms to survive and reproduce. If these were the only processes of evolutionary change, the organization of living things would gradually disintegrate. The effects of such processes alone would be analogous to those of a mechanic who changed parts in a motorcar engine at random, with no regard for the role of the parts in the engine. Natural selection keeps the disorganizing effects of mutation and other processes in check because it multiplies beneficial mutations and eliminates harmful ones.

Natural selection accounts not only for the preservation and improvement of the organization of living beings but also for their diversity. In different localities or in different circumstances, natural selection favours different traits, precisely those that make the organisms well adapted to their particular circumstances and ways of life.

The parameter used to measure the effects of natural selection is fitness, which can be expressed as an absolute or as a relative value. Consider a population consisting at a certain locus of three genotypes: A_1A_1, A_1A_2, and A_2A_2. Assume that on the average each A_1A_1 and each A_1A_2 individual produces one offspring, but that each A_2A_2 individual produces two. One could use the average number of progeny left by each genotype as a measure of that genotype's absolute fitness and calculate the changes in gene frequency that would occur over the generations (this, of course, requires knowing how many of the progeny survive to adulthood and reproduce). Evolutionists, however, find it mathematically more convenient to use relative fitness values—which they represent with the letter w—in most calculations. They usually assign the value 1 to the genotype with the highest reproductive efficiency and calculate the other relative fitness values proportionally. For the example just used, the relative fitness of the A_2A_2 genotype would be $w = 1$ and that of each of the other two genotypes would be $w = 0.5$. A parameter related to fitness is the selection coefficient, often represented with the letter s, which is defined as $s = 1 - w$. The selection coefficient is a measure of the reduction in fitness of a genotype. The selection coefficients in the example are $s = 0$ for A_2A_2 and $s = 0.5$ for A_1A_1 and A_1A_2.

The different ways in which natural selection affects gene frequencies are illustrated by the following examples.

Selection against one of the homozygotes. Suppose that one homozygous genotype, say A_2A_2, has lower fitness than the other two genotypes, A_1A_1 and A_1A_2. (This is the situation in many human diseases, such as phenylketonuria (PKU) and sickle-cell anemia. The heterozygotes and the homozygotes for the normal allele have equal fitness, higher than that of the homozygotes for the deleterious allele.) Call the fitness of these homozygotes $1 - s$ (the fitness of the other two genotypes is 1), and let p be the frequency of the normal allele (A_1) and q the frequency of the deleterious allele (A_2). It can be shown that the frequency of A_2 will decrease each generation by an amount given by $\Delta q = -spq^2/(1 - sq^2)$. The deleterious allele, A_2, will continuously decrease in frequency until it is eliminated. The rate of elimination is fastest when $s = 1$ (*i.e.*, $w = 0$); this occurs with fatal diseases, such as untreated PKU, when the homozygotes die before the age of reproduction.

Because of new mutations, the elimination of a deleterious allele is never complete. A dynamic equilibrium frequency will exist when the number of new alleles produced by mutation is the same as the number eliminated by selection. If the mutation rate at which the deleterious allele arises is u, the equilibrium frequency for a deleterious allele that is recessive is given approximately by $q = \sqrt{u/s}$, which, if $s = 1$, reduces to $q = \sqrt{u}$.

The mutation rate for many human recessive diseases is about 1 in 100,000 ($u = 10^{-5}$). If the disease is fatal, the equilibrium frequency becomes $q \cong \sqrt{10^{-5}} = 0.003$, or about 1 recessive lethal allele for every 300 normal alleles. That is roughly the frequency in human populations of alleles that in homozygous individuals, like those with PKU, cause death before adulthood. The equilibrium frequency for a deleterious, but not lethal, recessive allele is much higher. Albinism, for example, is due to a recessive gene. The reproductive efficiency of albinos is, on average, about 0.9 that of normal individuals. Therefore, $s = 0.1$ and $q = \sqrt{u/s} = \sqrt{10^{-5}/10^{-1}} = 0.01$, or 1 in 100 genes rather than 1 in 300 as for a lethal allele.

For deleterious dominant alleles, the mutation-selection equilibrium frequency is given by $p = u/s$, which for fatal genes becomes $p = u$. If the gene is lethal even in single copy, all the genes are eliminated by selection in the same generation in which they arise, and the frequency of the gene in the population is the frequency with which it arises by mutation. One deleterious condition that is caused by a dominant allele present at low frequencies in human populations is achondroplasia. Because of abnormal growth of the long bones, achondroplastics have short, squat, often deformed limbs, along with bulging skulls. The mutation rate from the normal allele to the achondroplasia allele is about 5×10^{-5}. Achondroplastics reproduce only 20 percent as efficiently as normal individuals; hence, $s = 0.8$. The equilibrium frequency of the allele can therefore be calculated as $p = u/s = 6.25 \times 10^{-5}$.

Overdominance. In many instances the heterozygotes have a higher degree of fitness than the homozygotes for one or the other allele. This situation, known as heterosis or overdominance, leads to the stable coexistence of both alleles in the population and, hence, contributes to the widespread genetic variation found in populations of most organisms. The model situation is:

Greater fitness of heterozygotes

Genotype	A_1A_1	A_1A_2	A_2A_2
Fitness (w)	$1 - s$	1	$1 - t$

It is assumed that s and t are positive numbers between 0 and 1, so that the fitnesses of the two homozygotes are somewhat less than 1. It is not difficult to show that the change in frequency per generation of allele A_2 is $\Delta q = pq(sp - tq)/(1 - sp^2 - tq^2)$. An equilibrium will exist when $\Delta q = 0$ (gene frequencies no longer change); this will happen when $sp = tq$, at which the numerator of the expression for Δq will be 0. The condition $sp = tq$ can be rewritten as $s(1 - q) = tq$ (when $p + q = 1$), which leads to $q = s/(s + t)$. If the fitnesses of the two homozygotes are known, it is possible to infer the allele equilibrium frequencies.

A colour polymorphism in the marine copepod *Tisbe reticulata* is one of many well-investigated examples of overdominance in animals. Three colour morphs found in the lagoon of Venice are known as violacea (homozygous

genotype $V^V V^V$), maculata (homozygous genotype $V^M V^M$), and violacea-maculata (heterozygous genotype $V^V V^M$). The colour polymorphism persists in the lagoon because the heterozygotes survive better than either one of the two homozygotes. In laboratory experiments, the fitness of the three genotypes depends on the degree of crowding, as shown by the following comparison of their relative fitnesses:

Genotype	Fitness in low crowding	Fitness in high crowding
$V^V V^V$	0.89	0.66
$V^V V^M$	1	1
$V^M V^M$	0.90	0.62

The greater the crowding—with more competition for resources—the greater the superiority of the heterozygotes.

Sickle-cell anemia

A particularly interesting example of heterozygote superiority among humans is provided by the gene responsible for sickle-cell anemia. Human hemoglobin in adults is for the most part hemoglobin A, a four-component molecule consisting of two α and two β hemoglobin chains. The normal β hemoglobin chain consists of 146 amino acids and is coded for by the gene Hb^A. A mutant allele of this gene, Hb^S, causes the β chain to have in the sixth position the amino acid valine instead of glutamic acid. This seemingly minor substitution modifies the properties of hemoglobin so that homozygotes with the mutant allele, $Hb^S Hb^S$, suffer from a severe form of anemia that in most cases leads to death before the age of reproduction.

The high frequency of the Hb^S allele in some African and Asian populations formerly was puzzling because the severity of the anemia, representing a strong natural selection against homozygotes, should have eliminated the defective allele. The situation was understood after it was noticed that the Hb^S allele occurred at high frequency precisely in regions of the world where a particularly severe form of malaria (caused by the parasite *Plasmodium falciparum*) was endemic. It was hypothesized that the heterozygotes, $Hb^A Hb^S$, were resistant to malaria, whereas the homozygotes $Hb^A Hb^A$ were not. In malaria-infested regions, then, the heterozygotes survived better than either one of the two homozygotes, which were more likely to die from either malaria ($Hb^A Hb^A$ homozygotes) or anemia ($Hb^S Hb^S$ homozygotes). This hypothesis has been confirmed in various ways. Most significant is that most hospital patients suffering from severe or fatal forms of malaria are homozygotes $Hb^A Hb^A$. In a study of 100 children who died from malaria, only one was found to be a heterozygote, while 22 were expected to be so according to the frequency of the Hb^S allele in the population.

Table 2 shows how the relative fitness of the three β-chain genotypes can be calculated from their distribution among the Yoruba people of Ibadan, Nigeria. The frequency of the Hb^S allele among adults is estimated as $q = 0.1232$. According to the Hardy–Weinberg law, the three genotypes will be formed at conception in the frequencies p^2, $2pq$, and q^2, which are the expected frequencies given in Table 2. The ratios of the observed frequencies among adults to the expected frequencies give the relative survival efficiency of the three genotypes. These are divided by their largest value (1.12) in order to obtain the relative fitness of the genotypes. Sickle-cell anemia reduces the probability of survival of the $Hb^S Hb^S$ homozygotes to 13 percent of that of the heterozygotes; but the homozygotes for the normal allele, $Hb^A Hb^A$, have their survival probability reduced by malaria infection to 88 percent.

Frequency-dependent selection. The fitness of genotypes can change when the environmental conditions change. White fur may be protective to a bear living on the Arctic snows, but not to one living in a California forest; there an allele coding for brown pigmentation may be favoured over one that codes for white. The environment of an organism includes not only the climate and other physical features, but also the organisms of the same or different species with which it is associated.

Effect of population density on fitness

Changes in genotypic fitness are associated with the density of the organisms present. Insects and other short-lived organisms experience enormous yearly oscillations in density. Some genotypes may possess high fitness in the spring, when the population is rapidly expanding, because such genotypes yield more prolific individuals. Other genotypes may be favoured during the summer, when populations are dense, because these genotypes make for better competitors, more successful at securing limited food resources. Still others may be at an advantage during the long winter months, because they increase the population's hardiness, or ability to withstand the inclement conditions that kill most members of the other genotypes.

The fitness of genotypes can also vary according to their relative numbers, and genotype frequencies may change as a consequence. This is known as frequency-dependent selection. Particularly interesting is the situation in which genotypic fitnesses are inversely related to their frequencies. Assume that two genotypes, *A* and *B*, have fitnesses related to their frequencies in such a way that the fitness of either genotype increases when its frequency decreases and vice versa. When *A* is rare, its fitness is high, and therefore *A* increases in frequency; but as it becomes more and more common, the fitness of *A* gradually decreases, so that its increase in frequency eventually comes to a halt. A stable polymorphism occurs at the frequency where the two genotypes, *A* and *B*, have identical fitnesses.

In natural populations of animals and plants frequency-dependent selection is very common and may contribute importantly to the maintenance of genetic polymorphism. In the vinegar fly *Drosophila pseudoobscura*, for example, three genotypes exist at the gene locus coding for the enzyme malate dehydrogenase: the homozygous *SS* and *FF* and the heterozygous *SF*. When the *SS* homozygotes represent 90 percent of the population, they have a fitness about two-thirds that of the heterozygotes, *SF;* but when the *SS* homozygotes represent only 10 percent of the population, their fitness is more than double that of the heterozygotes. Similarly, the fitness of the *FF* homozygotes relative to the heterozygotes increases from less than half to nearly double as their frequency goes from 90 to 10 percent. All three genotypes have equal fitnesses when the frequency of the *S* allele, *p*, is about 0.70, so that there is a stable polymorphism with frequencies $p^2 = 0.49$ for *SS*, $2pq = 0.42$ for *SF*, and $q^2 = 0.09$ for *FF*.

Advantage of genotype mixtures

Frequency-dependent selection may arise because the environment is heterogeneous and because different genotypes can better exploit different subenvironments. When a genotype is rare, the subenvironments that it exploits better will be relatively abundant. But as the genotype becomes common, its favoured subenvironment becomes saturated. That genotype must then compete for resources in subenvironments that are optimal for other genotypes. It follows, then, that a mixture of genotypes exploits the environmental resources better than a single genotype. This has been extensively demonstrated. When the three *Drosophila* genotypes mentioned above were mixed in a single population, the average number of individuals that developed per unit of food was 45.6. This was greater than the numbers of individuals that developed when only one of the genotypes was present, which averaged 41.1 for *SS*, 40.2 for *SF*, and 37.1 for *FF*. Plant breeders know that mixed plantings are more productive than single stands, although farmers avoid them for reasons such as increased harvesting costs.

Sexual preferences can also lead to frequency-dependent selection. It has been demonstrated in some insects, birds, mammals, and other organisms that the mates preferred are precisely those that are rare. People also experience this rare-mate advantage; blonds may seem attractively exotic to Latins, or brunets to Scandinavians.

Table 2: Fitnesses of the Three Genotypes at the Sickle-cell Anemia Locus in a Population from Nigeria

	genotype				
	$Hb^A Hb^A$	$Hb^A Hb^S$	$Hb^S Hb^S$	total	frequency of Hb^S
Observed number	9365	2993	29	12,387	
Observed frequency	0.7560	0.2416	0.0023	1	0.1232
Expected frequency	0.7688	0.2160	0.0152	1	0.1232
Survival efficiency	0.98	1.12	0.15		
Relative fitness	0.88	1	0.13		

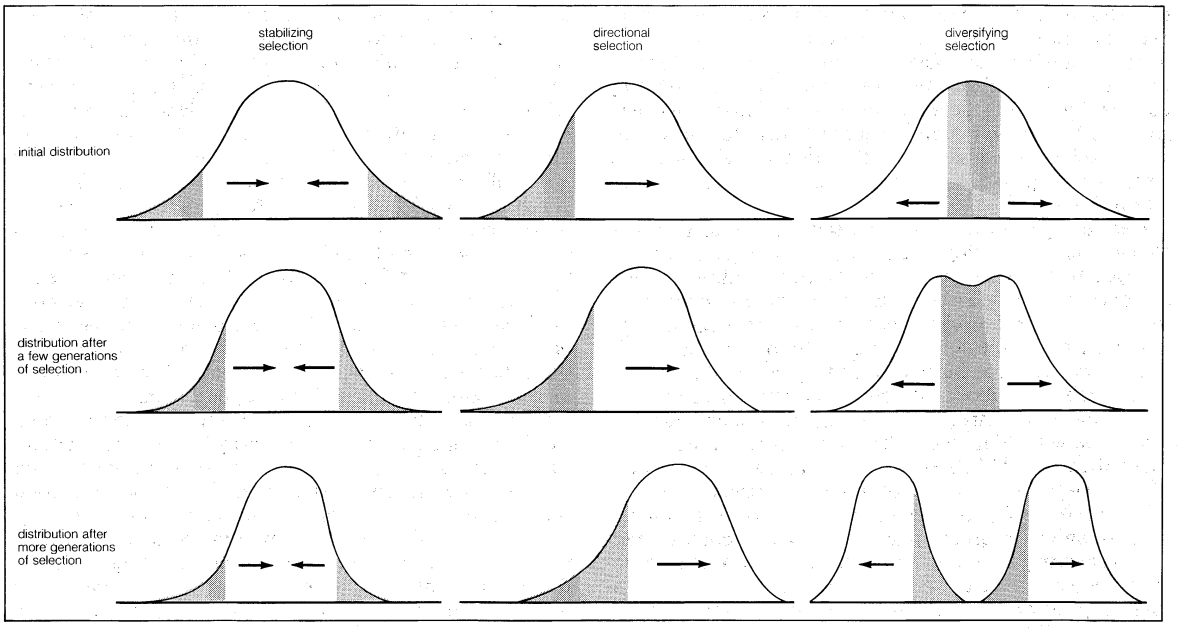

Figure 4: Three types of natural selection showing the effects of each on the distribution of phenotypes within a population. The shaded areas represent the phenotypes against which selection acts. Stabilizing selection acts against phenotypes at both extremes of the distribution, favouring the multiplication of intermediate phenotypes. Directional selection acts against only one extreme of phenotypes, causing a shift in distribution toward the other extreme. Diversifying selection acts against intermediate phenotypes, creating a split in distribution toward each extreme.

Types of selection. *Stabilizing selection.* Natural selection can be studied by analyzing its effects on changing gene frequencies; but it can also be explored by examining its effects on the observable characteristics—or phenotypes—of individuals in a population. Distribution scales of phenotypic traits such as height, weight, number of progeny, or longevity typically show greater numbers of individuals with intermediate values and fewer and fewer toward the extremes (the so-called normal distribution). When individuals with intermediate phenotypes are favoured and extreme phenotypes are selected against, the selection is said to be stabilizing. The range and distribution of phenotypes then remains approximately the same from one generation to another. Stabilizing selection is very common. The individuals that survive and reproduce more successfully are those that have intermediate phenotypic values. Mortality among newborn infants, for example, is highest when they are either very small or very large; infants of intermediate size have a greater chance of surviving.

Stabilizing selection is often noticeable after artificial selection. Breeders choose chickens that produce larger eggs, cows that yield more milk, and corn with higher protein content. But the selection must be continued or reinstated from time to time, even after the desired goals have been achieved. If it is stopped altogether, natural selection gradually takes effect and turns the traits back toward their original intermediate value.

Genetic homeostasis

As a result of stabilizing selection, populations often maintain a steady genetic constitution with respect to many traits. This attribute of populations is called genetic homeostasis.

Directional selection. The distribution of phenotypes in a population sometimes changes systematically in a particular direction. The physical and biological aspects of the environment are continuously changing, and over long periods of time the changes may be substantial. The climate and even the configuration of the land or waters vary incessantly. Changes also take place in the biotic conditions; that is, in the other organisms present, whether predators, prey, parasites, or competitors. Genetic changes occur as a consequence, because the genotypic fitnesses may be shifted so that different sets of alleles are favoured. The opportunity for directional selection also arises when organisms colonize new environments where the conditions are different from those of their original habitat. In addition, the appearance of a new favourable allele or a new genetic combination may prompt directional changes, as the new genetic constitution replaces the preexisting one.

The process of directional selection takes place in spurts. The replacement of one genetic constitution with another changes the genotypic fitnesses at other loci, which then change in their allelic frequencies, thereby stimulating additional changes, and so on in a cascade of consequences.

Directional selection is possible only if there is genetic variation with respect to the phenotypic traits under selection. Natural populations contain large stores of genetic variation, and these are continuously replenished by additional new variants that arise by mutation. The nearly universal success of artificial selection and the rapid response of natural populations to new environmental challenges are evidence that existing variation provides the necessary materials for directional selection.

In modern times, human actions have been an important stimulus to this type of selection. Mankind transforms the environments of many organisms, which rapidly respond to the new environmental challenges through directional selection. Well-known instances are the many cases of insect resistance to pesticides, synthetic substances not present in the natural environment. Whenever a new insecticide is first applied to control a pest, the results are encouraging because a small amount of the insecticide is sufficient to bring the pest organism under control. As time passes, however, the amount required to achieve a certain level of control must be increased again and again until finally it becomes ineffective or economically impractical. This occurs because organisms become resistant to the pesticide through directional selection. The resistance of the housefly, *Musca domestica,* to DDT was first reported in 1947. Resistance to one or more pesticides has now been recorded in more than 100 species of insects.

Industrial melanism

Another example is the phenomenon of industrial melanism—the gradual darkening of the wings of many species of moths and butterflies living in woodlands darkened by industrial pollution. The best investigated case is the peppered moth, *Biston betularia,* of England. Until the middle of the 19th century these moths were uniformly peppered light gray. Darkly pigmented variants were first detected in 1848 in Manchester, Eng., and shortly afterward in other industrial regions where the vegetation was blackened by soot and other pollutants. By the middle of the 20th century the dark varieties had almost completely

replaced the lightly pigmented forms in many polluted areas, while in unpolluted regions light moths continued to be the most common. The shift from light to dark moths was an example of directional selection brought about by bird predators. On lichen-covered tree trunks, the light-gray moths are well camouflaged, whereas the dark ones are conspicuously visible and therefore fall victim to the birds. The opposite is the case on trees darkened by pollution (Figure 5).

Over geologic time, directional selection leads to major changes in morphology and ways of life. Evolutionary changes that persist in a more or less continuous fashion over long periods of time are known as evolutionary trends. Directional evolutionary changes increased the cranial capacity of the human lineage from the small brain of *Australopithecus,* human ancestors of 3,000,000 years ago, which were about 500 cubic centimetres in volume, to a brain nearly three times as large in modern humans, *Homo sapiens.* The evolution of the horse family from more than 50,000,000 years ago to modern times is another well-studied example of directional selection.

Diversifying selection. Two or more divergent phenotypes in an environment may be favoured simultaneously by diversifying selection. No natural environment is homogeneous; rather, the environment of any plant or animal population is a mosaic consisting of more or less dissimilar subenvironments. There is heterogeneity with respect to climate, food resources, and living space. Also, the heterogeneity may be temporal, with change occurring over time, as well as spatial, with dissimilarity found in different areas. Species cope with environmental heterogeneity in diverse ways. One strategy is the selection of a generalist genotype that is well adapted to all of the subenvironments encountered by the species. Another strategy is genetic polymorphism, the selection of a diversified gene pool that yields different genotypes, each adapted to a specific subenvironment.

There is no single plan that prevails in nature. Sometimes the most efficient strategy is genetic monomorphism to confront temporal heterogeneity but polymorphism to confront spatial heterogeneity. If the environment changes in time, if it is unstable relative to the life span of the organisms, each individual will have to face diverse environments appearing one after the other. A series of genotypes, each well adapted to one or another of the conditions that prevail at various times, will not succeed very well, because each organism will fare well at one period of its life but not at others. A better strategy is to have a population with one or a few genotypes that survive well in all the successive environments.

Strategies for adaptation to diverse environments

With respect to spatial heterogeneity, the situation is likely to be different. A single genotype, well adapted to the various environmental patches, is a possible strategy; but a variety of genotypes, with some individuals optimally adapted to each subenvironment, might fare still better. The ability of the population to exploit the environmental patchiness is thereby increased. Diversifying selection refers to the situation in which natural selection favours different genotypes in different subenvironments.

The efficiency of diversifying natural selection is quite apparent in circumstances in which populations living a short distance apart have become genetically differentiated. In one example, populations of bent grass grow on heaps of mining refuse heavily contaminated with metals such as lead and copper. The soil has become so contaminated that it is toxic to most plants, but the dense bent grass stands growing over these refuse heaps have been shown to possess genes that make them resistant to high concentrations of lead and copper. Nonresistant bent grass plants grow a few metres from the contaminated soil. Bent grasses reproduce primarily by cross-pollination, so that the resistant grass receives wind-borne pollen from the neighbouring nonresistant plants. Yet they maintain their genetic differentiation because nonresistant seedlings are unable to grow in the contaminated soil. In nearby uncontaminated soil, the nonresistant seedlings outgrow the resistant ones. The evolution of these resistant strains has taken place in the fewer than 400 years since the mines were first opened.

Protective morphologies and coloration exist in many animals as a defense against predators or as a cover against prey. Sometimes an organism mimics the appearance of a different one for protection. Diversifying selection often occurs in association with mimicry. A species of swallowtail butterfly, *Papilio dardanus,* is endemic in tropical and southern Africa. The males have yellow and black wings, with the characteristic tails in the second pair of wings. But the females in many localities are conspicuously different from the males; their wings lack tails and have colour patterns that vary from place to place. The explanation stems from the fact that *P. dardanus* can be eaten safely by birds. Many other butterfly species are noxious to birds, and so they are carefully avoided as food. In localities where *P. dardanus* coexists with noxious butterfly species, the *P. dardanus* females have evolved an appearance that mimics the noxious species. The birds confuse the mimics with their models and do not prey upon them. In different localities the females mimic different species; there are some areas where two or even three different female forms exist, each mimicking different noxious species. Diversifying selection has resulted in different phenotypes of *P. dardanus* as a protection from bird predators.

Sexual selection. Mutual attraction between the sexes is an important factor in reproduction. The males and fe-

Figure 5: Industrial melanism in the peppered moth, *Biston betularia.* A typical light-gray moth and a darkly pigmented variant rest on two oak trees. On the lichen-covered trunk (left), the light-gray moth is inconspicuous; it is quite conspicuous on the soot-covered tree (right).

males of many animal species are similar in size and shape except for the sexual organs and secondary sexual characteristics such as the breasts of female mammals. There are, however, species in which the sexes exhibit striking dimorphism. Particularly in birds and mammals, the males are often larger and stronger, more brightly coloured, or endowed with conspicuous adornments. But bright colours make animals more visible to predators; the long plumage of male peacocks and birds of paradise and the enormous antlers of aged male deer are cumbersome loads in the best of cases. Darwin knew that natural selection could not be expected to favour the evolution of disadvantageous traits, and he was able to offer a solution to this problem. He proposed that such traits arise by "sexual selection," which "depends not on a struggle for existence in relation to other organic beings or to external conditions, but on a struggle between the individuals of one sex, generally the males, for the possession of the other sex."

The concept of sexual selection as a special form of natural selection is easily explained. Other things being equal, organisms more proficient in securing mates have higher fitness. There are two general circumstances leading to sexual selection. One is the preference of one sex (often the females) for individuals of the other sex that exhibit certain traits; the other is increased strength (usually among the males) that yields greater success in securing mates.

Selection by females among competing males

The presence of a particular trait among the members of one sex can make them somehow more attractive to the opposite sex. This type of "sex appeal" has been experimentally demonstrated in all sorts of animals, from vinegar flies to pigeons, mice, dogs, and rhesus monkeys. When, for example, *Drosophila* flies, some with yellow bodies and others with the normal yellowish-gray pigmentation, are placed together, normal males are preferred over yellow males by females with either body colour.

Sexual selection can also come about because a trait—the antlers of a stag, for example—increases prowess in competition with members of the same sex. Stags, rams, and bulls use antlers or horns in contests of strength; a winning male usually secures more female mates. Therefore, sexual selection may lead to increased size and aggressiveness in males. Male baboons are more than twice as large as the females, and the behaviour of the docile females contrasts with that of the aggressive males. A similar dimorphism occurs in the northern sea lion, *Eumetopias jubata,* where males weigh about 1,000 kilograms, about three times as much as females. The males fight fiercely in their competition for females; large, battle-scarred males occupy their own rocky islets, each holding a harem of up to 20 females. In many mammals that live in packs, troops, or herds—such as wolves, horses, and buffalos—there usually is a hierarchy of dominance based on age and strength, with males that rank high in the hierarchy doing most of the mating.

Altruism

Kin selection. The apparent altruistic behaviour of many animals is, like some manifestations of sexual selection, a trait that at first seems incompatible with the theory of natural selection. Altruism is a form of behaviour that benefits other individuals at the expense of the one that performs the action; the fitness of the altruist is diminished by its behaviour, whereas individuals that act selfishly benefit from it at no cost to themselves. Accordingly it might be expected that natural selection would foster the development of selfish behaviour and eliminate altruism. This conclusion is not so compelling when it is noticed that the beneficiaries of altruistic behaviour are usually relatives. They all carry the same genes, including the genes that promote altruistic behaviour. Altruism may evolve by kin selection, which is simply a type of natural selection in which relatives are taken into consideration when evaluating an individual's fitness.

Natural selection favours genes that increase the reproductive success of their carriers, but it is not necessary that all individuals with a given genotype have higher reproductive success. It suffices that carriers of the genotype reproduce more successfully on the average than those possessing alternative genotypes. A parent shares half of its genes with each progeny, so a gene that promotes parental altruism is favoured by selection if the behaviour's cost to the parent is less than half of its average benefits to the progeny. Such a gene will be more likely to increase in frequency through the generations than an alternative gene that does not promote altruistic behaviour. Parental care is, therefore, a form of altruism readily explained by kin selection. The parent spends some energy caring for the progeny because it increases the reproductive success of the parent's genes.

Kin selection extends beyond the relationship between parents and their offspring. It facilitates the development of altruistic behaviour when the energy invested, or the risk incurred, by an individual is compensated in excess by the benefits ensuing to relatives. The closer the relationship between the beneficiaries and the altruist, and the greater the number of beneficiaries, the higher the risks and efforts warranted in the altruist. Individuals that live together in a herd or troop usually are related and often behave toward each other in this way. Adult zebras, for instance, will turn toward an attacking predator to protect the young in the herd, rather than flee to protect themselves.

Altruism also occurs among unrelated individuals when the behaviour is reciprocal and the altruist's costs are smaller than the benefits to the recipient. This reciprocal altruism is found in the mutual grooming of chimpanzees and other primates as they clean each other of lice and other pests. Another example appears in flocks of birds that post sentinels to warn of danger. A crow sitting in a tree watching for predators, while the rest of the flock forages, incurs a small loss by not feeding; but this is well compensated by the protection it receives when it itself forages and others of the flock stand guard.

Social behaviour among insects

A particularly valuable contribution of the theory of kin selection is its explanation of the evolution of social behaviour among ants, bees, wasps, and other social insects. In the honeybee, for example, the female workers build the hive, care for the young, and gather food, but they are sterile; the queen bee alone produces progeny. It would seem that the workers' behaviour would in no way be promoted or maintained by natural selection. Any genes causing such behaviour would seem likely to be eliminated from the population, because individuals exhibiting the behaviour do not increase their own reproductive success, but that of the queen. The situation is, however, more complex.

Queen bees produce some eggs that remain unfertilized and develop into males, or drones, having a mother but no father. Their main role in the colony is to engage in the "nuptial flight," during which one of them fertilizes the queen. Other eggs laid by queen bees are fertilized and develop into females, the large majority of which are workers. A queen typically mates with a single male once during her lifetime; the male's sperm is stored in the queen's spermatheca, from which it is gradually released as she lays fertilized eggs. All the queen's female progeny therefore have the same father, so that workers are more closely related to one another and to any new sister queen than they are to the mother queen. The female workers receive one-half of their genes from the mother and one-half from the father, but they share among themselves three-quarters of their genes. One half of their genes come from the father; this half of the set is the same in every worker, because the father had only one set of genes rather than two to pass on (the male developed from an unfertilized egg, so all his sperm carry the same set of genes). The other half of the workers' genes come from the mother, and on the average half of them are identical in any two sisters. Consequently, with three-quarters of her genes present in her sisters but only half of her genes able to be passed on to a daughter, a worker's genes are transmitted one-and-a-half times more effectively when she raises a sister (whether another worker or a new queen) than if she produces a daughter of her own.

Species and speciation

THE CONCEPT OF SPECIES

Darwin sought to explain the splendid multiformity of the living world: thousands of organisms of the most diverse kinds, from lowly worms to spectacular birds of paradise,

from yeasts and molds to oaks and orchids. His *Origin of Species* is a sustained argument showing that the diversity of organisms and their characteristics can be explained as the result of natural processes.

Species come about as the result of gradual change prompted by natural selection. Environments are continuously changing in time, and they differ from place to place. Natural selection, therefore, favours different characteristics in different situations. The accumulation of differences eventually yields different species.

Everyday experience teaches that there are different kinds of organisms and how to identify them. Everyone knows that people belong to the human species and are different from cats and dogs, which in turn are different from each other. There are differences among people, as well as among cats and dogs; but individuals of the same species are considerably more similar among themselves than they are to individuals of other species.

External similarity is the common basis for identifying individuals as being members of the same species. But there is more to it than that; a bulldog, a terrier, and a golden retriever are very different in appearance, but they are all dogs because they can interbreed. People can also interbreed with one another, and so can cats, but people cannot interbreed with dogs or cats, nor these with each other. It is, then, clear that although species are usually identified by appearance, there is something basic, of great biological significance, behind similarity of appearance; individuals of a species are able to interbreed with one another but not with members of other species. This is expressed in the following definition: Species are groups of interbreeding natural populations that are reproductively isolated from other such groups.

Ability of species members to interbreed

The ability to interbreed is of great evolutionary importance, because it determines that species are independent evolutionary units. Genetic changes originate in single individuals; they can spread by natural selection to all members of the species but not to individuals of other species. Individuals of a species share a common gene pool that is not shared by individuals of other species. Different species have independently evolving gene pools because they are reproductively isolated.

Although the criterion for deciding whether individuals belong to the same species is clear, there may be ambiguity in practice for two reasons. One is lack of knowledge; it may not be known for certain whether individuals living in different sites belong to the same species, because it is not known whether they can naturally interbreed. The other reason for ambiguity is rooted in the nature of evolution as a gradual process. Two geographically separate populations that at one time were members of the same species later may have diverged into two different species. Since the process is gradual, there is not a particular point at which it is possible to say that the two populations have become two different species.

A related situation pertains to organisms living at different times. There is no way to test whether or not today's humans could interbreed with those who lived thousands of years ago. It seems reasonable that living people, or living cats, would be able to interbreed with people, or cats, exactly like those that lived a few generations earlier. But what about the ancestors removed by 1,000 or 1,000,000 generations? The ancestors of modern humans that lived 500,000 years ago (about 20,000 generations) are classified in the species *Homo erectus,* whereas present-day humans are classified in a different species, *Homo sapiens.*

Relation of *Homo sapiens* to remote ancestors

There is not an exact time at which *Homo erectus* became *Homo sapiens,* but it would not be appropriate to classify remote human ancestors and modern humans in the same species just because the changes from one generation to the next are small. It is useful to distinguish between the two groups by means of different species names, just as it is useful to give different names to childhood and adulthood, even though there is no one moment when one passes from one to the other. Biologists distinguish species in organisms that lived at different times by means of a commonsense morphological criterion. If two organisms differ from each other about as much as two living individuals belonging to two different species differ, they will be classified in separate species and given different names.

The definition of species given above applies only to organisms able to interbreed. Bacteria and blue-green algae do not reproduce sexually, but by fission. Organisms that lack sexual reproduction are classified into different species according to criteria such as external morphology, chemical and physiological properties, and genetic constitution.

THE ORIGIN OF SPECIES

Reproductive isolation. In sexual organisms individuals able to interbreed belong to the same species. The biological properties of organisms that prevent interbreeding are called reproductive isolating mechanisms (RIM's). Oaks on different islands, minnows in different rivers, or squirrels in different mountain ranges cannot interbreed because they are physically separated, but not necessarily because they are biologically incompatible. Geographic separation, therefore, is not an RIM, since it is not a biological property of organisms.

There are two general categories of reproductive isolating mechanisms: prezygotic (those that take effect before fertilization) and postzygotic (those that take effect after). Prezygotic RIM's prevent the formation of hybrids between members of different populations through ecological, temporal, ethological (or behavioral), mechanical, and gametic isolation. Postzygotic RIM's reduce the viability or fertility of hybrids or their progeny.

Ecological isolation. Populations may occupy the same territory but live in different habitats and so not meet. The *Anopheles maculipennis* group consists of six mosquito species, some of which are involved in the transmission of malaria. Although the species are virtually indistinguishable morphologically, they are isolated reproductively, in part because they breed in different habitats. Some breed in brackish water, others in running fresh water, and still other in stagnant fresh water.

Temporal isolation. Populations may mate or flower at different seasons or different times of day. Three tropical orchid species of the genus *Dendrobium* flower for a single day; the flowers open at dawn and wither by nightfall. Flowering occurs in response to certain meteorological stimuli, such as a sudden storm on a hot day. The same stimulus acts on all three species, but the lapse between the stimulus and flowering is eight days in one species, nine in another, and 10 or 11 in the third. Interspecific fertilization becomes impossible because at the time when the flowers of one species open, those of the other species have already withered or are not yet mature.

A peculiar form of temporal isolation exists between pairs of closely related species of cicadas, in which one species of each pair emerges every 13 years, the other every 17 years. The two species of a pair may be sympatric (live in the same territory), but they have an opportunity to form hybrids only once every 221 (13×17) years.

Ethological (behavioral) isolation. Sexual attraction between males and females may be weak or absent. In most animal species, members of the two sexes must first search for each other and come together. Complex courtship rituals then take place, with the male often taking the initiative and the female responding. This in turn generates additional actions by the male and responses by the female, and eventually there is copulation (or, in the case of some aquatic organisms, release of the sex cells for fertilization in the water). These elaborate rituals are specific to a species and play a significant part in species recognition. If the sequence of events in the search-courting-mating process is rendered disharmonious by either of the two sexes, then the entire process will be interrupted. Courtship and mating rituals have been extensively analyzed in some mammals, birds, and fishes, and in a number of insect species.

Species-specific courtship rituals

Ethological isolation is often the most potent RIM to keep animal species from interbreeding. It can be remarkably strong even among closely related species. The vinegar flies *Drosophila serrata, D. birchii,* and *D. dominicana* are three sibling species (that is, they are nearly indistinguishable morphologically) that are endemic in Australia and on the islands of New Guinea and New Britain. In many

areas these three species occupy the same territory, but no hybrids are known to occur in nature. The strength of their ethological isolation has been tested in the laboratory by placing groups of 10 females of one strain and 10 males of another together for several days. In groups in which the two strains were of the same species but from different geographic origins, a large majority of the females (usually 90 percent or more) were fertilized; but no inseminations or very few (less than 4 percent) took place when males and females were of different species, whether from the same or different geographic origins.

It should be added that the rare interspecific inseminations that did occur among the vinegar flies produced hybrid adult individuals in very few instances, and the hybrids were always sterile. This illustrates a common pattern: reproductive isolation between species is achieved by several RIM's in succession; if one breaks down, others are still present. In addition to ethological isolation, hybrid inviability and hybrid sterility prevent successful breeding between members of the three *Drosophila* species and many other animal species as well.

Species recognition during courtship involves stimuli that may be chemical (olfactory), visual, auditory, or tactile. Pheromones are specific substances that play a critical role in recognition between members of a species; they have been chemically identified in ants, moths, butterflies, and mammals. The "songs" of birds, frogs, and insects (which produce them by vibrating or rubbing their wings) are species recognition signals. Some form of physical contact or touching occurs in many mammals, but also in *Drosophila* flies and other insects.

Mechanical isolation. Copulation is often impossible between different animal species because of incompatible shape and size of the genitalia; in plants, variations in flower structure may impede pollination. In two species of sage from California, the two-lipped flowers of *Salvia mellifera* have stamens and style in the upper lip, whereas *S. apiana* has long stamens and style and a specialized floral configuration. *S. mellifera* is pollinated by small or medium-sized bees that carry pollen on their backs from flower to flower. *S. apiana,* however, is pollinated by large carpenter bees and bumblebees that carry the pollen on their wings and other body parts. Even if the pollinators of one species visit flowers of the other, pollination cannot occur because the pollen does not come into contact with the style of the alternative species.

Floral defenses against interspecies pollination

Gametic isolation. Marine animals often discharge their eggs and spermatozoa into the surrounding water, where fertilization takes place. Gametes of different species may fail to attract one another. For example, the sea urchins *Strongylocentrotus purpuratus* and *S. franciscanus* can be induced to release their eggs and sperms simultaneously, but most of the fertilizations that result are between eggs and sperms of the same species. In animals with internal fertilization, spermatozoa may be unable to function in the sexual ducts of females of different species. In plants, pollen grains of one species typically fail to germinate on the stigma of another species, so that the pollen never reaches the ovary and fertilization cannot occur.

Hybrid inviability. Occasionally, prezygotic mechanisms are absent or break down so that interspecific zygotes are formed. These zygotes, however, often fail to develop into mature individuals. The hybrid embryos of sheep and goats, for example, die in the early developmental stages before birth. Hybrid inviability is common in plants, whose hybrid seeds often fail to germinate or die shortly after germination.

Hybrid sterility. Hybrid zygotes sometimes develop into adults, such as mules (hybrids between horses and donkeys), but the adults fail to develop functional gametes and are sterile.

Hybrid breakdown. In plants more than in animals, hybrids between closely related species are sometimes partially fertile. Gene exchange may nevertheless be inhibited because the offspring are poorly viable or sterile. Hybrids between the cotton species *Gossypium barbadense, G. hirsutum,* and *G. tomentosum* appear vigorous and fertile, but their progenies die in seed or early in development, or they develop into sparse, weak plants.

A model of speciation. Since species are groups of populations reproductively isolated from one another, asking about the origin of species is equivalent to asking how reproductive isolation arises between populations. Two theories have been advanced to answer this question. One theory considers isolation as an accidental by-product of genetic divergence. Populations that become genetically less and less alike (as a consequence, for example, of adaptation to different environments) may eventually be unable to interbreed because their gene pools are disharmonious. The other theory regards isolation as a product of natural selection. Whenever hybrid individuals are less fit than nonhybrids, natural selection will directly promote the development of RIM's. This occurs because genetic variants interfering with hybridization have greater fitness than those favouring hybridization, given that the latter are often present in poorly fit hybrids.

Two means of speciation

These two theories of the origin of reproductive isolation are not mutually exclusive. Reproductive isolation may indeed come about incidentally to genetic divergence between separated populations. Consider, for example, the evolution of many endemic species of plants and animals in the Hawaiian archipelago. The ancestors of these species arrived in the Hawaiian Islands several million years ago. There they evolved as they became adapted to the environmental conditions and colonizing opportunities found on the islands. Reproductive isolation between the populations evolving in Hawaii and the continental populations was never directly promoted by natural selection because their geographic remoteness forestalled any opportunities for hybridizing. Nevertheless, reproductive isolation became complete in many cases as a result of gradual genetic divergence over thousands of generations.

Frequently, however, the course of speciation involves the processes postulated by both theories; reproductive isolation starts as a by-product of gradual evolutionary divergence but is completed by natural selection directly promoting the evolution of prezygotic RIM's.

The two sets of processes identified by the two speciation theories may be seen, therefore, as two different stages in the splitting of one evolutionary lineage into two species. The process can start only when gene flow is somehow interrupted between two populations. Interruption may be due to geographic separation, or it may be initiated by some genetic change that affects some but not other individuals living in the same territory. Absence of gene flow makes it possible for the two populations to become genetically differentiated as a consequence of adapting to diverse local conditions and of genetic drift. It is necessary that gene flow be interrupted, because otherwise the two groups of individuals would still share in a common gene pool and fail to become genetically different. The two genetically isolated groups are likely to become more and more different as time goes on. Eventually some incipient reproductive isolation may take effect because the two gene pools are no longer coadapted. Hybrid individuals will carry genes combined from two gene pools and will therefore have reduced viability or fertility.

Separation of gene pools

The circumstances just described may persist for so long that the populations become completely differentiated into separate species. It happens quite commonly, however, in both animals and plants, that opportunities for hybridization arise between two populations that are becoming genetically differentiated. Two outcomes are possible. One is that the hybrids manifest little or no reduction of fitness, so that gene exchange between the two populations proceeds freely, eventually leading to their integration into a single gene pool. The second possible outcome is that reduction of fitness in the hybrids is sufficiently large for natural selection to favour the emergence of prezygotic RIM's preventing the formation of hybrids altogether. This situation may be identified as the second stage in the speciation process.

How natural selection brings about the evolution of prezygotic RIM's can be understood in the following way. Assume that there are gene variants in one of two populations, P1, that increase the probability that P1 individuals will choose P1 rather than P2 mates. Such gene variants will increase in frequency in the P1 population, because

they are more often present in the progenies of P1 × P1 matings, which have normal fitness. The alternative genetic variants that do not favour P1 × P1 matings will be more often present in the progenies of P1 × P2 matings, which have lower fitness. The same process will enhance the frequency in the P2 population of genetic variants that lead P2 individuals to choose P2 rather than P1 mates. Prezygotic RIM's may therefore evolve in both populations and lead to their becoming two separate species.

Two-stage speciation process

The two stages of the process of speciation can be characterized, finally, by outlining their distinctions. The first stage primarily involves the appearance of postzygotic RIM's as accidental by-products of overall genetic differentiation rather than as express targets of natural selection; the second stage involves the evolution of prezygotic RIM's that are directly promoted by natural selection. The first stage may come about suddenly, in one or a few generations, rather than as a long, gradual process. The second stage succeeds the first in time but need not always be present.

Geographic speciation. One common mode of speciation is known as geographic, or allopatric (in separate territories), speciation. The general model of the speciation process advanced in the previous paragraphs applies well to geographic speciation. The first stage begins as a result of geographic separation between populations. This may occur when a few colonizers reach a geographically separate habitat, perhaps an island, lake, river, isolated valley, or mountain range. In another process, a population may be split into two geographically separate ones by topographic changes, such as a cessation of water flow between two lakes, or by an invasion of competitors, parasites, or predators into the intermediate zone. If these types of geographic separation continue for some time, postzygotic RIM's may appear as a result of gradual genetic divergence.

In the second stage, an opportunity for interbreeding may later be brought about by topographic changes establishing continuity between the previously isolated territories or by ecological changes making the intermediate territory habitable for the organisms. If the fitness of hybrids of the formerly separated populations is sufficiently reduced, natural selection will foster the development of prezygotic RIM's, and the two populations may then evolve into two species.

Investigation has been made of many populations that are in the first stage of geographic speciation. There are fewer well-documented instances of the second stage, presumably because this occurs fairly rapidly (in evolutionary time).

Both stages of speciation are present in a group of six closely related species of New World *Drosophila* that have been extensively studied by evolutionists for more than three decades. Two of these sibling species, *D. willistoni* and *D. equinoxialis,* consist of groups of populations in the first stage of speciation and identified as different subspecies. Two *D. willistoni* subspecies live in continental South America; *D. w. quechua* lives west of the Andes and *D. w. willistoni* east of the Andes. They are effectively separated by the Andes because the flies cannot live at high altitudes. It is not known whether their geographic separation is as old as the Andes, but it has existed long enough for postzygotic RIM's to evolve. When the two subspecies are crossed in the laboratory, the hybrid males are completely sterile if the mother came from the *quechua* subspecies; but in the reciprocal cross all hybrids are fertile. If hybridization should occur in nature, selection would favour the evolution of prezygotic RIM's because of the complete sterility of half of the hybrid males.

Drosophila equinoxialis equinoxialis and *D. e. caribbensis* are another pair of subspecies. *D. e. equinoxialis* inhabits continental South America, and *D. e. caribbensis* lives in Central America and the Caribbean. Crosses made in the laboratory between these two subspecies always produce sterile males, irrespective of the subspecies of the mother. Natural selection would, then, promote prezygotic RIM's between these two subspecies more strongly than between those of *D. willistoni.* But laboratory experiments show no evidence of ethological isolation or any other prezygotic RIM, presumably because the geographic isolation of the subspecies has forestalled hybridization between members.

One more sibling species of the group is *Drosophila paulistorum,* a species that includes groups of populations well into the second stage of geographic speciation. Six such groups have been identified as semispecies, or incipient species, two or three of which are sympatric (occupying the same territory) in many localities. Male hybrids between individuals of the different semispecies are sterile; laboratory crosses always yield fertile females but sterile males.

Ongoing speciation of *Drosophila paulistorum*

Whenever two or three incipient species of *D. paulistorum* have come into contact, the second stage of speciation has led to the development of ethological isolation, which ranges from incipient to virtually complete. Laboratory experiments show that when both incipient species are from the same locality, their ethological isolation is complete, so that only individuals of the same incipient species mate. When the individuals from different incipient species come from different localities, however, ethological isolation is usually present but far from complete. This is precisely as the speciation model predicts. Natural selection effectively promotes ethological isolation where the incipient species are sympatric; but the genes responsible for this isolation have not yet fully spread to populations in which another semispecies is not present.

The eventual outcome of the process of geographic speciation is complete reproductive isolation as can be observed among the species of the *Drosophila* group. *D. willistoni, D. equinoxialis, D. tropicalis,* and *D. paulistorum* coexist sympatrically over wide regions of Central and South America while preserving their separate gene pools. Hybrids are not known in nature and are virtually impossible to obtain in the laboratory; and all males at least are completely sterile. This total reproductive isolation has evolved, however, with very little morphological differentiation. Females from different sibling species cannot be distinguished by experts; the males can be identified only by small differences in the shape of their genitalia, unrecognizable except under a microscope.

Adaptive radiation. The geographic separation of populations derived from common ancestors may continue long enough so that the populations become completely differentiated species before ever regaining sympatry. As the allopatric populations continue evolving independently, RIM's develop and morphological differences may arise. The second stage of speciation—with natural selection directly stimulating the evolution of RIM's—never comes about in such situations, because reproductive isolation takes place simply as a consequence of the continued separate evolution of the populations.

This form of allopatric speciation is particularly apparent when colonizers reach geographically remote areas, such as islands, where they find few or no competitors and have an opportunity to diverge as they become adapted to the new environment. Sometimes a multiplicity of new environments becomes available to the colonizers, giving rise to several different lineages and species. This process of rapid divergence of multiple species from a single ancestral lineage is called adaptive radiation.

Galápagos finches

Many examples of speciation by adaptive radiation are found in archipelagos removed from the mainland. The Galápagos Islands are about 600 miles off the west coast of South America. When Darwin arrived there in 1835, he discovered many species not found anywhere else in the world—for example, 14 species of finch (known as Galápagos, or Darwin's, finches). These passerine birds have adapted to a diversity of habitats and diets, some feeding mostly on plants, others exclusively on insects. The various shapes of their bills are clearly adapted to probing, grasping, biting, or crushing—the diverse ways in which the different Galápagos species obtain their food (Figure 6). The explanation for such diversity is that the ancestor of Galápagos finches arrived in the islands before other kinds of birds and encountered an abundance of unoccupied ecological niches. The finches underwent adaptive radiation, evolving a variety of species with ways of life capable of exploiting opportunities that in continental faunas are exploited by other species.

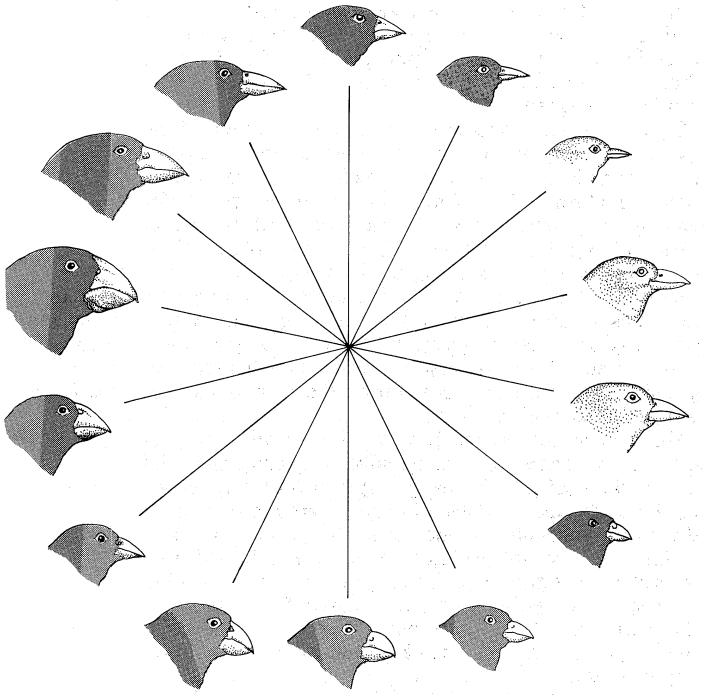

Figure 6: Fourteen species of Galápagos finches that evolved from a common ancestor. The different shapes of their bills, suited to different diets and habitats, show the process of adaptive radiation.
From P.R. Grant, *Ecology and Evolution of Darwin's Finches* (1986)

The Hawaiian Islands also provide striking examples of adaptive radiation. The archipelago consists of several volcanic islands, ranging from about 1,000,000 to more than 10,000,000 years in age, far away from any continent or even other large islands. In their relatively small total land area, an astounding number of plant and animal species exist. Most of the species have evolved in the islands. Among them about two dozen species (about one-third of them now extinct) of honeycreepers, birds of the family Drepanididae, all derived from a single immigrant form. In fact, all but one of Hawaii's 71 native bird species are endemic; that is, they have evolved there and are found nowhere else. More than 90 percent of the native species of flowering plants, land mollusks, and insects are also endemic, as are two-thirds of the 168 species of ferns.

There are more than 500 native Hawaiian species of *Drosophila* flies—about one-third of the world's total number of known species. Far greater morphological and ecological diversity exists among the species in Hawaii than anywhere else in the world. The species of *Drosophila* in Hawaii have diverged by adaptive radiation from one or a few colonizers, which encountered an assortment of ecological niches that in other lands were occupied by different groups of flies or insects but that were available for exploitation in these remote islands.

Quantum speciation. In some modes of speciation the first stage is achieved in a short period of time. These modes are known by a variety of names, such as "quantum," "rapid," and "saltational" speciation, all suggesting the shortening of time involved. They are also known as "sympatric" speciation, alluding to the fact that quantum speciation often leads to speciation between populations that exist in the same territory or habitat. An important form of quantum speciation, polyploidy, is discussed below.

Quantum speciation without polyploidy has been seen in the annual plant genus *Clarkia.* Two closely related species, *Clarkia biloba* and *C. lingulata,* are both native to California. *C. lingulata* is known only from two sites in the central Sierra Nevada at the southern periphery of the distribution of *C. biloba,* from which it evolved starting with translocations and other chromosomal mutations. Such chromosomal rearrangements arise suddenly but reduce the fertility of heterozygous individuals. *Clarkia* species are capable of self-fertilization, which facilitates the propagation of the chromosomal mutants in different sets of individuals even within a single locality. This makes hybridization possible with nonmutant individuals and allows the second stage of speciation to go ahead.

Chromosomal mutants

Chromosomal mutations are often the starting point of quantum speciation in animals, particularly in groups such as moles and other rodents that live underground or have little mobility. Mole rats of the group *Spalax ehrenbergi* in Israel and gophers of the group *Thomomys talpoides* in the northern Rocky Mountains are well-studied examples.

The speciation process may also be initiated by changes in just one or a few gene loci when these alterations result in a change of ecological niche or, in the case of parasites, a change of host. Many parasites use their host as a place for courtship and mating; so organisms with two different host preferences may become reproductively isolated. If the hybrids are poorly fit because they are not effective parasites in either of the two hosts, natural selection will favour the development of additional RIM's. This type of speciation seems to be common among parasitic insects, a large group comprising tens of thousands of species.

Polyploidy. The multiplication of entire sets of chromosomes is known as polyploidy. A diploid organism carries in the nucleus of each cell two sets of chromosomes, one inherited from each parent; a polyploid organism has three or more sets of chromosomes. Many cultivated plants are polyploid: bananas are triploid, potatoes are tetraploid, bread wheat is hexaploid, some strawberries are octaploid.

In animals, polyploidy is relatively rare because it disrupts the balance between the sex chromosome and the other chromosomes, a balance being required for the proper development of sex. Naturally polyploid species are found in hermaphroditic animals (individuals having both male and female organs), which include snails, earthworms, and planarians. They are also found in forms with parthenogenetic females (which produce viable progeny without fertilization), such as some beetles, sow bugs, goldfish, and salamanders.

All major groups of plants have polyploid species, but they are most common among flowering plants (angiosperms), of which about 47 percent are polyploids. Polyploidy is rare among gymnosperms, such as pines, firs, and cedars, although the redwood, *Sequoia sempervirens,* is a polyploid. Most polyploid plants are tetraploids. Polyploids with three, five, or some other odd-number multiple of the basic chromosome number are sterile, because the separation of homologous chromosomes cannot be achieved properly during formation of the sex cells. Some plants with an odd number of chromosome sets persist by means of asexual reproduction, particularly through human cultivation; the banana is one example.

Polyploidy is a mode of quantum speciation that yields the beginnings of a new species in just one or two generations. There are two kinds of polyploids: autopolyploids, which derive from a single species, and allopolyploids, which stem from a combination of chromosome sets from different species. Allopolyploid plant species are much more numerous than autopolyploids.

Origin of allopolyploids

An allopolyploid species can originate from two plant species that have the same diploid number of chromosomes. The chromosome complement of one species may be symbolized as *AA,* and the other *BB.* An interspecific hybrid, *AB,* will usually be sterile owing to abnormal chromosome pairing and segregation during formation of the gametes at meiosis. But chromosome doubling may occur as a consequence of abnormal mitosis, in which the chromosomes divide but the cell does not. In a hybrid, this results in a cell with four sets of chromosomes, *AABB.* Tetraploid plant cells may proliferate and produce branches and flowers. Because there are two chromosomes of each kind, functional diploid gametes with the constitution *AB* can be produced by the tetraploid flowers. The union of two such gametes at fertilization produces a tetraploid individual (*AABB*). In this way, self-fertilization in plants makes possible the formation of a tetraploid individual as the result of a single abnormal cell division.

Autopolyploids originate in a similar fashion, except that the individual in which the abnormal mitosis occurs is not

a hybrid. Self-fertilization thus enables a single individual to multiply and give rise to a population. This population is a new species, since polyploid individuals are reproductively isolated from their diploid ancestors. A cross between a tetraploid and a diploid yields triploid progeny, which are sterile.

GENETIC DIFFERENTIATION DURING SPECIATION

Genetic changes underlie all evolutionary processes. In order to understand speciation and its role in evolution, it is useful to know how much genetic change takes place during the course of species development. It is of considerable significance to ascertain whether new species arise by altering only a few genes, or whether the process requires drastic changes—a genetic "revolution," as postulated by some evolutionists in the past. The issue is best considered separately with respect to each of the two stages of speciation and to the various modes of speciation.

The question of how much genetic differentiation occurs during speciation has become answerable only in recent years, with the development of appropriate methods for comparing genes of different species. Genetic change is measured with two parameters: genetic identity (I), which estimates the proportion of genes that are identical in two populations; and genetic distance (D), which estimates the proportion of gene changes that have occurred in the separate evolution of two populations. The value of I may range between zero and one, which correspond to the extreme situations in which no or all genes are identical; D may range from zero to infinity. D can reach beyond unity because each gene may change more than once in one or both populations as evolution goes on for many generations.

Genetic identity and genetic distance

As a model of geographic speciation, the *Drosophila willistoni* group of flies offers the distinct advantage of exhibiting both stages of the speciation process. About 30 randomly selected genes have been studied in a large number of natural populations of these species. The results are summarized in Table 3. The most significant figures are those given in lines 2 and 3 of the Table, which represent the first and second stages, respectively, of the process of geographic speciation. $D = 0.230$ means that about 23 gene changes have occurred for every 100 gene loci in the separate evolution of two subspecies; that is, the sum of the changes that have occurred in the two separately evolving lineages is 23 percent of all the genes. These are populations well advanced in the first stage of speciation, as manifested by the sterility of the hybrid males.

The genetic distance between the incipient species is the same, within experimental error, as that between the subspecies, or 22.6 percent (line 3). This implies that the development of ethological isolation, as it is found in these populations, does not require many genetic changes beyond those that occurred during the first stage of speciation. Indeed, no additional gene changes were detected in these experiments. The absence of major genetic changes during the second stage of speciation can be understood by considering the role of natural selection, which directly promotes the evolution of prezygotic RIM's during the second stage, so that only genes modifying mate choice need to change. In contrast, the development of postzygotic RIM's during the first stage occurs only after there is substantial genetic differentiation between populations, because it comes about only as an incidental outcome of overall genetic divergence.

Sibling species, such as *D. willistoni* and *D. equinoxialis*, exhibit 58 gene changes for every 100 gene loci after their divergence from a common ancestor (line 4). It is noteworthy that this much genetic evolution has occurred without altering the external morphology of these organisms. In the evolution of morphologically different species (line 5), the number of gene changes is greater yet, as would be expected.

Table 3: Genetic Differentiation Between Populations of Drosophila Willistoni

level of comparison	I (genetic identity)	D (genetic distance)
1. Local populations	0.970 ± 0.006	0.031 ± 0.007
2. Subspecies	0.795 ± 0.013	0.230 ± 0.016
3. Incipient species	0.798 ± 0.026	0.226 ± 0.033
4. Sibling species	0.563 ± 0.023	0.581 ± 0.039
5. Morphologically different species	0.352 ± 0.023	1.056 ± 0.068

Genetic changes concomitant with one or other of the two stages in the speciation process have been studied in a number of organisms, from insects and other invertebrates to all sorts of vertebrates, including mammals. The amount of genetic change during geographic speciation varies among organisms, but the two main observations made in the *D. willistoni* group seem to apply quite generally. These are that the evolution of postzygotic mechanisms during the first stage is accompanied by substantial genetic change (a majority of values range between $D = 0.15$ and $D = 0.30$) and that relatively few additional genetic changes are required during the second stage of geographic speciation.

Genetic change in the first stage of speciation

The conclusions drawn from the investigation of geographic speciation make it possible to predict the relative amounts of genetic change expected in the quantum modes of speciation. Polyploid species are a special case; they arise suddenly in one or a few generations, and at first they are not expected to be genetically different from their ancestors. More generally, quantum speciation involves a shortening of the first stage of speciation, so that postzygotic RIM's arise directly as a consequence of specific genetic changes (such as chromosome mutations). Populations in the first stage of quantum speciation, therefore, need not be substantially different in individual gene loci. This has been confirmed by genetic investigations of species recently arisen by quantum speciation. For example, the average genetic distance between four incipient species of the mole rat *S. ehrenbergi* is $D = 0.022$, and between those of the gopher *T. talpoides* it is $D = 0.078$. The second stage of speciation is modulated in essentially the same way as in the geographic mode. Not many gene changes are needed in either case to complete speciation.

Patterns and rates of species evolution

RECONSTRUCTION OF EVOLUTIONARY HISTORY

Evolution within a lineage and by lineage splitting. Evolution can take place by anagenesis, in which changes occur within a lineage; or by cladogenesis, in which a lineage splits into two or more separate lines. Anagenetic evolution has, over the course of 2,000,000 years, doubled the size of the human cranium; in the lineage of the horse, it has reduced the number of toes from four to one. Cladogenetic evolution has produced the extraordinary diversity of the living world, with its more than 2,000,000 species of animals, plants, fungi, and microorganisms.

The most essential cladogenetic function is speciation, the process by which one species splits into two or more species. Because species are reproductively isolated from one another, they are independent evolutionary units; that is, evolutionary changes occurring in one species are not shared with other species. Over time, species become more and more divergent from one another as a consequence of anagenetic evolution. Descendant lineages of two related species that existed millions of years ago may now be classified into quite different taxonomic categories, such as different genera or even different families.

The evolution of all living organisms, or of a subset of them, can be seen as a tree, with branches that divide into two or more as time progresses. Such "trees" are called phylogenies. Their branches represent evolving lineages, some of which eventually die out, while others persist in themselves or in their derived lineages down to the present time. Evolutionists are interested in the history of life and hence in the topology, or configuration, of phylogenies. They are concerned as well with the nature of the anagenetic changes along lineages and with the timing of the events.

Phylogenies

Phylogenetic relationships are ascertained by means of several complementary sources of evidence. First, there are the discovered remnants of organisms that lived in the past, the fossil record, which provides definitive evidence of relationships among some groups of organisms. The

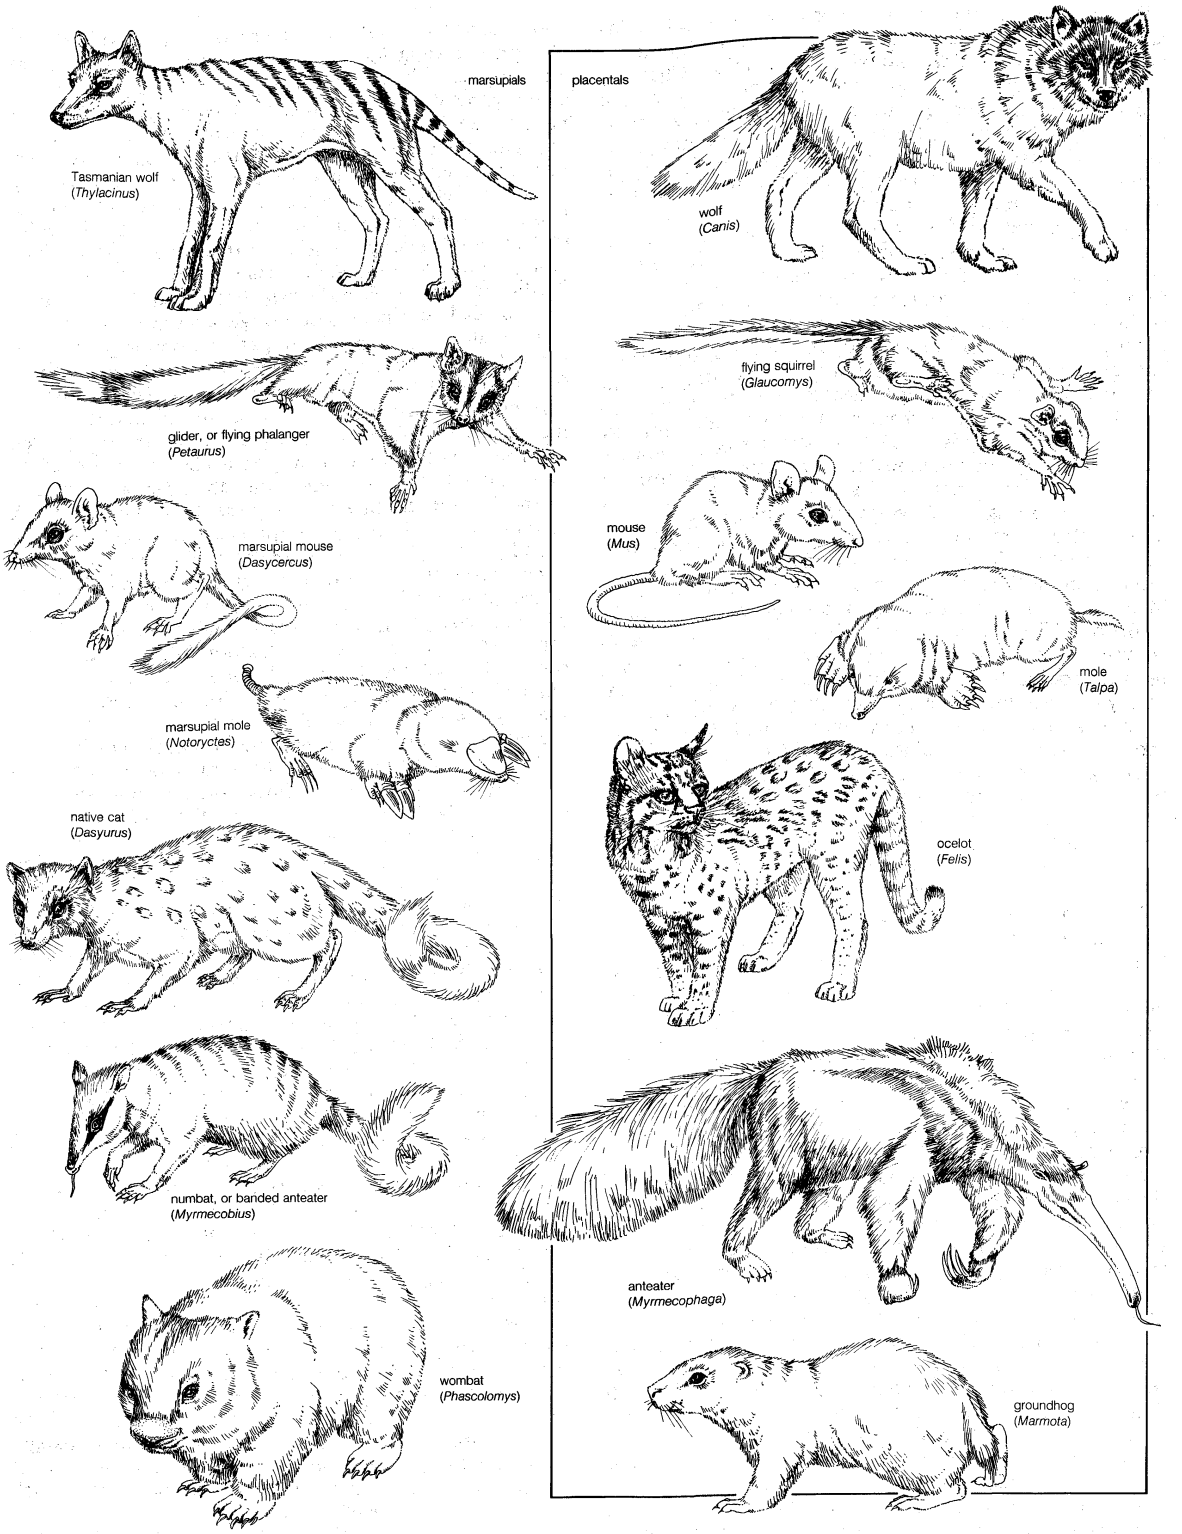

Figure 7: Parallel evolution of marsupial mammals in Australia and placental mammals on other continents.

fossil record, however, is far from complete and is often seriously deficient. Second, information about phylogeny comes from comparative studies of living forms. Comparative anatomy contributed the most information in the past, although additional knowledge came from comparative embryology, cytology, ethology, biogeography, and other biological disciplines. In recent years the comparative study of informational macromolecules—proteins and nucleic acids—has become a powerful tool for the study of phylogeny.

Morphological similarities among organisms have probably always been recognized. In ancient times, Aristotle and later his followers and those of Plato, particularly Porphyry, classified organisms (as well as inanimate objects) on the basis of similarities. The Aristotelian system of classification was further developed by some medieval Scholastics, notably Albertus Magnus and Thomas Aquinas. The modern foundations of taxonomy, the science of classification, were laid in the 18th century by Linnaeus and by the French botanist Michel Adanson. Lamarck dedicated much of his work to the systematic classification of organisms. He proposed that their similarities were due to ancestral relationships—in other words, to the degree of evolutionary proximity.

The modern theory of evolution provides a causal explanation of the similarities among living things. Organisms evolve by a process of descent with modification. Changes, and therefore differences, gradually accumulate over the generations. The more recent the last common ancestor of a group of organisms, the less their differentiation; similarities of form and function reflect phylogenetic propinquity. Accordingly, phylogenetic affinities can be inferred on the basis of relative similarity.

Convergent and parallel evolution. A distinction has to be made between resemblances due to propinquity of descent and those due only to similarity of function.

Homology and analogy

Correspondence of features in different organisms that is due to inheritance from a common ancestor is called homology. The forelimbs of humans, whales, dogs, and bats are homologous. The skeletons of these limbs are all constructed of bones arranged according to the same pattern because they derive from an ancestor with similarly arranged forelimbs (Figure 3). Correspondence of features due to similarity of function but not related to common descent is termed analogy. The wings of birds and of flies are analogous. Their wings are not modified versions of a structure present in a common ancestor but rather have developed independently as adaptations to a common function, flying. The similarities between the wings of bats and birds are partially homologous and partially analogous. The skeletal structure is homologous, owing to common descent from the forelimb of a reptilian ancestor; but the modifications for flying are different and independently evolved, and in this respect they are analogous.

Features that become more rather than less similar through independent evolution are said to be convergent. Convergence is often associated with similarity of function, as in the evolution of wings in birds, bats, and flies. The shark (a fish) and the dolphin (a mammal) are much alike in external morphology; their similarities are due to convergence, since they have evolved independently as adaptations to aquatic life.

Taxonomists also speak of parallel evolution. Parallelism and convergence are not always clearly distinguishable. Strictly speaking, convergent evolution occurs when descendants resemble each other more than their ancestors did with respect to some feature. Parallel evolution implies that two or more lineages have changed in similar ways, so that the evolved descendants are as similar to each other as their ancestors were. The evolution of marsupials in Australia paralleled the evolution of placental mammals in other parts of the world. There are Australian marsupials resembling true wolves, cats, mice, squirrels, moles, groundhogs, and anteaters. These placental mammals and the corresponding Australian marsupials evolved independently but in parallel lines by reason of their adaptation to similar ways of life. Some resemblances between a true anteater (*Myrmecophaga*) and a marsupial anteater (*Myrmecobius*) are due to homology—both are mammals. Others are due to analogy—both feed on ants.

Parallel and convergent evolution are also common in plants. New World cacti and African euphorbias are alike in overall appearance although they belong to separate families. Both are succulent, spiny, water-storing plants adapted to the arid conditions of the desert. Their corresponding morphologies have evolved independently in response to similar environmental challenges.

Serial homology

Homology can be recognized not only between different organisms but also between repetitive structures of the same organism. This has been called serial homology. There is serial homology, for example, between the arms and legs of humans, among the seven cervical vertebrae of mammals, and among the branches or leaves of a tree. The jointed appendages of arthropods are elaborate examples of serial homology. Crayfish have 19 pairs of appendages, all built according to the same basic pattern but serving diverse functions—sensing, chewing, food handling, walking, mating, egg carrying, and swimming. Serial homologies are not useful in reconstructing the phylogenetic relationships of organisms, but they are an important dimension of the evolutionary process.

Relationships in some sense akin to those between serial homologs exist at the molecular level between genes and proteins derived from ancestral gene duplications. The genes coding for the various hemoglobin chains are an example. About 500,000,000 years ago a chromosome segment carrying the gene coding for hemoglobin became duplicated, so that the genes in the different segments thereafter evolved in somewhat different ways, one eventually giving rise to the modern gene coding for α hemoglobin, the other for β hemoglobin. The β hemoglobin gene became duplicated again about 200,000,000 years ago, giving rise to the γ (fetal) hemoglobin. The α, β, γ, and other hemoglobin genes are homologous; similarities in their nucleotide sequences occur because they are modified descendants of a single ancestral sequence.

There are two ways of comparing homology between hemoglobins. One is to compare the same hemoglobin—for instance, the α chain—in different species of animals. The degree of divergence between the α chains reflects the degree of the evolutionary relationship among the organisms, because the hemoglobin chains have evolved independently of one another since the time of divergence of the lineages leading to the present-day organisms. A second way is to make comparisons between, say, the α and β hemoglobins of a single species. The degree of divergence between the different globin chains reflects the degree of relationship among the genes coding for them. The different globins have evolved independently of each other since the time of duplication of their ancestral genes. Comparisons between homologous genes or proteins within a given organism provide information about the phylogenetic history of the genes and, hence, about the historical sequence of the gene duplication events.

Whether similar features in different organisms are homologous or analogous—or simply accidental—cannot always be decided unambiguously, but the distinction must be made in order to determine phylogenetic relationships. Moreover, the degrees of homology must be quantified in some way so as to determine the propinquity of common descent among species. Difficulties arise here as well. Consider the forelimbs shown in Figure 3. It is not clear whether the homologies are greater between man and bird than between man and reptile, or between man and reptile than between man and bat. The fossil record sometimes provides the appropriate information, even though the record is deficient. Fossil evidence must be examined together with the evidence from comparative studies of living forms and with the quantitative estimates provided by comparative studies of proteins and nucleic acids.

Gradual and punctuational evolution. The fossil record indicates that morphological evolution is by and large a gradual process. Major evolutionary changes are usually due to a building up over the ages of relatively small changes. But the fossil record is discontinuous. Fossil strata are separated by sharp boundaries; accumulation of fossils within a geologic deposit (stratum) is fairly constant over time, but the transition from one stratum to another may involve gaps of tens of thousands of years. New species, characterized by small but discontinuous morphological changes, typically appear at the boundaries between strata, whereas the fossils within a stratum exhibit little morphological variation. That is not to say that the transition from one stratum to another always involves sudden changes in morphology; on the contrary, fossil forms often persist virtually unchanged through several geologic strata, each representing millions of years.

Gaps in the fossil record

The apparent morphological discontinuities of the fossil record are often attributed by paleontologists to the discontinuity of the sediments; that is, to the substantial time gaps encompassed in the boundaries between strata. The assumption is that, if the fossil deposits were more continuous, they would show a more gradual transition of form. Even so, morphological evolution would not always keep progressing gradually, because some forms, at least, remain unchanged for extremely long times. Examples are the lineages known as "living fossils": the lamp shell *Lingula*, a genus of brachiopod that appears to have remained essentially unchanged since the Ordovician Period, some 450,000,000 years ago; or the tuatara (*Sphenodon punctatus*), a reptile that has shown little morphological evolution for nearly 200,000,000 years since the early Mesozoic.

Some paleontologists have proposed that the discontinuities of the fossil record are not artifacts created by gaps in the record, but rather reflect the true nature of morphological evolution, which happens in sudden bursts associated with the formation of new species. The lack of morphological evolution, or stasis, of lineages such as *Lingula* and *Sphenodon* is in turn due to lack of speciation within those lineages. The proposition that morphological evolution is jerky, with most morphological change occurring during the brief speciation events and virtually no change during the subsequent existence of the species, is known as the punctuated equilibrium model of morphological evolution.

Whether morphological evolution in the fossil record is predominantly punctuational or gradual is a much debated question. The imperfection of the record makes it unlikely that the issue will be settled in the foreseeable future. Intensive study of a favourable and abundant set of fossils may be expected to substantiate punctuated or gradual evolution in particular cases. But the argument is not about whether only one or the other pattern ever occurs; it is about their relative frequency. Some paleontologists argue that morphological evolution is in most cases gradual and only rarely jerky, whereas others think the opposite is true.

Much of the problem is that gradualness or jerkiness is in the eye of the beholder. Consider the evolution of rib strength (the ratio of rib height to rib width) within a lineage of fossil brachiopods of the genus *Eocelia*. An abundant sample of fossils from the Silurian Period in Wales has been analyzed, with the results shown in Figure 8.

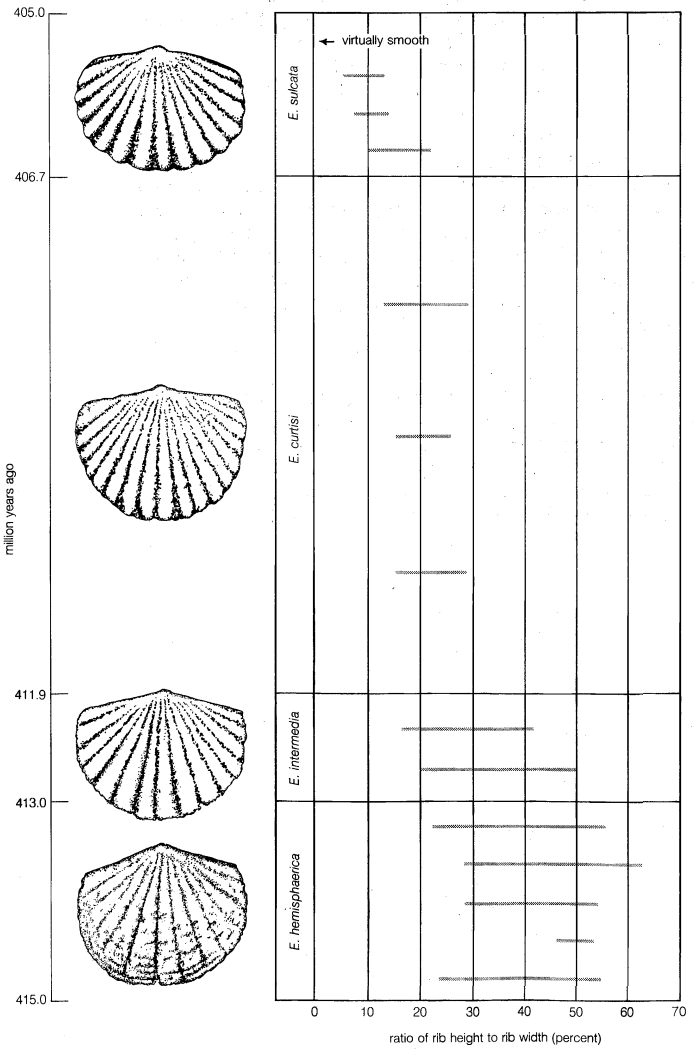

Figure 8: Rib strength in the evolution of the brachiopod *Eocelia*. The horizontal bars indicate the observed range of rib strength among fossilized finds.

One possible interpretation of the data is that rib strength changed little or not at all from 415,000,000 to 413,000,000 years ago; rapid change ensued for the next 1,000,000 years, with virtual stasis from 412,000,000 to 407,000,000 years ago; another short burst of change occurred around 406,000,000 years ago, followed by a final period of stasis. On the other hand, the record shown in the Figure may be interpreted as not particularly punctuated but rather as a gradual process, with the rate of change somewhat greater at particular times.

Problems of interpreting fossil data

The proponents of the punctuated equilibrium model propose not only that morphological evolution is jerky but also that it is associated with speciation events. They argue that phyletic evolution—that is, evolution along lineages of descent—proceeds at two levels. First, there is continuous change through time within a population. This consists largely of gene substitutions prompted by natural selection, mutation, genetic drift, and other genetic processes that operate at the level of the individual organism. The punctualists maintain that this continuous evolution within established lineages rarely, if ever, yields substantial morphological changes in species. Second, they say, there is the process of origination and extinction of species, in which most morphological change occurs. According to the punctualist model, evolutionary trends result from the patterns of origination and extinction of species rather than from evolution within established lineages.

Species are groups of interbreeding natural populations that are reproductively isolated from any other such groups. Speciation involves, therefore, the development of reproductive isolation between populations previously able to interbreed. Paleontologists recognize species by their different morphologies as preserved in the fossil record, but fossils cannot provide evidence of the development of reproductive isolation because new species that are reproductively isolated from their ancestors are often morphologically indistinguishable from them. Speciation as seen by paleontologists always involves substantial morphological change because paleontologists identify new species by morphological differences. This situation creates an insuperable difficulty for resolving the question whether morphological evolution is always associated with speciation events. If speciation is defined as the evolution of reproductive isolation, the fossil record provides no evidence of a necessary association between speciation and morphological change. But if new species are identified in the fossil record by morphological changes, then all such changes will occur concomitantly with the origination of new species.

Speciation and morphological change

MOLECULAR EVOLUTION

DNA and protein as informational macromolecules. The advances of molecular biology have made possible the comparative study of proteins and the nucleic acids, DNA and RNA. The DNA is the repository of hereditary (evolutionary and developmental) information. The relationship of proteins to the DNA is so immediate that they closely reflect the hereditary information. This reflection is not perfect, because the genetic code is redundant and, consequently, some differences in the DNA do not yield differences in the proteins. Moreover, it is not complete, because a large fraction of the DNA (about 90 percent in many organisms) does not code for proteins. Nevertheless, proteins are so closely related to the information contained in the DNA that they, as well as the nucleic acids, are called informational macromolecules.

Nucleic acids and proteins are linear molecules made up of sequences of units—nucleotides in the case of nucleic acids, amino acids in the case of proteins—which retain considerable amounts of evolutionary information. Comparing two macromolecules establishes the number of their units that are different. Because evolution usually occurs by changing one unit at a time, the number of differences is an indication of the recency of common ancestry. Changes in evolutionary rates may create difficulties, but macromolecular studies have two notable advantages over comparative anatomy and the other classical disciplines. One is that the information is more readily quantifiable. The number of units that are different is readily estab-

lished when the sequence of units is known for a given macromolecule in different organisms. The other advantage is that comparisons can be made even between very different sorts of organisms. There is very little that comparative anatomy can say when organisms as diverse as yeasts, pine trees, and human beings are compared; but there are homologous macromolecules that can be compared in all three.

Molecular information about lineage history

Informational macromolecules provide information not only about the topology of evolutionary history (cladogenesis) but also about the amount of genetic change that has occurred in any given lineage (anagenesis). It might seem at first that quantifying anagenesis for proteins and nucleic acids would be impossible, because it would require comparison of molecules from organisms that lived in the past with those from living organisms. Organisms of the past are sometimes preserved as fossils, but their DNA and proteins have largely disintegrated. Nevertheless, comparisons between living species provide information about anagenesis.

The following is an example of such comparison: Two living species, C and D, have a common ancestor, the extinct species B (Figure 9). If C and D were found to differ

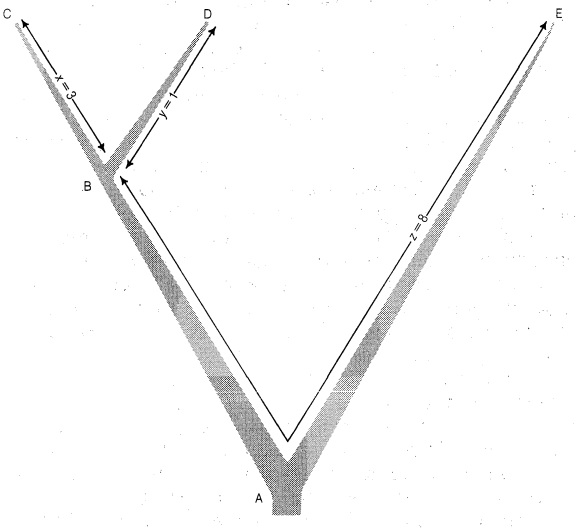

Figure 9: Amount of change in the evolutionary history of three living species (C, D, and E), inferred by comparing amino-acid differences in their myoglobin molecules.

by four amino-acid substitutions in a single protein, then it could safely be assumed that two substitutions (four total changes divided by two species) had taken place in the evolutionary lineage of each species. This assumption, however, could be invalidated by the discovery of a third living species, E, that is related to C, D, and their ancestor, B, through an earlier ancestor, A. The number of amino-acid differences between the protein molecules of the three living species may be as follows:

C and D = 4
C and E = 11
D and E = 9

Figure 9 proposes a phylogeny of the three living species, making it possible to estimate the number of amino-acid substitutions that have occurred in each lineage. Let x denote the number of differences between B and C, y denote the differences between B and D, and z denote the differences between A and B as well as A and E. The following three equations can be produced:

$$x + y = 4$$
$$x + z = 11$$
$$y + z = 9$$

Solving the equations yields $x = 3$, $y = 1$, and $z = 8$.

As a concrete example, consider cytochrome c, a protein involved in cell respiration. The sequence of amino acids in this protein is known for many organisms, from bacteria and yeast to insects and humans; in animals, cytochrome c consists of 104 amino acids. When the amino-acid sequences of humans and rhesus monkeys are compared, they are found to be different at position 66 (isoleucine in humans, threonine in rhesus monkeys), but identical at the other 103 positions. When humans are compared with horses, 12 amino-acid differences are found; but when horses are compared with rhesus monkeys there are only 11 amino-acid differences. Even without knowing anything else about the evolutionary history of mammals, one would conclude that the lineages of humans and rhesus monkeys diverged from each other much more recently than they diverged from the horse lineage. Moreover, it can be concluded that the amino-acid difference between humans and rhesus monkeys must have occurred in the human lineage after its separation from the rhesus monkey lineage (see Figure 10).

Molecular phylogenies of species. Protein sequencing is one of several molecular methods developed for estimating genetic change during evolution. The effectiveness of this method can be illustrated by again using as an example the protein cytochrome c, whose amino-acid sequences are well known. Phylogenies can be constructed based on the number of amino-acid differences between species. But the amino-acid sequence of a protein contains more information than is reflected in the number of amino-acid differences. This is because the replacement of one amino acid by another in some cases requires no more than one nucleotide substitution in the DNA that codes for the protein but, in other cases, requires at least two nucleotide changes. Table 4 shows the minimum number of nucleotide differences in the genes of 20 separate species that are necessary to account for the amino-acid differences in their cytochrome c. Figure 11 proposes a phylogenetic tree based on the data in Table 4, showing the minimum numbers of nucleotide changes in each branch.

The relationships between species as shown in Figure 11 correspond fairly well with the relationships determined from other sources, such as the fossil record. According to Table 4, chickens are less closely related to ducks and pigeons than to penguins, and humans and monkeys diverged from the other mammals before the marsupial kangaroo separated from the nonprimate placentals. These are known to be erroneous relationships; but the power of the method is apparent in that a single protein yields a fairly accurate reconstruction of the evolutionary history of 20 organisms that started to diverge more than 1,000,000,000 years ago.

Cytochrome c is a slowly evolving protein. Widely different species have in common a large proportion of the amino acids in their cytochrome c, making possible the study of genetic differences among organisms only remotely related. For the same reason, however, comparing cytochrome c cannot determine evolutionary change in closely related species. For example, the amino-acid sequence of cytochrome c in humans and chimpanzees is

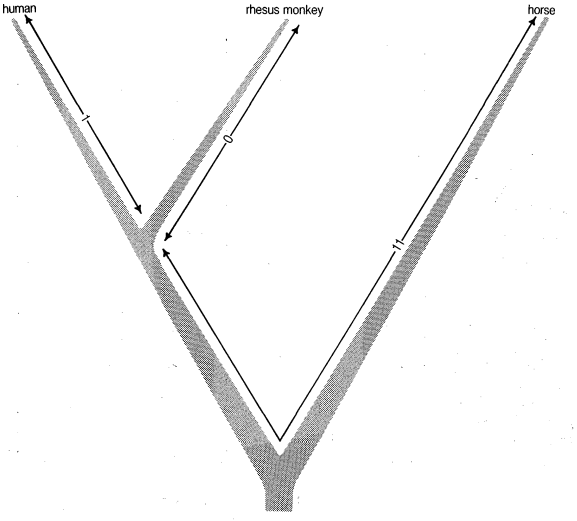

Figure 10: Phylogeny of the human, rhesus monkey, and horse, based on amino-acid substitutions in the evolution of cytochrome c in the lineages of the three species.

Table 4: Minimum Number of Nucleotide Differences in Genes Coding for Cytochrome c in 20 Different Organisms

identical, although they diverged about 10,000,000 years ago; between humans and rhesus monkeys, who diverged from their common ancestor 50,000,000 to 40,000,000 years ago, it differs by only one amino-acid replacement.

Other proteins that evolve more rapidly can be studied in order to establish phylogenetic relationships among closely related species. Genetic changes in the evolution of such species can also be studied by DNA sequencing, DNA hybridization, immunology, and gel electrophoresis.

Molecular phylogenies of genes. It is now possible to obtain the nucleotide sequence of the DNA. Although the number of genes that have been sequenced is relatively small, new sequences are being worked out at a fast rate. The use of DNA sequences in evolutionary research has so far been rewarding, particularly in the study of gene duplications. The genes that code for the hemoglobins in humans and a few other mammals provide the best example.

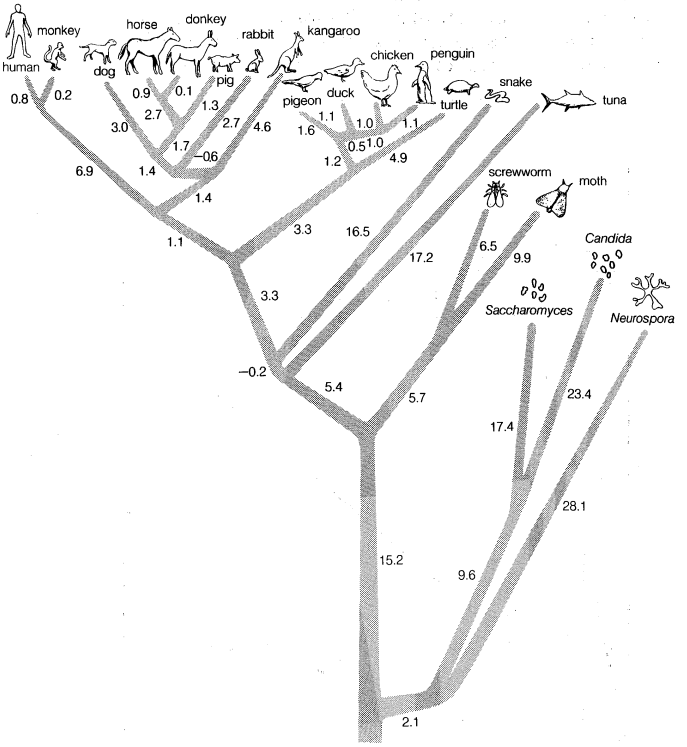

Figure 11: Phylogeny based on differences in the protein sequence of cytochrome c in organisms ranging from *Neurospora* mold to humans. The numbers estimate the nucleotide substitutions that have occurred along the lineages in the gene coding for this protein.

Hemoglobin studies

The amino-acid sequences of the hemoglobin chains and of myoglobin, a closely related protein, are known for humans as well as for other organisms. These sequences have made it possible to reconstruct the evolutionary history of the duplications that gave rise to the corresponding genes. But direct examination of the nucleotide sequences of the coding for these proteins has shown that the situation is more complex, and also more interesting, than it appears from the protein sequences.

The DNA sequence studies on human hemoglobin genes have shown that their number is greater than previously thought. The hemoglobins are tetramers, consisting of two polypeptides of one kind and two of another kind. One of the two kinds of polypeptide is ε in embryonic hemoglobin, γ in fetal hemoglobin, β in adult hemoglobin A, and δ in adult hemoglobin A_2. (Hemoglobin A makes up about 98 percent, and hemoglobin A_2 about 2 percent, of human adult hemoglobin). The other kind of polypeptide is ζ in embryonic hemoglobin and α in fetal and adult hemoglobin. The genes coding for one kind of polypeptide (ε, γ, β, and δ) are located on chromosome 11; the genes coding for the second kind of polypeptide (ζ and α) are located on chromosome 16.

But there are additional complexities. Two γ genes exist, known as G_γ and A_γ, as do two α genes (α_1 and α_2). Furthermore, there are two β pseudogenes ($\psi\beta_1$ and $\psi\beta_2$) and two α pseudogenes ($\psi\alpha_1$ and $\psi\alpha_2$), as well as a pseudo-ζ. These pseudogenes are very similar in nucleotide sequence to the corresponding functional genes, but they include terminating codons and other mutations that make it impossible for them to yield functional hemoglobins.

The similarity in the nucleotide sequence of the globin genes, and pseudogenes, of both the α and β gene families indicates that they are all homologous; that is, that they have arisen through various duplications and subsequent evolution from a gene ancestral to all. Moreover, homology also exists between the nucleotide sequences that separate one gene from another. The evolutionary history of the globin genes is summarized in Figure 12.

The molecular clock of evolution. One conspicuous attribute of molecular evolution is that differences between homologous molecules can readily be quantified and expressed, as, for example, proportions of nucleotides or amino acids that have changed. Rates of evolutionary change can, therefore, be more precisely established with respect to DNA or proteins than with respect to phenotypic traits of form and function. Studies of molecular evolution rates have led to the proposition that macromolecules may serve as evolutionary clocks.

Change in amino-acid sequence over time

It was first observed in the 1960s that the numbers of amino-acid differences between homologous proteins of any two given species seemed to be nearly proportional to the time of their divergence from a common ancestor. If the rate of evolution of a protein or gene were approximately the same in the evolutionary lineages leading

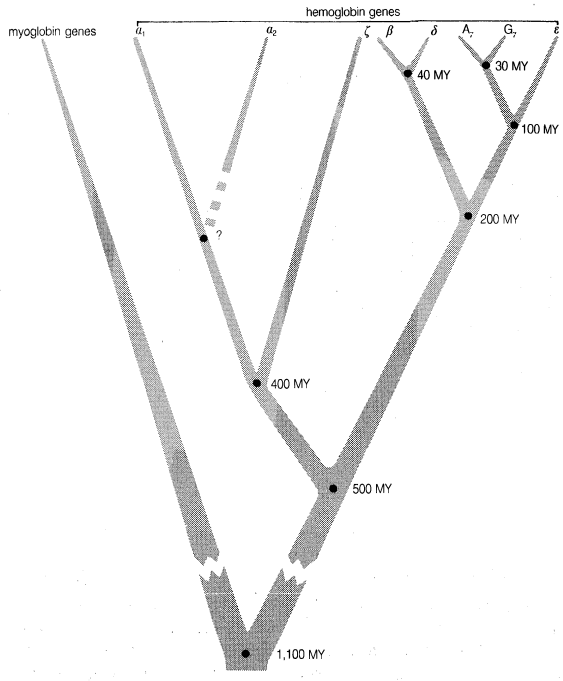

Figure 12: Evolutionary history of the globin genes. The dots indicate points at which ancestral genes duplicated, giving rise to new gene lineages. The approximate times when these duplications occurred are indicated in millions of years (MY) ago. The time when the duplication of α_1 and α_2 occurred is uncertain.

to different species, proteins and DNA sequences would provide a molecular clock of evolution. The sequences could then be used not only to reconstruct the topology of a phylogeny—that is, the sequence of branching events—but also the time when the various events occurred.

Consider, for example, the phylogeny shown in Figure 11. If the substitution of nucleotides in the gene coding for cytochrome c occurred at a constant rate through time, one could determine the time elapsed along any branch of the phylogeny simply by examining the number of nucleotide substitutions along that branch. One would need only to calibrate the clock by reference to an outside source, such as the fossil record, that would give us the actual geologic time elapsed in at least one specific lineage.

The molecular evolutionary clock, of course, is not expected to be a metronomic clock, like a watch or other timepiece that measures time exactly, but a stochastic clock like radioactive decay. In a stochastic clock, the probability of a certain amount of change is constant, although some variation occurs in the actual amount of change. Over fairly long periods of time a stochastic clock is quite accurate. The enormous potential of the molecular evolutionary clock lies in the fact that each gene or protein is a separate clock. Each clock "ticks" at a different rate—the rate of evolution characteristic of a particular gene or protein (see Figure 13)—but each of the thousands and thousands of genes or proteins provides an independent measure of the same evolutionary events.

Evolutionists have found that the amount of variation observed in the evolution of DNA and proteins is greater than is expected from a stochastic clock; in other words, the clock is erratic. The discrepancies in evolutionary rates along different lineages are not excessively large, however. So it is possible, in principle, to time phylogenetic events with as much accuracy as may be desired; but more genes or proteins (about two to four times as many) must be examined than would be required if the clock were stochastically constant. The average rates obtained for several proteins taken together become a fairly precise clock, particularly when many species are studied and the evolutionary events involve long time periods (on the order of 50,000,000 years or more).

This conclusion is illustrated in Figure 14, which plots the cumulative number of nucleotide changes in seven proteins against the paleontological dates of divergence of 17 species of mammals. The overall rate of nucleotide substitution is fairly uniform. Some primates (shown by the dots at the lower left of the Figure) appear to have evolved at a slower rate than the average for the rest of the species. This anomaly occurs because the more recent the divergence of any two species the more likely it is that the changes observed will depart from the average evolutionary rate. As the length of time increases, periods of rapid and slow evolution in any lineage are likely to cancel one another out.

The neutrality theory of molecular evolution. In the late 1960s it was proposed that at the molecular level most evolutionary changes are selectively "neutral," meaning that they are due to genetic drift rather than to natural selection. Nucleotide and amino-acid substitutions appear in a population by mutation. If alternative alleles (alternative DNA sequences) have identical fitness—if they are identically able to perform their function—changes in allelic frequency from generation to generation will occur only by genetic drift. Rates of allelic substitution will be stochastically constant; that is, they will occur with a constant probability for a given gene or protein. This constant rate is the mutation rate for neutral alleles.

Alternative alleles with identical fitness

According to the neutrality theory, a large proportion of all possible mutants at any gene locus are harmful to their carriers; these mutants are eliminated by natural selection, just as standard evolutionary theory postulates. The neutrality theory also agrees that morphological, behavioral, and ecological traits evolve under the control of natural selection. What is distinctive in the theory is the claim that at each gene locus there are several favourable mutants, equivalent to one another with respect to adaptation, so that they are not subject to natural selection among themselves. Which of these increases or decreases in frequency in one or another species is purely a matter of chance, the result of random genetic drift over time.

Neutral alleles are those that differ so little in fitness that their frequencies change by random drift rather than by natural selection. This definition is formally stated as $4N_e s < 1$, where N_e is the effective size of the population, and s is the selective coefficient that measures the difference in fitness between the alleles.

Assume that k is the rate of substitution of neutral alleles per unit time in the course of evolution. The time units can be years or generations. In a random-mating popula-

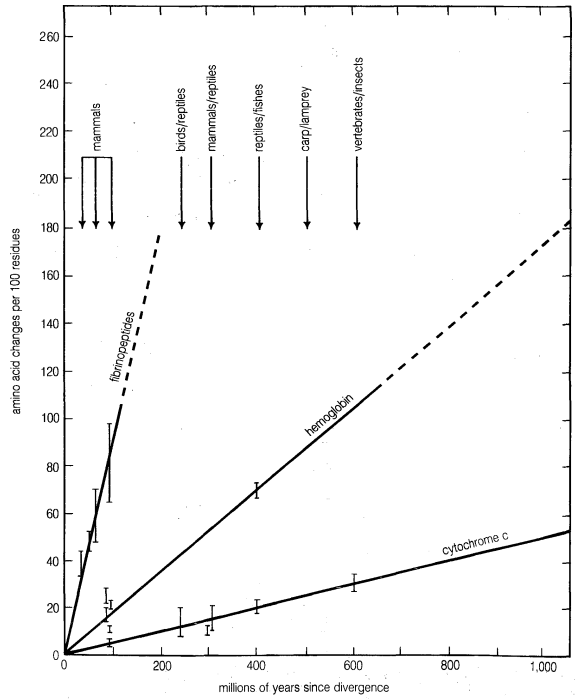

Figure 13: Three proteins with very different evolutionary rates: fibrinopeptides (very fast), hemoglobin (intermediate), cytochrome c (slow).

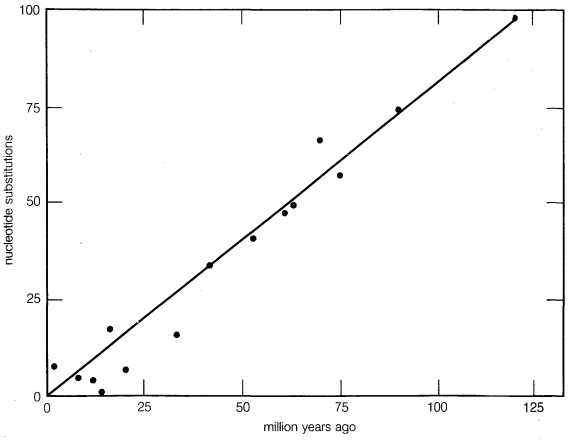

Figure 14: Rate of nucleotide substitution over paleontological time. Each dot marks (1) the point at which a pair of species diverged from a common ancestor and (2) the number of nucleotide substitutions, or protein changes, that have occurred since the divergence. The solid line drawn from the origin to the outermost dot gives the average rate of substitution.

From F.J. Ayala, E. McMullin (ed.), *Evolution and Creation* (1985)

tion with N diploid individuals, $k = 2Nux$, where u is the neutral mutation rate per gamete per unit time (time measured in the same units as for k) and x is the probability of ultimate fixation of a neutral mutant. The derivation of this equation is straightforward: there are $2Nu$ mutants per time unit, each with a probability x of becoming fixed. In a population of N diploid individuals there are $2N$ genes at each locus, all of them, if they are neutral, with an identical probability, $x = 1/2N$, of becoming fixed. If this value of x is substituted in the equation above ($k = 2Nux$), the result is $k = u$. In terms of the theory, then, the rate of substitution of neutral alleles is precisely the rate at which the neutral alleles arise by mutation, independently of the number of individuals in the population or of any other factors.

If the neutrality theory of molecular evolution is strictly correct, it will provide a theoretical foundation for the hypothesis of the molecular evolutionary clock, since the rate of neutral mutation would be expected to remain constant through evolutionary time and in different lineages. The number of amino-acid or nucleotide differences between species would, therefore, simply reflect the time elapsed since they shared the last common ancestor.

Debate over the neutrality theory

Evolutionists debate whether the neutrality theory is valid. Tests of the molecular clock hypothesis indicate that the variations in the rates of molecular evolution are substantially larger than would be expected according to the neutrality theory. Other tests have revealed substantial discrepancies between the amount of genetic polymorphism found in populations of a given species and the amount predicted by the theory. But defendants of the theory argue that these discrepancies can be assimilated by modifying the theory somewhat; by assuming, for example, that alleles are not strictly neutral, but their differences in selective value are quite small. Be that as it may, the neutrality theory provides a "null hypothesis," or point of departure, for measuring molecular evolution.

BIBLIOGRAPHY. Early seminal works of evolutionary theory include CHARLES DARWIN and ALFRED WALLACE, "On the Tendency of Species to Form Varieties, and on the Perpetuation of Varieties and Species by Natural Means of Selection," *Journal of the Proceedings of the Linnean Society*, 3(9):45–62 (1858); and CHARLES DARWIN, *On the Origin of the Species by Means of Natural Selection, or, The Preservation of Favoured Races in the Struggle for Life* (1859), also available in many modern editions, and *The Descent of Man, and Selection in Relation to Sex*, 2 vol. (1871, reprinted in 1 vol., 1981). G. MENDEL, *Experiments in Plant Hybridisation* (1965; originally published in German, 1866), provides the groundwork for all subsequent studies in heredity, including R.A. FISHER, *The Genetical Theory of Natural Selection*, 2nd rev. ed. (1958); and J.B.S. HALDANE, *The Causes of Evolution* (1932, reissued 1966). THEODOSIUS DOBZHANSKY, *Genetics and the Origin of Species* (1937, reprinted 1982), is the classic foundation of the synthetic theory of evolution; see also JULIAN HUXLEY, *Evolution: The Modern Synthesis*, 3rd ed. (1974).

The history of evolutionary theories from Darwin to the present is traced in RONALD W. CLARK, *The Survival of Charles Darwin: A Biography of a Man and an Idea* (1984, reissued 1986), which also presents an engaging biography of Darwin. The most authoritative historical treatise of evolutionary ideas from antiquity to the present is ERNST MAYR, *The Growth of Biological Thought: Diversity, Evolution, and Inheritance* (1982). ERNST MAYR and WILLIAM B. PROVINE (eds.), *The Evolutionary Synthesis: Perspectives on the Unification of Biology* (1980), contains historical articles by several of the great evolutionists who formulated the synthetic theory.

Modern treatments of evolutionary theory include G. LEDYARD STEBBINS, *Darwin to DNA, Molecules to Humanity* (1982), a readable discussion providing coverage of human evolution, both biological and cultural. A fairly comprehensive text requiring only general biology as background is FRANCISCO J. AYALA and JAMES W. VALENTINE, *Evolving: The Theory and Processes of Organic Evolution* (1979). A more advanced text is THEODOSIUS DOBZHANSKY *et al.*, *Evolution* (1977). FRANCISCO J. AYALA, *Population and Evolutionary Genetics: A Primer* (1982), provides an introduction to the genetics of the evolutionary process. A more advanced and mathematically demanding work is PHILIP W. HEDRICK, *Genetics of Populations* (1983, reissued 1985). The origin of species is the subject of MICHAEL J.D. WHITE, *Modes of Speciation* (1978); and of the more comprehensive ERNST MAYR, *Animal Species and Evolution* (1963), which is a classic work. G. LEDYARD STEBBINS, *Flowering Plants: Evolution Above the Species Level* (1974), discusses plant speciation and evolution.

A good introduction to the fossil record is a collection of articles from *Scientific American*, edited by LÉO F. LAPORTE, *The Fossil Record and Evolution* (1982). GEORGE GAYLORD SIMPSON, *The Meaning of Evolution: A Study of the History of Life and of Its Significance for Man*, 2nd rev. ed. (1967, reissued 1971), is written for the general reader yet is an authoritative work dealing particularly with paleontological principles and the evolutionary process through time; somewhat more technical is his *Major Features of Evolution* (1953, reprinted 1969). An authoritative treatise on paleontological principles is STEPHEN JAY GOULD, *Ontogeny and Phylogeny* (1977).

Two good introductions to molecular evolution are FRANCISCO J. AYALA (ed.), *Molecular Evolution* (1976); and MASATOSHI NEI and RICHARD K. KOEHN (eds.), *Evolution of Genes and Proteins* (1983). The neutrality theory is presented in full by its main theorizer in MOTOO KIMURA, *The Neutral Theory of Molecular Evolution* (1983); and the theory that evolutionary changes happen not gradually but abruptly is advanced by one of its originators in NILES ELDREDGE, *Time Frames: The Rethinking of Darwinian Evolution and the Theory of Punctuated Equilibria* (1985).
