Characteristic Egyptian sound changes

Phonology. The Egyptian hieroglyphic writing was not adapted for expressing vowels. By the Coptic period, when an alphabetic writing came into use, the Egyptian vowel system had undergone so radical a change that the original vowels can be reconstructed only very approximately. In the consonantal system the loss of the emphatics (except *p* from **ṗ* and *q* from **ḳ*) is characteristic, as are the changes of **-r* (at end of syllable) to -ʾ, **li-* and **lu-* to *ỉ-*, **ki-* and **ku-* to *ṯ* (pronounced as *tch*), **gi-* and **gu-* to *ḏ* (pronounced *dj*). In some cases *ṯ* and *ḏ* apparently reflect the affricates of the parent language. In addition, the original lateral sounds were lost as well as the postvelar stops and labialized velars, and the system of spirants was simplified. Beginning with Middle Egyptian, *d, ḏ,* and *ṯ* developed gradually to *t,* and many final consonants (*e.g.,* *-t, -r*) were dropped.

Word formation, morphology, and syntax. Word formation in Egyptian was similar to the Semitic type, although probably less consistent. As for the inflection, there may have been only two cases of the noun in Old Egyptian. The actor case coincided with the genitive, and this may have been responsible for a drastic rearrangement of the entire verbal system. Of the original Hamito-Semitic verbal forms only the stative ("pseudo-participle") is preserved; its subject, when a pronoun, is in the ancient direct (zero) case. Verbal forms expressing action were replaced by attributive and prepositional constructions, with the person of the actor being expressed by a suffixed possessive pronoun or by a noun in the genitive. Stem modifications are less developed in Egyptian than in Semitic; a habitative form with reduplication (repetition) of the third consonant of the root exists along with the normal imperfective of the main stem. In the later periods a new complicated system of secondary verbal tenses developed. Masculine gender was marked by zero (the absence of any ending) or **-aw-*, feminine gender by *-at-*, plural masculine by **-ā-w-*, and plural feminine probably by **-ā-w-āt-*.

Typical of Egyptian syntax are a construction in which two nouns, each in its complete case form, are connected by a pronoun, called the *nota genitivi;* and a *status constructus,* in which the governing noun appears in a shortened form before the governed noun in the genitive.

Hieroglyphic, hieratic, and demotic writing

Writing. The ancient Egyptian writing was a logosyllabic one, having symbols representing either complete words or syllables of words; identical signs were used for syllables with identical consonants but different vowels. According to the external form of the signs, the writing is classified as hieroglyphic when it is found on inscriptions on stone, metal, and other hard surfaces and as hieratic and later demotic when it is used for cursive writing on papyrus manuscripts. Typologically the three forms of writing are identical. Coptic was written in an alphabet based on Greek and partly on Demotic. There is a considerable literature in Egyptian and in Coptic (in the latter, mostly of a religious nature; see also WRITING: *Hieroglyphic writing*).

BERBER LANGUAGES

The Berber (Berbero-Libyan) branch is represented by a multitude of New Stage Berber dialects distributed all over North Africa, from the Siwa Oasis in the Arab Republic of Egypt to Senegal (about 11,000,000 speakers). The more important dialect clusters are Tamashek (Tuareg), in the central Sahara and south of the Niger; Shawia and Kabyle (Zouaouah), both in Algeria; Rif and Tamazight, predominantly in Morocco; Shluh (Tashelḥayt or Shilha), in Morocco and Mauritania; and Zenaga, in Senegal. Little is known of ancient Libyan, also called Numidian. It is attested by inscriptions found in Tunisia, Algeria, and elsewhere, dating from the times of the Roman Empire and written in a native consonantal quasi-alphabetic script still surviving in a modified form among the Tuaregs of Sahara. Whether the extinct language of the Guanches in the Canary Islands and of the Iberians of Spain belonged to the Berber branch or even to Hamito-Semitic is doubtful.

Ancient Numidian

Phonology. In the phonologies of these languages the vowels **a, *i, *u* were lost or reduced to *ə*, and **ā, *ī, *ū* became *a, i, u;* **w* and **y* may appear both as consonants and as vowels, and the emphatics are represented by *ḍ, gh* (but in reduplication *ṭṭ, qq*), and *ẓ.* The system of spirants has been simplified but retains *š* (*sh*) and *ž* (*zh*) sounds. Interdentals, laterals, and affricates were lost.

Word formation and morphology. Except in the verb, there are only traces of the internal inflection type of word formation characteristic of the Semitic branch. Among grammatical features, a former article no longer retaining its determinative function (masculine **hā-*, plural **hī,* feminine **tā-,* plural **tī-*) is prefixed under certain conditions to the noun, displacing the prefixed markers of gender, *w-* and *t-*. These latter gender markers are at present used in a form of the noun as an attribute or as a subject of a verb when following the predicate in the sentence. The plural of the noun is masculine *-ən* and *-an* and feminine *-in.* A *pluralis fractus* "broken plural" has also developed (mostly an infixation of *-a-*). The perfective of the main verbal stem also has a habitative form (reduplication of the second consonant of the root, or prefixation of *-tt-* to the word base). Tamashek has several verbal tenses.

There is little or no intelligibility between the dialects, except for historically neighbouring ones. A great number of Arabic borrowings are evident in most dialects; there are also a number of borrowings from Punic, Latin, and from the languages south of Sahara.

CUSHITIC LANGUAGES

The Cushitic branch goes back to a reconstructed Common Cushitic parent language; this, according to the Soviet scholar A.B. Dolgopolsky, was the dialect of Common Hamito-Semitic that best preserved the original phonological system. Whether or not West Cushitic (Omotic) is a descendant of Common Cushitic is not clear. The Cushitic languages are all from the New Stage and have about 16,000,000 speakers.

The five Cushitic language groups

Languages of the group. The Cushitic languages, including the West Cushitic group, can be subdivided into five groups. The Northern group is represented by Beja, or Bedawiye, spoken mainly in The Sudan close to the Red Sea and also in Eritrea; it has about 1,300,000 speakers. Typical linguistic features include the scanty representation of affricates, velars changing partly to ʾ, and postvelar consonants changing to *h.* Two or, in some cases, three verbal forms with prefixed actor markers exist ("strong conjugation"), but many verbs are conjugated by suffixes (developed from an auxiliary verb with prefix conjugation). There are stem modifications similar to those of Berber in the strong conjugation, formed by suffixes in the other verbs (this is also typical of the other Cushitic languages). In addition, declension of the noun, with traceable relics of the ancient type similar to the Semitic, also can be seen.

The Eastern group has several subgroups. The highland languages, spoken east of Addis Ababa, include Hadya-Libide (900,000 speakers), Kambata (300,000 speakers), Sidamo (1,100,000 speakers), Darasa (300,000 speakers), Burji, and some related languages. The total number of speakers of this subgroup is about 2,600,000. The other subgroups include Saho-Afar in Eritrea, northeast Ethiopia, and Djibouti, with 750,000 or more speakers; the Somali subgroup, with Somali, Bayso, Rendile, and other languages in Somalia, eastern Ethiopia, and eastern Kenya, having a total of more than 5,000,000 speakers; the Gallinya subgroup, comprising Oromo (Gallinya, with several dialects) in western, central, and southern Ethiopia and northern and eastern Kenya; the subgroup of Arbore, Dathanaic (Geleba), and other languages, together having about 13,000,000 speakers; Konso, Gidole, and related dialects, with about 80,000 speakers in western Ethiopia; Warazi (Warize) and related languages also in western Ethiopia, with about 50,000 speakers; and Mogogodo of northern Kenya. Typical features of the group are the presence of emphatic affricate sounds and the change of postvelar sounds to ʾ and *h;* in some languages the older **l* sound is represented as *j* or *r,* and **r* as *r, d,* or *n.* The number of verbs of the "strong conjugation" is very small in some languages and nonexistent in others. In addition, there are grammatical genders differing from the ancient type.

The Central, or Agau, group includes languages or dialects dispersed over Ethiopia. They include Bilin, Khamta, Awngi, and Kemant (Qimant), among others, and are spoken by more than 100,000 people. The Quara dialect, spoken formerly by the Falashas, an Ethiopian Jewish ethnic group, is now extinct. Although the vocabulary of all Agau dialects is very similar, there is little mutual intelligibility as a result of the dissimilarity in the phonetic reflexes of the Proto-Cushitic sounds and the strong influence of Ethiopic and Amharic.

The Southern group, located in Tanzania, south of the Equator, includes Iraqw and its related dialects, Asa, Ngomwia, and others. Characteristic of the group is the loss, for the most part, of emphatic consonants. The laterals, however, are partly preserved, as are the pharyngeal ʿ and a few of the affricates. Both **l* and **r* are reflected as *l-* and *-r-*. In spite of numerous innovations as a result of substratum influence, there are many similarities with Eastern Cushitic in grammar.

The Omotic languages

The Western group, also called the Omotic branch by some scholars, encompasses Ometo, a dialect cluster including the Walamo language, with about 1,600,000 speakers; Janjero (Yamma), Bworo (Shinasha, Gonga), Anfillo (Southern Mao), Benesho-She (Gimira), Ari-Banna, and others, all of which are languages with small numbers of speakers, perhaps about 120,000 in all; and Kafa (Kaficho)-Mocha, with more than 200,000 speakers. All of these languages are spoken along the western border of Ethiopia and in northern Kenya. Typical features include the change of **s* to *š,* the preservation of most affricates, but the loss of laterals and of all postvelar, pharyngeal, and laryngeal fricatives. The sonants **l,* **r,* and **n* are usually represented alike as *n-* and *-r-*. Some languages have tones that serve to differentiate word meaning. Also characteristic are drastic innovations in the pronoun and the verb. Traces of the genders are usually represented as masculine *-ō* (from **-aw*) and feminine *-ā* and *-ē* (perhaps from **-at* or **-ay*).

There have been some attempts to create a written language for Oromo and especially for Somali on the basis of Ethiopic, Latin, or Arabic writing. An original Somali writing system was invented in the beginning of the 20th century, but at present Somali is written in the Arabic alphabet.

Linguistic characteristics. *Phonology.* All the Hamito-Semitic groups of consonants were preserved in Common Cushitic, and separate reflexes of each group can be traced in the different Cushitic languages. Because of an imperfect development of the system of word formation by vowel infixation, however, the stability of the consonantal root was not as necessary for correlation of forms as in Semitic. The reflexes of the sounds of the protolanguage in the individual Cushitic languages therefore depend to a great extent on positional circumstances; thus, a Proto-Cushitic **c,* pronounced as *ts,* may have developed into a *d-* in an initial position and an *-s-* in an intervocalic or final position, and so forth. Emphatics are mostly preserved (*ḍ, ç* or *č̣, ḳ,* etc.); **ṗ* is distinguished from **p* by different reflexes (Omotic partly retains *ṗ*). Affricates (and also *d, š, s,* etc.) represent what in Semitic are interdental consonants.

Morphology. Verbal conjugation by means of prefixed actor markers is preserved only in a part of the verbs or else in traces; in most of the verbs it is replaced by a new system of conjugation (originally a combination of verbal noun plus prefix conjugation of an auxiliary verb). Two genders (masculine **-w,* feminine **-t*) and traces of noun declension can be observed; partial and sometimes complete reduplication of stems is used as a means of expressing the plural, along with the means known from the other branches. The pronominal system (except in Omotic) is very close to that of Semitic. In vocabulary, there are many borrowings from Ethiopic, Amharic, Arabic, and Nilo-Saharan.

CHADIC LANGUAGES

Hausa

Languages of the group. Of the Chadic (Chado-Hamitic) branch the most important language by far is Hausa. Its approximately 22,000,000 speakers live in northern Nigeria, in the Republic of the Niger, in the northern part of Ghana, in Cameroon, and in parts of Togo, Benin (Dahomey), the Chad Republic, and the Central African Republic. Hausa is also spoken as a second language by many speakers of other African languages. All the other languages of the Chadic branch are spoken by smaller ethnic groups; for example, the Bura, with about 1,500,000 people; the Mandara, with about 670,000; the Angas, with about 500,000; the Bolewa and Karekare, numbering about 220,000; and the Kanakuru, with about 150,000. In regard to the classification of the Chadic languages, some units are at times classified as languages but should preferably be treated as dialects, and vice versa, and the information on many languages (dialects?) is very scanty. Thus, all attempts at classification must be regarded as provisional only. The more important of the approximately 150 "languages" follow.

1. Western group: Hausa, Gwandara, Ngizim, Bedde (Bade), and related languages; Warjawa, Afawa (Paʾa), and related languages; Gezawa, Seiyawa, Barawa of the Dass region; Bolewa, Karekare, Kanakuru, and related languages; Angas, Sura, Ankwe, Gerka, and related languages; Maha (?).

2. Ron group: Fyer, Bokkos, Daffo-Butura, Sha, and Kulere.

3. Kotoko group: Logone, Buduma, Afade, Gulfei, and related languages and dialects.

4. Musgu (Musgum).

5. Masa group: Masa (Banana), Bana, Kulung; Mussoi (?); Marba (?); and Dari (?).

6. Eastern group: Somrai and related languages; Gaberi and related languages and dialects; Sokoro and related languages; Modgel; Tuburi (Kera); Mubi; Dangla-Jegu, Jonkor, and related languages.

The affiliation of the following languages and dialects to the Hamito-Semitic family has been questioned by some scholars:

7. Tera, Jera; Hona, Gaʾanda, and related languages; Bata, Gundu, and related languages; Margi, Bura, Chibak, and related languages; Higi (Hiji) and related languages; Laamang (Hidkala); Mandara (Wandala), Glavda, Yawotatakha, Sukur, and related languages.

8. Daba, Hina, Gauar, Musgoi (?); Matakam, Mofu, Gisiga, and related languages.

9. Gidder.

The total number of speakers of Chadic languages is probably about 26,000,000.

It is probable that the linguistic area of the Chadic branch formerly extended farther to the east, thus contacting the Omotic (Western Cushitic) group.

No Chadic language except Hausa has been reduced to writing; for Hausa, Arabic writing began to be used in the 16th century, and now a modification of the Latin alphabet is used.

Linguistic characteristics. In relation to the original phonological system of Proto-Hamito-Semitic, there are many missing sounds in the individual Chadic systems, but a comparison of the different Chadic groups shows that all the distinctive sounds of the parent language are represented in one way or another. Typical of all Chadic languages are tones serving to differentiate meaning in otherwise identical words.

The verb is for the most part a combination of an auxiliary verb (prefix conjugation) followed by a verbal noun (the reverse order is typical for Cushitic); the nominal part often has a vowel suffix pointing out certain qualities of the verb (transitiveness, intransitiveness, and so on). Verbal stem modifications exist, being expressed by such devices as reduplication and suffixes, but in most languages they are not strongly developed. Most of the languages have more or less clearly expressed genders but no declension. Plural is shown as in Cushitic and Berber. Chadic languages have innovations in the pronominal system. In vocabulary there are borrowings from English, Arabic (especially in Hausa), Fulani, and East Sudanic.

(I.M.D.)

KOREAN LANGUAGE

Korean is spoken by more than 55,000,000 people on the Korean peninsula and its coastal islands, and many among the approximately 558,000 Korean residents in Japan still speak the language. As the language of a sizable population occupying a strategic position in east Asia between China and Japan, Korean is important both historically and culturally. A considerable body of belles lettres and other literature is written in it.

Origin and classification. The direct precursor of the modern Korean language was the language of the ancient kingdom of Silla (*c.* 57 BC–AD 935), the original territory of which was in the southeastern part of the peninsula. The language of Silla spread over most of the peninsula when, in the 7th century, that kingdom conquered and annexed the territories of its rival states, Paekche (*c.* 18 BC–AD 660) in the southwest and Koguryŏ (*c.* 37 BC–AD 668) in the north. It is believed that the people of Silla and Paekche spoke dialects of the same language, while the people of Koguryŏ spoke a different, though related, language.

Possible relationship to Altaic

The most fruitful hypothesis concerning the affinity of Korean to other languages is that it belongs to the Altaic family, which includes the Manchu-Tungus, Mongol, and Turkic groups of languages. Like them, Korean is a language of the agglutinative type, and it shares with them many features of phonology and grammar. (Agglutinative languages combine into a single word several components, each of which remains relatively distinct in form and meaning). This theory is supported by a number of cognates and some sets of sound correspondences. The relationship is, however, probably a remote one.

Some scholars have proposed that Korean and Japanese are related. Their grammatical structures are similar in many ways, but their phonologies (sound systems) differ greatly. It is still an open question whether the sound correspondences demonstrated so far rigorously support a genetic relationship.

A standard spoken and written language is taught in the schools and used as the norm throughout Korea. This form of Korean was defined in the 1930s and is based primarily on the speech of the middle class of Seoul, with certain peculiarities excluded. Regional dialects, which are still vigorous, can be grouped into six major divisions: central, northeastern, northwestern, southeastern, southwestern, and Cheju-do, off the southern coast. These regional dialects differ from one another most conspicuously in intonation (the pitch pattern of a sentence), vocabulary, and the form of some grammatical endings.

Knowledge of the early stages of the language that existed before the introduction of the native Korean alphabet in the middle of the 15th century is still slight. The most extensive records of ancient Korean extant are 25 texts of songs, called *hyangga,* from the kingdom of Silla; these are quoted in works written in Chinese during the succeeding Koryŏ period (935–1392). In these writings Korean is written in Chinese characters used as phonetic and semantic symbols of Korean words.

Ancient Korean records

There are no generally agreed upon dates for the stages of development of the language. A possible dating is as follows: Old Korean (before the 12th century), Middle Korean (beginning of the 12th century to the end of the 16th century), Modern Korean (from the beginning of the 17th century).

The most penetrating external influence exerted on the language has been that of Chinese, from which many words were borrowed over the centuries. This influence has been limited largely to vocabulary. In addition, until the end of the 19th century, the prevailing written language of serious Korean literature was Chinese (*hanmun*) or, later, a deliberately Koreanized version of it.

Standardization of the spoken and written language became an urgent problem toward the end of the 19th century, when Korea undertook large-scale reforms to meet the social needs occasioned by internal changes and by pressures from the West. Efforts by Korean scholars, educators, and writers to develop a standard spoken and written language culminated in the publication by the Chosŏnŏ hakhoe (Society for the Study of the Korean Language) in 1933 of its *Han'gŭl mach'umppŏp t'ongiran* ("A Proposal for Unifying the Orthography") and its *P'yojunmal moŭm* ("Collection of Standard Forms of Words") in 1936. These standards became official only in 1945, upon Korea's liberation from Japanese rule. Some divergencies in the spelling system and in word usage have since developed in the north and in the south.

Native Korean alphabet

The writing system. The native Korean alphabet was introduced in 1446, after centuries of the use of cumbersome methods (known as Idu) to transcribe Korean with Chinese characters. The new set of 28 letters (not an adaptation of an existing alphabet) was designed by a group of scholars commissioned by Sejong (reigned 1419–50), the fourth king of the Yi dynasty (1392–1910). Although the alphabet was meant to be a "script for the people," as its original name *Hunmin-jŏngŭm* implies, it did not win acceptance as a respectable form of writing among the literati, or scholar-officials, who continued to write Hanmun. This alphabet, also called Ŏnmun (the common script), did, however, give rise to a body of premodern popular literature. Finally, in the beginning of the 20th century, the alphabet received general recognition as the national writing system. Today it is known as Han'gŭl in South Korea and as Chosŏn muntcha in North Korea.

Two methods of writing Korean are in use today: the purely alphabetic method and the "mixed script" method, in which Sino-Korean words (Chinese loanwords) may be written in their original characters and read in their Korean pronunciation. In North Korea only the alphabetic method has been in use since 1949; in South Korea both methods are in use, though it has been the government policy to dispense with Chinese characters in gradual stages. Four of the original 28 letters have gone out of use. The accompanying alphabet chart includes combinations of letters that are units in alphabetizing. Letters are grouped into syllable blocks, which contain at least an initial consonant plus a vowel. If the phonetic syllable has no initial consonant, a special letter is used as a filler for the initial consonant space in the syllable block and is silent in that position.

Linguistic characteristics. *Phonology.* The McCune-Reischauer system of transcription is used for the Korean in this article; see the alphabet chart for the phonetic values of the transcription symbols. In the phonology, the consonants show an unusual three-way distinction among a series of lenis (soft) consonants, *p, t, k, ch, s;* a fortis (hard), unaspirated series, *pp, tt, kk, tch, ss;* and a fortis, aspirated series, *p', t', k', ch'*. (Aspirated consonants are pronounced with an audible release of air.) These consonants are all typically voiceless (*i.e.,* pronounced without vibration of the vocal cords), but the lenis consonants *p, t, k,* and *ch* are voiced (*i.e.,* pronounced with vibrating vocal cords) when they come between voiced sounds, thus becoming pronounced as *b, d, g,* and *j* (as in "jam").

Three-way consonant distinction

The central characteristic of the Korean phonological system is that the consonants are more severely restricted as to position of occurrence within a word than within a morpheme (*i.e.,* within the stems and affixes of words). For example, the sound [s] cannot be pronounced at the end of a word, although some word stems do end in *s;* or such sequences as [s] + [k] cannot be pronounced in Korean,

Table 51: The Korean Alphabet (Han'gŭl)

	McCune-Reischauer romanization*			approximate equivalent sound in English		McCune-Reischauer romanization	approximate equivalent sound in English

*The system of phonetic transcription of Korean generally used for scholarly purposes in the United States. †Only seven consonant sounds (*k*, *t*, *p*, *n*, *l*, *m*, *ng*) are pronounced at the end of a word or before a consonant. Others are phonetically "reduced" to one of these seven when they occur in these positions; consequently, different letters may be romanized in the same way. The same letter may be romanized differently in different phonetic contexts because of sound changes. ‡Lenis (lax or softer than the corresponding tense consonant), voiceless, and slightly aspirated at the beginning of a word and typically voiced, except the sound *s*, between voiced sounds; *s* is palatalized as in English "she" when it comes before *i*, or *y* sounds. At the end of a word or before a consonant the sounds *k*, *t*, *p* are unreleased. §Tense (fortis or "reinforced"), voiceless, and unaspirated. ‖In South Korean published writing this letter is not found at the beginning of words except in some recent loanwords; in North Korean published writing it is found at the beginning of both Korean and foreign words. This letter, represented by *r*, is pronounced like the *t* in "water" when it comes between vowels or semi-vowels and at the beginning of words; when it comes at the end of a word or before a consonant, it is pronounced like English initial *l*. There is also a long *l* sound, romanized *ll*, that occurs between vowels or semi-vowels; this is the result of sound assimilations involving *l*. There is no special letter in the alphabet for it. ¶The sound of this letter in medial position is to be distinguished from *n'g*, which is the combination of *n* + *g* sounds. ♀Voiceless, and strongly aspirated. δThe *y* part of a diphthong is represented in the Korean orthography by an extra stroke added to the letter for a vowel. □The *w* part of a diphthong is represented in Korean orthography by the letter for the vowel *o* or the letter for the vowel *u*. ◇This diphthong has no close approximation in English.

but they can result from adding a suffix beginning with *k* to a stem ending in *s*. (The square brackets indicate that included letters stand for sounds pronounced rather than the conventional spelling.) The language has an extensive system of sound changes to resolve these conflicts between combining forms and permissible pronunciations. The standard orthography spells words in terms of the morphemes (constituent units) that comprise them, as long as the sound changes are covered by a regular phonological rule. Thus, most morphemes preserve their orthographic identity, although they may not be pronounced as spelled; *e.g.*, the noun stem for "five" is always spelled *tasŏs*, whether in the form *tasŏs-i* "five (as subject)," pronounced [tasŏsi], or in the form *tasŏs* "five (as a word by itself)," pronounced [tasŏt], with a final [t]. Forms based on the verb stem *pis-* "to comb," are spelled *pis-ŏ, pis-ko*, but are pronounced as [pisŏ] and [pikko] respectively. If sound changes are not covered by a phonological rule of the language, the principle is to spell words phonetically.

Grammar. Aside from interjections and primary (not derived) adverbs, a word in Korean typically consists of a stem plus an ending. Stems are of two types: (1) nouns and (2) verbs and adjectives. Nouns take endings that mark their syntactic role in the sentence—such as subject, topic (often equivalent to English "as for," as in "As for Korea, it's a peninsula."), object, genitive—or that express such meanings as "to, in, from." They are indifferent as to grammatical number and gender. Verbs and adjectives have much the same pattern of forms and enter into many of the same kinds of constructions. They may take one or a combination of two tense suffixes, roughly designated as past and future tense; the lack of a tense suffix indicates present tense or tenselessness. To the stem or to the stem plus the tense suffix is added an ending that concludes the sentence (called a sentence-conclusive form), or a conjunctive, nominal (noun), adnominal (*i.e.*, attributive), or adverbial form.

Basic clause structure

The basic structure of a clause is subject + predicate; in the predicate the main verb or adjective comes last. An example is [abŏjiga^1 ŏje^2 segŭmŭl^3 naesiŏssŭmnida^4] "Father^1 paid^4 his taxes^3 yesterday^2." This order applies to conjunctive clauses (*i.e.*, clauses similar to "but he left early" in "He came, but he left early.") as well as to independent clauses, and it holds, too, for independent clauses regardless of mood—declarative, interrogative, imperative, and so on; *e.g.*, [abŏjiga^1 ŏje^2 segŭmŭl^3 naesiŏssŭmnikka^4?] "Did Father^1 pay^4 his taxes^3 yesterday^2?"

The mood of the Korean sentence is specified by an ending on the verb or adjective that concludes the sentence. This ending expresses a complex of meanings—not only whether the sentence is a statement, a question, or a command, but also whether the speaker is reporting something from personal observation or from hearsay, and whether the speaker is certain or hesitant, and so on. At the same time, this ending specifies one of several possible levels of address for the sentence, reflecting the social relationship, conventionally defined, between the speaker and the person spoken to. For example, "Where^{2} is^{3} the post office^{1}?" is [uch'egugi^{1} ŏdi^{2} issŭ*mnikka*^{3}?] when spoken to a senior or a stranger, [uch'egugi ŏdi iss*ŏ*?] when asked of a friend, and [uch'egugi ŏdi in*ni*?] when addressed to a child. The relationship between speaker and person spoken to is one of three dimensions of a highly developed system of honorifics (forms showing deference). A second dimension, occurring between the speaker and the person spoken about (*i.e.,* the subject of the verb or adjective), requires a stem marked by the element [(ŭ)si-] when speaking of a senior. Thus, [abŏjiga^{1} sanpporŭl^{2} ka*si*nda^{3}] "Father^{1} is going^{3} for a walk^{2}" contrasts with [ch'ŏlsuga sanpporŭl kanda] "Ch'ŏlsu (a boy's name) is going for a walk." The third dimension concerns the speaker in speaking of himself before a senior.

Pronouns, especially those for 2nd person ("you"), are used sparingly. The pronoun subject or object may be left out and understood from the linguistic or nonlinguistic context.

Modifying elements precede that which is modified. The most characteristic way to modify nouns is by the use of adnominal (attributive) forms of verbs and adjectives or of whole clauses; examples are [chohŭ*n*^{1} nalssi^{2}] "weather^{2} that is good^{1}," or, "nice^{1} weather^{2}"; [naega^{1} tanidŏ*n*^{2} hakkyo^{3}] "the school^{3} that I^{1} attended^{2}"; [ka*l*^{1} ttae^{2}] "time^{2} to go^{1}." Adnominal + noun constructions play a variety of important roles in Korean syntax; *e.g.,* in nominalization processes (processes by which nouns or nounlike expressions are formed from verbs or verbal expressions, such as English "unifying" from "unify").

In multiclause sentences the clauses are attached one to the other in linear fashion. The last clause in the sentence is the main clause, containing the verb or adjective with the sentence-conclusive ending. The conjunctive relation is expressed by the conjunctive ending on the main verb or adjective in the preceding clause; *e.g.,* [mari tomada chokkŭmssik tarŭ*jiman*^{1} hakkyoesŏnŭn p'yojunmarŭl karŭch'inda^{2}] "Speech varies a bit from province to province, *but*^{1} in the schools they teach the standard language^{2}."

Vocabulary. Among the Sino-Korean words, which make up more than half of the vocabulary, there are many ordinary as well as learned words. Sino-Korean elements and now also Sino-Japanese ones are the primary resources for new technical terminology. Most Sino-Korean elements are used as nouns or nounlike units in Korean, regardless of their original part of speech. They can be made into verbs or adjectives by adding certain stems that mean "to do," "to be," "to become." This device is also used to form verbs and adjectives from native Korean nouns. (F.L.)

JAPANESE LANGUAGE

Japanese is the language of more than 121,044,000 persons on the islands of Japan, including the Ryukyus. In addition, there are more than 558,000 Koreans and about 44,000 Chinese in Japan who speak the language. Outside Japan a considerable number of people of Japanese parentage can speak the Japanese language with some degree of proficiency; these include 701,000 persons in the United States, 550,000 in Brazil, 60,000 in Peru, and 47,000 in Canada. In Korea and Taiwan the older generations speak Japanese as a second language.

For centuries there have been many dialects in Japan differing from each other to such an extent that some of them are mutually unintelligible. Since the Meiji Restoration, which ended with the promulgation of the Japanese constitution in 1889, the rapid development of elementary education has eliminated illiteracy in the country, and a common written language has been established, based on the dialect of the residential sections of Tokyo. At present, people of the various parts of Japan can speak the common language, although with their own accents, in addition to their own dialects. Since World War II, a common spoken language based on the same dialect of Tokyo has been exerting more and more influence upon the speech of the younger generation all over Japan via radio and especially via television; as a result, the local dialects are disappearing more rapidly than before.

The genetic relationship of Japanese to other languages has not been linguistically established. It is, however, probably related to Korean and possibly to the Altaic languages, which include the Manchu-Tungus, Mongolian, and Turkic families; all have similarities in their phonological and grammatical structures. Some lexical (vocabulary) and other resemblances, however, have been pointed out between Japanese and other East Asian languages and language families—*e.g.,* Austronesian (Malayo-Polynesian), Austroasiatic, Tibeto-Burmese, and Ainu.

Two major dialect groups

Dialects. Japanese can be divided into two major dialect groups: those of the mainland and those of the Ryukyu Islands. The mainland dialects are divided by some scholars into three groups—Eastern, Western, and Kyushu. In other systems, however, they are classified into the Eastern division and the Western division, which is then split into the Kansai (including the Chūgoku and Shikoku dialects) and the Kyūshū dialects. The Tokyo dialect belongs to the Eastern group, Westernized during the last two or three centuries; except for the accent and other features, it is not very different from that of Kyōto, a Kansai dialect, which was the most influential central dialect for more than 1,000 years. The peripheral dialects (*e.g.,* the dialects of remote areas—north Tōhoku and Kagoshima of south Kyūshū—as well as the Ryukyuan dialects) are very different from those of Tokyo and Kyōto and are incomprehensible in those cities.

There is evidence that there may have been a language spoken by the people of the Yayoi culture in north Kyūshū about 2,000 years ago that became the Proto-Japanese tongue—*i.e.,* the ancestor of all the present-day Japanese dialects. The Yayoi culture with its rice cultivation was brought from the Asian continent to Japan. If it is assumed that the people of this culture also brought the Proto-Japanese language, then it must also be assumed that the language of the remainder (if any) of the Proto-Japanese-speaking people on the Asian continent was extinguished by another language or languages; because there is no evidence of a language on the continent that is not only similar to Japanese but also differs from it enough to reflect the 2,000 years of separation.

A more probable hypothesis is that the Japanese language became separated from Korean 5,000 or more years ago and was spoken in Japan thousands of years before the Christian Era. In that case, Proto-Japanese was probably only one of the Japanese dialects spoken contemporaneously in most of Japan, including Kansai and the area east of it. The Yayoi culture is known to have diffused rapidly eastward from north Kyushu and apparently later stimulated the development of the Tumulus culture in Kinai (*i.e.,* the "Home Provinces," including Yamato, one of the centres of which was the city of Nara). The dialects that were contemporary with and different from Proto-Japanese must have been absorbed during the subsequent 2,000 years by the dialects that branched out from Proto-Japanese.

In the 8th century, however, people noticed that the Eastern dialects were remarkably different from those around Nara (and perhaps also from the Western dialects); some of their peculiarities were recorded. These peculiarities may have been non-Proto-Japanese features, which at that time were still resisting the influence of the central dialects but which have disappeared from the present-day Eastern dialects except for the dialect of a remote island, Hachijō-jima (about 300 kilometres south of Tokyo), that preserves some of the old peculiarities.

The differentiation of social dialects has been slight, but some peculiarities of the speech of the former samurai have been reported in several cities.

Phonological characteristics. Japanese is a polysyllabic language. Simple (*i.e.,* not compound) nouns consist of one or, more often, two or three syllables, to which various particles of one or more syllables are often suffixed. Various "inflectional forms" of simple verbs and adjectives usually consist of two or more syllables and some have various endings or particles or both suffixed as well. ("Inflectional forms" in Japanese are such forms [stems] as negative, preterite, conditional, imperative, and so forth.) The structure of the syllable is rather simple; syllables are ordinarily open (*i.e.,* they consist of one consonant and one vowel that is either short or long, with or without an intervening *y* after the consonant). The syllable can, however, be closed with a nasal sound (indicated by linguists with the symbol /N/) or a checked sound (conventionally symbolized as /Q/), which then acquire similar phonetic characteristics or become identical to the sound that follows. For example, /N/ becomes *m* before *p, b, m; n* before *t, d, n; ng* before *k, g, ng;* nasalized ĩ before *y;* nasalized ũ before *w;* and so forth. /Q/ is always followed by a consonant and is changed to an implosive *p, t, k, s,* etc., which forms a geminate sound (*i.e.,* a double consonant like the *t*'s in English "cattail") with the following explosive consonant. There are five vowels, *a, i, u, e, o,* similar to those of Italian. Short vowels are pronounced very short; the short *i* and *u* between voiceless sounds are devoiced (pronounced without vibrating vocal cords—voiceless) or omitted in the Tokyo speech. This tendency, remarkable in Tokyo, is less prevalent in some Western dialects.

Structures of the syllable

Japanese has the following consonants: *p, t, k, b, d, g, ts* (*ch*), *s* (*sh*), *z* (*j*), *m, n, r, h, y, w.* Basically, any vowel or *ya, yu, yo* can follow any of the above consonants. But there are restrictions to this rule that include several unacceptable combinations of sounds, among them *ti, tu, di, du, si, zi, wi, we,* and others. *Chi, tsu, ji, zu, shi, ji, i, e,* etc., occur in place of them, respectively. In pronunciation, the Japanese *p, t,* and *k* are not as aspirated as the initial *p, t,* and *k* of English (*i.e.,* they are not pronounced with a strong accompanying puff of breath). *B, d,* and *g* are fully voiced (pronounced with vibration of the vocal cords) as in French; *g* between vowels is usually a nasal *ng* (as in English "sing") in many Kinki (central) and Eastern dialects. Unlike the English sounds (which are formed with the tongue touching the gum ridge behind the upper teeth), *t, d,* and *n* are articulated against the teeth; *ch, sh,* and *j* are pronounced with the front of the tongue, not with the tip of the tongue as in English; initial *z* is pronounced like *dz* in English "adz" in Tokyo; and *r* is a flapped sound like the American *t* sound in "city."

Pitch accent

The majority of dialects, including those of Tokyo and Kyōto, have a word pitch accent. In Tokyo, for example, *hashi* with a high-low accent means "chopsticks," but with a low–high accent pattern it denotes "bridge"; in Kyōto, on the other hand, *hashi* means "edge, end" with high–high accent, "bridge" with high–low, and "chopsticks" with low–high. There are various patterns of pitch accent, and their geographical distributions are very complicated. The dialects of Tokyo and Hiroshima and those of Kyōto and Ōsaka have patterns quite different from each other. Some dialects in Tōhoku and Kyūshū, among others, have no pitch contrast at all.

It is a common feature of all the dialects, however, that they have no word stress accent (as occurs in English—*e.g.,* hăppy, fŏreigner, charactĕrístics). The sound of Japanese gives a very different impression from that of English, and it is said to be spoken with even stress and rhythm, as if a metronome were very rapidly ticking off each syllable.

Grammatical characteristics. Nouns have neither number (singular and plural) nor gender (masculine and feminine) and take no article (such as "the," "a," "an"). Case distinctions that show such grammatical features as subject and object are expressed with particles added to the ends of words; for example, *kodomo-ga* "a (the) child (children) [usually nominative]," *kodomo-no* "of a child," *kodomo-o* "a child [accusative]," *kodomo-ni* "to a child," *kodomo-kara* "from a child." Verbs have no person, no number, and no gender and are conjugated with the use of endings—*e.g., kaku* "write, writes, will write," *kakanai* "do (does, will) not write," *kake* "write [imperative]," *kakō* "I'll write, let's write," *kaite* "having written, writing," *kaita* "wrote, has (have) written," *kakeba* "if . . . write (writes)." Adjectives, which have no number, gender, or case, are also "conjugated" with suffixes—*e.g., shiroi* "is (are, am) white," *shiroku-nai* "is not white," *shiroku-te* "is white, and . . . ," *shirokatta* "was (were) white."

There are no relative pronouns. Demonstrative pronouns have a three-way distinction rather than the two-way division of English "this" versus "that"—*e.g., kore* "this," *sore* "that around you," and *are* "that far from both of us." Personal pronouns have a complex and intricate system: for the 1st person singular (English "I, me, my"), for example, there are *watakushi, watashi, washi, atakushi, atashi, temae, boku, ore,* and others; and for the 2nd person singular (English "you, your") there are *anatasama, anata, anta, kimi, omae, kisama, temé,* and others. The use of these forms depends on such factors as the social relationship of the addresser and the addressee(s) and the degree of intimacy between them, the formality of the speech, and the sex and age of the speaker. Verbs and adjectives also have conjugated forms corresponding to some of these distinctions. For example, *kakimasu, kakimasen, kakimashita* are used instead of *kaku, kakanai, kaita,* respectively, when the utterance is addressed to those who are superior or not intimate to the addresser. On the other hand, if the person who is the performer of the action *kaku* ("to write") is a superior to the speaker, then *oka-ki-ni naru* and *okaki-ni narimasu* are used instead of *kaku* and *kakimasu,* respectively. If the action is done for a superior, then *okaki suru* and *okaki shimasu* are used instead.

Order of words in sentences

The predicate stands at the end of a sentence. The subject, the object, adverb, adverbial phrase, and other elements of the sentence precede the predicate and can be omitted when possible. For instance, *Kaita,* which is a sentence consisting only of a predicate, can be translated as "I (he, they, etc.) wrote (have, has written) it," according to the context or the situation. The complement precedes the copula (a linking verb such as English "is"); *e.g., gakusei-da* "I (he, they, etc.) am (is, are) a student (students)" is composed of the complement *gakusei* "student" and the copula *da* "am, is, are." Sentences of the structure A-*wa* B-*da* (*wa* means "as for") have various structural meanings—*e.g., Are-wa daigaku-da* "That is a university" (*daigaku* = "university"), *Watashi-wa daigakuda* "I am for (from, in, etc.) the university," *Gakusei-wa gakusei-da* "A student is nothing but a student." The expressions that modify a noun directly precede it; *e.g., chiisana hitsuji* "a small sheep," *ōkina ōkami* "a large wolf,"

ōkami-no	*kutta*	*hitsuji* "the sheep that a wolf ate,"
wolf-[genitive]	ate	sheep

hitsuji-o	*kutta*	*ōkami* "the wolf that ate the sheep."
sheep-[accusative]	ate	wolf

Vocabulary. Although the greater proportion of the basic Japanese words are native words, a large percentage of the whole vocabulary is composed of Chinese loan elements—comparable to the loanwords from Greek, Latin, and French in English. In early times Japanese apparently borrowed a number of cultural words from Korean, but from the 6th century through the 9th century the direct contact with Chinese culture had a much greater influence on Japanese; the phonology, grammar, and basic vocabulary, however, were not as strongly affected. During those centuries several Sanskrit words entered into Japanese through Chinese in connection with Buddhism—*e.g., danna* "patron, master" (from *dannapati*), *hachi* "bowl" (from *pātra*), *kawara* "tile" (from *kapāla*). Later, in the 12th and 13th centuries, Zen priests introduced several words from Middle Chinese, such as *manjū* "bean-jam bun," *yōkan* "sweet paste," *udon* "noodle,"

*H = *hiragana*; K = *katakana*; E = equivalent. Some *kana* undergo a change in pronunciation in specific situations.

†*Tsu* is also used to indicate a doubled consonant. In such cases the *tsu kana* is written slightly below the line (in horizontal texts) or slightly to the right of the line (in vertical texts) and sometimes also in slightly smaller script. Other *kana* are also positioned in this manner when they serve special functions.

‡Romanized *m* before *b*, *p*, and *m*.

§All five vowels have long forms, which in a Japanese text can be indicated in one of several ways. Romanized long vowels are indicated by macrons, except *i*, which is written *ii*.

isu "chair," and *futon* "bedding." Around the end of the 16th century, Japanese borrowed several words from Portuguese, like *pan* "bread," *kasutera* "sponge cake," *rasha* "woollen cloth," and *karuta* "cards." During the 18th and 19th centuries the language acquired several words from Dutch—*e.g., buriki* "tinplate," *garasu* "glass pane," *rappa* "trumpet," and *zukku* "duck, canvas."

A large part of the Chinese loanwords in contemporary Japanese are compound terms or derivative words coined in Japan since the Meiji Era; these combine two or more Chinese morphemes (word elements) that were borrowed in ancient times. *Kisha* "train," for example, is a Japanese compound of this kind that consists of *ki* "steam" and *sha* "car"; the Chinese equivalent, *ch'i ch'e,* means "automobile." The newly coined Japanese compound *jidōsha* "automobile" consists of three Chinese loan elements—*ji* "self," *dō* "to move," and *sha* "car"—but Chinese has no corresponding compound such as *tzu tung ch'e.* Some of these new Japanese compounds have been borrowed back into Chinese through the medium of Chinese characters.

Influence of Chinese characters on word formation

The Chinese characters play a very peculiar but important role in the word formation of written Japanese, which naturally has an influence on the spoken language. Every character usually has two readings: the *kun,* which is an indigenous Japanese word, and the *on,* which is an old Chinese loan morpheme. These two readings are closely associated with each other and alternate freely in word formation. For instance, *Keiō Daigaku* "Keio University" is abbreviated to *Kei-dai,* using the original *on* reading; whereas *Waseda Daigaku* "Waseda University" becomes *Sō-dai,* formed from the *on* reading for the indigenous Japanese word *wase* in *Waseda. Wase,* which means "early-ripening variety of rice," is shown by a combination of two Chinese characters meaning "early" and "rice," respectively. The *on* reading of the character meaning "early" is *sō,* hence *Sō-dai.*

In the vocabulary of contemporary Japanese, all the words beginning with *p-* are either onomatopoetic or recent loanwords from European languages—*e.g., pan* "bread" (from Portuguese), *pen* "pen" (from English) —because the initial *p-* of Old Japanese has changed into *h-* in Modern Japanese. In addition, there are very few indigenous words ending in a nasal sound. Such phonological peculiarities are now utilized by pharmaceutical and other companies, who coin for their new products names containing a *p* or a nasal sound so that they sound like something modern or imported. Especially since World War II, commercialism has deluged the language with English and other European words, many of which are short-lived. In general, however, almost all the foreign words have been adapted to Japanese sound patterns (*e.g., baiorin* "violin," *bisuketto* "biscuit," *rejā* "leisure"), and only a few have brought new sound combinations such as *ti, di* (*e.g., pātī* "party," *birudingu* "building").

Early records of Japanese

History. There is no evidence that the Japanese had their own script before they adopted the *kanji* (Chinese characters) early in the Christian Era. The earliest records of Japanese consist of several words found in a Chinese book of history, the *Wei Chih,* of the late 3rd century. A few words written with *kanji* are found on the swords and the mirrors of the 5th and 6th centuries, but the earliest extant Japanese documents of any length are the *Kojiki* (712) and the *Manyōshū* (later than 771) of the Nara period. From the 9th century on, records, mainly of the Kyōto dialect and the common written language, abound. The history of the language is usually divided into Old Japanese (to the 8th century), Late Old Japanese (9th–11th centuries), Middle Japanese (12th–16th centuries), and Modern Japanese (from the 17th century). Old Japanese was considerably different from Modern Japanese in phonology, morphology, and vocabulary, but not so much in syntax (the arrangement of words and word elements in sentences).

From Old Japanese to Modern Japanese there have been numerous sound changes, among them the shift of initial *p-* to *h-* in most of the modern dialects and the loss of three vowels, usually represented as *ï, ë,* and *ö.* Some remnant of vowel harmony was seen in Old Japanese. In vowel harmony certain vowels are restricted by the language structure from occurring in successive syllables of a word. Thus, in one word root or stem *ö* never co-occurred with *o,* and rarely with *u* and *a; e.g.,* the *-kö* ending in *kökö* "here," *sökö* "there" appears as *-ku* and *-ko* in *iduku* "where" and *miyako* "metropolis (*miya* "palace"). These words have become *koko, soko, doko, miyako* in Modern Japanese.

In Old Japanese and Late Old Japanese there was a distinction between "finite" forms (which occur at the end of a sentence as the predicate) and noun-modifying forms of verbs and adjectives—*e.g.,* the finite forms *uku* "receive(s)," *oku* "get(s) up," *shiroshi* "is white" differ from the corresponding noun-modifying forms *ukuru, okuru, shiroki* (later *shiroi*). In Middle Japanese the latter began to replace the finite forms (*uku, oku, shiroshi*), which ultimately disappeared from the spoken language. In Old Japanese and Late Old Japanese there was a rule of peculiar syntactic agreement: when the predicate verb or adjective was preceded by a word suffixed with such a particle as *zo* (emphatic), *ka* (interrogative), and so forth, the sentence was finished with the noun-modifying form instead of the finite form. This syntactic restriction disappeared, however, as the result of the above-mentioned change in syntax. Later, on the analogy of the forms such as *ukete* "having received" and *okite* "having got up," *ukuru* and *okuru* changed into the present forms—*ukeru* "to receive," *okiru* "to get up."

Kanji and *kana*

Writing systems. During the several centuries after the adoption of the *kanji,* the Japanese apparently used classical written Chinese as their formal written language. As they became accustomed to the characters, however, they tried to write Japanese with them, and in the process the *on* and *kun* of every *kanji* became established. Each *kanji* represents a Chinese word or morpheme, which has its own sound and meaning. The *on* is a Japanese imitation of the Chinese sound; *e.g.,* the 8th-century Chinese forms *pat* "eight" and *tap* "answer" became Japanese *pati* and *tafu,* respectively. The *kun* of a *kanji* is an indigenous Japanese word with a meaning similar to that of the Chinese; it is this reading that the Japanese are accustomed to give the *kanji.* Because the Chinese word *pat* means "eight," the *kun* reading of the *kanji* for this word is *ya,* which is a Japanese term for eight. The *kanji* for the Chinese word *pa* "wave" was read by the Japanese either as *pa* (an *on*) or as *nami* (a *kun*). When a *kanji* is used to represent a Japanese syllable by means of its *on* or *kun* without reference to its meaning, it becomes a kana, a phonogram. For instance, when the *kanji* for the Chinese word *pa* "wave" is used for the sound *pa* in such Japanese words as *pana* "flower" and *payashi* "fast," it becomes a *kana.* As early as the 6th century, there are examples of *kanji* used as *kana.* Although the *Kojiki* and the *Manyōshū* of the 8th century are written exclusively in *kanji,* the language represented is Japanese, not Chinese. The *Kojiki,* however, uses more *kun* readings, mixing them with *kanji* used according to the Chinese syntax, while the *Manyōshū* uses many more *kana.* This is why *kanji* used as *kana* are called *manyōgana* (*kana* often becomes *gana* in compounds).

As it was a toilsome task to write Japanese with the *kanji* (which are squarish and complicated in shape), the Japanese began to write them in such a cursive and simplified way of their own that the symbols retained little or no vestige of their original shape. The resulting syllabic characters, called *hiragana,* "common *kana*" (but known as *onna-de* "letters for women" in the Heian period), began to appear in the 9th century. These simplified characters were used extensively by women, who wrote many poems, diaries, and novels during that period. There is, however, evidence that men also learned and used the script, although they wrote their diaries in *kanji.* Parallel with this script another system of syllabic writing developed in the 9th century; it was called *katakana* (*kata* "one side, one of a pair"). When the priests of the temples in Nara read Chinese texts, especially Buddhist scriptures, they would translate into Japanese as they went along, and would jot down beside the *kanji* for their own memory the Japanese particles, endings, and so forth that were lacking in Chinese. This was done with symbols made for private use, The growing popularity of hiragana

mainly symbols formed by abbreviating the strokes of the *kanji.* Originally every sect, and sometimes every person, had a special system, so that there were various symbols for one and the same syllable. In the 10th century, however, more common features began to appear, indicating that the symbols were becoming more common and popular in use. In this way Japanese began to be written with *kanji* and *katakana* intermixed and sometimes only with *katakana.* In the 15th century, however, the *hiragana* symbols, which were cursive and fine in shape, became the more popular script; literary works were written in *hiragana,* while scholarly or practical books were written in *katakana.* Even some literary works written with *kanji* and *katakana* in earlier days were rewritten with *kanji* and *hiragana.* The present orthography is in *kanji* and *hiragana,* and only European loanwords and onomatopoetic words are written with *katakana.* Only *katakana,* however, is used in telegrams and in notes typed or printed with machines in companies and offices.

Orthographic reform

In the beginning of the Meiji Era, the grammar of the language written with *kanji* and *kana* still was archaic, based mainly on that of Old Japanese and early Late Old Japanese. Toward the end of the 1880s, however, famous writers such as Futabatei Shimei, Yamada Bimyō, and Ozaki Kōyō began a successful movement to write in the colloquial style. The orthography, with its thousands of *kanji* symbols, was difficult to learn and to use. Therefore, after World War II, the government carried out a series of reforms that had been advocated for many years. The *kana* spelling, based on the sounds of early Late Old Japanese, was changed to conform to the contemporary pronunciation; and the *kanji* characters, which had been used without restriction, were limited to 1,850 symbols for official and daily use, and their shapes and strokes were greatly simplified.

There also have been a number of advocates of romanization since the Meiji Era, but such a program presents many difficulties. Old Japanese syllables had a much simpler structure than those of the contemporary Chinese, which is a monosyllabic language without word endings. Therefore, many different Chinese words or morphemes became homophones (words pronounced alike) in Japanese as early as the 8th and 9th centuries; *e.g.,* the Japanese imitated the Chinese *k, k', x* (and *g,* γ) sounds with only a single *k* sound. Moreover, sound changes in Japanese during the succeeding 12 centuries produced a great number of homophones; for example, the sound sequences *au* (from Chinese *au* and *ang*), *afu, ou,* and *ofu* that were distinct from each other in Old Japanese and early Late Old Japanese have all become the same *ō* today. Accordingly, Japanese now has a great many homophonous *kanji*, so that the Chinese loan morphemes that clearly convey certain meanings when written with *kanji* would very often become incomprehensible when romanized. Moreover, *kanji* have more characteristic configurations than would the same words written with roman letters, and thus enable rapid reading. In addition, a high literacy rate prevails throughout the entire Japanese nation, and the people are presumed to be so accustomed to the *kanji* and *kana* that such a great change in writing as romanization would undoubtably encounter very strong resistance. (S.Ha.)

AUSTRONESIAN LANGUAGES

The Austronesian language family, also called Malayo-Polynesian, consists of languages spoken in almost the whole of Malaysia and the Indonesian Archipelago, all of the Philippines, parts of Vietnam, Kampuchea (Cambodia), and Taiwan (Formosa), Madagascar, and on all of the main island groups of the South and Central Pacific (except for Australia and a large part of New Guinea, which contain languages belonging to other stocks). In terms of the number of its languages and of their geographic spread, the Austronesian language family is among the world's largest.

Austronesian languages are generally divided into two primary subgroups: a Western, or Indonesian, branch contains perhaps 200 languages, including such well-known tongues as Malay, Indonesian, Javanese, and Pilipino, the national language of the Philippines (based on Tagalog); and an Eastern branch, more commonly termed Oceanic, comprises about 300 small languages, scattered throughout the South and Central Pacific, the best known of which are the Polynesian group and Fijian. The classification of a small residue of languages is uncertain. While around 170,000,000 people speak languages belonging to the Western Austronesian branch, only about 1,000,000 speak Oceanic languages.

The challenge of piecing together the complex history of a family of languages with such an enormous distribution, and with speakers of such great cultural and physical diversity, has attracted scholars to the study of Austronesian languages. Recently, the Austronesian languages have also received attention because of their structural characteristics and, in addition, have served as a testing ground for subgrouping methods and theories of linguistic change.

HISTORY AND CLASSIFICATION

Eastern and Western Austronesian groups

Resemblances between the languages of Madagascar, the East Indies, and Polynesia were first pointed out in 1706 by Hadrian Reland, a Dutch scholar. It was not until the second half of the 19th century, however, that the languages of the intervening island groups of Melanesia and Micronesia were recognized as belonging to the same family. At that point it became customary to divide Austronesian languages into four groups coinciding with the geographic regions known as Indonesia, Melanesia, Micronesia, and Polynesia. More recently, it has become clear that such a classification is not linguistically valid. Though arguments continue over the position of certain languages, it is generally agreed that most Austronesian languages fall into only two groups. The majority of the languages formerly assigned to the Melanesian and Micronesian divisions, together with the Polynesian group, form a single, although internally very diverse, subgroup: Eastern Austronesian (more often called Oceanic). The Western division coincides fairly closely with the old Indonesian grouping, comprising most, and possibly all, Austronesian languages spoken west of New Guinea, together with two found in Micronesia.

The main areas of disagreement in classification concern the position of the Formosan languages, of certain languages located in eastern Indonesia and on or near the western tip of New Guinea, and of the more divergent languages in Melanesia. The Formosan languages are usually treated as Western Austronesian, though some scholars have suggested that they represent a third primary branch of Austronesian. The languages of east Indonesia, including the western end of New Guinea, more diverse than those of west Indonesia and the Philippines, are sometimes treated as a single subgroup of Western Austronesian, and sometimes regarded as composed of a number of primary branches, each coordinate with Oceanic and with a group comprising the remaining members of Western Austronesian. Similarly troublesome are a number of languages of the north coast of New Guinea and certain regions of insular Melanesia. These languages share very few related words with each other and with other languages in the family, although in grammar they usually show quite strong resemblances to members of the Oceanic subgroup. They are generally regarded as aberrant Oceanic languages, but other theories have been advanced to explain their divergent character.

Proto-Austronesian. A protolanguage is a parent language, or early form of a language or group of languages. It can either be a hypothetical reconstruction or may actually exist in written records, as does Latin, the protolanguage of the Romance tongues. There are no actual records of Proto-Austronesian, but it has been the subject of research and reconstruction by linguists. Because it is

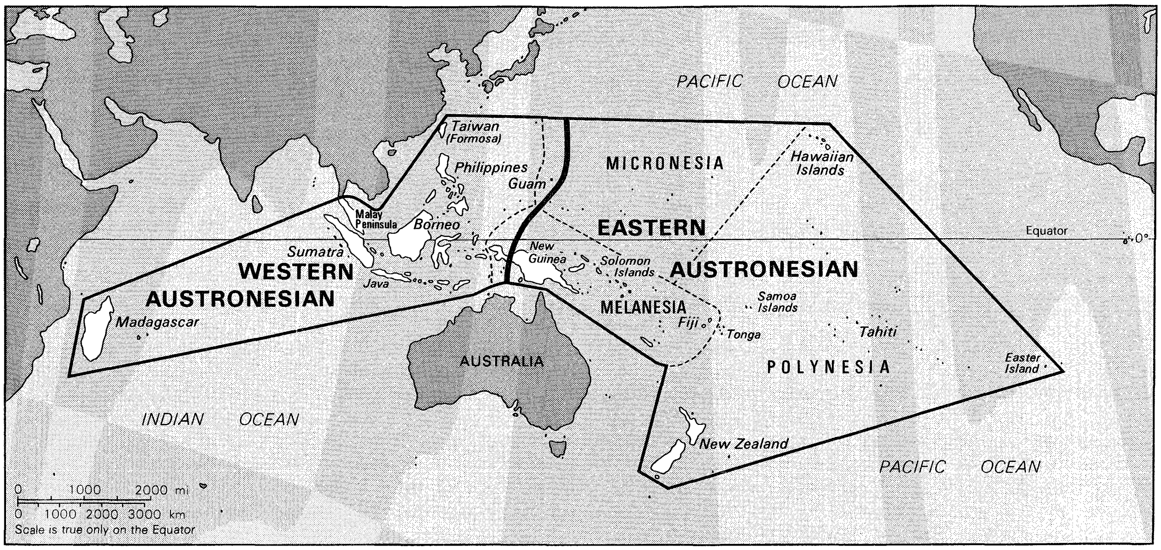

Figure 28: Major divisions of the Austronesian languages.

clear that the Proto-Austronesian speech community possessed agriculture and may have been responsible for its introduction—along with that of several other important cultural innovations—into the Pacific, the reconstruction of Proto-Austronesian and the history of the dispersal of Austronesian languages has been of considerable concern to culture historians as well as linguists.

Location. The location of Proto-Austronesian has been the subject of much speculation but little systematic investigation. At various times in the past the parent tongue has been placed somewhere in the Southeast Asian mainland, South China, and even in India and Mesopotamia. There is increasing evidence of an archaeological, geographic, and linguistic nature, however, that the homeland lay in the region of Indonesia and New Guinea.

Chronology. The best evidence for dating and determining the directions of the dispersal of Austronesian languages comes from Oceania, where it is easier to correlate linguistic and archaeological findings than in the west. It is clear that Austronesian languages were already in Fiji and Tonga, near the eastern margin of Austronesian territory, by 1000 BC. Archaeological excavations indicate that the coastal area of Fiji was widely settled by that date, that by then Tonga also had been settled by a people with a material culture essentially identical to that of the first inhabitants of Fiji, and that Samoa was inhabited a few centuries later. In each place there is continuity of material culture—and, one may assume, continuity of language—right through to the period of European contact. The first Europeans found Fiji and Polynesia (and indeed the whole of the neighbouring island groups—the New Hebrides, New Caledonia, and Micronesia) to be occupied exclusively by Austronesian-speaking peoples. Glottochronology, a technique for dating the division between languages (known as linguistic splits) based on the assumption that there is a stable rate of basic vocabulary replacement in languages, places the separation of the Fijian and Polynesian subgroups at between 3,000 and 4,000 years ago. The divergence of Proto-Polynesian into separate branches is dated at between 1,800 and 2,500 years ago.

These are relatively recent branchings, far down on the Oceanic limb of the Austronesian family tree, and it follows that the separation of the common ancestor of Fijian and Polynesian from more distant branches of Oceanic must have occurred somewhat earlier. Glottochronological estimates indicate that diversification of Austronesian languages began around 4,000 to 5,000 years ago in the New Hebrides, in New Caledonia, and in the Solomons, and earlier still in the region of New Guinea. Very little archaeological work has been done in these areas, but assemblages of artifacts similar to those found in early Fijian and Tongan sites have been unearthed in New Caledonia and the central New Hebrides and dated at 800 BC and 600 BC respectively. The general trend, at least, is clear. The dispersal of Austronesian languages in Oceania cannot have begun later than around 2000 BC, with 3000 BC appearing to be a more realistic estimate.

Glottochronological computations suggest that the differentiation of the Western Austronesian languages was well advanced by 1000 BC.

Relationships to other families. Many different proposals have been made to link Austronesian with other language groups—Mon-Khmer, Munda, and Vietnamese of the Austroasiatic language family, Tai-Kadai, Sino-Tibetan, and Indo-European, among others. None has been convincing. Ultimately, no doubt, Austronesian languages, like every other family in Oceania, must derive from ancestral stages spoken in Asia at some remote period. Discovery of such distant connections, however, will have little bearing on the question of where the ancestral Austronesian language itself developed.

Reconstructions of Otto Dempwolff

Reconstruction. Many scholars have worked to reconstruct the Proto-Austronesian sound system and word stock. The reconstructions of Otto Dempwolff, a German ethnologist and linguist, published between 1920 and 1938, have remained the point of departure for all subsequent comparative studies. Dempwolff attributed to Proto-Austronesian a four-vowel system, consisting of a low vowel *a* and three higher vowels—*i* (front), *e* (central), and *u* (back). The reconstructed consonants are the voiced stops *b, d, D, j, g* (a stop is a sound made with complete stoppage of the breath from the lungs); the matching voiceless stops *p, t, T, c, k* and the glottal stop *q;* the nasal consonants *m, n, ñ,* ŋ (nasals are pronounced with the breath going through the nose); the semivowels *w* and *y;* plus *l, r, R, h, s, z,* and *Z.* (Phonetic value of phonemes represented by capital letters, and that of certain other reconstructed symbols, cannot be precisely determined.) Most word bases consisted of two syllables, the commonest shape being consonant-vowel-consonant-vowel-consonant or consonant-vowel-consonant-consonant-vowel-consonant. Clusters of consonants were restricted to a few types and occurred only in the middle of words and possibly in initial position. Words with initial vowels or final vowels or both were probably more common than Dempwolff's reconstructions allow.

Although some languages, particularly certain members of the Oceanic group, have changed this sound system drastically, it is still reflected fairly faithfully by many Western Austronesian languages. Indeed, in both Western Austronesian and Oceanic languages, many words seem to have persisted in almost unchanged form, a condition unparalleled in the Indo-European languages, for example. Table 53 compares the forms of some Proto-Austronesian words with the cognate terms in four modern languages.

Systematic reconstruction of Proto-Austronesian grammar has scarcely begun. Structural features retained by a majority of languages in both major branches include a

fairly constant form for each grammatical and vocabulary element, with boundaries between elements in words being clearly definable, and a relatively simple morphology of verbs and nouns. In addition, in the verb phrase, a number of elements indicating tense, aspect, and voice are present; they were evidently prefixes and infixes (particles inserted within the body of a word) in Proto-Austronesian. Reduplication, the repetition of a word or a portion thereof, occurs in the case of the verb root and has several functions. Most roots are capable of being used either as nouns or verbs. Adjectives, numerals, and markers indicating negatives can act as verbs. Noun subclasses include personal names, marked by a personal article; common nouns, marked by a common article; locatives, place names, and directionals, marked by a locative particle; and temporals, which are not marked. Personal pronouns include distinct forms for 1st person including the hearer and 1st person excluding the hearer; pronouns marking subject or possessor differ in form from those marking object or focus.

Current research. Since World War II the descriptive and comparative study of Austronesian languages has expanded considerably, with centres at universities in the Philippines, Indonesia, Australia, New Zealand, the United States, and Europe. Reasonably good dictionaries and grammars are now available for most of the better known Western Austronesian languages and many of the Polynesian languages. Several large areas remain poorly known, however, including most of Melanesia and much of Borneo and east Indonesia. A good deal of recent research has concentrated on classification and associated problems in the methodology of subgrouping and the theory of linguistic change. A major work has been a lexicostatistical classification of over 200 Austronesian languages prepared by the American linguist Isidore Dyen (1965).

Lexicostatistical classification

A lexicostatistical classification uses statistics to compare the vocabularies of two or more related languages; the method is similar to glottochronology (see above) but assumes a constant rate of change only within a given language family.

WESTERN AUSTRONESIAN (INDONESIAN)

The Austronesian languages lying west of New Guinea, together with the Chamorro and Palauan tongues of Micronesia, are often called Indonesian. The term is unfortunate in that it does not do justice to the wide geographic distribution of the languages concerned and can be confused with the name of Indonesia's national language. The commonly used alternative, Western Austronesian, is, therefore, employed here.

The classification of Western Austronesian languages is not completely agreed upon. There is, however, fairly general recognition of one very large grouping containing most of the languages of west Indonesia and of Malaysia, all the languages of the Philippines and Madagascar, some languages of the northern Celebes, and the Chamic group of Vietnam and Kampuchea. The name Hesperonesian has recently achieved some acceptance as a convenient label for this grouping. Disagreement centres around the place of the Austronesian languages of Taiwan and east Indonesia, including the western end of New Guinea. Many linguists regard these languages as being most closely related to Hesperonesian, and, in particular, treat the Formosan languages of Taiwan as a branch of Hesperonesian with closest relatives in the Philippines. In this view, the term Western Austronesian refers to a primary subgroup of Austronesian, contrasting with Oceanic, as indicated in the family tree in Table 54.

Other scholars regard the east Indonesian–west New Guinea languages as forming a number of primary subgroups, each coordinate with Hesperonesian and Oceanic. Similarly, a case recently has been made for treating the Atayalic group in Taiwan as a primary branch of Austronesian. The Atayalic languages share a very low percentage of basic vocabulary with all other members of the family, including other Formosan languages. There is, then, some support for an alternative family tree, with several primary branchings, representable roughly as in Table 55.

Branches of the Hesperonesian group

The Hesperonesian group is generally regarded as dividing into two main branches (see Table 54). One, Western Indonesian, includes the languages of Malaya, Sumatra, Java, Madura, Bali, and Lombok, south Borneo, Madagascar, and probably the Chamic group of Vietnam and Kampuchea. The other, Northern Indonesian, encompasses the Philippine languages, some of the languages of north Borneo and the northern Celebes, and possibly the Formosan languages.

Regional division of Western Austronesian languages. In the following sections, the main Western Austronesian languages are discussed in more detail under the appropriate regional headings.

Western Indonesia and Malaysia, Madagascar, Vietnam. The west Indonesian–Malaysian region includes the islands of Sumatra, Java, Madura, Bali, Lombok, and Borneo, and the Malay Peninsula. Except for a few Mon-Khmer languages in the interior of Malaya, its indigenous languages are all Austronesian. There have been important influences on the languages and cultures from mainland Asia, however, and, more recently, from Europe. Hindu culture reached Java and Sumatra in the 1st century AD, and from the 4th century diffused to Borneo and the Celebes. Many languages of western Indonesia contain extensive borrowings from Sanskrit. Islāmic influence began in the 7th century and spread over much of Indonesia and the Philippines. European colonization, beginning in the 16th century, added a third layer of borrowings to the Sanskrit and Arabic.

Malay in its several dialects is the native language of some 11,000,000 people occupying both sides of the Strait of Malacca. Its expansion throughout Malaya is apparently recent; until the 13th century it was confined to

Bahasa Indonesia

east and south Sumatra and the facing coastline of the Malay Peninsula. For some centuries prior to European contact, a simplified form of Malay, Bazaar Malay, had been the lingua franca in coastal regions of the whole Indonesian Archipelago. This status was attained because of the strategic position of Malacca on the trade routes and its function as a dispersal centre of Islām, and also because of the seafaring and trading skills of the Malay speakers. Malay was in turn adopted by the Dutch and British administrations as their lingua franca. In the present century, the language, now the national tongue of the Indonesian state, is called Bahasa Indonesia, or Indonesian. The choice of Malay as a politically acceptable national language was facilitated by the fact that it was the first tongue of only a small minority of Indonesians (in contrast to such languages as Javanese and Sundanese) but was, at the same time, widely used in Indonesia as a second language. The Indonesian variant of Malay has undergone spelling reforms, and a large new vocabulary has been coined to cover modern technical concepts. Many words have also been borrowed from European languages and Javanese.

Malay is closely related to most of the other languages of Sumatra, including Minangkabau, Kerintji (Kinchai), Rejang, and Achinese, and to Madurese of Madura Island. Other well-known Sumatran languages are Gayo and Toba-Batak, spoken in the north and somewhat less closely related to Malay. In all, Sumatra contains between 12 and 15 languages (the boundaries between dialects and languages not being clear-cut) spoken by more than 13,000,000 people. Engganese, used on a small island off southeast Sumatra, is an extremely divergent Indonesian language that shares only about 10 percent of basic vocabulary with the rest.

Styles, or registers, of Javanese

Java, the most populous island of Indonesia, is linguistically one of the most uniform, with only three indigenous languages. Javanese, with about 54,000,000 speakers, is numerically the largest Austronesian language after Indonesian (which is known by over 100,000,000 people, but mainly as a second language). Javanese dialects are spoken throughout central and east Java and in sections of western Java. Old Javanese is known from inscriptions dating back to the 9th century AD. The language was extensively influenced by Sanskrit between the 9th and 15th centuries, during the time of the Indianized kingdoms of east Java. Thoroughly documented by Dutch linguists in a series of grammars and dictionaries produced over the last 250 years, Javanese is now generally written in the roman (Latin) alphabet and continues to flourish alongside Indonesian as a literary language and as the daily medium of communication of many Javanese newspapers, magazines, and radio stations. Several registers, or styles, distinguishing degrees of respect and marked by vocabulary differences, have arisen out of the elaborate stratification of Javanese society.

Sundanese, with about 17,000,000 speakers, is found throughout west Java, with the exception of small islands of Javanese speakers along the north coast of Banten and in the region of Indramayu. The language has been written in various scripts since the 14th century, roman now being in general use. The dialect spoken around Bandung is considered to be the most prestigious, or the standard form. Madurese is the language of Madura Island and smaller offshore islands, but about half of its 8,700,000 speakers now reside in east Java. There are two principal variants of Madurese—Eastern and Western; an Eastern dialect, Sumenep, has been adopted for educational purposes as the standard dialect. Madurese shows greater similarities to the Malay–Sumatran group than to Javanese or Sundanese. Balinese, with about 2,600,000 speakers, is spoken on Bali and the western part of Lombok; Sasak is the language of eastern Lombok.

Linguistically the most diverse of the islands of the western Indonesian region, Borneo is also the least known. It is sparsely populated, and most coastal areas have been occupied in relatively recent times by speakers of Malay-type languages, such as Iban (Sea Dayak), Brunei Malay, Kutai Malay, Banjarese, and Sambas Malay, all of which are closely related dialects or languages. The most important Bornean language is Ngadju (Ngaju), spoken as the native language in southwest Borneo in the region of the Barito, Kapuas, Kahayan, Kaitingan, and Sampit (Mentaya) rivers; it is more widely used as the lingua franca of most of south Borneo. In northeast Borneo there are a number of languages with close relatives in the Philippines, including Illanum (Lanum), Bajau, Sulu, and the various Murut dialects. Maanyan and closely related languages spoken in south Borneo are apparently the closest relatives of the Malagasy dialects of Madagascar.

The Malagasy dialects

The Malagasy dialects probably derive from Bornean traders who journeyed to Indian, Arabian, and East African ports and settled the previously uninhabited island of Madagascar. A quite close correspondence in basic vocabulary (45 percent agreement) between Maanyan and Malagasy indicates separation around 2,000 years ago. The Malagasy dialects show sufficient internal diversity to justify classification into two or three different languages. The Merina dialect, now official in Madagascar, has around 8,800,000 speakers. A small group of Austronesian languages spoken in Vietnam and Kampuchea—the Chamic languages—probably falls into the Western Indonesian subgroup. Cham, with 76,000 speakers in Vietnam and until 1975 about 90,000 speakers in Kampuchea, has been the subject of several studies. Rade, Curu (Chru, Cru), and Jarai, spoken in Vietnam, may be closely related to Cham.

The Philippines and Taiwan. At least 70 languages are spoken in the Philippines in a land area a little larger than that of Great Britain. There are two main subgroups. A Central (Mesophilippine) division includes many of the languages of central and southern Luzon, Mindoro, Palawan, and the Visayan Islands. In the early 1980s Tagalog was the mother tongue of about 11,400,000 people in central and southwest Luzon, including the region of the capital city, Manila, and, parts of coastal Mindoro. A standardized form of Tagalog was selected as the national language after the Philippines gained independence in 1946. This language, officially called Pilipino, is now spoken as a first or second language by a considerable proportion of the 50,000,000 Filipinos. Although it faces competition from English and other important local languages, it is increasingly used in education and government and in the popular press, radio, and literature of the Philippines. Closely related to Tagalog are the Bikol or Bicol dialects (over 3,500,000 speakers in southeast Luzon and smaller adjacent islands). Also in the Central branch are Cebuano, or Sugbuhanon, with about 12,400,000 speakers, and Hiligaynon, or Ilongo, with more than 4,800,000 speakers, the two main members of the Bisayan subgroup. Spoken primarily in Cebu, Bohol, west Leyte, and the eastern third of Negros, Cebuano is used as a trade language throughout Mindanao. Hiligaynon is spoken in Panay and on smaller adjacent islands and in Negros. Pampangan (Kapampangan) is another important language, spoken in Luzon on the northwest flank of the Tagalog speech area.

Northern Philippine subgroup

The second major Philippine group, called Northern or Cordilleran, contains most of the languages of northern Luzon. Chief among them is Ilocano (Iloko), the lingua franca in northern Luzon, which has more than 5,400,000 speakers in much of northwest and northern Luzon. Other members of this branch include the languages of the Igorot mountain tribes, including Bontoc, Ifugao, and Tinggian, the Gaddang group, Isneg, Isinay, and Kalinga. Pangasinan, spoken by 1,100,000 in the province of the same name, probably belongs to the Northern subgroup.

A number of Philippine languages fall outside the two large subgroups. Maranao, Tiruray, Bilaan, and Tagabili are languages of important groups in the southern Philippines, while Luzon contains several unclassified tongues—Ilongot, Casiguran, and others. These languages share around 30 percent of basic vocabulary and many structural characteristics with other Philippine languages but are not closely related to any large subgroup. The Sulu Archipelago has Tau Sug and Samal; both are also spoken on Borneo, where Tau Sug is known as Sulu. The major Philippine languages—Tagalog, Cebuano, and Ilocano—have extensive literatures, and together with other important languages, are widely used in broadcasts and newspapers.

Prior to the arrival of the Chinese, Austronesian languages were probably spoken over most of Taiwan. The surviving languages are now confined to small communities in less accessible regions. The Formosan languages of Taiwan are internally fairly diverse, but there is some evidence for treating them as a single subgroup of Western Austronesian. The Atayalic or Northern group contains the Atayal dialects and Seedik. Although some central, eastern, and southern languages share less than 25 percent of basic vocabulary with each other, most of them are generally assigned to a single group (Central or East Formosan). Its members include Ami, Paiwan, Bunun, and Thao. Tsou, Saaroa, and Kanabu (central Taiwan), though they probably may form a third subgroup, are ordinarily treated as members of the Central division.

Two languages of Micronesia, Chamorro (Mariana Islands) and Palauan (Palau, western Carolines), are generally regarded as deriving from the Philippines or Indonesia.

Austronesian tongues in eastern Indonesia and west New Guinea

Celebes, eastern Indonesia, west New Guinea. Eastern Indonesia is centred in the Lesser Sunda Islands and the Moluccas. The large island of Celebes occupies a position intermediate between Borneo, the Philippines, and eastern Indonesia. Approximately 100 different Austronesian languages are spoken in eastern Indonesia, in places on the coast of west New Guinea, and on the Aru Islands south of the Doberai (Vogelkop) Peninsula, west New Guinea. Papuan languages are spoken in parts of Timor in the Lesser Sundas and Halmahera in the Moluccas.

Dutch and Indonesian linguists have long recognized that this region contains many disparate Austronesian groups but have generally assigned them to a relatively small number of divisions: Bima–Sumba, Ambon–Timor, Sula-Batjan, south Halmahera–west New Guinea, and several Celebes groups. Very thorough lexicostatistical comparisons provide little support for most of these larger groupings and indicate instead that east Indonesia–west New Guinea harbours many small, genetically diverse subgroups, most of which are members of or have their closest relationships with the Hesperonesian group and with each other, with a residue not at present assignable to any large subgroup of Austronesian.

The Celebes, with more than 40 languages, is the most diverse area. Buginese, with about 3,400,000 speakers, is the most important language of the group. Gorontalo and Suwawa, in the north Celebes, and Sangir (Sangihe [Sangir] Islands, north of the Celebes) show closer agreement with Philippine languages than with other Celebes tongues. Other numerically large speech communities in or near the Celebes are the Sidjai, Duri, and Mandar (Andian), Kendari, Muna (Muna Island), and Butung (Butung Island). Sikka of Flores Island and Solor of nearby Solor Island appear to be quite closely related to each other, with a 37 percent common basic vocabulary. Endeh of Flores is more distant. Havunese, spoken on Sawu and Raijua, between Flores and Timor, and Sumba (Sumba Island) appear to be fairly distant from all other eastern Indonesian languages. A large number of similar isolated languages exists on smaller islands in this region; one such small group includes Ambonese of Ambon Island and the adjacent coastal area of Seram. Buli and Minyafuin, of Halmahera, may belong to a group that also includes As, spoken on the western tip of New Guinea, and Biga, from Wakde Island in northwest New Guinea. The Bomberai Peninsula group in west New Guinea has close relatives on east Seram. Most of the Austronesian languages on the north coast of west New Guinea, as far east as Sorera Bay, however, show no close relationship to the Hesperonesian, eastern Indonesian, or Oceanic languages.

Great internal diversity of western Austronesian

Characteristics of Western Austronesian. The Western Austronesian languages are so diverse internally that little can be said about their common characteristics apart from what has already been said of Proto-Austronesian. Most of the members of this division maintain distinctions in the Proto-Austronesian sound system that are lost in Oceanic; *e.g.,* the distinction between **b* and **p.* (An asterisk indicates an unattested, hypothetical, reconstructed form.) The original verb morphology is also generally retained more completely than in the Oceanic division, but it is difficult to isolate common innovations that mark off Western Austronesian languages in the absence of detailed reconstructions of Proto-Austronesian grammar.

The Philippine languages, typologically the most uniform of the large subgroups of Western Austronesian have been the best described. No doubt owing to their long coexistence in a single region, as well as to their relatively close relationship, members of this subgroup of Hesperonesian are more alike in their sound systems (though not in vocabulary) than the languages of the West Indonesian subgroup. Consonants usually include three voiceless stops, *p, t, k,* and the glottal stop *q;* three voiced stops, *b, d,* and *g,* and the nasals *m, n,* and ŋ; plus *l, r, h, s, w,* and *y.* In many languages, borrowings from Spanish have resulted in the addition of two new vowels, *e* and *o,* to the original four (*a, i, u,* and ɨ or ə) retained from Proto-Austronesian. The morphology of the verb and, to a lesser extent, of the noun is fairly complex. The use of affixes and reduplication distinguishes several tenses (past, future, and present or general), various aspects (progressive, distributive, causative, etc.), and two modes (obligatory and indicative).

Philippine voice and case systems

The grammar of Philippine languages is most famous for its complex voice and case systems. (Voice, in grammar, indicates the relationship of the subject of the verb to the action that the verb expresses. A grammatical case is a form of a word that shows the relationship of the word to other words.) Besides distinguishing so-called active (*e.g.,* "John washed the dishes") and passive (*e.g.,* "The dishes were washed by John") constructions, Philippine languages possess at least three kinds of passive. The noun phrase occurring as "topic" or "focus" in the sentence can represent the actor (subjective or active constructions), the goal or object (goal or object-focus passives), the referent (benefactive or location-focus passives), or the instrument (instrumental-focus passives). The distinctions are expressed by three devices. One uses affixes to mark voice in the verb: subjective voice is usually indicated by an infix *-um-* and the prefixes *ma-, mag-, maka-* (the actual choice varies with the different verb classes); objective voice is shown by the suffix *-in* or *-en;* referential voice by *-an;* and instrumental voice by the prefix *i-.* The other methods of distinguishing passives include the marking of case with nominal (noun) particles and transposing phrases and changing stress. An example from Tagalog is: "The child bought the mango," *b-umili, ang bata, n-ang mangga; bili* is the verb "buy" with the subjective infix *-um-*, *bata* is "child," and *mangga* is "mango"; *ang* marks the focus common-noun phrase ("the child"), and *n-ang* indicates the nonfocus common-noun phrase ("the mango"). To say "The mango was bought by the child," the sentence construction is rearranged to *b-in-ili nang bata ang mangga,* which in actual Tagalog order is "buy-objective voice, the child, the mango." A number of other arrangements of the sentence elements are possible to cover the instrumental and referential voices.

Members of the Western Indonesian and Formosan groups share a great deal of morphological and syntactic structure with the Philippine languages, although they are typologically less homogeneous. Most of the Indonesian languages have developed more elaborate vowel systems than that of Proto-Austronesian, with five (Havunese), six (Malay, Balinese, Buginese), seven (Sundanese), eight (Javanese, in one analysis), or nine (Cham) contrasting vowels. Maanyan and the Malagasy dialects retain the four original vowels. Most Western Indonesian languages preserve the distinction between four voiced and four voiceless stops (the voiced *b, d, j, g,* and the voiceless *p, t, c, k*) and four nasals (*m, n, ñ,* ŋ), plus *l, r, w, y, s,* and *h.* Only Javanese, however, also distinguishes retroflex stops and alveolar stops (made with the tip of the tongue touching the ridge behind the upper teeth). This distinction seems likely to have arisen from the later influence of Sanskrit, which possessed retroflex consonants, on Javanese. As in all branches of Austronesian, most word bases may be used in the function of nouns or verbs. There are numerous transformative and formative affixes in Western Indonesian that derive adverbs, adjectives, nouns, comparative

Possible influence of Sanskrit on Javanese forms, ordinal forms, and various verb constructions, in addition to several kinds of verb reduplication; these features also appear in the Philippine languages.

The large Hesperonesian group, in general, appears to be the most conservative branch of Austronesian. A high proportion of the 2,207 words attributed to Proto-Austronesian, for example, are retained by Tagalog (1,125), Toba–Batak (1,299), Javanese (1,446), Malay (1,627), and Ngaju (1,170). Much lower proportions are present in Oceanic languages (Bauan Fijian 461, Tongan 328, Samoan 385).

Eastern Indonesian languages in general appear to be morphologically simpler than members of the Hesperonesian group, in which regard they resemble Oceanic languages. They have, however, retained several distinctions in sound that have been lost in the Oceanic group.

Although books and articles on Western Austronesian languages run into several thousands, documentation of the speech traditions of many of the smaller, minority communities is still poor, and many gaps remain in the understanding of the history of the group as a whole. Indonesian and Filipino linguists are now working extensively on their own languages, while several Dutch and American universities, and the Summer Institute of Linguistics in the Philippines (an association of Protestant missionary linguists that specializes in studying unrecorded languages) are active in both descriptive and comparative studies.

European languages contain a number of words borrowed from the better known languages of the Indonesian region. From Malay derive such English words as sarong, (to run) amuck, mandarin (through Portugese), the kris (or creese) dagger, and the names of several animals (orangutan, pangolin, dugong, kalong) and plants or plant products (kapok, paddy, nipa). Javanese contributions include junk (sailing vessel) and batik. The American English word boondocks is from Tagalog *bundok* "mountain."

EASTERN AUSTRONESIAN (OCEANIC)

Roughly 300 Austronesian languages are spoken east of Sorera Bay in New Guinea and on the islands of Melanesia, Micronesia, and Polynesia.

Classification. The classification of these languages remains somewhat controversial. Dempwolff found evidence to indicate that all known Austronesian languages in the Oceanic region, apart from Chamorro and Palauan, belong to a subgroup that excludes Western Austronesian languages. The names Oceanic and, less commonly, Eastern Austronesian are now applied to this grouping. The evidence consists of a number of common innovations in the treatment of Proto-Austronesian sounds. All Oceanic languages agree in having lost the original final consonants of most word bases in most contexts, and in simplifying the initial and medial consonants as shown in Table 56. In addition, Oceanic languages reflect a five-vowel system in which Proto-Austronesian *a, i, u* were retained, *ay* became *e,* and *e* and *aw* became *o* in Proto-Oceanic.

Table 4: Correspondences Between Proto-Austronesian (PAN) and Proto-Oceanic (POC) Consonants

PAN	p b	mp mb	t nt	d D	nd nD	l r		(n)s (n)z (n)j (n)Z
POC	p	mp	t nt	d	nd	l r		s,z
PAN	k g	ŋk ng	m	n ñ	ŋ w	q R	h	y
POC	k	ŋk	m	n	n w	q R	Ø (zero)	y

Though the evidence cited above is not challenged, the conclusions drawn from it have been. Scholars remain puzzled by the great differences among Oceanic languages, especially in vocabulary items. Comparisons of basic vocabulary show that several New Guinea–West Melanesian groups share less than 15 percent of a common basic vocabulary with all other members of Austronesian, indicating a divergence from the parent language at least 5,000 years ago. It has been suggested that the Oceanic languages may not constitute a single subgroup but may divide into several primary divisions within the Austronesian family, and indeed that West Melanesia may be the primary dispersal centre for Austronesian. A quite different theory, with a few modern adherents, explains the diversity among the languages of Melanesia by deriving them from relatively recent mixtures of Indonesian and Papuan languages, which results in disparate varieties of pidginized Indonesian with Papuan substrata in each island group.

Puzzling differences among Oceanic languages

There are increasing grounds for accepting Dempwolff's theory of the Western Austronesian–Oceanic division as correct, while still allowing for a more dramatic time depth. It is also evident that, after a period of development as a single language, most of the descendants of Proto-Oceanic that dispersed in the New Guinea–West Melanesian area were influenced by nearby Papuan languages; this, together with other factors, such as the small size of the speech communities, word taboos, and several millennia of separate development, probably account for the extreme diversity found in this part of Oceania. It is unlikely that the New Guinea–West Melanesia region was the primary dispersal centre for Austronesian languages, but it is certain that it was a very early one. From there Oceanic-speaking groups moved fairly rapidly into the unoccupied islands of East Melanesia, Micronesia, and Polynesia. As has been noted, both Fiji and Tonga were inhabited by 1000 BC, almost certainly by speakers of the branch of Oceanic ancestral to Fijian and Polynesian, while the Solomons, New Hebrides–Banks Islands, and New Caledonia were probably settled by 2000 BC or earlier. In New Guinea and the western Melanesian islands, Oceanic-speaking peoples encountered Papuan populations and in many places intermarried with them and borrowed from their languages. One result of this contact is that many Austronesian languages in that region have changed faster than those situated further east.

Austronesian encounter with Papuan languages

Characteristics of Proto-Oceanic. Among the additional evidence for Dempwolff's hypothesis that has come to light in recent years is the sharing by the Oceanic languages of many words and grammatical features that are not characteristic of Western Austronesian languages. More than 30 percent of Proto-Oceanic words from a standard list of 215 "basic vocabulary" meanings are not represented at all in Western Austronesian. Oceanic languages also agree in having peculiar forms for certain common Austronesian words; *e.g.,* the Proto-Oceanic forms are **au* "I," **mai* "come," **suRi* "bone horn," **pati* "four," **Moze* "sleep," **katoluR* "egg," where Western Austronesian languages reflect **aku, *maRi, *duRi* or **DuRi, *e(m)pat, *peZem, *teluR.* In grammar, a number of common simplifications and elaborations are observable. The general features of the following discussion of Proto-Oceanic grammar apply generally to present-day Oceanic languages, although some languages retain the parent system more completely than others. Most languages of the central and eastern Solomons, some languages of the central and northern New Hebrides and Banks Island, the Fijian dialects, the Polynesian group, and certain languages in New Guinea–West Melanesia appear to have preserved the Proto-Oceanic system more completely than others.

Some morphological simplifications occurred in Proto-Oceanic: many verb and noun affixes were lost, some prefixes lost their prefix quality and were assimilated as nonproductive elements into the word base, and some affixes normally appended to a word became reinterpreted as free-form particles. On the other hand, Proto-Oceanic developed several new prefixes and changed the shape or function of certain old ones.

Whereas tense, aspect, mode, and probably person and number of the verb were marked in Proto-Western Austronesian by affixes (*e.g.,* as in English "walk," "walked"), in Proto-Oceanic they were indicated by separate particles. Many verb bases also functioned as postverbal particles indicating direction or tense-aspect—*e.g.,* Proto-Oceanic **zake* "ascend," **zipo* "descend," **mai* "come," **nopo* "stay" also occurred as modifiers meaning "upward," "downward," "toward," and "progressive aspect," respectively.

Nominal (noun) phrases were of at least four types. Common nouns were marked by the "common article" **na,* personal pronouns and possibly personal names were indicated by personal articles (**i,* probably **a* or zero—unmarked—in certain contexts), locative nouns were shown by **(q)i* immediately preceding the base word, and temporal nouns were marked by a temporal prefix or zero (the lack of a prefix). One subclass of locatives, called relationals, used personal suffixes, as *(*q*)*i lalo-na* "at inside-his" (*i.e.,* "inside him").

Pronouns in Oceanic

As in Proto-Austronesian, personal pronouns fell into two sets of variants: subjective and possessive forms, and focus and objective forms. Examples from the Wayan dialect of Fijian that preserve the Proto-Oceanic forms are: "I go," *qu laka* (*qu* is the subjective pronoun "I," *laka* is "go"); "my arm," *qu-lima* (*qu* is the possessive pronoun "my," *lima* is "arm"); "It is I," *o au* (*o* is the personal article, *au* is the focal or emphatic pronoun "I"); "give (it to) me," *vaganī au* (*vaganī* is "give," *au* is the objective pronoun "me"). Several new distinctions appeared in Proto-Oceanic, however. One was the development of dual (two-person) and trial (three-or-more-person) suffixes. The forms **ru*(*a*) "two" and **tolu* "three" were suffixed when two or a few people, rather than an unlimited plurality, were referred to. Plurals were indicated by the simple nonsingular base, as Fijian *keda* "we plural (including hearer)" contrasting with *keda-ru* "we two (including hearer)" and *keda-tou* "we three (including hearer)."

It was in possessive constructions that Proto-Oceanic underwent some of the most distinctive elaborations. Common nouns in such structures fell into at least three "genders": edible (foods, drinks, etc.), familiar or inalienable (kinship terms, parts of a whole), and neutral. The possessor was linked to the possessed noun by a particle of variable form. When the possessed noun was of edible gender, the consonant of the possessive particle was **k*-; in instances of neutral gender it was **n*-; and when of familiar gender, the consonant was omitted. The vowel or vowels of the possessive particle varied according to whether the possessor was a personal pronoun, a common noun, or a proper noun. Similarly, word order depended on the class of the possessed and possessor nouns: the particle plus possessor normally followed the head noun, as in Fijian *na uvi kei Manu* "Manu's yam," *na vosa nei Manu* "Manu's speech," *na tina i Manu* "Manu's mother," but, when the possessor was a pronoun and the possessed noun was of other than familiar gender, then the particle and pronoun preceded, as Fijian *na ke-mu uvi* "your yam," *na no-mu vosa* "your speech" (but *na tina-mu* "your mother," *na mata-mu* "your eye").

Proto-Oceanic interrogative pronouns included several retained from Proto-Austronesian: **zapa* "what?", **zai* "who?", **piza* "how much? how many?", and **kuya* "how? in what state?" together with **pai* "where?", and **ŋ*(*a*)*iza* "when?". Demonstratives distinguished three positions or persons: *[*i,e*]*ni* "this, here, near me, now," **ina* "that, there (by hearer), then," and a form marking remote position in space and time.

As in Proto-Austronesian, most word bases, other than proper nouns, functioned as both verbs and nouns, and adjectives, numerals, and negatives played the role of verbs in sentences.

Subgroups of Oceanic languages. Many aspects of the subgrouping of Oceanic languages are still obscure. In the west, many small divisions are evident, but no large subgroup has been attested. In the east, there is some evidence for a wider subgroup—Eastern Oceanic—comprising the languages of the southeast Solomons, much of the New Hebrides–Banks Islands, Rotuma, Fiji, and Polynesia, and possibly also most of the Micronesian languages. Within Eastern Oceanic, there is fairly clear support for a subgroup consisting of Fijian and Polynesian, whose closest immediate relatives may lie in the central New Hebrides. Table 57 presents a classification that has some degree of general acceptance.

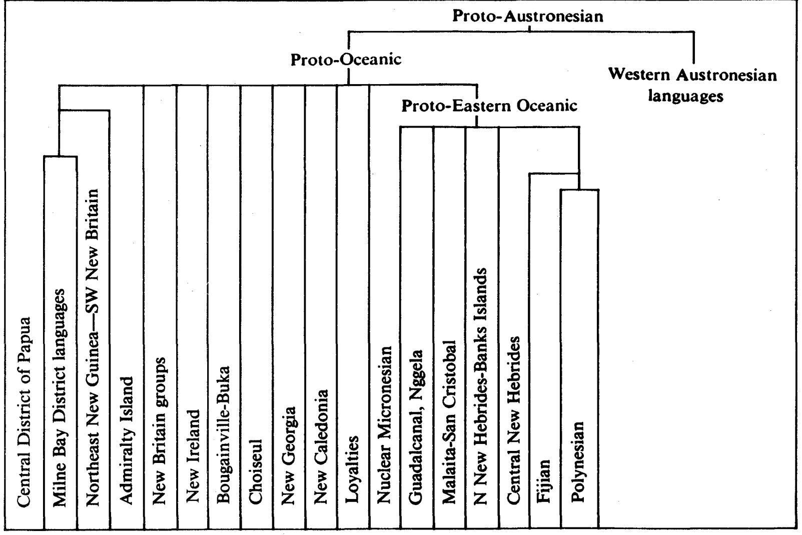
LANGUAGES OF MELANESIA

At a conservative estimate, 250 different Austronesian languages (not counting dialectal variants) are found in Melanesia. Most of them are spoken by communities of a few hundred to a few thousand people; with several exceptions they remain documented only by brief word lists and sketches. The term Melanesian is often applied to the Austronesian languages of Melanesia but has validity only as a geographical label, for these languages are not a linguistic unity comparable to the Polynesian and Nuclear Micronesian groups. Rather, Polynesian and Micronesian are each branches of particular Oceanic subgroups whose other members are in Melanesia (see Table 57).

Papuan and Austronesian languages in New Guinea

In New Guinea, Austronesian languages occur on the Doberai (Vogelkop) Peninsula, extending southwest as far as Kaimana, and in patches along the north coast, and along the southeast coast of Papua New Guinea as far west as Cape Possession (100 miles northwest of Port Moresby). Only in the Markham Valley and parts of the Central Province of Papua New Guinea are Austronesian languages found any distance inland. The interior and large stretches of the coast of New Guinea are occupied by Papuan. Apart from those tongues situated around Sorera Bay and on the Doberai (Vogelkop) Peninsula, all the New Guinea Austronesian languages appear to belong to the Oceanic division. The best known of them is Motu, spoken by about 13,600 people who occupy the coastal strip around Port Moresby. Police Motu, a simplified form of Motu, is used as a lingua franca throughout Papua. Motu is quite closely related to the eight other languages of Papua's Central Province. This group, in turn, appears to form a larger grouping with many of the languages spoken around the southeast tip of Papua New Guinea and the offshore islands, including Suau (Suau Island and adjacent coastal area) and Dobu (Dobu and Normanby Islands). These two languages, together with Kiriwina from

Table 57 : Classification of the Oceanic Languages



the Trobriand Islands and Wedau spoken around Wedan, have some currency as lingua francas in their respective regions of the Milne Bay Province.

Austronesian languages are found in coastal pockets in the Northern Province of Papua New Guinea, in the Morobe, Madang, East Sepik, and West Sepik provinces of Papua New Guinea, and on many offshore islands in these regions. Most of them have been strongly influenced by Papuan languages; *e.g.,* Yabêm and several closely related languages in the Morobe Province have developed tone, like their Papuan neighbours. Yabêm and Graged (Gedaged) of Kranket Island, in the Madang Province, have gained wider currency as the lingua francas of the Lutheran Mission in their regions. Some of the Morobe and Madang languages appear to fall into a subgroup with Kove (Kombe) and certain other languages of southwest New Britain.

Austronesian tongues of New Britain

The large island of New Britain contains around 25 extremely diverse Austronesian languages, the most important being Tolai (Kuanua, Tuna, Raluana), spoken around Rabaul on the Gazelle Peninsula and used extensively by missions in New Britain and New Ireland. New Ireland's languages are poorly known but appear to be of only moderate diversity. On the small Admiralty Islands group at least 20 (in some estimates as many as 50) different languages are found.

The Solomon Islands contain more than 60 languages that belong to several divergent groups. Bougainville is predominantly Papuan speaking, but several Austronesian languages are present on the north coast, and a few in the south and on offshore islands. The adjoining island of Buka contains several more, most of them closely related to the Bougainville languages.

On Choiseul Island are found an indeterminate number of languages and dialects closely related to each other but not to any outside group. Babatana is the literary language of a Methodist Mission there. Santa Isabel (Ysabel Island) is sparsely peopled by communities speaking perhaps 10 languages; Kia in the northwest and Bugotu in the southeast are the best known. Bugotu, the lingua franca of the Melanesian mission on Santa Isabel, is closely related to the Guadalcanal and Nggela languages. The New Georgia group contains more than a dozen languages—*e.g.,* Roviana (southwest New Georgia) and Marovo (east New Georgia and Vangunu Island)—most of which belong to a single division. Roviana is used by the Methodist Mission everywhere in the Solomons except on Vella Lavella. The languages of the southeast Solomons divide into two subgroups. Almost all those on Malaita and San Cristóbal belong to a single group whose best documented members are Sa'a, Kwara'ae (Fiu), Lau (all of Malaita), and Arosi (of San Cristóbal). The other group includes most of the Guadalcanal languages, together with Bugotu and Nggela, of Florida Island.

Polynesian languages spoken on several islands near the main Solomons group include: Nukuria, Nukumanu, Taku, Luangiua (Ontong Java), and Sikaiana to the north; Rennell–Bellona to the south; and Tikopia, Anuta, and Pileni–Taumako (Duff Islands) to the east. The latter is spoken in the Santa Cruz group, which also contains one Papuan and several little-known Austronesian languages.

Languages of the New Hebrides–Banks–Torres archipelago

Approximately 60 different languages, many of them dialectally very diverse, are spoken in the New Hebrides–Banks–Torres archipelago. The best known are Mota (of Mota or Sugarloaf Island, in the Banks group), used in the 19th century throughout the northern islands and in the Solomons as the lingua franca and literary language of the Melanesian Mission, and the Nguna–Tongoa dialects, spoken on north Efate and adjacent islands in the central New Hebride. Many of the central and northern languages are closely related to Fijian and Polynesian. Further south, Eromanga, Tana, and Aneityum harbour three languages that show no very close relationship to other members of the Oceanic group. Polynesian languages are spoken on Emae, Futuna, and Aniwa and on Mele and Vila islands in the New Hebrides.

Both New Caledonia and the Loyalty Islands are internally fairly diverse. New Caledonian languages appear to form a subgroup characterized by far-reaching sound changes. Languages of the central and far southern regions of the island are tonal. A Polynesian language, West Uvean, is spoken on, Beautemps-Beanpré (Heo) Island in the Loyalties.

Easily the best described, and politically the most important, language in Melanesia is Fijian, or Bauan Fijian, spoken as a first or second language by about 260,000 Fijians and also by other ethnic groups in the Fiji group. The Fijian dialects are sharply differentiated into Western and Eastern Divisions. Bauan, an Eastern dialect, became Fiji's lingua franca in the 19th century and is now widely used in the popular press, broadcasting, and administration. Rotuman, spoken on Rotuma Island, 200 miles north of Fiji, has borrowed heavily from Polynesian, but its classification as a language closely related to Fijian and Polynesian has been disputed.

LANGUAGES OF POLYNESIA

A triangle-shaped area, the apexes of which are Hawaii, Easter Island, and New Zealand, embraces almost all the islands of the central and eastern Pacific. Early European explorers found the inhabited islands in this region occupied by culturally homogeneous peoples speaking some 16 closely related languages. The name Polynesian was first applied to them by 19th-century scholars, who also observed that another 12 to 14 languages belonging to the Polynesian group are situated to the west of the Polynesian Triangle, on islands in Melanesia, and on the southern fringes of Micronesia; these are the Polynesian "Outliers."

Origins of the Polynesians

The question of Polynesian origins has been the subject of much romantic speculation. Various writers have pictured the ancestral Polynesians as migrating from such far-flung homelands as India, Egypt, Mesopotamia, and the Americas. It is now quite clear that, linguistically at least, the Polynesians developed their distinctive characteristics within Polynesia itself. Their languages form a subgroup of the Oceanic branch of Austronesian, whose immediate relatives lie in eastern Melanesia (see Table 57). Fijian, Polynesian, and certain languages of the New Hebrides were a single language until approximately 1000 BC, when some speakers of this early eastern Oceanic language appear to have moved from the New Hebrides into Fiji. There a dialect developed that subsequently split into Fijian and Polynesian branches. During several centuries of isolation somewhere in west Polynesia, probably in Tonga, the Polynesian branch underwent those further modifications that characterize all present-day Polynesian languages.

Characteristics of Proto-Polynesian. The general features of the following sketch of Proto-Polynesian are applicable to all its descendants. Each has changed some of the details for the Polynesian languages show an internal diversity comparable to the Romance or Germanic subfamilies of the Indo-European language family.

Phonology. Proto-Polynesian retained the five-vowel system of Proto-Oceanic but added a contrast between long, or geminate (double), vowels and short vowels. Several simplifications occurred in the consonant system, with the loss of the nasal element in stops (Proto-Oceanic *p* and *mp* both became *p; t* and *nt* became *t; k* and *ŋk* became *k*) and the loss of retroflex *R.* Proto-Polynesian consonants thus comprised four stops, *p, t, k,* and ʔ (the glottal stop); three nasal sounds, *m, n,* ŋ; three fricatives, *f, s, h*; plus *l, r,* and *w.* No consonant clusters or final consonants were permitted, but vowel sequences were common. Most word bases had two syllables, but longer forms were not uncommon, while some prebasic particles were monosyllabic—*e.g.,* **fale* "house," **waka* "canoe," **wai* "water," **uaua* "vein," **fafine* "woman," **tuakana* "older sibling of same sex," **maanifinifi* "thin," **ki* "to," **ma* "and," and **o* "of."

Significance of the phrase in Polynesian

Grammar. Proto-Polynesian retained most features of the Proto-Oceanic grammar, the main changes being in possessive constructions and in the development of distinctive passive and nominal (*i.e.,* verbless) sentence structures. The smallest natural phonological or pause unit was the phrase rather than the word, a phrase consisting of a head word flanked by affixes and particles. The verb phrase contained several classes of preposed particles: (1) tense-aspect particles (marking past, prospective, subjunctive, imperative, negative subjunctive, hypothetical, nonpast, and progressive); (2) subject-marking personal pronouns occurring between tense-aspect particle and verb; (3) manner particles, indicating the "manner" of the action; and (4) negatives. Verbal prefixes included **fe-* reciprocal, **faka-* causative, **ma-* abilitative (*i.e.,* "able to," "capable of"), **tua-* ordinal, **taki-* distributive, **toko-* human number. Verbal suffixes included a passive **-(C)ia,* instrumental **-aki,* and derivative or transformative **-(C)i, *-(C)aki.*

Noun phrases divided into common, personal, locative and temporal, each class of noun being marked by a distinctive article or other syntactic marker. Proto-Polynesian probably distinguished only two common articles, a definite **(t)e* and an indefinite **ha,* but several of its descendants have more elaborate series. Most interrogative pronouns were retained from Proto-Oceanic, but manner and temporal interrogatives were innovations. In personal pronouns the distinction between trial (three) and plural was lost, the old trial forms becoming the new plurals. Demonstratives included **eni* "this, these, here," **ena* "that, those, there (near hearer)," and **ia* "that, those (particular ones)."

In possessive constructions the three-way gender distinction of Proto-Oceanic was replaced by a two-way distinction between nouns subordinate to the possessor and nouns not subordinate to the possessor.

Case relations between noun phrases and the verb were indicated by particles placed at the beginning of the phrase. Active sentence structures normally consisted of verb phrase plus subject noun phrase plus complement, and contrasted with passive, nominal, and topicalized structures.

Samoan, Tahitian, and Hawai'ian

Languages and subgroups. The best known Polynesian languages are Samoan, spoken by about 200,000 people in Western and American Samoa and by sizable migrant communities in New Zealand and the United States; Tongan, with about 96,000 speakers; Tahitian, spoken as the native language in the Society Islands and as a second language by Marquesans, Tuamotuans, Magarevans, Austral Islanders (Îles Tubuai), and other ethnic groups in French Polynesia; New Zealand Maori, with about 100,000 speakers; and Hawai'ian, once the language of perhaps 100,000 people, but now used as a daily medium of communication by only a few hundred Hawai'ians. Samoan and Tongan are the national tongues of Western Samoa and the Kingdom of Tonga. Hawai'ian, Maori, and Tahitian, together with the languages of the Marquesas, Tubuai (Austral), Tuamotuan, and Cook island groups, and Magareva and Easter Island, form a well-marked subgroup known as Eastern Polynesian. Samoan with Futunan, Uvean, Tokelauan, Ellice, Pukapukan (in the northern Cooks), and all the Outlier languages spoken in Melanesia and Micronesia form a second division known as the Samoic-Outlier group. A third subgroup consists of Tongan and Niuean. Eastern Polynesian and Samoic-Outlier languages possess certain innovations that suggest they shared a period of common development after separating from the language ancestral to Tongan and Niuean. This wider grouping is known as Nuclear Polynesian.

The numerous subgroupings and language divisions in Polynesia are the result of the geography of this region. Around 2,000 years ago, following the breakup of Proto-Polynesian and the build-up of populations on the main islands in the west Polynesia area, there was a fairly rapid settlement of all the main uninhabited islands to the immediate east and west. Distances between most of the island groups were such that regular contact between them was impossible, and a distinct language evolved for each group. The last islands to be settled appear to have been the marginal east Polynesian islands, such as Hawaii, New Zealand, Mangareva (all settled about AD 1000), and some of the Outliers. Surprisingly, Easter Island was one of the first eastern islands to be settled, a fact attested by archaeological remains and by the considerable differences between the Easter Island language and those of other members of the Eastern Polynesian group.

The oral literature of Polynesia

The oral literature of Polynesia is extremely rich. Much of it has been recorded by Polynesian and European scholars and by missionaries, who in the 19th century developed excellent orthographies—using the roman alphabet—for Polynesian languages. In the precontact period, Easter Island was the only community to have developed a script of its own; it was an ideographic form of writing with very restricted uses. Missionary scholars also produced many excellent grammars and dictionaries, and intensive linguistic research continues, chiefly at universities in Hawaii and New Zealand.

European languages have borrowed many words from Polynesian. Among the English borrowings are taboo (Polynesian *tapu*), tattoo (Tahitian *tatau* "to mark"), mana, ukulele, hula, Kanaka (South Sea Islander), tapa cloth, kava (drink and plant), and the names of many plants and animals native to Pacific regions; *e.g.,* the New Zealand birds kiwi, moa, tui, huia, kaka, and takahe, the tuatara lizard, the kauri family of trees, and many others.

LANGUAGES OF MICRONESIA

The widely dispersed groups of small islands comprising Micronesia lie to the north of Melanesia, between the Philippines and the Polynesian Triangle. Micronesia has received linguistic infusions from each of the surrounding regions. Of the 13 or so languages native to Micronesia, two are intruders from the Philippines–Indonesia region, and two are Polynesian. The rest have probably been there longer but almost certainly derive ultimately from some part of Melanesia. Most or all of this last group fall into a single subgroup of Oceanic that has been called Nuclear Micronesian.

The two Indonesian-type languages are Chamorro, spoken in the Mariana Islands, and Palauan, spoken on Palau in the western Carolines. Chamorro, with about 63,000 speakers, most of them living on Guam, shows close resemblances to Philippine languages. The Palauan-speaking community numbers about 13,000. Palauan is Hesperonesian, but its immediate affiliations are uncertain. The two Polynesian languages in Micronesia are Nukuoro and Kapingamarangi; they are spoken on atolls lying south of Truk and Ponape by about 500 and 1,300 people respectively.

Nuclear Micronesian languages

Nuclear Micronesian languages include Marshallese (Marshall Islands, 30,000 speakers), Gilbertese (Gilbert Islands, 56,000 speakers), Trukese (Hall Islands, Truk, Mortlock Islands, 31,000 speakers), Ponapean (20,000 speakers on Ponape, Ngatik, Mokil, and Pingelap), Kosraean (Kosrae Island, 4,700 speakers), Carolinean (4,000 speakers, with a migrant community on Saipan in the Marianas and a source community in the eastern Carolines speaking a number of fairly diversified dialects), and Ulithian (originally applied to the dialect of Ulithi Island, but now used for the language or dialect continuum that extends from Tobi and Sonsoral through Ulithi and Woleai to Lamotrek, in the western Carolines). In addition, there are two languages that are possibly Nuclear Micronesian but their divergent structure and vocabulary make their membership doubtful at present. Yapese, spoken on Yap Island by about 5,800 speakers, is one of them, and Nauruan, with about 6,000 speakers on Nauru Island, is the other.

Nuclear Micronesian languages show a variability in vocabulary and structure exceeding that of the Polynesian group, thus indicating that their immediate common ancestor began to divide into several languages at least 3,000 years ago. Gilbertese and Marshallese, for instance, share only about 21 percent of related words in their basic vocabularies, while Kosraean and its neighbouring languages, Ponapean and Marshallese, share only about 26 percent and 24 percent, respectively. The figures for Yapese and Nauruan and other languages are still lower.

The greatest diversity lies in east Micronesia, suggesting that the homeland of Proto-Nuclear Micronesian may have been in that region. Further west, the languages are more alike; a continuum of mutually intelligible dialects or very closely related languages extends from Truk through the main body of the Caroline Islands southwest to Tobi Island, and includes the Trukese, Carolinean, and Ulithian languages.

The following features appear to be characteristic of Nuclear Micronesian languages (with the partial exception of

Gilbertese): velarized consonants (made with movement of the tongue toward the soft palate), long or geminate consonants, the assimilation of vowel pronunciations to neighbouring sounds, and a number of other fairly complex phenomena that modify the pronunciation of particular sounds in particular contexts. Grammatical features include verb phrases introduced by subject prefixes marking person and number, attachable to the verb or to one of the many preverbal tense-aspect particles; many subclasses of nouns distinguished in numerical and possessive constructions; elaborate sets of demonstrative pronouns paralleling many of the meaning distinctions found in personal pronouns; complex numeral and classifier systems; and several kinds of reduplication of base words carrying several grammatical–semantic functions.

In general, the Nuclear Micronesian languages have been among the most innovative of the Oceanic languages. They have considerably modified the original Oceanic sound system and lost a number of grammatical distinctions made in Proto-Oceanic, while elaborating others and developing several new features. Grammatical sketches exist for most of the languages, but as yet few dictionaries have been published. Micronesian communities are almost 100 percent literate. Because of the phonological complexity of many of the languages, however, few of the orthographic systems, all of which are in roman script, are as uniform or satisfactory as those for the Polynesian or Indonesian languages.

(A.K.Pa.)

PAPUAN LANGUAGES

The Papuan languages are those languages spoken in an area centred upon New Guinea and extending from the islands of Alor, Halmahera, and Timor in the west to the Santa Cruz Archipelago in the east. The group includes approximately 740 languages, used by about 3,000,000 speakers. The term Papuan was originally employed merely to distinguish these languages from the Austronesian (Malayo-Polynesian) and Australian languages, and, until recently, most Papuan languages were believed to be unrelated to each other. Intensive research by teams of linguists since the late 1950s, however, has resulted in a revolutionary change in the Papuan linguistic picture, and it is now known that about 350, and perhaps even as many as 450, of the approximately 740 identified Papuan languages are related. More than 500 of these are spoken by 2,900,000 speakers, who occupy almost three-quarters of the New Guinea mainland. Belonging to 76 to 105 language families (depending on the classification used), these languages together form the Central New Guinea macrophylum. (A macrophylum is a group of languages related less closely than those of a language family or stock.)

Recent extensive research into the Papuan languages has resulted in the preliminary classification of most of them. Numerous new languages have been discovered, though large areas, mainly in Irian Jaya, Indonesia, remain unknown. Despite the concentration of research on discovery and classification, a number of grammatical and lexical studies have been prepared, and folklore has been collected. The Summer Institute of Linguistics, an association of Protestant missionaries specializing in studying primitive languages and involved in literacy training and Bible translation, has carried out an extensive native language literacy program in New Guinea with a measure of success.

Classification and distribution. Interrelated language families are grouped in phyla, groups of languages more distantly related than those of a family or stock but more certainly or closely related than those of a macrophylum. Apart from the isolates, or unrelated languages, the number of known Papuan phyla is 21. Of these, 8 are small and consist of only 2 to 6 languages each. Of the remaining 13, 6 constitute the central New Guinea macrophylum, and 3 more can tentatively be included in it.

Central New Guinea macrophylum

The central New Guinea macrophylum comprises: (1) the East New Guinea Highlands phylum, found predominantly in the Highlands and Chimbu provinces of Papua New Guinea; (2) the Finisterre-Huon phylum in the Morobe and Madang provinces, Papua New Guinea; (3) the Central and South New Guinea phylum, located mainly in the Gulf and Western provinces of Papua New Guinea and in southern and northeastern Irian Jaya; (4) the West New Guinea Highlands phylum of the highlands area of Irian Jaya; (5) the South-East New Guinea phylum, in the Central, Northern, Morobe, and Milne Bay provinces of Papua New Guinea; (6) the Madang phylum in the Madang provinces of Papua New Guinea.

Tentative member phyla of the Central New Guinea macrophylum are: (1) the Adelbert Range phylum in the Madang province of Papua New Guinea; (2) the Middle Sepik-Upper Sepik-Sepik Hill phylum, which could also be classified as constituting three separate phyla; (3) the Anga stock (stocks are intermediate between phyla and families) spoken in the Eastern Highlands, Morobe, and Gulf provinces of Papua New Guinea.

Large Papuan phyla that are not members of the Central New Guinea macrophylum are the Ramu phylum in the Madang and East Sepik provinces of Papua New Guinea; the Torricelli phylum in the same provinces; the West Papuan phylum on the Doberai (Vogelkop) Peninsula of Irian Jaya, and in northern Halmahera, eastern Timor, and Alor; and the Bougainville phylum on the island of Bougainville. Small isolated phyla are located mainly in the West Sepik and Gulf provinces of Papua New Guinea and in the Santa Cruz Archipelago. The highest concentration of known isolates is also in these provinces and in the East Sepik Province, the New Britain-New Ireland area, and the Solomon Islands.

Some Papuan languages are difficult to classify because of strong Austronesian influence upon them. Most Papuan languages are of only regional importance, but a few have achieved some cultural significance outside their immediate area because of their use as missionary languages.

Of the known Papuan languages that cannot yet be linked with the macrophylum, about 130 belong to large groups, and 26 to small individual groups. Approximately 50 languages, called isolates, seem to be unrelated either to each other or to the established groups. Further research may well show that additional Papuan languages belong to the macrophylum, especially after hitherto linguistically unknown areas in New Guinea have been studied.

Enga, the numerically largest language

Each of the individual Papuan languages is, for the most part, spoken by only a few hundred to a few thousand people, though the numerically largest one, Enga, in Enga Province of Papua New Guinea, has more than 150,000 speakers, and several other languages are each spoken by tens of thousands. Even if related, the languages generally show considerable diversity, especially in vocabulary. A few basic grammatical characteristics are, however, shared by many languages. In numerous instances it is difficult to determine the border line between the languages and dialects, despite the presence of marked differences between two forms of speech.

Linguistic characteristics. Most Papuan languages show extreme grammatical complexity. Their verbs vary to reflect a wide range of numbers and other features of the subject as well as of the direct and indirect objects and the beneficiary. For example, in Kiwai, a language of the Central and South New Guinea phylum, the verb *ai-ni-mi-bi-du-mo-iauri-ama-ri-go* means "they three will certainly see us two." Similarly, in the Monumbo language of the Torricelli phylum *mbepe*$_1$*-nge*$_2$ *tsi*$_3$*-p*$_4$*-ing*$_5$*-em*$_6$ can be translated as "you gave him a taro." Literally, the parts of this utterance are: taro$_1$–singular$_2$, 2nd person singular subject (you)$_3$–give, past form$_4$–masculine class 3rd person singular indirect object (to him)$_5$–plant class singular direct object$_6$. Verbs also indicate tense, aspect, mood, and the direction and circumstances in which the action they designate is performed; *e.g.,* in Gadsup, of the East New Guinea Highlands phylum, *kùmù-`ə-nk-`əd ´əd-òn-ték-´əp-*

ón-ì-nó-ké, "had he indeed wanted to go down for him?", has several prefixes and suffixes indicating emphasis, tense, direction, and the question status. (The accent marks indicate tones; the ə is a sound pronounced like *a* in "sofa." The dashes separate the various components of the utterances, but do not normally appear in nonlinguistic texts).

Verb forms for one or more actions

There are, basically, two major types of verb forms in many Papuan languages. One, which can be referred to as the normal type, is found in sentences in which only one action is referred to; the other, which may be referred to as the special verb form, occurs in sentences in which more than one action is mentioned. In the latter type of sentence, which may have one or more special verb forms, the normal verb form also appears with the last verb in the sentence.

Numerous Papuan languages have gender and noun class systems, some with up to ten or more classes. Bewilderingly complex variations of adjectives, numerals, demonstratives, and subject and object markers often result, since these words have special forms for each of the various classes of nouns. An example is the sentence *ame akwum kuvambakwum sumupar amenakwum salikəmba,* "I saw my two big women," from Angoram of one of the small Sepik phyla. If "women," *akwum,* is replaced by "arrows," "gardens," or "frogs," etc., the entire sentence, rather than a single word, is changed: when "arrows" is substituted, the phrase becomes *ame pwanggli kəpanggli klupar amenakanggli salikəanggliya;* and when "gardens" is used, it changes to *ame konggəmbər kəvambər pələpar amenkəmbər salikəmbəra.*

Many languages are tonal, with changes of pitch in words and syllables that affect the meaning of the words. The interaction of Papuan tonal systems with patterns of stress and syllable length can be extremely intricate. (S.A.W.)

AUSTRALIAN ABORIGINAL LANGUAGES

There are approximately 260 Australian Aboriginal languages. This group of genetically interrelated tongues embraces the entire Australian continent as well as the western islands of Torres Strait, but apparently excludes Tasmania. The languages are characterized by great similarities in their sound systems and considerable agreement in grammar but often by markedly few similarities in vocabulary. Intelligibility between neighbouring forms of speech is common, and dialect chains stretching over amazing distances occur, though the two extremes of such a chain seem to be quite distinct languages.

Secret languages and special vocabularies

Every tribe speaks at least one distinct dialect, but bilingualism and multilingualism are common in many areas. Many individual languages have parallel forms, characterized by special vocabularies and sometimes by special sounds that are used in cultural avoidance situations (*e.g.,* to mothers-in-law) or as secret languages among initiated men on certain occasions.

No genetic link is known to exist between the Australian languages and any outside language. It is believed that languages ancestral to the present-day ones were introduced into Australia by peoples that crossed Arnhem Land in northern Australia many millennia ago. With the apparent exception of the influence of Papuan languages on the languages of the Cape York Peninsula, the Australian languages remained free from outside influence until the arrival of European settlers late in the 18th century.

The great majority of the Australian languages were nearing extinction by the third quarter of the 20th century, with about 50 or more extinct, predominantly in the east, south, and west of the continent. Speakers of languages believed extinct for decades are, however, occasionally discovered. Most languages have very few surviving speakers; still-vigorous languages have, for the most part, only a few hundred speakers each, though Mabuiag (the language of the western Torres Strait islands) and the Western Desert language have 8,000 and 4,000 speakers, respectively. About 45,000 Aborigines may still have some knowledge of an Australian language, but accurate figures of the speakers of individual languages are almost impossible to obtain.

Extensive research on the Australian languages has been carried out since 1960, largely through the Australian Institute of Aboriginal Studies in Canberra. The results of this and earlier research have shown the Australian languages to be interrelated and have made it possible to explain their structural differences in terms of a typological development from a simple to a complex structure. In addition, a considerable amount of detailed information on the grammar of numerous languages has been recorded.

Genetic relationship of all Australian languages

Classification. Earlier classifications regarded the northern and northwestern languages, which are structurally rather different from the southern languages, as genetically distinct from the latter. (The interrelationship of the southern languages was recognized quite early.) Later, various classifications based on language type were established, and these demonstrated the ultimate unity of all Australian languages. The most recent classification is based on the degree of lexical (vocabulary) interrelationship between the languages; it subdivides the languages into 28 families, of which 27 are located in the north and northwest, covering about one-eighth of the continent, and a single family is found occupying the remaining seven-eighths of Australia. This skewed picture may be the result of the thorough spreading of a language form referred to as Common Australian (dated at about 5,000–6,000 years ago) from somewhere in northwestern Australia through most of the continent except the north and northwest regions. This diffusion appears to have coincided with that of an archaeologically recognized cultural revolution. The spreading of this Common Australian language may have brought about greater linguistic uniformity in much of Australia. Most of the 28 families are subdividable into groups and often into subgroups of individual languages. In the following list of language families these abbreviations are used: G = group or groups; SG = subgroups; L = language or languages.

Family
Tiwian (1L)
Yiwadjan (4G, 2SG, 5L)
Kakadjuan (1L)
Mangerian (2G, 2L)
Gunavidjian (1L)
Nagaran (1L)
Gunwingguan
(6G, 3SG, 11L)
Bureran (2G, 2L)
Nunggubuyuan (1L)
Andilyaugwan (1L)
Maran (2G, 2SG, 3L)
Mangaraian (1L)
Ngewinan (1L)
Yanyulan (1L)
Djingili-Wambayan
(2G, 3L)
Karawan (2G, 2L)
Minkinan (1L)
Larakian (2G, 2L)
Kungarakanyan (1L)
Warraian (1L)
Daly (3G, 4SG, 10L)
Murinbatan (1L)
Djamindjungan (4L)
Djeragan (2G, 5L)
Bunaban (2G, 2L)
Wororan (3G, 12L)
Nyul-Nyulan (4L)
Pama-Nyungan
(41G, 50SG, 177L)

Some aspects of this classification are only tentative. The locations of the families are shown on the accompanying map.

Bidjandjara

In most areas in which Australian languages are still in daily use, individual languages have gained prominence over others and have become lingua francas (common languages), as a result either of their use as mission languages or of social and cultural factors active among the Aborigines themselves. One of the dialects of the Western Desert language, Bidjandjara (Pitjantjatjara), has become the Aboriginal lingua franca over a sizable portion of the western half of the continent.

Grammar. The Australian languages generally show considerable grammatical complexity. Affixes (word parts added initially, internally, or terminally) play an important role; prefixes used initially and suffixes used terminally are found in northern and northwestern Australia, and suffixes, for the most part, are used elsewhere. A peculiar feature of many languages is the suffixing of markers indicating the subject and object of the verb to

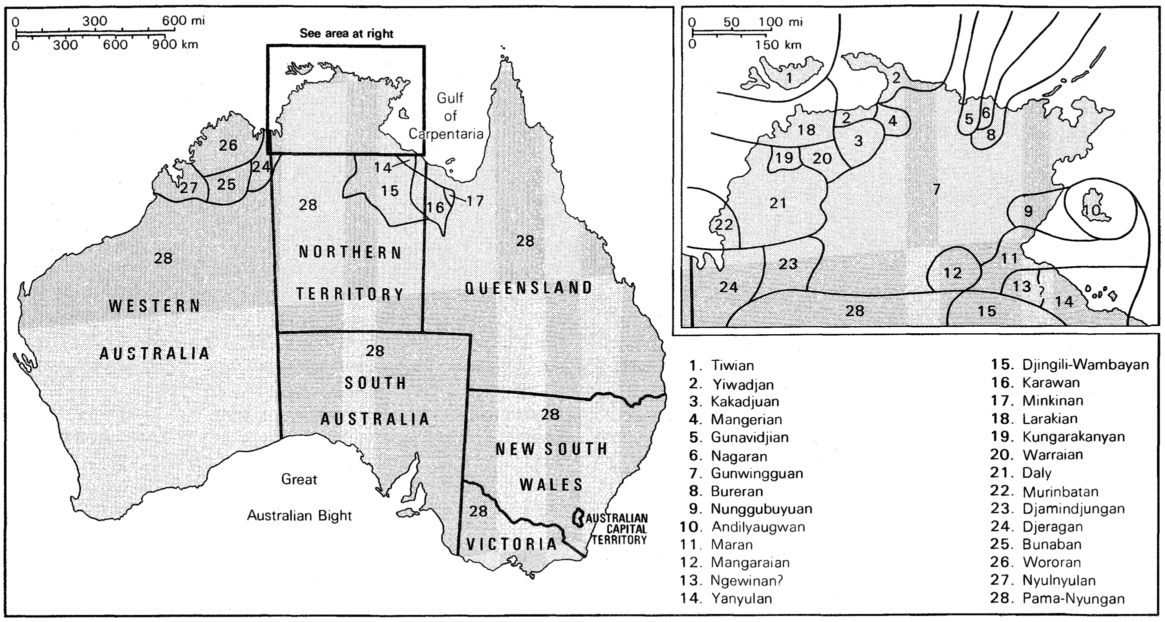


Figure 29: Distribution of the Australian Aboriginal languages.
Adapted from S.A. Warm, *Languages of Australia and Tasmania* (1971); Mounton & Co.

Common Australian words

the first word of the sentence, irrespective of what it is, or to special particles not connected with the verb. An example from Wanman of the Pama-Nyungan family is the use of the suffixes -ŋ*a* and -ŋ*ku* in *paral*^{y}*i-*ŋ*a-*ŋ*ku t*^{y}*i*ŋ*ka-*ŋ*a,* literally, "boomerang-I-you make-past," or "I made a boomerang for you." Another widespread feature is an ergative or agentive suffix, attached to nouns and pronouns, that indicates the actor of an action referred to by a transitive verb. In the Dungidjau language of the Pama-Nyungan family, *t*^{y}*a:n-tu pukin*^{y}*-n*^{y}*a pumi* is directly translated as "*man*-ergative *dog*-object *hit*-past." Here *-tu* is the ergative suffix; attached to *t*^{y}*a:n* ("man"), *-tu* signifies that "man" is the actor of the verb, thus rendering the meaning "the man hit the dog." Great freedom of word order is a feature of many Australian languages. A number of languages, mainly northern ones, have gender and noun class systems, with adjectives, numerals, and demonstratives showing special forms for each of the classes of nouns and often, also, for their number. For example, in Andilyaugwa of the Andilyaugwan family, "where is (located)" is expressed as ŋ*i-*ŋ*ampa na-mpil*^{y}*a* when referring to one man, but as *wunala-*ŋ*ampa wu-pil*^{y}*a* when referring to two men, *wura-*ŋ*ampa na-mpil*^{y}*a* in regard to three or more men, *ta-*ŋ*ampa i*ŋ*a mpil*^{ys}*a* to one woman, and *ma-*ŋ*ampa numa-mpil*^{y}*a* to a ship.

Phonology. The sound systems of the Australian languages are extremely similar. Most of them share from four to six different points of articulation for stop consonants (made with complete stoppage of the breath from the lungs) and nasal consonants (made with the airstream passing through the nose), with many languages having such consonants produced with the tip of the tongue placed between the teeth (interdental consonants), or behind the teeth (alveolar consonants), indicated as *t, n,* or curled up against the hard palate (retroflexed consonants), written as *ṭ, ṇ*. The series of consonants may thus include labial consonants (*p, m*), interdental consonants, alveolar consonants (*t, n*), retroflexed consonants, palatalized consonants (*t*^{y}, *n*^{y}), and velars (*k,* and ŋ as the *ng* in "sing"). In addition, most Australian languages show no distinction between voiced and voiceless stops (such as voiced *b* and voiceless *p* in English), no fricative consonants (*e.g., f, v, s, z*), only three vowels (*a, i, u*), but two or three distinct *r* sounds.

Vocabulary. In spite of the great vocabulary differences among the Australian languages, a number of common words are encountered in a great many languages all over the continent. These are believed to constitute a Common Australian element. In the vocabulary of a given language, various classes of words, such as nouns, verbs, and others, are clearly distinguishable and definable, and word formation is through the use of affixes. Australian languages have contributed to Australian English mainly animal and plant names and objects in nature—kangaroo, wallaby, kookaburra, budgerigar, galah, coolibah tree, billabong.

Collections of mythological and other text materials have been and still are being made in a number of languages. Native literacy in Australian languages is limited but is on the increase as a result of the work of members of the Summer Institute of Linguistics (an association of Protestant missionaries that specializes in studying primitive languages), who, like the people from the Methodist, Anglican, and Australian Inland missions, write the languages in specially adapted versions of the English alphabet.

(S.A.W.)

AFRICAN LANGUAGES

Although no definitive count exists, the number of separate and distinct African languages, as estimated by various authorities, ranges from 800 to more than 1,000. The linguistically most homogeneous area of Africa is the northern part, in which Arabic predominates from Egypt to Mauritania, albeit in a number of sharply distinguished dialects; the most important dialect cleavage is between the Egyptian–Sudanese varieties and those of the Maghrib (from Libya westward). Intermingled with the Maghrib dialects are the Berber languages, concentrated principally in Algeria and Morocco. They range as far east as the Siwa Oasis in western Egypt, as far west as the Senegalese–Mauritanian border area, and as far south as the southern rim of the Sahara. The nomadic Tuaregs speak a Berber language. Nubian, a totally different language, is spoken as far north as southern Egypt along the Nile, but its links are clearly with the languages of sub-Saharan Africa.

Sub-Saharan languages

In sub-Saharan Africa the linguistic picture is far more complex. Except for the Khoisan (Bushman and Hottentot) languages of the extreme south, approximately the entire southern third of Africa is occupied by the relatively closely interrelated Bantu languages. They extend eastward from roughly the Nigerian–Cameroon border to the Indian Ocean. Bantu and non-Bantu languages are considerably interspersed around the northern Bantu border, running through Cameroon, slightly south of the northern boundary of Zaire, and through Uganda and Kenya. There are Bantu enclaves as far north as Somalia and non-Bantu enclaves in northern Tanzania. It is the area north of the Bantu and south of the Sahara that is linguistically the most diverse; there the languages are most numerous and their interrelationships most remote and difficult to establish with certainty.

General considerations

African lingua francas

Because probably not more than 40 African languages have more than 2,000,000 native speakers, a number of lingua francas have developed in various areas as a means of coping with this enormous linguistic diversity. Arabic, in addition to having the largest number of native speakers of any language of the continent, is sometimes used as a lingua franca, in its literary form by educated non-Arab Muslims, and in a number of colloquial varieties by much of the non-Arab population of The Sudan and Chad. Swahili, a Bantu language heavily influenced by Arabic, is official in Tanzania and Kenya and is used as a lingua franca throughout most of East Africa including eastern Congo. Other important lingua francas include Lingala, also a Bantu language, in western Congo; Fanagalo (vulgarly known as "kitchen Kaffir" or "mine Kaffir"), a pidginized form of Zulu with many English and Afrikaans loanwords, in South Africa, particularly in the mines; and Sango, a pidginized form of Ngbandi (included in the Adamawa-Eastern subdivision of Niger-Congo by some scholars; see below) with many French loanwords, spoken in the Central African Republic.

In addition, there are Bambara-Maninka, a Mande language used in Mali, Guinea, and Ivory Coast; Hausa, spoken in northern Nigeria and neighbouring areas; Amharic, used throughout Ethiopia, where it is the official language; Wolof, the language of Dakar, widely spoken throughout Senegal and The Gambia; and Kongo (Kikongo), a Bantu language that is used in the area of the mouth of the Congo River and is also spoken in a pidginized variety known as Kituba.

Standard European languages, particularly English and French and, to a lesser extent, Portuguese and Italian, also serve as lingua francas, generally among the better educated, in areas in which they are or were the colonial languages and where they enjoy or have enjoyed official status. Localized varieties of European languages are also spoken in numerous parts of Africa, such as Pidgin English, a widely used lingua franca of Cameroon and West Africa; Krio, a creolized form of English, differing slightly from Pidgin English and used by the local population of Freetown, Sierra Leone; various forms of Creole Portuguese, spoken in the Cape Verde Islands, the islands of São Tomé and Príncipe, and Guinea-Bissau; and Afrikaans, an outgrowth of Dutch, which serves along with English as an official language of South Africa.

LANGUAGE CLASSIFICATION

Early attempts at classification

Although word lists of a number of sub-Saharan languages were recorded by Europeans as early as the 15th and 16th centuries, and the first grammar of a sub-Saharan language (Kongo) was published in 1659, extensive study of African languages and systematic attempts at grouping and classifying them did not begin until the 19th century. In 1854 Sigismund Koelle, a missionary living in Freetown, Sierra Leone, was able to collect substantial word lists of roughly 150 languages, principally of West Africa but also including some belonging to the Bantu family. He established 11 groups, leaving approximately 40 languages

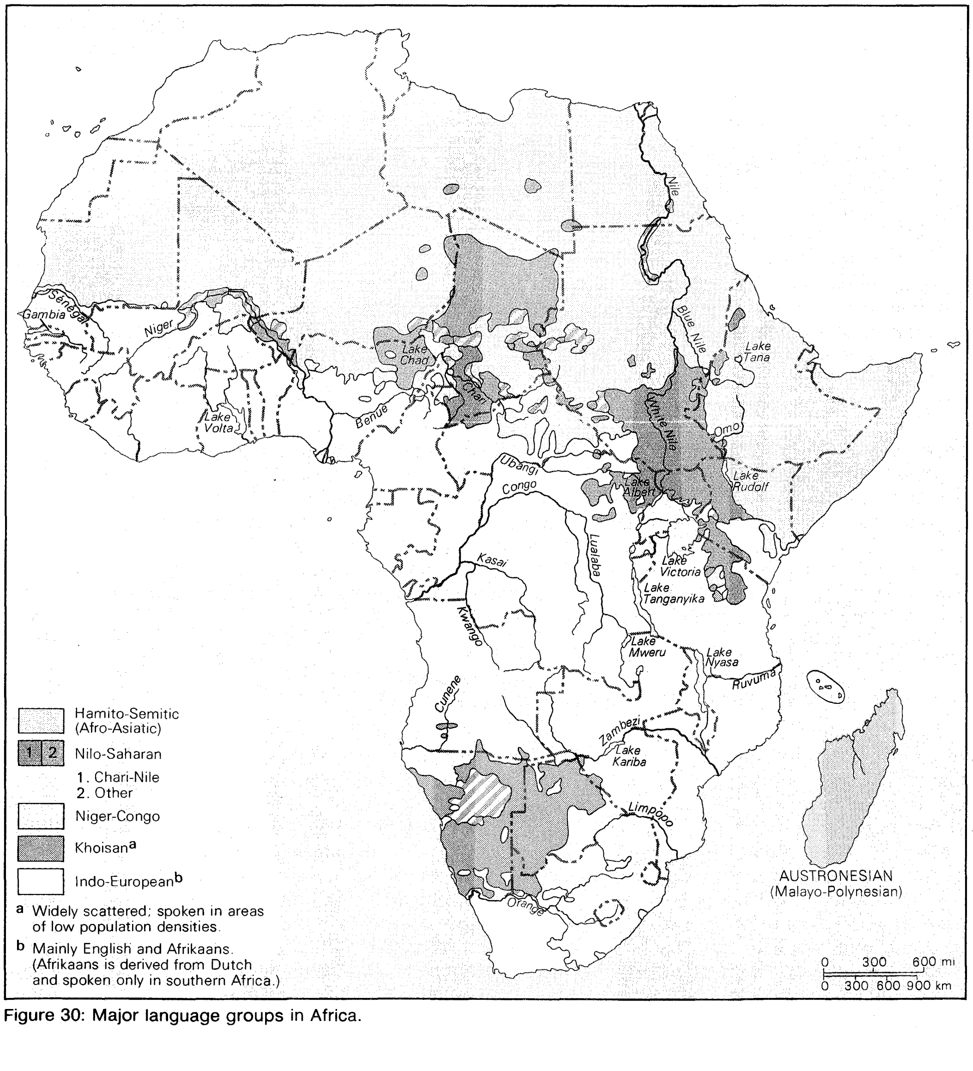

Figure 30: Major language groups in Africa.

unclassified. His groups are generally small, rarely exceeding 15 members, and he made no systematic attempt to explore wider relationships. He laid the groundwork for establishing the Mande family, which has been universally accepted ever since. (The term "family" is used loosely in this article, sometimes referring to large groupings of languages and sometimes referring to subgroups or branches of these groupings. Niger-Congo, for example, is usually called a language family, but its subgroups [*e.g.,* Mande] and its sub-subgroups [*e.g.,* Bantu] are often referred to as families as well.)

The unity of the Bantu family, although suggested by a number of earlier writers, was first established in 1862 by the German scholar Wilhelm Bleek, who gave it its name, the word for "people" in most languages of the family. During approximately the same period, the work of several scholars suggested that Ancient Egyptian, the Berber languages, certain languages of northeastern Africa called Cushitic (*e.g.,* Galla, Somali, Beja, and Afar [Danakil]), and perhaps others (*e.g.,* Hausa) were remotely related to one another and to the Semitic family. These languages were called Hamitic at the suggestion of a French Semitist, Ernest Renan, who was also the first to propose the name Cushitic, because the peoples speaking these languages coincided roughly with the descendants of Ham (one of whom was Cush), according to the biblical account in Genesis, just as the people speaking the Semitic languages coincided with the descendants of Shem (Sem).

The first attempts at an overall classification of African languages were those made by the Austrian linguist Friedrich Müller in 1876–88 and by the German Egyptologist Karl Richard Lepsius in 1880. Müller, who classified all the world's languages on the basis of a correlation of linguistic and racial groupings (the latter determined largely by hair type), set up the following divisions within Africa: (1) Bushman-Hottentot, as a subdivision of the languages of the tufted-haired peoples (the Papuan languages of New Guinea formed the other subdivision); (2) Bantu and (3) Negro, both subdivisions of the languages of the fleece-haired (*vliesshaarig*) peoples; (4) Hamitic, (5) Semitic, and (6) Nuba-Fulah, all three subdivisions of the languages of the wavy-haired (*lockenhaarig*) peoples. Linguistically, Nuba-Fulah was completely heterogeneous and was abandoned by later scholars.

Lepsius' classification

Lepsius proposed an alternative classification of the languages and peoples of Africa, of which the three major divisions were (1) Semitic; (2) Hamitic, including Hausa, which he grouped with the Berber or Libyan branch, and Hottentot, neither of which had been classed as Hamitic by Müller; and (3) the Negro languages, consisting of two subdivisions, Bantu and Mixed Negro, composed of many subgroups, and containing all the indigenous languages of Africa not included in the other divisions.

During the early part of the 20th century, a revision of this classification emerged from the work of the two leading German Africanists, Carl Meinhof and Dietrich Westermann. Meinhof added a number of languages to Lepsius' Hamitic grouping, namely Fulani, a major West African language, and a group of East African languages, including Masai and Bari. Westermann attempted to show the unity of virtually all the non-Bantu, non-Hamitic, and non-Semitic languages of Africa; he designated them Sudanic. Thus, a threefold division was established: Bantu, Hamitic, and Sudanic. The Bushman languages of southern Africa were sometimes treated as a separate group and sometimes linked with Sudanic, and Semitic was generally linked to Hamitic, though not included within it. Not everyone accepted this classification. French scholars, in particular Maurice Delafosse and Lilias Homburger, restricted Hamitic to Ancient Egyptian, the Berber languages of North Africa, and the more heterogeneous Cushitic group of languages of northeastern Africa. They connected Hottentot with the Bushman languages while grouping the other languages classed by Meinhof as Hamitic in the very general Negro-African or Sudano-Guinean family, to which they also believed the Bantu languages to be affiliated.

Westermann himself revised his views of the earlier classification scheme and came to regard the great majority of the languages of West Africa (*i.e.,* the Western Sudanic languages) as more closely related to Bantu than to the languages farther east, previously regarded as Sudanic. Sir Harry Johnston, a British Africanist, likewise pointed out similarities between Bantu and many West African languages that he termed Semi-Bantu.

Joseph Greenberg's classifications

No single scheme was generally accepted in 1955, when Joseph Greenberg, a United States linguist, presented the earlier version of his major classification of the languages of Africa. In 1963, Greenberg made public a substantially revised version of his work that consolidated previously unclassified languages and smaller language families into four large linguistic stocks—Niger-Kordofanian, Nilo-Saharan, Khoisan, and Afro-Asiatic (Hamito-Semitic). They included all the indigenous languages of Africa except Malagasy, the language of Madagascar, which belongs to the Austronesian (Malayo-Polynesian) family and is thus unrelated to the languages of the continent. The Niger-Kordofanian group consists of two branches, Niger-Congo, which is very extensive, and the much smaller Kordofanian group, so named because all of its members are located in Northern and Southern Kurdufān provinces, The Sudan. Kordofanian contains a number of subgroups, of which Kadugli-Korongo is most distantly related to the others. In fact, its inclusion within the group is open to serious question. Niger-Congo consists of Westermann's Western Sudanic group plus Bantu, whose interrelationship had earlier been advocated by Westermann. Greenberg differed from Westermann, however, in that he treated Bantu as a subgroup of one of the branches of Western Sudanic rather than an independent unit related to Western Sudanic as a whole. Greenberg also argued strongly for the inclusion of Fulani in this family. (Fulani had been regarded as Hamitic by Meinhof, but some French scholars had already advocated its relationship to other West African languages, such as Serer of Senegal.) Furthermore, Greenberg extended Niger-Congo eastward to include languages of Central Africa, such as Ngbandi of the Central African Republic and Azande (Zande) of Zaire, with which Westermann had not dealt.

The Nilo-Saharan group consists of six branches, of which Chari-Nile is by far the most heterogeneous. This family is the least adequately substantiated of the four. The Khoisan languages comprise the Bushman and Hottentot languages of southern Africa and two languages of Tanzania, Sandawe and Hadza (Hatsa). Afro-Asiatic, which is Greenberg's name for Hamito-Semitic, consists of five branches: (1) Semitic, represented in Africa by Arabic and the Ethiopic languages, of which the most important are Amharic, the official language of Ethiopia; Tigrinya, the predominant language of Eritrea; and Geʿez, the liturgical language of the Ethiopian Church, which is no longer spoken; (2) Ancient Egyptian, now extinct, and its daughter language, Coptic, the liturgical language of the Coptic Church of Egypt, (3) the Berber languages of northern Africa, including Kabyle of Algeria, Riffian and Shluh (Shilha) of Morocco, and Tuareg, or Tamashek, of the Sahara; (4) the extensive and diversified Cushitic group of northeastern Africa, whose most important members are Somali and Galla; (5) Chadic, spoken in Chad, Cameroon, and northern Nigeria, although Hausa, its best known and most widely spoken member, is used throughout much of West Africa.

Branches of Afro-Asiatic (Hamito-Semitic)

Hamito-Semitic languages also are spoken in the Middle East. For this reason, they are treated in a separate section (see *Hamito-Semitic languages*).

Because of the inexact nature of the procedures for establishing genetic classification and also because of incomplete data on the majority of African tongues, differences of opinion exist on various aspects of Greenberg's classification. Some scholars, such as the Hungarian linguist István Fodor and the English Bantuist Malcolm Guthrie, insist that genetic interrelationship of a group of languages can be established only by demonstrating regular phonological correspondences among them, as have been shown among the Bantu languages, for example. Greenberg and his supporters, however, maintain that similarities in both sound and meaning between two or more languages, which are too numerous to be dismissed as mere coincidence and are found in that part of language least susceptible to borrowing (*e.g.,* grammatical elements, body parts and functions, common natural objects and phenomena, and lower numerals), must be attributed to genetic relationship. Nevertheless, there are no rigorous procedures for determining how similar two items must be in sound and meaning to be considered evidence for genetic relationship or how many items are needed to rule out other explanations.

SIMILARITIES AND CORRELATIONS

Common features of the African languages. Although African languages are extremely diverse in structure, certain phonological and grammatical features are widespread throughout much of the continent or at least within extensive and well-defined areas.

Tones and clicks

Phonological features. Tone—*i.e.,* the use of pitch to distinguish words and grammatical forms that otherwise would be phonetically identical—occurs in the overwhelming majority of sub-Saharan languages. The famous click sounds are largely restricted to two language groups of southern Africa: the Bushman and Hottentot (Khoisan) languages and the southern Bantu languages (*e.g.,* Zulu, Xhosa, and Sotho), which borrowed them from the Bushman- and Hottentot-speaking peoples. Clicks are also common to three East African languages, Sandawe, Hadza, and Sanye, but nowhere else on the continent or outside it. The consonants *kp* and *gb,* called coarticulated labiovelar consonants, are, in Greenberg's words,

> distributed over a wide belt of languages of diverse genetic affiliations from the Atlantic Ocean almost to the Nile Valley. Outside of Africa these sounds are only known from a restricted area of Melanesia. . . .

Other phonological features common in Africa but rare in the rest of the world are word-initial combinations of a nasal sound plus another consonant (*e.g., mb* or *nd*), and implosive consonants.

Grammatical features. In some African languages, words generally consist of a root only, with grammatical affixes rare and even nonexistent in a few languages. These are often referred to as isolating languages. Other African languages have words that are composed of many elements. Those languages are subdivided into the agglutinative languages (in which each element of a word has a distinct and separate meaning and form) and inflectional languages (in which the various elements of meaning may be fused into such forms as prefixes or suffixes or the entire word may change internally to indicate grammatical relationships).

In some of these languages, a single word might be equivalent to a whole sentence in English or other European languages. Thus, in Swahili, a Bantu language, "we will not hit him" is expressed in a single word, *hatutampiga,* in which *ha* is the negative marker, *tu* the verb subject "we," *ta* the future-tense marker, *m* the verb object "him," and *piga* the verb "hit." The verb likewise may undergo modifications in meaning through the addition of suffixes; thus *pigwa* means "(to) be hit," and *pigana* "(to) hit one another."

Noun classes and gender

A widespread feature among African languages employing words composed of more than one element is a system of noun classes (see below *Benue-Congo subgroup*), particularly marked in the Bantu family but also occurring in a wide variety of West African languages, as well as in certain languages of the Northern and Southern Kurdufān provinces, The Sudan. All of these languages have been grouped by Greenberg in his Niger-Kordofanian family, although others in this family lack this feature altogether.

Grammatical sex gender is not nearly as widespread as noun classes. It is characteristic of the Semitic and Hamitic languages (although lacking in some members of the Chadic branch) and of other languages such as Hottentot and the closely related Naron Bushman language of South Africa and of the much more distantly related Sandawe and Hadza languages of Tanzania. Gender is likewise found in East Nilotic but not South Nilotic (these two comprise what was earlier known as "Nilo-Hamitic") or West Nilotic (previously known simply as Nilotic). Gender plays an even more restricted role in other African languages, such as Bongo, a language of the southwestern Sudan in which different pronouns are used for masculine and feminine 3rd person singular. The great majority of African languages, however, do not make this distinction, but many of them do distinguish between animate and inanimate personal pronouns.

Linguistic, racial, and cultural interrelations. It is difficult to find strict correlations between linguistic, cultural, and racial groupings, either in Africa or elsewhere in the world. Groups speaking identical or closely related languages may be strikingly different racially, culturally, or both; while groups that are very similar racially and culturally may speak different and even unrelated languages. Thus the Damara (or Bergdama) of South West Africa/Namibia, who speak the language of the Nama Hottentot, are sharply distinguished from the latter both racially and culturally. The Damara have much darker pigmentation and other more Negroid physical features and are predominantly nonpastoralists. Likewise, the Arusha of northern Tanzania, who speak the language of the pastoralist Masai, are horticultural (*i.e.,* agricultural without use of the plow). On the other hand, the forest-dwelling Pygmies, who are spread over much of central Africa, form a distinct racial and cultural group and are exclusively hunters and food-gatherers, yet they have no distinctive language. Instead, they speak the languages of their various neighbours, such as Bantu, Moru-Mangbetu (grouped by Greenberg in the Central Sudanic branch of Chari-Nile), and reportedly Sere-Mundu (grouped by Greenberg in the Adamawa-Eastern branch of Niger-Congo).

Broad correlations between race, language, culture

Some broad correlations can nevertheless be made between language groupings and the variables of race and culture, as long as these are not interpreted too rigidly. The Bushmen of southern Africa form a distinct racial, cultural, and linguistic group, and, though the Hottentot are akin to them linguistically and racially, they show important cultural differences, most notably that the Hottentot are pastoralists, not hunters and gatherers. The Berber-speaking peoples of North Africa likewise form a relatively homogeneous racial, cultural, and linguistic group; they are Caucasoid and pursue a mixed agricultural and pastoral way of life. Only the Sahara-dwelling Tuareg are exclusively pastoral nomads and caravaners. The Cushitic peoples of northeastern Africa, who like the Berbers speak languages of the Hamito-Semitic family, represent varying degrees of Caucasoid and Negroid elements. Some of the more prominent among them, such as the Beja or Bedawiye of The Sudan and the Saho-Afar and Somali of the Horn, are nomadic pastoralists. The Galla of southern Ethiopia, the most numerous of all Cushitic peoples, include some pure pastoralists, but the great majority practice agriculture and husbandry. Their neighbours to the north, the Agau of central Ethiopia, do likewise, though they have largely assimilated culturally to their Semitic-speaking neighbours, while retaining their Cushitic form of speech.

The unusually tall and slender Nilotes of The Sudan, such as the Dinka and Nuer, are sometimes considered a subrace of the Negroid; but it has also been suggested that their physical peculiarities are at least to some extent the result of differences in diet rather than heredity. Herding of cattle and other livestock is predominant among the majority of Nilotic peoples (including the socalled "Nilo-Hamites"), but nearly all practice some horticulture, with the striking exception of certain groups of Masai. Certain Nilotic peoples, however, are predominantly sedentary horticulturalists, such as the Anuak of The Sudan and the Luo, principally in Kenya, who are the most numerous of the Nilotic peoples.

The overwhelming majority of the Bantu and the peoples of western and central Africa are sedentary horticulturalists. Likewise, most of these peoples belong linguistically to Greenberg's Niger-Congo family, although some fall within Nilo-Saharan, and others within the Chadic branch of Hamito-Semitic; furthermore, they comprise the overwhelming majority of the Negro race, which, however, is no more homogeneous a physical group than the peoples

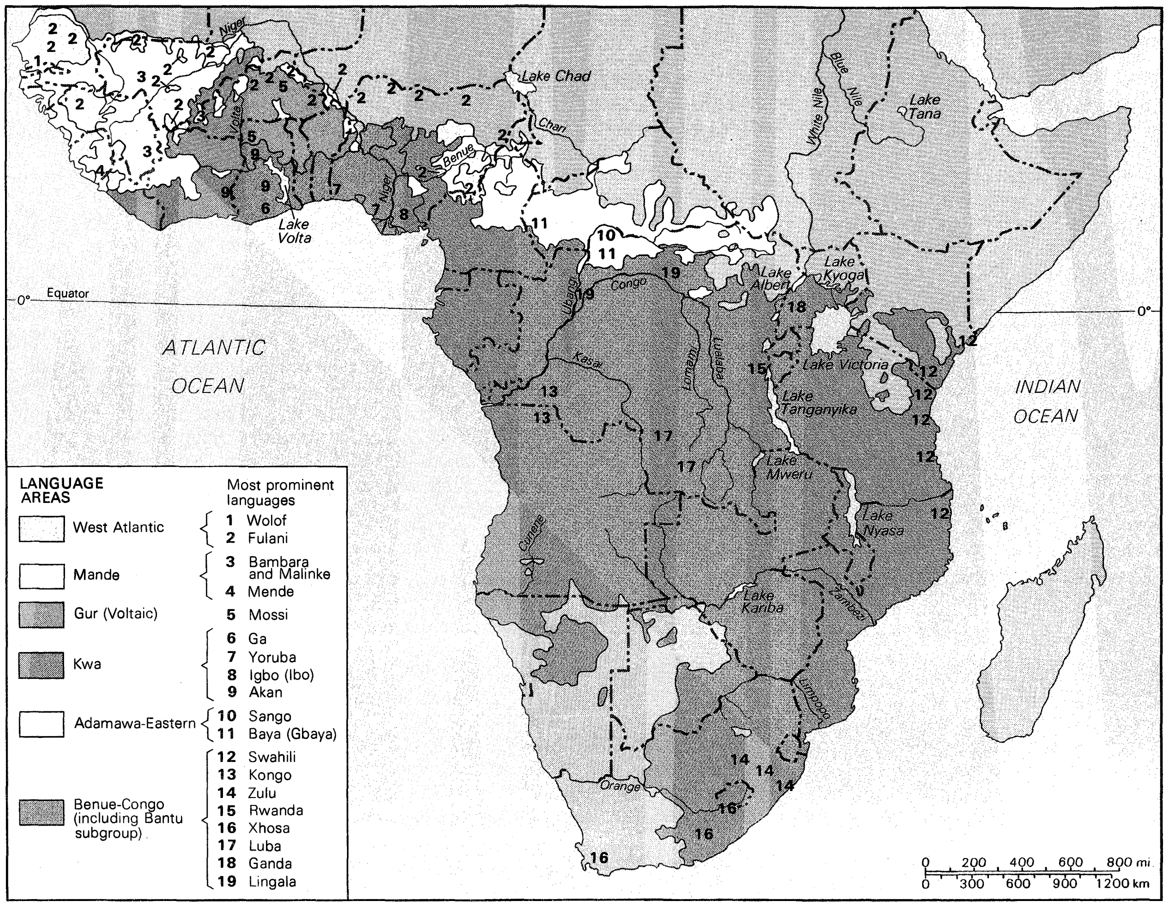

Figure 31: Distribution of the Niger-Congo languages.

West Africa are the cattle-herding Fulani, who are widely distributed over the savanna belt just south of the Sahara. They are physically as well as culturally distinct from their neighbours, but linguistically their closest affinities are with the sedentary horticultural Negroes of Senegal. Cattle raising likewise plays an important role among certain Bantu peoples of eastern and southern Africa, such as the Ganda, Nkole (Ankole), Sotho, and Nguni peoples. Among some of the East African Bantu (*e.g.,* the Nkole, Rwanda, and Rundi) cattle ownership has been the prerogative of a privileged group probably of Nilotic origin and known by various names, such as Hima (Panda) and Tutsi; these people are physically and culturally distinct from their agricultural neighbours, although totally assimilated to them linguistically. (M.F.Go.)

Niger-Congo languages

The Niger-Congo family is the largest family of languages in sub-Saharan Africa, with 890 known member languages. All of them are considered to be distinct languages and not simply dialects. The named dialects of these languages number in the many thousands; if the variant names for the same language or for the same dialect are to be counted, the figure must be further expanded. For example, for Swahili, there are 17 named separate dialects, 15 additional variant names for some of the dialects, and at least four "nicknames" for popularized or debased forms of the language.

The classification of such an enormous and diverse family was first accomplished in 1949 by Joseph Greenberg, who demonstrated the genetic unity of this group on the basis of an examination of documentation of all the languages of Africa. The primary sources for such a massive comparison consist of published descriptions or vocabularies of tribal languages made by missionaries and colonial officers; these were written in European languages because practically none of the African languages had any written tradition of their own. Usable documents stretch back for only about 125 years, and there are still a number of indigenous languages that either have not been reported at all or lack sufficient detail or accessibility to be included in any final count of Niger-Congo languages. As a consequence, the figure given here may have to be revised upward, especially as there is no evidence that the indigenous languages of sub-Saharan Africa are dying out. Quite to the contrary, of a list of such languages collected during the mid-19th century, only one is known to have become extinct.

Location of the Niger-Congo languages

The area in which the Niger-Congo languages are spoken is fairly easily demarcated (see map) and includes the entire sweep of sub-Saharan Africa with the exception of the Horn of Ethiopia. All indigenous peoples of sub-Saharan Africa west of the Nile are speakers of Niger-Congo languages with the exception of a few to the extreme south (Bushman-Hottentot peoples) and a more substantial number along the northern rim of the area (speakers of Chadic or Nilo-Saharan languages).

A conservative estimate of the total number of speakers of Niger-Congo languages is 300,000,000. Such a figure is obtained by adding the populations (as of the early 1980s) of the 32 countries of tropical and southern Africa and then subtracting the number of European and Asian speakers reported for South Africa. (It is assumed that the number of speakers of Niger-Congo languages in the countries to the north of the tropical belt omitted by this method—especially in Mali and Upper Volta—would be balanced out by the number of indigenous non-Niger-Congo speakers enumerated in the included populations—especially in Nigeria and Uganda.)

CLASSIFICATION

The Niger-Congo family is divided into six genetic subgroups. Viewed on a geographical continuum from northwest to southeast, these are:

1. West Atlantic, 43 languages
2. Mande, 26 languages

3. Voltaic (Gur), 79 languages
4. Kwa, 73 languages
5. Adamawa-Eastern, 112 languages
6. Benue-Congo, 557 languages

Niger-Kordofanian

This subclassification results from very fundamental and very old divisions in the language family, and each subgroup represents the results of separate developments that can be estimated to be about 5,000 to 10,000 years old at the least. Obviously, such a deep division has yielded widely separated languages—separate not only in geographic distribution but in elements of the sound systems, grammars, and vocabularies as well. It is surely safe to say that there is no one feature common to the entire group and that the recognition of their relationship depends upon a truly global view of the evolution of a few separate ancestral languages into the thousands of descendant languages spoken throughout the world today. Because this linguistic evolution is neither random nor chaotic, it is possible by means of a very careful plotting of common clusters of features to establish the approximate degrees of relationship even when neither the intermediate nor earliest stages of the protolanguages concerned have been reconstructed. Greenberg used this method to include the nearest relatives of the Niger-Congo languages with them in a superfamily that he designates as "Niger-Kordofanian." This grouping contains two branches: all the languages here considered, namely the Niger-Congo family, and a coordinate branch of the Kordofanian family of languages, spoken in the Nuba Hills (Jibāl an-Nūbah) of Southern Kurdufān province, The Sudan.

Table 58: Niger-Congo Languages with More Than Five Million Speakers

	subgroup	estimated number of speakers*
Fulani (Fulbe)	West Atlantic	11,500,000
Yoruba	Kwa	18,100,000
Igbo (Ibo)	Kwa	14,700,000
Akan group	Kwa	8,600,000
Kongo	Benue–Congo	6,300,000
Zulu	Benue–Congo	5,500,000
Rwanda (Banyaruanda)	Benue–Congo	5,200,000
Xhosa (Xosa)	Benue–Congo	5,300,000
Luba	Benue–Congo	5,100,000
Shona	Benue–Congo	5,400,000

*Figures rounded off to the nearest 100,000.

West Atlantic subgroup. The centre of gravity of the 43 West Atlantic languages would seem to lie in the Senegal–Guinea area, in which are found the two most important languages of the subgroup—Wolof and Fulani (the latter of which is also known as Fulbe, Fula, and Peul). The area is also the locus of the great majority of the other languages in the subgroup. Fulani, the language of a highly mobile pastoralist people numbering as many as 11,500,000, is also found in a scattered distribution as far east as Chad. The immense extension of this language, together with its association with cattle and Islām, led earlier researchers to give it a special place apart from the other West Atlantic languages—in fact, outside what is now recognized as Niger-Congo. It was first isolated in 1883 by an Englishman, Robert Needham Cust, who based his work on that of Friedrich Müller, an Austrian linguist. The German Karl Richard Lepsius classified it as one of the "mixed Negro" languages not fully sub-Saharan or Bantu (1880). Subsequently, it was included as a "Hamitic" language in the German Africanist Carl Meinhof's influential classification (1912), which was adopted by many scholars writing in English.

A feature of Fulani that is shared systematically with some of the other West Atlantic languages is an "alternation" whereby both the beginnings and the endings of words go through parallel changes according to grammatical considerations. This feature is found in its greatest elaboration only in Fulani; it is represented in either vestigial or undeveloped form in most of the other West Atlantic languages. This fact made Fulani appear more different from the others than it actually is and contributed to its misclassification. It is of interest to speculate why this most "vigorous" of the West Atlantic languages should be the most difficult or complex in its grammatical system. ("Vigorous" is used here in the sense that it has several millions of speakers, and also in the sense that it is associated with a dynamic expansionism). By comparison, Latin indicated grammatical case, gender, and number only by the endings of words, and English has virtually eliminated case and gender and has largely simplified number to a single suffix.

Bambara and Mende languages

Mande subgroup. The Mande subgroup includes 26 languages, of which the most prominent are Bambara of the Mali–Guinea area and Mende of Sierra Leone. In contrast to the classification of the West Atlantic subgroup, there has been little doubt as to the identification of the languages in the Mande subgroup. This certainty results from the subgrouping conforming closely to the "classic" expectation of language differentiation, in which a small number of contemporary languages are clearly seen to share a number of striking features not found elsewhere. Such features presumably provide evidence of early segregation of the ancestor language of the subgroup and of a continued effective isolation. Examples of such key features in the Mande languages are the systematic distinction between free and dependent nouns (see below) and the form and use of numerals.

As would be expected, however, the results of a longer period of independent development have also deflected the attention of many researchers to the differences of Mande from the Niger-Congo group—*i.e.,* to the common negative evidence of relationship with the rest of the Niger-Congo family. This negative evidence led Maurice Delafosse, in 1924, to propose two criteria for the identification of this subgroup: (1) a complete absence of the noun-class system that characterizes other West African languages and (2) a complete absence of tonal contrasts. Investigators who view Mande languages in terms appropriate to the group itself have shown that this is a prejudiced view and that a more positive formulation of these criteria is possible. Such a restatement would run somewhat as follows: (1) Instead of the particular distinctions among nouns reflected in the grammatical classes of the other subgroups of Niger-Congo, the Mande subgroup has elaborated a grammatical distinction between free and dependent nouns—nouns referring to "alienable" or "transferable" possessions, as opposed to "inalienable" possessions such as kinsmen or parts of the body. (2) The role of tone is tied to features other than those of semantic reference (*i.e.,* the meaning of the word taken in isolation).

Role of tone in the Mande languages

Whereas Chinese and other tone languages use changes of pitch to distinguish meaning in words with the same configuration of consonants and vowels (when pronounced by themselves), the Mande languages reveal a different use of tone, one that also differs from practically all the other Niger-Congo languages. In the Mande languages, a difference in meaning based on tone seems to demand a contrast of complete utterances, which are usually made up of more than one word. This contrast of entire utterances places Mande at one end of a continuum of distinctions based on tone, because linguists are still finding many variations in the situation of "meaningful semantic tone" or "contrastive tone patterns in isolation" that seem to demand some sort of context in order to be operative. In this respect, it is of interest that most of the differences in meaning between complete utterances that are identical except for tone in the Mande languages are more of a grammatical nature than of a semantic one. It must be stressed, however, that the Mande languages *are* tone languages and that the contrasts so produced are discrete and absolute and thus not of the "sliding" nature of speech melody. In form, they are closer to the question intonation of English, but in function they perform grammatical work internal to the sentence rather than coextensive with it.

It is striking that several independent writing systems based on the syllable (which is the unit that bears the tone) have been reported for Mande languages. the best known of these is the one devised for the Vai language, although Mende, Toma (Loma), and Kpelle also have indigenous syllabic writing systems. This type of writing is somewhat reminiscent of the writing system of Chinese (in which the syllable is often both the tone-bearing unit and the meaning-bearing unit) and of Cherokee, an American Indian language.

Voltaic (Gur) subgroup. The Voltaic (Gur) subgroup includes 79 languages spoken in Upper Volta and the upper halves of Ghana and Ivory Coast. Mossi is the most prominent of them. The term Gur was used as early as 1886 to designate the languages centred around Ouagadougou in what is now Upper Volta and northern Ghana. Languages with such names as Gurma or Grunshi (Gurunsi) were later related, and the first syllable of the names was taken as a name for the group. In 1911 Delafosse used the designation "Voltaic" for the same group, probably because many of the Gur languages are spoken in the Volta River Basin.

Typological significance of the Voltaic languages

The study of the Voltaic languages as a group is important because they do not partake strongly of any entrenched typological or grammatical "manifestations" (such as the "manifestations" of sex gender distinctions in Indo-European, triconsonantal roots in Semitic, and so on). A wide range of possibilities is present, and, if any "manifestation" is at all apparent, it is a tendency toward simplification and serial constructions. This means that there are a very small number of closed grammatical classes and a greater reliance on constructional markers. Nevertheless, it is important, when considering any of the 1,000 or more languages surveyed in this article, to emphasize that each language within the subgroup is also important for its own sake. Each language reveals a particular way of communicating about the world, a way that is fully developed and elaborated in its own terms. These spoken languages are certainly not "underdeveloped" or primitive. In fact, the very complexity of analyzing the Voltaic languages (or any other group of natural languages) in terms and categories sufficiently "universal" to be operational both for those who already speak the languages and those who want to learn something about them reflects their developed nature.

The most widely known characteristic of the Voltaic (Gur) languages is the realization of the Niger-Congo noun classes in the shape of parallel prefixes and suffixes, in which the suffixes appear to be dominant. In languages like Mõõre and Dagbane, for instance, nouns for a "person" end with the suffix *-a* (*-u* in Kasem), which is replaced by *-ba* in the plural. This feature is somewhat reminiscent of Fulani of the West Atlantic subgroup but differs in that it typically appears in the form of separable syllables in the Voltaic languages, rather than as an alternation or mutation of the beginning and ending consonants of the root itself, as in Fulani. The partial classification of human beings, animals, and liquids into separate grammatical classes provides evidence for the original nature of such classes in the ancestral Niger-Congo language. So does the fact that this classification governs the participation of variant forms of the detachable suffixes (or suffix–prefix frames) in sentence constructions calling for pronoun-like behaviour—referential, possessive, demonstrative, relative, and so on. Thus, Bargu has the suffix *-a* for the "person" class, a suffix that always "governs" the occurrence of *yé* as independent pronoun, *yù* as object marker, and *yè* as one demonstrative.

Ga, Yoruba, Igbo: prominent Kwa tongues

Kwa subgroup. The Kwa subgroup includes 73 languages, many of which are prominent (*e.g.*, Ga, Yoruba, Igbo). This grouping includes some of the most well known of the Niger-Congo languages and some with the greatest number of speakers. The Kwa languages are spoken in the belt of tropical forest through the southern section of the West African bulge. They are the languages of the former great kingdoms of tropical West Africa, such as Ashanti (Akan or Twi language), Dahomey (Ewe), Oyo (Yoruba), and Benin (Edo, or Bini language). In addition, the large decentralized group of Ibo (Igbo) also speak a Kwa language. Each of these languages has millions of speakers and a growing written literature, and one of them, Yoruba, boasts the earliest published dictionary and grammar written by a native speaker. It is symptomatic of the position of these languages in modern life, however, that these Yoruba works were written in English by an African Anglican churchman, Bishop Samuel Crowther. English or French remains the national language of the countries in which Kwa languages are spoken, and interest in employing the local languages is largely restricted to religious or academic institutions based on European models.

Like the Voltaic subgroup, the Kwa languages are diverse in their structure and characteristic features, and examples of this diversity are found in the roles of tone and vowel harmony. The continuum from clear tones in isolated dictionary citations to modification in sentence context referred to in connection with the Mande languages is particularly striking in the Kwa languages. Thus, some investigators heard consistent pitch levels that could be noted on a musical staff for any one speaker (in at least one Kwa language, Grebo of Liberia, there are four such levels). Others, such as those investigating Akan, heard just as clearly that there is a complicated system of pitches that are varied according to transitions between syllables or interrelations among syllables. It is as yet unclear just which, if either, of these systems is historically earlier: whether the clear tone levels are a crystallization of the distinctions imposed by contextual reactions with other tones or whether the languages that have almost lost all independent lexical tone are a newer reinterpretation of a previous system of fixed pitches.

Vowel harmony in the Kwa tongues

Vowel harmony involves a system of mutual selection or restriction among the vowels that can go into the makeup of a word. The vowels in a word are said to be in "harmony," with high vowels usually occurring with high vowels, front vowels with other front vowels, and so forth, in such a way that a constant feature seems to be realized throughout the word. Vowel harmony of a type peculiar to sub-Saharan languages is called "cross-height" vowel harmony by the British scholar John M. Stewart. In this situation, the higher of two varieties of a vowel selects the matching higher variety of another vowel and vice versa. Thus, *u* (as in "rule") would occur with *o* (as in "bone"), and the lower sound ʊ (as in "pull") with the correspondingly lower ɔ (as in "law"). Stewart also summarized evidence for contrast in the formation of the sounds in terms of the advancement of the root of the tongue. Under conditions of change of a vowel system, this leads to reinterpretations that cloud the nature of earlier contrasts and add to the variety found in the Kwa languages.

It is very difficult to provide a generalized "profile" of the Kwa languages that would give an idea of what is typical of a language of this subgroup. A stereotype would be that the words are mostly short and the nouns begin with vowels. Proper names often appear to be quite long, however, because they are compounds or phrases made up of several words. Many words of Kwa origin are found in the Americas, as is the pantheon of Yoruba gods in South America and the Caribbean.

Adamawa-Eastern subgroup. The Adamawa-Eastern subgroup comprises 112 languages spoken in the Central African Republic and northern parts of Cameroon and Zaire. These geographically remote languages are the least known of the Niger-Congo family. The subgroup's most prominent members are Sango and Baya (Gbaya). The name Adamawa-Eastern implies a combination of two recognized sub-subgroups: Adamawa and Eastern. None of the language names of this subgroup is well-known to outsiders, with the possible exceptions of the ethnographically noted Azande (Zande) and the trade language Sango.

Sango is clearly simplified from a dialect of one of the Adamawa-Eastern languages. It shows the result of contact with French as well as the usage of many river tribes in trade along the Ubangi River. It is the lingua franca of the Central African Republic and is extremely widespread as a second language in Central Africa. Many other pidginized trade languages based on an African vernacular are also spoken in this central area of the great rivers; *e.g.*, a pidgin dialect of Swahili, Kituba (a pidgin form of Kongo [Kikongo]), and Lingala.

Benue-Congo subgroup. The Benue-Congo subgroup comprises 557 languages, spoken from Nigeria to South Africa. Its most prominent members include Swahili, Kongo (Kikongo), and Zulu. In terms of numbers of speak-

Bantu, largest Benue-Congo subgroup

ers and geographical extension, Benue-Congo and Bantu are practically the same entity. That is, compared with the many millions of speakers of Bantu, the speakers of non-Bantu languages are only a tiny minority of Benue-Congo speakers. Furthermore, the Bantu speakers are spread out over most of middle and southern Africa, whereas the remainder of Benue-Congo speakers occupy only a corner of the northwest extension, mostly in Nigeria. The only two major non-Bantu Benue-Congo languages are Efik and Tiv, found in eastern Nigeria.

The following description sacrifices a consideration of the numerous but less important non-Bantu languages of the subgroup for a still superficial view of the Bantu languages. The most notable feature of the Bantu languages is their system of noun classes (concord). This has also been called "alliterative" concord because it often entails a repetition of the same syllable as prefixes at the head of successive words in the sentence. An example, drawn from Swahili, provides an illustration: *wa-tu wa-le wa-mefika* (noun-demonstrative-verb) "those people have arrived." Such prefixes as *wa* represent an intersection of two systems: one syntactic (function in the sentence) and the other paradigmatic (mutually exclusive replacements in the same position in the sentence). Syntactically, the shape of the prefix can vary according to the part of speech to which it is attached—a prefixed syllable may be different in the noun, adjective, possessive, locative, or verb. That there is agreement (*i.e.,* a concord element is present) with virtually all parts of speech creates an aesthetically pleasing system by means of an exhaustive display of marked relationships in the sentence.

Noun concord in Swahili

Paradigmatically, the system of concord is most simply viewed as being based upon the governing noun in its singular or plural form. That is, the noun belongs to one of a number of noun classes that determine the proper set of concording elements to be used throughout the part of the sentence dominated by that noun. These sets (which can be thought of as replacement sets) come in pairs according to whether the governing noun is singular or plural; *e.g.,* in Swahili, the singular form *m-tu yu-le a-mefika* "that person has arrived" contrasts throughout with the plural form *wa-tu wa-le wa-mefika* "those people have arrived." This alternation of singularity and plurality is, of course, more closely related to the semantics of the noun than to its purely grammatical function. The paradigmatic system goes even further in this direction by making a rather loose use of other possible semantic contrasts (especially: person–nonperson and countable–noncountable) in assigning nouns to noun classes. In no language, however, is there a strict relation between meaning and noun class. Nevertheless, the tendency in this direction again stimulates a sense of completeness of aesthetic form and has added to the fame of Bantu languages as abstract figures.

Correlates of these noun classes (in both form and function) are found in all branches of Niger-Congo except Mande and only slightly in Kwa. This led some early researchers to combine all of them as one subgroup and later led to a typological distinction between noun-class and non-noun-class languages. This distinction is not very useful, however, because there are a number of languages with rudimentary or partial noun-class systems, and it even seems possible for a language of entirely different ancestors to adopt noun prefix alternation.

Area of tonal reversal

Swahili remains the best known Bantu language. It is the national language of Tanzania and is used as a lingua franca throughout East Africa. The use of Swahili for this purpose is facilitated because it no longer makes use of tone—it is an isolated non-tone language in the Bantu area. There is another phenomenon related to tone in the Bantu languages besides its disappearance in Swahili that should be mentioned: there exists an area of "tonal reversal," a geographic area centred in the western Congo in which the tonal realizations in words and sentences are the mirror images of what they are elsewhere in Bantu languages; *i.e.,* high tones become low tones, and vice versa.

Another distributional characteristic is the presence of a prefix form made up of two syllables as opposed to the form with only one. Following out the implications of the geographic distribution as well as the function of this feature is of help in mapping the prehistory of the Bantu languages. As in all other areas of the world, however, it is the distribution of certain items of vocabulary, or of vocabulary replacements, combined with the application of laws of sound change, that produce the most valuable historical conjectures. An impressive amount of work has been done on the reconstruction of ancestral Bantu word roots and the sound system used to realize them. As early as the 1890s, Carl Meinhof postulated an original sound system and started working out the shifts that it had been subjected to in order to produce the various Bantu languages as they are spoken today. Meinhof called his systematic reconstruction Ur-Bantu, and most subsequent historical research (and much actual description of contemporary languages) has been based on his surprisingly trustworthy descriptions. *Comparative Bantu* (4 vol., 1967–70), by Malcolm Guthrie of the University of London, is a much fuller and more painstakingly detailed compendium of the entire geographical distribution of the Bantu languages.

Although textbooks and lessons have been published for many Niger-Congo languages, those of the Bantu area are by far the most numerous. In part, this availability reflects the influence of the South African linguist Clement Doke and the department of Bantu studies at the University of the Witwatersrand, which was in direct touch with a huge area of Bantu-speaking peoples.

ADOPTION OF FOREIGN WORDS AND SOUNDS

Borrowing of click sounds

All the subgroups of Niger-Congo contain languages that show evidence of intensive contact with each other or with languages outside the group to such an extent that special mechanisms are in operation for the inclusion of borrowed words (such as the assignment of nouns to a particular noun class). This does not make them especially unusual from the standpoint of the world's languages, but the borrowing of the very difficult click consonants from the neighbouring Bushman-Hottentot languages into the Bantu languages of South Africa is definitely remarkable. Clicks are especially widespread in Zulu and Xhosa—the first consonant of even the name Xhosa itself stands for a click. This dramatic exception to the theory of language change that states that languages alter in order to simplify or economize the effort of sound production seems to require a special explanation. Possibly in-marrying Bushman or Hottentot wives used their native click sounds as disguised forms of words that would be taboo in Zulu or Xhosa. (D.W.C.)

Chari-Nile and Nilo-Saharan languages

The term Chari-Nile refers to a group of languages presumed to be genetically interrelated, or descended from a common ancestral language. Joseph Greenberg proposed the Chari-Nile family as part of his overall classification of African languages. At first, he designated the group by the name Macro-Sudanic (1955), but in 1963 adopted the term Chari-Nile. The name Chari-Nile is geographically descriptive in that virtually all of the languages in the family are located in the watersheds of the Nile and the Chari rivers or in the areas in between them.

CLASSIFICATION

The larger Nilo-Saharan group. Greenberg, as of 1963, regarded Chari-Nile as only a branch of a larger family, Nilo-Saharan, of which it is by far the most heterogeneous. The other branches of Greenberg's Nilo-Saharan family are: (1) Songhai, an important language with no close relatives, which consists of a number of dialectal varieties (*e.g.,* Zerma) spoken along the Niger River in Mali and Niger; (2) Saharan, a language group including Kanuri, the major language of northeastern Nigeria, as well as its relative Teda and its more distant relative Zaghawa, both of which are spoken to the east of Kanuri, principally in Chad, but also in The Sudan; (3) Maba, a group of interrelated languages of Chad; (4) Koma (also written Coman), a group of interrelated languages of the Ethiopia–Sudan border area; and (5) Fur, a language of Northern and Southern Darfur provinces, The Sudan.

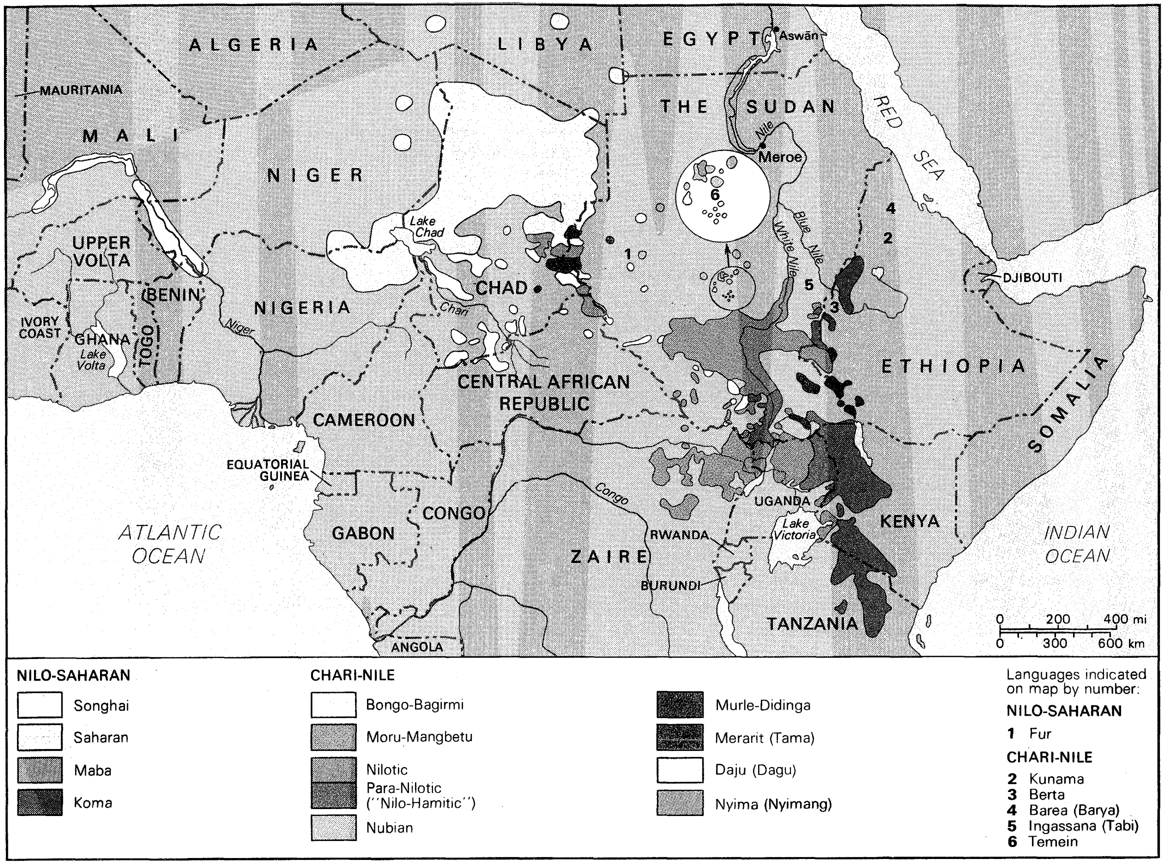

Figure 32: Distribution of the Nilo-Saharan and Chari-Nile languages.

Adapted from A.N. Tucker and M.A. Bryan, *Linguistic Analyses: The Non-Bantu Languages of North-Eastern Africa* (1966); Oxford University Press (for International African Institute), London

Languages of the Chari-Nile group. Greenberg considered Chari-Nile to be composed of four branches. The first, Kunama, is a language of northern Ethiopia (Eritrea), contiguous to Barea (Barya), an Eastern Sudanic language (see below); Berta, the second branch, is spoken in the Ethiopia–Sudan border area. Central Sudanic, a large and heterogeneous group of languages, extends over northwestern Uganda, the southern Sudan, northeastern Zaire, Chad, and the Central African Republic, although it is interspersed with languages of other groups. The British Africanists Archibald N. Tucker and Margaret A. Bryan (1956) regarded Central Sudanic as two distinct unities, which they hesitated to group together; one group is Bongo-Bagirmi, of which Bagirmi, Sara, and a number of other languages are found in Chad and the Central African Republic, while Bongo and its closest relatives are concentrated in the extreme south of The Sudan near the Zaire and Uganda boundaries. The other division is Moru-Mangbetu (like Bongo and Bagirmi, these are the names of individual languages), which is concentrated in northeastern Zaire but overlaps into Uganda. In addition, it includes Efe, Lendu, and Madi, which is linked to Moru. The fourth and most heterogeneous branch of Chari-Nile is Eastern Sudanic.

The 10 subgroups of Eastern Sudanic

Eastern Sudanic consists of 10 subgroups: (1) Nilotic extends from southern Sudan through Uganda, Kenya, and northern Tanzania, although it is interspersed with languages of other groups, and includes the so-called "Nilo-Hamitic" languages. (This name is controversial; see below *Nilotic and "Nilo-Hamitic."*) The Nilotic subgroup includes Shilluk, Dinka, and Nuer in the southern Sudan, Acholi in northern Uganda, and Luo, in western Kenya along Lake Victoria but overlapping into Tanzania. The Nilo-Hamitic languages include Bari and Lotuko (Lotuho) in the extreme south of The Sudan; Karamojong in northern Uganda (just to the west of Acholi) and its neighbour and close relative Turkana across the border in Kenya; Nandi and Suk, just to the south of Karamojong; and Masai, extending from southern Kenya into northern Tanzania.

(2) Nubian is spoken along the Nile from Aswān, Egypt to Meroe, The Sudan (*i.e.,* Nile Nubian), and a number of dialect enclaves in the Nuba Hills of Southern Kurdufān province, The Sudan (*i.e.,* Hill Nubian), as well as in two separate enclaves, Midobi and Birked, in Northern and Southern Darfur provinces, The Sudan. The relationship of Midobi and Birked to one another and to the other varieties is not close. Currently, Birked is giving way to Arabic. Nile Nubian consists of three languages, of which the northernmost, Kenuzi (Kenzi), and the southernmost, Dongolese, are closely related, almost to the point of mutual intelligibility; Mahas, located between the two, is a more distant relative and includes a subdialect, Fadidja, spoken to the north.

(3) Murle-Didinga designates a group of closely interrelated languages spoken on both sides of the Sudan–Ethiopia boundary; Murle and Didinga are individual languages within the group. (4) Barea (or Barya), a language of northern Ethiopia, is spoken just to the north of Kunama. (5) Merarit (also written Mararit), spoken on both sides of the Chad–Sudan border, comprises a group of closely interrelated languages; actually, Merarit is only one language of the division, which also includes Tama, for which the group is sometimes named. (6) Ingassana, also known as Tabi, is found in the eastern Sudan just north of Berta. (7) Daju, or Dagu, is the name of a group of closely related languages spoken in widely separated enclaves in Chad and The Sudan; most of them are called Daju or some variant of the name.

Recent additions to the Eastern Sudanic branch

Three subgroups of Eastern Sudanic were added by Greenberg in 1963; the first two had previously (1955) been treated as entirely independent language families, while the third had not been mentioned. These are: (8) Nyangiya, also known as Teuso, a group of dialects or closely related languages of northern Uganda, whose inclusion in Eastern Sudanic Greenberg regards as only tentative (this is omitted on the map); (9) Temein, a language of Northern and Southern Kurdufān provinces, The Sudan; and (10) Nyima, or Nyimang, also found in the

Kurdufān region. Another language, Afitti, spoken about 100 miles (160 kilometres) to the north, evidently should be grouped with Nyima.

Controversies concerning classification. There has been much disagreement about the classification of various groups of African languages and considerable confusion in terminology.

Objections to grouping Nilotic with "Nilo-Hamitic"

Nilotic and "Nilo-Hamitic." Some scholars have objected to grouping the so-called "Nilo-Hamitic" languages together with Nilotic. This question has been at issue since the earliest attempts at African linguistic classification. One of the first proposed systematic classifications (1877–78) established the very heterogeneous Nuba-Fula group, named for two of its members, Nubian (an Eastern Sudanic language, according to Greenberg) and Fula, or Fulani (a West African language). The group also included Masai, subsequently classified as "Nilo-Hamitic," but not the other Nilotic or "Nilo-Hamitic" languages. This classification, made in the 19th century by Friedrich Müller, was based mainly on a simplistic correlation with racial categories determined largely by hair type. Müller recognized a close affiliation between Bari (subsequently classed as "Nilo-Hamitic") and Dinka, a Nilotic language. Dinka, Shilluk, Nuer, and Bari were grouped under the heading Nile languages (*Nil-Sprachen*) within the Negro group, as distinct from the Nuba-Fula group. (Later Müller admitted the close affinities between Masai and Bari, previously pointed out by Karl Richard Lepsius, but attributed them to a mixture of two distinct elements in Bari.)

In 1880, Lepsius proposed another of the early classifications of African tongues. As a result of his views that Masai and Bari were related, the genetic affiliation of Masai, Bari, Nuer, Dinka, and Shilluk was generally accepted, and languages showing clear affinities to them were included as they became known (*e.g.,* Lotuko, Nandi-Suk, Luo).

In 1902 Sir Harry Johnston divided these languages into two groups, one of which he called Nilotic, including Dinka, Shilluk, Acholi, Alur, Lango, and Luo. He proposed no specific name for the second group, which later came to be known as "Nilo-Hamitic," but included in it Masai, Turkana, Lataka (*i.e.,* Lotuko), Nandi, Suk, and Karamojong. He posited a distant relationship between the two groups but also noted some striking lexical similarities between Somali (a Hamitic language) and the second, or "Nilo-Hamitic," group that led him to conclude that the latter resulted from a mixture of one group of people related racially and linguistically to the Somali and another related to the Nilotes.

Correspondence of Sir Charles Eliot's classification with Nilotic and "Nilo-Hamitic"

Most investigators of this period grouped these languages in much the same way as Johnston; for example, the English diplomat and scholar Sir Charles Eliot stated:

> East Equatorial Africa is the home of a group of tribes which cannot be called Bantu or Hamitic, and have received no satisfactory designation. The group contains at least two subgroups. One of these, including the Shilluk, Dinka, Bari, Acholi, and Jaluo [*i.e.,* Luo], inhabits the banks of the Nile and the shores of Lake Victoria; the other has its headquarters in the highlands of . . . East Africa. . . . Its chief members are the Masai, Nandi, Turkana, and Suk. . . . To these should probably be added Latuka [*i.e.,* Lotoho] but our information about it is slight. . . . Karamojo is not well known but is apparently closely allied to Turkana.

Except for Bari, which was put in the first group for reasons more geographic than linguistic, but which is actually closely related to Masai, Eliot's two divisions correspond exactly to Johnson's—namely, Nilotic and what later became known as "Nilo-Hamitic."

A sharply different view was introduced in 1912 by Carl Meinhof, who denied the linguistic unity of the two groups suggested by Johnston and Eliot. Meinhof regarded the term Nile (or Nilotic) merely as a geographic concept. He clearly considered Bari and Masai to be Hamitic languages (*i.e.,* related to Somali and Galla, among others) and also, presumably, Lotuko, Turkana, Nandi, and Suk. (He was not, however, explicit about these.) Dinka and its close relatives—Shilluk, Nuer, Luo, and others—were classified as Sudanic; the resemblances between the two groups (in particular those between Dinka and Bari, which had been pointed out by Müller) he attributed to borrowing. Meinhof's most important reason for allying Masai and its close relatives to the Hamitic languages was that in both groups nouns have grammatical gender and other inflectional complexities, which are absent in Nilotic languages such as Shilluk, Luo, and their close relatives.

Much earlier, Lepsius also had noted the presence of grammatical gender in Masai, a trait to which he attributed great importance for genetic classification, but he specifically ruled out any Hamitic affiliation because gender is expressed very differently in the Hamitic languages. Because of Meinhof's great prestige and preeminence among Africanist linguists, his views were widely accepted. The scholar Dietrich Westermann (in 1912), however, regarded all of the above as Nilotic languages, dividing them into the Niloto-Hamitic (Nilo-Hamitic) and Niloto-Sudanic subdivisions, which correspond to the groups delineated by Johnston. On the other hand, contrary to general practice, he also included among the Niloto-Sudanic languages another group, Moru-Madi, of western Uganda and eastern Congo. Greenberg subsequently included Moru-Madi within the Central Sudanic family, which he considered a branch of Chari-Nile and, thus, ultimately but distantly related to Nilotic.

Doubtful affiliation between "Nilo-Hamitic" and Hamitic

In 1935, Westermann claimed that the relation between Niloto-Sudanic and the Sudanic languages of West Africa was not as close as the relation of the latter to Bantu, whose interrelationship he had sought to demonstrate in 1927. Greenberg was to designate this family, Bantu included, as Niger-Congo. Westermann likewise expressed doubt as to the affiliation of "Nilo-Hamitic" to the Hamitic languages and reaffirmed the unity of Nilotic and "Nilo-Hamitic." Greenberg also adopted this position and argued persuasively against the relationship of "Nilo-Hamitic" to the Hamitic languages and, consequently, against the misleading nature of its name, which he changed to Great Lakes and which, together with Nilotic, formed the southern branch of his Eastern Sudanic family.

The German Africanist Oswin Köhler proposed, in 1955, the name Nilotic for the entire southern branch and divided it into three subdivisions: West Nilotic (including Nuer, Dinka, Shilluk, Luo), East Nilotic (including Bari, Masai, Lotuko, Karamojong), and South Nilotic (including Nandi, Suk, Tatoga). (The last two had usually been grouped together as Nilo-Hamitic, while the first had simply been designated Nilotic.) In 1963 Greenberg subsequently accepted Köhler's grouping and nomenclature. Tucker and Bryan, while still maintaining the unity of "Nilo-Hamitic" and hesitating to group it unequivocally with Nilotic (in the older restricted sense, equivalent to Köhler's West Nilotic), proposed a new name for the group, Para-Nilotic, thus avoiding any implication of Hamitic affiliation.

The wider relationships of the Nilotic family. The question of the relationship of Nilotic (in Köhler's extended use of the term) to other African languages and language families has been raised at various times. In 1920 the English anthropologist G.W. Murray noted similarities between Bari and Nubian and, in fact, between Nubian and the Nilotic and "Nilo-Hamitic" languages as a whole. He also linked these languages to Kunama, Barea, and the recently discovered Tabi (also known as Ingassana). Westermann suggested in 1935 that Didinga might be a distant branch of Nilotic and had earlier (1912) made a similar claim for the Moru-Madi group. All these languages were subsequently classed by Greenberg either as Eastern Sudanic or within the wider grouping of Chari-Nile.

Apart from Eastern Sudanic, the most heterogeneous subgroup of Chari-Nile is Central Sudanic. Its unity was first suggested in 1940 by Tucker, who included it in a group of languages that he called Eastern Sudanic, a term that he admitted was essentially geographic because it included another group of different and distinct languages, among them Ndogo-Sere and Azande. (Greenberg subsequently incorporated these into Niger-Congo.) Greenberg introduced a terminological confusion here by calling part of Tucker's Eastern Sudanic group Central Sudanic and using the name Eastern Sudanic for an entirely different group of languages. Although Tucker hesitated to unite the Moru-Madi and Bongo-Bagirmi languages—which together comprise Greenberg's Central Sudanic—into a single family, the evidence that he himself presented appeared to support such a grouping.

Opposition to Greenberg's groupings

Some scholars doubt that adequate evidence has been presented for regarding the whole of Eastern Sudanic as a valid subdivision of Chari-Nile or even for regarding the whole of Chari-Nile as a valid subdivision of Nilo-Saharan. Although Nilo-Saharan and the more heterogeneous subdivisions within it are far from conclusively established, no convincing alternatives have been suggested.

LINGUISTIC CHARACTERISTICS

The Chari-Nile languages are a very heterogeneous group whose structural features, both phonological and grammatical, are in no way uniform or easily characterized. Furthermore, the great majority of the languages are not adequately described, and their comparative study is still in its infancy.

Phonology. Nearly all Chari-Nile languages seem to be tonal (*i.e.,* words and grammatical forms are differentiated by pitch), as are the overwhelming majority of sub-Saharan languages. Some varieties of Nubian may be exceptions, but the question has yet to be fully investigated. Central Sudanic languages generally have only syllables that are open (*i.e.,* end in vowels); some final vowels in the Bongo-Bagirmi languages of this division, however, are semi-mute or whispered. Other Chari-Nile languages have syllables that are open as well as closed (*i.e.,* end in consonants). Central Sudanic languages likewise differ from other Chari-Nile languages in that they are the only ones with the labiovelar consonants *kp* and *gb* (articulated with both the lips and the soft palate), which are common in much of West and Central, but not East, Africa. As in other African language families, a large number of Chari-Nile languages distinguish dental from alveolar or retroflex stops, among them most Central Sudanic languages, Nyima, Temein, Murle-Didinga, Hill Nubian, and West Nilotic. (The dental stops, *t* and *d,* are pronounced with the tongue tip against the back of the upper teeth; the alveolar and retroflex stops are pronounced with the tongue tip farther back along the roof of the mouth.) Some Chari-Nile languages—most Central Sudanic languages, Daju, the Murle-Didinga group, and Bari (East Nilotic)—distinguish implosive and explosive voiced stops; the former are pronounced by drawing the air into the mouth, the latter by expelling it. The vowel systems of most Chari-Nile languages are fairly rich, the great majority seeming to distinguish seven or more vowel qualities. Apparent exceptions are Daju, Nile Nubian, and possibly Kunama, which have only five vowels. Many languages make distinctions in the length of vowels (*e.g.,* Nile Nubian, Nilotic, Daju, Kunama), but not all (*e.g.,* Central Sudanic, Nyima). In Nilotic languages a contrast exists between so-called breathy versus hard vowels, sometimes analyzed as close versus open. Nasal vowels occur in Sara-Mbai of the Bongo-Bagirmi group within Central Sudanic but in no other Chari-Nile language.

Vowel systems of the Chari-Nile languages

Grammar. No Chari-Nile language has concordial noun classes like those of Bantu (see above *Benue-Congo subgroup*) and many of its more distant relatives in West Africa, but grammatical gender is distinguished in three very different Chari-Nile groups. It is prominent in East Nilotic (*i.e.,* "Nilo-Hamitic" minus the Nandi-Suk-Tatoga group) but absent in the other Nilotic languages. There are two genders of nouns, normally indicated by a determiner (in Masai, these are *l* for masculine, *n* for feminine) with various grammatical functions. On the other hand, gender is not distinguished in the personal pronouns, but in Daju (grouped by Greenberg in Eastern Sudanic) there are three genders (masculine, feminine, neuter) distinguished in the 3rd person singular pronoun ("he," "she," "it") but not in the noun. The same usage occurs in Bongo but in no other Central Sudanic language.

A few Chari-Nile languages distinguish exclusive forms from inclusive forms of the 1st person plural pronoun. The exclusive pronoun excludes the hearer (*e.g.,* "he and I" = "we"); the inclusive includes him (*e.g.,* "You and I" = "we"). Among such languages are Lendu (alone among Central Sudanic languages), Daju, most West Nilotic languages, and Teso (alone among East Nilotic languages). Virtually all Chari-Nile languages except Berta and Nyima formally distinguish plural from singular nouns, some by means of prefixes (*e.g.,* the Moru-Mangbetu languages within Central Sudanic, and Temein) but most with suffixes (*e.g.,* the Bongo-Bagirmi languages within Central Sudanic, Kunama, Barya, Daju, Ingassana, Murle-Didinga, Nyangiya, and East and South Nilotic, which together comprise "Nilo-Hamitic"). West Nilotic utilizes suffixes sometimes, as well as change of tone, vowel length, or vowel quality. These processes can also be found to some extent in other branches of Nilotic. Affixes are sounds or groups of sounds that are added to the beginning (prefixes) or end (suffixes) of a word or inserted in the middle (infixes). In Chari-Nile, it has been noted that two pairs of singular-plural affixes are widespread, though not universal; these are also used to some extent outside this family. The affixes are *t* and *k,* confined principally to nouns, and *n* and *k,* principally used with pronominal elements. The *t* and *k* forms occur in fewer languages than the *n* and *k* ones, and only in languages in which the *n* and *k* are also found. The significance of these grammatical features for the historical and comparative study of the Chari-Nile languages remains to be investigated.

Widespread use of specific affixes in Chari-Nile

Writing. Only one Chari-Nile language, Nubian, has a written tradition of any antiquity. Dating from the 8th to the 11th centuries, the script was employed by Christianized Nubians in much the same area as that occupied by modern Nile Nubian speakers. Generally called Old Nubian, this written language most closely resembles Mahas among the modern dialects. It was abandoned after the Nubians adopted Islām and survives only in ancient manuscripts and inscriptions that were not deciphered until 1906. (Since the adoption of Islām, Nubian has occasionally been written in Arabic script.) Old Nubian utilized a script derived from that of Coptic, which in turn was adapted from the Greek alphabet. Coptic added seven non-Greek letters of Egyptian demotic origin to represent non-Greek sounds. Nubian retained three of these letters, in addition to adding three new ones from cursive forms of Meroitic letters.

Meroitic, the extinct language of an even more ancient Sudanese civilization (*c.* 300 BC to AD 100), may be related to the Chari-Nile languages, but too little is known to establish any conclusive tie. It is not closely allied to any existing language. Surviving only in inscriptions, Meroitic was written in a consonantal alphabet derived from Egyptian hieroglyphic writing and in a cursive form partly of Egyptian demotic and partly of indigenous origin. In the first decade of the 20th century the script was deciphered by the English Egyptologist Francis Griffith.

Languages using Latin-based alphabets

Since the colonial period a number of Chari-Nile languages, particularly in Kenya, Uganda, and The Sudan, have been written in derivatives of the Latin alphabet and are used for religious and educational purposes. Nearly all of the languages are Nilotic. Of these, Luo, a West Nilotic language and one of the major indigenous languages of Kenya, has the largest vernacular literature. It also has the largest number of speakers of any Nilotic tongue (and, in fact, of any Chari-Nile language). Other West Nilotic languages, however, such as Dinka and Nuer of The Sudan and Acholi of Uganda, have some vernacular literature, as does Kalenjin (Nandi-Kipsigi), a South Nilotic language of Kenya. (M.F.Go.)

Khoisan languages

The Khoisan languages are click languages spoken in southern Africa. The term Khoisan was created to refer to the related peoples known as Bushmen and Hottentots (*i.e.,* the Khoisanid peoples) under a common name and has become increasingly accepted since its creation in 1928. The word is derived from Khoikhoi and San, the names of the peoples called, respectively and pejoratively, Hottentots and Bushmen.

The languages of the group are now usually divided into three groups—North, Central, and South Khoisan. They are spoken by remnants of a pre-Bantu population, the so-called Bushmen, who are hunters and collectors liv-

ing in and around the Kalahari and who number about 78,000. A Khoisan language is also used by the so-called Hottentots, pastoralists surviving with about 50,000 Nama speakers in South West Africa/Namibia, where the Nama language has also been adopted by the Bergdama, a non-Khoisanid people (about 77,000), and by the Hai-⫽'om Bushmen (more than 3,000 speakers). The Khoisan family comprises about a dozen languages and dialect clusters such as Nama, !Kora, Naro, /Kham, !Khung, Kxoe, and others. (The unusual symbols in the names of the languages stand for clicks; they are listed in Table 59 and are explained below in the section on phonology.)

Problems of Khoisan genetic relationship

The assumption of a genetic relationship between all the languages of the Khoisanids and the application of the term Khoisan to this language "family" are problematic. Criteria brought forth against the point of view of a genetic relationship are the cleavage in morphology and vocabulary between sex-gender languages (Central Khoisan) and nongender languages (North Khoisan and South Khoisan), on the one hand, and a similar cleavage in morphology and vocabulary between North Khoisan and South Khoisan, on the other. These arguments are countered by the fact that there are a number of common words and a few particles, traceable by comparison of sound and meaning, in two or more of the three groups of Khoisan. These permit the establishment of a strong hypothesis for a genetic, though remote, relationship. Regular sound correspondence, however, has not been found in all common items; this is the most difficult part of the Khoisan problem.

The Khoisan hypothesis is built on: (1) common special features of the phonological system—*e.g.,* clicks are regarded as inherent to the languages; (2) widespread and common patterns of root formation, combined with special patterns of consonant distribution; (3) the occurrence of some probably related particles in more than one group; and (4) the occurrence of related words (sound-meaning units) in two of the groups, but more rarely in all three groups—*e.g.,* the terms for "chin," "lungs," "throat," and "wound."

In addition to Khoisan proper, there are two click languages, Sandawe and Hadza (Hatsa), spoken by peoples in Tanzania; these languages possess a few words, affixes, and particles that justify the assumption of a distant relationship with Khoisan. The apparent link between Central Khoisan and Sandawe is supported by the racial affinities of the Sandawe and Khoikhoi (Hottentot) peoples. The relations between Khoisan and Hadza are more remote. All studies on this subject are still in the initial stages. The U.S. linguist William E. Welmers proposed the tentative extension of the Khoisan family into Macro-Khoisan, including Sandawe and Hadza. In 1962 Joseph Greenberg subsumed Khoisan proper and Sandawe and Hadza under the title Khoisan.

Some Central Khoisan gender affixes were at one time considered as possibly related to the Hamitic languages. Today, the basis for the Hottentot-Hamitic hypothesis is

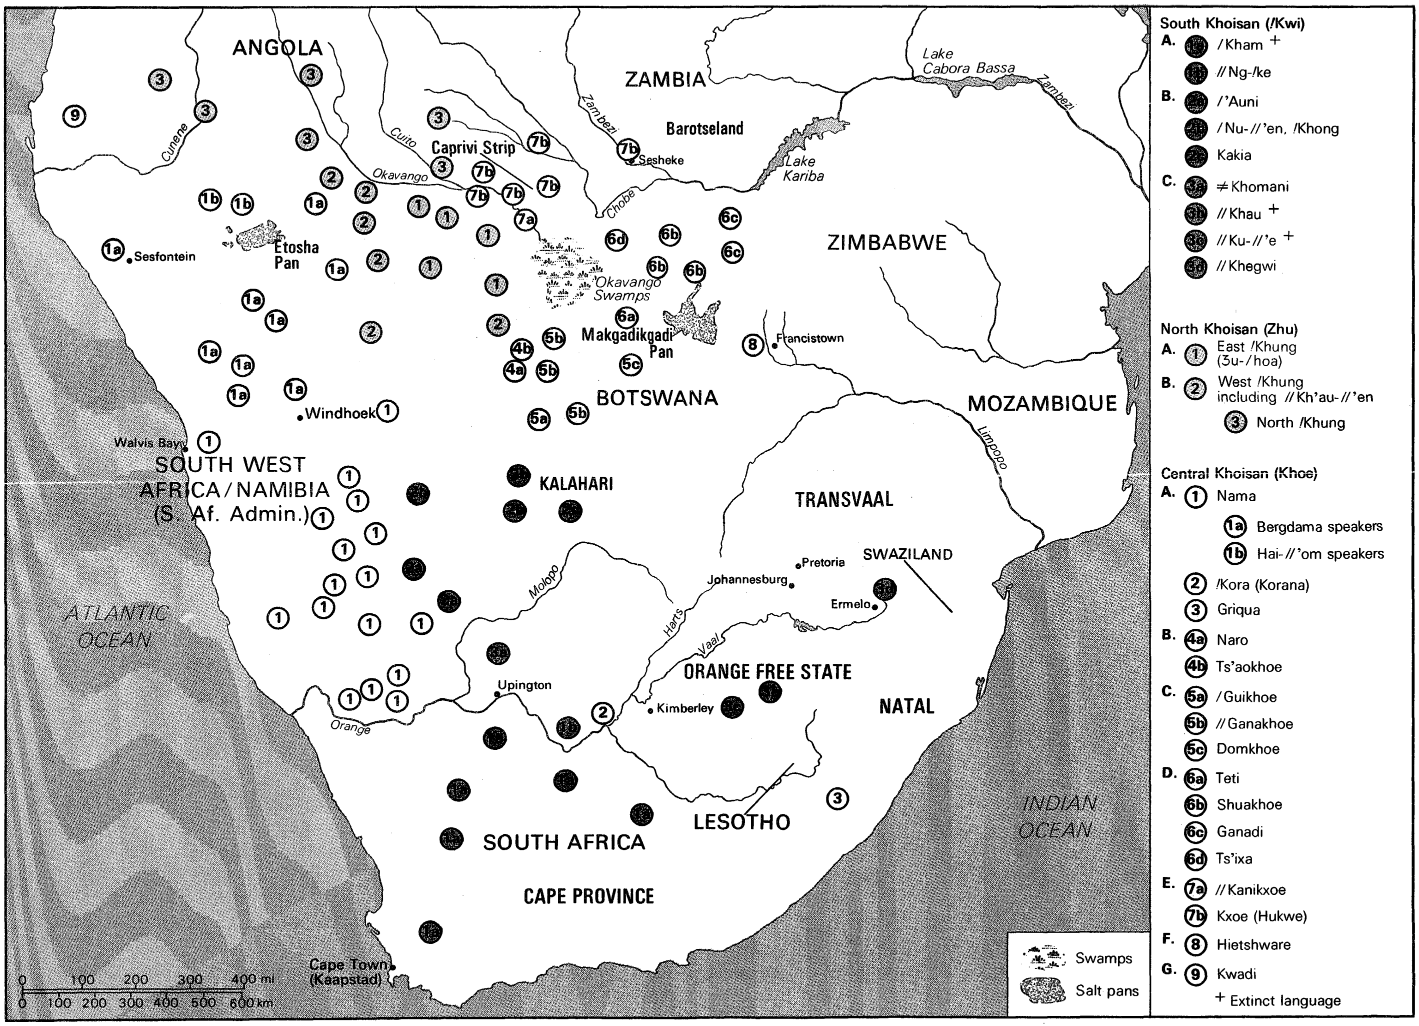

Figure 33: Tentative distribution of the Khoisan languages.

generally regarded as too narrow for conclusiveness and the hypothesis has been given up for lack of evidence.

CLASSIFICATION

All classifications of Khoisan are based on a general comparison of morphology and vocabulary. Lack of sufficient language material limits systematic comparative studies. While the division into groups is fairly consistent, the classification within the groups must be regarded as preliminary. The first classification of these languages, made by the German linguist Wilhelm Bleek in 1858, distinguished between the Hottentot and Bushman languages according to the gender-nongender dichotomy. This remained the traditional model until 1927, when Bushman was subdivided into Northern, Central, and Southern groups. These groups were maintained in D.F. Bleek's *A Bushman Dictionary* (1956), in which the Hadza language was included in the Central Group.

Modern theories of classification

Since 1950, several attempts at a reclassification of the languages of the Khoisanids have been proposed. The contribution of Greenberg to the Khoisan hypothesis was to include Hottentot in the Central group and, as mentioned above, to extend Khoisan to include the more closely related Sandawe and the more distantly related Hadza. Greenberg's main aim was to trace far-spread common elements in Khoisan as evidence for the genetic relationship of the groups. The method is based on sound-meaning comparison. The South African scholar E.O.J. Westphal separated the languages of the Bushmen from the gender languages that he interpreted as of Hottentot origin. Later, he divided the languages of the Khoisanids into five genetic groups, and in 1963 he further revised his classification of the non-Hottentot tongues by establishing four genetically unrelated groups, to which he gave the status of language families (1965); in 1971 he reduced these to three families. A new classification of Central Khoisan was put forth by Oswin Köhler in 1962, which showed the special position of the Nama and !Kora dialects of the Hottentots within the Central Khoisan group (see below).

There is no general agreement on the division of the South Khoisan languages. Some special phonological and morphological features characterize South Khoisan as a genetically related group of languages whose divergences must go back to a much older separation than that in Central and North Khoisan. South Khoisan speakers were probably the first Khoisanid migrants to reach South Africa.

The following is a classification, proposed by Köhler, of the languages subsumed in the three major Khoisan groups (a comma between languages indicates a close relationship; a semicolon designates a more distant relationship):

South Khoisan: /Kham, ⫽Ng-!ke; /'Auni, Xatia, /Nu-⫽'en, !Khong, /Namani, Kakia; ≠Khomani, /Nhuki, ⫽Khau, ⫽Ku-⫽'e, Seroa, ⫽Khegwi (Batwa), !Gãne.

North Khoisan (dialects): East !Khung (ʒu-/hoa), West !Khung (called ⫽Kh'au-⫽'en or Auen in its southern area), North !Khung (!'O-!Khung in Angola), closely related to West !Khung.

Central Khoisan: Nama, spoken by the Bergdama and by the Hai-⫽'om; !Kora (Korana); Griqua; Naro, Ts'aokhoe; /Guikhoe, ⫽Ganakhoe, ≠Heβa-khoe, Domkhoe; Teti, Danisa, Hura, Shuakhoe, Ts'ixa; ⫽Kanikxoe, Kxoe (Hukwe, Kwengo, Bumakxoe, including Bugakxoe); Hietshware, /Haitshuari, Mohisa; Kwadi (tentatively classified as Central Khoisan by Köhler in 1968 and Westphal in 1971).

Sandawe has similarities to Central Khoisan and may be regarded as distantly related. Hadza shows some relationships to Khoisan and relatively few connections to Sandawe. Its inclusion in Khoisan is problematic and assumes a very high, abstract level of classification, presupposing that the languages separated a long time ago and that a great number of cognates and common features that normally attest to a common origin were lost over an extended period. This high level of classification is also characteristic of all three Khoisan groups.

LINGUISTIC CHARACTERISTICS

Phonology. Most characteristic of the Khoisan languages are the click sounds, which form a subsystem of the consonants. Clicks are produced by simultaneous closure of the tongue with two areas in the mouth, one at the soft palate (the velum), and the other at such prevelar locations as the teeth, alveolar ridge, or palate. After the closures are made, the body of the tongue is moved down and back, so that the enclosed part of the mouth cavity becomes larger. This causes a lowering of the air pressure in the cavity. The click noise occurs when the tip of the tongue is lowered, breaking the partial vacuum and allowing air to rush into the cavity.

Click sounds as a subsystem of the consonants

There are two types of release of clicks. In one the bilabial, dental, and lateral closures are released by an imploding affricate (a sound beginning as a stop and ending with more or less distinctly audible friction); the alveolar and alveopalatal (or retroflex) closures are released by a hard implosive sound. Both releases are called ingressive, or influx, releases, meaning that the air rushes into the mouth. The second type is called egressive, or efflux, release; it results from the velar closure. In this case the air rushes out of the mouth. A click plus efflux are considered as a single sound rather than as a consonant cluster. In the South Khoisan languages there is also a bilabial click with labial closure; this is like the sound of a kiss. The Khoisan click mechanisms also combine with other phonetic features—*e.g.,* voicing (vibration of the vocal cords), nasalization—to produce additional sounds. The clicks occur only in initial position in word roots (also in compound roots), rarely in affixes and particles. Some of the Khoisan click sounds were adopted into Bantu languages, notably the Nguni group that includes Zulu and Xhosa (see Table 59 for click notations).

Unless followed by a vowel, the effluxive part of a click is represented by a separate symbol. In this text, the symbols are follows: /a = dental click plus vowel; /h = dental click plus aspiration; /x = dental click plus velarization; /x' = dental click plus velar ejected efflux; /' = dental click plus glottalization; and /n = dental click plus nasalization. According to this system, as well as in the general orthography of personal and place names, *k* or *g* is used to indicate the velar closure of the click to make the words readable for the general reader who omits the initial click sound. In this case *k* is used to indicate an unvoiced click and *g* a voiced click. The examples given above thus read as follows: /a = /ka or /ga; /h = /kh or /gh; /x = /kh or /gh; /x' = /kh' or /gh'; and /' = /k' or /g'. In the case of nasalization (/n), *k* and *g* are not usually written.

In the Khoisan languages, there are intricate systems of tones. The main vowels are *a, e, i, o,* and *u;* ɛ as in "bed" and ɔ as in "all" do occur, but not in all languages, and the *ə* sound, as the *a* in sofa, is relatively rare. Nasalized *ã, ĩ,* and *ũ* are most common. Pharyngealized (or pressed) vowels and vowels with intermittent glottalization occur in North Khoisan and, to a much lesser degree, in South Khoisan but seldom in Central Khoisan. (A pharyngealized vowel is one produced with constriction of the pharynx, the area at the back of the mouth before the esophagus.) A characteristic feature of the consonants is their use in clusters with final velarization (articulation of the back of the tongue with the velum, or soft palate), aspiration (an accompanying puff of breath), or glottalization (accompanying closure of the glottis). This occurs in all three Khoisan groups.

Grammar. Because the grammatical features of the various Khoisan languages are so divergent and lack overall uniformity, they will be discussed in three groups—South Khoisan, North Khoisan, and Central Khoisan.

South Khoisan. The languages of the South Khoisan group are characterized by a great number of different grammatical elements and processes. For example, the plurals are formed not only by the addition of suffixes but also by reduplication (*i.e.,* the repetition of an element to indicate plural, as "bird-bird" for "birds"), by partial change of the stems, and by completely different stems, called suppletive forms. In the formation of tenses and moods, a variety of particles occurs before the verb. Significantly, there is no class or gender distinction in the South Khoisan languages, except for a few traces in the /Kham language. The normal sentence order is subject-predicate-object.

Types of plural formation

North Khoisan. The North Khoisan dialects are characterized by an almost complete absence of affixes (endings, prefixes, and so on). The relations of the words to one another and their function in particular utterances are designated by particles (similar to English prepositions such as "to," "for," or "with") and by word order. The tense of roots functioning as verbs is shown by an optional preceding particle for present and future time, by nothing for the past tense, or by an expression describing time ("now," "tomorrow," etc.) if used in a sentence without context. As in the South Khoisan languages, there are suppletive (different) stems for some plurals; *e.g., !hũ* means "to kill one," but *!'oa* means "to kill many." The North Khoisan dialects, also in common with the South Khoisan tongues, lack a passive construction and have the basic sentence order of subject–predicate–object.

Central Khoisan. In the treatment of the Central Khoisan languages, the Kxoe language of the west Caprivi Strip (South West Africa/Namibia) will serve as representative. The Central languages have a highly developed morphology. Kxoe adds suffixes that indicate gender—masculine, feminine, and common in the dual and plural forms, and masculine, feminine, and neuter (*i.e.*, undetermined, with affix *a* or no affix) in the singular—to roots that take noun (nominal) endings. the same gender suffixes are added to the 3rd person pronouns (originally demonstratives). In grammatical gender, masculine implies "long, narrow, strong," and feminine suggests "short, round, broad, weak." For example, */u* or */uʘma* "canoe" is masculine, while */uʘhɛ* "ferry" is feminine. Gender distinction is also found in the 1st persons (except singular) and 2nd persons.

Masculine and feminine gender

There are six tenses for the verb, with the present tense also expressing whether the subject is standing, sitting, or lying. Unlike the other Khoisan groups, the Central Khoisan languages have a passive form, which is frequently used. In sentence order, subject–object–predicate is the most usual, but subject–predicate–object is also common, and object–subject–predicate occurs if the subject is a pronoun or a nominal.

Vocabulary. Khoisan vocabulary is highly adapted to the needs of life in a poor natural environment, especially to the hunt, to the gathering of food, and to all skills serving the preservation of life. As a result of contact with other cultures, loanwords have been adopted—*e.g.*, from European languages into Nama, from Bantu into Kxoe. Native Khoisan creations that reflect non-native innovations also occur; *e.g.*, Kxoe */am-mũ-'o-xo* "clock, watch" is literally "sun-see-on-thing." The use of words in a figurative sense to label new objects is another process for word-formation. Examples include Kxoe *yɛ-≠'am* "bridge," which is literally "hole upper side," and *kuru* "to drive [a car]," which derives from "to press the bellows." Gender symbolism also plays a role in the formation of words for objects in the contact cultures; *e.g.*, the Nama masculine term */nū-b* means "leg," while the feminine counterpart */nū-s* means "wheel."

Basic numbers exist for 1 and 2 and, in some languages, for 3; higher numbers, however, are circumscribed. For example, the number 4 in Kxoe is literally "lick hand bone quantity"—that is, "the finger with which one licks out a pot." The numbers in the languages of the Bushmen seldom go beyond 10; this contrasts greatly with the practice in Nama, and in Hottentot in general, in which there is a decimal system with noncompound numerals from 1 to 10.

In general, the unit of the vocabulary equivalent to the word in European languages is a root whose category as a noun or verb is determined by the context and by the use of noun and verb affixes or particles. Compound words are often used to extend meaning, as English derived words do (*e.g.,* in Kxoe, *kx'â-xò,* literally "drink [verb]-thing" means "beverage").

Writing and texts. About 10 Khoisan languages have been recorded with various degrees of intensity by missionaries and linguists. The best known are Nama, Kxoe, !Khung, and /Kham, followed, to a lesser degree, by !Kora, ≠Khomani, ⫽Khegwi, Naro(n), and /'Auni. The old individual methods for recording clicks were superseded by the Lepsius system (1854), which is, with some modifications, still in use. Studies in Kxoe, !Khung, !Khong, / Guikhoe, and Sandawe have been carried out in recent times, with current research concentrating on !Khung. In view of the difficulties of research among vanishing bands of peoples, the prospects of gathering sufficient material in the remnant Khoisan languages are not good.

Folklore collections

The largest collection of folkloristic texts was taken down in the now extinct /Kham language of the Cape of Good Hope. Next to /Kham, the most comprehensive collection of texts on history, folklore, and traditional and modern life was recorded in the Kxoe tongue. Texts on folklore and history also exist in Nama and Korana and to some extent in !Khung. Literacy is found only in the Nama language, among the Nama and Bergdama. In !Khung, the first two primers were printed in 1969. (O.R.A.K.)

LANGUAGES OF THE AMERICAS

Eskimo-Aleut languages

Eskimo and Aleut, once neighbour languages on the Alaska Peninsula, are related but quite distinct; together they form the Eskimo-Aleut language family.

Eskimo is spoken in Greenland by a native population of about 45,000, in Arctic Canada by 17,000 or more, in Alaska by some 37,000 native inhabitants, and on the coast of the Chukchi Peninsula in northern Siberia by about 900 of the Siberian Eskimos. In Greenland, Eskimo is used in the schools, in the church, and on the radio; in Canada and in Alaska the language is employed mainly as a means of religious education. It is the language of instruction in the first grade of primary school in the Soviet Eskimo area. There are numerous Eskimo dialects; between them there is a more or less clear-cut break at the Bering Strait and at Norton Sound in Alaska. Within each of the dialect chains the neighbouring dialects are mutually intelligible, but the cumulative differences impede or prevent understanding between the dialects at the geographical extremes.

Intelligibility of dialects

Aleut, now greatly reduced in number of speakers, is the smallest branch of the family. It is spoken in the Aleutian Islands and in the Pribilof Islands in the Bering Sea, settled in the 1820s, by fewer than 1,000 Aleuts; on the Soviet Commander Islands, settled in 1826, there are fewer than 100 Aleut speakers (1970). Three mutually intelligible Aleut dialects are left, although one is nearly extinct. The Eskimo language is unintelligible to the speakers of Aleut, and vice versa.

Classification. The Eskimo languages are usually classified into two main branches—an Inuk, or Inupik, branch, which spreads eastward from the Bering Strait and the Norton Sound, and a twofold Yuk, or Yupik, branch, consisting of Asian (Siberian) and Alaskan varieties. This grouping is based on the dialectal forms of the term for people or real people that most Eskimos use to refer to themselves. The exact interrelationship of the dialects remains to be clarified.

The term Aleut, introduced by Russian traders from Kamchatka in northeastern Siberia after 1741, is commonly used both for the Aleuts proper, who call themselves Unangan (or, on the island of Atka, Unangas), and for the Eskimos of former Russian Alaska. The linguistic relationship between Eskimo and Aleut, sensed as early as the 1820s by the Danish linguist Rasmus Rask, could be proved only through a fairly advanced analysis of both languages. The proposed relationship of Eskimo-Aleut with other language families, such as Chukchi-Kamchadal, Uralic, and/or Indo-European, remains speculative.

Relationship between Eskimo and Aleut

Alphabets and orthography. The first book in Eskimo was published in 1742 by Hans Egede, a Dano-Norwegian missionary to Greenland. It was printed in the Roman alphabet, with the letter *r* used to represent the Eskimo uvular fricative (a sound involving friction in the airstream, made at the back of the mouth with the appendage known as the uvula). The Greenlandic orthography was systematized in 1851 by Samuel Kleinschmidt, a German of the Moravian Brethren. He introduced a small capital ᴋ to distinguish the uvular stop, made with stoppage of the airstream by contact of the uvula and the back of the tongue (also written *q*), from the velar sound *k*, made with the back of the tongue touching the velum, or soft palate (like the English *k*). Three accents were introduced to differentiate long sounds from short ones; *e.g., anâna* (equivalent to *anaana*) "mother," *mána* (equivalent to *manna*) "this," *mãna* (equivalent to *maanna*) "now." That is, the circumflex,ˆ, marks a long vowel, the acute accent, ´, indicates a long consonant following the marked vowel, and the tilde,˜, notes a long vowel and a long succeeding consonant. The Kleinschmidt orthography is still used today, and similar orthographies have been employed by the Moravian Mission in Labrador since 1800.

In Russian Alaska, an adequate Cyrillic alphabet was designed for the Aleut language by the Orthodox missionary Ivan Veniaminov in about 1830. In 1848 it also became used for southern Eskimo. Books in both languages were published by the Russian Orthodox Church in America until 1903.

Adaptation of the Cree syllabary

In 1878 the syllabic characters originally designed for the Cree Indians were introduced to the Eskimos of central Canada by the Rev. Edmund J. Peck of the Church Missionary Society. Since 1953 this form of writing has also been used in an Eskimo periodical sponsored by the Canadian government, alongside a new, tentative orthography in the Roman alphabet.

The ordinary Roman alphabet was used for Alaskan Yupik by Moravian missionaries from Pennsylvania in the 1920s. From 1948 on, Protestant missionaries in northern Alaska developed an alphabet with seven additional letters. In 1961 a program was started at the University of Alaska, with the active participation of Yupik Eskimos, for working out a systematic Eskimo orthography in the Roman alphabet to be used in Alaskan public schools from 1971 on. In the Soviet schools for Asian Eskimos a Roman alphabet with two additional letters was introduced in 1932, but it was replaced by the Russian Cyrillic alphabet in 1937.

Phonological characteristics. Eskimo and Aleut have relatively simple systems of distinctive sounds. The accent (stress) depends upon the length of the syllables and never has independent value as in English.

In Eskimo there are four distinctive vowels. Three of them, usually written as *a, i, u,* vary considerably in pronunciation according to the consonants that follow or precede. These three vowels occur both short and simple, and combined into long vowels and diphthongs. The vowel combinations result primarily from the loss of former intervocalic consonants; *e.g.,* Greenlandic *ûvoq,* the equivalent of *uu-vuq* "is burnt," is related to the Asian Yupik form *ugu-,* which has a fricative *g* sound between the two vowels. The fourth Eskimo vowel is represented in Yupik by a short *e* and is pronounced somewhat like the vowels in "but" or "bird." In the Inupik area it has become identical with the vowel written *i*. The Aleut language has only *a, i,* and *u* in both short and long varieties. The fourth vowel has become identical with one of the first three or has been dropped from the language.

The consonantal system

Of consonants, Eskimo has from 13 to 21, depending on the dialect. The stop sounds include the uvular *q,* the velar *k,* the dental *t,* made with the tip of the tongue touching the back of the upper teeth, and the labial *p,* made with the lips; in Alaskan Yupik there is also a palatal *c* (like English *ch*), to which an *s* corresponds in the other dialects. In parts of Canada this has changed to *h*. The nasal sounds, made with the breath passing through the nose, include ŋ (as in "sing"), *n, m,* and, in Asian Yupik, also a voiceless *n,* made without vocal cord vibration. Voiced and voiceless varieties of the continuant consonants *r, g, l,* and *v* are distinctive sounds in the western dialects but in eastern Inupik they are only variants. In addition to *j,* pronounced as *y* in English "year," some dialects have sounds similar to English *r* or *z* or to *sh* (in Greenlandic written *ss*). Corresponding to *ss* in Aleut there is a fricative *d* (pronounced as the *th* in "that"); *e.g.,* Aleut *da-* "eye" is related to Eskimo *izi* and *ii* and to Greenlandic *isse.* Aleut shares with Eskimo most of the consonants articulated with the tongue, including *c* (the English *ch* sound) and *s,* but has *p* and labial fricatives (*f* and *v*) only in loanwords from Russian or English. Aleut *m* corresponds with both Eskimo *m* and *v;* to Eskimo *p* corresponds the Aleut *h* (in initial position) and the Aleut aspirated nasal sound *hm* (in noninitial positions)—*e.g.,* Aleut *hum-* "to swell" corresponds to Eskimo *puvi-;* Aleut *ahmat-* "to ask" is cognate with Yupik *ap(e)t-*. (An aspirated sound is one pronounced with an accompanying puff of air.)

In initial position, Inupik uses only a single stopped consonant (*i.e., p, t, k,* or *q*), or *s, n,* or *m* (rarely *l*); between vowels it employs at most two consonants, including double ones. In contrast, Yupik and Aleut have initial consonant clusters, resulting from the loss of a vowel in the first syllable from an older historical form; *e.g.,* Yupik and Aleut *sla* "weather," Inupik *sila.*

Grammatical characteristics. Eskimo has a great number of suffixes but practically no prefixes or compounds. In Aleut the word forms are simpler, but the syntactic constructions (the way the words are arranged in sentences) are more complicated. Suffixes are often accompanied by changes in the stem, especially in Eskimo; *e.g., nanuq* "polar bear," dual *nannuk* "two polar bears," plural *nannut* "several polar bears"; *inuk* "person," dual *innuk,* plural *inuit; umialik* "owner of boat (*umiaq*), chief," dual *umiallak,* plural *umialgit* (North Alaska dialect). Note the doubled consonants in the dual and plural forms of some terms, and the other consonant and vowel alternations.

Grammatical numbers—singular, dual, plural—combine with suffixes for person—*e.g., ulu-ga* "my knife," and *ulu-t-ka* "my knives," in which *-t-* means "several" and *-ga* or *-ka* "my." The possessor of someone or something occurs in the so-called relative, or subordinative, case—*e.g., umialgum pania* "the chief's (his) daughter," in which *pani-a* means "his or her daughter"; this is distinguished from the reflexive *panni* "his or her own daughter" and the stem *panik.*

Personal pronouns

The personal pronouns consist of a stem and person suffixes—*e.g.,* Aleut *ti-*ŋ "I, me," with the ending -ŋ as in *ada-*ŋ "my father"; Eskimo *uva-*ŋ*a* "I, me," with a demonstrative stem (*uva*) as in *uva-ni* "here." Corresponding to the separate personal pronoun forms in Aleut are the Eskimo suffixes for the 1st, 2nd, and reflexive 3rd persons (himself, etc.). These indicate the subject of an intransitive verb or the object of a transitive verb—*e.g.,* -ŋ*a* means "I" in *uqaqtu-*ŋ*a* "I said," and "me" in *uqautigaa-*ŋ*a* "he told me." A noun that would be the subject of "said" (the intransitive verb) or the object of "told" (the transitive verb) is in the absolute case (it is not marked with a suffix), whereas the subject of a transitive verb (*e.g.,* "tell") occurs in the subordinative case. For example, compare the unmarked form for "chief," *umialik,* in *umialik uqaqtuq* "the chief said" with its corresponding form *umialgum* in the subordinative case in *nukatpiarzuk umialgum uqautiga-a* "the young man (object), the chief told him" (*-a* "he - him"). With a 3rd person object ("him, them"), a transitive verb has largely the same suffixes as a noun—*e.g.,* the *-t-* and *-ka* in *ulu-t-ka* "my knives" and *tigu-gi-t-ka* "I took them" (*-gi-* is indicative) and the corresponding Aleut forms, *-ni-* and -ŋ in *ukina-ni-*ŋ and *su-ku-ni-*ŋ.

Eskimo nouns and pronouns have six adverbial cases, expressing relations such as "in," "to," "from," "along," "with," and "like"—*e.g., iglu-mi* "in the house," *iglu-pti*ŋ*-ni,* "in our house." In the Yupik dialects there are only five such adverbial cases. These are reduced to two (in/to, from/along) in Aleut and are limited to pronouns and relation words—*e.g., ula-m nag-a-n* "of house (*ula-m*) in its (*-a-*) interior"; this corresponds to Eskimo *iglu-m ilu-a-ni* "in the house."

Verbal modes include indicative ("he goes"), interrogative ("did he go?"), imperative ("go!"), optative ("may he go"), participles ("going, gone"), and other forms corresponding to subordinate clauses in English—*i.e.,* clauses beginning with "if," "when," etc. Other modal relations and tenses are specified by derivational suffixes, and in Aleut also by auxiliary verbs; *e.g., haqa-l sara-nar* "coming he slept" is equivalent to "he came yesterday." An Eskimo derivative form may also correspond to an English complex sentence—*e.g., tikit*$_1$*-qaar*$_2$*-mina*$_3$*-it*$_4$*-ni*$_5$*-ga*$_6$*-a*$_{7-8}$ is "he (A)$_8$ said$_{5-6}$ that he (B)$_7$ would not$_4$ be able$_3$ to arrive$_1$ first$_2$," or, in exact Eskimo order, "to arrive first be able would not said him he."

Vocabulary. A remarkable feature of the vocabulary is the great number of demonstratives, about 30 in western Eskimo and in Aleut. For example, in Aleut there is *hakan* "that one high up there" (as a bird in the air), *qakun* "that one in there" (as in another room), and *uman* "this one unseen" (heard, smelled, felt).

The vocabulary naturally has its local particularities, the various groups having lived under very different conditions. The Eskimo word that means "meat" from Greenland to Siberia means "fish" south of Norton Sound and also in the Aleut language. Word taboo has also played its part, as in East Greenlandic, in which the general Eskimo-Aleut word for "eye" (*da-, izi,* see above) has been replaced by *uitsatai (ui-sa + uta-i)* "those by which he keeps gazing."

Word formation by derivation

Eskimo-Aleut derived words (*e.g.,* similar to English "winter-ize" or "anti-dis-establish-ment-ari-an-ism") correspond quite often to simple, nonderived English words. The possibility of derivation is virtually unlimited in the languages, and the number of word stems is comparatively small; *e.g.,* there are fewer than 2,000 in well-known West Greenlandic. Examples of derivatives are: *nalu-voq* "is ignorant," *nalu-vâ* "does not know it," and *nalu-na-er-* "make not (*-er-*) to be (*-na-, -nar-*) ignored," which is equivalent to "communicate." *Nalunaer-asuar-ta-ut* "that by which (*-ut*) one communicates habitually (*-ta-, -tar-*) in a hurry (*-asuar-*)" is the form for "telegraph," a term coined in the 1880s.

In Greenlandic there are four loanwords from medieval Norse; from the colonial period after 1721 there have been surprisingly few borrowings until recently. In Aleut and in the Eskimo of former Russian Alaska there are many borrowings from Russian, and there are several in Asian Eskimo from English, and many from Chukchi, a Paleo-Siberian language. Notable Eskimo contributions to the vocabulary of English and other European languages are "igloo" (or *iglu*) and "kayak" (*qayaq*). (K.B.)

North American Indian languages

The term North American Indian languages usually refers to those languages that are indigenous to the United States and sub-Arctic Canada, and that are spoken north of the Mexican border. A number of language groups within this area, however, extend as far south as Central America. The present article will concentrate on the languages of Canada and the United States. (For further information on languages of Mexico and Central America, see *Meso-American Indian languages*; for languages of Arctic America, see above *Eskimo-Aleut languages*).

The Indian languages of North America are both numerous and diverse. Their original number has been estimated at 300; these tongues were spoken by a native population of approximately 1,500,000. The number of languages still used was estimated at around 200 by the American linguist Wallace Chafe in 1962. Some of these had only one or two elderly speakers. The numbers continue to drop, but with some notable exceptions—*e.g.,* Navajo is steadily increasing in number of speakers. As a consequence of the growing trend toward extinction in the American Indian languages, the field of study is becoming more concerned with the past than the future. Even so, the rich diversity of these languages provides a valuable laboratory for linguistic theory; certainly the discipline of linguistics could not have developed as it has, especially in the United States, without the native American languages. In this article, the present tense will be used in referring to both extinct and surviving languages.

Within the diversity of the North American Indian languages, no general characterization is possible; various features of structure are common to them, but there is no feature or complex of features shared by all. At the same time, there is nothing primitive about these languages. They draw upon the same linguistic resources and display the same regularities and complexities as do the languages of Europe. If historical connections are sought among the Indian tongues, some languages clearly show numerous and systematic resemblances comparable to those between Spanish, French, and Italian. These similarities strongly suggest classification as a linguistic family. North American languages can then be grouped into some 57 families. On this level, too, the diversity of some areas is notable. Thirty-seven families lie west of the Rockies and 20 in California alone; California thus shows more linguistic variety than all of Europe. Some families seem to be related to each other in more remote historical groupings, often called phyla. Such classifications border on speculation, however, partly because data are lacking on many languages (because they are extinct or still unstudied), and partly because of the difficulty in distinguishing, at the deeper historical levels, between resemblances caused by common origin and those resulting from linguistic borrowing.

Language families and phyla

In any case, no theory of common origin for the North American languages has become established. Although most anthropologists believe that North America was populated mainly by people who migrated across the Bering Strait from Asia, attempts to relate native American languages to Asian languages have not gained general acceptance. (There is one possible exception—the relationship of Eskimo-Aleut to certain Siberian languages.) The linguistic diversity of North America suggests, indeed, that the area was populated as a result of several waves of migration by peoples of distinct linguistic stocks of Asia; these stocks may have no modern survivors.

Classification. The first comprehensive classification into families of the North American Indian languages was made in 1891 by the American John Wesley Powell, who based his study on impressionistic resemblances in vocabulary. A principle of nomenclature adopted by Powell has been widely used ever since: families are named by adding *-an* to the name of one prominent member; *e.g.,* Caddoan is the family including Caddo and other languages. For this most obvious level of relationship, the Powell classification remains essentially unchallenged. Various scholars, however, have attempted to group the families into larger units that reflect deeper levels of historical relationship. Of these efforts, one of the most ambitious and best known is that of Edward Sapir, which was first published in the *Encyclopædia Britannica* in 1929. In Sapir's classification, all the languages are grouped into six phyla—Eskimo-Aleut, Algonkian-Wakashan, Na-Dené, Penutian, Hokan-Siouan, and Aztec-Tanoan—established on the basis of very general grammatical resemblances. In 1958, research of the American linguist Mary R. Haas revealed precise sound correspondences between the Algonkian languages and a "Gulf" group in the southeastern United States that Sapir had assigned to the Hokan-Siouan phylum. Since that time, various reconsiderations of Sapir's groupings have been proposed. A classificatory map published by Charles F. and Florence M. Voegelin in 1966 offers one such classification, and it is likely to serve as a standard reference point for some time. Although preserving Sapir's Eskimo-Aleut, Na-Dené, Penutian, and Aztec-Tanoan groups, it also proposes reconstituted Macro-Algonkian, Macro-Siouan, and Hokan phyla, and allows nine families to remain unclassified, pending further research.

Sapir's six phyla

Table 60, based on the Voegelin map, gives approximate indications of the aboriginal home territories and of the number of speakers estimated from published data in the early 1980s.

Language contact. The Indian languages of North America, like all languages in the world, have always existed in contact with other tongues. From this situation bilingualism, or multilingualism, has resulted; the extent is determined by sociological factors. The Indian languages show varying degrees of linguistic acculturation; *i.e.,* there may be borrowing between languages not only of vocabulary items, but also of phonological, grammatical, and semantic features. In aboriginal times, in areas where bilingualism was most important (*e.g.,* the Northwest), there tended to be well-defined linguistic areas in which languages of diverse genetic affiliations came to share numerous structural characteristics through the process of borrowing. As noted above, such phenomena create difficulties for attempts at genetic classifications. In a few cases, situations of language contact have given rise to a pidgin or compromise language that is composed of elements from various sources and is used as a second language, especially in trading. An example is the Chinook Jargon of the Northwest; this came to be used by many whites and absorbed many loanwords from French and English before its eventual obsolescence.

Pidgin languages

In more recent times, contact of Indian languages with European languages—French, English, Spanish, and Russian—has again resulted in bilingualism. With the Indian languages generally relegated to a socially subordinate position (and with many of them headed for extinction), borrowing, however, has involved the relatively superficial level of vocabulary more often than the deeper levels of language structure, such as the sound system or grammar. The effects on European languages are apparent mainly in place names like Massachusetts and Seattle and in names like squash and abalone for native American plants and animals. Among the Indians, the type and degree of linguistic adaptation to European culture has varied greatly, depending on sociocultural factors. For example, among the Karok of northwestern California, a tribe that suffered harsh treatment at the hands of whites, there are only a few loanwords from English (*e.g., ápus* "apples"), a few calques or loan translations (the "pear" is called *vírusur* "bear," because English "pear" and "bear" are merged in Karok pronunciation), but a large number of new formations from native materials; *e.g.,* a hotel is called *amnaam* "eating place."

Grammar. The term grammatical structure as used here refers to both the traditional categories of morphology—how words are made up—and syntax—how words are combined into sentences. It should again be emphasized that in grammar, as well as in phonological or semantic structure, neither the American Indian languages nor any other languages in the world display anything that could be called primitive in the sense of undeveloped or rudimentary. Every language has a structure as complex, as subtle, and as efficiently adaptable to cultural needs as that of Latin or English, for example.

The North American Indian languages display great diversity, so that it is not possible to characterize them as a group by the presence or absence of any particular grammatical peculiarities. At the same time, there are some characteristics that, though not unknown elsewhere in the world, are sufficiently widespread to be considered typical of the continent or of particular linguistic areas within North America. The phenomenon of polysynthesis, in which many sentence elements are expressed within the boundaries of a single word by compounding and affixation, is especially characteristic of Eskimo and Algonkian, but is also found elsewhere. An illustration from the Algonkian group is the Menominee form *nekeespestεh-wenah-nεεwaaw* "but I did see him on the way." Incorporation, the compounding of a noun with a verb, is rarely used in English (*e.g.,* "to baby-sit") but is common in some Indian languages; *e.g.,* Mohawk *ke-wẽna-weiẽhõ* "I-language-understand." (The symbols used that are not found in the Latin alphabet have been adopted from phonetic alphabets.)

Polysynthesis and incorporation

Some especially common characteristics of North American languages are the following:

1. In verbs, the person and number of the subject are commonly marked by prefixes; *e.g.,* Karok has *ni-'áhoo* "I walk," *nu-'áhoo* "he walks." In some languages, the prefix simultaneously indicates the object as well as subject; *e.g.,* Karok *ni-mmah* "I see him," *ná-mmah* "he sees me."

2. Tense and aspect of verbs are usually marked by suffixes, as in many languages throughout the world. But in some areas—*e.g.,* among the Athabascan languages—prefixes are used. For example, Chipewyan *hε-tsa*ɣ means "he is crying," ɣ*ĩ-tsa*ɣ is "he cried," and ɣ*wa-tsa*ɣ is "he will cry."

3. In noun forms, the concept of possession is widely expressed by prefixes indicating the person and number of the possessor. Thus Karok has *ávaha* "food," *nani-ávaha* "my food," *mu-ávaha* "his food," etc. When the possessor is a noun, as in "man's food," a construction like *ávansa mu-ávaha* "man his-food" is used. Many languages have inalienable nouns, which cannot occur except in such possessed forms. These generally designate such things as kinsmen or body parts; *e.g.,* Luiseño, a language in Southern California, has *no-yó'* "my mother," *o-yó'* "your mother," but no word for "mother" in isolation.

4. Nouns in many languages have forms with a meaning of location; *e.g.,* Karok *áas* "water," *áas-ak* "in the water." Such a construction is reminiscent of the case forms of Latin, and case systems do indeed occur in California and the southwest. For example, Luiseño has the nominative *kíiča* "house," accusative *kíiš,* dative *kíi-k* "to the house," ablative *kíi-ŋay* "from the house," locative *kíi-ŋa* "in the house," instrumental *kíi-tal* "by means of the house."

The following five grammatical features are less typically North American, but are nevertheless distinctive of many areas. First person pronouns in many languages show a distinction between a form inclusive of the addressee—"we" denoting "you and I"—and an exclusive form—"I and someone other than you." Some languages also have a distinction in number between singular, dual, and plural pronouns. Reduplication, the repetition of all or part of a stem, is widely used to indicate distributed or repeated action of verbs; *e.g.,* in Karok, *imyah* means "breathe," *imyáhyah* means "pant." In Uto-Aztecan languages, reduplication sometimes is associated with plural nouns, as in Pima *gogs* "dog," *go-gogs* "dogs." In many languages, verb stems are distinguished on the basis of the shape or other physical characteristics of the associated noun; thus in Navajo, in referring to motion, *'á*^{n} is used for round objects, *tá*^{n} for long objects, *tí*^{n} for living things, *lá* for ropelike objects, etc. Similar distinctions may refer to dual and plural number. Karok has *ikpuh* "one swims," *iθpuh* "two swim," *ihtak* "several swim."

Inclusive and exclusive pronouns

Verb forms also frequently specify the location or direction of an action by the use of prefixes or suffixes. In Karok, for example, from *paθ* "throw" is derived *páaθ-roov* "throw upriver," *páaθ-raa* "throw uphill," *paaθ-rípaa* "throw across-stream," and as many as 38 other similar forms. Some languages also specify the instrument of an action, generally by prefixation; *e.g.,* Pomo *phi-de-* "to move by batting with a stick," *phu-de-* "to move by blowing," *pha-de-* "to move by pushing with the end of a stick." Lastly, many languages have evidential forms of verbs that indicate the type of validity of the information reported; such distinctions may assume the importance played by tense and aspect in European languages. Thus Hopi distinguishes *wari* "he ran, runs, is running" as a reported event, from *warikŋwe* "he runs (*e.g.,* on the track team)," which is a statement of general truth, and from *warikni* "he will run," which is an anticipated event. In other languages verb forms consistently discriminate hearsay from eye-witness reports. Such a system might be very welcome in other societies; *e.g.,* especially as regards the reliability of news reports.

Phonology. The languages of North America are as diverse in their systems of pronunciation as they are in other ways. In terms of the number of contrasting sounds (phonemes), the Northwest Coast is characterized as a linguistic area by the unusual richness of its systems. A language like Tlingit has approximately 50 consonants and vowels (a comparable count for English would number 35). By contrast, Karok has only 23. The richest sound inventories seem to occur where bilingualism was commonest, and sounds were borrowed between languages.

The large number of consonants that is found in many Indian languages is based on the use of a number of phonetic contrasts that are relatively unfamiliar in European languages. In English, different consonants are produced by vibrating the vocal cords (which results in voiced sounds) or by not vibrating them (which gives unvoiced sounds); by shutting off the air momentarily, thus producing stops, or by letting the airstream pass through the mouth with friction (producing fricatives); and by placing the tongue in a variety of positions. The Indian languages also use

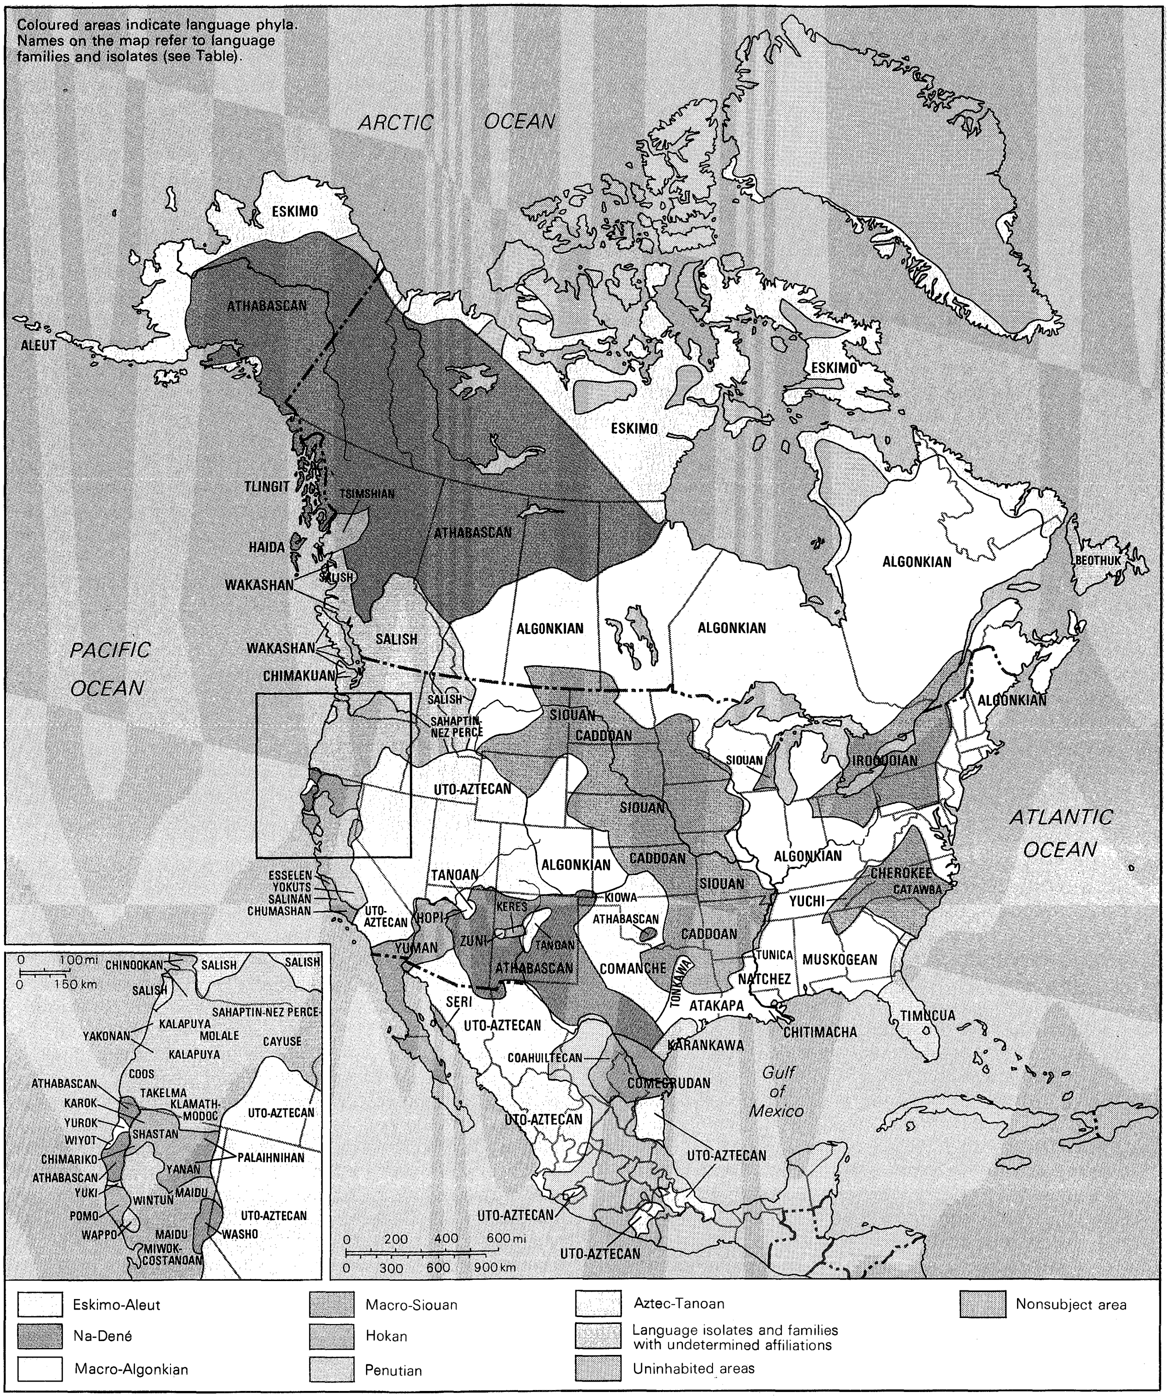
*Phyla given in boldface type; families given in italics (including those consisting of single languages); single languages, or dialect groups so closely related that they can be treated as single languages, given in roman type. †1981 estimate. ‡Minimal number of speakers; *i.e.*, under 10. §Extinct.



Coloured areas indicate language phyla. Names on the map refer to language families and isolates (see Table).

Figure 34: Distribution of North American Indian languages.

From C.F. and F.M. Voegelin, *Map of North American Indian Languages;* copyright 1966 by University of Washington Press

these mechanisms, but sometimes others as well. The glottal stop, an interruption of breath produced by closing the vocal cords (as in the middle of English *oh-oh!*) is a common consonant. A related phenomenon, widespread in western North America, is the use of glottalized consonants, as when a *t* is produced with near simultaneous closure and reopening of the vocal cords. This is recorded with an apostrophe; it differentiates terms like Hupa (Athabascan) *teew* "underwater" from *t'eew* "raw."

The number of consonantal contrasts is also frequently expanded by distinguishing a larger number of tongue positions than do most European languages. Many languages distinguish two types of velar sounds (sounds made with the back of the tongue)—a *k* much like an English *k*, and a uvular *q*, produced further back in the mouth. Some languages even differentiate three such *k* sounds—front, middle, and back. Labiovelars, velar sounds that have simultaneous lip-rounding, are also common. Thus Tlingit has 21 phonemes made in the velar area alone: *g*, *k*, uvular *G*, *q*, glottalized *k'*, *q'*, labiovelar g^w, k^w, k'^w, G^w, q^w, $q^{w'}$, in addition to the corresponding fricatives *ɣ* and *x*, with uvular *X*, glottalized *x'*, *X'*, and labiovelar x^w, X^w, x'^w, X'^w. In comparison, English has only two sounds, *k* and *g*, made in the same area of the mouth.

Another class of sounds common in North America, especially in the West, is that of the laterals, which are produced by stopping the breath with the central part of the tongue but allowing it to escape at the sides. Alongside the common lateral *l*, such as exists in English, many Indian languages have a voiceless counterpart, similar to the Welsh *ll;* this sound is approximated by the *thl* in northwestern place names such as Cathlamet. To this some languages also add glottalized varieties, as well as a close-knit *tl* unit, which may in turn be aspirated or glottalized, so that there may result, as in Navajo, a total of five distinguishable lateral sounds.

In some Indian languages, as in English, stress is significant in distinguishing the meaning of words. In others, musical pitch plays a linguistic function, as it does in Chinese; *e.g.,* in Navajo, *bíní'* is "his nostril," *bìnì'* is "his face," and *bìní'* is "his waist." (High and low pitches are indicated with the acute and grave accents, respectively.)

A peculiarity of some northwest coast languages is their use of complex consonant clusters, as in Bella Coola *tlk'*^{w}*ix*^{w} "don't swallow it." Some words even lack vowels entirely; *e.g., nmnmk'* "animal."

Phonological change

Processes of phonological change, in which differences of sound are associated with grammatical distinctions (as with English *f* and *v* in "half," "halves," "to halve"), are also found in North American languages. In some languages, for example, consonantal change is related to diminutive meaning: thus Luiseño *r* changes to *đ* in *ŋarúŋru-š* "pot," *ŋadúŋdu-mal* "pot-small." Vowel harmony, a process whereby vowels change to resemble adjacent ones, is further attested in North America. Yurok in northwestern California, for example, has an unusual *r* vowel, comparable to the sound in English "bird"; when this occurs in a suffix, stem vowels change to agree with it, thus *lo'σγ̥e* "black" + *-'r'y* (animate suffix) yields *lr'rγ̥r'r'y* "black animal."

Vocabulary. The word stock of American Indian languages, like those of other languages, is composed both of simple stems and of derived constructions; the derivational processes commonly include affixation (the use of prefixes, suffixes, etc.) in addition to compounding in some languages. A few languages use internal sound change, similar to the case of English "song" from "sing"; *e.g.,* Yurok *pontet* "ashes," *prncrc* "dust," *prncrh* "to be gray." New vocabulary items are also acquired by borrowing, as mentioned above.

It should be noted that, in languages generally, the meaning of a vocabulary item cannot be adequately inferred from a knowledge of its historical origin or from knowing the meaning of its parts. For example, the name of an early 19th-century trapper, McKay, entered Karok as *mákkay,* but with the extended meaning of "white man." It was then compounded with a native noun *váas* "deerskin blanket" to give the neologism *makáy-vaas* "cloth"; this in turn was compounded with *yukúkku* "moccasin" to give *makayvas-yukúkku* "tennis shoes." At each stage of vocabulary formation, meaning is determined not simply by etymology but also by arbitrary extensions or limitations of semantic value.

Semantic structure of Indian languages

It is in the area of semantic structure that American Indian vocabulary is likely to present some surprises to the investigator. It is frequently observed that the immense diversity of the physical universe is reduced by every society to a manageable set of classifications embodied in its vocabulary. But there are few universals in such classification, and every language makes its unique semantic divisions. One language may make many specific discriminations in a particular area, while another is content with a few general terms; the difference is correlated with the importance of the semantic area for the particular society. Thus English is highly specific in classifying bovines (bull, cow, calf, heifer, steer, ox), even to the point of lacking a general cover term in the singular (what is the singular of cattle?), but for other species it has only cover terms like camel, llama. North American Indian vocabularies, as would be expected, embody semantic classifications that reflect native American environmental conditions and cultural traditions.

Interest in the semantic classifications of American Indian languages, especially in Hopi, has been particularly stimulated by the work of the American investigator Benjamin Lee Whorf. When English discriminates "air-plane," "aviator," and "flying insect," Hopi generalizes with a single term *masa'ytaka,* roughly "flier"; but when English uses a single general term, "water," Hopi differentiates *pāhe* "water in nature" from *kēyi* "water in a container."

The vocabularies of different languages may differ not only in the categorization of particular items but also in the general principles of semantic organization; such differences may be found even between neighbouring languages in a single culture area. English, for example, tends to exhaust the universe of flora and fauna with multi-levelled hierarchical classifications such as "plant, bush, berry bush, gooseberry bush" or "animal, insect, louse, body louse," but the languages of northwestern California, by contrast, have relatively few generic terms and many vocabulary items that do not fall into any such hierarchy. The generic terms of Yurok refer, roughly, to "quadruped mammal," "fish," "snake," "bird," "tree," "bush," "grass," "flower," and "berry"; the organization in the neighbouring Tolowa language is simpler, lacking "quadruped mammal" and "fish." In such frameworks, a term like Yurok *wrrγ̥r* "body louse" cannot be subsumed in the larger classes of "louse" or "insect" because none exist. The placing of terms in semantic pigeonholes tends to be replaced, in these semantic systems, by identifying them in terms of similarity. A Yurok speaker, asked to identify a flowering bush for which he knows no name will describe it not as "a kind of bush," but as *sahsip seγ̥on* "similar to wild lilac." Such evidence suggests that the semantic structures of some American Indian vocabularies are based on classes defined less by their boundaries than by their centres.

Kinship terms

Another type of semantic structuring is illustrated by certain systems of kinship terms. In Fox, an Algonkian language, the term for maternal uncle also includes maternal grandmother's sister's son's son (a kind of second cousin). This can be accounted for by recognizing some very simple rules, rules that apply to the other terms of the kinship system as well: (1) siblings of the same sex, as linking relatives, are reckoned as equivalent; (2) a father's sister, as a linking relative, is equivalent to a sister, and conversely, a mother's brother's child is equivalent to a mother's brother. Then a mother's mother's sister's son's son, by rule 1, is equivalent to a mother's mother's son's son; but because one's mother's son is one's brother, this is the same as a mother's brother's son; and this in turn, by the converse of rule 2, is equivalent to a mother's brother. It is clear that the semantic systems of American Indian languages exhibit not only structures of hierarchy and similarity but also rules of semantic equivalence.

Language and culture. The exotic character of American Indian semantic structures, as manifested not only in their vocabularies but also in the relationships expressed by their morphological categories and syntactic patterns, has led a number of scholars to speculate on the relationships between language, culture, and habitual thought patterns or "world view." It was hypothesized that the unique organization of the universe that is embodied in each language might act as a determining factor in the individual's habits of perception and of thought, thus forming and maintaining particular tendencies in the associated nonlinguistic culture. As Edward Sapir put it,

> Human beings do not live in the objective world alone, . . . but are very much at the mercy of the particular language which has become the medium of expression for their society . . . The fact of the matter is that the "real world" is to a large extent unconsciously built up on the language habits of the group . . . We see and hear and otherwise experience very largely as we do because the language habits of our community predispose certain choices of interpretation.

The Whorfian hypothesis

This idea was further developed, largely on the basis of work with American Indian languages, by Sapir's student Benjamin Lee Whorf, and is now often known as the Whorfian hypothesis. Whorf's initial arguments focussed on the strikingly different organization of experience that can be found between English and Indian ways of saying "the same thing." From such linguistic differences, Whorf infers underlying differences in habits of thought. It then remains to show how these habits are manifested in nonlinguistic cultural behaviour. Thus, Whorf points out that, in Hopi, words referring to units of time (*e.g.,* "day") differ from other nouns in that they have no plural form; furthermore, they cannot be counted with the cardinal numerals ("one," "two," etc.) but only with the ordinals ("first," "second," etc.). From this he infers that when the English speaker speaks of "ten days," as if the days were an aggregate of separate units, the Hopi speaker, on the other hand, thinks in terms of the cyclic recurrence of a single phenomenon. Whorf attempts to support this idea by reference to Hopi ceremonial behaviour, which involves repeated preparation for future events. If, in the Hopi view, each day is really a recurrence, rather than something new, then it is reasonable to believe that the daily repetition of ceremonial acts will have a cumulative effect on the future. As Whorf says, the Hopi belief is diametrically opposed to the English proverb that "Tomorrow is another day."

More investigation is necessary to either prove or disprove the Whorfian hypothesis. In any case, the diversity of American Indian languages and cultures has continued to provide a rich laboratory for investigation. A particularly interesting problem is found in the area of northwestern California, where several small tribes have very similar cultures, but use languages of very diverse types. These are Karok, genetically classified as Hokan; Yurok and Wiyot, which are Algonkian; and Hupa and Tolowa, Athabascan languages. By the Whorfian hypothesis, one might expect that the difference in languages would have produced a greater diversity in the cultures; or failing that, one might expect the languages to have grown more similar to each other. In fact, both linguistic diversity and cultural uniformity seem to have made modest accommodations to each other. As an example of Whorfian linguistic determinism, the systems of biological taxonomy of Yurok and Tolowa, referred to in the previous section, may be noted. The Yurok have a larger number of generic classifications, which means they have more choice in nomenclature, because either a generic or a specific term can be used. This is consistent with the high degree of choice afforded in Yurok grammar, in which word order is nearly free and many morphological categories are optional. The sparser taxonomy of Tolowa offers less choice, corresponding to a much more rigid grammatical structure.

Language, culture, and prehistory

A different kind of relationship between language and culture is of more interest to the student of North American prehistory, namely, the fact that language retains traces of historical changes in culture and so aids in reconstructing the remote past. Here again the pioneering work was done by Sapir, who pointed out, for instance, that the original home from which a group of related languages or dialects has dispersed is more likely to be found in the area of great linguistic diversity; *e.g.,* there are much greater differences in the English dialects of the British Isles than of the more recently settled areas such as North America or Australia. To take an American Indian example, the Athabascan languages are now found in the Southwest (Navajo, Apache), on the Pacific Coast (Tolowa, Hupa), and in the Western Subarctic. The greater diversity of the Subarctic languages leads to the hypothesis that the original centre of Athabascan migration was from that area. This northern origin of the Athabascans was further confirmed in a classic study by Sapir in which he reconstructed parts of prehistoric Athabascan vocabulary, showing, for example, how a word for "horn" had come to mean "spoon" as the ancestors of the Navajo migrated from the far north (where they made spoons of deerhorns) into the Southwest (where they made spoons out of gourds). The correlation of such linguistic findings with the data of archaeology holds great promise for the study of American Indian prehistory.

Writing and texts. Although a writing system was in use among the Mayas of Meso-America at the time of first European contact, none was known in North America. All writing systems that have been used for North American Indian languages have resulted from the stimulus of European writing, or have actually been invented and introduced by whites. Perhaps the most famous system is that invented by Sequoyah, a Cherokee, for his native language. It is not an alphabet but a syllabary, in which each symbol typically stands for a consonant-vowel sequence. The forms of characters were derived in part from the English writing system, but without regard to their English pronunciation. Well suited to the language, the syllabary fostered widespread literacy among the Cherokee until their society was disrupted by government action; its use, however, has never died out, and attempts are now being made to revive it.

Other writing systems, invented by missionaries, teachers, and linguists, have also included syllabaries; *e.g.,* for Cree, Winnebago, and some northern Athabascan languages. Elsewhere, alphabetic scripts have been used, adapted from the Roman alphabet by the use of additional letters and diacritics. White educational policy, however, has generally not encouraged literacy in Indian languages. A rich oral literature of American Indian myths, tales, and song texts has been in part published by linguists and anthropologists, and there is now increasing encouragement for the training of Indians to transcribe their own traditions—*e.g.,* among the Navajo. It is possible that there may yet be a flowering of American Indian literature, not only in spoken but also in written form. (W.O.B.)

Meso-American Indian languages

Meso-American, or Middle American, Indian languages are spoken in an area of the aboriginal New World that includes central and southern Mexico, Guatemala, Belize (British Honduras), El Salvador, parts of Honduras and Nicaragua, and part of northwest Mexico. Though various centres of civilization have flourished in the area, sometimes concurrently, from 1000 BC down to the time of the Spanish conquest of Mexico in 1519, Meso-America as a whole has had a more or less common cultural history for 2,500 years.

Treatments of the languages of Meso-America are customarily organized on the basis of their genetic relationships, and only secondarily on that of geographical distribution. Thus, some languages treated as Meso-American are not in fact spoken in Meso-America proper but form linguistic families with languages that are spoken there. For information about languages of northeast, north central, and northwest Mexico that are not dealt with in this section, see above *North American Indian languages.* For languages of Central America not treated here, see below *South American Indian languages.*

Numbers of languages and speakers

Some 70 Indian languages are spoken today in Meso-America by perhaps 7,500,000 people. When the Spanish conquered Mexico in 1519, there may have been 20,000,000 people in Meso-America. Within 100 years of the conquest, the Indian population had decreased by 80 percent as a result of war, disease, forced labour, and starvation. Since then the Indian population has gone back to a higher level, but several languages—have become extinct. Meso-American languages with the greatest number of speakers in the mid-20th century are:

language	number of speakers	family
Aztec	1,200,000	Uto-Aztecan
Yucatec	600,000	Mayan
Quiché-Tzutujil-Cakchiquei	1,200,000	
Mam	450,000	
Kekchi	375,000	
Mixtec	350,000	Oto-Manguean
Zapotec	400,000	
Otomi	450,000	

The study of the Meso-American languages. During the 16th and 17th centuries, some Dominican and Franciscan missionaries devoted themselves to the study of native languages so that priests could deal in religious matters with monolingual Indians. They wrote grammars following a Latin model, devised orthographies applying values used in Spanish or Latin (occasionally inventing new letters), made dictionaries (usually vocabularies or glossaries), and translated Christian texts (confessionals, sacraments, and sermons) into Indian languages. Except for one heroic figure, the Spanish missionary priest Bernardino de Sahagùn, they neither collected nor fostered the collection of folklore. During this period grammars and dictionaries were written for such languages as Aztec, Zapotec, Mixtec, Tzeltal, Yucatec, Quiché-Tzutujil-Cakchiquel, Chortí, and Northwestern Otomí. These collections of data served the successors of the first missionaries. During the 18th century, the momentum of such work decreased, and,

after Mexico became independent in the first part of the 19th century, Spanish clerics were ousted, leaving further work on indigenous languages to travellers and gentlemen scholars—mostly people poorly qualified for such a task.

Extent of the studies of Meso-American languages

Modern linguistic techniques for the description of languages were not applied to Meso-American languages until North Americans turned their attention to the area in the 1930s and 1940s. Since then, much professional linguistic work has been done on these languages, especially those of Mexico. Almost every language of Meso-America has been worked on by at least one linguist, but the time spent and level of linguistic competence of the investigators have varied greatly. For most of the languages, grammatical and lexical data have been collected, much of which remains unpublished. A number of competent grammars and dictionaries have appeared; none of them however, is exhaustive or definitive. Folktales have been collected for a smaller number of languages. Spanish-based orthographies have been devised for most of the Meso-American languages in the 20th century, but not much reading matter is available in them. In short much work remains to be done.

CLASSIFICATION

Modern genetic groupings. The classification of Meso-American Indian languages presented here reflects generally accepted genetic groupings (as of the early 1970s), based on similarities in vocabulary and grammar and on the establishment of regular correspondences between sounds in cognate (related) words among the several languages. The languages grouped together are presumed to have developed from a common ancestor, called a protolanguage. Not all of the languages of Meso-America have been convincingly assigned to a specific group. A few of these languages are currently thought to be unrelated to any of the established genetic groupings and are listed individually in the table; these solitary languages are called isolates.

Within a given genetic grouping, there may be several levels of relatedness. Glottochronology (or lexicostatistics), developed by two United States linguists—Morris Swadesh and Robert Lees—is a controversial and not universally accepted procedure for measuring degrees of difference between related languages in terms of years of separation. Based on the assumption that all languages change more or less to the same degree in a given period of time the method employs a list of 100 items of "basic" or "noncultural" concepts, which are assumed to be expressible by vocabulary items in any language. Over a period of 1,000 years, different words will have been substituted to express 14 percent of the 100 concepts every 1,000 years, two languages that separated 1,000 years ago will share 74

*Indicates centuries of separation. †Not spoken in Meso-America. ‡There is some doubt whether these groups should be given the status of complexes. §Sonoran languages spoken in Meso-America. ‖Varieties of the same language spoken in different countries (and having different names).

percent cognates (86 percent of 86 is 74 percent). The following are terms and categories for degree of relatedness, correlated with glottochronological time depths, that will be used to describe the various Meso-American language groups. The figures given are minimal bounds.

term	centuries of separation	percentage of cognates
dialects	0–5	86–100
language complex	7–11	71–81
language group	13–17	60–68
branch (or family if there is no superordinate category)	19–26	45–56
language family	35–45	26–35
stock or phylum	55–65	14–19

In Table 61 every family (group) and isolate has a separate number from 1 to 21. Each of the 21 headings specifies the name of a grouping, with alternative names. Numbers in parentheses following language names indicate that there are several closely related languages all referred to by the same name. For each language grouping the various levels of relatedness are specified, including glottochronological figures (*c* = centuries), which are Swadesh's, except for Mixe-Zoque, Mayan, and Xincan, which are those of the U.S. linguist Terrence Kaufman. Family and stock names are formed in the following ways: (1) A typical language, usually the most widely spoken, is suffixed with *-an* (*e.g.,* Mixtecan). (2) Two typical names are chosen and compounded (*e.g.,* Mixe-Zoque). (3) Parts of two or more language names are joined, and *-an* is suffixed (*e.g.,* Oto-Manguean, Oto-Pamean, Mis-Uluan/Misumalpan).

Group names end in *-an* if the groups are further subgrouped but do not end in *-an* if they are immediately divided into discrete languages.

Outliers

The map gives the approximate geographical distribution of the 21 language groupings and isolates of Meso-America. None of the extinct undocumented languages is indicated. Except for some outliers, separate languages within a grouping are not localized. An outlier is a language that has been carried into a foreign cultural and linguistic context by migration; *e.g.,* Mangue is a Chiapanec outlier in Misumalpan territory, Subtiaba is a Tlapanec outlier in Misumalpan territory, Pipil is a Nahua (Aztec) outlier in Quichéan, Xinca, Lencan, and Misumalpan territories.

In the following paragraphs the numbers in parentheses refer to groupings in Table 61.

Uto-Aztecan (1). The Uto-Aztecan family consists of some 27 languages that are universally recognized to fall into eight groups or branches—the Plateau group, Tubatulabal, the Southern California branch, Hopi, the Piman group, the Yaquian branch, the Coran group, and the Nahuan group. Tubatulabal and Hopi contain just one language each. The first four groups are commonly, but not universally, recognized as forming a Shoshonean division within the family. None of the Shoshonean languages is spoken in Meso-America, and no distribution or population data is cited for them in Table 61 (see above *North American Indian languages*). There are two common ways of grouping the remaining languages, depending on the position assigned the Nahuan group. Either Nahuan is considered as separate and the rest as forming a Sonoran division, thereby producing three divisions—Shoshonean, Sonoran, and Nahuan—or else Nahuan is included within Sonoran, thereby producing a Shoshonean versus Sonoran dichotomy, which is the arrangement used in this article. Several scholars believe that the "division" concept is faulty here and that Uto-Aztecan contains eight groups and branches that are not to be further grouped in any special way.

Only some Sonoran languages are spoken in Meso-America (indicated by signs [§] in Table 61). The extinct Tubar belongs to the Yaquian branch, but whether to the Tarahumara complex, the Câhita complex, or neither, is not clear. The Nahuan group includes the extinct Pochutec, formerly spoken on the coast of Oaxaca, Mexico, and poorly documented; Pochutec is clearly very divergent from the rest of the group. The Aztec complex is considered by some to be a single language with several dialects. The three Aztec languages were spoken within the Aztec Empire as it was constituted in 1519. Pipil speakers, who also refer to their language as *nawat*, were not a part of the Aztec culture and probably represent a Toltec expansion from several centuries earlier.

Various scholars' work on Uto-Aztecan

In 1859, Johann Karl Buschmann, a German philologist, correctly identified all the then-known Uto-Aztecan languages as forming a family. In 1883 a French philologist, Hyacinthe de Charencey, divided Uto-Aztecan into Oregonian (=Shoshonean) and Mexican (=Sonoran), and, in 1891, in the United States, anthropologist Daniel Brinton recognized Shoshonean and divided the Sonoran division (of this article) into Nahuatlan (=Nahuan) and Sonoran (=the Sonoran of this article minus Nahuan). Brinton's division was followed by the United States biologist John Wesley Powell in his classification of North American languages.

Buschmann in 1859 and United States anthropological linguist Edward Sapir in 1915 contributed to the comparative study of Uto-Aztecan by assembling sizable numbers of cognate sets.

A number of now-acculturated and racially absorbed Indian ethnic groups of northern Mexico are believed by many to have spoken Uto-Aztecan languages, although only the language names are known, and not the languages themselves. These are: Suma, Jumano, Lagunero, Cazcán, Tecuexe, Guachichil, and Zacatec.

Uto-Aztecan is generally accepted by specialists as related to the Kiowa-Tanoan family of North America and with it to form the Aztec-Tanoan stock (or phylum).

Cuitlatec (2). The now extinct Cuitlatec language has not been linked convincingly with any other language or family, though the idea that it might be related to Uto-Aztecan has been entertained.

The Hokan hypothesis (3–5). In 1919 two United States anthropologists, Roland Dixon and Alfred Kroeber, tried to improve on an older North American classification by reducing the multiplicity of language groupings in California (about 50) to a manageable number of families and stocks. Working over a period of several years, they developed the hypothesis that most California languages belong to one of two great groupings (called phyla or superstocks), Hokan and Penutian. The formulation was accepted and extended by others. Hokan included Shasta, Achumawi, Atsugewi, Chimariko, Karok, Yanan, Pomoan, Washo, Esselen, Yuman, Salinan, and Chumashan. By 1891/92 it had been suggested that Yuman, Seri (3), and Tequistlatec (4) were related. In 1915 the matter was re-examined in the light of the Hokan hypothesis, and it was concluded that all of the languages named above are related. Since then most scholars familiar with Yuman languages have believed that Seri and Yuman are related, and many who accept the Hokan hypothesis believe that Seri and Yuman form a special group within Hokan.

Jicaque (5), which is very poorly documented, though still spoken, has plain, aspirated, and glottalized stops (different varieties of consonant sounds), as do many Hokan languages. In 1953 it was suggested that Jicaque is a Hokan language. The general acceptance of the proposition may have been uncritical, because the available data on Jicaque is hardly reliable.

Documented dead languages

Extinct languages of northeast Mexico. All of the several languages once spoken in northeast Mexico and South Texas have become extinct. Documented languages of Mexico are: Coahuilteco, Comecrudo, Cotoname, Naolan, and Tamaulipec (or Maratino). Those of Texas are Karankawa (and Klamkosh), Atakapa, and Tonkawa. John Wesley Powell classified the first three as forming a Coahuiltecan family. The other Mexican languages were unknown until recently. Each of the three Texan languages was considered by Powell to be an isolate. In 1920 Coahuiltecan was redefined to include Karankawa and Tonkawa and to be coordinate with Hokan in a Hokan-Coahuiltecan (=Hokaltecan) superphylum.

Tlapanec (6). The Tlapanec complex was first correctly identified by Walter Lehmann, a German physician, in 1920. In 1925 Edward Sapir tried to establish Subtiaba as a Hokan language, proposing some Proto-Hokan reconstructions that could account for the Subtiaba forms. This classification is generally accepted. More recently, however, Calvin Rensch, a U.S. missionary linguist, tried to validate the Oto-Manguean hypothesis (see below) by means of full-scale phonological reconstruction. He believed Tlapanec to be Oto-Manguean; others considered it to be intermediate between Oto-Manguean and Hokan. It must be kept in mind that most of the specialists who have immersed themselves in the study of large numbers of American Indian languages believe that almost all of them are genetically related to one another. This relationship derives from a period, perhaps 20,000 to 30,000 years ago, when some of the languages were still spoken in Asia. With such a point of view, correct grouping (or degree of relationship) is a more interesting question than genetic relatedness.

Oto-Pamean (7). The Oto-Pamean stock contains four groups and complexes, Chichimec, Pamean, Matlatzinca, and Otomían, of which only the last two are spoken within Meso-America. The exact number of languages within the Otomí complex is not yet determined, though there seem to be four. Oto-Pamean was first correctly identified in 1892.

Popolocan (8). The Popolocan family (which might more appropriately be called Mazatecan) was correctly identified in 1926. The exact number of languages within the Mazatec complex has not yet been determined, though there are at least two.

Problem of classifying Amuzgo

Mixtecan (9). There is some difference of opinion as to how the various languages here included within Mixtecan are to be grouped. The main problem is whether Amuzgo is Mixtecan or a separate branch within Oto-Manguean. It has been included within Mixtecan in some systems and excluded from it in others. There seem to be three languages within the Mixtec group, a subdivision of Mixtecan.

Zapotecan (10). The Zapotecan family was correctly identified by William Mechling in 1912, but only Francisco Belmar, a Mexican philologist, correctly recognized that Papabuco is a separate language, neither Zapotec nor Chatino (in 1905). Belmar, however, incorrectly included Chinantec within Zapotecan. The Chatino language has several dialects. Within the Zapotec complex there are at least four languages, and perhaps more.

Chinantecan (11). The Chinantecan group contains approximately four languages, the exact number as yet undetermined. The separateness of Chinantecan within Oto-Manguean was recognized in 1912.

Manguean (12). The Manguean group was correctly identified by Belmar in 1905. Its members, formerly spoken in Chiapas (Mexico), and in Nicaragua, Honduras, and Costa Rica, are now extinct.

The Oto-Manguean hypothesis (7–12 or 6–13). Ever since 1891, it has been proposed that two or more of the above families (7–12) should be linked. Since about 1925,

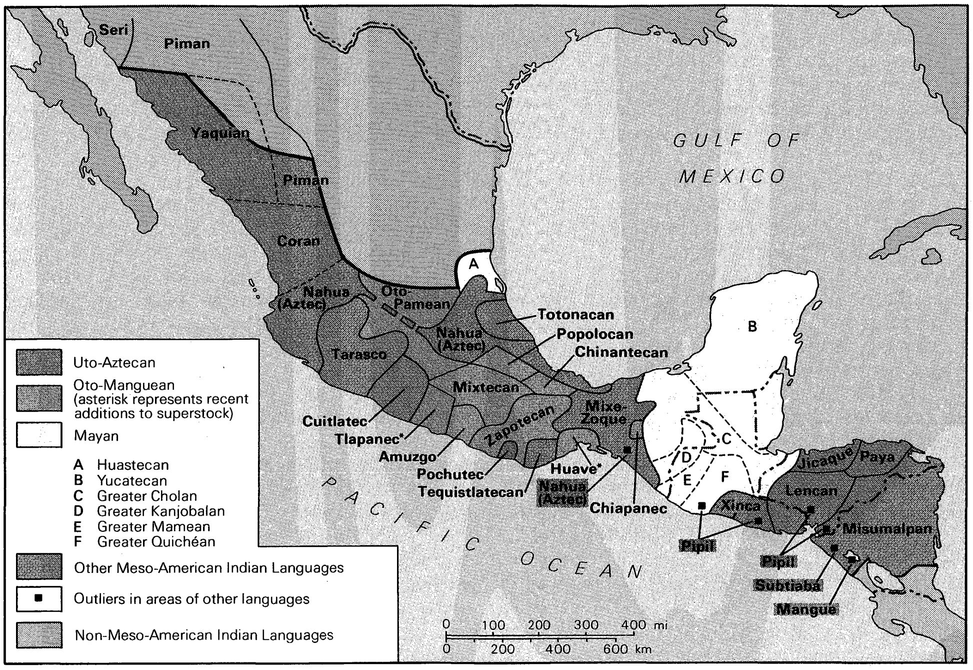

Figure 35: Distribution of Meso-American Indian languages *c.* AD 1500. Boundaries are schematic.

it has been generally accepted by specialists that the Oto-Pamean, Popolocan, Mixtecan, Zapotecan, Chinantecan, and Manguean groups form a larger genetic grouping (phylum), commonly labelled Oto-Manguean. This may be called the "classical Oto-Manguean formulation." Since 1950, work has been going on in the reconstruction of parent languages for each of the constituent families and groups. Since 1961, two revisions have been proposed in the formulation of what constitutes Oto-Manguean: the Tlapanec language complex has been recognized as included in or closely related to Oto-Manguean, and Huave has been proposed as an Oto-Manguean language. In the early 1970s, therefore, most Oto-Manguean specialists considered the grouping to consist of groups 6–13.

Reconstruction of Oto-Manguean phonology

The comparative study of the Oto-Manguean phylum has resulted in the first case in the Western Hemisphere in which the remote common ancestor of several language families has been phonologically reconstructed. Comparative linguistics at the phylum level has been largely unsuccessful with other postulated superstocks because of the relatively small number of cognates that can be identified. Except for Manguean, all Oto-Manguean languages are spoken in central Mexico.

Huave (13). Early proposals linked Huave to Mixe-Zoque and Mayan. Although this has not been generally accepted by many specialists, it has been uncritically repeated in most compilations. Recently, Morris Swadesh presented a reasonably well documented proposal for Huave as an Oto-Manguean language.

Mixe-Zoque (14). The Mixe-Zoque family consists of eight languages, which, comparative phonology and grammar suggest, form two branches—a Zoquean group, and a Mixean group including Tapachultec. Glottochronological figures, however, suggest a three-way division, as shown in the Table. The Mixe-Zoque family was correctly identified by Hyacinthe de Charencey in 1883. The Texistepec, Sayula, and Oluta languages of this family are all locally called Populuca.

Totonacan (15). The Totonacan family contains just two languages, of which one (Totonac) has at least three dialects. Possibly, Totonac is a complex.

Mayan (16). The Mayan family was correctly identified by a German ethnographer, Otto Stoll, in 1884. This family, with 24 languages and nearly 3,500,000 speakers, is the most diversified and populous language family of Meso-America. The Huastec language is separated by more than 1,000 miles from the nearest other Mayan language. Taken with the fact that the Huastecs did not share in the Classic Maya civilization, this requires a historical explanation involving the separation of Huastec from the rest of the family more than 2,500 years ago. Though the geographical extent of the Mayan languages is considerable, the Mayan peoples, languages, and cultures (as contrasted with those of the Aztecs), have never been particularly expansionist.

A number of attempts have been made to classify the Mayan languages, each one availing itself of more data than the last. The classification given here as of 1971 recognizes, at the lowest level, ten groupings. Specialists have disagreed on the precise positions of Tojolabal and Chuj, Motozintlec, Aguacatec, Uspantec, and Kekchí and have held no firm opinions about the Yucatec or Huastec complexes. Not much comparative work on the Mayan family has seen print, but much data has recently been collected. The main contributors to Mayan comparative studies have been the U.S. linguists Norman McQuown (1950s and 1960s) and Terrence Kaufman (1960s).

Hypotheses concerning superstocks

The Macro-Mayan and Macro-Penutian hypotheses. In 1931 L.S. Freeland, a U.S. anthropological linguist, tried to show that Mixe (Zoque) is related to the "Penutian" languages, a superstock that up until then had been limited to California, Oregon, Washington, and British Columbia. In 1935 it was suggested that the similarities between Uto-Aztecan, Tanoan, Kiowa, Penutian, Mixe-Zoque, and Mayan were such as to indicate the existence of a superstock, which it was proposed to call Macro-Penutian. This hypothesis had favour for a period but was never demonstrated nor taken very seriously by specialists. Since then the first three have been generally joined in Aztec-Tanoan. In 1942 it was suggested that Mixe-Zoque and Totonacan might be related genetically to each other and the two in turn might be related to Mayan, the resultant superstock to be called Macro-Mayan. Recently it has been claimed that Tarasco (17) probably belongs in Macro-Mayan as well, though the attempt to prove this has not been convincing to most Mayanists, to whom, minus Tarasco, the Macro-Mayan hypothesis seems as reasonable as the Hokan hypothesis.

Tarasco (17). Tarasco has been linked genetically by some not only to Marco-Mayan but also to both Zuni (in North America) and Quechua (in South America), but without general scholarly acceptance.

Xinca and Lencan (18–19). It has been suggested that Xinca and Lencan are related and that one or both of them is related to Mayan (16), Chibchan (in South America), or Uto-Aztecan (1). None of these hypotheses has been demonstrated as probable.

Languages outside Meso-America proper. The Paya language (20) and the Misumalpan family (21) are Central American languages spoken outside of the cultural area of Meso-America proper, though they have Meso-American outliers in their territory. Paya (20) has been linked in hypotheses to Chibchan and Cariban (both in South America), and perhaps to others, but not convincingly. The Misumalpan family (21) has been recognized since 1895. Since that date some scholars have believed that the three languages and complexes listed are coordinate, and others have believed that the first two constitute one group and the other consitutes a second group. Although the family relationship can be verified on inspection, no supporting comparative work has been published. Previous comprehensive classifications of the Meso-American Indian languages were presented by the U.S. anthropologists Cyrus Thomas and John R. Swanton in 1911 in *Indian Languages of Mexico and Central America and Their Geographical Distribution,* by Edward Sapir in the 14th edition of *Encyclopædia Britannica* (1929), and by Morris Swadesh in 1967 in *Handbook of Middle American Indians.*

Newly discovered languages and reconstructions. Although there are probably no uncharted areas in Meso-America, it is not necessarily the case that all the Indian languages of Meso-America have been correctly identified, and there are probably some multilingual Indian communities as well that are not known to be such. In 1967 Terrence Kaufman discovered a hitherto undocumented Mayan language spoken by several hundred Indians in four or five towns in southeast Chiapas and west central Guatemala. Although it appears to be closely related to Mam, Kaufman considered it a separate language and christened it Teco. Kaufman identified two more new Mayan languages in the course of a linguistic survey of Guatemala. These two new languages—Sacapultec (formerly considered Quiché) and Sipacapa (formerly assumed to be Mam)—are not documented in print and both belong to the Quiché complex.

Reconstruction of earlier forms of the Meso-American Indian languages has focussed primarily on phonology and vocabulary. Phonological and lexical comparative studies as well as reconstruction have been done for the following groups: Uto-Aztecan; Oto-Manguean—Oto-Pamean, Popolocan, Mixtecan, Zapotecan, Chinantecan, Manguean; Mixe-Zoque; and Mayan (in part). A small amount of grammatical comparison has been done within Oto-Manguean and Mixe-Zoque. In addition, some studies have been done of reconstructed vocabulary for the purpose of hypothesizing about the culture of the speakers of the protolanguages.

RELATION OF LANGUAGES TO HISTORICAL AND CULTURAL INFLUENCES

Pre-Columbian diffusion. The following are some of the important civilizations that have flourished in Meso-America:

civilization	period	location
Olmec	1200 BC–400 BC	Gulf Coast, Mexico
Monte Albán	400 BC–AD 700	Oaxaca, Mexico
Teotihuacán	AD 100–600	Central Mexico
Classic Maya	AD 300–900	Chiapas, Mexico; Petén, Guatemala
Toltec	900–1200	Central Mexico
Aztec	1300–1500	Central Mexico

The Aztecs spoke Nahuatl, as did the Toltecs. The Classic Maya probably spoke two or three Mayan languages, and the people of Monte Albán probably spoke one or more Zapotecan languages. No one knows what either the Teotihuacán people or the Olmecs spoke, but it has been surmised that at least some Olmecs spoke Mixe-Zoque languages and that the Teotihuacán people may have spoken Otomían languages (though an Aztec tradition says Totonac).

In the pre-Columbian period, there was naturally contact among Meso-American languages and occasional borrowing of vocabulary and other linguistic features. Partly because of the unavailability of grammars and dictionaries, actual cases of such diffusion have not been much studied.

Known contacts between various Indian groups

Some of the known contacts resulting in borrowing are the following: (1) Mixe-Zoque languages (Olmecs?) have given words to Mayan, Mixtecan, Zapotecan, Otomían, Aztec, Lencan, Xinca, and Jicaque; (2) Zapotecan languages (Monte Albán) have given words to Huastec and Yucatec; (3) Mayan languages (Mayas) have given words to Xinca, Lencan, and Jicaque; and (4) Nahuatl (Toltecs and Aztecs) has given words to Mayan, Lencan, other Uto-Aztecan languages, as well as to other Meso-American languages. Words diffused from these sources provide evidence that contact took place. Scholars know that contact must have taken place at particular times and places, and therefore can form hypotheses about where certain languages may have been spoken in the more remote past.

External relationships and contacts. Various scholars have suggested that some Meso-American language or family is related to a language or family (other than Uto-Aztecan) outside of Meso-America. These suggestions are mostly parts of larger attempts to synthesize the language classification of the New World, or of the whole world, and are usually based on the sometimes unexpressed view that all the languages of the Western Hemisphere or even of the whole world are ultimately genetically related. Although the assumption may be true, the proposed connections have been unconvincing to specialists in Meso-American languages. The only generally accepted larger groupings are Hokan and Penutian. Most scholars do not have the breadth of knowledge to be able to evaluate these vast proposals.

Prehistoric linguistic connection between Meso-America and the Andes

One proposal of external relationship probably has some merit. In 1961 it was suggested that Chipaya—a language spoken on the shores of Lake Titicaca in Bolivia—is genetically related to the Mayan languages. The hypothesis, proposed by Ronald Olson, a U.S. missionary linguist, was based on 120 sets of lexical comparisons between Chipaya and Proto-Mayan. The data cited are subject to more than one interpretation, because many of the comparisons involve semantic notions and word forms that are widespread in the Western Hemisphere; also, Chipaya has been so influenced grammatically by Aymara (which all Chipayas can speak) that any grammatical peculiarities it may once have shared with Mayan have disappeared. Because a core of data showing regular sound correspondences remains, it is probably necessary to assume that there is a historical connection between Chipaya and Mayan, possibly, but not demonstrably, a genetic relationship. The connection may have been direct—presumably from Meso-America to Bolivia via land—or there may be other languages in western South America that show prehistoric contacts with Mayan. The acceptance of a prehistoric linguistic connection, neither extremely remote nor extremely recent, between Meso-America and the Andes is quite provocative, inasmuch as other evidence exists for early culture contact between Meso-America and the Andes, Meso-America generally being the donor and the Andes generally being the beneficiary; *e.g.,* in the case of corn. Later diffusion from South America to Meso-America also occurred; *e.g.,* witness the transference of peanuts, metallurgy, hammocks.

Interaction between Spanish and Indian languages. In modern Meso-America, the dominant European language is Spanish. The speakers of all Meso-American Indian languages include some who are bilingual; and a few languages are spoken by almost totally bilingual populations. Most Indian languages spoken by sizable populations have at least 50 percent monolingual speakers. All Meso-American languages with a significant number of bilingual speakers have been influenced by Spanish, primarily in the areas of vocabulary, particles, and word order. Since the Spanish conquest, Meso-American languages have been borrowing words from Spanish, and, because the kind of Spanish spoken has changed somewhat over the years, both in vocabulary and pronunciation, different historical periods are usually distinguishable in lexical borrowings. For a variety of reasons, certain function words, primarily conjunctions and adverbs, are frequently borrowed from Spanish; *e.g., ya* "already," *pero* "but," *hasta* "until," *y* "and," *o* "or," *ni* "not even," *hasta* "even," *si* "if," *cuando* "when," *porque* "because," *por eso* "therefore, so," *entonces* "then." Some languages have assimilated the Spanish word order of subject–verb–object.

Conversely, the Spanish of Meso-America has been the recipient of vast amounts of lexical material from local languages, primarily Nahuatl. The borrowing has provided names of plants, animals, artifacts, and social forms indigenous to Meso-America and lacking names in Spanish. Among the reasons that Nahuatl has been the primary source is that the Aztecs were the first Meso-American people conquered by the Spaniards; the Aztecs had outposts in many parts of Meso-America; the Spaniards recruited Aztecs, particularly as guides, into their military force to assist their venture of subduing the rest of Meso-America; and, for several decades, Aztec, written in Roman orthography, was used in many parts of Meso-America to keep official records, such as deeds, wills, and censuses.

Many of the words borrowed into Spanish from Aztec have since passed in turn into English; *e.g.,* chili, chile, or chilli (Spanish *chile*), avocado (Spanish *aguacate*), chicle, chocolate, peyote, coyote, tomato (Spanish *tomate*), ocelot (Spanish *ocelote*), guacamole, mescal.

Bilingualism among Indians

In some parts of Meso-America, because of economic and social conditions, an Indian may speak one or more Indian languages besides his own. This is common in Guatemala, where some areas have been recently colonized by speakers of more than one language, or some communities have received outside settlers in the more remote past.

The names used in this article for the Meso-American Indian languages are English versions of the Spanish terms for them. Only in a few cases are these names the ones actually used by the people who speak the languages in question. First, most of the names are of Aztec origin, because at the outset the Spanish learned of local phenomena primarily via Aztec. Secondly, some languages have no special name of their own, simply being called "our language."

Pre-Columbian writing. Most of the Meso-American cultures shared a mathematical notation and calendrical system that had been developed and diffused in the distant past, probably before 500 BC. At the time of European contact the Aztecs, Zapotecs, Mixtecs, Otomís, Mayans, and perhaps some others were all producing records on stone (inscriptions) and on a type of homegrown paper (produced from the amate tree, *Ficus glabrata*), these latter being commonly called codices. Except for the Mayan system, which probably originated before AD 1, the records cannot properly be called writing, in that it was not possible to represent all of speech, but only numbers, dates, and names (pictographically). The Mayan system, besides representing all these, was also used to represent morphemes (words and word elements) and phonemes (distinctive sounds). Presumably the symbols used in this system (called glyphs) represent individual phonemes, syllables, and morphemes; and they give semantic information as well to take the ambiguity out of homophonous readings. Several scholars have devoted much time to the study of Mayan writing, but, to date, the results have not been very impressive. A few scholars outside the Meso-American field believe the Mayan writing system is purely ideographic and hence inherently undecipherable without a bilingual inscription or text in a known language. All specialists within the Mayan field hold that the Mayan is a mixed ideographic and phonological system.

What may be delaying progress in the deciphering of Mayan writing is the absence of reconstructions for intermediate groupings within the Mayan family (*e.g.,* Proto-Yucatecan, Proto-Cholan, and others) and ignorance of Mayan languages other than colonial Yucatec on the part of the investigators. Efforts are being made to correct these deficiencies, particularly by Mexican specialists. It is not known whether Mayan writing was used to write more than one language and, if so, what the languages were. If only one, it was probably either Proto-Cholan or Proto-Yucatecan. The symbols used in all the pre-Columbian notation systems are obviously pictographic in origin, as was the case in the ancient Egyptian, Sumerian, ancient Chinese, and Indus Valley writing systems.

LINGUISTIC CHARACTERISTICS

Diverse types of sound systems and grammars

In general, all the languages of a particular family are typologically similar to one another both in phonology and grammar. Among the 21 language groupings in Meso-America, there are several types of sound systems and grammatical systems. Because study in this area has hardly begun, nothing very secure can be asserted here, but some general characteristics can be outlined on the basis of data for the following reasonably well-documented languages: Tequistlatec, Otomí, Mazatec, Mixtec, Zapotec, Chinantec, Aztec, Zoque, Totonac, Quiché, and Tarasco.

Phonologically, there is a wide diversity among Meso-American languages. Voiced spirants—*i.e.,* sounds like English *v, z,* or *th* in "then"—are missing from all Meso-American languages. Other phonological features in these languages include a voiceless lateral spirant sound, *lh* (in Tequistlatec and Totonac); a lateral affricate, *tl* (in Aztec and Totonac); a postvelar stop, *q,* in contrast with a velar stop, *k* (in Quiché and Totonac); glottalized vowels (in Zapotec, Zoque, Aztec, and Totonac); glottalized consonants (in Tequistlatec, Quiché, Otomí, and Mazatec); aspirated stops (in Tarasco, Otomí, and Mazatec); voiced stops (in Tequistlatec, Otomí, Mazatec, and Chinantec); prenasalized stops (in Otomí, Mazatec, and Mixtec); nasalized vowels (in Otomí, Mazatec, Mixtec, and Chinantec); a labiovelar stop, *kw,* sometimes contrasting with a bilabial stop, *p* (in Otomí, Mazatec, Mixtec, Aztec); tone and stress accent (tone in Otomí, Mazatec, Mixtec, Chinantec, Zapotec; stress in Tarasco and Tequistlatec); and initial and final consonant clusters (in Tequistlatec).

Grammatically, Meso-American languages are rather diverse, but, according to available data, they fall into three main types: Type A, an Oto-Manguean type, is rightward expanding (*i.e.,* modifiers follow the elements they modify) and synthetic to a low degree (*i.e.,* characterized by relatively few morphemes per word). It employs prefixes and prepositions, and it seldom uses compounding to form words. Type B, an intermediate type, is prepositional, like A, and averagely synthetic, making some use of prefixes (subjects, objects, and possessors) and much use of suffixes. It is mildly leftward expanding (*i.e.,* modifiers precede the elements they modify) and is mainly represented by Mayan and Uto-Aztecan languages but partially by Mixe-Zoque and Totonacan. Type C, a leftward expanding type, is highly synthetic with great use of suffixes and postpositions and active ablaut (an interchange among consonants and vowels for the purpose of derivation or inflection). It is represented by Tarasco and, partially, by Totonacan and Mixe-Zoque.

Grammatical generalizations

There are a number of grammatical generalizations that can be made about all, or most, Meso-American Indian languages. (1) The genitive relationship between nouns or noun phrases is (except for Tarasco) expressed by means of a possessive pronoun with the possessed noun; *e.g.,* "the dog's fleas" is expressed as "his fleas the dog." (2) Locative notions, such as "above," "below," "in," "on," "beside," are not expressed by prepositions and adverbs, as in European languages, but by means of location nouns (meaning "aboveness," "belowness," "belly," "surface," "side," and so forth), which are always combined with a possessive pronoun, the function of which is to indicate the "object" of the prepositional–adverbial notion. Most languages, however, have at least one generic relational particle that is combined in a phrase with a location noun and its object and has "generic prepositional" function; thus "on the table" is expressed "at (generic particle) its-top the table," or "in the box" is expressed "at its-inside the box." Whereas in most languages the generic relational particles are prepositions, Zoque and Tarasco have postpositions, which are in part related to location nouns.

(3) Within the verbal system, aspect (type of action—*e.g.,* ongoing, habitual, finished, potential, and so forth) is well developed, and tense (time—*e.g.,* now, in the past, in the future) is generally weakly developed. (4) The copula, or equational verb "be," is not expressed in most Meso-American languages. (5) Case suffixes are generally absent,

being present in just three languages: Tarasco has a genitive case, an objective case, and various locational cases; Aztec and Zoque have only locational cases, and these are usually related to location nouns. (6) A relative clause that modifies a noun follows it in all the languages of the sample above; *e.g.,* "the man whom I saw (on the street yesterday)." (7) Some Oto-Manguean languages and some Mayan languages distinguish an inclusive pronoun "we" ("I and you") from an exclusive "we" ("I and he/they").

(8) Gender, or inflectional agreement of other word classes in the noun phrase with the noun itself, is rare in Meso-American languages and is limited to some Oto-Manguean languages. (9) Noun subclassification in the context of possession is not uncommon. In some languages, some nouns undergo form changes when possessed; these languages, therefore, have at least two classes of nouns. In other languages, the possessive pronouns differ in form according to how they are associated with different classes of nouns. In languages in which the semantic motivation for such a subdivision is clear, the main kind of distinction is between intimate possession (body parts, kinship terms, articles of clothing) and casual possession (domestic animals, tools). (10) Some languages (Mayan, Mixe-Zoque) distinguish between the subject (actor) of a transitive verb and that of an intransitive verb by the form of the associated affixed pronoun. (11) Most Meso-American languages average more than one morpheme per word, and Tarasco and Totonac average more than two morphemes per word. (12) Most Meso-American languages (except Aztec) have consonantal or vocalic ablaut, or else show in their vocabulary sets of words that seem to be related through a formerly functional ablaut system.

(13) The numeral systems are vigesimal–decimal; that is, counting is from 1 to 10, then from 11 to 20, then from 21 to 40 (adding 1–20 to 20), then from 41–60 (adding 1–20 to 40), and so on, with special terms for 400 (20 × 20), 8,000 (20 × 20 × 20), 160,000 (20 × 20 × 20 × 20), and so on. In most languages (except Mayan) the numeral expressions for 6 through 9 (sometimes 5 through 9) are compounds of 5 + 1, 5 + 2, 5 + 3, 5 + 4, or the like. (14) In all the languages referred to here, a numeral precedes the noun it quantifies. (Te.K.)

South American Indian languages

South American Indian languages once covered and today still partially cover all of South America, the Antilles, and Central America to the south of a line from the Gulf of Honduras to the Nicoya Peninsula in Costa Rica. Estimates of the number of speakers in that area in pre-Columbian times vary from 10,000,000 to 20,000,000. In the early 1980s there were approximately 15,900,000, more than three-fourths of them in the central Andean areas. Language lists include around 1,500 languages, and figures over 2,000 have been suggested. For the most part, the larger estimate refers to tribal units whose linguistic differentiation cannot be determined. Because of extinct tribes with unrecorded languages, the number of languages formerly spoken is impossible to assess. Only between 550 and 600 languages (about 120 now extinct) are attested by linguistic materials. Fragmentary knowledge hinders the distinction between language and dialect and thus renders the number of languages indeterminate.

Number of languages and speakers

Because the South American Indians originally came from North America, the problem of their linguistic origin involves tracing genetic affiliations with North American groups. To date only Uru-Chipaya, a language in Bolivia, is surely relatable to a Macro-Mayan phylum of North and Meso-America. Hypotheses about the probable centre of dispersion of language groups within South America have been advanced for stocks like Arawakan and Tupian, based on the principle (considered questionable by some) that the area in which there is the greatest variety of dialects and languages was probably the centre from which the language groups dispersed at one time; but the regions in question seem to be refugee regions, to which certain speakers fled, rather than dispersion centres.

South America is one of the most linguistically differentiated areas of the world. Various scholars hold the plausible view that all American Indian languages are ultimately related. The great diversification in South America, in comparison with the situation of North America, can be attributed to the greater period of time that has elapsed since the South American groups lost contact among themselves. The narrow bridge that allows access to South America (*i.e.,* the Isthmus of Panama) acted as a filter so that many intermediate links disappeared and many groups entered the southern part of the continent already linguistically differentiated.

Investigation and scholarship. The first grammar of a South American Indian language (Quechua) appeared in 1560. Missionaries displayed intense activity in writing grammars, dictionaries, and catechisms during the 17th century and the first half of the 18th. Data were also provided by chronicles and official reports. Information for this period was summarized in Lorenzo Hervás y Panduro's *Idea dell' universo* (1778–87) and in Johann Christoph Adelung and Johann Severin Vater's *Mithridates* (1806–17). Subsequently, most firsthand information was gathered by ethnographers in the first quarter of the 20th century. In spite of the magnitude and fundamental character of the numerous contributions of this period, their technical quality was below the level of work in other parts of the world. Since 1940 there has been a marked increase in the recording and historical study of languages, carried out chiefly by missionaries with linguistic training, but there are still many gaps in knowledge at the basic descriptive level, and few languages have been thoroughly described. Thus, classificatory as well as historical, areal, and typological research has been hindered. Descriptive study is made difficult by a shortage of linguists, the rapid extinction of languages, and the remote location of those tongues needing urgent study. Interest in these languages is justified in that their study yields basic cultural information on the area, in addition to linguistic data, and aids in obtaining historical and prehistorical knowledge. The South American Indian languages are also worth studying as a means of integrating the groups that speak them into national life.

Research on the languages

Classification of the South American Indian languages. Although classifications based on geographical criteria or on common cultural areas or types have been made, these are not really linguistic methods. There is usually a congruence between a language, territorial continuity, and culture, but this correlation becomes more and more random at the level of the linguistic family and beyond. Certain language families are broadly coincident with large culture areas—*e.g.,* Cariban and Tupian with the tropical forest area—but the correlation becomes imperfect with more precise cultural divisions—*e.g.,* there are Tupian languages like Guayakí and Sirionó whose speakers belong to a very different culture type. Conversely, a single culture area like the eastern flank of the Andes (the Montaña region) includes several unrelated language families. There is also a correlation between isolated languages, or small families, and marginal regions, but Quechumaran (Kechumaran), for instance, not a big family by its internal composition, occupies the most prominent place culturally.

Most of the classification in South America has been based on inspection of vocabularies and on structural similarities. Although the determination of genetic relationship depends basically on coincidences that cannot be accounted for by chance or borrowing, no clear criteria have been applied in most cases. As for subgroupings within each genetic group, determined by dialect study, the comparative method, or glottochronology (also called lexicostatistics, a method for estimating the approximate date when two or more languages separated from a common parent language, using statistics to compare similarities and differences in vocabulary), very little work has been done. Consequently, the difference between a dialect and language on the one hand, and a family (composed of languages) and stock (composed of families or of very differentiated languages) on the other, can be determined only approximately at present. Even genetic groupings recognized long ago (Arawakan or Macro-Chibchan) are probably more differentiated internally than others that have been questioned or that have passed undetected.

Extinct languages present special problems because of poor, unverifiable recording, often requiring philological interpretation. For some there is no linguistic material whatsoever; if references to them seem reliable and unequivocal, an investigator can only hope to establish their identity as distinct languages, unintelligible to neighbouring groups. The label "unclassified," sometimes applied to these languages, is misleading: they are unclassifiable languages.

Problem of language names

Great anarchy reigns in the names of languages and language families; in part, this reflects different orthographic conventions of European languages, but it also results from the lack of standardized nomenclature. Different authors choose different component languages to name a given family or make a different choice in the various names designating the same language or dialect. This multiplicity originates in designations bestowed by Europeans because of certain characteristics of the group (*e.g.,* Coroado, Portuguese "tonsured" or "crowned"), in names given to a group by other Indian groups (*e.g.,* Puelche, "people from the east," given by Araucanians to various groups in Argentina), and in self-designations of groups (*e.g.,* Carib, which, as usual, means "people" and is not the name of the language). Particularly confusing are generic Indian terms like Tapuya, a Tupí word meaning enemy, or Chuncho, an Andean designation for many groups on the eastern slopes; terms like these explain why different languages have the same name. In general (but not always), language names ending in *-an* indicate a family or grouping larger than an individual language; *e.g.,* Guahiboan (Guahiban) is a family that includes the Guahibo language, and Tupian subsumes Tupí-Guaraní.

There have been many linguistic classifications for this area. The first general and well-grounded one was that by U.S. anthropologist Daniel Brinton (1891), based on grammatical criteria and a restricted word list, in which about 73 families are recognized. In 1913 Alexander Chamberlain, an anthropologist, published a new classification in the United States, which remained standard for several years, with no discussion as to its basis. The classification (1924) of the French anthropologist and ethnologist Paul Rivet, which was supported by his numerous previous detailed studies and contained a wealth of information, superseded all previous classifications. It included 77 families and was based on similarity of vocabulary items. Čestmír Loukotka, a Czech language specialist, contributed two classifications (1935, 1944) on the same lines as Rivet but with an increased number of families (94 and 114, respectively), the larger number resulting from newly discovered languages and from Loukotka's splitting of several of Rivet's families. Loukotka used a diagnostic list of 45 words and distinguished "mixed" languages (those having one-fifth of the items from another family) and "pure" languages (those that might have "intrusions" or "traces" from another family but totalling fewer than one-fifth of the items, if any). Rivet and Loukotka contributed jointly another classification (1952) listing 108 language families that was based chiefly upon Loukotka's 1944 classification. Important work on a regional scale has also been done, and critical and summarizing surveys have appeared.

Current classifications

Current classifications are by Loukotka (1968); a U.S. linguist, Joseph Greenberg (1956); and another U.S. linguist, Morris Swadesh (1964). That of Loukotka, based fundamentally on the same principles as his previous classifications, and recognizing 117 families, is, in spite of its unsophisticated method, fundamental for the information it contains. Those of Greenberg and Swadesh, both based upon restricted comparison of vocabulary items but according to much more refined criteria, agree in considering all languages ultimately related and in having four major groups, but they differ greatly in major and minor groupings. Greenberg used short lexical lists, and no evidence has been published in support of his classification. He divided the four major groups into 13 and these, in turn, into 21 subgroups. Swadesh based his classification upon lists of 100 basic vocabulary items and made groupings according to his glottochronological theory (see above). His four groups (interrelated among themselves and with groups in North America) are subdivided into 62 subgroups, thus, in fact, coming closer to more conservative classifications. The major groups of these two classifications are not comparable to those recognized for North America, because they are on a more remote level of relationship. In most cases the lowest components are stocks or even more distantly related groups. It is certain that far more embracing groups than those accepted by Loukotka can be recognized—and in some cases this has already been done—and that Greenberg's and Swadesh's classifications point to many likely relationships; but they seem to share a basic defect, namely, that the degree of relationship within each group is very disparate, not providing a true taxonomy and not giving in each case the most closely related groups. On the other hand, their approach is more appropriate to the situation in South America than a method that would restrict relationships to a level that can be handled by the comparative method.

At present, a true classification of South American languages is not feasible, even at the family level, because, as noted above, neither the levels of dialect and language nor of family and stock have been surely determined. Beyond that level, it can only be indicated that a definite or possible relationship exists. In the accompanying chart—beyond the language level—recognized groups are therefore at various and undetermined levels of relationship. Possible further relationships are cross-referenced. Of the 82 groups included, almost half are isolated languages, 25 are extinct, and at least 10 more are on the verge of extinction. The most important groups are Macro-Chibchan, Arawakan, Cariban, Tupian, Macro-Ge, Quechumaran, Tucanoan, and Macro-Pano-Tacanan.

Macro-Chibchan. Macro-Chibchan languages, which form the linguistic bridge between South and Central America, are spoken from Nicaragua to Ecuador. Spread compactly in Central America and in western Colombia and Ecuador, they include approximately 40 languages spoken by more than 400,000 speakers. The group is probably more differentiated than a stock, languages not belonging to Chibchan being strongly differentiated. In the Colombian Andes a now extinct Chibchan language was the language of the highly developed Muisca culture. Important present-day languages include Guaymí (about 20,000 speakers) and Move (about 15,000) in Panama, Cuna (600) and Páez (37,000) in Colombia, and Cayapa, or Colorado (4,000), in Ecuador. A connection with Cariban has been suggested, and it is possible that such a relationship could be found through Warao (Warrau) and Waican (Waikan) on the one hand and through Chocó (Cariban) on the other.

Extent of the Arawakan languages

Arawakan. Arawakan languages formerly extended from the peninsula of Florida in North America to the present-day Paraguay–Argentina border, and from the foothills of the Andes eastward to the Atlantic Ocean. More than 55 languages are attested, many still spoken. Around 40 groups still speak Arawakan languages in Brazil, and others are found in Peru, Colombia, Venezuela, Guyana, French Guiana, and Surinam. Taino predominated in the Antilles and was the first language to be encountered by Europeans; although it rapidly became extinct, it left many borrowings. As did most languages of the tropical forest, the Arawakan languages receded with the influx of Spanish and Portuguese, mainly through group extinction; thus, 14 groups became extinct in Brazil between 1900 and 1957. Important languages still spoken are Goajiro (52,000 speakers) in Colombia, Campa (41,000) and Machiguenga (11,000) in Peru, and Mojo (more than 15,000) and Bauré (4,500) in Bolivia. Although most Arawakan languages have been recognized as such for a long time, they are greatly differentiated. They are most probably related to both the Macro-Pano-Tacanan and Macro-Mayan language groups.

Cariban. Cariban languages, numbering approximately 50, were spoken chiefly north of the Amazon but had outposts as far as the Mato Grosso in Brazil. The group has undergone drastic decline, and only about 22,000 people speak Cariban languages today, mostly in Venezuela and Colombia; they have disappeared from the Antilles and have been much reduced in Brazil and the Guianas. The

Table 62: South American Indian Language Groups*

language	location
1. Alacalufan (47): Aksanas or Kaueskar, Alacaluf, Caucau or Caucawe	Chile
2. Andoque (9)	Colombia
3. Araucanian or Mapuche (32, 37)	Chile, Argentina
4. Arawakan (43, 44)	
A. Amuesha	Peru
B. Apolista or Lapachu†	Bolivia
C. Arauan: Araua†, Curina, Madihá, Paumarí, Yamadí	Brazil
D. Chamicuro	Peru
E. Maipurean	
1. Achagua, Amarizana, Capite Minanei, Cauyarí, Guarú, Guayupé, Maipure†, Piapoco, Resígaro, Tariana, Warakena†, Yucuna	Colombia
Anauya, Baré, Curipaco, Guinau, Mandawaca, Parau-jano [Parauhano]	Venezuela
Araikú†, Aruan†, Cariay†, Carútana, Catapolítani, Cawishana†, Hohodene, Manao†, Mapanai, Marawá†, Mariate†, Maulieni, Moriwene, Pasé†, Siusí, Wainumá†, Wiriná, Yabaana, Yumana	Brazil
Arawak or Lokono	Guyana, Fr. Guiana
Goajiro	Colombia, Venezuela
Adzaneni, Ipeca	Brazil, Colombia
Island Carib	Dominica
2. Atorai, Mapidian	Guyana
Wapishana	Guyana, Brazil
3. Baníva, Yavitero	Venezuela
4. Bauré, Mojo or Ignaciano, Muchojeone, Pauna, Paicone	Bolivia
5. Campa, Machiguenga, Piro	Peru
Canamari, Chontaquiro [Chontakiro], Cuniba†, Cushineri†, Ipuriná	Brazil
Inapari	Bolivia
6. Caripuna, Marawan	Brazil
7. Chané†	Argentina
Guaná	Paraguay, Brazil
Quiniquiano, Tereno	Brazil
8. Paressí	Brazil
Sarave	Bolivia
F. Taino†	Antilles
G. Morique [Morike] or Mayoruna	Peru
5. Atacama or Cunza or Lincan Antai†	Argentina, Chile
6. Auake or Arutani	Brazil, Venezuela
7. Auishiri [Awishira]	Peru
8. Baenan	Brazil
9. Bora-Huitotoan (2)	
A. Boran: Bora or Miraña, Emejeite, Muinane	Colombia
B. Huitotoan [Witotoan]:	
Andoquero, Huitoto [Witoto]	Colombia
Coeruna†	Brazil
Ocaina, Orejone†, Nonuya or Achote [Achiote]	Peru
10. Canichana	Bolivia
11. Capixana or Canoe	Brazil
12. Cariban (70)	
A. 1. Acawai (Arecuna, Camaracoto, Ingarico) Waica	Venezuela
Taulipang or Ipuricoto or Pemon	Brazil, Venezuela
2. Apalai, Aracajú, Upurui	Brazil
Oyana	Suriname
Rucuyen	Fr. Guiana
3. Apiacá or Apingi†, Arara†, Parirí†	Brazil
4. Atroahi (Yauaperi), Quirixana, Waimiri [Waimiry]	Brazil
5. Bakairi† [Bacairi], Nahukua (Nahucua), Yaruma†	Brazil
6. Bonari†, Hishkariana, Parucoto, Waiboi, Waiwai	Brazil
7. Cachuene or Caxuiana, Mutuan†, Pauxí†, Saluma, Wayewé	Brazil
Chiquena [Chikene] or Shikiana	Brazil, Guyana
8. Carare, Opone	Colombia
9. Caribe or Calina or Galibi	Antilles, Guianas
Carif	Belize, Honduras
10. Carijona (Guaque [Guake], Umaua)	Colombia
11. Colima†, Muzo, Pijiao	Colombia
12. Cumanagoto† (Chayma†, Tamanaco), Tivericoto†	Venezuela
13. Keseruna, Macushí, Paraviyana†, Purukoto†, Zapara	Brazil
14. Mariquitare or Decuana	Brazil, Venezuela
Yecuana or Mayongong (Cunuana, Ihuruana)	Venezuela
15. Mapoyo or Nepoyo, Yauarana	Venezuela
16. Motilon	Colombia, Venezuela
17. Palmela† [Palmella]	Brazil
18. Panare	Venezuela
19. Patagon	Peru
20. Pawishana	Brazil
21. Pianocoto	Brazil
Tliometesen	Suriname
Trio (Ocomayana, Urucuyena [Urucuena], Wama)	Suriname, Brazil
22. Pimenteira†	Brazil
23. Yao†	Fr. Guiana, Trinidad
B. Chocó: Chamí, Sambú [Sambo], Waunana	Colombia
13. Cariri or Kiriri	Brazil
14. Catacao†: Catacao†, Colan	Peru
15. Catembri or Mirandela†	Brazil
16. Catuquina [Catukina]: Bendiapa (Canamari, Parawa), Catuquina [Catukina] or Wiridyapa, Catauxi, Tucundiapa [Tucundyapa]	Brazil
17. Cayuvava (70)	Bolivia
18. Chapacura: Chapacura or Huachi, Itene or Moré, Itoreauhip, Nape, Pacahanovo. Quitemo†	Bolivia
Cumaná (Abitana), Torá, Urupá (Yarú [Jarú]), Wañám [Wanyam]	Brazil
19. Chiquito or Tarapecosi (42)	Bolivia
20. Cholonan: Cholona or Seeptsá†, Híbito†	Peru
21. Cofán	Colombia, Ecuador
22. Culli or Ilinga†	Peru
23. Erikbaktsa or Canoeiro	Brazil
24. Gamela†	Brazil
25. Gorgotoqui	Brazil
26. Guahiboan (4): Chiricoa, Guahibo	Venezuela, Colombia
Churuya, Guayabero	Venezuela
27. Guaycurú-Charruan	
A. Charruan†: Chaná†	Uruguay
Charrúa† (Guenoa or Minuan†)	Uruguay, Argentina, Brazil
B. Guaycuruan: Abipón or Callaga†	Argentina, Paraguay
Caduveo or Mbayá or Guaycurú	Brazil, Argentina, Paraguay
Guachí†	Brazil
Mocoví	Argentina
Payaguá or Lengua	Paraguay
Toba-Pilagá	Argentina, Bolivia
28. Guamo†	Venezuela
29. Guató	Bolivia, Brazil
30. Guennaken or Gununa-Kune or Puelche†	Argentina
31. Huarian: Huari or Corumbiara, Masaca or Aicana	Brazil
32. Huarpean† (37): Allentiac†, Millcayac†	Argentina
33. Iranxe (4)	Brazil
34. Jirajaran: Ayomán, Gayón†, Jirajara	Venezuela
35. Kaliana or Sape	Venezuela

F. Kuruaya† (Curuaya), Mundurukú	Brazil
G. Manitsawá†, Shipaya†, Yuruna	Brazil
H. Puruborá	Brazil
71. Tushá	Brazil
72. Tuyoneiri or Arasairi or Huachipairi	Peru
73. Uman or Huamoi	Brazil
74. Xukurú or Ichikile	Brazil
75. Yabutí†: Aricapú†, Mashubi†, Yabutí or Quipiu†	Brazil
76. Yagua: Masamae, Peba or Nijamo, Yagua or Mishara, Yameo or Camuchivo	Peru
77. Yámana† or Yaghan (41)	Chile
78. Yunca or Chimú or Muchic or Chincha†: Puruhá-Cañari†	Ecuador
Yunca†	Peru
79. Yurí†	Brazil, Colombia
80. Yurimangui†	Colombia
81. Zamuco: Chamacoco (Ebidoso, Tumrahá), Zamuco (Ayoré, Moro)	Paraguay
82. Záparo: Arabela, Iquito (Cahuarano), Shimigae† (Semigae)†, Andoa, Záparo†	Peru

*Only languages attested linguistically are included. Extinct languages are marked with †. A number in parentheses after the name of a group indicates a possible relationship with the group identified by that number. Languages are separated by commas, names in parentheses are of dialects, and names in brackets are alternative spellings. Except for Arawakan, Macro-Ge, and Tupian, most groupings are geographical, but those identified by capital letters represent in general markedly differentiated groups. Spelling follows the most common usage for each language or group, thus it is not consistent. Equivalent spellings: *b* = *v*; *g* = *j* = *y*; *gu* = *hu* = *u* = *w*; *i* = *y*; *h* = (nothing); *h* = *j*; *k* = *c* (before *a*, *o*, *u*); *k* = *qu* (before *i*, *e*); *sh* = *x* = *ch*; *s* = *z*; *ñ* = *nh* = *ny*; *x* = *j*. Names are arranged alphabetically within each subdivision.

most important group today—Chocó in western Colombia—is distantly related to the rest of the stock. Other languages are Carib in Suriname, Trio in Suriname and Brazil, and Waiwai, Taulipang, and Makushí (Macusí) in Brazil. A relationship with Tupian seems certain.

The Tupí and Guaraní languages

Tupian. With the exception of Emerillon and Oyampi of French Guiana and northeastern Brazil, Tupian languages were spoken south of the Amazon, from the Andes to the Atlantic Ocean and down to the Río de la Plata. There are approximately 50 attested languages related on the stock level and subdivided into eight families. Tupinambá, the language spoken along the Atlantic coast at the time of discovery, became important in a modified form as a lingua franca, and the closely related Guaraní became the national language in Paraguay, being one of the few Indian languages that does not seem to yield under the influence of Spanish or Portuguese. At the time of discovery, Tupí-Guaraní tribes were moving everywhere south of the Amazon, subjugating other tribes; some of these tribes adopted Tupí-Guaraní. Both Tupí and Guaraní are among the languages that have exerted a great influence on Portuguese and Spanish language. Tupí groups have declined markedly, 26 groups becoming extinct in Brazil between 1900 and 1957, and at least 14 languages disappearing during the same period. The westernmost language, Cocama in Peru, is still spoken by about 19,000 speakers, and Chiriguano in Bolivia has about 20,000 speakers. Other languages have a much smaller number of speakers; there are 19,000 speakers for the 26 surviving groups in Brazil. The total number of Indian speakers of Tupian languages is approximately 60,000, but there are also about 3,000,000 culturally non-Indian speakers of Guaraní in Paraguay. Besides the connection with Cariban, further relationships possibly exist with Macro-Ge, various small families like Zamuco and Mataco-Maccá and isolated languages like Cayuvava.

Macro-Ge. Macro-Ge is geographically the most compactly distributed of the big South American language families. Ge proper extends uninterruptedly through inland eastern Brazil almost as far as the Uruguayan border. There are about ten Ge languages with a total of 2,000 speakers. Most of the other families, now extinct, were located closer to the Atlantic coast, from where they probably were displaced by Tupian expansion. The Bororan family is represented by Bororo in Brazil and by the Otuké language in Bolivia. It seems likely that Macro-Ge has its closest relationship with Tupian.

Quechumaran. Quechumaran, which is composed of the Quechuan and Aymaran families, is the stock with the largest number of speakers—7,000,000 for Quechuan and 1,000,000 for Aymaran—and is found mainly in the Andean highlands extending from southern Colombia to northern Argentina. The languages of this group have also resisted displacement by Spanish, in addition to having gained in numbers of speakers from the time of the Incas to the present as several other groups adopted Quechuan languages. Cuzco-Bolivian Quechua is spoken by well over 1,000,000 speakers, and there are around seven Quechuan languages in Peru with almost 100,000 speakers each. Although most Quechuan languages have been influenced by Spanish, Quechuan in turn is the group that has exerted the most pervasive influence on Spanish. No convincing further genetic relationship has been yet proposed.

Tucanoan. Tucanoan, which is spoken in two compact areas in the western Amazon region (Brazil, Colombia, and Peru), includes about 30 languages with a total of

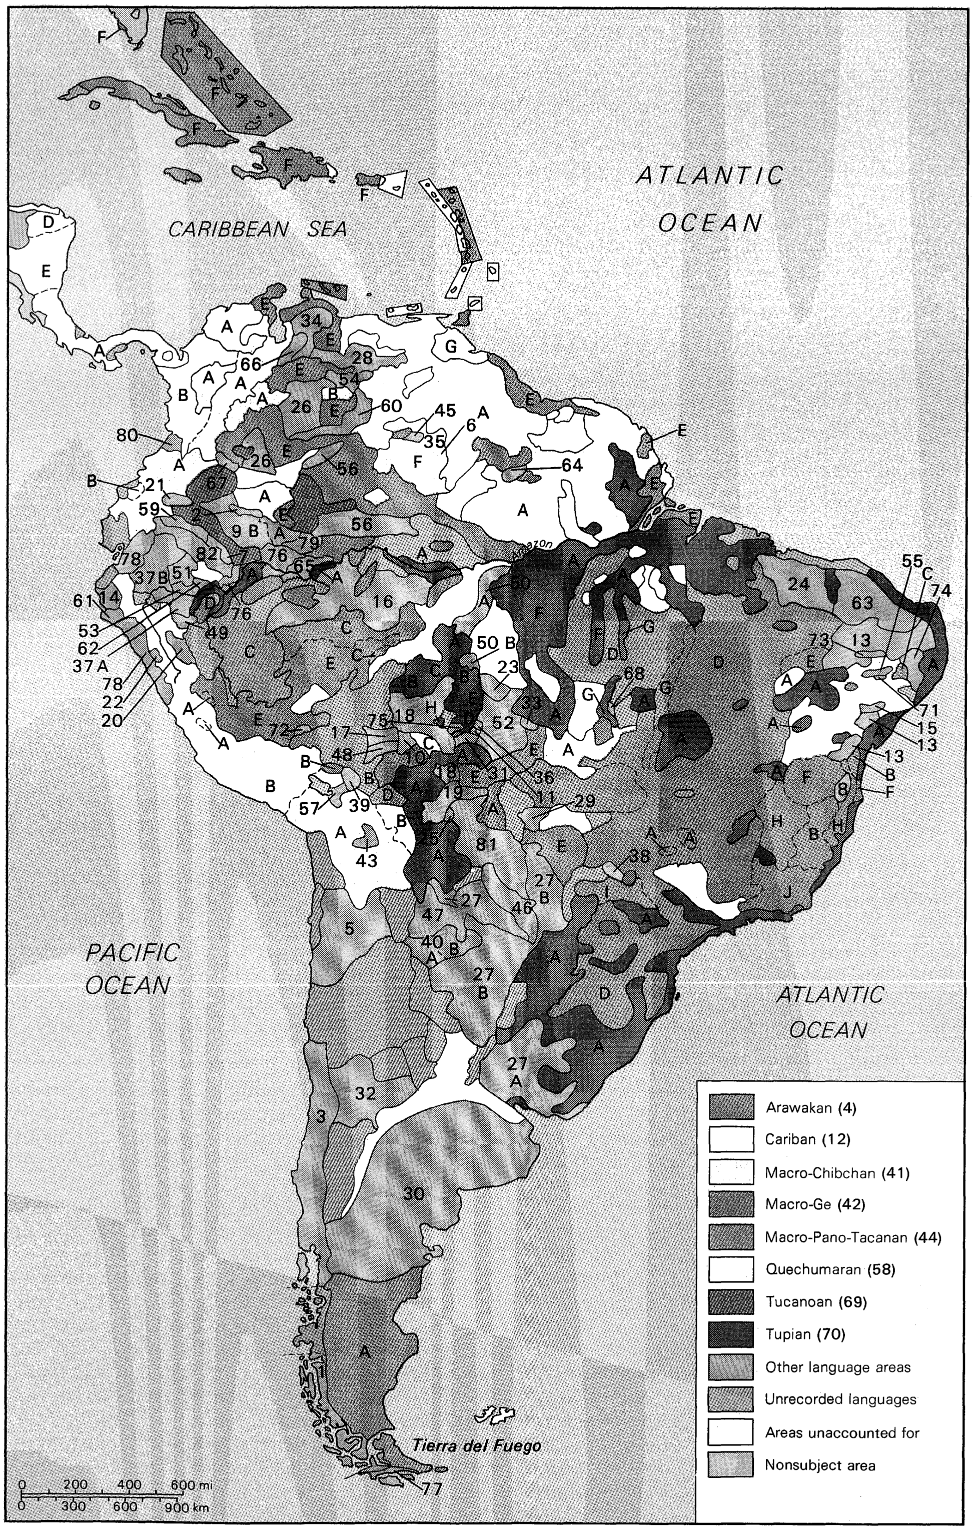

Figure 36: Distribution of the South American Indian languages. The numbers and letters refer to the numbers and letters in Table 62.

over 30,000 speakers. One of the languages is a lingua franca in the region.

Macro-Pano-Tacanan. Macro- Pano-Tacanan, a group more distantly related than a stock, includes about 30 languages, many of them still spoken. The languages are located in two widely separated regions: lowland eastern Peru and adjoining parts of Brazil and lowland western Bolivia on the one hand, and southern Patagonia and Tierra del Fuego on the other. In the latter region the languages are practically extinct.

Other language groups

By number of component languages, or by number of speakers, or by territorial extension, the other language groups are not as significant as those just listed. Most of these small families and isolated languages are located in the lowlands, which form an arch centred on the Amazon from Venezuela to Bolivia and include the bordering parts of Brazil.

Lingua francas and cultural tongues. Lingua francas as well as situations of bilingualism arose mainly under conditions furthered or created by Europeans, although a case like that of the Tucano language, which is used as a lingua franca in the Río Vaupés area among an Indian population belonging to some 20 different linguistic groups, may be independent of those conditions. Quechua, originally spoken in small areas around Cuzco and in central Peru, expanded much under Inca rule, coexisting with local languages or displacing them. It was the official language of the Inca Empire, and groups of Quechua speakers were settled among other language groups, although the language does not seem to have been systematically imposed. The Spaniards, in turn, used Quechua in a great area as a language of evangelization—at one period missionaries were required to know the language—and continued to spread it by means of Quechua speakers who travelled with them in further conquests. During the 17th and 18th centuries it became a literary language in which religious, historical, and dramatic works were written. Today its written literary manifestations are not spontaneous, but there is abundant oral poetry, and in Bolivia radio programs are broadcast entirely in this language.

Dispersion of Tupí-Guaraní dialects, taking place shortly before the arrival of Europeans and even after it, resulted not from imperial expansion—as for Quechua—but from extreme tribal mobility and the cultural and linguistic absorption of other groups. Under Portuguese influence the modified form of Tupinamba known as *língua-geral* ("general language") was the medium of communication between Europeans and Indians and among Indians of different languages in Brazil. It was still in common use along the coast in the 18th century, and it is still spoken in the Amazon. Tupí, now extinct, was an important language of Portuguese evangelization and had a considerable literature in the 17th and 18th centuries. Another dialect, Guaraní, was the language of the Jesuit missions and also had abundant literature until the middle of the 17th century when the Jesuits were expelled and the missions dispersed. Nevertheless, Guaraní survived in Paraguay as the language of a culturally non-Indian population and is today the only Indian language with national, although not official, status—persons not speaking Guaraní being a minority. Paraguayan Guaraní is also a literary language, not so much for learned works—for which Spanish is used—but for those of popular character, especially songs. There is a more or less standardized orthography, and persons literate in Spanish are also literate in Guaraní. A great mutual influence exists between Guaraní and Spanish.

Grammatical diversity

Grammatical characteristics. Diversity rather than common traits characterizes the grammar of South American Indian languages. Features commonly encountered seem to reflect facts of frequency in general typology rather than traits specific to this area. The greatest number of languages are probably suffixing languages like Quechumaran and Huitotoan, or use many suffixes and some prefixes like Arawakan and Panoan. Also very numerous are those languages having few prefixes and suffixes, such as Ge, Carib, or Tupian. Languages employing only prefixes to show grammatical distinctions have not been reported. There are a few with many prefixes but still more suffixes (Jebero, or Chêbero); others, like Ona and Tehuelche, with almost no affixing, are also rare.

Similarly, the complexity of words varies a great deal. In Guaraní words with three components and in Piro (Arawakan) words with six elements are of average complexity for the respective languages. In languages like the Cariban or Tupian ones, word roots are nominal (nouns) or verbal (verbs) and may be converted into the other class by derivational affixes; in languages like Quechua or Araucanian, many word roots are both nominal and verbal. Languages like Yuracare form many words by reduplication (the repetition of a word or a part of a word), a process that does not occur systematically in the Tupian languages. Compounding, the joining of two or more words to form new words, is a very widespread type of word formation, but it can be nearly absent, as in the Chon languages. Verb stems in which the nominal (noun) object is incorporated are also rather frequent. Many languages are of the agglutinative type (Quechuan, Panoan, Araucanian); *i.e.,* they combine several elements of distinctive meaning into a single word without changing the element. Others (Cariban, Tupian) show a moderate amount of change and fusion of the elements when combined in words.

Grammatically marked gender in nouns occurs in Guaycuruan (Guaicuruan), and a difference in masculine and feminine gender in the verb occurs in Arawakan, Huitotoan (Witotoan), and Tucanoan, but genderless languages are more common. Singular and plural in the 3rd person ("he, she, it") is not obligatorily distinguished in Tupian and Cariban, but languages like Yámana and Araucanian have singular, dual, and plural. A very common distinction is that between inclusive 1st person ("you and I," hearer included) and exclusive 1st person ("he and I," hearer exluded). Pronominal forms differentiated according to categories that indicate whether the person is present or absent, sitting or standing, and so forth occur in Guaycuruan languages and Movima. Case relations in nouns are generally expressed by suffixes or postpositions; the use of prepositions is rare. Possession is indicated predominantly by prefixes or suffixes, and systems in which possessive forms are the same as those used as the subject of intransitive verbs and as the object of transitive ones are rather common. Classificatory affixes that subclassify nouns according to the shape of the object occur in the Chibchan, Tucanoan, and Waican groups.

Indication of case relationships

Very frequently the verbal forms express the subject, object, and negation in the same word. The categories of tense and aspect seem to be about evenly represented in South American languages, but the specific categories expressed vary a great deal from language to language: Aguaruna (Jívaroan) has a future form and three past forms differentiated as to relative remoteness, while in Guaraní the difference is basically between future and nonfuture. Other languages like Jebero express fundamentally modal categories. Very common are affixes indicating movement, chiefly toward and away from the speaker, and location (*e.g.,* in Quechumaran, Záparo, Itonama), and in some stocks like Arawakan and Panoan there are many suffixes in the verb with very concrete adverbial meaning, such as "by night," "during the day." Classificatory affixes indicating the way the action is performed—by biting, striking, walking—occur in Jebero and Tikuna (Ticuna). Actions done individually or collectively are differentiated paradigmatically in Carib, while in Yámana and Jívaro different verbal stems are used according to whether the subject or the object is singular or plural. There are also various languages (Guaycuruan, Mataco, Cocama) in which some words have different forms according to the sex of the speaker.

Equational sentences are very common. These are formed by juxtaposing two nominal expressions (nouns) without a linking verb, a fact that usually correlates with the absence of a verb "be" for expressing identification or location (*e.g.,* "John good man," "my house there"). Sentences in which the predicate is a noun inflected like a verb with the meaning "being" or "having" that thing designated by the noun also occur in Bororo and Huitoto (Witoto); *e.g.,* "I-knife" = "I have a knife." Sentences in which the subject is the undergoer of the action are frequent, but true passive sentences in which the undergoer and the agent are expressed are rare, though they do occur in Huitoto. Subordinate sentences are rarely introduced by conjunctions; subordination is usually expressed by postposed elements or special forms of the verbs such as gerunds, participles, or subordinate conjugations.

Phonological characteristics. As in grammar, there are no phonological features common to all South American languages that would be specific to them alone. The number of distinctive sounds (phonemes) may vary from 42 in Jaqaru (Quechumaran) to 17 in Campa (Arawakan). Jaqaru has 36 consonants, while Makushí (Cariban) has 11; some Quechuan languages have only three vowels, whereas Apinayê (Macro-Ge) has ten oral vowels and seven nasal ones. A dialect of Tucano (Tucanoan) exhibits three contrasting points of articulation, while Chipaya (Macro-Mayan) has nine. Many types of contrasting sounds occur although not with equal frequency. Voiceless stops (*e.g.*, *p*, *t*, *k*) occur everywhere, but voiced stops (*e.g.*, *b*, *d*, *g*) may be absent, and fricatives (*e.g.*, *f*, *v*, *s*, *z*) may be few in number. Glottalized voiceless stops—consonants made with simultaneous closure of the glottis and without vibration of the vocal cords—are rather common (Quechumaran, Chibchan), but not glottalized voiced stops (in which the vocal cords vibrate). Also less frequent are aspirated (Quechumaran) and palatalized sounds (Puinave); glottalized nasal sounds (Movima) and voiceless laterals (*l*-like sounds, as in Vilela) are rare. A distinction between velar and postvelar sounds occurs in Quechumaran and Chon, between velar and labiovelar in Tacana and Siona (Sioni); palatal retroflex consonants, made with the tip of the tongue turned up touching the palate, occur in Pano-Tacanan and Chipaya.

Great variety in distinctive sounds

Systems with nasal vowels are common (Macro-Ge, Sabelan), but in several languages (Tupian, Waican) nasalization is a feature not of vowels and consonants but of whole words. There is an apparent absence of front rounded vowels (*ü*, *ö*), but central or back unrounded vowels (ɨ, *i*) are common. Systems with long vowels occur in Chipaya and some Cariban languages, and glottalized vowels occur in Tikuna and Chon languages. Very common are pitch-stress systems with high and low tones on stressed syllables; *e.g.*, in Panoan, Huitotoan, and Chibchan. More complex systems with three tones as in Acaricuara, four as in Mundurukú (Mundurucú), and five as in Tikuna are rare. Syllables are generally without complex consonant clusters.

The typology proposed by Tadeusz Milewski, a Polish linguist, classifies American Indian languages into three types: (1) Atlantic, with few oral consonants but complex systems of nasal consonants, and oral and nasal vowels, of which the Ge languages would be typical; (2) Pacific, with complex systems of oral consonants (many contrasting points and modes of articulation) but with few nasal consonants and few vowels, as exemplified by Quechumaran; and (3) Central, with consonant systems more like the Pacific type and vowel systems like the Atlantic, of which Chibcha would be typical. The typology is probably too gross to accommodate meaningfully every language type found in South America, but it holds to a certain extent, especially for the Atlantic type (Macro-Ge, Tupian, and Cariban).

Vocabulary. Indian languages vary significantly in the number of loanwords from Spanish and Portuguese. Massive borrowing has taken place in areas where languages have been in intense and continued contact with Spanish or Portuguese, especially where groups are economically dependent on the national life of the country and there is a considerable number of bilingual persons, as in Quechuan, or where no cultural differences correlate with language differences, as in Paraguayan Guaraní. Borrowings have not been limited to designations of artifacts of European origin but affect all spheres of vocabulary, having displaced native terms in many cases. Neither are they limited to lexical items; they include function elements such as prepositions, conjunctions, and derivative suffixes. Sound systems have also been modified. In some contact situations in which the Indian group displayed an antagonistic attitude toward the European conquest, purism developed and loans are comparatively few; *e.g.*, Araucanian. When contact has been frequent but superficial, loanwords are usually scant, but the meaning of native terms has shifted or new descriptive terms have been coined to designate new cultural traits, as in Tehuelche.

Loanwords from Spanish and Portuguese

Borrowings among Indian languages may have been more numerous than yet reported, judging from the wide and rapid diffusion that loans from Spanish and Portuguese had through the central part of South America. Borrowings between Quechua and Aymara have occurred in great number, but the direction of borrowing is difficult to determine. Many Indian languages in the Andes and the eastern foothills have borrowed from Quechua either directly or through Spanish. In Island Carib (an Arawakan language), borrowings from Carib (a Cariban language) have formed a special part of the vocabulary, properly used only by men; these words were adopted after the Island Carib speakers were subjugated by Caribs.

In turn, some Indian languages have been a source of borrowing into European languages. Taino (Arawakan), the first language with which Spaniards had contact, furnished the most widespread borrowings, including "canoe," "cacique," "maize," and "tobacco," among many others. No other South American Indian language has furnished such widespread and common words, although Quechua has contributed some specialized items such as "condor," "pampa," "vicuña." The larger number of Arawakan borrowings results from these languages having been predominant in the Antilles, a region where Dutch, French, English, Portuguese, and Spanish were present for a long time. Cariban languages, the other important group in that region, do not seem to have furnished many words, but "cannibal" is a semantically and phonetically modified form of the self-designation of the Caribs. The influence of some Indian languages on regional varieties of Spanish and Portuguese has been paramount. Thus Tupí accounts for most Indian words in Brazilian Portuguese, Guaraní in the Spanish of Paraguay and northeast Argentina; and Quechua words are abundant in Spanish from Colombia to Chile and Argentina. In addition, Quechuan and Tupí-Guaraní languages account for most place-names in South America.

Language and culture

No detailed studies are available concerning the relationship of the vocabularies of Indian languages to the culture. Certain areas of vocabulary that are particularly elaborated in a given language may reflect a special focus in the culture, as for example the detailed botanical vocabularies for plants of medical or dietary importance in Quechua, Aymara, and Araucanian. Shifts in cultural habits may also be reflected in the vocabulary, as in Tehuelche, which formerly had a vocabulary designating different kinds of guanaco meat that is now very much reduced, because the group no longer depends on that animal for subsistence. Kinship terminology is usually closely correlated with social organization so that changes in the latter are also reflected in the former: in Tehuelche, former terms referring to paternal and maternal uncles tend to be used indiscriminately, even replaced by Spanish loans, because the difference is not functional in the culture any more.

Proper names, to which different beliefs are attached, offer a variety of phenomena, among them the practice of naming a parent after a child (called teknonymy) in some Arawakan groups; the repeated change of name according to various fixed stages of development, as in Guayaki; word taboo, forbidding either the pronunciation of one's own name or the name of a deceased person, or both, as in the southernmost groups (Alacaluf, Yâmana, Chon) and in the Chaco area (Toba, Terena); and the use of totemic names for groups, as in Panoan tribes.

Writing and texts. The existence of pre-Columbian native writing systems in South America is not certain. There are two examples, that of the Cuna in Colombia and an Andean system in Bolivia and Peru, but in both cases European influence may be suspected. They are mnemonic aids—a mixture of ideograms and pictographs—for reciting religious texts in Quechua and ritual medical texts in Cuna. The Cuna system is still in use.

Although the linguistic activity of missionaries was enormous and their work, from a lexicographic and grammatical viewpoint, very important, they failed to record texts reflecting the native culture. The texts they left for most languages are, with a few exceptions, of a religious nature. Most of the folklore has been collected in the 20th century, but many important collections (*e.g.,* for the Fuegian and Tacanan tribes) are not published in the native language but rather in translation. There are good texts recorded in the native language for Araucanian, Panoan, and Cuna, for instance, and more are being recorded by linguists now, though not necessarily analyzed from a linguistic point of view.

Efforts are being made in several areas to introduce literacy in the native Indian languages. For some, practical orthographies have existed since the 17th century (Guaraní, Quechua); for several others, linguists have devised practical writing systems and prepared primers in recent years. The success of these efforts cannot yet be evaluated. (J.A.S.)

LANGUAGE ISOLATES

Sumerian language

Sumerian is the oldest written language in existence. First attested about 3100 BC in southern Mesopotamia, it flourished during the 3rd millennium BC. About 2000 BC, Sumerian was replaced as a spoken language by Semitic Akkadian (Assyro-Babylonian) but continued in written usage almost to the end of the life of the Akkadian language, around the beginning of the Christian era. Sumerian never extended much beyond its original boundaries in southern Mesopotamia; the small number of its native speakers was entirely out of proportion to the tremendous importance and influence Sumerian exercised on the development of the Mesopotamian and other ancient civilizations in all their stages.

History. Four periods of Sumerian can be distinguished: Archaic Sumerian, Old or Classical Sumerian, New Sumerian, and Post-Sumerian.

Archaic Sumerian covered a period from about 3100 BC, when the first Sumerian records make their appearance, down to about 2500 BC. The earliest Sumerian writing is almost exclusively represented by texts of business and administrative character. There are also school texts in the form of simple exercises in writing signs and words. The Archaic Sumerian language is still very poorly understood, partly because of the difficulties surrounding the reading and interpretation of early Sumerian writing and partly because of the meagreness of sources.

Old, or Classical, Sumerian

The Old, or Classical, period of Sumerian lasted from about 2500 to 2300 BC and is represented mainly by records of the early rulers of Lagash. The records are business, legal, and administrative texts, as well as royal and private inscriptions, mostly of votive character; letters, both private and official; and incantations. These sources are much more numerous than those of the preceding period, and the writing is explicit enough to make possible an adequate reconstruction of Sumerian grammar and vocabulary.

During the period of the Sargonic dynasty, the Semitic Akkadians took over the political hegemony of Babylonia, marking a definite setback in the progress of the Sumerian language. At this time the Akkadian language was used extensively throughout the entire area of the Akkadian empire, while the use of Sumerian gradually was limited to a small area in Sumer proper. After a brief revival during the 3rd dynasty of Ur, the New Sumerian period came to an end about 2000 BC, when new inroads of the Semitic peoples from the desert succeeded in destroying the 3rd dynasty of Ur and in establishing the Semitic dynasties of Isin, Larsa, and Babylon.

The period of the dynasties of Isin, Larsa, and Babylon is called the Old Babylonian period, after Babylon, which became the capital and the most important city in the country. During this time the Sumerians lost their political identity, and Sumerian gradually disappeared as a spoken language. It did, however, continue to be written to the very end of the use of cuneiform writing. This is the last stage of the Sumerian language, called Post-Sumerian.

In the early stages of the Post-Sumerian period the use of written Sumerian is extensively attested in legal and administrative texts, as well as in royal inscriptions, which are often bilingual, in Sumerian and Babylonian. Many Sumerian literary compositions, which came down from the older Sumerian periods by way of oral tradition, were recorded in writing for the first time in the Old Babylonian period. Many more were copied by industrious scribes from originals now lost. The rich Sumerian literature is represented by texts of varied nature, such as myths and epics, hymns and lamentations, rituals and incantations, and proverbs and the so-called wisdom compositions. For many centuries after the Old Babylonian period, the study of Sumerian continued in the Babylonian schools. As late as the 7th century BC, Ashurbanipal, one of the last rulers of Assyria, boasted of being able to read the difficult Sumerian language, and from an even later period, in Hellenistic times, there are some cuneiform tablets that show Sumerian words transcribed in Greek letters.

Rediscovery. Around the time of Christ, all knowledge of the Sumerian language disappeared along with that of cuneiform writing, and in the succeeding centuries even the name Sumer vanished from memory.

Unlike Assyria, Babylonia, and Egypt, whose histories and traditions are amply documented in biblical and classical sources, there was nothing to be found in non-Mesopotamian sources to make one even suspect the existence of the Sumerians in antiquity, let alone fully appreciate their important role in the history of early civilizations.

Decipherment of Sumerian cuneiform

When the decipherment of cuneiform writing was achieved in the early decades of the 19th century, three languages written in cuneiform were discovered: Semitic Babylonian, Indo-European Persian, and Elamite, of unknown linguistic affiliation. Only after the texts written in Babylonian had become better understood did scholars become aware of the existence of texts written in a language different from Babylonian. When the new language was discovered it was variously designated as Scythian, or even Akkadian (that is, by the very name now given to the Semitic language spoken in Babylonia and Assyria). It was only after knowledge of the new language had grown that it was given the correct name of Sumerian.

Characteristics. The linguistic affinity of Sumerian has not yet been successfully established. Ural-Altaic (which includes Turkish), Dravidian, Brahui, Bantu, and many other groups of languages have been compared with Sumerian, but no theory has gained common acceptance. Sumerian is clearly an agglutinative language in that it preserves the word root intact while expressing various grammatical changes by adding on prefixes, infixes, and suffixes. The difference between nouns and verbs, as it exists in the Indo-European or Semitic languages, is unknown to Sumerian. The word *dug* alone means both "speech" and "to speak" in Sumerian, the difference between the noun and the verb being indicated by the syntax and by different affixes.

The distinctive sounds (phonemes) of Sumerian consisted of four vowels, *a, i, e, u,* and 16 consonants, *b, d, g, ŋ, h, k, l, m, n, p, r, s, ś, š, t, z.* In Classical Sumerian, the contrast between the consonants *b, d, g, z* and *p, t, k, s* was not between voiced (with vibrating vocal cords) and voiceless consonants (without vibrating vocal cords) but between consonants that were indifferent as to voice and those that were aspirated (pronounced with an accompanying audible puff of breath). The semivowels *y* and *w* functioned as vocalic glides.

In the noun, gender was not expressed. Plural number was indicated either by the suffixes *-me* (or *-me + esh*), *-hia,* and *-ene,* or by reduplication, as in *kur + kur* "mountains." The relational forms of the noun, corresponding approximately to the cases of the Latin declension, include: *-e* for the subject (nominative), *-a*(*k*) "of" (genitive), *-ra* and *-sh*(*e*) "to," "for" (dative), *-a* "in" (locative), *-ta* "from" (ablative), *-da* "with" (commitative).

The Sumerian verb

The Sumerian verb, with its concatenation of various prefixes, infixes, and suffixes, presents a very complicated picture. The elements connected with the verb follow a rigid order: modal elements, tempo elements, relational elements, causative elements, object elements, verbal root, subject elements, and intransitive present–future elements. In the preterite transitive active form, the order of object and subject elements is reversed. The verb can distinguish, in addition to person and number, transitivity and intransitivity, active and passive voice, and two tenses, present-future and preterite.

Several Sumerian dialects are known. Of these the most important are *eme-gir,* the official dialect of Sumerian, and *eme-SAL,* the dialect used often in the composition of hymns and incantations (see also WRITING).

(I.J.G.)

Etruscan language

The Etruscan language was spoken by close neighbours of the ancient Romans. The Romans called them Etrusci or Tusci; in Greek they were called Tyrsenoi or Tyrrhenoi; in Umbrian, and Italic language, their name can be found in the adjective *turskum.* The Etruscans' name for themselves was *rasna* or *raśna.*

The Etruscans lived in Italy in the region of modern Tuscany, in an area bounded by the Arno River on the north, the Tiber River on the southeast, and the Tyrrhenian Sea on the west. At one time they controlled most of an area extending south from Milan through Marzabotto and Sarsina to the Adriatic Sea north of Ancona, and to the southwest their rule extended as far as Capua, Naples, and Pompeii. For the history of the Etruscans and Etruria, see GRECO-ROMAN CIVILIZATION: *Ancient Italic peoples.*

Inscriptions

Records and scholarship. The Etruscan language is known mainly from epigraphic records originating in the Tuscan area and dating from the 7th century BC to the first years of the Christian Era. There are some 10,000 of these inscriptions, mainly brief and repetitious epitaphs or dedicatory formulas, as well as votive or owner's inscriptions on paintings in tombs and accompanying engraved figures on small artifacts such as metal mirrors. There are, however, some remarkable exceptions to the general brevity of the inscriptions, and there are important differences in their origins. The longest single text, of 281 lines (about 1,300 words), now in the National Museum at Zagreb, is written on a roll of linen that had been cut into strips and used in Egypt as a wrapping for a mummy; a clay tablet found at Capua contains some 250 words; a stone slab from Perugia has two adjacent sides elegantly engraved with an inscription of 46 lines (some 125 words); a bronze model of a liver found at Piacenza, which probably represents the Etruscan microcosm in a form used for instruction in divination, has some 45 words; and a heavy rectangular block found on the island of Lemnos in the northern Aegean has an engraving of what is probably a warrior with one inscription of perhaps 18 words surrounding the head and another of 16 words in three lines on an adjacent side. In 1964 two inscriptions on gold tablets, one in Phoenician and the other in Etruscan, were unearthed at Pyrgi.

In the Museo Archeologico Nazionale dell'Umbria, Perugia, Italy

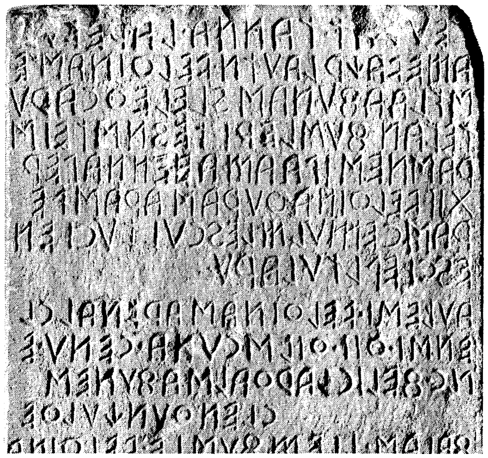

Figure 38: Etruscan inscription from a section of the "Cippus of Perugia."

Despite many attempts at decipherment and some claims of success, the Etruscan records still defy translation. While the possibility always remains that an imaginative conjecture or a brilliant inference will suddenly provide the key to the mystery, this now seems remote. The etymological method of investigation, which ultimately depends upon the recognition of presumed cognates from related languages, seems to have failed because no clear and certain relationship between Etruscan and any other language has ever been established. The procedure sometimes called the combinatory method now appears to be the most efficacious if not indeed the only useful one. It requires, first, that note be made of anything unusual in the provenance of the object on which Etruscan writing is found (such as that the mummy wrapping came from Egypt and the Lemnos inscription from the Aegean) and likewise of anything unusual in the object itself (*e.g.,* that it is a bronze replica of a liver or the representation of a god or mythological figure). Finally, each word and phrase and formula is compared with every recurrence of the same element or elements elsewhere, and all variations in the physical and the linguistic contexts are recorded. By this means it has been possible to assign some words to grammatical categories such as noun and verb, to identify some inflectional endings, and to assign meanings to a few words of very frequent occurrence.

Linguistic relationships

The problem of Etruscan origins is insoluble until the language can be translated. While nothing at all is certain other than the existence of Etruscans in Italy, some Etruscan writing in Egypt, and an Etruscan inscription on Lemnos, the weight of all the evidence seems to favour a non-Italic but certainly Mediterranean place of origin of the Etruscan people. It is unlikely, therefore, that the Etruscan language is genetically related to any language or language family existing in an area remote from the Mediterranean. On the other hand, it does not follow that Etruscan must be related to a language or language fragment that can be found in the Mediterranean area.

The Etruscan alphabet. Etruscan is written in an alphabet probably derived from one of the Greek alphabets.

It is of very great importance that Etruscan is written in a recognizable alphabet related to the Greek and Semitic because sound values can be assigned with some degree of precision to each symbol. Etruscan writing proceeded from right to left and in earliest times had no word division or punctuation. In about the 6th century BC a system of points, or dots, consisting of four, three, or two dots inscribed vertically, was introduced to mark word boundaries and, in some instances, apparently, to indicate syllables and possibly abbreviations.

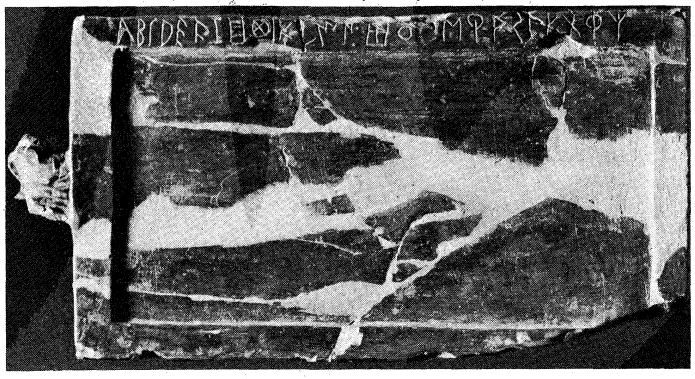

Figure 39: Etruscan alphabet on the edge of a writing tablet from Marsiliana d'Albegna, 7th century. In the Museo Archeologico, Florence.

There were four vowels in Etruscan, *i, e, a,* and *u* or *o,* and symbols in the alphabet for *p, t, c, m, n, l, r, z* and for the equivalents of the Greek *phi, theta,* and *chi,* which in Etruscan as in classical Greek were the aspirated stops *ph, th, ch* (pronounced as *p, t, k* with an added brief puff of air). There were two sibilants, written *s* and *ś,* for which the precise pronunciation is uncertain; two front fricatives, *f* and *v,* articulated either with the two lips (bilabial) or with the lower lip approaching the upper front teeth (labiodental); and an *h,* which nearly always occurs at the beginning of words and is used to represent, inconsistently, the rough breathing of Greek (*e.g.,* Greek *Hēraklēs,* Etruscan *hercle* or *ercle*). There were also a *k* and a *q,* of which the precise pronunciation is unknown. A marked tendency to make all vowels in a word similar or identical (qualitative vowel harmony) is characteristic: Greek *Klutaimēstra,* which if transliterated directly into Etruscan would be *cluthemestha,* actually occurs as *cluthumustha* and *clutmsta.*

Both historical changes and dialectal differences can be observed. Diphthongs became single letters. Thus Greek *Aiwas* became Etruscan *aivas, eivas,* and *evas,* successively; *au* alternated with *a*; *eu* (like *ai*) became *e* (Greek *Kleopatra* is Etruscan *clepatra;* Greek *Poludeukēs* is, with Etruscan vowel harmony, *Pultuce*). Among consonants the most noticeable changes are *c* to *ch* to *h* (*e.g., casri* becomes *chasri, caspr* becomes *haspr*); similarly, *p* changes to *ph* to *f* to *h* and *t* to *th* to *h.* Throughout the history of Etruscan, a first syllable usually remains unchanged, whereas later syllables tend to weaken or lose vowels, at least in writing. Older Etruscan *lavtun* "family" becomes in later Etruscan *lavtn;* other examples are *mutana* changing to *mutna,* Greek *Adonis* written *atunis* and then *atuns,* Greek *Alexandros* appearing as *elchsntre.* The consonant cluster of *elchsntre,* while extreme, is not untypical of Etruscan spelling; words thus written have led some to suggest that a very economical spelling system may have been used that was far removed from the reality of pronunciation, requiring the introduction of lightly stressed vowels in actual utterance. (For a short history and a chart of the Etruscan alphabet, see WRITING: *Alphabetic writing.*)

Grammatical characteristics. The minimal unit of meaning seems to have been a verbal root, such as *zic* or *zich,* meaning "write." The suffixing of any vowel or certain consonants (*c* or its variant *ch, t* or its variant *th, l, r,* or *n*) produced a noun. The vowel *u* was used to form a gerund that, without further change, could be used as an agent noun; thus *zicu* meant "writing," then, further, "scribe," and then the equivalent of the Roman name Scribonius. From these verbal nouns, denominative verbs could be made; thus from *zicu* plus *-ce,* a past tense of perfective affix, was made *zichuche* "he wrote, he has written."

The *genitivus genitivi*

Because of the large number of names occurring in the inscriptions, the noun declension system can be understood reasonably well. Similar to the process of word building is the construction called *genitivus genitivi,* or "genitive of the genitive," in which several possessive suffixes may be added to a word in succession. Thus, the simple genitive of *larth,* a proper name, is *larthal* "Larth's"; a second genitive suffix added gives *larthalisa* "of that which is Larth's."

There is apparently no grammatical gender in Etruscan. In late Etruscan an *-i* suffix marks some women's names; still later, apparently (or possibly in a different dialect area), *-ia* is similarly used. Although these suffixes appear to be the same as the final elements in some words designating exclusively female functions, such as *puia* "wife" (in one occurrence spelled *pui,* if it is the same word) and *ati* "mother" (in one occurrence *atiu,* if it is the same word), there is no evidence for any syntactic use of gender, and there is no formal marker that can be shown to have marked gender consistently.

Case endings do not differ from singular to plural; in the singular they are suffixed directly to the word stem, and in the plural they are added to the stem, along with one of the plural markers *ar, er, ur.* There is no distinctive nominative (subject) case marker, the word stem or, in some cases, the root alone serving as the nominative. A final marker *-s,* however, does appear to have been added in some instances of a probable nominative case.

The repetitive nature of most Etruscan inscriptions is such that very few distinctively different verb forms are available for analysis. Indeed, probably the only really certain verbal suffix is *-ce.* It must not be assumed, however, that the paucity of the verbal data from inscriptions reflects an impoverished verb system in the language; indeed, judging from the variety of verbal stems to which the recurring *-ce* is added, it is more likely that the Etruscan verb had a more complicated structure than the noun.

Vocabulary. Since the language is undeciphered, meaning can be assigned with certainty to only a few Etruscan words that occur very frequently in the texts. Some kinship terms are sure—among these are *ati,* "mother," *clan* "son," *śec* "daughter," *puia* "wife." Less certain but probably correct are words designating members of the larger societal organization: *lavtn* "family," *zilc* "official," *maru* "official," *spur* "city," *rasna* or *raśna* "Etruscan, Etruria." A pair of dice certainly have on them the names of the numbers from one through six. Although the order of these numbers has been and still is disputed, the arrangement most generally accepted is this: *thu* "one," *zal* "two," *ci* "three," *śa* "four," *mach* "five," *huth* "six."

Among the continuing mysteries of Etruscan are the reasons why the Etruscans left no written records of their great civilization other than inscriptions and occasional texts and why the Romans, who knew the Etruscans intimately, transmitted little or nothing to posterity about either Etruscan literature or their language, which must certainly have been spoken, or at least preserved, by some families in Rome long after the period of Etruscan greatness had passed. (M.Fo.)

Basque language

Basque, the only remnant of the languages spoken in southwestern Europe before the region was romanized, is currently used in a narrow area of approximately 10,000 square kilometres (3,900 square miles) in Spain and France. The number of Basque-speaking persons outside that territory, in Europe and in the Americas, however, is far from insignificant. In Spain the Basque-speaking region comprises the province of Guipúzcoa, parts of Vizcaya and Navarra, and a corner of Álava, and in France the western region of the *département* of Pyrénées-Atlantiques. Although few statistics are available, the number of speakers, who are largely bilingual, might be judiciously estimated at 1,000,000. Most of them live in the highly industrialized Spanish part of the Basque country.

The Basques have derived their name, Euskaldunak, from Euskara, the native word for their language. According to the classification of the 19th-century philologist Prince Louis-Lucien Bonaparte, there are eight modern dialects of Basque. Dialectal division is not strong enough to mask the common origin or to preclude mutual understanding. Basque attained official status for a short period (1936–37) during the Spanish Civil War, under Basque autonomous government. In 1978, Basque and Castilian Spanish became the official languages of the autonomous Basque Country, which includes Guipúzcoa, Vizcaya, and Álava provinces of Spain.

Origins and classification. Basque remains an isolated language with no known linguistic relatives. The hypothesis of the German philologist Hugo Schuchardt (1842–1927), which once had wide currency, posited an intimate genetic connection between Basque and Iberian (see below) and the Hamito-Semitic (Afro-Asiatic) language group. This theory was superseded by attempts to establish a more or less close link between Basque and Caucasian, the language group indigenous to the Caucasus region. A lack of common linguistic characteristics between the Basque and Hamito-Semitic languages makes Schuchardt's hypothesis extremely dubious. There are, however, some common features that favour the relationship between Basque and Caucasian. Still, proof of a genetic relationship beyond reasonable doubt appears remote. Perhaps the most promising theory involves the comparison of Basque with the long-extinct Iberian, the language of the ancient inscriptions of eastern Spain and of the Mediterranean coast of France. But, despite amazing phonological coincidences, Basque has so far contributed next to nothing to the understanding of the now-readable Iberian texts. Therefore, it is possible that the similarity may have resulted from close contact between Basques and Iberians and not from a genetic linguistic relationship.

Link between Basque and Iberian

History of the language. At the beginning of the Christian Era, dialects of Euskarian (Basque) stock were probably spoken north and south of the Pyrenees and as far east as the Valle de Arán in northeastern Spain. It is likely that only the disruption of Roman administration in these regions saved the Basque dialects from being completely overcome by Latin. It is also likely that the Basque tongue, which had a firm foothold in the country that then began to be called Vasconia, experienced a substantial expansion toward the southwest, which carried it to the Rioja Alta (High Rioja) region in Old Castile and near Burgos. The more eastern Basque dialects, separated from the main area by Romance-speaking populations, were doomed. During the Middle Ages, Basque, the language of a population more peasant than urban, could not possibly hold the field as a written language against Latin and its successors, Navarrese Romance and, to a certain extent, Occitan (the *langue d'Oc,* also called Provençal) in the kingdom of Navarre. Since the 10th century, Basque has slowly but steadily lost ground to Castilian Spanish; in the north, however, where French is a more modern rival, the Basque-speaking area is practically the same as it was in the 16th century. In the last two centuries, above all in industrial centres, Basque has had to fight for survival in the heart of the Basque-speaking country, as well as on the frontier of the Basque-speaking area.

Basque records and writing

Latin inscriptions from the Roman period, found mostly in southwestern France, record a handful of proper names of unmistakable Basque etymology. From AD 1000 on, records consisting chiefly of proper names but also of Basque phrases and sentences grew more numerous and reliable. The first printed Basque book, dating from 1545, began an uninterrupted written tradition. Scholarly Basque literature, with its prevailing religious interests, has been neither abundant nor varied until recent times. Intense efforts are now being made to introduce Basque as a vehicle of private primary education. In addition, a model of a unified, standard written language also seems to be gaining increasing acceptance.

Phonology. The sound pattern of Basque is, on the whole, similar to that of Spanish. The number of distinctive sounds is relatively low compared with other languages. Combinations of sound (*e.g.,* consonant clusters) are subject to severe constraints. It can confidently be asserted that certain types of consonant clusters, such as *tr, pl, dr,* and *bl,* were all but unknown about two millennia ago. The common sound system underlying the systems of the present Basque dialects has five (pure) vowels and two series of stopped consonants—one voiced (without complete stoppage in many contexts), represented by *b, d, g,* and the other voiceless, represented by *p, t, k.* Nasal sounds include *m, n,* and palatal *ñ,* similar to the sound indicated by *ny* in "canyon." In this respect, as in others, Basque orthography coincides with the Spanish norm. There are two varieties of *l,* the common lateral *l* and a palatal variety, *ll,* as in Spanish, that sounds similar to the *lli* in "million" (as *l* + *y*). The Basque *r,* made by a single tap of the tongue against the roof of the mouth, contrasts with a rolled or trilled *r,* written *rr.* Two phonological features are worthy of special attention. Sibilants (both fricatives and affricates) made with the area of the tongue directly before the dorsum (the back of the tongue) are distinct from the apical sibilants, produced with the tip of the tongue. The letter *z* in Basque symbolizes the predorsal fricative, and *tz,* the predorsal affricate sound; *s* and *ts* represent the apical fricative (similar to Castillian Spanish *s*) and affricate, respectively. (A fricative is a sound, such as English *f* or *s,* produced with friction and, hence, without complete stoppage in the vocal tract; an affricate is a sound, such as *ch* in "church" or *j* in "jam," that begins as a stop and ends as a fricative, with incomplete stoppage.) In addition to these hissing sibilants, Basque also includes the hushing ones, written as *x* and *tx*; they are like the English *sh* and *ch.* The *x* and *tx* sounds, along with the palatal sounds written as *ll* and *ñ,* often have an expressive value (diminutive, endearing) in comparison with their nonpalatal counterparts; *e.g., hezur* means "bone" and *hexur* "little bone" (fish bone, for example); *sagu* is "mouse" and *xagu* "little mouse."

Varieties of sibilants

The phonology of some Basque dialects may be more complex than that presented in the preceding paragraph. In the easternmost Souletin region, for example, the dialect has acquired, by internal development or by contact with other languages, a sixth oral vowel—rounded *e* or *i*—and nasal vowels, voiced sibilants, and voiceless aspirated stops. The aspiration accompanying stop consonants consists of a small puff of air. There is also, word-initially and between vowels, an aspirated *h,* once common but now peculiar to the northern dialects. It has also been retained in the proposed standard form of Basque.

Grammar. The mention of two features is unavoidable in describing Basque syntax. Basque is, in the first place, a language of the so-called ergative type. That is, it has a case denoting the agent of an action. Hence, what in English would stand for the subject of a transitive verb is expressed in Basque by means of a suffix *-k*; for example, in the sentence "the foot serves the hand, and the hand serves the foot," *oinak zerbitzatzen du eskua, eta eskuak oina,* the first word, meaning "the foot," is composed of three elements, *oin* "foot," *-a,* "the," and *-k,* which marks the Basque equivalent of the subject of the verb. The fourth word, meaning "the hand," does not have the *-k* ending. In the second clause, *eta eskuak oina,* the word for hand, *eskuak,* now has the ergative *-k* ending to indicate that the hand is the agent of the clause "the hand serves the foot." The subject of an intransitive verb, which is not distinguished from the object of a transitive verb, has no overt mark—*e.g.,* in "if the belly does not eat, the belly itself will fail," *sabelak jaten ez ba du, sabela bera ihartuko da,* the first term, *sabelak* "the belly," has the *-k* marker because it is the agent of a transitive verb "eat"; but, in the second clause, *sabela* is the subject of the intransitive verb "fail" and, therefore, has no overt grammatical mark.

The second characteristic feature of Basque concerns the finite verb, which acts as a summary of all the noun phrases in the sentence. It has markers for all three persons—the 1st, 2nd, and 3rd—and may contain as many as three personal references (for subject, direct object, and indirect object). *Da,* for example, means "is," *du* means "he has it," and *dio* means "he has it for him" in the sentence *oinari ez dio eskuak kolperik emaiten* "the hand does not give a blow [*kolpe*] to the foot [*oin-a-ri*]." In certain situations the interlocutor can also be referred to within the verb. Further, most Basque verbs have only a compound conjugation; *e.g., erori da* "he has fallen," literally, "he is fallen," and *jaten du* "he eats [is eating] it."

Although some ancient prefixes are still apparent in modern Basque, they are no longer productive, so that Basque can be characterized as an over-all suffixing language; that is, it appends suffixes to words. There is one declension with suffixes or postpositions to indicate number and case; *e.g., etxe-a* "the house," but *etxe berri-a* "the new house," and *etxe berri-a-ri* "to [for] the new house." Suffixes, under certain restrictions, may be heaped upon one another. Theoretically, genitival endings indicating possession may be added to one another without limit. This is similar to the case in English of "the button of the coat of the son of the Major of York"; in Basque, however, the phrase "of the" is indicated by an ending, *-(r)en,* added to the noun. Noun suffixes can also be attached to verb forms in order to express subordination of the clauses in which the verb forms appear; *e.g., da* "is," *den* "which is," *dena* "that (*-a*) which is," *denean* "when there is," literally, "in that which is." Prefixes are also used for that purpose; *e.g., ez du jaten* "he does not eat" with the particle *ba* "if" becomes "if [the belly] does not eat," *jaten ez ba du.*

Vocabulary. Basque has preserved a peculiar and distinctive appearance, despite the overwhelming pressure to which it has been subjected over a period of at least 2,000 years. Nevertheless, its borrowings from the neighbouring languages, especially of words and idioms, can hardly be underrated. Loanwords from the Romance languages are numerous. Some of them bear the unmistakable stamp of their archaic Latin ancestry; *e.g., bake* "peace" from Latin *pax, pacis, bike* "pitch" from Látin *pix, picis,* and *errege* "king" from Latin *rex, regis.* Contrary to a widely held opinion, Indo-European loanwords of non-Latin origin are extremely scarce. Derivation, the formation of new words by the use of suffixes, is accomplished partly through the use of borrowed suffixes. This practice, as well as the compounding of nouns to form new words, as in *bizkar-hezur* "backbone," has been very much alive throughout the history of the language. On the other hand, Basque itself has contributed but little vocabulary to the Spanish, Occitan, French, and English languages. But family and place names of Basque coinage are frequently encountered in Spain and in Latin America, where they can be found in such proper names as Aramburu, Bolívar, Echeverría, and Guevara.

Latin loanwords

(L.M.)

PIDGIN

The term pidgin is applied to a number of varieties of speech that have grown out of English or other languages and that have been used in various parts of the world since the 17th century. Often termed "bastard jargons," "mongrel lingos," or the like, these tongues in fact are languages like any others and can be accurately delimited and described.

Definitions of lingua franca, pidgin, and creole. When a language is used as a means of communication between persons having no other language in common (*e.g.,* French in 18th-century diplomacy) it is a lingua franca. A lingua franca native to none of those using it and with a sharply reduced grammar and vocabulary is called a pidgin. (This definition of pidgin excludes both the broken English of a beginning learner and the skillful but non-native use of English in such countries as India.) When a whole speech community gives up its former language or languages and takes a pidgin as its mother tongue, the pidgin becomes a creole (is creolized).

Situations in which pidgins developed

Origins. A number of pidgins and creoles have arisen on the basis of various European languages. The first known pidgin, Lingua Franca, or "Westerners' language," of the medieval Levant and the Barbary Coast, was based chiefly on Italian. The American Indians first encountered by Englishmen in the 17th century were a tribe known as Pidians near the mouth of the Orinoco; the reduced language that emerged was termed Pidgin (= Pidian) English. Later in the same century, other varieties of Pidgin English grew up in China as a result of English commercial contacts and in Africa in connection with slave-trading activities. (Some authorities derive the word "pidgin" from a variation of English "business".) Establishment of plantation economies in the Caribbean area, with large groups of Negro slaves from different language backgrounds in West Africa, led to a number of pidgins based on English, French, Spanish, and Portuguese. Many have survived as creoles; *e.g.,* Gullah off the Sea Islands of South Carolina, the Negro English of the Antilles, and Sranantongo (formerly called Taki-Taki) in Suriname (formerly Dutch Guiana), all based on English; the French-based creoles of Louisiana, Haiti, and the Lesser Antilles; and the Papiamento of Curaçao, an outgrowth of Pidgin Spanish and Portuguese. Early contacts between settlers and natives led to the formation of pidgins in Australia and New Zealand, whereas the Pidgin English of the South Seas (called Beach-la-Mar) grew out of whaling, trading, and recruiting native labour. Pidgin English is extinct in New Zealand and the Caroline Islands and moribund in Australia but still flourishes in Melanesia (New Hebrides, Solomon Islands, New Guinea) and has become creolized in Hawaii. One variety, that of the Rabaul area (New Britain), has become the widespread and indispensable lingua franca of Papua New Guinea because of the official sanction given its use under German rule (1884–1914) and later Australian administrations.

Development and persistence of pidgins

Survival. Pidgin languages spring from the initial, non-intimate contacts between speakers of different languages, when quick comprehension is more highly valued than grammatical correctness or fine shades of meaning. As contacts grow closer, normally one group learns the other's language more fully, and pidgins survive the stages of initial contact only in special circumstances. Pidgins persist where a dominant group regards another as childlike or capable only of a simplified version of the "superior" language, as in the relations between Europeans and American Indians, West Africans, or South Sea natives. On plantations and in other situations where European masters were in permanent contact with native servants or labourers, pidgins served as status languages, as in New Guinea. Caste distinction, however, is not a necessary function of a pidgin; Russonorsk, for instance, was a reduced language used by Russians and Norwegians in the Arctic at the beginning of the 20th century. Chinese Pidgin English survived for three centuries and not only in master–servant relations; it also was in use between English merchants and Chinese dignitaries, primarily because each side desired to keep the other at arm's length. Slaves on Caribbean plantations, New Guinea natives in newly founded multilingual villages, and others who have come to live together with no language in common save a pidgin have used the pidgin as the customary language of the group. In such instances, the resultant creole has usually re-expanded its structure and vocabulary by borrowing from the language of a culturally dominant group; *e.g.,* Haitian Creole from French, Sranantongo and Papiamento from Dutch, and Melanesian Pidgin from English.

Spelling and sounds

Orthographies. In its original function as a lingua franca among unlettered folk, a pidgin language is a medium of purely oral communication, as also are creoles in their initial stages. Only afterward, and usually in connection with missionary or other educational programs, are spelling systems devised for pidgins or creoles. Speakers of European languages have often applied the orthographical conventions of their own languages, as when the Melanesian Pidgin sentence for "Why did you hit this policeman?" is written *Belong what name you fight 'im dis fellow police boy?* Such a spelling embodies all the inconsistencies of English orthography and is therefore difficult to learn; it distorts the structure of pidgin; and it confirms the naïve European or American in his belief that pidgin is only a ridiculous reduction of English. Those who have devised orthographies, for ease of learning, accuracy in representing linguistic structure, and emphasis on the independent status of the language, have used phonemically based systems. The most effective orthographies of this type use the letters available on typewriters or in printshops, but consistently and predictably. Thus, the Melanesian Pidgin sentence just quoted reads, in the officially recognized orthography: *Bilong wonem yu faitim dispela plisboi?* In the following discussion, forms are cited only in this type of transcription.

Phonology. The simplification which characterizes pidgin extends to all aspects of linguistic structure (sounds, forms, constructions) as well as vocabulary. In some varieties stress is automatically on the first syllable; *e.g., bíkos* "because," *míshin* "machine." A minimum of five distinctive vowels is necessary, those represented in Latin or Italian pronunciations by *a* ("ah"), *e* ("eh"), *i* ("ee"), *o* ("oh"), *u* ("oo"), as in *antap* "up," *em* "he," *winim* "defeat," *kot* "coat," *tu* "also." The vowel sound *a* ("ah") combines with *i* ("ee") and *u* ("oo") in the basic diphthongs *ai* (English "i") and *au* ("ow"), as in *dai* "cease" and *nau* "now." Some, but not all, speakers make further distinctions—*e.g.,* between the *e* of *em* "he" and the *ei* ("ay") of *neim* "name." In almost all varieties of pidgin English, the two consonant sounds represented by English *th* have merged with *t* and *d* respectively: *saut* "south," *dispela* "this." Many speakers of Melanesian Pidgin merge *f* and *p* (in current official orthography, both are represented by *p*) and also merge *ch* and *sh* with *s*: *tumas* "very" (from English "too much"), *masin* "machine." Users of pidgin often carry over habits of sound production from their native languages; *e.g.,* many Melanesian languages have *mb, nd* as variants of *b, d* between vowels, and thus Melanesians often pronounce *tabak* "tobacco" as *tambak,* and *sidaun* "sit" as *sindaun.*

Morphology. Grammatical categories—such as number, gender, case, person, tense, mood, voice—are almost absent from pidgin and creole languages, as from many other languages of the world. Pidgin is not, however, "devoid of grammar," as is often asserted. Melanesian Pidgin, for example, has three inflected parts of speech: pronouns, adjectives, and verbs. The suffix *-pela* added to pronouns makes plurals, in *mi* ("I, me") versus *mipela* ("we, us") and *yu* ("you" singular) versus *yupela* ("you" plural). Another suffix, *-pela,* serves as a marker for adjectives of one syllable, demonstratives, indefinites, and numerals: *naispela* "pretty," *dispela* "this," *sampela* "some," *wanpela* "one." Verbs having a direct object (expressed or implied) take the suffix *-im,* and verbs without this suffix are intransitive or passive: *e.g., rausim* "eject, remove" versus *raus* "be out, come out." Other parts of speech—nouns, prepositions, adverbs, conjunctions—are invariable but are distinguished by the types of combinations in which they occur. In other varieties of Pidgin English, the specific criteria for distinguishing classes of linguistic forms are different, but the basic structure is similar. Chinese Pidgin nouns and pronouns, for example, can take the locative suffix *-said,* in *doksaid* "at the dock (docks)," *maisaid* "at my house," and the verb suffix *-em* forms passive participles, as in *dis tri blong spoilem* "this tree is rotten."

Phrases and clauses

Syntax. The basic types of combination—phrases and clauses—found in pidgin are the same as those of English; here again, however, many details of syntax are different. Melanesian Pidgin nouns are followed not only by possessive phrases (*haus bilong mi* "house of me, my house") but also by modifying nouns (*haus pepa* "house [for] paper, office"), verbs (*haus kuk* "house [for] cooking, kitchen"), adverbs (*man nogud* "evil man," *nogud* being an adverb meaning "undesirably"), and clauses (*man mi lukim em* "the man I saw"). In Chinese Pidgin, pronouns simply precede nouns to indicate possession (*hi fes* "his face"), and relative position is shown by a noun preceding an adjective (*Ning-Po mo fa* "further than Ning Po"). With third person subjects, Melanesian Pidgin predicates are normally preceded by the predicate-marker *i-*: *ol i-singaut* "they call"; *balus i-no kamap yet* "the plane hasn't arrived yet." Melanesian Pidgin has the clause type called "equational" (also found in such languages as Russian and Hungarian) in which no verb is present: *dispela kaikai i-gudpela* "this food [is] good." Chinese Pidgin, on the other hand, has the copulative, or linking, verb *blong* "be" with nouns and adjectives in the predicate (*e.g., yu fut blong plenti sor* "your foot is very sore") but uses no verb with an adverb in the predicate indicating location: *tumuchi dast tebal tapsaid* "a lot of dust [is] on the table."

Vocabulary

Lexicon. Since vocabulary is restricted (about 700 words in Chinese Pidgin, 2,000 in Melanesian), each word necessarily has a greater range of meaning than its English counterpart. The central meaning of Melanesian Pidgin *sori* is not "sorry" but "emotionally moved," as shown by its extension to "sympathetic, grateful, glad"; similarly, *dai* means "cease" ("die" is *dai tru* "stop for good"); and *stap* is "be located; remain; continue." For many concepts, pidgin uses phrases rather than single words: with *skru* "screw; joint" are formed *skru bilong arm* "elbow," *skru bilong leg* "knee," etc. Some pidgin words represent different parts of speech from their English counterparts; *e.g.,* the Melanesian Pidgin preposition *belong* "of" and the Chinese Pidgin copulative verb *blong* "be" from English "belong." Non-English meanings of pidgin words often reflect native social structure, as when *papa* means "uncle," since a boy's maternal uncle rather than his father (*papa tru*) is primarily responsible for his upbringing in New Guinea. Speakers of English are often naïvely amused or shocked by certain shifts of meaning, as when *ars* "buttocks" is extended to mean "bottom (of anything), foundation, reason, cause, source"; for example, *ars bilong diwai* "the base of the tree," or *God i-ars bilong olgeda samting* "God is the source of all things." In the context of native society and attitudes, however, these concepts are not taboo and no stigma attaches to the words or their use.

Non-English vocabulary. The proportion of vocabulary elements in Pidgin English derived from non-English sources is small. Of the approximately 2,000 words in Melanesian Pidgin, not over 10 percent are of non-English origin. Of these, perhaps half are Melanesian (such as *kiau* "eggbomb," *diwai* "tree," *malolo* "rest," *balus* "pigeon, airplane"), and one quarter were borrowed from German, such as *mark* "shilling," *tais* "pond," *langsam* "slow," and *beten* "prayer." The remainder are from various languages—a few from Malay (such as *karabau* "water buffalo") and three from Romance sources: *save* "know," *pikinini* "child," and *pato* "duck." The percentage of non-English elements in Chinese Pidgin is even smaller.

Structural changes from English

Restructuring. In the structural reduction from English to pidgin, the main grammatical characteristics have been kept (the part-of-speech system, the dichotomy between subject and predicate, the use of phrases functioning as single parts of speech), though often with different identifying features. The various kinds of Pidgin English are definitely English and Indo-European, not (as is often said) "native languages spoken with English words." A more sophisticated version of this latter theory is that indigenous vocabulary is simply replaced with new words by "relexification," with indigenous grammatical habits continuing. However, when new functional elements (*e.g.,* pronouns, inflectional suffixes, syntactic patterns) are also taken over, the process is one of complete language-substitution, involving replacement of grammatical structure ("regrammaticalization") as well. Nevertheless there have been extensive carryovers from non-English structural patterns because speakers of native languages have translated their own constructions into pidgin, especially in the early stages of its formation. For instance, in Chinese a numeral modifying a noun must be accompanied by a special word indicating a measure of quantity, called a "numeral-classifier," as in *sān ge rén,* literally "three piece man." This type of combination was reflected in older Chinese Pidgin *tufela man* "two men," *forpisi naif* "four knives," etc., with *-fela* for animate objects, *-pisi* for inanimate objects. However, in modern Chinese Pidgin, *-fela* has not survived, and *-pisi* has lost its independent status and become simply a numeral-suffix, as in *tupisi man* "two men." Similarly, the presence of separate pronouns for "we (excluding the hearer)" and "we (including the hearer)" in Melanesian languages has led to the establishment in Melanesian Pidgin of a parallel contrast between *mipela* "we (but not you)" and *yumi* "we (including you)."

Modern function. With the coming of modern civilization and technology to New Guinea and similar areas, pidgin has proved indispensable in education and political life. Earlier opposition to pidgin—partly on puristic, partly on anticolonialistic grounds—has proved unfounded. In New Guinea and the Solomons, and in many parts of West Africa, pidgin is no longer a status language or imposed on the people by white colonialists, but is the people's own lingua franca, indispensable for communication and easier to learn than English, which is both more complicated and more foreign to them. If skillfully used, pidgin can serve as both a medium of instruction and a bridge to English. In any case, it is clearly destined to remain as an increasingly useful lingua franca, with already manifest prospects of extensive creolization and resultant permanence as the native language of ever larger groups. (R.A.H.)

BIBLIOGRAPHY

Languages of the world. E.H. STURTEVANT, *Linguistic Change* (1917, reprinted 1961), was an important text in Indo-European comparative linguistics, until replaced by WINFRED P. LEHMANN, *Historical Linguistics: An Introduction* (1962). EDWARD SAPIR, *Language: An Introduction to the Study of Speech* (1921, reprinted 1957), presents a revision of the 19th-century whole-language typology. For an example of modern application of subsystem typology, see A.K. RAMANUJAN and COLIN MASICA, "Toward a Phonological Typology of the Indian Linguistic Area," in *Current Trends in Linguistics,* vol. 5, pp. 543–577 (1969); and for an example of lexical domain typology, see BRENT BERLIN and PAUL KAY, *Basic Color Terms: Their Universality and Evolution* (1969). ANTOINE MEILLET and MARCEL COHEN (eds.), *Les Langues du monde,* new ed. (1952), is a survey of languages of the world organized in terms of their genetic classification. Languages are also classified genetically in two more recent surveys: C.F. and F.M. VOEGELIN, "Languages of the World," in *Anthropological Linguistics,* vol. 6–8 (1964–66); and THOMAS A. SEBEOK (ed.), *Current Trends in Linguistics,* 13 vol. (1963–75)—individual volumes deal with geographic areas, and typological information on particular languages is presented. JOSEPH H. GREENBERG, "The Indo-Pacific Hypothesis" (pp. 807–871), and S.A. WURM, "The Papuan Linguistic Situation" (pp. 541–657), both in *Current Trends in Linguistics,* vol. 8 (1971), exemplify variation in proposals for remote genetic relationships among the same set of languages. EDWARD SAPIR, "Central and North American Languages," in *Encyclopædia Britannica,* 14th ed. (1929), presented a classification of these languages in terms of six phyla; this classification was revised by a conference of specialists that resulted in the publication of C.F. and F.M. VOEGELIN (comps.), *Map of North American Indian Languages,* rev. ed. (1967). The culture areas of North American Indians are described in HAROLD E. DRIVER, *Indians of North America,* 2nd ed. rev. (1969).

Indo-European languages. The introductory, classic, and most comprehensive works on Indo-European languages are in German and French. Several publications, however, are written in English.

KARL BRUGMANN, *Grundriss der vergleichenden Grammatik der indogermanischen Sprachen,* 2nd ed., 3 vol. (1897–1916), the latest completed full treatment of the whole family; ANTOINE MEILLET, *Introduction à l'étude comparative des langues indo-européennes,* 8th ed. (1937, reprinted 1964), the best introduction to the subject; JERZY KURYLOWICZ (ed.), *Indogermanische Grammatik* (1968–), vol. 2, *Akzent, Ablaut,* by JERZY KURYLOWICZ (1968), and vol. 3, pt. 1, *Geschichte der indogermanischen Verbalflexion,* by CALVERT WATKINS (1969), when completed, this work will present an account of the entire family—less detailed than Brugmann's, but much more up-to-date; JULIUS POKORNY, *Indogermanisches etymologisches Wörterbuch,* 2 vol. (1951–69), the most recent etymological dictionary of the whole family; CARL DARLING BUCK, *A Dictionary of Selected Synonyms in the Principal Indo-European Languages* (1949), a mine of information about Indo-European words for several hundred basic concepts; HOLGER PEDERSEN, *Sprogvidenskaben i det nittende aarhundrede* (1924; Eng. trans., *Linguistic Science in the Nineteenth Century,* 1931; reissued as *The Discovery of Language,* 1962), a very good account of 19th-century work in the field; GEORGE CARDONA, HENRY M. HOENIGSWALD, and ALFRED SENN (eds.), *Indo-European and Indo-Europeans* (1970), a collection of recent papers on aspects of Indo-European language, culture, and mythology, especially valuable for the attempt to combine linguistic and archaeological evidence about Indo-European prehistory; FREDRIK OTTO LINDEMAN, *Einführung in die Laryngaltheorie* (1970), an excellent brief account of the main advance in Indo-European phonology since 1900.

Anatolian languages. The best general handbook on Anatolian history and civilization, in German, is A. GOETZE, *Kleinasien,* 2nd ed. (1957), with succinct chapters on thé Anatolian languages (pp. 45–63). An excellent, more popular account of Anatolia with marked emphasis on the Hittite period is O.R. GURNEY, *The Hittites,* rev. ed. (1961). This book deals with languages and races in ch. 6. The general handbook on the Anatolian languages, both Indo-European and non-Indo-European, written by scholars, is A. KAMMENHUBER *et al., Altkleinasiatische Sprachen* (1969), although in some chapters the book is perhaps too detailed for the general reader. J. FRIEDRICH (ed.), *Kleinasiatische Sprachdenkmäler* (1932), is still a very valuable collection of texts, chosen to illustrate the various languages of Anatolia. Although written from the viewpoint of the Indo-Hittite hypothesis, E.H. STURTEVANT and E.A. HAHN, *A Comparative Grammar of the Hittite Language,* rev. ed. (1951), was a major achievement. In many respects it is still the best grammar of Hittite. H. PEDERSEN, *Hittitisch und die anderen Indoeuropäischen Sprachen* (1938), was directed against the Indo-Hittite hypothesis and should be used with Sturtevant and Hahn's book. J. PUHVEL's contribution "Dialectal Aspects of the Anatolian Branch of Indo-European," in H. BIRNBAUM and J. PUHVEL (eds.), *Ancient Indo-European Dialects,* pp. 235–247 (1966), gives a good survey of the main characteristics of the Anatolian subgroup. The best recent introduction to the "Indo-European problem" with a notable emphasis on Anatolian matters is R.A. CROSSLAND, *Immigrants from the North,* fasc. 60 of the *Cambridge Ancient History,* rev. ed. (1967). The best introduction to the Anatolian languages and to Hittite literature may be found in two highly authoritative and very well written scientific contributions by H.G. GUTERBOCK: "Toward a Definition of the Term Hittite," *Oriens,* 10:233–239 (1957) and "A View of Hittite Literature," *Journal of the American Oriental Society,* 84:107–115 (1964). The history of the various decipherments has been dealt with by J. FRIEDRICH, *Entzifferung verschollener Schriften und Sprachen,* 2nd ed. (1966).

Indo-Iranian languages. *Indo-Aryan languages (general works):* JULES BLOCH, *L'Indo-aryen du veda aux temps modernes* (1934; rev. Eng. trans., *Indo-Aryan from the Vedas to Modern Times,* 1965), a masterly survey of Indo-Aryan throughout its history; R.L. TURNER, *A Comparative Dictionary of the Indo-Aryan Languages* (1966), an indispensable source in which Sanskrit word headings are given Middle Indo-Aryan forms and New Indo-Aryan cognates; M.B. EMENEAU, "The Dialects of Old Indo-Aryan," in HENRIK BIRNBAUM and JAAN PUHVEL (eds.), *Ancient Indo-European Dialects,* pp. 123–138 (1966), a good summary, with discussion of proposed theories and references; SURYAKANTA, *A Practical Vedic Dictionary* (1981).

Old Indo-Aryan: THOMAS BURROW, *The Sanskrit Language,* new and rev. ed. (1973), a summary of the prehistory and history of Sanskrit, with references to Middle Indo-Aryan, which contains somewhat personal views but is valuable for its discussion of non-Aryan influences on Sanskrit; LOUIS RENOU, *Histoire de la langue sanskrite* (1956), an insightful summary of the grammar, vocabulary, and style of different stages of Sanskrit, with text selections and translations; MANFRED MAYRHOFER, *Kurzgefasstes etymologisches Wörterbuch des Altindischen* (*A Concise Etymological Sanskrit Dictionary*), 4 vol. (1953–80), contains sober etymologies, full references, and a discussion of loanwords and words supposed to have been borrowed from Dravidian.

Middle Indo-Aryan: RICHARD PISCHEL, *Grammatik der Prākrit-Sprachen* (1900; Eng. trans., *Comparative Grammar of the Prākrit Languages,* 2nd ed., 1965), an encyclopaedic grammar of all the Prākrits except Buddhist Hybrid Sanskrit and Pāli, which includes a good discussion of the different Prākrits in the introduction (now in need of updating); S.M. KATRE, *Prakrit Languages and Their Contribution to Indian Culture,* 2nd ed. (1964), a general survey of the Prākrits, including Pāli; LUDWIG ALSDORF, *Apabhraṃśa-Studien,* pp. 5–17, 20–37 (1937, reprinted 1966, important studies discussing noun and verb inflection.

Modern Indo-Aryan: JOHN BEAMES, *A Comparative Grammar of the Modern Aryan Languages: To Wit, Hindi, Panjabi, Sindhi, Gujarati, Marathi, Oṛiya,* and *Bangali,* 3 vol. (1872–79, reprinted 1966); and A.F.R. HOERNLE, *A Comparative Grammar of the Gaudian Languages with Special Reference to the Eastern Hindi* (1880, reprinted 1975), general comparative grammars of the New Indo-Aryan languages—though in need of modernization, still indispensable; SIR GEORGE A. GRIERSON, *On the Modern Indo-Aryan Vernaculars* (1931), a reprint of two long articles, tracing the phonologic developments that led to New Indo-Aryan; S.K. CHATTERJEE, *Indo-Aryan and Hindi,* 2nd rev.

ed. (1960), a series of lectures briefly tracing the history of Indo-Aryan, with particular emphasis being given to Hindi and its relation to other Indo-Aryan languages, and to the general language problem in India.

Iranian languages (general works): An important comprehensive treatment of the Iranian languages in general is WILHELM GEIGER and ERNST KUHN (eds.), *Grundriss der iranischen Philologie,* 2 vol. (1895–1904, reprinted 1974). This invaluable work is now in many respects antiquated, and it contains no account of several Middle Iranian languages that have been made known only in this century. A more recent account in less detail is provided by the *Handbuch der Orientalistik,* vol. 1, sect. 4, *Iranistik,* pt. 1, *Linguistik* (1958). There is an introduction to the subject in Russian: ИОСИФ МИХАЙЛОВИЧ ОРАНСКИЙ, *Введение в иранскую филологию* (1960). Some useful bibliography with brief guidelines is given by D.N. MACKENZIE, "Iranian Languages," in THOMAS A. SEBEOK (ed.), *Current Trends in Linguistics,* vol. 5, *Linguistics in South Asia,* pp. 450–477 (1969).

Old Iranian: All known Old Persian texts except for recent discoveries are given in transcription and translation in ROLAND KENT, *Old Persian,* 2nd ed. rev. (1953). Information on Old Persian linguistic problems is contained in WILHELM BRANDENSTEIN and MANFRED MAYRHOFER, *Handbuch des Altpersischen* (1964). On the Avestan language the article by GEORG MORGENSTIERNE, "Orthography and Sound-System of the Avesta," in *Norsk Tidsskrift for Sprogvidenskap,* 12:30–82 (1942), is of great importance. A useful bibliographical guide to recent work on Avestan is provided by J. DUCHESNE-GUILLEMIN, "L'Étude de l'iranien ancien au vingtième siècle," *Kratylos,* 7:1–44 (1962).

Middle Iranian: The verbal system of Parthian is described by A. GHILAIN, *Essai sur la langue parthe, son système verbal d'après les textes manichéens* (1939, reprinted 1966); and for Middle Persian by W. HENNING, "Das Verbum des Mittelpersischen der Turfanfragmente," *Zeitschrift für Indologie und Iranistik,* 9:158–253 (1933). A Pahlavi dictionary for students is D.N. MACKENZIE, *A Concise Pahlavi Dictionary* (1971). The grammar of Sogdian has received detailed treatment in ILYA GERSHEVITCH, *A Grammar of Manichean Sogdian* (1954); and of Khotanese in R.E. EMMERICK, *Saka Grammatical Studies* (1968). A brief sketch of Khwārezmian is given in W.B. HENNING, "The Khwarezmian Language," *Zeki Velīdi Togan'a Armağan,* pp. 421–436 (1955).

Modern Iranian: An important recent work is GILBERT LAZARD, *Grammaire du persan contemporain* (1957). For the early stages of Modern Persian, Lazard's *Langue des plus anciens monuments de la prose persane* (1963), is invaluable. The same author has provided a comprehensive guide to the most important linguistic features of Tazhik in "Caractères distinctifs de la langue tadjik," *Bulletin de la Société linguistique de Paris,* 52:117–186 (1956). A treatment of Baluchi dialects is J.H. ELFENBEIN, *The Baluchi Language* (1966). Of the many works describing Kurdish dialects, a comprehensive modern work is D.N. MACKENZIE, *Kurdish Dialect Studies,* 2 vol. (1961–62). For the history of the Pashto language, GEORG MORGENSTIERNE, *An Etymological Vocabulary of Pashto* (1927), remains standard. Morgenstierne's *Indo-Iranian Frontier Languages,* 4 vol, in 6, 2nd. rev. and with new material (1973), is the work most often quoted for most of the minor languages. Ossetic has been described by a native speaker: V.I. ABAEV, *A Grammatical Sketch of Ossetic* (1964; orig. pub. in Russian, 1959).

Greek language. *Ancient Greek:* M. VENTRIS and J. CHADWICK, *Documents in Mycenaean Greek: Three Hundred Selected Tablets from Knossos, Pylos, and Mycenae, with Commentary and Vocabulary* (1956), a study of both the writing system and the content of the tablets, by the authors of the decipherment; L.H. JEFFERY, *The Local Scripts of Archaic Greece* (1961), a description of all the local varieties of the Greek alphabet from the 8th to the 5th century BC; C.D. BUCK, *The Greek Dialects* (1955), a summary of the dialectal features of Ancient Greek within the scope of a traditional descriptive grammar; A. MEILLET, *Aperçu d'une histoire de la langue grecque,* 7th ed. (1965), the first and still fundamental endeavour to define the characteristics of Greek in a diachronic perspective; E. SCHWYZER and A. DEBRUNNER, *Griechische Grammatik,* 3 vol. (1939–53), a complete and accurate description with exhaustive bibliography; P. CHANTRAINE, *La Formation des noms en grec ancien* (1933), deals with the history of noun suffixes throughout the history of Greek; H. FRISK, *Griechisches etymologisches Wörterbuch,* 2 vol. (1954–70), up to date and wisely selective (but often underrating Mycenaean data).

Koine and Byzantine: For Koine, see F. BLASS and A. DEBRUNNER, *Grammatik des neutestamentlichen Griechisch,* 10th ed. (1959; Eng. trans., *A Greek Grammar of the New Testament and Other Early Christian Literature,* 1961), a translation and revision of a classic work by R.W. FUNK. T.M. DAWKINS, "The Greek Language in the Byzantine Period," in N.H. BAYNES and H.ST.L.B. MOSS, *Byzantium* (1948); and R. BROWNING, *Medieval and Modern Greek* (1969), cover later periods.

Modern Greek: S.A. SOFRONIOU, *Teach Yourself Modern Greek* (1962); and J.T. PRING, *A Grammar of Modern Greek on a Phonetic Basis* (1950), are good elementary introductions. There is no reasonably complete dictionary of literary demotic, but J.T. PRING, *The Oxford Dictionary of Modern Greek (Greek-English)* (1965), is adequate for the spoken language. In general, English–Greek dictionaries are intended for Greeks and fail to mark the stylistic level of Greek equivalents; A.N. JANNARIS, *A Concise Dictionary of the English and Modern Greek Languages* (1895, frequently reprinted), has not been improved on. F.W. HOUSEHOLDER, K. KAZAZIS, and A. KOUTSOUDAS, *Reference Grammar of Literary Dhimotiki* (1964), is useful; and for a convenient summary of the development of demotic, see R. Browning (cited above). For dialects, see B.E. NEWTON, *The Generative Interpretation of Dialect: A Study of Modern Greek Phonology* (1972).

Italic languages: General surveys of the history of Italic languages include: J. WHATMOUGH, *The Foundations of Roman Italy* (1937); G. DEVOTO, *Gli antichi Italici,* 3rd ed. (1967), in Italian; and E. PULGRAM, *The Tongues of Italy* (1958).

The fundamental works on Osco-Umbrian are R. VON PLANTA, *Grammatik der oskisch-umbrischen Dialekte,* 2 vol. (1892–97), in German; and R.S. CONWAY (ed.), *Italic Dialects,* 2 vol. (1897). The most complete edition of texts (with the exception of Venetic) is E. VETTER, *Handbuch der italischen Dialekte,* vol. 1, *Texte mit Erklärung, Glossen, Wörterverzeichnis* (1953), in German. The best introduction for beginners continues to be C.D. BUCK, *A Grammar of Oscan and Umbrian,* 2nd ed. (1928). For special studies of the Iguvine Tables, see G. DEVOTO, *Tabulae Iguvinae,* 3rd ed. (1962), in Latin; and J.W. POULTNEY, *The Bronze Tables of Iguvium* (1959). For Faliscan, see G. GIACOMELLI, *La lingua falisca* (1963); and for Venetic, see G.B. PELLEGRINI and A.L. PROSDOCIMI, *La lingua venetica,* 2 vol. (1967), both works in Italian.

Remains of other languages within ancient Italy, including Venetic, are treated in R.S. CONWAY, J. WHATMOUGH, and S.E. JOHNSON, *The Prae-Italic Dialects of Italy,* 3 vol. (1934).

Romance languages: I. IORDAN and J. ORR, *An Introduction to Romance Linguistics,* revised reprint of the 1937 edition, with an additional essay, "Thirty Years On" by REBECCA POSNER (1970), describes the work done in Romance during the 19th and 20th centuries and provides an extensive bibliography of all works written both on the family as a whole, and on individual languages. On the Romance languages in general, two books written in English will prove useful: the more philologically oriented *The Romance Languages* by W.D. ELCOCK (1960); and the more popular, linguistically oriented *The Romance Languages: A Linguistic Introduction* by REBECCA POSNER (1966). Outstanding is Y. MALKIEL, *Essays on Linguistic Themes* (1968), which includes several articles on the Romance languages and Romance linguistics. On the individual languages, among works in English particularly to be recommended, are L.R. PALMER, *The Latin Language* (1954); BRUNO MIGLIORINI, with T. GWYNFOR GRIFFITH, *Storia della lingua italiana* (1960, Eng. trans., *The Italian Language,* 1966); A.E. EWERT, *The French Language,* 2nd ed. (1961); and WILLIAM ENTWISTLE, *The Spanish Language* (1936).

Germanic languages. *History and classification of the Germanic languages:* The reconstruction of Proto-Germanic and the derivation of Proto-Germanic from Proto-Indo-European are treated in FRANS VAN COETSEM (ed.), *Toward a Grammar of Proto-Germanic* (1972); EDUARD PROKOSCH, *A Comparative Germanic Grammar* (1939); HERMANN HIRT, *Handbuch des Urgermanischen,* 3 vol. (1931–34); ANTOINE MEILLET, *Caractères généraux des langues germaniques,* 7th ed. (1949); WILHELM STREITBERG, *Urgermanische Grammatik* (1896, reprinted 1963). See also ANATOLY LIBERMAN, *Germanic Accentology,* vol. 1 (1982).

East Germanic and Gothic: (*General survey*): JAMES W. MARCHAND, "The Gothic Language," *Orbis,* 7:492–515 (1958). (*Texts*): WILHELM STREITBERG (ed.), *Die gotische Bibel,* 3rd ed. (1950). (*Grammar*): JOSEPH WRIGHT, *Grammar of the Gothic Language . . . ,* 2nd ed. (1954); FERNAND MOSSE, *Manuel de la langue gotique,* 2nd ed. (1956); THEODOR WILHELM BRAUNE, *Gotische Grammatik,* 16th ed. (1961); WOLFGANG KRAUSE, *Handbuch des Gotischen* (1953). (*Dictionary and concordance*): ERNST SCHULZE, *Gothisches Glossar* (1848). (*Etymological dictionary*): SIGMUND FEIST, *Vergleichendes Wörterbuch der gotischen Sprache,* 3rd ed. (1939). (*Ostrogothic*): FERDINAND WREDE, *Über die Sprache der Ostgoten in Italien* (1891). (*Vandalic*): FERDINAND WREDE, *Über die Sprache der Wandalen* (1886). (*Bibliography*): FERNAND MOSSE, "Bibliographia Gotica," *Mediaeval Studies,* 12:237–324 (1950), supplements in 15:169–183 (1953), and 19:174–196 (1957).

Frisian: (*General survey*): BO SJOLIN, *Einführung in das*

Friesische (1969). (*Old Frisian, grammar and phonology*): WALTHER STELLER, *Abriss der altfriesischen Grammatik* (1928). (*Dictionary*): FERDINAND HOLTHAUSEN, *Altfriesisches Wörterbuch* (1925). (*Modern West Frisian, grammar*): K. FOKKEMA, *Beknopte Friese Spraakkunst*, 2nd ed. (1967). (*Phonology*): ANTONIE COHEN *et al., Fonologie van het Nederlands en het Fries*, 2nd ed. (1961). (*Dictionary*): H.S. BUWALDA, G.A.G. MEERBURG, and Y.R. POORTINGA (eds.), *Frysk Wurdboek*, 2 vol. (1952–56), Netherlandic-Frisian, Frisian-Netherlandic. (*Dialects*): NILS ARHAMMER, "Friesische Dialektologie," in *Germanische Dialektologie*, vol. 1, pp. 264–317 (1968).

Netherlandic: (*General*): WALTER LAGERWEY, *Guide to Dutch Studies: Bibliography of Textual Materials for the Study of Dutch Language, Literature, Civilization* (1961); C.B. VAN HAERINGEN, *Netherlandic Language Research*, 2nd ed. (1960). (*History*): MORITZ SCHONFELD, *Historische Grammatica van het Nederlands*, 6th ed. (1960); C.G.N. DE VOOYS, *Geschiedenis van de Nederlandse Taal*, 5th ed. (1952). (*Old Low Franconian*): ROBERT L. KYES (ed.), *The Old Low Franconian Psalms and Glosses* (1969). (*Phonology*): ANTONIE COHEN *et al., Fonologie van het Nederlands en het Fries*, 2nd ed. (1961); B. VAN DEN BERG, *Foniek van het Nederlands*, 2nd ed. (1960); EDGAR BLANCQUAERT, *Practische Uitspraakleer van de Nederlandse Taal*, 4th ed. (1953). (*Grammar*): ETSKO KRUISINGA, *A Grammar of Modern Dutch* (1924). (*Dialects*): A.A. WEIJNEN, *Nederlandse Dialectkunde* (1966).

Afrikaans: (*History*): G.G. KLOEKE, *Herkomst en Groei van het Afrikaans* (1950). (*Phonology*): MEYER DE VILLIERS, *Afrikaanse Klankleer: Fonetiek, Fonologie en Woordbou*, 3rd ed. (1965). (*Grammar*): H.J.J.M. VAN DER MERWE, *An Introduction to Afrikaans* (1952). (*Dictionary*): D.B. BOSMAN, I.W. VAN DER MERWE, and L.W. HIEMSTRA, *Tweetalige Woordeboek*, vol. 1, *Afrikaans-Engels* and vol. 2, *Engels-Afrikaans*, 5th ed. (1964; 7th ed., 1 vol., 1967). (*Comparison with Netherlandic*): JAMES L. WILSON, *Some Phonological, Morphological and Syntactic Correspondences Between Standard Dutch and Afrikaans* (1967; available from University Microfilms).

German: (*History*): W.B. LOCKWOOD, *An Informal History of the German Language, with Chapters on Dutch and Afrikaans, Frisian and Yiddish* (1965); JOHN T. WATERMAN, *A History of the German Language* (1966); ADOLF BACH, *Geschichte der deutschen Sprache*, 8th ed. (1965). (*Pronunciation*): WILLIAM G. MOULTON, *The Sounds of English and German* (1962); THEODOR SIEBS, *Deutsche Aussprache: Bühnenaussprache*, 19th ed. (1969); MAX MANGOLD (ed.), *Duden Aussprachewörterbuch* (1962). (*Spelling*): *Duden: Rechtschreibung der deutschen Sprache und der Fremdwörter*, 16th rev. ed. (1967). (*Grammar*): HERBERT LEDERER, *Reference Grammar of the German Language* (1969), trans. and adapted from HEINZ GRIESBACH and DORA SCHULZ, *Grammatik der deutschen Sprache*, 6th ed. (1967); HERBERT L. KUFNER, *The Grammatical Structures of English and German* (1962); PAUL GREBE (ed.), *Duden Grammatik der deutschen Gegenwartssprache*, 2nd ed. (1966). (*Dialects*): R.E. KELLER, *German Dialects* (1961); ADOLF BACH, *Deutsche Mundartforschung*, 2nd ed. (1950); V.M. SCHIRMUNSKI, *Deutsche Mundartkunde* (1962; orig. pub. in Russian, 1956).

Yiddish: The main works up to 1958 are listed in URIEL and BEATRICE WEINREICH, *Yiddish Language and Folklore: A Selective Bibliography for Research* (1959). Significant recent works include: *For Max Weinreich on His Seventieth Birthday: Studies in Jewish Languages, Literature, and Society* (1964); *The Field of Yiddish: Studies in Language, Folkore and Literature*, 2nd collection, ed. by URIEL WEINREICH (1965); *The Field of Yiddish: Studies in Language, Folklore, and Literature*, 3rd collection, ed. by MARVIN I. HERZOG, WITA RAVID, and URIEL WEINREICH (1969); JOSHUA A. FISHMAN, *Yiddish in America: Socio-linguistic Description and Analysis* (1965); MARVIN I. HERZOG, *The Yiddish Language in Northern Poland: Its Geography and History* (1965); URIEL WEINREICH, *Modern English-Yiddish, Yiddish-English Dictionary* (1968), and "Yiddish Language," *Encyclopaedia Judaica*, vol. 16, col. 789–798 (1971).

Scandinavian: (*North Germanic*): A survey of research on Scandinavian languages since 1918 by EINAR HAUGEN and THOMAS L. MARKEY is presented in THOMAS A. SEBEOK (ed.), *Current Trends in Linguistics*, vol. 11 (forthcoming). Important recent contributions are treated in *The Nordic Languages and Modern Linguistics*, ed. by H. BENEDIKTSSON (1970). (*Histories*): Compact histories of all the languages are presented in ELIAS WESSEN, *Die nordischen Sprachen* (1968); and EINAR HAUGEN, *The Scandinavian Languages* (forthcoming). Detailed histories include: D.A. SEIP, *Norsk språkhistorie til omkring 1370*, 2 vol. (1955; German trans., 1971), for Old Norwegian; PETER SKAUTRUP, *Det danske sprogs historie*, 4 vol. and index (1944–68), for Danish; ELIAS WESSEN, *Svensk språkhistoria*, 3 vol. (1965), for Swedish; GUSTAV L. INDREBO, *Norsk målsoga* (1951), for Norwegian; and EINAR HAUGEN, *Language Conflict and Language Planning* (1966), for the modern Norwegian period. (*Grammars*): The classic grammars of the older languages are ADOLF G. NOREEN, *Altisländische und altnorwegische Grammatik*, 4th ed. (1923); and *Altschwedische Grammatik* (1904); and JOHANNES BRONDUM-NIELSEN, *Gammeldansk grammatik*, 5 vol. (1950–65). For introductory purposes the best grammar is E.V. GORDON, *An Introduction to Old Norse*, 2nd ed. rev. by A.R. TAYLOR (1981). Grammars of the modern languages are: PAUL DIDERICHSEN, *Elementaer dansk grammatik*, 2nd ed. (1957), for Danish, and Diderichsen's compendium *Essentials of Danish Grammar* (1964), as well as AAGE K. HANSEN, *Moderne dansk*, 3 vol. (1967); ADOLF G. NOREEN, *Vårt språk*, 9 vol. (1903–24), for Swedish; AUGUST WESTERN, *Norsk riksmåls grammatikk* (1921), for Dano-Norwegian; OLAV T. BEITO, *Nynorsk grammatikk* (1970), for New Norwegian; W.B. LOCKWOOD, *An Introduction to Modern Faroese* (1955), for Faeroese; STEFAN EINARSSON, *Icelandic: Grammar, Texts, Glossary* (1945). See also JONATHAN WYLIE and DAVID MARGOLIN, *The Ring of Dancers: Images of Faroese Culture* (1981), which treats the language. Introductory textbooks for English-speaking users are (beside the two just preceding) ELIAS BREDSDORFF, *Danish* (1956); EINAR HAUGEN and KENNETH G. CHAPMAN, *Spoken Norwegian*, rev. ed. (1964); NILS-GUSTAV HILDEMAN and ANN-MARI BEITE (eds.), *Learn Swedish*, 2nd ed. (1964); and volumes in the "Teach Yourself" series. (*Dictionaries*): There are many-volumed native dictionaries for each language. Only some bilingual dictionaries are listed here: HERMANN VINTERBERG and JENS AXELSEN, *Dansk-engelsk ordbog*, 7th ed., 2 vol. (1967); RICHARD CLEASBY and GUDBRAND VIGFUSSON, *An Icelandic-English Dictionary*, 2nd ed. (1957); W.E. HARLOCK, *Svensk-engelsk ordbok* (1944); the technical I.E. GULLBERG, *Svensk-engelsk fackordbok* (1964); and EINAR HAUGEN (ed.), *Norwegian-English Dictionary* (1965). EINAR HAUGEN, *Scandinavian Language Structure* (1982), is a comparative survey.

English language. *Dictionaries: The Oxford English Dictionary*, 13 vol. (1933), is the reissue of *The New English Dictionary on Historical Principles* (1884–1928); it is updated by a Supplement (1972–), projected to be four volumes upon completion. Derivative dictionaries include *The Shorter Oxford English Dictionary on Historical Principles*, 2nd ed., 2 vol. (1939); *The Concise Oxford Dictionary of Current English*, 6th ed. (1976); *The Pocket Oxford Dictionary of Current English* (1969); *The Little Oxford Dictionary of Current English*, 4th ed. (1969); *Oxford Illustrated Dictionary*, 2nd ed. (1975); and *The Oxford Advanced Learner's Dictionary of Current English*, 3nd ed. (1974); and the *Oxford American Dictionary* (1980). Other one-volume dictionaries include *Chambers' Twentieth Century* (1972); *The Universal Dictionary of the English Language*, rev. by E.H. PARTRIDGE (1952); *Longmans English Larousse* (1968); and P. HANKS, *Encyclopedic World Dictionary* (1971).

The leading American dictionary is *Webster's Third New International Dictionary of the English Language* (1961), actually 8th in the series since the first appeared in 1828; it is updated by a separately published "Addenda" section, *6,000 Words* (1976). *Webster's New Collegiate Dictionary* (1979) is an abbreviated version. Other comprehensive dictionaries are *The New Century Dictionary of the English Language*, 2 vol. (1959); and *Funk and Wagnalls New Standard Dictionary of the English Language* (1963). Two comprehensive dictionaries are outstanding: *The Random House Dictionary of the English Language* (1966); and *The American Heritage Dictionary of the English Language* (1969).

Reliable etymological dictionaries include ERNEST WEEKLEY, *An Etymological Dictionary of Modern English*, 2 vol. (1921, reprinted 1967); E.H. PARTRIDGE, *Origins*, 5th rev. ed. (1971); and ERNEST KLEIN, *A Comprehensive Etymological Dictionary of the English Language*, 2 vol. (1966–67). *The Oxford Dictionary of English Etymology* (1966) will long remain the most authentic work in this field.

The two great historical dictionaries of American English are: SIR WILLIAM A. CRAIGIE and JAMES R. HULBERT (eds.), *A Dictionary of American English on Historical Principles*, 4 vol. (1936–44); and MITFORD M. MATHEWS, (ed.), *A Dictionary of Americanisms on Historical Principles*, 2 vol. (1951).

Modern usage: H.W. FOWLER's somewhat eccentric *A Dictionary of Modern English Usage* (1926) was thoroughly updated by SIR ERNEST GOWERS (1965). It has its transatlantic counterpart in the following two works: BERGEN and CORNELIA EVANS, *A Dictionary of Contemporary American Usage* (1957); and MARGARET NICHOLSON, *A Dictionary of American-English Usage* (1957). See also *Roy H. Copperud, American Usage and Style* (1980).

Grammar and structure of English: A.A. HILL, *Introduction to Linguistic Structures: From Sound to Sentence in English* (1958); SAMUEL JAY KEYSER and PAUL M. POSRAL, *Beginning English Grammar* (1976); PAUL ROBERTS, *English Sentences* (1962); MARTIN JOOS, *The English Verb* (1964); H.A. GLEASON, *Linguistics and English Grammar* (1965); N.C. STAGEBERG, *An Introductory English Grammar*, 3rd ed. (1977); A.E. DAR-

BYSHIRE, *A Description of English* (1967); R. QUIRK *et al., A Grammar of Contemporary English* (1972); B.M.H. STRANG, *Modern English Structure,* 2nd ed. rev. (1968); R.W. ZANDVOOST, *A Handbook of English Grammar,* 7th ed. (1975).

Phonetics of English: Handbooks include HANS KURATH and R.I. MCDAVID, *The Pronunciation of English in the Atlantic States* (1961); and A.C. GIMSON, *An Introduction to the Pronunciation of English* (1963).

Histories: An excellent account of the "external history" of the language is given by A.C. BAUGH in *A History of the English Language,* 3rd ed. (1978). FERNAND MOSSÉ, *Esquisse d'une histoire de la langue anglaise* (1947), is a masterpiece—brief, lucid, and profound. KARL BRUNNER, *Die englische Sprache: Ihre geschichtliche Entwicklung,* 2nd ed., 2 vol. (1960–62), is indispensable to advanced students.

Two brief surveys written early in the 20th century are recognized classics and remain stimulating: HENRY BRADLEY, *The Making of English* (1904, rev. by SIMEON POTTER, 1968); and J.O.H. JESPERSEN, *Growth and Structure of the English Language* (1905, reprinted 1971). Other fairly substantial histories include STUART ROBERTSON, *The Development of Modern English,* 2nd ed. rev. by FREDERIC G. CASSIDY (1954); M.M. BRYANT, *Modern English and Its Heritage,* 2nd ed. (1962); M.W. BLOOMFIELD and L.D. NEWMARK, *A Linguistic Introduction to the History of English* (1963); W.N. FRANCIS, *The English Language, an Introduction* (1965); THOMAS PYLES, *The Origins and Development of the English Language,* 2nd ed. (1971); SIMEON POTTER, *Our Language,* rev. ed. (1968); J.W. CLARK, *Early English: A Study of Old and Middle English* (1967); A.C. PARTRIDGE, *Tudor to Augustan English* (1969); J.A. SHEARD, *The Words We Use,* rev. ed. (1970); JOSEPH M. WILLIAMS, *Origins of the English Language: A Social and Linguistic History* (1975); and B.M.H. STRANG, *A History of English* (1970). F.T. VISSER, *An Historical Syntax of the English Language,* 3 vol. (1963–73), provides copious illustrations and bibliographies.

Special studies: GEORGE W. TURNER, *The English Language in Australia and New Zealand* (1966); SIMEON POTTER, *Changing English* (1969); JOHN W. SPENCER (ed.), *The English Language in West Africa* (1971); MITFORD M. MATHEWS (ed.), *The Beginnings of American English* (1931); THOMAS PYLES, *Words and Ways of American English* (1952); ALBERT H. MARCKWARDT, *American English,* 2nd. ed. rev. by J.L. DILLARD (1980); and *Black English: Its History and Usage in the United States* (1972), also by Dillard.

Bibliographies: ARTHUR G. KENNEDY, *A Bibliography of Writings on the English Language from the Beginning of Printing to the End of 1922* (1927); HAROLD B. ALLEN, *Linguistics and English Linguistics,* 2nd ed. (1977). New books are recorded in the *Annual Bibliography of English Language and Literature,* edited for the Modern Humanities Research Association, and in *The Year's Work in English Studies* (annual), edited for the English Association. Books and contemporary studies are listed in the *MLA International Bibliography of Books and Articles on the Modern Languages and Literatures* (annual) of the Modern Language Association.

Armenian language. S.L. KOGIAN, *Armenian Grammar* (1949); H. HUBSCHMANN, "Armenische Grammatik," *Armenische Etymologie* (1897); A. MEILLET, *Esquisse d'une grammaire comparée de l'arménien classique,* new ed. (1936); GERHARD DEETERS, *Armenisch und Südkaukasisch* in *Caucasica* (1927); HEINRICH ZELLER, "Armenisch," in *Geschichte der indogermanischen Sprachwissenschaft,* vol. 4 (1927). For ancient Armenian, see A. MEILLET, *Altarmenisches Elementarbuch* (1913); and H. JENSEN *Altarmenische Grammatik* (1959). Medieval Armenian is treated in J. KARST, *Historische Grammatik des Kilikisch-Armenischen* (1901). For modern speech, see H. ADJARIAN, *Classification des dialectes arméniens* (1909); and A. ABEGHIAN, *Neuarmenische Grammatik* (1936).

Tocharian language. E. SIEG and W. SIEGLING (eds.), *Tocharische Sprachreste* (1921), gives the transcription of all the manuscripts in dialect A. A small companion volume, *Tafeln,* reproduces a number of the best preserved leaves in facsimile. E. SIEG, W. SIEGLING, and W. SCHULZE, *Tocharische Grammatik* (1931), is an exhaustive grammar of dialect A, with a verbal index identifying and listing all verb forms in that dialect. H. PEDERSEN, *Tocharisch vom Gesichtspunkt der indoeuropäischen Sprachvergleichung* (1941), is still the best overall comparative study from the Indo-European point of view, even though extensive published materials in dialect B were not available. E. SIEG and W. SIEGLING, *Tocharische Sprachreste, Sprache B,* 2 pt. (1949–53), contain all the Berlin manuscripts in dialect B plus a few from other collections (especially the Hoernle collection in London). Part 1 is an edition of the Udānālaṅkāra fragments with translation and glossary. W. KRAUSE, *Westtocharische Grammatik,* vol. 1, *Das Verbum* (1952), is indispensable for the verb in dialect B (a second volume was never published). W. KRAUSE and W. THOMAS, *Tocharisches Elementarbuch,* vol. 1, *Grammatik* (1960), vol. 2, *Texte und Glossar* (1964), including both dialects, now replace all earlier introductions to the study of Tocharian. Two articles by G.S. LANE, "On the Interrelationship of the Tocharian Dialects," in H. BIRNBAUM and J. PUHVEL (eds.), *Ancient Indo-European Dialects* (1966); and "Tocharian: Indo-European and Non-Indo-European Relationships," in G. CARDONA, H.M. HOENIGSWALD, and A. SENN (eds.), *Indo-European and Indo-Europeans* (1970), attempt to solve some of the problems concerning the varied uses of the two dialects and the general problem of the position of Tocharian within the Indo-European family of languages.

Celtic languages. H. LEWIS and H. PEDERSEN, *A Concise Comparative Celtic Grammar* (1937), is the most recent survey of the entire field. The early history of the British group is discussed in detail by K.H. JACKSON, *Language and History in Early Britain* (1953); for the later history of Welsh and Breton, J. MORRIS JONES, *A Welsh Grammar* (1913), and F. GOURVIL, *Langue et littérature bretonnes* (1952), give useful information. P. BERRESFORD ELLIS, *The Cornish Language and Its Literature* (1974), deals with the early period, as well as with the recent Cornish language revival movement. R. THURNEYSEN, *Grammar of Old Irish,* rev. ed. (1946), is a classic among linguistic handbooks; for the later development of Irish, T.F. O'RAHILLY, *Irish Dialects Past and Present* (1932), is full of information and contains chapters on Scottish Gaelic and Manx. B.O CUIV (ed.), *A View of the Irish Language* (1969), containing 12 essays by various hands, maps, and illustrations; and D. GREENE, *The Irish Language* (1966), are directed to the general reader rather than to the linguist. The relevant sections of GLANVILLE PRICE, *The Present Position of Minority Languages in Western Europe* (1969), give full bibliographies of works dealing with the political and social status of the surviving Celtic languages.

Baltic languages. There are very few works on the Baltic languages in English aside from LEONARDAS DAMBRIŪNAS, ANTANAS KLIMAS, and WILLIAM R. SCHMALSTIEG, *Introduction to Modern Lithuanian* (1966); TERĒZA BUDIŅA LAZDIŅA, *Teach Yourself Latvian* (1966); and JANIS ENDZELĪNS, *Baltų kalbų garsai ir formos* (1957; Eng. trans., *Comparative Phonology and Morphology of the Baltic Languages,* 1971). *Baltic Linguistics,* ed. by THOMAS F. MAGNER and WILLIAM R. SCHMALSTIEG (1970), is a collection of papers on various aspects of Baltic linguistics.

Works in other languages include REINHOLD TRAUTMANN, *Die altpreussischen Sprachdenkmäler* (1910); JOHANN ENDZELIN, *Lettische Grammatik* (1922; trans. into Latvian, 1951); KAZIMIERAS BŪGA, *Lietuvių kalbos žodynas* (1924–25), the introduction to this dictionary contains much valuable information on the history of the Baltic languages; *Rinktiniai raštai,* 3 vol. (1958–61); JANIS ENDZELĪNS, *Senprūšu valoda* (1943; trans. into German, 1944, without a glossary); *Ievads baltu filoloģijā* (1945), an introduction to Baltic linguistics, in Latvian; ERNST FRAENKEL, *Die baltischen Sprachen* (1950), a general introduction; ALFRED SENN, "Die Beziehungen des Baltischen zum Slavischen und Germanischen," *Zeitschrift für vergleichende Sprachforschung,* vol. 71 (1954), discusses the relationship of Baltic to Slavic and Germanic; *Mūsdienu latviešu literārās valodas gramatika,* 2 vol. (1959–62), a grammar of the modern Latvian literary language; ARTURS OZOLS, *Veclatviešu rakstu valoda* (1965), treats Old Latvian; JAN OTREBSKI, *Gramatyka języka litewskiego,* 3 vol. (1956–65), a Lithuanian grammar, in Polish; MARTA RUDZĪTE, *Latviešu dialektoloģija* (1964), treats Latvian dialectology; *Lietuvių kalbos gramatika,* 2 vol. (1956, 1971), the most authoritative grammar of the Lithuanian language; ZIGMAS ZINKEVICIUS, *Lietuvių dialektologija* (1966), a valuable treatment of Lithuanian dialectology; CHRISTIAN S. STANG, *Vergleichende Grammatik der Baltischen Sprachen* (1966), the only scholarly comparative grammar of the Baltic languages; VYTAUTAS J. MAZIULIS (comp.), *Prūsų kalbos paminklai* (1966), contains and discusses all the photographed Old Prussian texts; ALGIRDAS SABALIAUSKAS, "Lietuvių kalbos leksikos raida," *Lietuvių kalbotyros klausimai,* 8:5–140 (1966), treats the development of the vocabulary of Lithuanian; JONAS PALIONIS, *Lietuvių literatūrinė kalba XVI–XVII a.* (1967), a treatment of the Lithuanian literary language in the 16th and 17th centuries; JONAS KAZLAUSKAS, *Lietuvių kalbos istorinė gramatika* (1968), the only historical grammar of Lithuanian; VYTAUTAS MAZIULIS, *Baltų ir kitų indoeuropiečių kalbų santykiai* (1970), treats the relationship of Baltic and the other Indo-European languages.

The largest dictionaries of Baltic languages are: K. MULENBACHS, *Latviešu valodas vārdnīca,* 4 vol. (1923–32); *Lietuvių kalbos žodynas,* 8 vol. (1941–70); and ERNST FRAENKEL, *Litauisches etymologisches Wörterbuch,* 2 vol. (1955–65).

Slavic languages. ROMAN JAKOBSON, *Slavic Languages,* 2nd ed. (1955), is the best short structural sketch. A useful general survey is REINHOLD TRAUTMANN, *Die slavische Völker und Sprachen* (1947). The comparative grammar is described in the following works: ANTOINE MEILLET, *Le Slave com-*

mun, 2nd ed. rev. (1934), the best introduction to Proto-Slavic from the point of view of Indo-European; VACLAV VONDRAK, *Vergleichende slavische Grammatik,* 2 vol. (1924–28), rich in material; JOOSEPPI J. MIKKOLA, *Urslavische Grammatik,* 3 vol. (1913–50), condensed, but not quite up-to-date now. The general drift of the languages is seen in RAJKO NAHTIGAL, *Slovanski jeziki,* 2nd ed. (1952). A traditional approach to the history of the phonemic systems is exemplified in САМУИЛ БОРИСОВИЧ БЕРНШТЕЙН, *Очерк сравнительной грамматики славянских языков,* vol. 1 (1961); ANDRE VAILLANT, *Grammaire comparée des langues slaves,* vol. 1 (1950); and PEETER ARUMAA, *Urslavische grammatik,* vol. 1 (1964); recent developments in the diachronic phonology are summarized in ROMAN JAKOBSON, *Selected Writings,* 2nd ed., 6 vol. (1971–); FRANTISEK MARES, *The Origin of the Slavic Phonological System and Its Development Up to the End of Slavic Language Unity* (1965); GEORGE SHEVELOV, *A Prehistory of Slavic* (1964); CHRISTIAN S. STANG, *Slavonic Accentuation* (1957); and NICHOLAS VAN WIJK, *Les Langues slaves, de l'unité à la pluralité,* 2nd ed. rev. (1956). The dialectal differentiation of Proto-Slavic from the point of view of comparative phonology is analyzed in ANTONI FURDAL, *Rozpad języka prasłowjańskiego w świetle rozwoju głosowego* (1961); and HENRIK BIRNBAUM, "The Dialects of Common Slavic," in HENRIK BIRNBAUM and JAAN PUHVEL (eds.), *Ancient Indo-European Dialects* (1966).The problem of the original territory and migrations of the speakers of Proto-Slavic is discussed in the light of linguistic and archaeological evidence in the following works: TADEUSZ LEHR-SPLAWINSKI, *O pochodzeniu i praojczyzńie Słowian* (1964), a brilliant survey using archaeological data; KAZIMIERZ MOSZYNSKI, *Pierwotny zasiąg języka prasłowiańskiego* (1957), employs a strictly linguistic approach, and is hardly convincing; K.H. MENGES, *An Outline of the Early History and Migrations of the Slavs* (1953), cites important Oriental sources; MARIJA GIMBUTAS, *The Slavs* (1971), provides an archaeological and linguistic survey of Slavic migrations to Central Europe and the Balkan Peninsula; and S.H. CROSS, *Slavic Civilization Through the Ages* (1948, reprinted 1963), provides some general information. The only reliable Common Slavic etymological dictionary remains the unfinished work of ERICH BERNEKER, *Slavisches etymologisches Wörterbuch,* 2nd ed., vol. 1 (1924). Of essential value for proof of the close links between Slavic and Baltic is REINHOLD TRAUTMANN, *Baltisch-Slavisches Wörterbuch* (1923); on Slavic, Baltic, and Germanic see CHRISTIAN S. STANG, *Lexikalische Sonderüberstimmungen Zurischen dem Slavischen, Baltischen, und Germanischen* (1972); the study of verbal forms is presented in CHRISTIAN S. STANG, *Das slavische und baltische Verbum* (1942); and H. KOLLN, *Oppositions of Voice in Greek, Slavic and Baltic* (1969). For the accentual pattern of Slavic as compared to Baltic, see especially ВЛАДИСЛАВ МАРКОВИЧ ИЛЛИЧ-СВИТЫЧ, *Именная акцентуация в балтийской и славянском* (1963). The only English textbook introduction to concrete data on each language remains R.G.A. DE BRAY, *Guide to the Slavonic Languages,* rev. ed. (1969). Russian phonetics is treated in KÁLMÁN BOLLA, *A Conspectus of Russian Speech Sounds* (1981).

Albanian language. P.L. HORECKY (ed.), *Southeastern Europe: A Guide to Basic Publications,* pp. 102–111 (1969}, includes a compilation by E.P. HAMP of about 50 major annotated items on Albanian scholarship, language, literature, folklore, ethnography, and folk music, with references to other supporting work; E.P. HAMP, "Albanian," in T.A. SEBEOK (ed.), *Current Trends in Linguistics,* vol. 9, pp. 1626–92 (1972), a review of work since 1918, with copious bibliography; LEONARD NEWMARK, P. HUBBARD and PETER PRIFTI, *Standard Albanian* (1982), a reference grammar.

Uralic languages. *General works:* The following manuals primarily reflect the views of their authors, but should serve as a basis for further study (especially in the numerous grammars of Uralic languages and articles on problems of Uralic linguistics—few of which are available in English). BJORN COLLINDER, *Fenno-Ugric Vocabulary: An Etymological Dictionary of the Uralic Languages* (1955), presents comparative Uralic word lists; *An Introduction to the Uralic Languages* (1965); and *Survey of the Uralic Languages* (1957), give short sketches of all but a few of the Uralic languages, with the lesser languages receiving only superficial treatment; LAURI HAKULINEN, *The Structure and Development of the Finnish Language* (Eng. trans. from the Finnish, 1961), an excellent presentation of Finnish from its earliest stages; TOIVO VUORELA, *The Finno-Ugric Peoples* (Eng. trans. from the Finnish, 1964), an anthropological survey.

Works dealing with specific languages: PETER HAJDU, *The Samoyed Peoples and Languages* (Eng. trans from the Hungarian, 1963); ROBERT T. HARMS, *Estonian Grammar* (1962), with an appendix that surveys numerous approaches to the problem of quantity in Estonian; THOMAS A. SEBEOK and FRANCES J. INGEMANN, *An Eastern Cheremis Manual* (1961), a clear, concise description of one of the lesser languages; JOHN ATKINSON, *Finnish Grammar* (1956); and ZOLTAN BANHIDI, ZOLTAN JOKAY, and DENES SZABO, *Learn Hungarian* (1965), two basic grammars.

Altaic languages. N. POPPE, *Introduction to Altaic Linguistics* (1965), is the best up-to-date manual, giving a short but complete picture of the Altaic languages, their history and structure, as well as the theory of the relationship of these languages. *Philologiae Turcicae Fundamenta* (1959); *Handbuch der Orientalistik:* vol. 5, pt. 1, *Turkologie* (1963); pt. 2, *Mongolistik* (1964); and pt. 3, *Tungusologie* (1968), give systematic descriptions of the various historical and contemporary languages with much bibliographic data. K.H. MENGES, *The Turkic Languages and Peoples* (1968), is the best recent account of Turkic linguistics, supplementing the bibliographies in the works mentioned above. G.J. RAMSTEDT, *Einführung in die altaische Sprachwissenschaft,* vol. 1, *Lautlehre* (1957), and vol. 2, *Formenlehre* (1952), is the classical summary of the theory of relationship among the Altaic languages. R. LOEWENTHAL, *The Turkic Languages and Literatures of Central Asia* (1956); D. SINOR, *Introduction à l'étude de l'Eurasie Centrale* (1963); and G. HAZAI (ed.), *Sovietico-Turcica* (1960), are useful bibliographies that complement one another.

Dravidian languages. R. CALDWELL, *A Comparative Grammar of the Dravidian or South-Indian Family of Languages,* 3rd ed. by J.L. WYATT and T.R. PILLAI (1913, reprinted 1956 and 1961), the classic work that laid the foundations of Dravidian linguistics; G.A. GRIERSON (ed.), *Linguistic Survey of India,* vol. 4, *Munḍā and Dravidian Languages,* by S. KONOW (1906); T. BURROW and M.B. EMENEAU, *A Dravidian Etymological Dictionary* (1961, reprinted 1966; *Supplement,* 1968), the first etymological dictionary of the family, marking a new era in Dravidian studies (indispensable point of departure for any further work in the field); B. KRISHNAMURTI, *Telugu Verbal Bases: A Comparative and Descriptive Study* (1961), an indispensable study of the phonology and derivational morphology of Dravidian, with a much wider coverage of problems than the title suggests; "Comparative Dravidian Studies," *Linguistics in South Asia,* pp. 309–333, vol. 5 of *Current Trends in Linguistics* (1969), a summary treatment of the latest developments in the field; K. ZVELEBIL, *Comparative Dravidian Phonology* (1970), the first systematic compendium of the comparative phonology of Dravidian; J. BLOCH, *Structure grammaticale des langues dravidiennes* (1946; Eng. trans., *The Grammatical Structure of Dravidian Languages,* 1954), an excellent description of the main morphological and syntactic features of the family that ignores phonology totally; F.B.J. KUIPER, "The Genesis of a Linguistic Area," *Indo-Iranian Journal,* 10:81–102 (1967), a brief and brilliant treatment of the problems of Aryan and Dravidian convergence; M.S. ANDRONOV, *Materials for a Bibliography of Dravidian Linguistics* (1966); M. ISRAEL, "Additional Materials for a Bibliography of Dravidian Languages," *Tamil Culture,* 12:69–74 (1966); S.E. MONTGOMERY, "Supplemental Materials for a Bibliography of Dravidian Linguistics," *Studies in Indian Linguistics,* pp. 234–246 (1968), three bibliographies that provide fairly complete coverage.

Austro-Asiatic languages. H.L. SHORTO, J.M. JACOB, and E.H.S. SIMMONDS (comps.), *Bibliographies of Mon-Khmer and Tai Linguistics* (1963), is an unannotated bibliography of linguistic books and articles from the beginning (1790) to 1960, which does not include the Munda subfamily or the Viet-Muong branch but incorporates the (Austronesian) Cham languages into Mon-Khmer. See W. SCHMIDT, *Grundzüge einer Lautlehre der Mon-Khmer-Sprachen* (1906); *Die Mon-Khmer-Völker: Ein Bindeglied zwischen Völkern Zentralasiens und Austronesiens* (1906; French trans., "Les Peuples Mon-Khmer: trait-d'union entre les peuples de l'Asie Centrale et de l'Austronésie," in *Bulletin de l'École française d'Extrême-Orient,* 7: 213–263 and 8:1–35, 1907–08); and W.W. SKEAT and C.O. BLAGDEN, *Pagan Races of the Malay Peninsula,* 2 vol. (1906). Schmidt's articles for the first time supported the Austro-Asiatic hypothesis with lexical, phonological, and morphological evidence. They remain until today the basic work of Austro-Asiatic studies. Blagden compiled a very large comparative vocabulary but did not attempt any analysis. H.J. PINNOW, *Versuch einer historischen Lautlehre der Kharia-Sprache* (1959), an ambitious project with somewhat uncertain results, contains an analysis and systematic comparison of the phonologies of Munda languages and establishes connections with the rest of the Austro-Asiatic group. The *Mon-Khmer Studies* (Linguistic Circle of Saigon), 4 vol. (1964–), are collections of short technical articles mostly on the Montagnard languages of South Vietnam, with topics varying from basic vocabulary to phonology, morphology, syntax, folk taxonomies, and oral literature.

Sino-Tibetan Languages. *General works:* PAUL BENEDICT, *Sino-Tibetan: A Conspectus* (1971), a comprehensive and original study; G.A. GRIERSON, *Tibeto-Burman Family,* in the *Linguistic Survey of India,* vol. 3 (1909), a wealth of material but of uneven quality; FRANK M. LEBAR, GERALD C. HICKEY, and

JOHN K. MUSGRAVE, *Ethnic Groups of Mainland Southeast Asia* (1964), an excellent reference work; HENRI MASPERO, "Langues de l'Asie du Sud-Est," in ANTOINE MEILLET and MARCEL COHEN (eds.), *Les Langues du Monde,* new ed., pp. 524–644 (1952), the most authoritative concise treatment of Sino-Tibetan to date; C.F. and F.M. VOEGELIN, "Languages of the World: Sino-Tibetan," *Anthropological Linguistics,* vol. 6 and 7 (1964–65), much information of a semitechnical nature; ROBERT SHAFER, *Introduction to Sino-Tibetan,* 3 vol. (1966–), a comprehensive and extensive, but technical, series; and *Bibliography of Sino-Tibetan Languages,* 2 vol. (1957–63), indispensable for further research.

Chinese: NICHOLAS C. BODMAN, "China: Historical Linguistics," in THOMAS A. SEBEOK (ed.), *Current Trends in Linguistics,* vol. 2, pp. 3–58 (1967); KUN CHANG, "China: Descriptive Linguistics," *ibid.,* pp. 59–90; YUEN-REN CHAO, *Mandarin Primer* (1948), excellent chapters on script and grammar; and with LIEN-SHENG YANG, *Concise Dictionary of Spoken Chinese* (1947), the best dictionary of modern Chinese, with an excellent introduction; JOHN DeFRANCIS, *Nationalism and Language Reform in China* (1950), informative and readable; and "China: Language and Script Reform," in *Current Trends in Linguistics,* vol. 2, pp. 130–150 (1967); SOREN EGEROD, "China: Dialectology," *ibid.,* pp. 91–129, technical in nature; R.A.D. FORREST, *The Chinese Language,* 2nd ed. rev. (1965), a standard reference work that also treats related and contiguous languages; BERNHARD KARLGREN, *Études sur la phonologie chinoise,* 4 pt. (1915–26), an epoch-making work but very technical; *Compendium of Phonetics in Ancient and Archaic Chinese* (1954), also technical; *Grammata Serica: Script and Phonetics in Chinese and Sino-Japanese* (1957), the standard dictionary of Old Chinese characters; *Sound and Symbol in Chinese,* rev. ed. (1962), very readable, but somewhat out of date; *The Chinese Language* (1949), a popular account of phonetic reconstructions; and *Easy Lessons in Chinese Writing* (1958), an interesting account of the etymology of Chinese characters; PAUL KRATOCHVIL, *The Chinese Language Today* (1968), very readable and up to date.

Tibeto-Burman and Karen: KUN CHANG, "China: National Languages," in *Current Trends in Linguistics,* vol. 2, pp. 151–176 (1967), treats minority languages in China; ROBERT B. JONES, *The Burmese Writing System* (1953), offers the best description; *Karen Linguistic Studies* (1961), up to date but technical; ROY A. MILLER, *The Tibetan System of Writing* (1956), offers the best description of the subject; "The Tibeto-Burman Languages of South Asia," *Current Trends in Linguistics,* vol. 5, pp. 431–449 (1969), informative and up to date; STUART N. WOLFENDEN, *Outlines of Tibeto-Burman Linguistic Morphology* (1929), the classic statement.

Tai languages. M.R. HAAS, *Thai-English Student's Dictionary* (1964), a concise dictionary arranged according to the order of the Thai alphabet with a brief description of the phonological and grammatical system, and with H.R. SUBHANKA, *Spoken Thai,* 2 vol. (1947), a textbook for learning spoken Thai step by step; F.M. LABAR, G.C. HICKEY, and J.K. MUSGRAVE, *Ethnic Groups of Mainland Southeast Asia,* pt. 3, pp. 187–244 (1964), a detailed description of different Tai ethnic groups, including their location, demography, and social organization; FANG KUEI LI, "Consonant Clusters in Tai," *Language,* 30:368–379 (1954), an article demonstrating the existence of a large number of initial consonant clusters in the protolanguage and their simplification in the modern dialects; "A Tentative Classification of Tai Dialects," in S. DIAMOND (ed.), *Culture in History,* pp. 951–959 (1960), a classification establishing three groups of Tai languages and dialects according to lexical distribution and phonological development, and "The Tai and the Kam-Sui Languages," *Lingua,* 14:148–179 (1965), a discussion of the relationship of these two language groups; R.B. NOSS, *Thai Reference Grammar* (1964), a detailed descriptive and structural analysis of the Thai language; P.K. BENEDICT, "Thai, Kadai and Indonesian: A New Alignment in Southeastern Asia," *American Anthropologist,* 44:576–601 (1942), a provocative attempt to show the relationship of the Tai languages to the Indonesian languages; TATSUO HOSHINO and RUSSELL MARCUS, *Lao for Beginners* (1981).

Paleo-Siberian languages. ROMAN JAKOBSON, GERTA HUTTLWORTH, and JOHN FRED BEEBE, *Paleosiberian Peoples and Languages: A Bibliographical Guide* (1957, reprinted 1981), very useful, with informative appendix; DEAN WORTH, "Paleosiberian," in T.A. SEBEOK (ed.), *Current Trends in Linguistics,* vol. 1, *Soviet and East European Linguistics,* pp. 345–373 (1963), good coverage of Soviet work since World War II. The best and most recent source on Paleosiberian languages is in Russian: П.Я. СКОРИК *et al.* (eds.), *Языки народов С.С.С.Р.,* vol. 5, *Монгольские, тунгусоманьчжурские и лалеоазиатские языки* (1968).

Caucasian languages. *General works of reference:* G. DEETERS, *Armenisch und kaukasische Sprachen* (1963), a general survey and a combined presentation of the structure of the Caucasian languages according to the most characteristic features of phonology, morphology, and syntax, with an extensive bibliography; G.A. KLIMOV, *Die kaukasischen Sprachen* (1969; orig. pub. in Russian, 1965), a brief exposition of the history and structures of the Caucasian languages, with a general characterization of each group, including an extensive bibliography; A.H. KUIPERS, "Caucasian," in THOMAS A. SEBEOK (ed.), *Current Trends in Linguistics,* vol. 1, *Soviet and East European Linguistics,* pp. 315–344 (1963), a useful brief survey of Caucasian linguistics, with a selected bibliography; A. DIRR, *Einführung in das Studium der kaukasischen Sprachen* (1928), contains a survey of the structure of individual Caucasian languages and their interrelationships; "Jazyki Narodov SSSR," IV. *Iberijsko-Kavkazskie jazyki* (1967), a brief exposition of the structures of all the Caucasian languages, with a selected bibliography.

South Caucasian languages: The following is a selection of the more important special works on the South Caucasian languages: G. DEETERS, *Das kharthwelische Verbum: Vergleichende Darstellung des Verbalbaus der südkaukasischen Sprachen* (1930), a comprehensive comparative study of the verb structure of the Kartvelian languages; A.S. CHIKOBAVA, *Drevnejšaja struktura imennyx osnov v kartvel'skix jazykax* (1942; in Georgian, with a Russian and French summary), a comparative analysis of the ancient structure of nominal stems in the Kartvelian languages, with an interpretation of certain prefixes as the ancient classmarkers; K.H. SCHMIDT, *Studien zur Rekonstruktion des Lautstandes der südkaukasischen Grundsprache* (1962), a detailed analysis of sound correspondences with a reconstruction of the Proto-Kartvelian phonemic system; T.V. GAMKRELIDZE and G.I. MACHAVARIANI, *Sistema sonantov i ablaut v kartvel'skikh iazykakh* (1965; in Georgian with a Russian summary), a detailed comparative analysis of the Kartvelian phonological and morphophonological system, with a reconstruction of resonants and ablaut alternations in Proto-Kartvelian and their typological evaluation. For the grammars of the individual languages see A.G. SHANIDZE, *Osnovy gruzinskoj grammatiki,* vol. 1 (1953), a most comprehensive exposition (in Georgian) of the structure of modern Georgian; and H. VOGT, *Grammaire de la langue géorgienne,* rev. ed. (1971). An account of the Georgian sound system is given in G. AXVLEDIANI, *Osnovy obščej fonetiki* (1949, in Georgian). For a detailed descriptive analysis of the Svan verb system according to dialects, see V.T. TOPURIA, *Svanskij jazyk,* vol. 1, *Glagol* (1931; 2nd ed., 1967), in Georgian, with a Russian summary. Much useful information about Georgian and the history of Georgian (Kartvelian) studies is contained in S.V. DZIDZIGURI, *The Georgian Language* (Eng. trans. 1968). A useful practical guide to Georgian is K. TSCHENKELI, *Einführung in die georgische Sprache,* vol. 1, *Theoretischer Teil,* vol. 2, *Praktischer Teil* (1958). See also DEE ANN HOLISKY, *Aspect and Georgian Medial Verbs* (1981).

North Caucasian languages: P.K. USLAR, *Etnografija Kavkaza. Jazykoznanie,* 6 vol. (1887–96), contains descriptive grammars of the individual North Caucasian languages; A. TSCHIKOBAVA, "Die ibero-kaukasischen Gebirgssprachen und der heutige Stand ihrer Erforschung in Georgien," *Acta Orientalia Academiae Scientiarum Hungaricae,* 9:109–161 (1959), a brief survey of the North Caucasian languages, containing an extensive bibliography; N. TRUBETZKOY, "Nordkaukasische Wortgleichungen," *Wiener Zeitschrift für die Kunde des Morgenlandes,* vol. 37, no. 1–2 (1930), establishes sets of sound correspondences between the West and East Caucasian languages and deals with the history of their consonantism; G. DUMEZIL, *Études comparatives sur les langues caucasiennes du nord-ouest* (*morphologie*) (1932), a comparative analysis of the grammatical structure of the Abkhazo-Adyghian languages; A.H. KUIPERS, *Phoneme and morpheme in Kabardian* (*Eastern Adyghe*) (1960), a detailed analysis of the phonemic structure of morphemes in Kabardian with a typological comparison with other linguistic systems; W.S. ALLEN, "Structure and System in the Abaza Verbal Complex," *Transactions of the Philological Society of London,* pp. 127–176 (1956), a comprehensive analysis of the verb structure in Abaza; A. SOMMERFELT, "*Études comparatives sur le caucasique du nord-ouest, Norsk Tidsskrift for Sprogvidenskap,* vol. 7 and 9 (1934–38), a comparative study of the sound system of the Nakh languages; E.A. BOKAREV, *Vvedenie v sravnitel'no-istoričeskoe izučenie dagestanskix jazykov* (1961), a comparative study of the vocalism and consonantism of the languages of Dagestan; T.E. GUDAVA, *Konsonantizm andijskix jazykov* (1964), a reconstruction of the original consonant system of the Avaro-Ando-Dido languages.

Hamito-Semitic languages. *General works:* There is still no general survey of the field (including bibliography) to replace I.M. DIAKONOFF, *Semitohamitskie iazyki* (1965; Eng. trans., *Semito-Hamitic Languages,* 1965), although the developments in the field after 1965 have been considerable (see the *Hamito-Semitic a,* 1975). Among other general surveys are

G.R. CASTELLINO, *The Akkadian Personal Pronouns and Verbal System in the Light of Semitic and Hamitic* (1962), and T.W. THACKER, *The Relationship of the Semitic and Egyptian Verbal Systems* (1954).

The theoretical problems of the Hamito-Semitic family have, until recently, been studied mostly on the basis of the Semitic branch alone. Especially important in this respect are I.J. GELB, *Sequential Reconstruction of Proto-Akkadian* (1969); JERZY KURYŁOWICZ, *L'Apophonie en sémitique* (1961); FRITHIOF RUNDGREN, *Intensiv und Aspektkorrelation* (1959). Perhaps the most crucial problem of the Proto-Hamito-Semitic linguistic typology is the reconstruction of the verbal system, for which, besides the above-mentioned works, see also MARCEL COHEN, *Le Système verbal sémitique et l'expression du temps* (1924); O. ROESSLER, "Akkadisches und libysches Verbum," *Orientalia,* vol. 20 (1951): A. KLINGENHEBEN, "Die Präfix- und die Suffixkonjugation des Hamitosemitischen," *Mitteilungen des Instituts für Orientforschung,* vol. 2 (1957), and the critical, although certainly not final review of some later ideas in PELIO FRONZAROLI, "Ricostruzione interna del verbo semitico in alcuni studi recenti," *Accademia Toscana "La Colombaria,"* pp. 71–85 (1972). Another theoretical problem is broached in I.M. DIAKONOFF, "Problems of Root Structure in Proto-Semitic," *Archiv Orientální,* 38:453–480 (1970). The best general review of the Semitic branch of Hamito-Semitic is GOTTHELF BERGSTRAESSER, *Einführung in die semitischen Sprachen* (1928, reprinted 1963). See also GEORGIO LEVI DELLA VIDA (ed.), *Semitic Linguistics: Present and Future* (1961); SABATINO MOSCATI, *An Introduction to the Comparative Grammar of the Semitic Languages* (1964); I.M. DIAKONOFF, *Jazyki drevnej Perednej Azii* (1967), on languages of the Ancient Near East, including Semitic and a general survey of Common Hamito-Semitic. Recent developments are evaluated in *Current Trends in Linguistics,* vol. 6: *Linguistics in South West Asia and North Africa,* with a comprehensive bibliography. JOSHUA BLAU, *The Renaissance of Modern Hebrew and Modern Standard Arabic* (1981), is a comparative study.

For treatment of the individual Semitic languages and the other branches of Hamito-Semitic, the following works may be consulted:

Akkadian: WOLFRAM VON SODEN, *Grundriss der akkadischen Grammatik,* 2nd ed. (1969), and *Akkadisches Handwörterbuch* (1959–); ERICA REINER, *A Linguistic Analysis of Akkadian* (1966); *The Assyrian Dictionary,* published by the Oriental Institute, the University of Chicago (1956–).

Northern Central Semitic: C.H. GORDON, *Ugaritic Textbook,* 2nd ed. (1965); JOSEPH AISTLEITNER, *Wörterbuch der ugaritischen Sprache* (1963); I.J. GELB, "La lingua degli Amoriti," *Rendiconti d. Accademia Nazionale dei Lincei,* 13:143–164 (1958); GIOVANNI GARBINI, *Il Semitico di Nord-Ovest* (1960); Z.S. HARRIS, *Development of the Canaanite Dialects* (1939); JOHANNES FRIEDRICH, *Phönizisch-punische Grammatik* (1951); GEORG BEER and RUDOLF MEYER, *Hebräische Grammatik,* 2 vol. (1952–55); WILHELM GESENIUS and GOTTHELF BERGSTRAESSER, *Hebräische Grammatik,* 29th ed., 2 vol. (1918–29); HANS BAUER and PONTUS LEANDER, *Historische Grammatik der Hebräischen Sprache des Alten Testamentes* (1922); H.B. ROSEN, *A Textbook of Israeli Hebrew,* 2nd ed. (1966); LUDWIG KOEHLER and WALTER BAUMGARTNER, *Lexicon in Veteris Testamenti Libros* (1958); E. BEN YEHUDA, *Thesaurus totius Hebraitatis* (1908–58); FRANZ ROSENTHAL, *Die aramaistische Forschung seit Th. Nöldeke's Veröffentlichungen* (1939) and *A Grammar of Biblical Aramaic* (1961); PONTUS LEANDER, *Lautund Formenlehre des Ägyptisch-Aramäischen* (1928, reprinted 1966); JEAN CANTINEAU, *Le Nabatéen,* 2 vol. (1930–32); HARRIS BIRKELAND, *The Language of Jesus* (1954); E.Y. KUTSCHER, *Studies in Galilean Aramaic* (1952); THEODOR NOELDEKE, *Kurzgefasste syrische Grammatik* (1880, reprinted 1966); CARL BROCKELMANN, *Syrische Grammatik,* 8th ed. (1960); RUDOLF MACUCH, *Handbook of Classical and Modern Mandaic* (1965); KONSTANTIN CERETELI, "Abriss der vergleichenden Phonetik der modernen assyrischen Dialekte," in FRANZ ALTHEIM, *Geschichte der Hunnen,* vol. 3, pp. 218–266 (1961); IRENE GARBELL, *The Jewish Neo-Aramaic Dialect of Persian Azerbaijan* (1965); CHARLES F. JEAN and JACOB HOFTIJZER, *Dictionnaire des inscriptions sémitiques de l'Ouest* (1960–65); MARCUS JASTROW, *A Dictionary of the Targumim, The Talmud Babli and Jerushalmi, and the Midrashic Literature,* 2 vol. (1950); ROBERT PAYNE SMITH, *Thesaurus Syriacus,* 2 vol. (1868–1901); E.S. DROWER and RUDOLF MACUCH, *A Mandaic Dictionary* (1963).

Southern Central Semitic, or Arabic: CHAIM RABIN, *Ancient West Arabian* (1951); HENRI FLEISCH, *L'Arabe classique* (1956); JEAN CANTINEAU, *Cours de phonétique arabe* (1960) *and La Dialectologie arabe* (1955); A. SUTCLIFFE, *Grammar of the Maltese Language* (1936); E.W. LANE, *An Arabic-English Lexicon,* 8 vol. (1863–93).

Southern Peripheral Semitic: A.F.L. BEESTON, *A Descriptive Grammar of Epigraphic South Arabian* (1962); MARIA HOEFNER, *Altsüdarabische Grammatik* (1943); EWALD WAGNER, *Syntax der Mehri-Sprache* (1953); WOLF LESLAU, *Lexique soqoṭri* (1938); M. BITTNER, "Charakteristik der Sprache der Insel Soqoṭra," *Anzeiger der Wiener Akademie der Wissenschaften, Ph.-hist. Kl.,* vol. 55 (1918)—the same author has published a number of studies on the important languages Mahrī and Shaḥrī ("Shkhauri") in the *Sitzungsberichte* of the *Wiener Akademie* between 1909 and 1917; CHRISTIAN DILLMANN, *Ethiopic Grammar,* 2nd ed. (1907) and *Lexicon linguae Aethiopicae* (1865); WOLF LESLAU, *Étude descriptive et comparative du Gafat* (1956) and *Etymological Dictionary of Harari* (1963); EDWARD ULLENDORFF, *The Semitic Languages of Ethiopia: A Comparative Phonology* (1955).

Egyptian: ELMAR EDEL, *Altägyptische Grammatik* (1955–64); A.H. GARDINER, *Egyptian Grammar,* 3rd ed. (1957); WALTER TILL, *Koptische Grammatik (Saïdischer Dialekt)* (1955); ADOLF ERMAN and HERMANN GRAPOW (eds.), *Wörterbuch der ägyptischen Sprache,* 6 vol. (1926–31, reprinted 1955); WOLJA ERICHSEN, *Demotisches Glossar* (1954).

Berber: ANDRE BASSET, *Handbook of African Languages,* vol. 1, *La Langue berbère* (1952), and *Articles de dialectologie berbère* (1959). An extensive classified bibliography is provided by JOSEPH R. APPLEGATE as a sequel to his article "The Berber Languages" in *Current Trends in Linguistics,* vol. 6 (1970).

Cushitic: M.L. BENDER, "The Languages of Ethiopia: A New Lexicostatistic Classification and Some Problems of Diffusion," *Anthropological Linguistics,* vol. 13 (1971); A.B. DOLGOPOL'SKIJ, *Sravitel'no-istoricheskaja fonetika kušitskikh jazykov* (1973); on the individual branches and languages of Cushitic, see C.R. BELL, *The Somali Language* (1953), a manual of the Isāq dialect; M.M. MORENO, *Il somalo della Somalia* (1955), devoted to the Benadir, Darod, and Digil dialects; ENRICO CERULLI, *Studi etiopici,* 4 vol. (1936–51), contains grammars and vocabularies of Sidamo, Janjero, some Ometo dialects, and Kafa (Kaficho). For a good survey of the individual branches and languages of Cushitic, see F.R. Palmer, "Cushitic," in *Current Trends in Linguistics,* vol. 6, pp. 571–585.

Chadic: On the general problems of the Chadic branch see PAUL NEWMAN and ROXANA MA, "Comparative Chadic: Phonology and Lexicon," *Journal of African Languages,* vol. 5 (1966); D. WESTERMANN and M. BRYAN, "Languages of West Africa," *Handbook of African Languages,* vol. 2 (1952); JOSEPH H. GREENBERG, "Studies in African Linguistic Classfication, IV, Hamito-Semitic," *SWest. J. Anthrop.,* vol. 6 (1950). Among the studies of individual Chadic languages those devoted to Hausa are the most numerous of all; the following may be especially useful: C.T. HODGE and IBRAHIM UMARU, *Hausa: Basic Course* (1963); CHARLES H. KRAFT, *A Study of Hausa Syntax,* 3 vol. (1963); R.C. ABRAHAM, *The Language of the Hausa People* (1959). Among the grammatical studies of the other Chadic languages are HERRMANN JUNGRAITHMAYR, *Die Ron-Sprachen* (1970); CARL HOFFMAN, *A Grammar of the Margi Language* (1963); and H.D. FOULKES, *Angass Manual* (1915). Of the many vocabularies of Hausa the most important is G.P.A. BARGERY (comp.), *A Hausa-English Dictionary and English-Hausa Vocabulary* (1934).

Korean language. The McCune-Reischauer system of transcription used in this article is the one most widely used; it is described in detail in G.M. MCCUNE and E.O. REISCHAUER, "The Romanization of the Korean Language," *Trans. Korea Brch R. Asiat. Soc.,* vol. 29 (1939), and in an abbreviated account in *ibid.,* vol. 38 (1961). For the history and development of the Korean alphabet, see the English resumé in KI-MOON LEE, *Kugŏ P'yogippŏp ŭi Yŏksajŏk Yŏn'gu* (1963). For Chinese characters in Korea, see HYONG-GYU KIM, "Chinese Characters and Korean Language," *Korea Journal,* vol. 3 (1963). The introductory chapter, "A Short History of Korean Literature," in DOO SOO SUH, *Korean Literary Reader* (1965), points out relations between Korean writing systems and literature. Surveys and bibliographies of studies in Korean linguistics are found in FRED LUKOFF, "The Republic of Korea," in THOMAS A. SEBEOK (ed.), *Current Trends in Linguistics,* vol. 2 (1967), and in KI-MOON LEE, "Linguistics," in SUNG-NYONG LEE (ed.), *Korean Studies Today* (1970). The basic western work in the field of Korean grammar, and one which has provided much of the inspiration and direction for studies in Korean historical and comparative linguistics, is G.J. RAMSTEDT, "A Korean Grammar," *Mémoires de la Société Finno-Ougrienne,* vol. 82 (1939). SAMUEL E. MARTIN, *Korean Morphophonemics* (1954), is the most comprehensive technical description of sound alternations in Korean phonology. There is no general grammatical description of Korean in English available as yet. A.A. KHOLODOVICH, *Ocherk grammatiki koreiskogo iazyka* (1954), presents a description in Russian of modern Korean phonology, morphology, and syntax. RENE DUPONT and JOSEPH MILLOT, *Grammaire coréene*

(1965), assumes some familiarity with Korean writing and phonology on the part of the student but serves as a good reference work for modern Korean morphological forms and syntax, illustrated by many example sentences. BRUNO LEWIN, *Morphologie des koreanischen Verbs* (1970), contains a concise description of Korean verb forms and an alphabetically arranged list of the endings, with example sentences. The following textbooks constitute complete courses in the elementary spoken language and include explanations of phonology and grammar: FRED LUKOFF, *Spoken Korean,* 2 vol. (1945–47); CHANG HAI PARK, *An Intensive Course in Korean,* 2 vol. (1961–65); B. NAM PARK, *Korean Basic Course,* 2 vol. (1968–69); SAMUEL E. MARTIN and YOUNG SOOK C. LEE, *Beginning Korean* (1969). The method of writing and reading *Han'gŭl* is explained and illustrated in the first chapter of ANTHONY V. VANDESANDE and FRANCIS Y.T. PARK, *Myŏngdo's Korean '68,* pt. 1 and 2 (1967). A comprehensive dictionary of the spoken and written language compiled for western students of Korean is SAMUEL E. MARTIN, YANG HA LEE, and SUNG UN CHANG, *A Korean-English Dictionary* (1967), with the entries in *Han'gŭl* and their pronunciations recorded in transcription.

Japanese language. TAMAKO NIWA and MAYAKO MATSUDA, *Basic Japanese for College Students* (1964); and TEC COMMITTEE ON JAPANESE, *TEC Japanese: The Basic Course,* 2 vol. (1968–70), are both recommended for learning spoken Japanese. The latter is accompanied by magnetic tapes that record all the utterances in the books in very good standard pronunciation. ELEANOR H. JORDEN and H.I. CHAPLIN, *Beginning Japanese,* 2 pt. (1962–63), also has good examples of Japanese sentences. HOWARD HIBBETT and GEN ITASAKA, *Modern Japanese: A Basic Reader,* 2 vol. (1965), is a good book for learning written Japanese. ESTHER M.T. SATO, L.I. SHISHIDO, and M. SAKIHARA, *Japanese Now,* vol.1 (1982), is a modern text.

ROY ANDREW MILLER, *The Japanese Language* (1967), an up-to-date and comprehensive outline of the language with a good selective bibliography, includes chapters on the historical and geographical setting, genetic relationship, written systems, dialects, phonology, loanwords, "special and notable" utterances, and grammar and syntax. THOMAS A. SEBEOK (ed.), *Current Trends in Linguistics,* vol. 2, *Linguistics in East Asia and South East Asia* (1967), includes very good accounts on various aspects of Japanese linguistics, with selective bibliographies.

The following works are in Japanese: SHINKICHI HASHIMOTO, *Chosakushū,* 13 vol. (1946–), includes the most fundamental and comprehensive articles on Japanese and Japanese linguistics. SANKI ICHIKAWA and SHIRO HATTORI (eds.), *Sekai Gengo Gaisetsu,* vol. 2 (1955), contains a good outline of Japanese. HIDEYO ARISAKA, *Kokugo On'inshi no Kenkyū,* rev. ed. (1957), is a collection of excellent papers treating various phonetic and phonological problems in the history of Japanese; his *Jōdai On'inkō* (1955) is a fundamental detailed study on the sounds of 8th-century Japanese. *Nihongo no Rekishi* (1947) contains good concise articles on the various periods of the history of Japanese by several authors. Among the dictionaries, the following are recommended: KOKUGOGAKKAI, *Kokugogaku Jiten* (1955), a dictionary of Japanese linguistics and philology; KYOSUKE KINDAICHI (ed.), *Jikai* (1952), a comprehensive dictionary of Japanese with accent notation; *Jidai-betsu Kokugo Daijitsen: Jōdaihen* (1967) lists exhaustively the vocabulary of Old Japanese; SENKICHI KATSUMATA, *New Japanese–English Dictionary* (1954).

Austronesian languages. The classic comparative work is OTTO DEMPWOLFF, *Vergleichende Lautlehre des austronesischen Wortschatzes,* 3 vol. (1934–37), in German, which followed a series of important earlier essays by RENWARD BRANDSTETTER, some of which appear in *An Introduction to Indonesian Linguistics,* trans. by C.O. BLAGDEN (1916). ISIDORE DYEN, *The Proto-Malayo-Polynesian Laryngeals* (1953), modifies some of Dempwolff's reconstructions, while the same author's *A Lexicostatistical Classification of the Austronesian Languages* (1963), presents a subgrouping of 214 languages. G.W. GRACE, *The Position of the Polynesian Languages Within the Austronesian (Malayo-Polynesian) Language Family* (1959), also contains an excellent discussion of previous comparative work. R.H. CODRINGTON, *The Melanesian Languages* (1885), and S.H. RAY, *A Comparative Study of the Melanesian Island Languages* (1926), are now important chiefly for the many grammatical sketches they contain. A. CAPELL, "Oceanic Linguistics Today," *Current Anthropology* 3:371–396, 422–428 (1962), reviews comparative work up to 1960. *A Pacific Bibliography,* 2nd ed. by C.R.H. TAYLOR (1965), and H.R. KLIENEBERGER (comp.), *Bibliography of Oceanic Linguistics* (1957), contain excellent bibliographies of earlier works. More-up-to-date information may be found in *Oceanic Linguistics* (semi-annual), chief among the several journals that publish work on Austronesian; in T.A. SEBOEK (ed.), *Current Trends in Linguistics,* vol. 8, *Oceania* (1971); and in C.F. and F.M. VOEGELIN, *Languages of the World: Indo-Pacific Fascicles* (1964–). See also OTTO C. DAHL, *Proto-Austronesian,* 2nd rev. ed. (1977), and *Early Phonetic and Phonemic Changes in Austronesian* (1981).

Papuan languages. Most earlier general studies have become obsolete. Comprehensive recent bibliographical and factual information may be found in D.C. LAYCOCK and C.L. VOORHOEVE, "History of Research in Papuan Languages," in *Current Trends in Linguistics,* vol. 8, *Linguistics in Oceania* (1971); and in S.A. WURM, "Papuan Linguistic Situation," *ibid.,* updated in *Papuan Languages of Oceania* (1972). Individual language descriptions are given in H. MCKAUGHAN (ed.), *Languages of the Eastern Family* (1971). Extensive descriptive and comparative materials on Papuan languages appear in the serial publications *Pacific Linguistics.*

Australian Aboriginal languages. A concise discussion of all aspects of the study of Australian Aboriginal languages, with extensive bibliography, is provided in S.A. WURM, *Languages of Australia and Tasmania* (1972); extensive information may be found in the contributions by A. CAPELL, G.N. O'GRADY, and S.A. WURM in T.A. SEBOEK (ed.), *Current Trends in Linguistics,* vol. 8, *Linguistics in Oceania* (1971); and in G.N. O'GRADY and C.F. and F.M. VOEGELIN, *Classification and Index of the World's Languages* (1977). Numerous articles and monographs on Australian languages appear in the serials *Australian Aboriginal Studies,* Canberra; *Pacific Linguistics,* Canberra; *Oceania,* Sydney; *Oceania Linguistic Monographs,* Sydney. See also the overview in BARRY J. BLAKE, *Australian Aboriginal Languages* (1981).

African languages. *General works:* ISTVAN FODOR, *The Problems in the Classification of the African Languages: Methodological and Theoretical Conclusions Concerning the Classification System of Joseph H. Greenberg* (1959); JOSEPH H. GREENBERG, *Studies in African Linguistic Classification* (1955), Greenberg's first classification of African languages, includes articles that originally appeared in the *Southwestern Journal of Anthropology;* "Africa As a Linguistic Area," in W.R. BASCOM and M.J. HERSKOVITS (eds.), *Continuity and Change in African Cultures,* pp. 15–27 (1959); *The Languages of Africa* (1963), a revision of Greenberg (1955), representing the most up-to-date version of the author's classification; SIR HARRY H. JOHNSTON, *A Comparative Study of the Bantu and Semi-Bantu Languages,* 2 vol. (1919–22), a pioneering study showing many significant similarities between Bantu and many West African languages, both in structure and vocabulary; RICHARD LEPSIUS, *Nubische Grammatik, mit einer Einleitung über die Völker und Sprachen Afrika's* (1880), a grammar of Nubian with an extensive introduction containing one of the earliest overall classification of African languages; CARL MEINHOF, *Die Sprachen der Hamiten* (1912), discusses a selection of languages considered by the author to be Hamitic, including Masai, and the linguistic characteristics that link them; FRIEDRICH MUELLER, *Grundriss der Sprachwissenschaft,* 4 vol. (1876–88), contains one of the earliest attempts at an overall classification of African languages; GEORGE PETER MURDOCK, *Africa: Its Peoples and Their Culture History* (1959); THOMAS A. SEBEOK (ed.), *Current Trends in Linguistics,* vol. 7, *Linguistics in Sub-Saharan Africa* (1971); ARCHIBALD N. TUCKER and MARGARET A. BRYAN, *The Non-Bantu Languages of North-Eastern Africa* (1956), the most detailed survey of all the Chari-Nile languages and language groups, plus many others; *Linguistic Analyses: The Non-Bantu Languages of North-Eastern Africa* (1966), linguistic sketches of the languages included in Tucker and Bryan (1956); DIEDRICH WESTERMANN, *Die Sudansprachen, eine sprachvergleichende Studie* (1911), an attempt to demonstrate the interrelationship of five West African languages (Twi, Ga, Ewe, Yoruba, and Efik) and three from East Africa (Kunama, Nubian, and Dinka), thereby seeking to show the unity of all the Sudanic languages; *Die westlichen Sudansprachen und ihre Beziehungen zum Bantu* (1927), weakens the case for the interrelationship of all the Sudanic languages by showing a closer interrelationship between the Western Sudanic and Bantu languages; "Charakter und Einteilung der Sudansprachen," *Africa,* 8:129–148 (1935), revises the author's earlier views on the Sudanic languages; and with MARGARET A. BRYAN, *The Languages of West Africa* (1952), the most detailed survey of the languages of West Africa. Also useful is MELVIN K. HENDRIX, *An International Bibliography of African Lexicons* (1982).

Niger-Congo languages: Current Trends in Linguistics, vol. 7, *Linguistics in Sub-Saharan Africa (op. cit.),* is the most authoritative source on the Niger-Congo languages. This volume includes, among others, articles on West Atlantic, Mande, Voltaic, Kwa, Adamawa-Eastern, Benue-Congo (exclusive of Bantu), and Bantu. Significant light is thrown on the history and current research in these languages, and the "Check-List of African Language and Dialect Names" by WILLIAM E. WELMERS is an indispensable guide to the problem of variant names for languages. A summary of selected facts about the languages may be found in the series called *Handbook of African Languages,* sponsored by the International African Institute, especially the two volumes on Bantu by C.M. DOKE (1945 and 1954), the two on the same subject by MALCOLM GUTHRIE (1948 and 1953), and the one by DIEDRICH WESTERMANN and MARGARET A. BRYAN on the *Languages of West Africa* (*op. cit.*). The most important comparative study of the Bantu languages is presented in MALCOLM GUTHRIE, *Comparative Bantu: An Introduction to the Comparative Linguistics and Prehistory of the Bantu Languages,* 4 vol. (1967–70). The following periodicals are devoted entirely to articles on African languages, of which the overwhelming majority are concerned with Niger-Congo: *Bantu Studies, Journal of African Languages, Journal of West African Languages, Afrika und Übersee, Studies in African Linguistics; African Language Studies,* and the *African Language Review.*

Chari-Nile languages: MERVYN W.H. BEECH, *The Suk: Their Language and Folklore,* with introduction by SIR CHARLES ELIOT (1911); MARGARET A. BRYAN, "The T/K Languages: A New Substratum," *Africa,* 29:1–21 (1959); "The *N/*K Languages of Africa," *J. Afr. Lang.,* 7:169–217 (1968); MORRIS GOODMAN, "Some Questions on the Classification of African Languages," *Int. J. Am. Linguistics,* 36:117–122 (1970); OSWIN KOEHLER, "Geschichte der Erforschung der Nilotischen Sprachen," *Afrika und Übersee,* vol. 28 (1955), a history of the investigation of the Nilotic languages, including "Nilo-Hamitic," and suggesting a new subgrouping; G.W. MURRAY, "The Nilotic Languages: A Comparative Survey," *Jl. R. Anthrop. Inst.,* 50:327–368 (1920), an attempt to prove the common ancestry of Nubian, Bari, Masai, and Shilluk; P.L. SHINNIE, *Meroe: A Civilization of the Sudan* (1967), includes a discussion of the Meroitic language; BRUCE G. TRIGGER, "Meroitic and Eastern Sudanic: A Linguistic Relationship?" *Kush,* 12:188–194 (1964); ARCHIBALD N. TUCKER, *The Eastern Sudanic Languages* (1940), compares, among others, the languages renamed Central Sudanic by Greenberg, and concentrates on the Moru-Madi group and Lendu; DIEDRICH WESTERMANN, *The Shilluk People: Their Language and Folklore* (1912), discusses the classification of the Nilotic languages.

Khoisan languages: (*Classification*): E.O.J. WESTPHAL, "A Reclassification of Southern African Non-Bantu Languages," *J. Afr. Lang.,* 1:1–8 (1962): "The Click Languages of Southern and Eastern Africa," *Current Trends in Linguistics,* 7:367–420 (1971); and "The Linguistic Prehistory of Southern Africa: Bush, Kwadi, Hottentot, and Bantu Linguistic Relationships," *Africa,* 33:237–265 (1963), with maps; L.W. LANHAM and D.P. HALLOWES, "Linguistic Relationships and Contacts Expressed in the Vocabulary of Eastern Bushman," *Afr. Stud.,* 15:45–48 (1956); for a comprehensive list of classified languages, see D.F. BLEEK, *A Bushman Dictionary* (1956). (*Distribution*): OSWIN KOEHLER "Die Khoe-sprachigen Buschmänner der Kalahari: Ihre Verbreitung und Gliederung," *Kölner Geogr. Arbeiten. Festschrift Kurt Kayser,* pp. 373–411 (1971), with map. (*Phonology*): C.M. DOKE, "An Outline of the Phonetics of the Language of the Chũ: Bushmen of North-West Kalahari," *Bantu Stud.,* 2:129–166 (1925); D.M. BEACH, *The Phonetics of the Hottentot Language* (1938). (*Grammar*): OSWIN KOEHLER, "Noun Classes and Grammatical Agreement in !Xũ," *Actes du VIII^e Congrès Intern. de Linguistique Africaine,* pp. 489–522 (1971); J.W. SNYMAN, *An Introduction to the !Xu (!Kung) Language* (1970); D.F. BLEEK, "Bushman Grammar: A Grammatical Sketch of the Language of the /xam-ka-!k'e'," *Zeitschrift für Eingeborenen-Sprachen,* vol. 19–20 (1928–30); L.F. MAINGARD, "The ≠Khomani Dialect of Bushman," in J.D.R. JONES and C.M. DOKE (eds.), *Bushmen of the Southern Kalahari* (1937); F. RUST, *Praktische Namagrammatik* (1965), based on material of H. Vedder and J. Olpp. (*Comparative studies*): OSWIN KOEHLER, "Studien zum Genussystem und Verbalbau der zentralen Khoisan-Sprachen," *Anthropos,* 57:529–546 (1962), deals with gender and verb system of Central Khoisan; D.F. BLEEK, "A Short Survey of Bushman Languages," *Zeitschrift für Eingeborenen-Sprachen,* vol. 30 (1939–40). (*Vocabulary*): D.F. BLEEK, *A Bushman Dictionary* (1956), a compilation of all language material available, except Hottentot; J.G. KROENLEIN, *Wortschatz der Khoi-Khoin-Namaqua-Hottentoten* (1889), on Nama. (*Oral literature*): W.H.I. BLEEK and L.C. LLOYD, *Specimens of Bushman Folklore* (1911), texts in /Xam with translation and annotations. (*General information*): I. SCHAPERA, *The Khoisan Peoples of South Africa* (1930), deals also with distribution and classification. (*Eyasian languages*): O. DEMPWOLFF, *Die Sandawe* (1916), with a chapter on language and vocabulary; D.F. BLEEK, "Traces of Former Bushman Occupation in Tanganyika Territory," *S. Afr. J. Sci.,* 28:423–429 (1931).

Eskimo-Aleut languages. For bibliography, demographic data, and literacy programs, see M.E. KRAUSS, "Eskimo-Aleut," in T.A. SEBEOK (ed.), *Current Trends in Linguistics,* vol. 10 (in prep.). Supporting evidence is given in: L.L. HAMMERICH, "The Western Eskimo Dialects," *Proc. 32nd Int. Congr. Americanists, Copenhagen 1956,* pp. 632–639 (1958); KNUT BERGSLAND, "The Eskimo Shibboleth *Inuk/Yuk,*" in *To Honor Roman Jakobson,* pp. 203–221 (1967), and "The Eskimo-Uralic Hypothesis," *Journal de la Société Finno-Ougrienne,* vol. 61 (1959). S.P. KLEINSCHMIDT, *Grammatik der grönländischen Sprache* (1851; restated by MORRIS SWADESH in HARRY HOIJER *et al., Linguistic Structures of Native America,* pp. 30–54, 1946), is a classic in the field. See also C.W. SCHULTZ-LORENTZEN, *Dictionary of the West Greenland Eskimo Language* (1927).

North American Indian languages. J.W. POWELL, "Indian Linguistic Families of America North of Mexico," *U.S. Bureau of American Ethnology, 7th Annual Report,* pp. 1–142 (1891), the first comprehensive classification; FRANZ BOAS, *Handbook of American Indian Languages,* 3 pt. (1911, 1922, and 1933–38), a classic introduction, with sketches of sample languages; HARRY HOIJER *et al., Linguistic Structures of Native America* (1946), a summary of work on language classification and sketches of languages; C.F. and F.M. VOEGELIN, *Map of North American Indian Languages,* rev. ed. (1966), presents the classification used in this article; T.A. SEBEOK (ed.), *Current Trends in Linguistics,* vol. 10, *North America* (1973), surveys of different aspects of the field, with extensive bibliographies (see esp. the valuable article of JOEL SHERZER, "Areal Linguistics in North America"); M.R. HAAS, *The Prehistory of Languages* (1969), a discussion of the principles in the historical study of American Indian languages; WALLACE CHAFE, "Estimates Regarding the Present Speakers of North American Indian Languages," *International Journal of American Linguistics,* 28:162–171 (1962), and 31:345–346 (1965), gives data used in the present article; EDWARD SAPIR, *Selected Writings in Language, Culture, and Personality* (1949), articles on the relationship of language and culture in aboriginal North America; B.L. WHORF, *Language, Thought, and Reality: Selected Writings* (1956), classic articles on American Indian language and world view.

Meso-American Indian languages. Few books ever appear treating the Meso-American Indian languages as a group, although many dictionaries and grammars for individual languages have been prepared. The most up-to-date overview can be gotten from three articles in the *Handbook of Middle American Indians,* vol. 5, *Linguistics* (1967): MARIA TERESA FERNANDEZ DE MIRANDA, "Inventory of Classificatory Materials," which is an annotated bibliography; MORRIS SWADESH, "Lexicostatistic Classification," in which the author applies glottochronology to the classification of all the Meso-American Indian languages; and ROBERT LONGACRE, "Systemic Comparison and Reconstruction," a review of what has been accomplished in the historical-comparative field to date. For linguistic characteristics of Meso-American languages, see TERRENCE KAUFMAN, "Areal Linguistics and Middle America," *Current Trends in Linguistics,* vol. 11 (1972). For Uto-Aztecan, see CHARLES F. and FLORENCE M. VOEGELIN and KENNETH L. HALE, *Typological and Comparative Grammar of Uto-Aztecan* (1962); and WICK R. MILLER, *Uto-Aztecan Cognate Sets* (1967). For Mayan and "new languages," see TERRENCE KAUFMAN, "Teco—A New Mayan Language," *Int. J. Am. Linguistics,* 35:154–174 (1969). For "external contacts," see RONALD D. OLSON, "Mayan Affinities with Chipaya of Bolivia," *ibid.,* 30:313–324 (1964) and 31:29–38 (1965).

South American Indian languages. CESTMIR LOUKOTKA, *Classification of South American Indian Languages* (1968), contains a full list of languages, an extensive and detailed bibliography, the location and classification of languages, and a map; J.A. MASON, "The Languages of South American Indians," in J.H. STEWARD (ed.), *Handbook of South American Indians* (U.S. Bureau of American Ethnology Bulletin 143), 6:157–317 (1950), has an extensive bibliography, general information on language groups, a discussion of classifications, and a map. See also N.A. MCQUOWN, "The Indigenous Languages of Latin America," *Am. Anthrop.,* 57:501–570 (1955), a critical appraisal of classifications with useful lists of languages and families, the location and classification of languages, and a map; C.F. and F.M. VOEGELIN, "Languages of the World: Native America," *Anthrop. Linguistics,* vol. 6, no. 6 and vol. 7, no. 7 (1964–65), general information on American Indian languages, much information on groups and individual languages, and a discussion of classifications; T.A. SEBEOK (ed.), *Current Trends in Linguistics,* vol. 4, *Ibero-American and Caribbean Linguistics,* pt. 2, "Linguistics of Non-Ibero-American Languages" (1968), critical surveys of work done during the last 20 years; M. SWADESH, "Afinidades de las lenguas amerindias," in *Akten des 34. Internationalen Amerikanisten Kongress,* pp. 729–738 (1964), and J.H. GREENBERG, "The General Classification of Central and South American Languages," in *Men and Cultures: Selected Papers of the 5th International Congress of Anthropological and Ethnological Sciences, Philadelphia 1956* (1959), two recent classifications of South American languages.

Sumerian language. ARNO POEBEL, *Grundzüge der sumerischen Grammatik* (1923), partly out of date, but still the only full grammar of Sumerian in all its stages; ADAM FALKEN-

STEIN, *Grammatik der Sprache Gudeas von Lagaš,* 2 vol. (1949–50), a very thorough grammar of the New Sumerian dialect, and *Das Sumerische* (1959), a very brief, but comprehensive survey of the Sumerian language; CYRIL J. GADD, *Sumerian Reading Book* (1924), outdated, but the only grammatical tool in English; SAMUEL N. KRAMER, *The Sumerians* (1963), provides a general introduction to Sumerian civilization.

Etruscan language. The following sources provide accurate and reliable information on Etruscan. M. PALLOTTINO, *Etruscologia,* 6th ed. (1968; Eng. trans., *The Etruscans,* 1955), the standard work; A.J. PFIFFIG, *Die etruskische Sprache* (1969), an excellent and complete statement of what is known about the Etruscan language; MURRAY FOWLER and R.G. WOLFE, *Materials for the Study of the Etruscan Language,* 2 vol. (1965), which contains the inscriptions with indexes of several kinds for easy reference—there is no grammatical information included.

Basque language. RENE LAFON, "La lengua vasca," *Enciclopedia lingüística hispánica,* vol. 1 (1960), perhaps the best short introduction to Basque, both descriptive and historical; HUGO SCHUCHARDT, *Primitiae linguae Vasconum,* 2nd ed. (1968), detailed commentary of an Old Basque text; P. LAFITTE, *Grammaire basque,* 2nd ed. (1962), a standard normative grammar; J. COROMINES, *Estudis de toponímia catalana,* 2 vol. (1965–70), presents new data on the survival of Basque dialects in the Middle Ages; J.M. LACARRA, *Vasconia medieval* (1957), authoritative review by an historian of the linguistic situation in and around the Basque country; LUIS MICHELENA, *Fonética histórica vasca* (1961), essay on the reconstruction of the phonological system of Proto-Basque; LUIS MICHELENA (ed.), *Textos arcaicos vascos* (1964), an annotated collection of documents from antiquity to 1700; RENE LAFON, *Le Système du verbe basque au XVIe siècle,* 2 vol. (1943), the best account of form and function of the Basque verb; A. TOVAR, *La lengua vasca,* 2nd ed. (1954; abridged Eng. trans., *The Basque Language,* 1957), and *The Ancient Languages of Spain and Portugal* (1961), a discussion of the problem of the position of Basque among these now extinct languages.

Pidgin. An extensive discussion and bibliography of the problems of pidgins and creoles is given in R.A. HALL, JR., *Pidgin and Creole Languages* (1966). A specialized grammar study is PIETER MUYSKEN (ed.), *Generative Studies on Creole Languages* (1981). See also HENRI TINELLI, *Creole Phonology* (1981).

The History of Latin America

As the term is generally understood, Latin America comprises the entire continent of South America, as well as Central America and Mexico (called Middle America), and the islands of the Caribbean. "Hispanic America" has often been suggested as a more suitable designation since it specifically indicates the Spanish and Portuguese heritage of the region. However, the Indian and black African heritage, as well as United States, British, and French cultural and colonial influence, nullify any advantages of such a change. Despite territorial contiguity and, for much of the area, ties of a similar culture, history, and aspirations for the future, the physiographic, climatic, economic, political, ethnic, and linguistic differences make the term Latin America as connoting a homogeneous region fall short of a true description. Only in deference to popular usage and for lack of a better term, the area remains Latin America.

This article is divided into the following sections:

The Pre-Columbian period

Men of Mongoloid stock entered the Americas at least 20,000 years ago, probably from Siberia by way of Alaska. They spread over North and Middle America, reached South America by way of the Isthmus of Panama, and, between 3,000 and 5,000 years ago, reached the tip of South America. Evidence of other major migration routes such as a trans-Pacific routes from Asia directly to Peru, Middle America, or British Columbia is, as yet, unsatisfactory. However, certain classical Maya art motifs, such as seated cross-legged figures, hint at the possibility of such an event. Older beliefs concerning land bridges and lost continents are now rejected.

Major Pre-Columbian cultural groups

Until recently the Pre-Columbian Indian population had been estimated at 15,500,000. However, recent researchers claim a population that large in central Mexico alone, and any definitive total must await further investigation. Indian cultures ranged from very primitive to highly developed. They may be divided into six major cultural groups (each composed or several language and political groups) as follows: (1) Pima-Pueblo (southwestern United States and northern Mexico); (2) Nahua-Maya (central Mexico, Yucatán, and Guatemala); (3) circum-Caribbean and semi-marginal (Central America south of Guatemala, Panama, northern and western Colombia, Venezuela west of the Orinoco, the Greater Antilles, and the western headwaters of the Amazon); (4) central Andean (western Ecuador, Peru, and northwestern Bolivia); (5) marginal tribes of South America (southern Chile, most of Argentina, eastern Bolivia, Uruguay, east-central Brazil northward to the Brazilian bulge); and (6) tropical forest and southern Andean tribes (occupying the Lesser Antilles, the Amazon basin, the western half of the Orinoco flood plain, the Guiana Highlands, and much of the east coast of Brazil south to the Uruguayan border, then west to Paraguay and central and northern Chile). Within these groups only the central Mexican, Maya, Chibcha, and Andean Indians had reached a high level of culture. The others varied from Paleolithic to late Neolithic.

Within their general cultural groupings, the numerous tribes into which the Indians were divided continuously fought for the control of better lands. Defeated tribes retreated into less hospitable areas, were gradually exterminated, or paid tribute to their conquerors. In a sense the Spanish and Portuguese conquest was but another phase in the struggle for control of land and labour. The Indian tribes were divided into hierarchies of chiefs, nobles, priests, commoners, servile labourers, and slaves. The idyllic life of the noble savage did not exist on the American continent; the struggle for existence and status was strong.

Diversity marked much of Indian life. In addition to the internecine struggle, there were wide variations in physique and language. Languages derived from many basic roots, and the dialects have been estimated to number 2,000 or more. Even the great empires were not linguistically united. The Incas forced Quechua as a lingua franca upon the people that they subdued. The Aztecs governed peoples with a mélange of dialects. Tribes more than 75 or 100 miles apart spoke different dialects if not different languages. Buildings varied from stick-and-thatch hovels to the magnificent stone palaces of the Incas and the temple-topped pyramids of the Maya. Primitive tribes wore little more than breechcloths to cover their nakedness while the upper classes in the high civilizations wore elaborate costumes, sometimes covered with exquisite featherwork. Advanced groups wove fine cotton and woollen cloth; others contented themselves with hides and bark cloth. Techniques and artistic sensitivity in the making of jewelry, pottery, and statuary covered a wide spectrum of differences. While the Maya possessed a system of writing, a vigesimal number system, and a calendar more accurate than that used by contemporary Europeans, the Incas relied on mnemonic devices to keep historical and statistical accounts. Other groups simply depended upon memory or pictographs.

Agriculture

Agricultural techniques and basic crops also varied greatly. Only corn (maize)—apparently first domesticated in Mexico—was raised throughout the New World, although the cultivation of beans and squash was also widely disseminated. While North American Indians planted mainly seed crops—corn, beans, and squash—the South American and West Indian peoples preferred tubers, such as cassava (manioc) and sweet potatoes. Because of its importance in the diet of the early conquistadors, cassava has been called the bread of the conquest. The white potato, native to the Andes, was raised in large quantities in the higher altitudes there where corn would not grow well. Perhaps the greatest deficiency in the Indian diet was the lack of a plentiful meat supply. Except for the guinea pigs and dogs, which were often raised for food, only in the Andean region, where the llama and alpaca were found, was there a dependable, if small, source of meat. Wild game and wild fowl were fairly abundant in some areas. The practice of cannibalism was widespread. Agricultural techniques ranged from fire agriculture (the milpa, in which corn was planted in burned-over forest land in a hole punched in the ground with a stick) to intensive irrigated, fertilized, and terraced agriculture. At best, Indian agriculture was an intensive hoe culture since there were no draft animals to draw a plow. Through their centuries of occupation of the New World the Indians had found the most fertile and productive areas for their techniques, and there the most populous empires developed. To a great extent, early Spanish conquest and settlement simply followed the lines of available food, labour, and cultivable land.

In addition to the more advanced peoples such as the Aztecs, several groups on a lower cultural level are worth noting. The Araucanians of Chile, a high agricultural group, were only partially conquered by the Incas. Soon after the Spanish conquest began, they acquired horses and used them to good account, tenaciously resisting the white invaders. Mounted Araucanians crossed the Andes into the southern pampas and exacted a heavy toll from the Spaniards. They were not completely pacified until the 19th century. In northern Mexico the Apaches and Comanches presented a similar problem. But the neighbouring Pueblos, except for a few sharp rebellions, were generally peaceful. The Guaraní of central South America, just becoming agriculturalists, proved rather docile. The Spaniards and Portuguese used them as farm labourers and slaves while the Jesuits organized them in missions. Brazilian Indians, such as the Tupí, were culturally among the most backward groups in the New World. Their low culture status undoubtedly contributed to their gradual disappearance, under the strain of working on the sugar plantations. Many Brazilian Indians fought the Portuguese to the bitter end; others aided the Europeans in establishing settlements.

In sum, several Indian peoples capitulated with hardly a struggle, while most resisted the Europeans to the best of their abilities, usually in vain. Their descendants, both pure-blooded and mixed, live scattered over the length and breadth of Latin America.

The colonial period

Spanish and Portuguese expansion into the New World was but a facet of their dynamic national policies. Portugal was a wealthy, expanding, trading nation with a large African and island empire. The leadership of Ferdinand and Isabella, the "Catholic Kings," transformed Spain into a national state marked by growing royal power and centralized administration. They kindled a wave of nationalist and religious fervour that eventually led to the expulsion of the Moors and Jews and carried Spaniards beyond the peninsula. Soon Spanish troops were fighting in Italy, the Netherlands, and central Europe to secure the domains of Charles I (better known to English-speaking people as Charles V, the Holy Roman emperor) and Philip II and to contain Protestantism. Overseas Spain fought to enlarge its domain and to convert the heathen Indian. As with the other nations of western Europe, Spain and Portugal were affected by the commercial revolution, and their merchants and crowns were interested in new trade contacts. An ardent, revived religious and nationalistic spirit, a drive for trade and land, a military caste seeking adventure and rewards, monarchs desirous of expanding and unifying their realms, all contributed to the Iberian conquest of the New World.

To say that "gold, glory, and gospel" were the major motivations of the Iberians is a misleading oversimplification. It is true that many individuals who participated in the incredible adventure of New World conquest sought plunder, and that priests converted the heathen. But to call this the cause of conquest is equivalent to saying that the western United States was settled by glory-mad cavalrymen, gold-hungry forty-niners and mountain men, zealous Calvinists, and Indian-cheating, treaty-breaking, landgrabbing frontiersmen and farmers. Iberians, during their 325 years of dominion, left an indelible impression upon the culture and life of the lands that they occupied. Spain preserved an Indian nobility, and many Spaniards took Indian wives. As soon as the wars of conquest and plunder were over, Spaniards and Portuguese staked out land for agriculture, founded cities, opened trading posts, and prospected for mines, advancing their nations' realms. They established the church of their faith and converted millions to Christianity. The evils of the Iberian conquest cannot be overlooked, but they were the horrors common to all European colonial systems. (Ed.)

THE SPANISH CONQUEST OF AMERICA

Search for a sea route to the East

Extensive European exploration of America was a by-product of European efforts in the 15th century to find a sea route to the East and thereby to end the monopoly of Italian and Levantine middlemen over the lucrative trade in spices and other Oriental products. Portugal took a decisive lead; it had the advantages of a long Atlantic seaboard with excellent harbours, a large number of fishermen and sailors, and an aristocracy that had learned to supplement its meagre revenue from the land with income from trade and shipbuilding. In 1497 a fleet of four Portuguese ships commanded by Vasco da Gama sailed from Lisbon on a voyage that inaugurated the age of European imperialism in Asia. After rounding the Cape of Good Hope, Vasco sailed into the Indian Ocean and up the coast of East Africa and then to Calicut, the great spice-trade centre on the west coast of India.

The voyages of Christopher Columbus. The search for a sea road to the Indies inspired more than one solution. An obscure Italian seafarer, Christopher Columbus, became convinced that it was possible to reach the East from Europe by sailing westward across the Atlantic and that his proposed route was shorter than the route around Africa, a conception that underestimated the size of the earth and overestimated the size and eastward extension of Asia. About 1484 Columbus, who then resided in Lisbon, offered to make a voyage of discovery for John II of Portugal, but the king turned it down. Columbus next turned to Castile, where, after eight years of discouraging delays and negotiations, Queen Isabella agreed to support the "Enterprise of the Indies." The contract made by the Queen with Columbus named him admiral, viceroy, and governor of the lands he should discover and promised him a generous share in the venture's profits.

The "Enterprise of the Indies"

On August 3, 1492, Columbus sailed from Palos with three small ships—the "Pinta," the "Santa María," and the "Niña"—manned not by the jailbirds of legend but by experienced crews under competent officers. The voyage was remarkably prosperous, with fair winds the whole way out. On October 12 they made landfall at an island in the Bahamas, which Columbus named San Salvador. Cruising southward through the Bahamas, Columbus came to the northeastern coast of Cuba, which he mistook for part of Cathay (China). Next he sailed eastward to explore the northern coast of an island that he named Española (Hispaniola), where he lost his flagship, the "Santa María." He then returned to Spain to report his supposed discovery of the Indies.

In response to Portuguese charges of encroachment on an area in the Atlantic reserved to Portugal by a previous treaty with Castile, King Ferdinand and Queen Isabella appealed for help to Pope Alexander VI, himself a Spaniard. The pontiff issued a series of bulls (1493) that assigned to Castile all lands discovered or to be discovered by Columbus and drew a line from north to south 100 leagues (345 miles) west of the Cape Verde Islands. To the west of this line was to be a Spanish sphere of exploration; to the east, Portuguese. To John II this line seemed to threaten Portuguese interests in the south Atlantic and the promising route around Africa to the East. Yielding to Portuguese pressure, Ferdinand and Isabella signed, in 1494, the Treaty of Tordesillas, establishing a boundary 270 leagues (930 miles) farther west.

Columbus returned to Española at the end of 1493 with a fleet of 17 ships carrying 1,200 colonists. The settlers soon gave themselves up to gold hunting and preying on the Indians; and Columbus, a foreigner, lacked the power and the personal qualities to control them. In 1496 he returned to Spain to report his new discoveries and to answer charges sent by disgruntled settlers.

The first two voyages had not paid their way, but the Spanish sovereigns still had faith in Columbus and outfitted a third fleet in 1498. On this voyage he discovered the island of Trinidad and the mouths of the Orinoco. He arrived in Española to find chaos. The Spaniards, disappointed in their hopes of quick wealth, blamed Columbus for their misfortunes and rose in revolt. To appease the rebels Columbus had to issue pardons and grant land and Indian slaves. Meanwhile, a stream of complaints against Columbus had caused the sovereigns to send out an agent, Francisco de Bobadilla, to supersede Columbus and investigate the charges against him. Bobadilla seized Columbus and sent him to Spain in chains. Although Isabella ordered Columbus' release, he never again exercised the functions of viceroy and governor in the New World. His monopoly on New World exploration and colonization ended as privileges were granted to other explorers. Columbus made one more voyage—in 1502–04—an unsuccessful search for a strait that would lead into the Indian Ocean. From Española, where he was not permitted to land, he crossed the Caribbean to the coast of Central America and followed it southward to the Isthmus of Panama. He finally departed for Española but was forced to land on Jamaica, where he and his men were marooned for a year.

Complaints against Columbus

When Nicolás de Ovando arrived in 1502 to serve as governor with an expedition of 2,500 persons, including 73 families, the colony numbered only 300. In a short while more than 1,000 of Ovando's group died. During the six years of Ovando's governorship conditions were stabilized. New cities were founded, gold output expanded, and food production increased under a system of forced Indian labour supplemented by slavery. With a permanent beachhead in the Indies, it was now possible (and the attrition of the Indian population of Española made it necessary) to begin the conquest of other islands in the West Indies as well as portions of the Caribbean coast. Having served its purpose as the advance base of the conquest, Española sank into decadence until its economic renaissance in the late 18th century.

Other early explorations. Other explorers followed and gradually made known the immense extent of the mainland coast of South America. In 1499 Alonso de Ojeda, accompanied by the Florentine Amerigo Vespucci, sailed to the mouths of the Orinoco and explored the coast of Venezuela. Vespucci personally directed another voyage, in 1501–02, under the flag of Portugal; this expedition, sent to follow up the discovery of Brazil by Pedro Álvares Cabral in 1500, explored the Brazilian coast and discovered the Río de la Plata before turning back. To Vespucci it was obvious that the landmass thought by Columbus to be a part of Asia was really a new continent—a "fourth part of the world." Vespucci's letters circulated widely in the early 1500s and gave him the fame of being the first European to set foot on the South American continent. A German geographer, Martin Waldseemüller, honoured Vespucci by assigning on a map the name America to the area of Brazil. The name caught on and presently was applied to the whole of the New World.

The naming of America

In 1500 Vicente Yáñez Pinzón explored the northern coast of Brazil from Cape São Roque to the Guianas, discovering the mouth of the Amazon, while in the same year Diego de Lepe explored the coast of the Guianas and Rodrigo de Bastidas in 1501 and 1502 the coast from Lake Maracaibo to Nombre de Díos, Panama (just south of modern Colón). The discovery of pearls along this coast led to the establishment of a lucrative industry based on exploiting Indian divers. Juan de la Cosa in 1504 explored the Gulf of Urabá (Darién) in the crook between Panama and South America.

Following Columbus' last voyage in 1502–04, which explored from Honduras south to Panama, Pinzón and Juan Díaz de Solís in 1506 explored the east coast of Yucatán and the Gulf of Honduras. Along with the stabilization of Española, these explorations led to a rash of colonizing activity. Juan Ponce de León began the conquest of Puerto Rico in 1508 and went on to discover Florida in 1513. Juan de Esquivel began the settlement of Jamaica in 1509, while in 1511 Diego Velázques de Cuéllar started the conquest of Cuba, founding Havana in 1515. Thus ended the first stage of Spanish exploration, the conquest and settlement of the islands of the Caribbean. Alonso de Pineda completed the mapping of the coast of the Gulf of Mexico in 1519 by sailing west from Florida to about modern Veracruz in Mexico and discovering the mouth of the Mississippi River on the way.

Beginnings of colonization

A growing shortage of Indian labour and a general lack of economic opportunities for new settlers on Española incited Spanish slave hunters and adventurers to explore and conquer Puerto Rico, Jamaica, and Cuba between 1509 and 1511. In the same period efforts to found colonies on the coast of northern Colombia and Panama, led by Alonso de Ojeda and Diego de Nicuesa, failed disastrously, and the remnants of two expeditions were united under the conquistador Vasco Núñez de Balboa to form the settlement of Darién on the Isthmus of Panama. Moved by Indian tales of a great sea, south of which lay a land overflowing with gold, Balboa led an expedition across Panama to the shores of the South Sea (Pacific Ocean). This aroused the jealousy of his father-in-law, Pedrarias Dávila, sent out by Charles V in 1514 as governor of the Isthmus, who contrived charges of treason and desertion; Balboa was tried, condemned, and beheaded in 1519. By this date exploration had pushed to the Pacific coast, and the city of Panama had been founded.

The exploration of the west coast of Central America and Mexico was done by Gaspar de Espinoza (1516–19) and Andrés Niño and Gil González Dávila (1522–23) who sailed north from Panama as far as Nicaragua. Pedrarias then began sending men northward into Central America where they finally encountered expeditions sent south overland from Mexico by Hernán Cortés.

The discovery of the South Sea helped confirm Vespucci's view that the so-called Indies formed no part of Eastern Asia. After 1513 the work of discovery centred on the search for a waterway to the East through or around the American continent. Ferdinand Magellan's circumnavigation of the globe in 1519–22 was too long to have commercial value. The net result was to enhance the value of America in Spanish eyes. Disillusioned with the dream of easy access to the East, Spain turned with concentrated energy to the task of extending its American conquests and to the exploitation of the human and natural resources of the New World.

The conquest of Mexico. In 1517 a slave-hunting expedition outfitted by Gov. Diego Velázquez, first governor of Cuba, explored the Yucatán Peninsula of Mexico, inhabited by Maya Indians whose pyramids, temples, and gold ornaments revealed a native culture far more advanced than any the Spaniards had previously encountered. Encouraged by the gold and other signs of Indian wealth brought back by the expedition, Velázquez outfitted a new venture, which he entrusted to his kinsman Juan de Grijalba. Grijalba coasted down the Yucatán Peninsula and, in June 1518, reached the limits of the Aztec Empire. From near what is now the port of Veracruz, Grijalba sent one ship back to Cuba with the gold that had been gained by barter with the coastal Indians and sailed on westward with three other ships, perhaps as far as the river Pánuco, marking the northern limits of the Aztec Empire. He returned to Cuba in November.

Cortés' expedition to Mexico

Velázquez sent a third expedition, with some 600 men under Hernán Cortés, to conquer the Mexican mainland in February 1519. Because Velázquez had not yet secured from the emperor Charles V an agreement authorizing conquest and settlement of the mainland, Cortés' instructions permitted him only to trade and explore.

Cortés' fleet first touched land at the island of Cozumel, off the coast of Yucatán. In March 1519, Cortés landed on the coast of Tabasco and defeated local Indians. In April he dropped anchor near the site of modern Veracruz, founding the town of Villa Rica de la Vera Cruz and appointing its first officials, into whose hands he surrendered the authority he had received from Velázquez. These officials then conferred on Cortés the title of captain general with authority to conquer and colonize the newly discovered lands (Cortés thus drew on Spanish medieval traditions of municipal autonomy to vest his disobedience with a cloak of legality).

Some days later the Aztec king Montezuma's (Moctezuma) ambassadors appeared in the Spanish camp. Apparently convinced that Cortés was the god Quetzalcóatl, who was returning to reclaim his lost realm, the envoys brought precious gifts—the finery of the great gods Quetzalcóatl, Tlaloc, and Tezcatlipoca; a gold disk in the shape of the sun, as big as a cartwheel; an even larger disk of silver, in the shape of the moon; and a helmet full of small grains of gold—while pleading with Cortés not to seek a meeting with their king. By plying Cortés–Quetzalcóatl with gifts Montezuma hoped to dissuade him from advancing into the interior and reclaiming the god's lost throne. Suavely Cortés informed the ambassadors that he had come a long way to see and speak with Montezuma, and he could not return without doing so.

Cortés, becoming aware of the bitter discontent of tributary towns with Aztec rule, began to play a double game. He encouraged the Totonac Indians of the coast to seize and imprison Montezuma's tax collectors, and he then promptly obtained their release and sent them to the king with expressions of regard and friendship. He took two other steps before beginning the march on the Aztec capital at Tenochtitlán (now Mexico City). First, he sent dispatches to the emperor Charles V seeking approval for his actions by describing the extent and value of discoveries; and second, to stiffen the resolution of his followers by cutting off all avenues of escape, he scuttled and sank all his remaining ships on the pretext that they were not seaworthy. Then, with his small army, he began a march on Tenochtitlán.

Advancing into the sierra, Cortés met and defeated in battle the Tlaxcalan Indians, traditional enemies of the Aztecs; the Tlaxcalans then formed an alliance with the white invaders. Next Cortés marched on Cholula, centre of the cult of Quetzalcóatl, where he claimed that the Cholulans were conspiring to attack him and staged a mass slaughter of the Cholulan nobility and warriors after they had assembled at his bidding in a great courtyard. Montezuma sent new envoys who brought rich gifts to Cortés but urged him to abandon his plan of visiting the Aztec capital; all of Montezuma's stratagems failed, and he welcomed Cortés at the entrance to the capital as a rightful ruler returning to his throne. The Aztec ruler even allowed himself to be kidnapped from his palace and taken to live as a hostage in the Spanish quarters.

Greeting of Cortés by Montezuma

A blunder on the part of his lieutenant Pedro de Alvarado thwarted Cortés' plan to use Montezuma as a puppet ruler. In Cortés' absence Alvarado ordered a massacre of the leading Aztec chiefs and warriors during a religious festival. This caused an uprising that forced the Spaniards to retreat to their own quarters. The tribal council deposed the captive Montezuma and elected a new chief, who launched vigourous attacks on the white invaders. In the midst of the struggle Montezuma died—killed by his own people as he appealed for peace, according to Spanish accounts; strangled by the Spaniards themselves, according to Indian sources. Threatened by a long siege and famine, Cortés evacuated Tenochtitlán at a heavy cost in lives. The surviving Spaniards and their Indian auxiliaries at last reached Tlaxcala.

In December 1520 Cortés, strengthened by Spanish reinforcements from Cuba, again marched on Tenochtitlán. A struggle began in late April 1521. On August 23, after a siege of four months, the last Aztec king, Cuauhtémoc, surrendered; and Cortés took possession of the ruins that had been the city of Tenochtitlán.

Once in control of central Mexico, Cortés dispatched expeditions to explore northward to the Gulf of California and southeast into Guatemala and Honduras. The Gulf of California was discovered in 1532 and Lower California the next year. Not until 1539 did Francisco de Ulloa explore the gulf and prove that Lower California was a peninsula, not an island. Juan Rodríguez Cabrillo, in 1542, explored the coasts of Lower and Upper California to about 40° N latitude.

Conquest of Central America

From the Valley of Mexico the tide of conquest flowed in all directions. Guatemala was reduced by Pedro de Alvarado; Honduras, by Cortés himself. In 1527 Francisco de Montejo began the conquest of Yucatán (in 1542 the Maya Indians rose in a revolt that was crushed with great slaughter). Meanwhile, expeditions from Darién subjugated the Indians of Nicaragua. Pedrarias' and Cortés' men soon met in armed clashes. A royal settlement relieved Pedrarias as governor of Panama in 1526 and named him governor of Nicaragua, a post he held until his death. Later, the entire area north of Panama was attached to Mexico as the captaincy general of Guatemala. Generally speaking, this area was neglected because of its lack of economic opportunities, and, with the exception of Guatemala where a brilliant nucleus of culture flourished, it became one of the backwaters of the Spanish Empire in America. Thus the two streams of Spanish conquest, both originally starting from Española, came together again.

For a brief time Cortés was undisputed master of the old Aztec Empire, renamed the "Kingdom of New Spain." The crown granted him the title of "Marquis of the Valley of Oaxaca" and the tribute and labour services of 23,000 Indian vassals. But the characteristic royal distrust of the great conquerors soon asserted itself. He was removed from his office of governor, and in 1539 he returned to Spain.

Cortés' conquests as well as those of his lieutenants were carried out with a minimum of bloodshed. In contrast, the adventurers who followed, penetrating northern Mexico and governing virtually unchecked, opened a chapter of wholesale pillaging and bloodletting.

Explorations of North America

Much of northern Mexico and the southwestern United States owes its exploration and eventual colonization to the adventures of Álvar Núñez Cabeza de Vaca. In 1536 he and three companions were found wandering in northern Mexico, the last survivors of Pánfilo de Narváez' expedition of 300 men shipwrecked in Florida eight years before. Núñez' stories of his journey from Florida to northwestern Mexico led to the organization of expeditions to explore the territories he had traversed. Hernando de Soto, financed by a fortune accumulated during his participation in the conquest of Peru, landed in Florida in 1539 with about 600 men and until his death in 1542 roamed over what is now the southeastern United States. He discovered no wealth; the survivors sank his body in the Mississippi and straggled back to Mexico. Fray Marcos de Niza and a guide named Esteban who had accompanied Núñez were sent by Viceroy Antonio de Mendoza in 1539 to retrace Núñez' steps in northern Mexico. Fray Marcos reported the existence of Seven Golden Cities, one of which he said was larger than Mexico City. A 300-man expedition led by Francisco de Coronado left Compostela in western Mexico in 1540; for two years they searched in vain for a golden empire, meanwhile wandering over New Mexico, Arizona, Texas, Oklahoma, Colorado, Kansas, and Nebraska. The failures of De Soto and Coronado, coupled with fruitless searches for a sea-to-sea passage via the Colorado River and the futile explorations of Rodríguez Cabrillo, dampened for the time being further interest in expansion in North America. Spanish policy turned toward settling and developing what had proved fertile and productive, exploiting the mines which were being discovered with increasing frequency and preaching the gospel. Only Florida was colonized in the 1560s to protect the Bahama Channel against pirates and European interlopers.

Silver mining in northwestern Mexico supported the establishment of several stable and prosperous communities that late in the 16th century were the scenes of renewed interest in what is now the southwestern United States. Juan de Oñate, nephew of one of the conquistadors of western Mexico, finally managed to plant the first colony in New Mexico, founding San Juan in 1598, and made a series of explorations ranging from the Colorado River east into Kansas. Oñate's hopes of finding great silver mines and using the labour of the sedentary Pueblo Indians proved abortive. New Mexico remained an isolated outpost surrounded by fierce Indians until the spread of missions over the next 200 years added this area to the cattleman's frontier.

Westward across the Pacific

After the voyage of Ferdinand Magellan, it was recognized that the New World itself was not only a barrier to the Far East (instead of being an extension of it) but also that it hid a tremendous ocean. Attempts to discover a strait from the Atlantic to the Pacific resulted only in the exploration of the west coast from Oregon south to Panama. The Spaniards also attempted to find a dependable route across the Pacific. Acting on royal orders to annex the Philippines to the viceroyalty of New Spain (Mexico), Viceroy Luis de Velasco dispatched an expedition in 1564 under Miguel López de Legazpi with Andrés de Urdaneta second in command. Legazpi remained to conquer the Philippines. Urdaneta, discovering the Japan Current, followed it to the California coast and thence south to Acapulco. The so-called Manila galleon soon plied regularly between Manila and Acapulco to trade Mexican silver for Eastern wares, particularly raw silk, which was woven in Mexico. In 1583 an *audiencia* was established in Manila subordinate to the viceroy in Mexico City.

The conquest of Peru. The conquest of Mexico challenged other Spaniards to match the exploits of Cortés and his companions and to discover the golden kingdom rumoured to lie beyond the South Sea. In 1519 Pedrarias founded the town of Panamá on the western side of the isthmus, which became a base for exploration along the Pacific coast. Three years later Pascual de Andagoya crossed the Gulf of San Miguel and returned with more information about a land of gold called Birú (Peru). Pedrarias then entrusted command of a voyage of discovery southward to Francisco Pizarro, who, in turn, recruited two partners—Diego de Almagro, an adventurer of obscure origin, and Hernando de Luque, a priest who acted as financial agent for the trio. Two preliminary expeditions (1524 and 1526) yielded enough finds of gold and silver to confirm the existence of the elusive kingdom. Pizarro then left for Spain to obtain royal sanction for the exploration of Peru. He returned to Panamá with the titles of captain general and *adelantado* (provincial governor) accompanied by his four brothers and other followers.

Pizarro in Peru

In December 1530 Pizarro again sailed southward from Panamá with a force of some 200 men and landed in the spring on the Peruvian coast. Civil war was raging in the Inca Empire. Atahuallpa, son of the late emperor Huayna Capac by a secondary wife, had defeated and imprisoned the lawful heir to the throne, Huáscar, and was moving toward the imperial capital of Cuzco when he received news of the arrival of white strangers. After an exchange of messages and gifts between Pizarro and Atahuallpa, the two armies advanced toward a meeting at the town of Cajamarca, high in the mountains.

Pizarro planned to win a quick, relatively bloodless victory by seizing the emperor as Cortés had done with Montezuma. When Atahuallpa and his escort appeared in the square of Cajamarca, they found it deserted, for Pizarro had concealed his men in some large buildings opening on the square. At a signal from Pizarro his soldiers, supported by cavalry and artillery, rushed forward to kill hundreds of terrified Indians and take the Inca prisoner.

Atahuallpa attempted to gain his freedom by offering to fill his spacious cell with gold higher than a man could reach. Pizarro accepted the offer; but when the room had been filled to the stipulated height, he informed the Inca that he was to remain in "protective custody." Pizarro proposed to use Atahuallpa as a puppet ruler to ensure popular acceptance of the new order, but he became convinced that Atahuallpa was organizing a resistance movement against the Spaniards. After a farcical trial, a Spanish court found the Inca guilty of polygamy, idolatry, and the murder of his brother Huáscar, and it condemned him to burn at the stake—a sentence commuted to strangling when he accepted baptism. Atahuallpa's enormous ransom of gold was divided among the Spaniards, and Hernando Pizarro was sent to Spain with the emperor Charles's share of the plunder. Hernando's arrival in Spain with his load of gold caused feverish excitement, and a new wave of Spanish fortune hunters flowed to the New World.

Diego de Almagro led an expedition to conquer Chile in 1535. Losing many of his force of Spaniard and Indian porters on the trip south, Almagro found a land without gold, peopled by fierce Indians. Dejected, he turned north, crossing the Atacama Desert to reach Peru. Only a handful of his men reached Cuzco, the old Inca capital, which Almagro seized and declared to be his.

Francisco Pizarro, posing as the defender of the legitimate Inca line, now proclaimed Huáscar's brother, Manco, as the new Inca. But a formidable revolt, organized and led by Manco himself, broke out in many parts of the empire. A large Indian army besieged Cuzco for 10 months but failed to take the city. Defeated by superior Spanish weapons and tactics and by food shortages in his army, Manco retreated to a fastness in the Andean Mountains; there he and his successors maintained a kind of Inca government-in-exile until 1572, when a Spanish military expedition entered the mountains, broke up the imperial court, and captured the last Inca, Topa Amaru, who was beheaded in a solemn ceremony at Cuzco.

The siege of Cuzco had barely ended when fighting broke out between one group of the conquerors, headed by the Pizarro brothers, and another, led by Almagro, over possession of the city. Before these struggles ended Francisco Pizarro had been murdered and two Almagros, father and son, had suffered death on the block. A new round of fighting began in 1544 when a new viceroy, Blasco Núñez Vela, arrived in Peru to proclaim the protective Indian legislation known as the "New Laws of the Indies." Led by Gonzalo Pizarro, the desperate conquistadors rose in revolt. The conquistadors defeated the new viceroy, and Núñez Vela was beheaded. The rebellion collapsed after the arrival of a new crown envoy, Father Pedro de la Gasca, who suspended the New Laws and offered pardons and rewards to all repentant rebels. Gonzalo Pizarro, however, resisted to the last and was captured and executed. Peace and order were not solidly established in Peru until the administration of Viceroy Francisco de Toledo, who arrived in 1569.

Conquest of Chile

Pedro de Valdivia, to whom Pizarro had given Almagro's concession, achieved the distinction of conquering Chile. In 1540, after terrible hardships, Valdivia's expedition reached Chile and began the slow conquest of the land from the fierce Araucanian Indians. After supporting Gasca (who reconfirmed his concession), Valdivia returned to Chile to prosecute his campaign. Chile offered neither wealthy civilizations to plunder nor mines to exploit. But the land was fertile, and the Indian population ample, if warlike. Valdivia granted land in large tracts, but often the would-be conquistador had to work with his Indians—and keep his weapons handy. Valdivia founded the cities of Santiago de Chile in 1541, Valparaíso in 1544, and Concepción in 1550. An expedition sent over the Andes into what is now western Argentina founded the cities of Mendoza (1561) and Tucumán in 1565.

Valdivia's most formidable opponents were the chiefs Lautaro and Caupolicán. According to tradition, Lautaro had learned Spanish military tactics while serving the conquerors as a stable boy. Lautaro defeated and captured Valdivia in 1553 and had him executed. In turn, Lautaro and Caupolicán were eventually captured and killed. Lautaro is now regarded as a Chilean national hero, immortalized in the epic poem *La araucana* by Alonso de Ercilla y Zúñiga. After a half century of war, peace was finally agreed upon when the Spaniards recognized the Bío-Bío River as the southern boundary of Chile, permitting the Araucanians to roam free to the south.

Conquest of Ecuador and Colombia

Peru served also as the nucleus for expansion eastward and northward. After the fall of the Inca Empire, Francisco Pizarro commissioned Sebastián de Belalcázar to secure the kingdom of Quito (Ecuador). Belalcázar, with the aid of Almagro, carried out his commission and founded the city of San Francisco de Quito in 1534. In 1540 Gonzalo Pizarro led an expedition from Quito over the Andes into the Amazon Valley in search of cinnamon. Finding themselves in sore straits, they built a number of boats to help forage for food. Francisco de Orellana took the boats and with a group of men sailed down the Amazon to the Atlantic. Whether Orellana was carried away by the current or deserted is still a moot question. Gonzalo returned to Quito with a handful of survivors. Meanwhile, Belalcázar was working north from Quito, incorporating northern Ecuador and southern Colombia into the Spanish domain. He eventually pushed his way to the highlands of Colombia, the homeland of the Chibcha Indians. There he met two other expeditions. One, led by Nicolaus Federmann, a German in the service of the banking house of Welser, had come southwest from Venezuela. The second expedition, however, under Gonzalo Jiménez de Quesada, which had come up the Magdalena River from the Caribbean coast, had reached the area first by a few days. The three men agreed to submit their case to the crown for judgment. Quesada was made a nobleman and alderman of the city of Santa Fe de Bogotá, which he had founded in 1538; Belalcázar was made governor of Popoyán in southern Colombia; Federmann received nothing.

Federmann's presence was the result of an unusual chapter in the early history of the Indies. After the failure of Ojeda's expedition to northern South America, the area was deserted except for pearl fishers, slave hunters, and an abortive attempt to found an ideal Indian state by Fray Bartolomé de Las Casas. In 1528 Charles V mortgaged Venezuela to the banking house of Welser of Augsburg, Germany, as a hereditary fief conditioned upon their developing the area. A complex formula was set up for dividing the produce of the mines, and the Welsers could enslave all the necessary Indian labour. Ambrosius Alfinger arrived in 1528 as governor. Failing to find gold, he set the colony upon an economic base of slave trading. Killed by Indians in 1531, he was succeeded by Georg Hohermut von Speyer as governor and Nicolaus Federmann as captain general. Federmann's expedition to the highlands near Bogotá was one of several fruitless attempts by him and Speyer to recoup the colony's fortunes. Charles V cancelled the contract in 1547. With the discovery of gold in 1560 the colony was placed on a more permanent footing, although it remained basically a peaceful out-of-the-way agricultural area.

Settlement of the Río de la Plata

The final major area of Spanish exploration, conquest, and settlement was the Río de la Plata. Juan Díaz de Solís discoverd the great estuary in 1516; Magellan explored it in 1520; Sebastian Cabot sailing up the Paraná River in 1526 ascertained that it was not a strait to the Pacific. Cabot picked up a number of silver trinkets which had filtered eastward from Peru. Believing himself to be close to their source, he named the region Río de la Plata (River of Silver). A full-scale attempt at colonization was made in 1535 by Pedro de Mendoza, who had received a royal patent to all lands from the Río de la Plata to the Straits of Magellan and then west to the Pacific. Theoretically, Chile had been granted twice: first to Almagro and then to Mendoza. Mendoza's expedition of 11 ships and 1,200 men soon came to grief on the inhospitable pampas occupied by hostile natives. Santa María de Buenos Aires, named after the patroness of the voyage, was the scene of starvation and cannibalism by the whites until it was destroyed by Indian attacks. Mendoza died at sea while returning to Spain for aid. The remnants of the expedition were led northward by Mendoza's lieutenants, Juan de Ayolas and Domingo Martínez de Irala, who founded the city of Asunción. Ayolas was lost in an unsuccessful attempt to reach Peru. Under Irala's guidance and by virtue of the docile nature of the Guaraní Indians, Asunción prospered. Large grants of land and Indians, as well as open polygamy, made Irala quite popular and, except for the years 1542–43 when Álvar Núñez Cabeza de Vaca ruled as governor, he governed until his death in 1556. Buenos Aires was refounded in 1580 by Juan de Garay to serve as a seaport for Asunción.

The first permanent settlements in modern Argentina were made in the northwest of that nation. Silver strikes at Potosí (in modern Bolivia) led to the establishment of ranches and handicraft industries in the area now comprising the states of Salta and Jujuy to supply the mines with horses, burros, meat, leather, and textiles. The settlement of Buenos Aires in 1580 marked the end of the second, or continental, stage of Spanish expansion. Spain now concentrated upon filling in the broad areas staked out during the first century and only slowly expanded the limits of its dominion. The three major areas of new expansion were northward from Mexico toward California and Texas, southward from the central valley of Chile, and into the plains surrounding the Río de la Plata and the Paraná River.

SPAIN'S COLONIAL EMPIRE

Political organization

The political organization of the Spanish Empire in America reflected the centralized, absolutist regime by which Spain itself was governed. In the Indies, as in Spain, there was a frequent contrast between the formal concentration of authority in the hands of royal officials and the actual exercise of supreme power on the local level by the great landowners.

The pattern of Spain's administration of its colonies was formed in the period between 1492 and 1550. The final result reflected the steady growth of centralized rule in Spain and the application of a trial and error method to the problems of colonial government. To Columbus, Cortés, Pizarro and other great expeditionary leaders, the Spanish kings granted sweeping powers that made these men practically sovereign in the territories they had won or proposed to conquer. Once the importance of these conquests had been revealed, however, royal jealousy of the great conquistadors quickly appeared; their authority was soon revoked or strictly limited, and the institutions that had been used in Spain to achieve centralized political control were transferred to the Western Hemisphere for the same end. By the mid-16th century the political organization of the Indies had assumed the definitive form that it was to retain, with slight variations, until late in the 18th century.

The Council of the Indies. The Council of the Indies, chartered in 1524, stood at the head of the Spanish imperial administration almost to the end of the colonial period. Although great nobles and court favourites were appointed to the Council, especially in the 17th century, its membership consisted predominantly of lawyers. Under the king, whose active participation in its work varied from monarch to monarch, it was the supreme legislative, judicial, and executive organ of colonial government. One of its most important functions was the nomination of all high colonial officials to the king. It also framed a vast body of legislation for the Indies—the famous Laws of the Indies, first codified in 1681—and sought to obtain detailed information on the history, geography, resources, and population of the colonies (the *relaciones,* which incorporated this information, represent a rich mine of materials for students of colonial Spanish America). Often staffed by conscientious and capable officials in the early Habsburg period, the quality of the Council's personnel tended to decline under the inept princes of the 17th century.

Principal royal agents

Viceroys, captains general, and audiencias. The principal royal agents in the colonies were the viceroys, the captains general, and the *audiencias* (high courts). Viceroys and captains general had essentially the same functions, differing only in the greater importance and extent of the territory assigned to the jurisdiction of the former; each was the supreme civil and military officer in his territory. At the end of the Habsburg era, in 1700, there were two great American viceroyalties—the viceroyalty of New Spain, with its capital at Mexico City, included all Spanish possessions north of the Isthmus of Panama; that of Peru, with its capital at Lima, embraced all of Spanish South America except the coast of Venezuela. Captains general, theoretically subordinate to the viceroys but in practice virtually independent of them, governed large subdivisions of these vast jurisdictions. Smaller subdivisions, called *presidencias,* were governed by *audiencias,* with the judge-president acting as governor but with military authority usually reserved to the viceroy.

A colonial viceroy enjoyed an immense delegated authority, which was augmented by the distance that separated him from Spain. By background he might be a lawyer or even a priest, but more often he came from one of the great noble and wealthy houses of Spain. A court modelled on that of Castile, a numerous retinue, and the constant display of pomp and circumstance testified to his exalted status. In theory his freedom of action was limited by the laws and instructions issued by the Council of the Indies, but recognition of the need to adapt the laws to existing circumstances gave him a vast discretionary power. The 16th century saw some able and even distinguished viceroys in the New World; in the 17th century, however, the quality of the viceroys declined (in 1695, for example, the viceroyships of Peru and Mexico were, in effect, sold to the highest bidders).

The *audiencia*

A viceroy or captain general was assisted in the performance of his duties by an *audiencia*, which served as his council of state. The joint decisions of viceroy and *audiencia* had the force of law, giving the *audiencia* a legislative character, roughly comparable to that of the Council of the Indies, in relation to the king. Although the viceroy was not obliged to heed the advice of the *audiencia,* its immense prestige and its right to correspond directly with the Council of the Indies made it a potential check on the viceregal authority. The crown thus developed a system of checks and balances that assured ample deliberation and consultation on all important questions but that also encouraged indecision and delay.

Provincial government. Provincial administration in the Indies was entrusted to royal officials, who governed districts of varying size and importance from their chief towns and who usually held the title of *corregidor.* Some were appointed by the viceroy; others, by the crown. They possessed supreme judicial and political authority in their districts and represented the royal interest in the town councils (*cabildos*). If not trained as a lawyer, a corregidor was assisted by a legal counsel (*asesor*) in the trial of judicial cases. Certain civil and criminal cases could be appealed from the municipal magistrates (*alcaldes*) to the *corregidor,* and from him to the *audiencia.*

Corregidores were of two kinds. Some presided over Spanish towns; others, *corregidores de indios,* administered Indian towns (*pueblos*), which paid tribute to the crown. A principal duty of a *corregidor de indios* was to protect the natives against fraud or extortion on the part of whites, but the *corregidor* was himself the worst offender in this respect. Perhaps the worst abuse of this authority arose in connection with the practice of *repartimiento*—the mandatory purchase of goods from the *corregidor* by the Indians of his district. Originally designed to protect the Indians from the frauds of private Spanish traders, the *corregidor's* exclusive right to trade with the Indians became a means for his speedy enrichment at the expense of the natives.

Restrictions on public officials. A series of regulations was designed to ensure good and honest performance on the part of public officials. Viceroys and *oidores* (members of an *audiencia*) were forbidden to engage in trade or own land within their jurisdictions or to accept gifts or fees; even their social life was restricted. All royal officials faced a judicial review (*residencia*) of their conduct at the end of their term of office. This took the form of a public hearing at which all who chose could appear before the "judge of residence" to present charges or testify for or against the official in question. At the end of the process the judge found the official guilty or innocent of all or part of the charges and handed down a sentence, which could be appealed to the Council of the Indies. Another device, the *visita,* was an investigation of official conduct, usually made unannounced, by a *visitador* especially appointed for this purpose by the crown; or, in the case of lesser officials, by the viceroy in consulation with the *audiencia.* As a rule, the *visita* was no more effective than the *residencia* in preventing or punishing official misdeeds.

Municipal government. The only colonial institution that satisfied to some degree local aspirations for self-

Royal control of local officials

rule was the town council, known as the *cabildo* or *ayuntamiento.* At an early date, however, the crown assumed the right to appoint the councilmen (*regidores*) and municipal judges; under Philip II and his successors it became the established practice for the king to sell these posts to the highest bidder, with a right of resale or bequest, on condition that a certain portion of the price be paid to the crown as a tax at each transfer. Throughout the colonial period the municipal governments were self-perpetuating oligarchies of rich landowners, mineowners, and merchants who frequently received no salaries and who used their positions to distribute municipal lands to themselves, to assign themselves Indian labour, and to serve the narrow interests of their class. Vigilantly supervised by the *corregidor,* who frequently intervened in its affairs, the *cabildo* soon lost such autonomy as it may have possessed in the early days.

Other government offices. The officials and agencies described above represented a small part of the apparatus of colonial government. There were large numbers of such officers as secretaries (*escribanos*), police officers, tax collectors of "the royal fifth," and *alcaldes* with special jurisdiction. Under Charles V such offices were often in the gift of high Spanish officials, who sold them to persons who proposed to go to the Indies to exploit their fee-earning possibilities; beginning with Philip II, many of these offices were withdrawn from private patronage and sold directly by the crown, usually to the highest bidder. In the second half of the 17th century, the sale of offices spread from fee-earning positions to higher salaried posts; as a result, in this period corruption became structural in the government of the Indies.

Power of the landowners

Although royal authority—represented by viceroys, *oidores, corregidores,* and other officials—was more or less supreme in the capitals and the surrounding countryside, the same was not true of the more distant regions. In such areas the royal authority was very remote, and the power of the great landowners was virtually absolute. On their large, self-sufficient estates they dispensed justice in the manner of feudal lords, holding courts and imprisoning peons in their own jails, and raising and maintaining their own private armies. Sometimes these powerful individuals combined their de facto military and judicial power with an official title that made them representatives of the crown in their vicinities. The contrast between the nominal concentration of power in the central government and the effective supremacy of great landowners on the local level was a legacy of the colonial period to independent Latin America, and it still remains a characteristic of the political life of many Latin American republics.

SPAIN'S INDIAN POLICY

From the first days of the conquest the Spanish government faced a problem of defining its attitude toward the American natives (wrongly called Indians) and of determining what relations should exist between the conquerors and the conquered. The Indian question had several facets; the first and most urgent was to harmonize the demand of the conquistadors for cheap Indian labour—frequently employed in a wasteful and destructive manner—with the crown's interest in preserving a large tribute-paying Indian population. There was a political issue, too; the Spanish kings were determined to prevent a concentration of land and Indians in the hands of colonists that might lead to the rise of feudal lords independent of royal authority.

The church also had a major interest in the Indian problem. If the Indians died out, there would be no pagan souls to save, and the good name of the church would suffer. Moreover, the church largely relied on Indian labour for the construction and service of its churches and monasteries in the Indies. For these reasons the church, in general, sympathized with and aided crown efforts to protect the Indians against excessive exploitation.

The Spanish dispute over Indian policy quickly assumed the form of a struggle of ideas. Spanish thought of the 16th century was strongly scholastic in character, and jurists and theologians argued over such questions as the nature and cultural level of the Indians, whether they were a subhuman race who might properly be conquered and made to serve the Spaniards, and the rights and obligations the papal donation of America to the Spanish monarchs conferred upon them. Behind these disputations, however, was a struggle between the crown, the church, the colonists, and the Indians themselves over who should control Indian labour and tribute—the foundations of the Spanish Empire in America.

The *encomienda*

Española was the first testing ground of Spain's Indian policy. Eager to prove to the crown the value of his discoveries, Columbus compelled the natives to bring in a daily tribute of gold dust. Later, yielding to the demands of rebellious settlers, Columbus distributed the Indians among them, along with the right to use the forced labour of the natives. This temporary arrangement, formalized in the administration of Gov. Nicolás Ovando and sanctioned by the crown became the *encomienda*, which consisted of the assignment to a colonist of a group of Indians who were to serve him with tribute and labour, while he assumed the obligation of protecting his Indians, paying for the support of a parish priest, and helping to defend the colony. In practice the *encomienda* in the West Indies proved to be a hideous slavery that decimated the Indian population of Española.

The first protests against this state of affairs were made by a group of Dominican friars who arrived in Española in 1510. King Ferdinand responded to their agitation by approving a code of Spanish–Indian relations—the Laws of Burgos (1512–13). These laws contained detailed regulations prescribing good treatment of Indian labourers; but these provisions were not enforced, and they did little more than sanction and regularize the existing situation.

A former *encomendero,* Bartolomé de Las Casas, joined the struggle against enslavement and mistreatment of the Indians. Las Casas argued that the papal grant of America to the crown of Castile had been made solely for the purpose of conversion, and it gave the Spanish king no temporal power or possession in the Indies; the Indians had rightful possession of their lands by natural law and the law of nations; all Spanish wars and conquests in the New World were illegal. Las Casas' mature program called for the suppression of all *encomiendas,* liberation of the Indians from all forms of servitude except a small tribute to the crown in return for its gift of Christianity, and even the restoration of the ancient Indian states and rulers. Over these states the Spanish king would preside as "emperor over many kings" in order to fulfill his sacred mission of bringing the Indians to the Catholic faith and the Christian way of life. Las Casas' proposals seemed radical, but objectively they served the royal aim of preventing the rise of a powerful colonial feudalism in the New World. Not humanitarianism but self-interest explains the partial official support that Las Casas' reform efforts received during the reign of Charles V (ruled 1516–56).

The New Laws of the Indies

The climax of royal intervention came with the proclamation of the New Laws of the Indies (1542), which appeared to doom the *encomienda.* They prohibited the enslavement of Indians, ordered the release of Indian slaves to whom legal title could not be proved, barred compulsory personal service by the Indians, regulated tribute, and declared that existing *encomiendas* were to lapse on the death of the holder.

The New Laws provoked a great revolt in Peru; in New Spain they caused a storm of protest by the *encomenderos* and a large part of the clergy. Under this pressure the crown again retreated; it reaffirmed the laws forbidding Indian slavery and forced labour, but the right of inheritance by the heir of an *encomendero* was recognized and extended by stages to a third, fourth, and, sometimes, even a fifth life. Thereafter, or earlier in the absence of an heir, the *encomienda* reverted to the crown. In the natural course of events, the number of *encomiendas* steadily diminished and that of crown towns increased.

Meanwhile, the economic value of the *encomienda* to the colonists was declining. They had lost the right to demand labour from their tributaries (1549); they had also lost their fight to make the *encomienda* perpetual. The heaviest blow of all, however, was the catastrophic decline of the Indian population in the second half of the 16th century. In New Spain, according to recent calculations, the Indian population dropped from about 25,000,000 in 1519 to slightly over 1,000,000 in 1605. Disease, especially disease of European origin, against which the Indians had no acquired immunity, was the major immediate cause; but overwork, social disorganization, and loss of will to live were largely responsible for the terrible mortality associated with the great epidemics and even with epidemic-free years.

As the number of their tributaries fell and their income declined proportionately, many *encomenderos* and other Spaniards began to engage in the more lucrative pursuits of agriculture, stock raising, and mining. The decline of the Indian population, sharply reducing the flow of foodstuffs to Spanish cities and mining centres, stimulated a rapid growth of Spanish estates (haciendas), producing grain and meat.

The *repartimiento*

A new system, the *repartimiento*—under which all adult male Indians had to give a certain amount of their time in rotation throughout the year to work in Spanish mines and factories, on farms and ranches, and on public works—replaced the *encomienda.* The crown thus sought to regulate the use of an ever-diminishing pool of Indian labour. The Indians received a token wage for their work, but the *repartimiento* was also essentially a disguised slavery. In Peru, where great numbers of Indians were conscripted for labour in the silver mines of Potosí and in the Huancavelica mercury mine, the *repartimiento* (there known as the *mita*) was particularly disastrous.

The *repartimiento* did not provide a dependable and continuing supply of labour, and Spanish *hacendados* turned increasingly to the use of so-called free labour. From the first, such labour was closely associated with the system of debt peonage, which helped to bind and hold workers in a time of rapid population decline. The heavy weight of tribute and *repartimiento* burdens on the ever-diminishing native population, and the contraction of Indian communal lands as a result of Spanish encroachments, caused many Indians to become farm labourers working for wages, mostly paid in kind. An advance of money or goods bound the peon to work for his employer until the debt was paid, a miracle that rarely occurred. Despite its later evil reputation, peonage had some advantages for many Indians; it usually freed an Indian from the recurrent tribute and *repartimiento* burdens, and it often gave him a piece of land that he could work for himself and his family.

If the hacienda offered many Indians a means of escape from intolerable burdens, it aggravated the difficulties of those who remained on their ancestral lands. The hacienda expanded at the expense of the Indian pueblo, absorbing whole towns and leaving others without enough land for its people when the population decline ended in the first half of the 17th century and a slow recovery began. The hacienda lured labourers from the pueblo, making it difficult for the Indian town to meet its tribute and *repartimiento* obligations.

Debt servitude assumed its harshest form in the numerous workshops (*obrajes*), producing cloth and other goods, that developed in many areas in the 16th and 17th centuries. Convict labour, assigned to employers by Spanish judges, was early supplemented by the "free" labour of Indians, who were often lured into these workshops by an offer of liquor or a small sum of money. Once inside the gates, they were never let out again.

Black slavery

Side by side with the disguised slavery of *repartimiento* and debt servitude existed black slavery. For a variety of reasons—including the fact that Spaniards and Portuguese were accustomed to holding Muslim black slaves and the belief that blacks were better able to support the hardships of plantation labour—Spanish defenders of the Indian did not display the same zeal on behalf of the enslaved Africans. The rapid rise of sugarcane agriculture in the West Indies in the early 1500s brought an insistent demand for black slave labour to replace the vanishing Indian. There arose a lucrative slave trade, chiefly carried on by foreigners under a system of contract (*asiento*) between an individual or a company and the Spanish crown. The high cost of slaves limited their use to the more profitable plantation cultures or to domestic servitude in the homes of the wealthy.

A small class of genuinely free, paid workers also came into existence at an early date; it included resident and migrant farm workers, miners, unskilled urban labourers, and skilled workers who practiced their trades in the Spanish towns, sometimes as journeymen, in Spanish-controlled guilds from which Indians, mestizos (persons of mixed Indian and European ancestry) and mulattoes were excluded as masters. Except for skilled workers, wages tended to remain at the subsistence level throughout the colonial period.

SPAIN'S COLONIAL ECONOMY

The conquest disrupted the traditional economy of the Indians and transformed the character and tempo of Indian economic activity. When the frenzied scramble for treasure had exhausted the available gold and silver objects, the *encomienda* became the principal instrument for extracting wealth from the vanquished. The Aztec and Inca peoples were accustomed to paying tribute to their rulers and nobility, but the Spaniards' demands were unlimited. Driven by visions of infinite wealth, the Spaniards exploited the Indians mercilessly.

Spanish colonial agriculture

As noted above, the Indian population decline, causing acute food shortages in the Spanish towns, created new economic opportunities for Spanish farmers and ranchers; moreover, it left vacant large expanses of land, which Spanish colonists occupied for wheat raising or as sheep and cattle ranges. By the end of the 16th century the Spanish-owned haciendas produced the bulk of agricultural commercial production and pressed ever more aggressively on the shrinking Indian sector of the colonial economy. The establishment of an entail (*mayorazgo*) assured perpetuation of the consolidated property in the hands of the owner's descendants.

Spanish colonial agriculture early produced wheat on a large scale for sale in such urban centres as Mexico City, Lima, Veracruz, and Cartagena, and maize, for the large Indian consumers' markets in Mexico City, Lima, and other cities. Sugar was brought from the Canary Islands to Española and became the foundation of the island's prosperity. From the West Indies, sugar quickly spread to Mexico and Peru. Sugar refining, with its large capital outlays for equipment and Negro slaves, was the largest scale enterprise in the Indies.

Wine and olives as well as sugar were produced in quantity in the irrigated coastal valleys of Peru. The silk industry flourished briefly in Mexico, but it soon declined because of labour shortages and competition from Chinese silk brought from the Philippines to the port of Acapulco. Other products cultivated by colonists on a capitalist plantation basis were tobacco, cacao, and indigo. Cochineal, a blood-red dye, was a unique Mexican and Central American export highly valued by the European cloth industry.

Spain enriched American economic life by introducing various domestic animals—chickens, mules, horses, cattle, pigs, and sheep. The mules and horses revolutionized transport, and the cattle and smaller domesticated animals greatly enlarged the continent's food resources, while providing hides for export to Spain and other European centres of leather manufacture, and hides and tallow for the domestic market, especially in mining areas. Sheep raisers found a large wool market in the textile factories that arose in many parts of the colonies.

In populous central Mexico, cattle trampled the Indian crops, causing untold damage, and the close grazing of sheep caused massive erosion by torrential rain on the slopes of valleys. By the end of the 16th century, however, the Mexican cattle industry had become stabilized; the exhaustion of virgin pasture lands, the mass slaughter of cattle for their hides and tallow, and the official efforts to halt grazing on Indian harvest lands, greatly reduced the herds. Gradually, the cattle ranches and sheep herds moved from the densely settled south and central areas to new permanent grazing grounds in the semiarid north.

A rapid increase of horses, mules, and cattle also took place in the empty grasslands (pampas) of the Río de la Plata, modern Argentina. The inhabitants of this area, forbidden to trade directly with the outside world and lacking precious metals or abundant Indian labour, traded illegally with Dutch and other foreign traders, who carried their hides and tallow to Europe; they also sent mules and horses, hides and tallow, to the mining regions of Upper Peru (Bolivia). Another centre of the cattle industry was the West Indies.

Mining

Mining, as the principal source of royal revenue in the form of the royal fifth (*quinto*) of all gold, silver, or other precious metals obtained in the Indies, received the crown's special attention and protection. Silver was the principal mining product. The great silver mine of Potosí in Upper Peru was discovered in 1545 and produced enormous quantities of the metal between 1579 and 1635; the rich Mexican silver mines of Zacatecas and Guanajuato were opened up in 1548 and 1558, respectively. The introduction of the patio process for separating the silver from the ore with mercury (1556) gave a great stimulus to silver mining. In the same period, important gold placers were found in central Chile and in the interior of New Granada (Colombia). The mining industry brought prosperity to a few and failure to the great majority.

Inefficient production methods, lack of capital to finance technological improvements, flooding, and similar problems, led to a sharp decline of silver production from about 1630 to the end of the century. This mining crisis depressed trade with Europe, since silver was the most important export item in Spanish America's balance of trade, and also had an adverse effect on internal commerce. Colonial agriculture and stock raising, which had expanded to satisfy the demand of the mining centres for grain, meat, hides, tallow, and work animals, also suffered.

Throughout the colonial period the majority of the natives continued, as before the Conquest, to supply their own needs for pottery, clothing, and other household goods. In the Spanish towns craft guilds, modelled on those of Spain, arose in response to the high prices for all Spanish imported goods. These guilds maintained control over the quantity and quality of production in luxury industries serving the needs of the colonial upper class. The 17th century saw a rapid growth of *obrajes,* many of which produced cheap cotton and wool goods for popular consumption. Most were privately owned, but some were operated by Indian communities to meet their tribute payments. Other primitive factories produced such items as soap, chinaware, and leather. A 17th-century depression, restricting colonial capacity to purchase imports, promoted this growth of colonial industry.

COMMERCE, SMUGGLING, AND PIRACY

Colonial trade

Control over all colonial trade, under the Royal Council of the Indies, was vested in the Casa de Contratación (House of Trade), established in 1503 in Seville. Commerce with the colonies was restricted until the 18th century to the wealthier merchants of Seville and Cádiz, who were organized in a guild that exercised great influence in all matters relating to colonial trade. Trade was concentrated in the three American ports—Veracruz in New Spain, Cartagena in New Granada, and Nombre de Dios (later Portobelo) on the Isthmus of Panama. The Seville merchant oligarchy and related merchant groups in the Indies (particularly the merchant guilds at Mexico City and Lima) deliberately kept the colonial markets understocked and in general played into each other's hands at the expense of the colonists, who were forced to pay exorbitant prices for all European goods acquired legally. Inevitably, the system generated colonial discontent and stimulated the growth of contraband trade.

To enforce a closed-port policy and protect merchant vessels against foreign attack, an elaborate fleet system was developed in the 16th century to convoy ships between American ports and to and from Spain. In the 17th century, as a result of Spain's economic decline and growing contraband trade, the fleet sailings became increasingly irregular.

Spanish industry, handicapped by its guild organization and technical backwardness, could not supply the colonies with cheap and abundant manufactures in return for colonial foodstuffs and raw materials. Prices to the colonial consumer also were raised by a multitude of taxes. As a result, the more advanced industrial nations of northern Europe sought to break into the large and unsatisfied Spanish-American markets, rejecting Spain's claim of domination over all the Western Hemisphere except the portion that belonged to Portugal. The foreign challenge to Spain's monopoly assumed the forms of smuggling, piracy, and colonization, as well as efforts to seize and occupy portions of the Indies.

Foreign challenge to Spain

England, under Queen Elizabeth, emerged as the principal threat to Spain's empire in America. Sir John Hawkins' slave-trading voyage to the West Indies in 1562 opened the English drive to penetrate the Spanish-American market and culminated in the near destruction of Hawkins' trading fleet by a Spanish naval force at Veracruz in 1568. English voyages of reprisal followed; they included the expedition of Francis Drake (1577), undertaken with the secret sponsorship and support of Queen Elizabeth, whose objects were to seize Spanish treasure ships, ravage Spanish colonial towns, and display English maritime prowess through a second circumnavigation of the globe.

In the 17th century foreign piracy and smuggling were supplemented by efforts to found colonies not only on the American mainland but in the Caribbean. The Dutch, at war with Spain with brief intervals since 1576, launched a military and commercial offensive against the Spanish West Indies; their principal instrument was the Dutch West India Company, organized in 1621. The Dutch captured the whole homebound Veracruz treasure fleet off the coast of Cuba in 1628. Capture of Curaçao, hard off the coast of Venezuela (1634), gave the Dutch an invaluable smuggling base and emboldened the French and English to seize both unoccupied and occupied Spanish islands—Barbados and St. Christopher, Martinique and Guadeloupe. In 1655 an English fleet, defeated in an effort to capture Santo Domingo, easily captured Jamaica. In the same period French corsairs began to settle the northwest corner of Española, virtually abandoned by Spaniards since 1605; by 1655 this region had become the French colony of Saint-Domingue, with a governor appointed by the trading Compagnie des Indes.

In this period piracy in the West Indies became a highly organized and large-scale activity often enjoying the open or covert protection of the English governors of Jamaica and the French governors of Saint-Domingue. Piracy entered a decline following the Treaty of Madrid (1670) between England and Spain, by which the British government agreed to aid in suppression of the corsairs in return for Spanish recognition of its sovereignty over the British West Indian islands. French buccaneers, however, continued activity until the Treaty of Rijswijk (1697), by which Spain formally recognized French possession of Saint-Domingue.

Smuggling

Pirates and privateers, however, inflicted fewer losses on Spain than those caused by foreign smugglers. Contraband trade steadily increased in the 16th and 17th centuries; and the European establishments in Jamaica, Saint-Domingue, and the lesser Antilles became bases for contraband trade with the Spanish colonies. Buenos Aires was another funnel through which Dutch and other foreign traders poured immense quantities of goods that penetrated as far as Peru. Smuggling flourished even at Seville and Cádiz where, by the end of the 17th century, French companies operating behind the facades of Spanish merchant houses dominated the legal trade with the Indies.

Spanish economists of the 17th century understood the principal cause of Spain's plight: its economic weakness. They offered sound criticisms and constructive proposals for reform. But they were powerless to change the course of Spanish policy, dictated by small mercantile and aristocratic cliques whose special interests and privileges were incompatible with the cause of reform.

THE CHURCH IN SPANISH AMERICA

Royal control over church affairs, in both Spain and the Indies, was founded on the institution of royal patronage (the *patronato real*). Under diplomatic pressure from King Ferdinand, in 1508 Pope Julius II accorded to Spain's rulers the exclusive right to nominate all Church officials, collect tithes, and found churches and convents in America, ostensibly to assist them in the work of converting New World pagans.

The missions. Beginning with Columbus' second voyage, one or more clergymen accompanied every expedition that sailed for the Indies; and they came in growing numbers to the conquered territories. The friars who came to America in the first decades after the Conquest were, in general, an elite group. The products of a revival of asceticism and discipline in the medieval church, and especially of a reform movement, this vanguard group frequently combined with missionary zeal a sensitive social conscience and love of learning.

Conversion of Indians

The friars converted prodigious numbers of natives. In Mexico, the Franciscans claimed to have converted more than 1,000,000 by 1531; when persuasion failed, pressures of various kinds, including force, were used to obtain conversions. (To facilitate the missionary effort the friars studied the native languages and wrote grammars and vocabularies. Scholars devoted themselves to preserving and recording the history, religion, and customs of the ancient Indian peoples.) The work of conversion was less than wholly successful. The result of the missionary effort was generally a fusion of pagan and Christian religious ideas. To this day Indians in such lands as Guatemala and Peru continue to perform rites dating from the time of the Maya and the Inca.

The clergy had to battle not only the Indian tendency toward backsliding but also divisions within their own ranks. A serious conflict was waged during the 16th century between the secular and the regular clergy. Finally, a royal decree of 1583 stated the principle that secular clergy were to be preferred over friars in all appointments to parishes. From first to last, however, the colonies were a scene of strife between groups of clergy over their fields of jurisdiction.

A gradual loss of sense of mission and of morale among the regular clergy also contributed to the decline of their intellectual and moral influence. By the late 16th century there were frequent complaints against the church's excessive number of convents and growing wealth. The principal sources of this wealth were legacies and other gifts from rich donors; invested in land and mortgages, it brought in more wealth. The last important order to arrive in Spanish America, the Society of Jesus (1572), had the largest number of rich benefactors and the most efficient administration.

Material wealth

Inevitably, this concern with material wealth weakened the ties between the clergy and the Indian and mixed-blood masses. Hand in hand with a growing materialism went an increasing laxity of morals (except among the Jesuits); concubinage became so common among the clergy of the later colonial period that it seems to have attracted little official notice or rebuke.

The missionary impulse of the first friars survived longest on the frontier, "the rim of Christendom." Franciscans first penetrated the great northern interior of New Spain; they also accompanied the Juan de Oñate expedition of 1598 into what is now New Mexico and dominated the mission field there until the end of the colonial period; and they were also found in such distant outposts of Spanish power as what are now Florida and Georgia. The early Jesuits worked among the Indians of California, were active in converting and pacifying the tough Chichimec Indians of the north central plateau of Mexico and had exclusive charge of the conversion of the Indian tribes of the northwest coast of Mexico. Following the expulsion of the Jesuits from the Indies in 1767, the Franciscans replaced them in directing missionary work in California.

The mission was one of three closely linked institutions—the other two being the presidio, or garrison, and the civil settlement—designed to serve the ends of Spanish imperial expansion and defense on the northern frontier. This three-pronged attack on the frontier was not very successful. Certain tribes on the northern frontier, such as the Apache of Arizona, New Mexico, and Texas and the Comanche of Texas, never were reduced to mission life. The missionaries had greater success among such sedentary tribes as the Pueblo Indians of New Mexico; but even among these peaceful tribes, Indian revolts and desertions were frequent. In 1680 the supposedly Christianized Pueblo Indians revolted, slaughtered the friars, and maintained a decade of tenacious resistance to Spanish efforts at reconquest. The civil settlements were no more successful. By the end of the colonial period there were only a few scattered towns on the northern frontier, and continuous Indian raids made life and property insecure. Ultimately, the whole task of defending and civilizing the frontier fell on a chain of presidios stretching approximately along the present border between the United States and Mexico. In the end Spain was forced to adopt a policy of neutralizing the Apache and Comanche by the periodic distribution of gifts to these warlike tribes. When the outbreak of the Wars of Independence stopped the flow of gifts, the hostile Indians drove through the useless line of presidios into the interior of Mexico.

The Jesuits in Paraguay. The most successful missionary effort, at least from an economic point of view, was that of the Jesuit establishment in Paraguay, which included more than 30 missions or reductions; these formed the principal field of Jesuit activity in America. Their strict discipline, centralized organization, and absolute control over the labour of thousands of docile Indians producing cotton, tobacco, hides, and other products enabled the Jesuits to make their missions a highly profitable business enterprise. Every effort was made to limit contact with the outside world. The life of the Indians was rigidly regimented in dress, housing, and the routines of work, play, and rest. Jesuit mission activity in the colonies ended as a result of a royal decree (1767) ordering the expulsion of the order from the colonies. Motives for this action included the conflict between the nationalistic church policy of the Bourbons and Jesuit emphasis on papal supremacy, suspicion of Jesuit meddling in state affairs, and belief that the Jesuit mission system constituted a state within a state.

Expulsion of the Jesuits

The Inquisition. The Inquisition formally entered the Indies with the establishment by Philip II of tribunals of the Holy Office at Mexico and Lima in 1569. Before that time its functions were performed by clergy who were vested with or assumed inquisitorial powers. Its great privileges, its independence of other courts, and the dread with which Spaniards generally regarded the charge of heresy made the Inquisition an effective check on "dangerous thoughts," whether religious, political, or philosophical. Most of the cases tried by its tribunals, however, dealt with offenses against morality or with such minor deviations from orthodox religious conduct as blasphemy. Like the Spanish Inquisition, the Inquisition in the Indies relied largely on denunciations by informers and employed torture to secure confessions. Indians were originally subject to the jurisdiction of Inquisitors but were later exempted because as recent converts of supposedly limited mental capacity they were not fully responsible for their deviations from the faith.

COLONIAL BRAZIL

Brazil's existence was unknown when the Treaty of Tordesillas of 1494, between Spain and Portugal, assigned to Portugal a large stretch of the South American coastline. In 1500 Pedro Álvares Cabral, who had been sent with a large fleet to India, was driven far off his course and touched on the Brazilian coast. Cabral claimed the land for Portugal and sent a report of his discovery to the king. Portugal's limited resources, already committed to exploitation of the wealth of Africa and the Far East, made impossible full-scale colonization of Brazil. But the presence of a valuable dyewood (brazilwood) attracted merchant capitalists, who obtained concessions to engage in the brazilwood trade with the Indians. A few settlers—some castaways, others *degredados* (criminals exiled from Portugal to distant parts of the empire)—arrived and were often well received by the local Indians.

In 1503 the Portuguese crown awarded Fernão de Noronha, a converted Jewish nobleman and merchant, a concession to cut brazilwood for three years. In time, settlements near the sites of modern Recife and Salvador were founded, an agricultural base was established, and numbers of Jews newly converted to Christianity emigrated to Brazil to escape the Inquisition's surveillance.

Both Noronha and the Portuguese crown profited from the arrangement, but incursions by Spaniards, Englishmen, and particularly Frenchmen dictated the necessity of defense by the mother country. Cristóvão Jaques in 1516 destroyed a French fleet leaving Brazil and established a trading post in what would later be the captaincy (now state) of Pernambuco; this post began the first cultivation of sugarcane in Brazil in 1521. Jaques' settlement was destroyed by the French in 1530. The Portuguese crown was then forced to reconsider its Brazilian policy. Towns and villages were growing in the harbours and islands along the coast; the gestation period was clearly over. Portugal then needed an aggressive policy to secure Brazil and prepare for further expansion.

In 1530 Martim Afonso de Sousa was sent with a fleet to drive out the French, to set up new settlements and administrative systems, and to recommend a form of colonization adapted to Brazil's needs. He carried out his assignment in excellent order: he established Portuguese claims to northern Brazil and founded settlements near Bahia (modern Salvador), Rio de Janeiro, and present-day Santos, the latter destined to become the entryway to the rich province of São Paulo. Brazil's new government, however, was set up before Martim Afonso returned to Lisbon.

Colonization. Portugal's heavy commitments in the spice-rich East forced its kings to assign to private individuals major responsibility for colonization of Brazil. In 1533, John III divided the Brazilian coastline into 15 parallel strips extending inland to the uncertain line of Tordesillas. These strips were granted as hereditary captaincies to a dozen individuals, each of whom agreed to colonize, develop, and defend his captaincy or captaincies at his own expense. The captaincy system represented a fusion of feudal and capitalist elements. The grantee was both a vassal owing allegiance to his suzerain, the king, and an entrepreneur who hoped to derive large profits from his estates and from taxes obtained from colonists to whom he gave land. These were large grants of land to an individual (called a *donatário*) endowed with ample economic and political privileges in return for his pledge to secure colonists and develop his grant. Along with tax exemptions and certain monopolistic privileges, they were given the right to enslave Indians for their estates and sell a certain number in Portugal each year. The *donatários* laboured hard at peopling and developing their grants; many sold or mortgaged their property in Portugal and moved to Brazil. Enormous sums of money were spent in transporting families and opening new agricultural districts. Few of the captaincies proved successful because few grantees possessed the capital and administrative ability required to attract settlers and defend against Indian attacks and foreign intruders. Only the captaincies at Olinda (that of Pernambuco) and São Vicente (near modern Santos) were financial successes, but the primary objective of securing the coast with permanent colonies was achieved. To supply the needed unity, John III named Tomé de Sousa a captain general in 1549 to head a central government. He founded the city of Bahia as his capital and it was an immediate success. Six Jesuits accompanied Sousa and became the forerunners of a most influential group in the new country.

Hereditary captaincies

Peopling Brazil was a difficult task. Forests taxed the strength of the most ambitious and with the stubborn Indian resistance, one *donatário* was moved to write the king: "The land you granted us in leagues we have had to conquer in inches." But the restless Brazilian frontiersmen continued to push north and south, as well as westward. The 17th century witnessed a tremendous burst of activity as the northern edge of the Brazilian bulge was settled to eliminate French and Dutch interlopers and Manaus, a thousand miles up the Amazon, was first settled in 1660. At the same time a wave of settlement moved up the Rio São Francisco as the Indians were driven out and cattle ranchers moved in. A third area of expansion was São Paulo in the south. Cut off by an escarpment from the coast where São Vicente cultivated sugar, São Paulo, on the plateau, found wealth by taking advantage of its position of easy access to the interior. Large slaving expeditions from São Paulo filled the demand for slaves with Indians when the African supply of blacks was insufficient. These expeditions, whose members were called *bandeirantes* (from a word meaning "banner" or "military company"), penetrated as far west as Paraguay, raiding the Jesuit missions and forcing the fathers to move west. Attempts by Portuguese Jesuits to control slavery proved unavailing, and the order in Brazil even had black slaves of its own. It was due to the activities of the *bandeirantes* that Brazil was able to claim its present southwestern boundaries far to the west of the line of demarcation. By the 1740s settlements extended as far south as Rio Grande do Sul, and by the 1780s as far west as the present Brazilian border. Of particular importance was the founding of Tabatinga (1780) on the upper Amazon which fixed Brazil's claims there. Black slaves were of prime importance, and by the end of the colonial period, they numbered about 1,000,000, constituting the backbone of plantation labour. Brazilian blacks were not always docile. Several large revolts and the setting up in the jungle of slave kingdoms called *quilombos* (one had 20,000 people) marked the colonial era. *Bandeirantes* made excellent slave catchers and broke up the runaways' *quilombos*.

Slave hunters. By the mid-16th century sugar had replaced brazilwood as the foundation of the Brazilian economy. Favoured by its soil and climate, the Northeast (now the states of Pernambuco and Bahia) became the seat of a sugarcane civilization featured by the large estates (*fazendas*), monoculture, and slave labour. The problem of labour was first met by raids on Indian villages, but Indian labour was unsatisfactory because the natives worked poorly and offered resistance ranging from attempts at flight to suicide. After 1550, planters turned increasingly to the use of black slave labour imported from Africa; but the supply of black slaves was often cut off or sharply reduced by the activity of Dutch pirates and other foreign foes, and the services of Brazilian slave hunters were in large demand throughout the colonial period. The most celebrated slave hunters were the *bandeirantes* from the upland settlement of São Paulo; often part Indian, they made slave raiding in the interior their principal occupation. As the Indians near the coast dwindled in numbers or fled before the invaders, the *bandeirantes* pushed ever deeper southward and westward, expanding Brazil's frontiers in the process.

Jesuit missionaries were the first to protest the enslavement and mistreatment of the Indians. The Jesuit program for the settlement of their Indian converts in *aldeas* ("villages"), where they would live under the tutelage of the priests, provoked the slave hunters and the planters. The Portuguese crown pursued for two centuries a policy of compromise that satisfied neither Jesuits nor planters. A decisive turn came in the mid-18th century under the Marques de Pombal, the foreign minister and later prime minister of José I, who, in 1759, expelled the Jesuits from Portugal and Brazil and secularized their missions. Pombal forbade Indian raids and enslavement and thus accepted the Jesuit thesis of Indian freedom; but, unlike the Jesuits, his policy did not segregate the Indians from the Portuguese community; it made them available as paid workers by the colonists, and it encouraged mingling between the two races. Meanwhile, the growth of the African slave trade, also encouraged by Pombal, reduced the demand for Indian labour and this brought a greater measure of peace to the Indians.

Rivals to the Portuguese. The dyewood, sugar, and tobacco of Brazil early attracted foreign powers. The French made sporadic efforts to entrench themselves on the coast, and, in 1555, they founded Rio de Janeiro as the capital of what they called La France Antarctique (Antarctic France). But French colonization in Brazil was weakened by Catholic–Huguenot strife at home, and, in 1567, the Portuguese ousted the French and occupied Rio de Janeiro.

French and Dutch incursions

Portugal itself fell under Spanish rule in 1580 when Philip II seized the vacant throne. Brazil was a fine addition to Philip's empire: its 17,000 Europeans controlled about an equal number of Indians and black labourers, who turned out 180,000 arrobas (one arroba = 25.36 pounds) of sugar a year. In Bahia alone there were more than 100 citizens with fortunes of $100,000 in modern purchasing power. Twenty years later the population was estimated at 25,000 whites, 18,000 Indians, and 14,000 black slaves and the capital investment at $22,000,000. Philip left Brazilian affairs in Portuguese hands; the Brazilians used their opportunity to push westward across the line of demarcation and trade with the Spanish colonies.

The Dutch posed a more serious threat to Portuguese sovereignty over Brazil. The Dutch West India Company seized and occupied (1630–54) the richest sugar-growing portions of the Brazilian coast. Ultimately, weakened by tenacious Brazilian resistance and a simultaneous struggle with England, the Dutch withdrew, taking their capital and the lessons they had learned in the production of sugar and tobacco and transferring both to the West Indies. Thus the Caribbean islands were soon competing with Brazilian sugar in the world market, with a resulting fall of prices, and by the end of the 16th century the Brazilian sugar industry was on the point of collapse.

Shift to the south. The discovery of gold (1690) in the southwestern region opened a new economic cycle and began a major shift of Brazil's economic and political centre from north to south. Large numbers of colonists from the Northeast, accompanied by their slaves and servants, swarmed into the mining area, causing an acute shortage of field hands in the older regions, which continued until the gold boom had run its course by the mid-18th century. In 1709 the mining region was elevated to the status of a captaincy, with the name Minas Gerais. A few years later, in 1729, came the discovery that certain stones in the area, hitherto thought to be crystals, were really diamonds; and many adventurers turned from gold to diamond washing.

By 1750 the river gold washings of Minas Gerais were nearly exhausted; the diamond district also suffered a progressive exhaustion of deposits. But the mineral cycle left a permanent mark in the form of new settlements in the southwest, not only in Minas Gerais but in what later became the provinces of Goiás and Mato Grosso—Brazil's far west. The mining decline also spurred efforts to promote the agricultural and pastoral wealth of the region. The southward movement of population and economic activity was formally recognized in 1763 when Rio de Janeiro became the seat of the viceregal capital.

Meanwhile, the Northeast experienced a partial revival based on increasing European demand for sugar, cotton, and other semitropical products. Brazilian cotton production made significant advances between 1750 and 1800, but then declined rapidly because of competition from the more efficient cotton growers of the United States. The beginnings of the coffee industry also date from the late colonial period.

The cattle industry

Cattle raising contributed to the advance of the Brazilian frontier and to the growing importance of the south. The intensive commercial agriculture of the coast and the concentration of population in such coastal cities as Baía and Recife created a demand for meat that gave an initial impulse to cattle raising. Because the expansion of plantation agriculture in the coastal zone did not leave enough land for grazing, the cattle industry had to move inland; and by the second half of the 17th century the penetration of the San Francisco Valley was well under way. Powerful cattlemen, with their herds, their *vaqueiros* ("cowboys"), and their slaves, entered the backcountry; drove out the Indians; and established fortified ranches and villages for their retainers. The cattle industry later expanded to the extreme southern region of Rio Grande do Sul, colonized by the government to defend against Spanish expansionist designs. The cattle industry provided meat for the coastal cities and mining camps, draft animals for the plantations, and hides for export to Europe.

Trade. During the Portuguese union with Spain (1580–1640), Brazil's commerce was restricted to Portuguese nationals and ships. The Dutch, who had been the principal carriers of Brazilian sugar and tobacco to European markets, responded with extensive smuggling and with a direct attack on the sugar-growing northeast. Following its successful revolt against Spain, Portugal made a trade treaty with England whereby British merchants were permitted to trade between Portuguese and Brazilian ports. English ships, however, frequently neglected the formality of touching at Lisbon and plied a direct trade with the colony. Because Portuguese industry was incapable of supplying the colonists with the requisite quantity and quality of manufactured goods, England provided cargoes of textiles and other manufactures. The decree of free trade of 1808, issued by Prince John following the flight of the Portuguese royal family from Portugal to Brazil after French invasion of his country, only confirmed the virtual English monopoly of trade with Brazil.

Government and church. The donatory system of government soon proved unsatisfactory, because few donatories could cope with the tasks of defense and colonization they had assumed. A governmental reform followed. In 1549 Tomé de Sousa was sent out as governor general to head a central colonial administration for Brazil; and Bahía, situated about midway between the flourishing settlements of Recife and São Vicente, became his capital. Gradually the hereditary rights and privileges of the donees were absorbed by governors appointed by the king. As the colony expanded, new captaincies were created. In 1763, as noted above, the governor of Rio de Janeiro replaced his colleague at Bahía as head of the colonial administration with the title of viceroy. In practice, however, his authority over the other governors was negligible.

Colonial administration

During the period of Spanish–Portuguese union their colonial policies were aligned by the creation, in 1604, of the Conselho da India, whose functions resembled those of the Spanish Council of the Indies. In 1736 a newly created ministry of Marinha e Ultramar (marine and overseas) assumed the functions of the Conselho; under the king, this body framed laws for Brazil, appointed governors, and supervised their conduct. The governor or viceroy combined in himself military, administrative, and even some judicial duties. His power tended to be absolute but was tempered by the constant intervention of the home government, which bound him with precise, strict, and detailed instructions; by the counterweights of other authorities, especially the high courts (*relações*), which were both administrative and judicial bodies; and the existence of special administrative organs, such as the intendencies created in the gold and diamond districts, which were completely independent of the governor. His authority was also diminished by the vastness of the country, the scattered population, the lack of social stability, and the existence of enormous landholdings in which the feudal power of great planters and cattle barons was virtually unchallenged.

The Senado de Camara, or municipal council, was the most important institution of local government. Elected either by a restricted property-owning electorate or chosen by the crown, its membership represented the ruling class of planters, merchants, and professional men; its authority was limited by frequent intervention of the royal judge (*ouvidor*), who usually combined his judicial functions with the administrative duties of *corregidor.* Generally speaking, the greater the size and wealth of the city, and the farther it was from the viceregal capital, the greater were its powers.

The evils of Spanish colonial administration—inefficiency, bureaucratic attitudes, slowness, and corruption—were also prominent in the Portuguese colonial system. In vast areas of the colony, however, administration and courts were virtually nonexistent. Outside the few large towns, local government often meant the rule of great landowners, for it was from their ranks that royal governors invariably appointed the *capitães môres,* or district militia officers. With unlimited power to enlist, command, arrest, and punish, the *capitão môr* became a symbol of despotism and oppression. (The feudalism that still dominates the Brazilian backcountry can be traced to these colonial origins.)

Some improvement, at least on the higher levels of administration, took place in the 18th century under Pombal, who abolished the remaining hereditary captaincies, reduced the special privileges of the municipalities, and increased the power of the viceroy. He sought to promote the economic advance of Brazil in order to rehabilitate Portugal, whose state was truly forlorn.

Church affairs

In Brazil, as in the Spanish colonies, church and state were intimately united. By comparison with the Spanish monarchs, however, the Portuguese kings were almost niggardly in their dealings with the church; but their control over its affairs, exercised through the *padroado*—the ecclesiastical patronage granted by the pope to the Portuguese king in his realms—was as absolute. Rome, however, maintained a strong indirect influence through the Jesuits, who were very influential in the Portuguese court until expelled from Portugal and Brazil in 1759.

With some honourable exceptions, notably that of the Jesuits, the tone of clerical morality and conduct in Brazil was low. The clergy provided such educational and humanitarian establishments as existed in the colony; and from its ranks—which were open to talents and even admitted indivduals of mixed blood, despite the formal requirement of a special dispensation—came most of the distinguished names in Brazilian colonial science, learning, and literature.

Masters and slaves. Race mixture played a decisive role in the formation of the Brazilian people. The scarcity of white women, the freedom of the Portuguese from puritanical attitudes, and the despotic power of great planters over Indian and black slave women, all gave impetus to miscegenation. Of the three possible combinations—white–black, white–Indian, black–Indian—the first was most common.

In principle, and to a considerable degree in practice, colour lines were strictly drawn. But the enormous number of mixed unions and the resulting large progeny, some of whom were regarded with affection by white fathers and provided with some education and property, inevitably led to some blurring of colour lines and to a fairly frequent phenomenon of "passing," with a tendency to classify individuals racially, if their colour was not too dark, on the basis of social and economic position rather than by physical appearance.

Slavery in Brazil

Slavery played as important a role in Brazil's organization as did race mixture in its ethnic make-up. Slavery corrupted both master and slave, festered harmful attitudes toward the dignity of labour, and retarded the nation's economic development. The virtual monopoly of labour by slaves sharply limited the number of socially acceptable occupations in which whites or free mixed bloods could engage. This gave rise to a large class of vagrants, beggars, "poor whites," and other degraded elements who would not or could not compete with slaves in agriculture and industry. Given the lack of incentive to work on the part of the slave, the level of efficiency and productivity of his labour was very low.

The 20th-century Brazilian sociologist Gilberto Freyre has emphasized the patriarchal relations between masters and slaves in the sugar plantation society of the Northeast. But the slaves described by Freyre were usually house slaves, who occupied a privileged position and whose situation was different from that of the great majority of slaves, who worked on the sugar and tobacco plantations of Bahía and Pernambuco. A royal dispatch of 1700 denounced the barbarity with which owners of both sexes treated their slaves. The very low rate of reproduction among slaves and frequent suicides speak eloquently about their condition; many slaves ran away and formed *quilombos* (settlements of fugitive slaves) in the bush. The most famous of these was the so-called republic of Palmares, whose destruction required a major military campaign in the 17th century.

The nucleus of Brazilian social and economic organization was the *fazenda,* based on black slavery and centred about the *casa grande* (the "big house"); it constituted a patriarchal community that included the owner and his family, his chaplain and overseers, his slaves, his sharecroppers (*obrigados*), and his *agregados,* or retainers. The system implied relations of mutual aid and a paternalistic interest in the welfare of the landowner's people; but it did not exclude intense exploitation of those people or the display of the most ferocious cruelty if they should dispute his absolute power.

Planter aristocracy

In the sugar-growing northeast, the great planters became a distinct aristocratic class. Most colonial towns were mere appendages of the countryside, dominated politically and socially by the rural magnates. These men often left supervision of their estates to majordomos and overseers, preferring to live in the cities. In the cities lived other social groups that disputed or shared power with the great landowners: high officials of the colonial administration; dignitaries of the church; wealthy professional men, especially lawyers; and merchants, usually European-born, who monopolized the export–import trade and financed the industry of the planters. The conflict between native-born landowners and European-born merchants, aggravated by nationalist resentment of upstart immigrants, sometimes led to armed struggle. An illustration is the War of the Mascates (1710–11) between Olinda, provincial capital of Pernambuco, dominated by the sugar planters, and its neighbouring seaport of Recife, controlled by the merchants.

THE BOURBON REFORMS AND SPANISH AMERICA

Reforms. After the War of the Spanish Succession (1702–13), Spain was left with a more manageable, more truly Spanish, empire consisting of the kingdom of Castile and Aragon, and the Indies, and then turned its attention to implementing a program of reform. The ensuing revival of Spain is associated with three princes of the House of Bourbon—Philip V (ruled 1700–46) and his two sons, Ferdinand VI (ruled 1746–59) and Charles III (ruled 1759–88). The work of national reconstruction reached its climax under Charles III, who attempted to revive Spanish industry and agriculture.

The outbreak of the French Revolution, which followed by a few months the death of Charles III in December 1788, brought the reform era effectively to a halt. Frightened by the overthrow of the French monarchy, Charles IV and his ministers turned sharply to the right; the leading reformers were banished or imprisoned, and the importation of French rationalist and revolutionary literature was forbidden. Yet the clock could not be entirely turned back, either in Spain or its colonies. Under Charles IV, for example, an expedition sailed from Spain (1803) to carry the procedure of vaccination to the Spanish dominions in America and Asia.

With colonial reform the Bourbons moved slowly and cautiously, because of the powerful vested interests identified with the status quo. There was no intention of giving more self-government to the colonists or of permitting them to trade more freely with the non-Spanish world. On the contrary, the Bourbons centralized colonial administration still further, with a view to making it more efficient, and their commercial reforms were designed to diminish smuggling and strengthen the exclusive commercial ties between Spain and its colonies.

Commercial and administrative reforms

Under the first Bourbons, efforts were made to check smuggling in the Caribbean by the use of *guardacostas,* which prowled the main lanes of trade in search of ships loaded with contraband. The depredations of these *guardacostas* led to English demands for compensation and finally to war between England and Spain in 1739.

The first Bourbons made few changes in the administrative structure of colonial government, contenting themselves with efforts to improve the quality of administration by more careful selection of officeholders. One major reorganization was the separation of the northern Andean region (present-day Ecuador, Colombia, and Venezuela) from the viceroyalty of Peru and its elevation to the status of a new viceroyalty, named New Granada, with its capital at Santa Fé (modern Bogotá). This change reflected a desire to provide better protection for the Caribbean coast and especially the fortress of Cartagena; it also reflected the rapid growth of population in the central highlands of Colombia. Within the new viceroyalty, Venezuela was named a captaincy general, with its capital at Caracas and virtually independent of Santa Fé.

Colonial reform, like domestic reform, reached its peak under Charles III. In 1765 commerce with the West Indies was thrown open to seven ports besides Cádiz and Seville; this, coming at a time when Cuban sugar production was beginning to expand, stimulated the island's economy.

This privilege was extended to other regions until, by a decree of free trade of 1778, commerce was permitted between all qualified Spanish ports and all the American provinces except Mexico and Venezuela, which were opened to trade on the same terms in 1789. Restrictions on intercolonial trade were also progressively lifted, but this trade was largely limited to non-European products. A major beneficiary of this was the Río de la Plata area, which, in 1776, was opened to trade with the rest of the Indies. Meanwhile, the Casa de Contratación steadily declined in importance until it closed its doors in 1790. A similar fate overtook the venerable Council of the Indies; most of its duties were entrusted to a powerful colonial minister appointed by the king.

Failure of colonial reforms

The entrance of new trading centres and merchant groups into the Indies trade, the reduction of duties, and the removal of irksome restrictions, had the effect of increasing commerce, reducing prices, and perhaps diminishing contraband. But the Bourbon commercial reform ultimately failed in its aim of reconquering colonial markets for Spain for several reasons—first, the opposition of the still dominant merchant oligarchs of Cádiz, who resisted intercolonial trade and efforts to replace French and English manufactures in the export trade to the colonies with noncompetitive Spanish products; second, Spain's continuing industrial weakness, which the best efforts of the Bourbons could not overcome; and, third, Spain's closely related inability to keep its sea-lanes to America open in time of war with England, when foreign traders again swarmed in Spanish American ports.

Colonial economic growth. Perhaps the most significant result of the Bourbon commercial reforms was the stimulus given to economic activity in Spanish America. To what extent this economic growth should be ascribed to the Bourbon reforms and to what degree it resulted from the economic upsurge in western Europe in the 18th century cannot be stated with certainty. Stimulated by the Bourbon reforms and a growing European demand for sugar, coffee, tobacco, hides, and other staples, production of these products rose sharply. But this increase in agricultural production resulted from more extensive use of land and labour rather than from the use of improved implements or techniques. The inefficient *latifundio* (a large, poorly cultivated estate), using poorly paid peon labour, and the slave plantation accounted for the bulk of agricultural production. Such natural disasters as drought or excessive rains easily upset the precarious balance between food supplies and population, producing frightful famines (as in 1785–87 in central Mexico, when thousands died of hunger or diseases).

What sugar, cacao, and coffee were for the Caribbean area, hides were for the Río de la Plata. Rising European demand for leather and the opening of direct trade with Spanish ships in 1735 sparked an economic upsurge in the Plata area. By the end of the 18th century the *estancias* (cattle ranches) were often huge, with as many as 80,000 or 100,000 head of cattle. Meat gained in value as a result of the demand for salt beef. Markets for salt beef were found above all in the Caribbean area, especially Cuba, chiefly for feeding the slave population. The growth of cattle raising in La Plata was attended by concentration of land in ever fewer hands and took place at the expense of agriculture, which remained in a depressed state.

Silver mining revival

The 18th century also saw a strong revival of silver mining in the Spanish colonies. Peru and Mexico shared in this advance, but the Mexican mines forged far ahead of their Peruvian rivals. The crown, especially under Charles III, made serious efforts to encourage the industry by such means as tax reductions and the dispatch of foreign and Spanish experts to Mexico and Peru. These efforts were largely frustrated by the traditionalism of the mine owners, lack of capital to finance changes, and mismanagement. Yet the production of silver steadily increased; supplemented by the gold of Brazil, it helped to spark the industrial revolution in northern Europe and stimulated commercial activity on a worldwide scale. More especially, American silver helped the Bourbons meet the enormous expenses of their chronic wars.

Colonial manufacturing, on the other hand, began to decline late in the 18th century, principally because of competition from cheap foreign wares. The textile and wine industries of western Argentina and the textile production of Quito in Ecuador decayed as they lost their markets to lower-priced foreign wines and cloth. In the Mexican city of Puebla, production of chinaware slumped catastrophically between 1793 and 1802. Although Spain adopted mercantilist legislation designed to restrict colonial manufacturing, this legislation seems to have been a small deterrent to the growth of large-scale manufacturing. More important were lack of investment capital, preference for land and mining as fields of investment, and a semiservile system of labour that was harmful equally to the workers and to productivity.

Spanish and Portuguese America in 1784.

Decentralization. Under Charles III the work of territorial reorganization continued. The viceroyalty of Peru was further curtailed by the creation (1776) of the viceroyalty of the Río de la Plata, with its capital at Buenos Aires. In 1783 the establishment of a royal *audiencia* at Buenos Aires completed the liberation of the Plata provinces from the distant rule of Lima. The inclusion of Upper Peru in the new viceroyalty, with the resulting redirection of the flow of Potosí silver from Lima to Buenos Aires, signified a major victory for the landlords and merchants of Buenos Aires over their mercantile rivals of Lima.

The trend toward decentralization reflected not only a struggle against foreign military and commercial penetration but also an awareness of the problems of communication and government posed by the great distances between the various provinces. One indication of this was the greater autonomy and the increased number of the captaincies general in the 18th century. Venezuela was raised to a captaincy general in 1777, Chile, in 1778.

The intendant system

Between 1782 and 1790 the intendant system was introduced to the colonies. The intendants—provincial governors who ruled from the capitals of their provinces—were expected to relieve the overburdened viceroys of many of their duties, especially in financial matters. The offices of *corregidor* and *alcalde mayor,* holders of which were notorious as oppressors of the Indians, were replaced in Indian districts by that of *subdelegado,* nominated by the intendants and confirmed by the viceroys. Many intendants at the height of the reform era were capable, cultivated men who not only worked to increase economic activity and revenue collection but also promoted education and other cultural projects. Most *subdelegados,* however, soon became as notorious as their predecessors for their oppressive practices; a common complaint was that they compelled the Indians to trade with them, although forbidden by the Ordinance of Intendants. The failure of the Indian and mixed-blood masses to profit by the 18th-century economic advance—whose principal beneficiaries were Creole (American-born Spaniards) landowners, mine owners, and merchants—helped to produce popular revolts of 1780–81 (of Topa Amaru in Peru and of the *comuneros* in New Granada), which, although suppressed, shook Spanish power to its foundations in those areas.

Defense of the empire. Increased revenue was a major objective of the Bourbon commercial and political reforms, needed for strengthening the sea and land defenses of the empire. Spanish losses in the Seven Years' War (1756–63), and especially the loss of Havana and Manila to the English (1762), resulted in efforts to improve the defense system of the colonies. Fortifications of important American ports were strengthened and colonial armies were created. Regular units were stationed permanently in the colonies or rotated between peninsular and overseas service, and a colonial militia was filled by volunteers or conscripts. To make military service attractive to the Creole upper class, which provided the officer corps of the new force, the crown granted extensive privileges and exemptions to Creole youth who accepted commissions, thus adding to the lure of prestige and honours protection from civil legal jurisdiction and liability, except for certain specified offenses. This led to the development of a special officer class, which survives in many Latin American countries.

The wars of independence

BACKGROUND FOR THE WARS

The Bourbon reforms combined with the growing European demand for colonial products in the 18th century to bring material prosperity and other benefits to the upper class Creoles. The improvements and refinements introduced by enlightened viceroys and intendants made life in the colonial cities more attractive; educational reforms and opportunities widened the intellectual horizons of Creole youth. These advances, however, only enlarged Creole aspirations and discontents. Increased production strained against the trade barriers maintained by Spanish mercantilism. Awareness of their economic importance made intolerable to the Creoles their virtual exclusion from commanding posts in government and the church.

Creole discontent

The conflict of interests between Spain and its colonies found expression in the cleavage between Creoles and peninsular Spaniards. This cleavage was a major cause of the Spanish American wars of independence.

Enlightenment and revolutionary influences. Enlightenment ideas contributed to Creole restlessness and discontent. The forbidden writings of G.T. Raynal, Montesquieu, Voltaire, and Rousseau undoubtedly were read by educated Creoles; and scientific works based on the premises of Descartes, Leibnitz, and Newton circulated freely in the colonies and helped to spread Enlightenment ideas. By 1800 such influences had partly renovated the intellectual climate of Spanish America and had given a rationalist, pragmatic stamp to Creole thought.

The United States War of Independence contributed to the growth of "dangerous ideas" in the Spanish colonies. Spain was aware of the ideological as well as the political threat to its empire posed by the United States. After 1783 a growing number of U.S. ships touched legally or illegally at Spanish American ports, sometimes introducing such subversive documents as the writings of the revolutionists Thomas Paine and Thomas Jefferson.

The French Revolution exerted greater influence on the Creole mind. The Colombian Antonio Nariño translated and printed the French Declaration of the Rights of Man of 1789; he was sentenced to prison in Africa for 10 years but later led the successful independence movement in Colombia. The French Revolution soon took a radical turn, and the Creole elite became disenchanted with it as a model. The most important direct result of the French Revolution was a slave revolt in the French part of Haiti under Toussaint-Louverture and other black leaders; by January 1, 1804, black revolutionaries in Haiti had established the first liberated territory in Latin America, but their achievement dampened rather than aroused support for independence among the Creole elite of the colonies.

Beginnings of the independence movement. In 1806 the revolutionary Francisco de Miranda landed on the shores of his native Venezuela with a force of some 200 foreign volunteers, but his call for an uprising met with no response, and he hastily withdrew. The colonial independence movement might have remained ineffectual if not for decisions and actions by European powers with very different ends in view.

Spanish–French alliance

A major cause of the revolutionary crisis was Spain's involvement in the European wars unleashed by the French Revolution. Spain became France's ally in 1796, and English sea power promptly drove Spanish shipping from the seas, virtually cutting off communication between Spain and its colonies. The alliance with France had other results. An English fleet sailed with a regiment of soldiers against Buenos Aires (1806). The English soldiers entered Buenos Aires meeting only token resistance, but Creoles and peninsular Spaniards soon rallied to expel their unwanted liberators; a volunteer army attacked and routed the occupation force, capturing the English general and 1,200 of his men. A second British invasion was beaten back with heavy losses. Impressed by the tenacious defense, the British commander agreed to evacuate both Buenos Aires and the town of Montevideo. With this victory, the Creoles of Buenos Aires had tasted power and would not willingly relinquish it again.

In Europe, Napoleon gradually reduced Spain to a helpless satellite. In 1807 Napoleon obtained from Charles IV permission to invade Portugal through Spain; and the Portuguese royal family and court escaped to Brazil in a fleet under British convoy. Popular resentment at the French presence in Spain forced Charles IV and his son Ferdinand to abdicate; Napoleon tried to place his brother Joseph on the Spanish throne.

An insurrection against the French occupation forces began in Madrid and spread across Spain beginning in 1808; it led to the formation of a national Cortes, or parliament, which met in Cádiz from 1810 to 1814 under the protection of English naval guns. The constitution, approved by the Cortes in 1812, provided a limited monarchy and freedom of speech and assembly, and it abolished the Inquisition. But the Cortes made few concessions to the American colonies; it invited American delegates to join its deliberations but made clear that the system of peninsular domination and commercial monopoly would remain essentially intact.

Creole plans for gaining power

In Spanish America events had transformed the remote prospect of independence into a realistic goal. Confident that the French armies would crush all opposition, Creole leaders prepared to take power with the pretext of loyalty to the "beloved Ferdinand." The confusion caused among Spanish officials by the arrival of rival emissaries who proclaimed Ferdinand or Joseph Bonaparte the legitimate king of Spain aided the Creole plans. In the spring of 1810, with the fall of Cádiz seemingly imminent, the Creole revolutionaries moved into action; charging viceroys and other royal officials with doubtful loyalty to Ferdinand, they organized demonstrations in Caracas, Buenos Aires, Santiago, and Bogotá that forced these authorities to surrender control to Creole-dominated local juntas. Their hopes of a peaceful transition to independence, however, were doomed to failure; their claims of loyalty did not deceive the groups truly loyal to Spain, and fighting soon broke out between patriots and loyalists.

THE INDEPENDENCE OF SOUTH AMERICA

The Latin American struggle for independence lacked a unified direction or strategy that was caused not only by the vast distances and other geographical obstacles to unity, but also by the economic and cultural isolation of the various Latin American regions. Moreover, the Latin American movement for independence lacked a strong popular base—the Creole elite, itself part of an exploitative white minority, feared the Indians, blacks, and oppressed castes and usually sought to keep their intervention in the struggle to a minimum. This lack of regional and class unity helps explain why it took Latin America so long to achieve independence.

The struggle for independence had four main centres. In Spanish South America there were two principal theatres of military operations—one flowed southward from Venezuela, the other ran northward from Argentina; these two currents joined at Peru, the last Spanish bastion on the continent. The third centre, Brazil, achieved its own swift and relatively peaceful separation from Portugal. Finally, Mexico had to travel a difficult, devious road toward independence.

Bolívar's involvement in the movement

Spanish America. Simón Bolívar of Venezuela is the symbol and hero of the struggle for independence in northern South America. Soon after his return to Venezuela from a visit to Europe (1804–07), he became involved in conspiratorial activity directed at overthrow of the Spanish regime. In April 1810, the Creole party in Caracas forced the captain general to abdicate, and a Creole-dominated junta took power. In 1811 a Venezuelan congress proclaimed the country's independence and framed a republican constitution that abolished special privileges and Indian tribute, but retained black slavery and made Catholicism the state religion. Meanwhile, the veteran revolutionary Francisco de Miranda had returned from England and assumed command of the patriot army.

Differences soon broke out between Miranda and his young officers, especially Bolívar. Amid these disputes came the earthquake of March 26, 1812, which caused great loss of life and property in Caracas and other patriot territory, but spared the regions under Spanish control. The royalist clergy proclaimed this disaster a divine retribution against the rebels. A series of military reverses completed the discomfiture of the revolutionary cause. With his forces disintegrating, Miranda negotiated a treaty with the royalist commander and then tried to flee the country, taking with him part of the republic's treasury. Bolívar and some of his comrades, regarding Miranda's act a form of treachery, seized him before he could embark and turned him over to the Spaniards. Miranda died in a Spanish prison four years later.

Bolívar was saved from a Spanish reaction by the influence of a family friend. Under a safe conduct, he departed for Colombia, which was still partially under patriot control. Given command of a small force to clear the Magdalena River of enemy troops, he employed a strategy featured by swift movement and aggressive tactics; he also judged his soldiers on merit without regard to social background or colour. His success gained Bolívar the rank of general in the Colombian army and won him the approval of a plan of his for liberation of Venezuela.

In a forced march of three months, Bolívar led a force of 500 men across jungles and swamps toward Caracas; as he approached the capital, the Spanish forces withdrew. He entered Caracas in triumph and received from the city council the title of "liberator"; soon afterward the congress of the restored republic voted to grant him dictatorial powers.

Bolívar's success was short-lived. The fall of Napoleon, in 1814, brought Ferdinand VII to the Spanish throne, released Spanish troops for use in America, and heartened the royalists. Meanwhile, the *llaneros,* or cowboys, of the Venezuelan plains joined the royalist cause. A mass of *llaneros* invaded Caracas, crushing all resistance; and in July 1814 Bolívar hastily abandoned the city and retreated toward Colombia with the remains of his army.

Bolívar found Colombia on the verge of chaos; despite the imminent threat of a Spanish invasion, the provinces quarrelled with each other and defied the authority of the weak central government. Concluding that the situation was hopeless, Bolívar left in May 1815 for the British island of Jamaica. Meanwhile, a Spanish army landed in Venezuela, completed the reconquest of the colony, and then sailed to lay seige to Cartagena; the city surrendered in December, and the rest of Colombia was pacified within a few months. Of all the Spanish American provinces, only Argentina remained in revolt.

Bolívar's "Letter from Jamaica"

Bolívar had an unshakable faith in the triumph of independence. From Jamaica he wrote a famous document—"The Letter from Jamaica"—in which he affirmed his faith and argued that monarchy was foreign to the genius of Latin America; only a republican regime would be accepted by its peoples. Bolívar boldly forecast the destiny of the different regions, taking account of their economic and social structures (Chile, for example, seemed to him to have a democratic future; Peru, on the other hand, was fated to suffer dictatorship because it contained gold and slaves).

From Jamaica, Bolívar went to Haiti, where he received a sympathetic hearing and the offer of some material support. After two efforts to gain a foothold on the Venezuelan coast failed, Bolívar decided to establish a base in the Orinoco River Valley, distant from the centres of Spanish power. Roving patriot bands still operated in this region, and Bolívar hoped to win the allegiance of the *llaneros,* who were becoming disillusioned with their Spanish allies. In September 1816 Bolívar sailed for the Orinoco River Delta and made his headquarters at the town of Angostura (modern Ciudad Bolívar).

The patriot guerrilla bands accepted Bolívar's leadership, and he also gained the support of the *llaneros.* The end of the Napoleonic Wars had idled a large number of British soldiers; and many of these veterans came to Venezuela, forming a British legion that distinguished itself in battle on the patriot side. Bolívar was also helped by English merchants, who made loans that enabled him to secure men and arms, and by the mulish attitude of Ferdinand VII, whose refusal to make any concessions to the colonists caused the British government to lose patience and regard favourably the prospect of Spanish American independence.

Liberation of Colombia and Venezuela

On the eve of the decisive campaign of 1819, Bolívar summoned to Angostura a congress that vested him with dictatorial powers. His strategy for the liberation of Venezuela and Colombia was to strike a blow at Spanish forces from a completely unexpected direction; he advanced with an army of some 2,500 men along the Orinoco and Arauco rivers across the plains and then ascended the Colombian Andes until he reached the plateau where lay Bogotá. On the field of Boyacá the patriot army surprised and defeated the royalists in a short, sharp battle and entered Bogotá. He then prepared for the liberation of Venezuela; in June 1821 patriot troops crushed the last major Spanish force in Venezuela at Carabobo. Save for some coastal towns and forts held by beleaguered royalists, Venezuela was free.

The independence of Spanish America remained precarious as long as the Spaniards held the immense mountain bastion of the central Andes. While Bolívar prepared an offensive from Bogotá against Quito, he sent his lieutenant José Antonio de Sucre by sea from Colombia's Pacific coast to seize the port of Guayaquil. Even before Sucre arrived, the Creoles of Guayaquil revolted, proclaimed independence, and placed the port under Bolívar's protection. Advancing into the Ecuadorian highlands, Sucre defeated a Spanish army on the slopes of Mount Pichincha, near Quito. Royalist resistance crumbled on news of Sucre's victory; and the provinces composing the viceroyalty of New Granada—the future republics of Venezuela, Colombia, Ecuador, and Panama—were free. They were temporarily united into a large state named Great Colombia (Gran Colombia), established at the initiative of Bolívar by the union of New Granada and Venezuela in 1821.

Ever since the defeat of the British invasions of 1806–07, the Creole party, nominally loyal to Spain, had effectively controlled Buenos Aires. In May 1810, when word came that French troops had entered Seville and threatened Cádiz, an open town meeting convened to decide

Liberation of Argentina

the future government of the colony. This first Argentine congress voted to depose the viceroy and establish a junta to govern in the name of Ferdinand. In 1813 a national assembly gave the country the name United Provinces of the Río de la Plata and enacted such reforms as the abolition of *mita, encomienda,* titles of nobility, and the Inquisition. A declaration of independence, however, was delayed until 1816.

The junta promptly attempted to consolidate its control over the vast viceroyalty. The western interior provinces were subdued after sharp fighting. Montevideo, across the Río de la Plata, remained in Spanish hands until 1814, when it fell to an Argentine siege. The junta met even more tenacious resistance from the gauchos of the Uruguayan pampa, led by José Gervasio Artigas, who demanded Uruguayan autonomy in a loose federal connection with Buenos Aires; but Artigas became caught between pressure from Buenos Aires and Portuguese forces who claimed Uruguay for Brazil, and he had to flee to Paraguay (Uruguay did not achieve complete independence until 1828). The Creoles of Paraguay defeated a force sent from Buenos Aires to liberate Asunción and proceeded to depose Spanish officials and proclaim the independence of Paraguay.

The junta's efforts to liberate the mountainous province of Upper Peru failed because of steep terrain, long lines of communication, and the apathy of the Indian population.

Upper Peru in Spanish hands represented a standing threat to the security of the La Plata provinces. The military genius of José de San Martín of Argentina offered a solution to the problem. San Martín was a colonel in the Spanish army when revolution broke out in Buenos Aires. He promptly sailed for La Plata to join the patriot junta and was soon raised to command the army of Upper Peru. San Martín proposed a march across the Andes to liberate Chile, where a Spanish reaction had toppled the revolutionary regime established by Bernardo O'Higgins and other patriot leaders in 1810. Having liberated Chile, the united forces of La Plata and Chile would descend upon Peru from the sea.

San Martín's liberation of Chile and Peru

San Martín obtained an appointment as governor of the province of Cuyo, whose capital, Mendoza, lay at the eastern end of a strategic pass leading across the Andes to Chile. He spent two years recruiting, training, and equipping his Army of the Andes. The army began the crossing of the cordillera in January 1817, and in 21 days it issued on Chilean soil. A decisive victory at Chacabuco in February opened the gates of Santiago to San Martín. Another victory at Maipú (1818) ended the threat to Chile's independence. Rejecting Chilean invitations to become supreme ruler of the republic, a post assumed by O'Higgins, San Martín secured a number of ships in England and the United States and, in August 1820, sailed for Peru in a fleet of seven ships of war and 18 transports. He landed his army about 100 miles (160 kilometres) south of Lima but delayed moving on the Peruvian capital; he hoped to obtain its surrender by economic blockade, propaganda, and direct negotiation with Spanish officials. His strategy was successful; in June 1821 the Spanish army evacuated Lima and retreated toward the Andes. San Martín entered the capital and proclaimed the independence of Peru. But he then had to deal with counterrevolutionary plots and the resistance of Lima's elite to his program of social reform. Meanwhile, a large Spanish army manoeuvred in front of Lima, challenging San Martín to a battle which he dared not join with his much smaller force. San Martín became convinced that only monarchy could bring stability to Spanish America, and he sent a secret mission to Europe to find a prince for the throne of Peru.

San Martín met with Bolívar in Guayaquil (July 26–27, 1822); the proceedings are surrounded with an atmosphere of mystery. Argentine historians hold that San Martín came to Guayaquil in search of military aid but was rebuffed by Bolívar, who was unwilling to share with a rival the glory of bringing the struggle for independence to an end; San Martín then magnanimously decided to leave Peru and allow Bolívar to complete the work he had begun. Venezuelan historians argue that San Martín came to Guayaquil primarily to recover that city for Peru; they deny that he asked Bolívar for more troops and insist that he left Peru for reasons having nothing to do with the conference. Both interpretations tend to diminish the stature and sense of realism of the two liberators—San Martín must have understood that Bolívar alone combined the military, political, and psychological assets needed to solve the factional problems in Peru and to gain final victory over the powerful Spanish army in the sierra; given the situation in Lima, San Martín's presence there could only hinder the performance of those tasks. Viewed in this light, the decision of Bolívar to assume sole direction of the war and of San Martín to withdraw reflected a realistic appraisal of the Peruvian situation and the solution it required.

San Martín returned to Lima to find that in his absence his enemies had usurped his power. In September 1822, before the first Peruvian congress, he announced his resignation as protector and his impending departure. San Martín's departure left Lima and the territory under its control in serious danger of reconquest by the strong Spanish army in the sierra. Bolívar allowed the situation to deteriorate until May 1823, when the Peruvian Congress called on him for help. The scare produced by a brief reoccupation of the capital by the Spanish army prepared the Creole leaders to accept Bolívar's absolute rule.

Bolívar arrived in Peru in September 1823 and needed almost a year to achieve political stability and to weld his army and the different national units under his command into a united force. After a difficult ascent of the sierra, patriot forces won a victory near the lake of Junín (August 6, 1824). To Sucre fell the glory of defeating the Spanish army in the last major engagement of the war, at Ayacucho (December 9, 1824). Only scattered resistance at some points in the highlands and on the coast remained to mop up. The work of continental liberation was achieved.

Brazil. Brazil made a swift, almost bloodless transition to independence. The idea of Brazilian independence first arose in the late 18th century as a Creole reaction to the Portuguese policy of tightening political and economic control over the colony. The first significant conspiracy against Portuguese rule was organized in Minas Gerais, but it was easily crushed. The French invasion of Portugal (1808), followed by the flight of the Portuguese court to Rio de Janeiro, brought large changes and benefits to Brazil. The Portuguese prince regent John opened Brazil's ports to the trade of friendly nations, permitted the rise of local industries, and founded a "Bank of Brazil." Brazilian Creoles took satisfaction in Brazil's new role and the growth of educational and economic opportunities; but this feeling was mixed with resentment at the thousands of Portuguese who came with the court and competed with Brazilians for jobs and favours.

The Portuguese court in Brazil

The revolution of 1820 in Portugal precipitated Brazil's break with the mother country. The Portuguese revolutionaries framed a liberal constitution for the kingdom, but assumed a conservative posture toward Brazil; they demanded the immediate return of Prince John to Lisbon, an end to the system of dual monarchy that he had devised, and the restoration of the Portuguese commercial monopoly. John approved the new constitution and sailed for Portugal, leaving behind his son and heir Dom Pedro as regent and advising him that, in the event the Brazilians demanded independence, he should assume leadership of the movement and set the Brazilian crown on his head.

Soon it became clear that the Portuguese Cortes intended to abrogate all the liberties and concessions won by Brazil since 1808. One of its decrees insisted on the immediate return of Dom Pedro from Brazil in order that he might complete his political education. But Dom Pedro, urged on by Creole advisers who saw a golden opportunity for an orderly transition to independence, rejected the Portuguese demand, issued his famous Fico ("I remain"), and in December 1822, having overcome slight resistance from Portuguese elements, was formally proclaimed constitutional emperor of Brazil.

THE INDEPENDENCE OF MEXICO

In Mexico the movement for independence took an unexpected turn; the Indian and mixed-blood masses joined the struggle and for a time converted it from a quarrel between the Creole and Spanish-born peninsular elites into a social revolution.

A social revolution

In 1810 a Creole plot for independence was being hatched in the important industrial and mining centre of Querétaro; its leaders included Miguel Hidalgo, a priest in the town of Dolores known for his sympathy with the Indians. Informed that their plot had been denounced to Spanish officials, the conspirators decided to launch their revolt before preparations were complete. On September 16, 1810, Hidalgo called on the Indians of his parish to rise against their Spanish rulers; he appealed to the religious fanaticism of the natives by proclaiming the Virgin of Guadalupe the patron of his movement. After his first victories Hidalgo issued decrees abolishing slavery and Indian tribute and ordering the restoration of lands to the Indian communities. These measures gave the Mexican revolution a popular character largely absent from the movement for independence in South America, but they alienated the many Creoles who desired independence without social revolution.

Hidalgo could not weld his Indian horde into a disciplined army or capitalize on his early victories. Within a year he was captured, condemned as a heretic by an Inquisitorial court, and shot. A mestizo priest, José María Morelos, assumed leadership of the revolutionary struggle; he liberated most of southern Mexico, then summoned a congress that proclaimed independence and framed a republican constitution. Morelos extended Hidalgo's social reforms by prohibiting all forced labour and forbidding the use of racial terms. Like Hidalgo, Morelos also had differences with Creole associates that hampered his conduct of the war, and his premature efforts to install a constitutional regime also hindered his military efforts. In 1815 he, too, was captured by the Spaniards and shot.

The revolution then declined into a guerrilla war waged by many rival chiefs. Royalist armies gradually extinguished the remaining centres of resistance. The Spanish revolution of 1820 abruptly changed this state of affairs. Fearing the loss of their privileges, conservative clergy, army officers, and merchants in Mexico schemed to separate from the mother country and establish independence under conservative auspices. Their instrument was the Creole officer Agustín de Iturbide, who had waged implacable war against the patriots. Iturbide offered peace and reconciliation to the principal rebel leader, Vicente Guerrero; his plan combined independence, monarchy, the religious supremacy of the Roman Catholic Church, and the civil equality of Creoles and Spaniards. For the moment Iturbide's program offered advantages to both sides.

Conservative–rebel alliance

The united forces of Iturbide and Guerrero swiftly overcame scattered loyalist resistance. On September 28, 1821, Iturbide proclaimed Mexican independence; and eight months later a congress selected by Iturbide confirmed him as Agustín I, emperor of Mexico. Iturbide's empire included the captaincy general of Guatemala (which included present-day Guatemala, El Salvador, Honduras, Nicaragua, and Costa Rica). Iturbide's empire had no popular base, however, and within a few months he was forced to abdicate and depart for Europe, with a warning never to return. The captaincy general of Guatemala, following Iturbide's departure, declared its independence in 1823, forming the United Provinces of Central America. The constitution adopted by the United Provinces permitted a great amount of individual state autonomy and gave the federal government supreme power only in foreign affairs. This weak central government, although directed by the notable statesman Francisco Morazán, had almost no income and lacked the military force needed to subdue the frequent disorders that arose among the states. Poor communications, jealousy of the power of Guatemala, and inexperience in self-government led to secession and the end of the United Provinces in 1837–38. In 1824 Iturbide landed on the Mexican coast with a small party, was promptly captured by troops of the new republican regime, and was shot.

(B.K.)

Reaction and anarchy, 1825–50

The new republics

For a quarter of a century after 1825 the new republics were plagued by social and economic paralysis and political chaos. Independence had not released the shackles of inherited backwardness. Traditional society had been deprived of its legal framework, but it had not been destroyed. Its legacy of prejudices and customs remained, as did a colonial mentality and an intellectual dependence upon Europe. Latent social disorganization was everywhere in evidence. Different civilizations and stages of culture existed side by side.

The working class, "a melancholy sea of illiterates," had no sense of their stake in good government. African slavery remained in either legal or extralegal form. The large Indian population, accustomed to servitude, showed a strong desire to isolate itself from Europeanized sectors, thereby surrendering any political privileges it might have claimed as citizens. Mestizos and mulattoes, more aggressive than the Indians but distrusted by the Creoles, were essentially a frustrated and unruly lot. Their prototypes were the gauchos (cowboys) of Argentina and *llaneros* (plainsmen-cowboys) of Venezuela who often welcomed the opportunity to join private armies in order to strike out against their supposed oppressors. The privileged groups were the only social elements with permanent standards and values. They were blind to the evils that their systems might bring societies that had not elaborated acceptable substitutes for the displaced Spanish and Portuguese kings and the weakened Roman Catholic Church. The members of the privileged elements (the elites of land and church and the intellectuals) were individualistic to the point of being anarchistic. The laws they wrote were to be applied to others, not to themselves. It is with the failure of the privileged groups to couple liberty with law in mind that the tumultuous quarter-century after independence should be viewed.

POLITICAL GROUPS AND ISSUES

Liberals versus Conservatives

Within the larger framework of extreme individualism two groups vied for power. Between 1825 and 1850 each faction assumed that the primary problem of the new republics was a political one. One group, generally referred to as liberals, was led by the intellectuals of the cities; the other group, commonly designated conservatives, was directed by the aristocrats of the countryside. Those who looked to the intellectuals were in general oriented toward northern Europe and the United States and were anticlerical. They favoured a federal type of government with narrowly delimited executive power, and they were so strongly committed to liberty and the right of individuals that they professed to prefer disintegration to tyranny. Those who accepted the leadership of the landed elites were essentially Spanish in their outlook and encouraged the church to continue as the interpreter of the social value system. They desired efficient, centralized states directed by strong executives to such an extent that they seemed to favour tyranny to disintegration.

Before 1830 the landed elites had established their ability to neutralize the intellectuals. Their victory over the intellectuals was one of the rural areas over the urban centres, or, as the Argentine president Domingo Faustino Sarmiento said, "of thirteenth century feudalism over nineteenth century liberalism." The success of the elitists did not mean either the total defeat of the intellectuals or the resolution of the differences that had separated the contenders for power. The intellectuals retained sufficient influence to keep alive islands of radicalism that prevented the aristocratic elements from achieving completely the social rigidity their system demanded. Arrangements were made and compromises were reached on basic issues. The Conservative political leadership was able to reaffirm the area's attachment to its Spanish-Catholic heritage, but the intellectuals continued to encourage the flow of ideas from abroad, and by 1850 France had become a cultural prop for all of Latin America. By mid-century, too, even the Liberals had generally conceded that, in practice if not in theory, a strong executive was absolutely essential to orderly government; when representatives of the Liberals did attain power it was not unusual for them to disregard democratic forms. It often appeared that Liberalism was invoked in order to impose tyranny. The new states, defeated in their efforts to win for themselves the religious patronage that the Spanish and Portuguese crowns had enjoyed, had accepted the privilege of presentation of lists from which the Vatican selected the high ecclesiastical officials to serve in the republics. The anticlericals intensified their efforts to circumscribe the church's temporal activities—the registration of births and deaths, participation in marriages, control of cemeteries, leadership in education, participation in politics and economic activities—which gave that institution such strength as to make it a threat to the viability of any administration.

The importance of the issues that were delineated and then compromised by the contending power groups should not be discounted, but they alone do not explain the state of Latin America after three decades of independence. There were other considerations of equal or greater significance.

Violence. In the political area, probably the most far-reaching development before 1850 was the elevation of violence to the level of a political fundamental. In order to seize the initiative from the intellectuals, the landholding elites had recourse to the military forces that had been nurtured to maturity during the wars of independence. Their victory, thus, was one of violence, and success through violence engendered more violence. Armies soon came to serve a dual political function. They acted as the final arbiters of political matters, and they provided the guarantee that the privileged groups could fight among themselves over their political, social, and economic preferences without creating a power vacuum into which the masses might rush.

Private armies

Once force was injected into politics the juridical concept of representative democracy was ignored. Facts prevailed against constitutions—sometimes against their letter, usually against their spirit. Differences were settled by the breaking of heads rather than the counting of them. Bullets replaced ballots. Those who rose to power tended to monopolize it to such a degree that quite often their holds could be ended only by the bloody remedy of revolution. There was no place in such political systems for the popular masses, who constituted as much as 90 percent of the population in certain of the republics. They were, in effect, driven into a political wilderness.

Caudillism. Violence paved the way for the caudillos. They were violent men of destiny who broke all the bonds of national and social order. They were individualists who could not be restrained by party or ideology. To them electoral platforms were written to satisfy a formality and not a necessity. In the words of the Argentine sociologist Carlos Bunge, they were "rulers by the will of men without will." Some caudillos were generals from the wars of independence, who, in the course of the 15-year-long struggle for freedom, first lost contact with the people and then developed a proprietary interest in the states that their swords had helped to create. They were the liberators who turned upon the liberated. Some of the caudillos were mere adventurers who profited from the widespread disorder of the day. Many were *hacendados* ("large landowners") who took to the field to redress grievances against the central government or in response to the need of property owners for protection that the states did not provide. Once in possession of an army it was but a short step to using it for the purpose of achieving high public office.

The caudillos bore a striking resemblance to Max Weber's "charismatic leader." They regarded themselves as indispensable, and in office they exercised personal authority regardless of the representation of collective interests. Since the objectives of the caudillos were primarily personal they were forced to rely upon their personal magnetism to win followings. They had to be *muy hombre* ("very much a man"). Personalism (*personalismo*) in politics, consequently, became a fetish. Political parties were little more than ad hoc associations of friends, strong in victory, only to disintegrate in defeat. Prior to 1850 Chile and Colombia offered the only exceptions to the rule. If personalism was one of the strengths of the caudillos it was also one of their major weaknesses. Because their regimes were built on personalism, they were seldom able to consolidate their power sufficiently to pass it on to chosen successors. The opposition understood this phenomenon and was secure in the knowledge that sooner or later power might be expected to revert to it.

Personalism in politics

An often overlooked characteristic of the caudillos was their ideological and philosophical sterility. Although acts of brutality and destruction of property usually went along with the seizure and consolidation of power by caudillos, no caudillo before 1850 ever threatened a basic principle of the elite system of values. Except in Haiti and Brazil, they invariably paid lip service to the republican system of government. All spoke of government by the people, and no one of them felt secure until he legalized his administration by holding an election. They were no more successful than were regularly elected officials in bringing order out of political chaos. They added nothing new to the church–state issue. They were economic traditionalists at least to as great an extent as were those who opposed them. By the time they achieved power they were generally rich in land, and the constitutions they wrote reflected their property-owner mentality. Thus it was that in every major political, social, or economic area the caudillos tempered their actions with enough discretion always to make themselves appear safe. Each one stopped short of revolutionizing the existing social and economic systems.

Not one of the republics of Latin America was spared the price of political tumult born of caudillism. Argentina fell into the hands of "bloody" Juan Manuel de Rosas, who was raised to power by a combination of reactionary churchmen, wealthy landowners, and the gauchos of the Argentine pampas. Brazil experienced more than a decade of civil war after 1835 led by caudillos who threatened to divide Brazil as the Spanish area had been splintered earlier. Mexico barely survived the machinations of the superficially brilliant Antonio López de Santa Anna, who tempered tyranny with treason. The Central American Federation collapsed in a fit of quarrels kept alive by petty tyrants. Colombia, Bolivia, Peru, Ecuador, and Uruguay were surrendered to war lords and adventurers. Paraguay and Venezuela enjoyed rather prolonged periods of paternalistic dictatorship punctuated by blood baths perpetrated upon the citizenry by power-hungry politicians in military uniforms. Haiti, neglected by Europe and shunned by a race-conscious United States, stumbled from one despot to another, and the Dominican Republic was shaken by the onslaught of "the Haitians," the aggressiveness of its own strong men, and the ambitions of Spain. Only Chile, in the 1820s, after a period of extreme anarchy, evolved a political system that fettered the man on horseback. There the landed oligarchy, comprised of not more than a few hundred families, seized power and through a combination of aristocratic supervision and autocratic administration guaranteed its control. The military forces were brought under civilian leadership, and the president was given extensive control over a highly centralized government. The church was given full partnership with the state. Property and literacy qualifications limited the franchise to the point where not more than 10 percent of the population could qualify for the vote. The requisites for office holding eliminated all but a few thousand.

THE ECONOMICS OF ANARCHY

Although violence and caudillism were essentially political phenomena, no major area of activity was spared the pervasive anarchy they generated. Particularly did the disorderliness of the 1825–50 period add to the economic problems inherited from the mother countries and the wars of independence. The crucial economic problem of the new republics was the system of land tenure, the peculiar feature of which was the large estate or the latifundio. Rooted in the colonial period, the latifundio was consolidated during the years after independence as the republics recklessly distributed their public domains to political favourites, and then protected the new holdings with tax systems that taxed the product of the land but not the land itself, and legal systems that provided for primogeniture and debt, slavery, or peonage. Once in debt

The landowners and peasants

the Indian was obligated to the *patrón* until the money was repaid. Since he ordinarily found it impossible to regain solvency, if he had ever enjoyed such a blissful state, his labour obligations tended to become permanent. There was no place in such a tenure system for the growth of a property-owning middle class such as appeared in the United States before 1850.

To the heavy burden of the latifundios and peonage were added other economic problems of somewhat lesser long-range consequence but immediately important to the struggling nations. First Spain's colonial policy, and after independence the fact that the new republics were outside the well-established international trade routes, served to isolate Latin America from Europe and thus to prolong the time needed for European traders and financiers to acquire a somewhat realistic working knowledge of the republics. Violence also delayed the rehabilitation of many of the mines that suffered from destruction and neglect during the war years—mines that might have provided the means of earning an important part of the foreign exchange that Bolivia, Peru, Colombia, and Mexico needed so desperately. Finally, the recurrent political plots and uprisings strengthened the well-developed propensity that domestic capitalists had for investing in rural properties because of the indestructibility of land and the prestige associated with it in agricultural communities.

LEARNING AND THE ARTS

The literature of politics

The ravages of civil war left little time, money, or inclination for developing learning or the arts. Antagonism of the new governments to the clergy resulted in the neglect and disappearance of many colonial educational institutions and the loss of educational and professional services of the religious teaching orders. Meanwhile, the new republics, concerned with other problems and lacking in financial resources, did little to promote public education. Only Chile, which in the 1840s combined stability and wealth, was able to give impetus to learning at all levels. The arts suffered from the general decline of wealth. Almost no new churches and very few public buildings were constructed. There was little demand for art other than religious art. Literature fared somewhat better because it was made to serve political ends. Men of letters were generally on the side of justice, by which was meant justice for the privileged groups. Often from homes in exile—Chile and Uruguay were the favourite refuges from Argentina—writers carried on their campaigns against tyranny. The schoolteacher president of Argentina, Domingo Faustino Sarmiento, spent many of his most productive years fighting the tyrant Rosas from across the Andes in Chile. Esteban Echeverría described the crimes of Rosas and articulated the needs of his homeland from Uruguay. Through the efforts of Echeverría, the Chilean, José Victorino Lastarria, and others, Romanticism was accepted in poetry and then spread to drama and the novel.

Era of material progress, 1850–1914

For a quarter of a century after independence was achieved the conviction persisted that the problems of the inchoate republics could be resolved if only workable political systems could be found. The small politically articulate element of society threw vast amounts of efforts into what proved to be a fruitless search for exclusively political solutions to the dilemmas of the area. An enormous amount of property was destroyed as opposing elements uncompromisingly supported either arbitrary or rational politics as the most direct means of attaining their objectives through constitutionalism. The price was so great, the wounds so deep, that many of the republics still have not fully recovered. But as early as the 1840s in Chile and by the 1850s and 1860s in Argentina, Brazil, and Mexico, many within the responsible elements of society had agreed that the purely political approach had failed. They looked to Great Britain and the U.S. for alternatives, and the experiences of those countries taught that the successful functioning of democratic representative government, the ultimate goal of the Latin-American republics, was closely related to economic progress and that order was requisite to both. Economic development became an obsession in several of the republics. It dominated the era from 1850 to World War I as completely as politics had dominated the antecedent era.

Foundations of mining and agriculture

Latin America turned to economic solutions to its problems just as the world economy under European leadership was fostering a high degree of regional and international specialization. The basic effect of this development was to divide the world into industrialized nations on the one hand and nonindustrialized countries on the other. Latin America fell into the latter category. Mining, traditionally oriented toward export, was now greatly expanded. Agriculture was commercialized and given the same orientation. Enormous acreages were put to the plow for the first time in Argentina, Brazil, and Uruguay. Barbed-wire fences, blooded bulls, and refrigeration combined to transform cattle raising into a highly complex, modern enterprise. At the end of the century coffee became the economic backbone of several republics and bananas of several others.

Prolonged cycles of good markets enriched landowners to the point where many of them could afford to live in the capital cities or in Europe. Absentee landlordism, with all of its abuses, became prevalent in such countries as Argentina, Brazil, Chile, and Uruguay. As the tempo of international trade increased nations became the slaves of their mines and fields as minerals, livestock, cereals, and coffee provided the means of payment for imports of machinery and tools and the soft goods to which an expanding consumer class had become accustomed. Prior to World War I the dependence of the republics upon export markets did not often give rise to serious problems because the consumption of primary products by the manufacturing nations showed a strong tendency to expand and Latin America was ordinarily able to dispose of all it produced for export.

FOREIGN CAPITAL AND TECHNICIANS

The orientation of their economies to overseas markets made the republics more economically dependent upon Europe and the United States. The shift to large-scale commercial agriculture was financed through foreign-controlled banking institutions. The modernization of mines, beyond the economic capacity of domestic capitalists to carry out, fell to foreign investors, although in Chile domestic capital was heavily invested in the mineral economy. Commercial agriculture and modern mining involved the expansion of transportation and public utilities whose development was assumed by foreign capitalists and foreign technicians.

Foreign capital entered the republics without serious restraints of any kind, and the foreign investor showed a distinct preference for those states where the leadership displayed a reasonable capacity to maintain order. Thus it was that foreign venture capital went primarily into Brazil, where a respected monarch (Pedro II) moderated the differences of disparate groups; into Argentina, where a landowning aristocracy firmly controlled the government; into Chile, where power was shared by the landowners and the entrepreneurs of commerce and mining; and into Mexico, where Porfirio Díaz' policy of "bread or the stick" had brought order and stability out of extreme chaos.

Investment by Great Britain and the United States

Great Britain was easily the largest supplier of funds in South America as its capital went into commerce, utilities, railroads, shipping, mines, and agriculture. By 1914 Argentina was an economic colony of Great Britain. "Take Canada from us, but not Argentina," cried one Englishman. The United States did not become a creditor nation until World War I, but before that time United States private capital began flowing into the Caribbean and Central American agriculture and Mexican mines, railroads, and petroleum fields. By 1914 the United States was the largest foreign investor in Middle America. Foreigners had approximately $8,500,000,000 invested in Latin America when World War I broke out; one-third in Argentina, one-fourth in Brazil, and one-fourth in Mexico. In many enterprises, including railroads, mining, and bananas, the investment of foreigners greatly exceeded that of the nationals.

Technicians and managers, ordinarily from Great Britain and the United States, poured into the republics to fill a scientific and technological void left by the humanistic training that the institutions of higher learning continued to impart. In general the teaching of the sciences fell to the military academies. Except in Brazil, where army engineers were active, foreign engineers were primarily responsible for the construction of railroads and ports, and they supervised the work of thousands of native labourers.

IMMIGRATION

The economic expansion induced by foreign capital and technicians provided job opportunities in field and factory for millions of unskilled and semiskilled labourers from Europe. Steamships disgorged most of their human cargo at Rio de Janeiro and Santos (the port for São Paulo) in Brazil, Buenos Aires in Argentina, and Montevideo in Uruguay.

Underpopulation had been a recognized problem in Latin America ever since the independence era. In 1823 Brazil, comprising approximately half the South American continent, had only 4,700,000 inhabitants. Uruguay had a population of only 60,000 when it began its struggle for freedom from Spain. As late as 1852 Argentina's population was about 1,200,000. In a bid for immigrants, several states rewrote their constitutions to provide for freedom of worship for non-Catholics. The Argentine theorist Juan Bautista Alberdi at mid-century declared that "to govern is to populate." The Argentine constitution of 1853, which he fathered, enjoined upon the government the responsibility of promoting European immigration. What Alberdi had in mind was the filling in of the great expanses of his country with landowners, not farm hands. At the time he wrote there was no real shortage of workers in the republic because it had not yet shifted from subsistence to commercial agriculture.

A new dimension was given to the problem of underpopulation as a result of the course that economic development took after 1850. With ready markets in Europe for their products, landowners not only were discouraged from parting with their holdings but bid land prices up in enlarging them. Those who looked to trade with Europe wanted farm hands, railroads, better port facilities, and more public utilities. Also, the growth of retail trading and the beginning of the factory system required many more workers than could be provided locally.

Although several of the republics desperately sought immigrants after 1850, they did not at first find it easy to attract the restless from Europe. Most of those people preferred the United States, with its abundance of cheap land and its rapidly growing industrial system. Also, Latin America's reputation for political and economic instability was disturbing to potential settlers from abroad. Latifundism tended to exclude the newcomers from the ownership of land. Much of the area where lands were available was in the tropics or distant from commercial centres and ports. There was little industrial growth anywhere. Transportation and communications were poor; educational and medical facilities, primitive. Brazil tolerated black slavery until 1888, and Europeans were reluctant to work alongside slave labour. As late as the 1870s, in both Argentina and Chile, marauding Indians periodically encroached upon sparsely settled areas.

There were countervailing forces. Political discontent, famine, and grinding poverty in Europe drove many to take refuge wherever they could find it. In the republics there was some house cleaning as groups determined to promote material progress gained ascendancy and demanded order. So Europeans emigrated, at first in small numbers as traders and miners from the British Isles, and as farmers, mostly from Switzerland and the German principalities, and later in swarms from Italy, Spain, and Portugal.

Latin-American statistics on immigration are notoriously unreliable. According to those that appear most trustworthy, the swarming to Argentina began in the 1880s. Between 1857 and 1900 Argentina had a net inflow of 1,200,000 (equal to the total population of the nation in 1852). The peak year in Argentina was 1913 when 302,000 entered and 157,000 departed. By 1914 Argentina had received 4,660,500 immigrants, for a net gain of 2,640,000. Italians numbered about 1,200,000 and Spaniards about 1,000,000.

Argentine immigration

The impact of the immigrants upon Argentina was profound. The nation's population expanded to 10,215,787 by 1924. The population of the rich pampas increased 625 percent, and the republic's total agricultural acreage increased 60 times between 1865 and 1914. The immigrants helped to introduce farm machinery and mechanical arts and to hold the frontier against the Indians until the latter were finally subdued by Gen. Julio Roca in the late 1870s. They also added to Argentina's contacts with Europe. Their labour raised land values and made railroad building feasible. They popularized dairy products and vegetables in the Argentine diet and mongrelized the Argentine language. The Italian immigrants, who ran the country stores and victimized the gauchos, became the whipping boys of Argentine literature, while the shiftless gaucho assumed the role of a national hero. The flood of immigrants made Argentina more racially European than any other republic of Latin America with the possible exception of Uruguay. But, in the final analysis, the immigrants' greatest influence was probably felt in the city of Buenos Aires. Unable to buy land and unwilling permanently to accept the hard terms of rural employment and tenancy, they flowed into the capital city. There they entrenched themselves in the retail trade, small factories, the building trades, and in the maintenance department of public utility companies. In the burgeoning capital the rootless thousands, caught between the Old World and the New World, quickly developed social types that were new to Argentina and added to the European content of its way of life.

Those who emigrated to Uruguay came from the same places and at about the same time as did those who made their way to Argentina, and the contributions of the two groups were basically the same. By 1889 Montevideo with a total population of 214,000 contained 100,000 foreign born. By 1900 the newcomers possessed more than half of the declared national wealth.

Chile did not have a shortage of labour but actually exported labour throughout the 19th century. The only land the republic had to give away was heavily wooded and in areas where the rainfall was far greater than advisable for profitable agriculture. But the stability of the republic early made it attractive to German settlers. Moving into the forested regions around Valdivia and Puerto Montt as early as the 1840s, and later occupying part of the island of Chiloé, the Germans, although always constituting a relatively small portion of the total population, were able to put their imprint on much of the area south of the Bío-Bío River. By the middle of the 20th century the Germans of the area played an economic, educational, and military role in the region out of all proportion to their numbers.

Brazilian immigration

The most dependable figures available indicate that between 1851 and 1888 an average of about 10,000 newcomers a year entered Brazil and that the flow of immigrants reached its peak during the decade following the abolition of slavery. Approximately 2,500,000 émigrés from Europe entered Brazil between 1888 and 1914. More than 50 percent went to the state of São Paulo; the states of Rio de Janeiro and Rio Grande do Sul were other important recipients. As in the case of Argentina, Italy provided the largest single bloc of newcomers, but in Brazil the Portuguese rather than the Spaniards held second place. Although the Germans never entered Brazil in large numbers—probably not more than 100,000 by 1914—they prospered and had large families, and by 1924 numbered 360,000. Their influence in the state of Rio Grande do Sul was and is as pronounced as that of the Germans in southern Chile. In general, they needed to adapt less than did the Germans who came to the United States because they were concentrated in remote and thinly populated areas and were left to organize their own economic, social and educational life. Japanese emigration to Brazil began in 1908. Only a few thousand entered the republic before World War I but between 1920 and 1940 approximately 200,000 followed; they engaged in all types of agriculture and trade.

Overall, the role of the immigrants in Brazil was similar to that of their counterparts in Argentina and Uruguay. Their labour made possible large-scale commercial agriculture—in Brazil it was coffee. They became the principal source of labour in the cities of São Paulo and Rio de Janeiro. It may be said without qualification that those areas of Brazil where the immigrant went have prospered much more than have those regions where he refused to settle. The city of São Paulo, the Chicago of Latin America, is the handiwork of the newcomers and their descendants, and the greatest monument to the immigrant in Brazil.

Migration to the other republics, when of numerical significance at all, was for the most part non-European. By 1875 more than 74,000 Chinese had entered Peru to work on the sugar plantations, in the guano deposits, and on railroad construction projects. Lima still has a large Chinatown. In 1861 there were nearly 35,000 Chinese in Cuba. By 1899 the number of Chinese in Cuba had declined to less than 15,000. Blacks from the British West Indies entered Panama in large numbers during the construction of the Panama Canal. They were also brought into the coastal areas of Honduras, Nicaragua, Guatemala, and Costa Rica when the banana was commercialized, about 1900.

Haiti, with one of the densest populations in the Western world, traditionally has exported labour, principally to the Dominican Republic and Cuba. In periods of prosperity the Haitian workers have been welcomed; in depressions they have often been made to bear the brunt of attacks of Dominican and Cuban demagogues beating the drums of nationalism. Mexicans like Haitians, have emigrated. The ability of the U.S. to absorb Mexican farm labour has served as a safety valve for Mexico as it seeks to industrialize in order to provide jobs for its ever growing labour force.

TECHNOLOGICAL CHANGE AND ECONOMIC DEVELOPMENT

Growth of transport and communications

Aided by capital, technicians, and labour from abroad the economic and technological advances of the 1850–1914 period were spectacular given the area's inheritance from the colonial era and the anarchic quarter-century following independence. Railroads were laid from mines and farming centres to the ports. In all, 60,000 miles of railroads were built by 1914, including 21,800 (1914) in Argentina; 15,800 (1913) in Mexico; 15,445 (1913) in Brazil; 5,000 (1913) in Chile; and 1,656 (1913) in Peru. River steamboats were put on the Magdalena, Orinoco, Amazon, São Francisco, Jacuí, and La Plata-Paraná river systems. Old port facilities were renovated, as in Rio de Janeiro and Veracruz, and new ones were built. The port of Buenos Aires was dug out of the mud of the Río de la Plata. Rosario, Argentina, became one of the greatest grain-shipping ports in the world when a port was completed there after 1900. Steamship lines were subsidized in an effort to increase contacts with Europe and the United States. Before the end of the century hundreds of vessels flying British, French, Italian, German, and United States flags were carrying raw materials, finished products, and immigrants to all parts of the area but particularly to Argentina and Brazil. Private and public capital combined to put more than 100,000 miles of telegraph lines in operation by 1914. The area had submarine cable connections with Europe by 1876 and with the United States by 1894. The first telephone systems were introduced in the 1880s, and the first modern water and sewer systems were begun in the 1850s. Gas began to replace whale oil for public lighting in the 1850s and by the 1890s electricity in turn had began to supplant gas. During the era public transportation in the larger cities passed through three phases. Beginning with horse-drawn coaches it progressed to horse-drawn streetcars and to electric trolleys. Before 1910, Buenos Aires had in operation an excellent crosstown subway.

As a result of economic development during the era, Argentina became one of the world's major breadbaskets. Brazil strengthened its claim to the title of "coffee king." Chile became the leading exporter of natural nitrates. Mexico became one of the world's largest producers of petroleum by 1911. The total international trade of the area rose from slightly more than $1,000,000,000 annually in the early 1890s to $1,800,000,000 in 1907, and $3,100,000,000 in 1913. In the latter year Latin America accounted for 6.5 percent of the world's imports and 7.9 percent of its exports. The growth of trade and commerce in the more advanced countries gave a strong impetus to banking and insurance, a development which did not come about until after World War I in such countries as Colombia and Venezuela and the Central American republics.

Urban growth

Consequences of economic change. In the republics that had by 1914 established their leadership in the technological fields, the economic transformation brought nearer into balance the wealth, income, and population of the rural areas and the urban centres. The added importance given to land by the commercialization of agriculture was counterbalanced by the fact that the cities were the first to feel the effects of economic expansion because the industrial and commercial sectors, centred in the cities, received the greatest share of the capital and skills from abroad. The new and relatively well-paid management element associated with transportation and finance was essentially urban. The urban centres were the chief benefactors of the growth of both internal commerce and international trade. Villagers and those newly arrived from Europe, discontented with the terms of employment and tenancy in the rural areas, took advantage of cheap modern transportation to move into the cities, and Latin America at this time entered a sustained period of rapid urbanization. Buenos Aires trebled its population between 1895 and 1914, as did Montevideo between 1887 and 1914. São Paulo's population spurted from 65,000 to 350,000 between 1890 and 1910. During the same years Pôrto Alegre grew from 52,-000 to 130,000. Chile's population was 43 percent urban by 1910. On the other hand, the Indian countries, such as Paraguay, Bolivia, Ecuador, Nicaragua, and Honduras remained overwhelmingly rural, as did Brazil, where in 1914 less than 15 percent of the population was urban.

Two new socioeconomic elements emerged in the cities. They were the entrepreneurs, managers, and technicians of industry and commerce, who were added to the middle groups of society, and the urban industrial working class.

New alliance of intellectuals and the business community

The politics of progress. By the outbreak of war in Europe in 1914, the economic transformation and the growth of cities had had a significant impact upon the political life of the republics. In Uruguay, Argentina, Chile, and Mexico the new socioeconomic groups of the cities were making common cause with dissatisfied intellectuals and professionals against the political hegemony of the old elites. The intellectuals had good reason to welcome the new groups as political allies. The alliance of the intellectuals with the elites originally had been dictated by economic necessity rather than ideological compatibility, and consequently when their earnings eroded rapidly under the inflationary pressures that accompanied heavy investment in long-range enterprises, there was little left to keep the old working relationship alive. On the other hand, the intellectuals had much in common with the new business elements. Both groups were centred in the cities, were oriented overseas, supported rapid technological development, favoured public education as a means of limiting the influence of the church, and opposed the use of force in politics.

The urban labouring groups provided the popular support for the new middle sector politicians who opposed the entrenched leadership. Politically immature and organizationally weak, urban labour came under the influence of the middle sectors after a brief and stormy association with leaders who had been brought up in the traditions of anarcho-syndicalism then prominent in southern Europe. Political affiliations with the middle groups gave labour a certain respectability; in turn, worker militancy and intractability gave the new political forces an aggressiveness they would not otherwise have had.

The leaders of the new urban political alliance lacked practical experience in the formulation of policies but this did not deter them. They promised economic progress and social democracy. To the political and moral abstractions which the intellectuals had fought for during the independence wars, the new politicians, in their search for votes, added the demand that a greater share of the material and cultural benefits of 20th-century technology be made accessible to a greater part of the population.

Nationalism and a new type of militarism. Political nationalism and a more professionalized military class were important by-products of the political thinking that resulted from the influx of tens of thousands of hardworking immigrants, the construction of railroads, and investment in industry. Politicians began to envisage the day when their countries would teem with productive citizens and the empty spaces and corners of the republics would be needed to provide living space for growing populations. National boundaries, consequently, had to be guaranteed and, when possible, expanded. Although most international disputes were settled without resort to force, military establishments were strengthened in almost every republic in order to back up the claims of politicians.

Power of the army

The new emphasis upon the army as an instrument of national policy had at least two important consequences. A costly arms race developed, and the republics, feeling that the stakes were rising, turned increasingly to military professionalization. Also, the rise of modern armies equipped with costly armament marked the death knell of the provincial caudillo who had only his personal fortune with which to outfit his private army and keep it in the field.

CULTURAL CHANGES

Catholicism and anticlericalism. Between 1850 and 1914 the position of the Roman Catholic Church in Latin America became increasingly unstable. Severe anticlerical laws were put in force, for example, in Mexico, Venezuela, Chile, and El Salvador. In several countries church and state were separated and at the same time the church was burdened with strict state control. Although retaliatory vengeance for clerical political activities continued to be a cause for assault upon the church, a greater consideration as the century grew to a close was the emergence of socioeconomic groups in the cities whose members attacked the church as an obstacle to economic and social progress. Under the new leadership, anticlericalism to a degree became a political philosophy and a plan of action pointing the way to the modern world. The great mass of the people were unaffected by the attacks upon the church. Communities went along as before. They retained their patron saints, whose names were sometimes added to the names of the towns. Families had saints which they honoured. Other saints were expected to protect certain occupations or guard specialized groups.

Education and the arts. In the rush to modernize, learning was left behind. There were numerous exponents of educational reform, but few projects got beyond the planning stage because leaders in education seldom possessed the capacity for political leadership that would have enabled them to translate their theories into practice. But in any event to incorporate into society a large mass of indigenous peoples through education was beyond the comprehension of those who led the republics. The Catholic Church continued to dominate primary and secondary education, despite steadily growing support in favour of public instruction. Between 1850 and 1914 the Catholic University of Chile, in Santiago, founded in 1888, was probably the outstanding addition to the church's list of institutions of higher learning.

Only Argentina, Chile, and Uruguay, each of which had homogeneous, largely European populations, made major achievements in public education between 1850 and 1914. In response to the demands for a more responsible citizenry and the requirements of the new technical age, but above all because of the driving determination of Pres. Domingo Faustino Sarmiento to create a literate nation, Argentina moved ahead rapidly to become the educational leader of Latin America. Matriculation in Argentine normal schools increased from less than 1,300 to more than 7,200 between 1890 and 1912 and in the same period enrollment in public and private elementary schools rose from about 300,000 to 720,000. Enrollment in the University of Buenos Aires reached 4,600 in 1915. The University of La Plata, founded at the turn of the century, became one of the great institutions of the area before Juan Perón dispersed its faculty during the decade after 1946. Although Chile failed to maintain the very fine record it had set in the 1840s, it ranked in the prewar period as a leader in the field of public instruction. By 1908 enrollment in public elementary schools stood at 240,000 and 18,700 in public secondary schools by 1910. Uruguay placed the emphasis upon elementary instruction while establishing their principle of free and obligatory education under secular control at all levels.

Culture of the newly rich

Although important changes did take place, the economic-technological transformation stopped considerably short of generating a social revolution. Inequities became more pronounced as industry and commerce gave rise to more and greater fortunes than farms and mines had ever supported. Gaudy homes went up in exclusive residential districts. Conspicuous consumption was appreciably more evident in the cities than it had been on the haciendas. Novelists geared their writings to the new rich who wished to read of themselves in glittering palaces and travelling abroad. Portrait painting was popularized as the number of those who could afford such luxury multiplied. Academies of arts were founded and national museums were established. History societies flourished, as the new nationalism aroused interest in the past, and archives were searched for evidence to support boundary claims. A few cities, notably Rio de Janeiro and Buenos Aires, supported operas. The demand for newspapers grew as learning slowly filtered down to the urban working elements and immigrants bought foreign-language newspapers in order to keep abreast of developments in Europe. But the rigid system of social classes remained largely intact. "The darker one's skin the lower one's social position" remained the rule. Although gradations existed, the essential division in the social hierarchy was between the dominating privileged classes and the people. The interpreters of society either ignored the masses or treated them in a residual manner. Many Brazilians wrote against slavery, but they ordinarily attacked the institution on moral rather than social grounds.

THE END OF AN ERA

Well before World War I there were many indications that large parts of Latin America were breaking with their Spanish and Portuguese pasts and that several republics were taking their first steps toward becoming modern nations. Slavery as a legalized institution in the Western Hemisphere was finally ended in 1888 when Brazil decreed the emancipation of approximately 850,000 blacks then held in bondage within its borders. The following year Brazil forswore monarchism, which had become an anachronism in the New World, in favour of republicanism, thus bringing its political system into line with the other hemisphere nations. Political leaders especially in Argentina, Uruguay, and Chile increasingly involved the urban working groups in national affairs.

The republics established an enviable record for the peaceful solution for controversies, expecially in the settlement of boundary disputes. The more recalcitrant cases were submitted to arbitration, and before World War I arbitration had for practical purposes become a part of international law as it applied in Latin America.

The modern political limits of the area were drawn when Cuba won its freedom from Spain (1899) and became an independent republic in 1902, and the number of nations was raised to 20 when Panama separated from Colombia and achieved sovereign status in 1903.

All the republics were invited to the second Hague Peace Conference held in 1907. Although the position taken by the Latin-American delegates against armed intervention for the collection of debts was accepted only after significant modification, the conference was important because it was the first of worldwide scope in which the Latin-American republics participated.

Influence of the United States

As the 20th century began, the republics were deeply conscious of the fact that their future was clouded by an ominous shadow cast over them by the United States. The "Colossus of the North" controlled Cuba through the

Platt Amendment. It had created Panama. Pres. Theodore Roosevelt's big stick policy had not only sanctioned intervention in Latin America but had claimed for the United States a monopoly of the right to engage in it, thereby making the United States not only the policeman of the hemisphere but its judge as well. President William Howard Taft's dollar diplomacy was followed by the sending of Marines into the Caribbean and Central America. President Woodrow Wilson did little to quiet the fears of the Latin-American leaders when he intervened in the internal affairs of Mexico by more or less openly calling for the overthrow of Dictator-Pres. Victoriano Huerta. By 1914 the United States furnished 32 percent of the imports of the entire area and took 36 percent of the exports of the republics.

Distrust of the United States had much to do with the official attitudes of the Latin-American republics in World War I. Despite great sympathy on the part of the privileged groups for France, only eight of the countries declared war against Germany, and only two, Cuba and Brazil, offered military aid. Seven of the eight republics that declared war were dominated financially by either the United States or Great Britain. Only Brazil made its choice with comparative freedom. Five of the republics broke relations, and seven, including Argentina, Chile, Colombia, and Mexico, remained neutral. Mexico was actually pro-German for at least part of the struggle. Early in the war international trade was brought to a near halt, but by the end of the conflict the republics were supplying food and strategic materials in abundance. The foreign commerce of the 20 republics rose to $3,900,000,000 in 1918 after having fallen to $2,200,000,000 in 1914. The fact that under the stress of war the Allies failed to provide the manufactured goods to which the population had become accustomed gave a fillip to domestic manufacture of consumer goods.

Between the wars, 1918–39

By the end of World War I it was quite apparent that the 20 republics were in widely varying states of development and that the differences among them were actually increasing. Bolivia, Ecuador, Paraguay, Peru, Venezuela, and the Caribbean and Central American republics, except Costa Rica, lived in the mid-19th century. They were politically immature, plagued by meaningless revolutions, economically backward and burdened with foreign debts, and generally lacking in social awareness.

Colombia was in a category by itself. It was dominated by a narrow oligarchy that at times had shown unusual administrative skill, but the structure of the country retained most of its colonial features and the nation was just beginning to enter international markets. With tremendous potential compared to many of its neighbours, it was nearly prostrate from civil strife that bordered on anarchy.

By 1920 Argentina, Chile, Costa Rica, Uruguay, and Mexico were clearly in the vanguard, and Brazil joined them in the 1930s. It is with these six republics, containing two-thirds of the land area and two-thirds of the population, and annually producing approximately two-thirds of the gross product of the 20 republics that the remainder of this article is primarily concerned. Between 1918 and 1968 it was in these republics—joined by Venezuela after 1960—that one found most of the region's dynamism, its new self-confidence, its desire to create and its very conscious groping for self-expression. It was to the seven republics that, for one reason or another, the other republics looked, when they looked at all, for leadership.

THE NEW POLITY

Political recognition of the popular masses. During the century after independence the leaders of Latin America had at first sought essentially political and then economic solutions to the problems of the republics. Between World War I and World War II the leadership in the more progressive republics not only merged politics and economics but added a social ingredient to their ideology. Socioeconomic problems were made the fundamental political problems. Democracy, which earlier had been thought of primarily as a theory of government and which in practice was more nominal than real, was expanded to include economic and social democracy. The exaggerated individualism of the 19th century gave way to an emphasis upon social solidarity. The concept of the state as a passive organism, limited largely to maintaining order and collecting taxes, was supplanted by a concept of the vital state that would provide leadership in the economic and social fields as well as in the political. Politicians spoke more of social justice, less of legal justice; more of social equality, less of political equality; and masses came to prefer good government to self-government as they knew it.

Movements toward social reform

There was a twofold explanation for the new concern with the issue brought to the surface by the transformation of the pre-World War I era. The urban working groups, aroused by the knowledge that the stirrings of European workers immediately after the war had won official recognition of their problems, demanded action on their behalf. The middle sector politicians, in their struggle for power with the old elites, had been forced to go to the workers for electoral support. Once the workers were brought into the political arena their social anxieties, frustrations, and discontents could no longer go unheeded.

Under the influence of the new political philosophy the traditional concept of the role of private property in society was challenged. The Mexican constitution of 1917 defined private property in terms of social function. The Chilean constitution of 1925 established the superiority of the state over private property.

Workers' welfare

By 1930 there were numerous indications of the growing concern over working conditions and the welfare of workers. Article 123, often called the Magna Carta of Mexican labour, of the constitution of 1917 not only enjoined the state to foster a strong Mexican labour movement but recognized labour as a status, a way of life, for which the minimum essentials must be guaranteed. By the end of the 1920s Uruguay had adopted legislation providing for the eight-hour day, minimum wages, equal pay for equal work, protection on the job, and fixing the terms under which minors might be employed and workers might be separated from their jobs. Article 56 of the Uruguayan constitution of 1934 made the state responsible for promoting the organization of trade unions, enacting standards for the recognition of their juridical personality, and promoting the creation of tribunals of conciliation and arbitration. The Costa Rican constitution of 1925 contained elaborate guarantees to both urban and rural labour. The Chilean labour code of 1931 embodied radical principles and general practices regarding labour. In Brazil, Pres. Getulio Vargas put many social measures into law: a minimum wage, old-age pensions, accident insurance, workers' savings banks, vacations with pay, cheap housing. As early as 1925 the Chilean government wrote an imaginative program of social security, including an elaborate structure of social security funds to which workers, employers, and the state contributed. Uruguay carried on public works programs as insurance against unemployment. In Mexico, Pres. Lázaro Cárdenas spoke of "land for those who worked it."

Material gains and social welfare for the workers were often delayed and seldom measured up to expectations. A vast share of all social legislation remained as little more than statement of aspirations. Still, the self-respect and the sense of belonging to the nation that the new official attitude gave the labourers in Mexico, Uruguay, and Chile was immediate and profound. On the other hand, the failure of Argentina's "don't-touch-agriculture" leadership of the 1920s and the 1930s to give recognition to the workers prepared them for the acceptance of Perón's quasi-Fascist administration in the 1940s.

State interventionism. In the 1930s the national governments in several of the more advanced states began to reject the laissez-faire doctrines of the 19th century. They broadened their economic responsibilities in search of faster and better ways of fulfilling the social obligations they had assumed. The governments justified their action on three grounds: (1) Industry could not survive without protection from outside competition and only the state could provide that protection. (2) Since the accrual of domestic private capital was slow, the state, with its ability to accumulate capital relatively rapidly through taxation and foreign loans, must intercede in the industrial sphere. (3) Solicitude for the labouring classes required that the state exercise some control over the prices of necessaries.

The economies that the governments sought to vitalize were reeling from repeated blows. The international economy had been severely jolted by World War I and had not been reconstructed in the uncertain political and economic environment of the 1920s. Economic nationalism in Europe had placed at a disadvantage countries, such as those of Latin America, that depended upon the export of primary products. The fact that each republic continued to rely on one or two basic exports had weakened further their bargaining position in the new world economy. The economic dislocations and problems of the 1920s were heightened by the Depression of the 1930s, which saw the drying up of foreign loans, the complete collapse of the world economy, and widespread defaulting on debts. Chile's and Bolivia's exports dropped 80 percent between 1929 and 1932.

The Great Depression

There were many instances in the 1930s of states investing directly in economic enterprises, as, for example, in Uruguay and in Mexico following the nationalization of the railways and the expropriation of the foreign-owned oil properties. But before World War II the general practice was for governments to limit their intervention to placing restrictions on imports, using exchange controls, licensing arrangements, imposing embargoes in order to promote domestic manufactures, and creating autonomous and semiautonomous institutes to assist designated sectors of the economy. These measures mainly represented attempts by nations to protect their foreign exchange earnings. Economic nationalism was at best a secondary consideration.

The manufacturing sector of the economies made significant advances in the 1930s, probably as much because of the impetus given by the Depression, when the foreign exchange situation left no alternative to domestic production of a wide range of manufactures, as to state promotion and planning. While manufacturing made appreciable gains there was a marked decline in capital invested in transportation as revenues dropped and funds for upkeep and replacements were not forthcoming from other sources. Agriculture, still the principal source of foreign exchange for a majority of the republics, was neglected.

THE NEW SOCIETY

Social mobility. The interwar years produced social mobility and social ferment on an unprecedented scale. Increased opportunities for learning, coupled with the growing demand for intellectual and technical skills in the public and private bureaucracies and in education, permitted many persons from the lower groups to achieve middle-sector status. Employment opportunities in factories, commercial establishments, public utilities, and the building trades attracted hundreds of thousands from the rural villages into the burgeoning cities.

In Uruguay, Argentina, Chile, and Costa Rica, where the populations were overwhelmingly European, there was little change in the ethnic composition of the social groups or the cities. But in Mexico the middle classes, the skilled working classes, and the cities all experienced a heavy Indian infiltration, and in Brazil there was a noticeable Africanization of the major industrial and commercial centres. Labourers who had become members of the middle class and farm hands who had become industrial workers experienced the frustrations inherent in passing from one socioeconomic group to another. The new social milieu placed those who knew the lower levels of society from first-hand experience beside those who had only a paternalistic interest in or a theoretical understanding of the working element. Those who depended upon labour leaders to defend their interests often worked for individuals who had an abhorrence for the labour movement. Those who had never owned property and were little concerned with property rights or infringements upon private enterprise were thrown together with persons strongly committed to the defense of private property and personal initiative. The clashes that resulted from the coming together of two essentially different cultures were often bitter, and there was much pulling and hauling as groups fought for advantage. But there was also a sharpening of the focus on the goals and aspirations of the people as they struggled with the crisis of growth, and there was no turning back of the clock as the workers retained, at least in principle, the gains they won.

Rise of Indians, blacks, and other groups

The family in a changing society. Under the pressures of modern life the family, which traditionally had served a political as well as a social role, began to weaken. This was particularly true in the cities where private dwellings began to give way to cramped apartments. Economic pressures forced many middle-class women to find employment outside the home; increased education and job opportunities for girls gave them a new freedom. Modern means of transportation encouraged young people to travel and make associations outside the family. Cinemas, clubs, and public parks bid against the family for the leisure time of its members. Youths left their homes to go into education, business, and the professions, and returned home with information that permitted them to reach decisions independently of the older members of the household. The new independence helped to weaken allegiance to the family as a political unit, and there was a strong tendency to transfer this allegiance to political groups. Political parties provided a common ground for those who had similar objectives based on education and occupational interest and social relationships outside the home.

THE NEW MILITARISM

The role of the military establishment underwent basic modifications between the two wars. The young men who had entered the armies at the turn of the century had now come to power. They were from the same socioeconomic groups as the new civilian leadership; as the economic and political influence of the middle sectors rose, the officers' inclination to associate themselves with the old elites declined. The officers, meanwhile, had learned to accept the working elements, if not always to trust them. Like the middle-sector leadership, the officers of the armed forces supported nationalism as a means of achieving rapid industrialization.

Professionalization of the military forces did not have the effect of keeping them out of politics, but it did lead to a new concept of the military's role in government and society. Under the influence of the new concept the officers tended to discard their historical subservience to an all-powerful strong man. Instead, they organized in such a way that when intervention took place it was in the name of the armed forces rather than of an individual, and government was by juntas in which all branches of the armed forces were represented. While the earlier military leaders had been content to declare for the general will, the new military statesmen felt compelled to define the content of the will. Several of the Caesar-statesmen who won recognition during the 1930s showed a distinct preference for Nazism and Fascism.

The army in politics

NATIONALISM

As a result of both external and internal developments during the 1920s and early 1930s, cultural nationalism was given wide play in the Latin-American area. France, to which Latin America traditionally had looked for cultural inspiration, failed after the war to regain its cultural hegemony in the Western world. The stream of immigrants from Italy, Spain, and Portugal diminished under the impact of the Depression. This development served to loosen the area's ties with the Mediterranean region, and the separation became more complete as those who had migrated before 1920 adapted themselves to their new surroundings. Simultaneously, financial leadership in the world passed from Great Britain to the United States, whose people were considered cultural barbarians by the Latin-American elites. These conditions were made-to-order for the new middle-sector political leaders who were bidding for power against the old elites. They argued that since Europe was losing its cultural position and Latin-American ties with the area were weakening, the old elites, "who lived with their feet in America and their heads in Europe," should be repudiated. They also contended that

Growing cultural independence of Latin America the decadent neo-European culture the elites had imposed upon Latin America could not withstand the increased pressures of an economically dominant United States. Finally they declared that since in the new order each social sector was worthy of representation in government it must be assumed that each group had something worthwhile to contribute to the national personality. It followed from these arguments that Latin America was obliged to look inward and search out the best that each of its social groups had to offer, and then to integrate the whole into a culture that would be truly representative of the national essence.

In the 1920s intellectuals had taken the lead in promoting the nationalization of their culture, and they had directed their appeals to the learned components of society. With the onset of the Great Depression, the states, at the same time that they expanded their social and economic responsibilities, seized the leadership from the intellectuals and added an embryonic economic nationalism to the earlier cultural nationalism. This integrated nationalism was brought down to the masses in concrete and politically charged form. As such it was soon raised to the level of a major political ideology and there it has remained. The glorification of a narrow nationalism was used to unite all elements in the swelling resentment against the exactions of economic imperialism and to cultivate the national spirit while undermining the atomistic assumptions of liberalism. It served as a vehicle for the adoration of collective power. In its more virulent form the new nationalism became anti-imperialism and more specifically anti-United States. At first it was directed against United States political intervention and cultural infiltration of the republics. Later it was manifested in attacks upon U.S. investors, who, it was generally charged, were depleting the area of its irreplenishable natural resources and discriminating against national employees.

World War II

The Good Neighbor Policy had helped to improve understanding between Latin America and the United States. When the second global war erupted, all of the republics except Chile and Argentina were prompt to throw their support to the Allies. By the end of January 1942, nine of the nations had declared war on the members of the Axis and nine others had severed relations with them. The war declarations became unanimous when the Fascist-oriented leadership in Argentina finally declared war in March 1945 and thereby qualified for a seat in the United Nations.

As in World War I, Latin America's contribution to the Allied cause was largely in the forms of foodstuffs and strategic materials. Brazil, however, sent an expeditionary force to the Mediterranean, and a Mexican air force squadron fought in the Pacific theatre of operations.

The Allied demands for foodstuffs and minerals resulted in nearly full employment in Latin America during the war years and lifted the gross product of the area to unprecedented heights. Increased industrial production for domestic consumption was achieved by placing added burdens on existing plants and equipment because the wartime economies of the Allies did not provide for the export of capital goods, except in most unusual circumstances. There was a moratorium on strikes. Labour–employer issues and social welfare demands were reduced to a secondary position as politicians (in Mexico, Chile, and Brazil, for example), and Communists and Communist sympathizers everywhere called for an end to class conflicts in the face of the grave threats from abroad. The United States, whose overriding consideration was strategic, helped to maintain stability in the area by providing incumbent regimes with military and economic aid.

The postwar years

THE ECONOMY

Industrialization was a principal obsession of the peoples of Latin America after World War II and heavy industry became the symbol of national progress. Figuratively speaking, the fiery furnaces of real and anticipated iron and steel plants fused the goals of the working elements and the hopes of the privileged groups into a national will, the expression of which was reflected in all major areas of human activity.

Latin America had been formulating its new views on industrialization for some time before they found expression after the defeat of Germany. The extractive and processing industries that had been promoted so assiduously before World War I and during the 1920s had not lived up to expectations. They drained off natural resources without, it most cases, providing real impetus to other sectors of the industrial economy. Industrial production, even at the expanded rate of the war years, had not brought the hoped-for economic emancipation, since the machines, and many of the raw materials and the fuels needed for the production of semidurable goods, had to be imported. World War II had shown the inconvenience of dependence upon the outside world for replacement parts and machine tools. Finally, it had become evident that the great powers were, in fact, great manufacturers. This meant that if the republics were to gain worldwide recognition and respect they must, among other things, have steel plants and make machines.

The new industrialism

Much of Latin America's industrial expansion has been and continues to be financed through inflationary borrowing. An intermittent phenomenon in Latin America since the late 19th century, inflation surged upward in the late 1930s and after World War II spiralled in several countries, notably Argentina, Bolivia, Brazil, and Chile. Borrowing has also substantially increased the external debt of most Latin-American countries and caused greater portions of national incomes to be devoted to repayment. Rampant inflation has tended to direct capital toward short-run speculative ventures, rather than basic industry requiring relatively long maturation periods. Industrial development, far from contributing to internal equilibrium, has in fact more typically distorted the economies by contributing to regional concentration of income. This is because industry has invariably grown up in the main urban centres where a steady demand for consumer goods exists and where skilled labour is most readily available.

As it has turned out, a large part of Latin America's commitment to industry has been made at the sacrifice of the agricultural sector. After 1945, farm production barely kept pace with population growth. In order to feed their people adequately some countries shifted to subsistence agriculture from commercial agriculture, the principal source of foreign exchange for all the republics except Bolivia (tin), Chile (copper), Mexico (tourism), Peru (industrial ores), and Venezuela (petroleum). As of the mid-1960s the agricultural sector contributed less than 20 percent of the gross product of the republics. Agriculture's contribution decreased further the next decade.

Land reform

Little progress has been made in the redistribution of land. The governments of Mexico, Bolivia, and Cuba have seized and divided land with little regard for the original owners. In Venezuela, the government has had the means to pay for land that it has acquired for redistribution to peasants. Elsewhere, nations and international technical experts and legislators search for legal means to penetrate on a broad front the tight ranks of landholders, who in Latin America exercise political power out of proportion to their economic contribution. In the late 1960s Chile, where Christian Democratic Pres. Eduardo Frei Montalva fought for agrarian legislation, provided the most interesting test as to whether effective agrarian reform could be instituted within a constitutional context. During the 1970s, agrarian reform became an important part of leftist movements, such as the Sandinistas in Nicaragua, in Latin America. This caused some governments, El Salvador for example, to initiate limited land reform policies.

Land redistribution tends to capture the imagination of the public, but as a short-range goal increased production may be equally as important and as difficult of solution. In many areas agricultural techniques are incredibly outdated. Landholders in general seem unconcerned about modernizing their methods and equipment. Many do not have the means to modernize should they choose to do so, while others are reluctant because of the threat of expropriation which is ever present.

State intervention. The clamour for rapid industrialization invited increased state intervention in economic life. Domestic private investors could provide only a small part of the necessary capital. Foreign investors were reluctant to enter the "politically charged" power and transportation fields, particularly when the threat of expropriation hung over them. Nationalists successfully prevented the investment of foreign capital in a large number of activities closely related to natural resources. The national governments, on the other hand, could and did raise capital through taxation and by borrowing abroad.

Government ownership of industry

Examples of large-scale government participation in industrial enterprises are numerous. In Brazil, Volta Redonda, one of the largest iron and steel plants in Latin America, is government controlled. The Brazilian government is the owner of numerous hydroelectric facilities, and Petrobras is a publicly-controlled petroleum monopoly. In Argentina the government controls the railroads and the petroleum industry. In Chile the central government has a direct interest in the production and sale of natural nitrates and has formed a partnership with the copper companies to regulate its production and exports. It also controls the iron and steel plant near Concepción. A saturation law gives an agency of the Chilean government power to exclude further investment in areas where production is deemed sufficient. In Colombia the iron and steel plant at Paz del Río has the unqualified support of the government. In Mexico the government through Pemex operates a petroleum monopoly, and the railroads are nationalized. The Nacional Financiera, most of the stock of which is owned by the Mexican government, is the channel for negotiating and administering loans obtained from abroad and is the principal source of funds for industrial development in the country. In Uruguay the government controls the production of electricity and operates the telephones, railroads, the port of Montevideo, insurance banks, and the meatpacking industry; it also imports and distributes coal, distills alcohol, and manufactures all cement used for public works. In Bolivia the central administration produces and markets most of the country's tin.

Economic diversification. By the 1960s industry and commerce accounted for 50 percent or more of the gross products of Argentina, Brazil, Chile, Colombia, Mexico, Uruguay, and Venezuela. At that time about 15 percent of the total labour force of Latin America was in manufacturing as opposed to about 45 percent in agriculture and 30 percent in service occupations. By the late 20th century industry and commerce accounted for more than 80 percent of the gross domestic product of Latin-American countries.

Industrial development has contributed appreciably to diversification within those sectors of the economies producing for internal consumption. The more highly industrialized countries are today producing a major share of their textiles, appliances, pharmaceuticals, and building materials, and are moving ahead in the manufacture of industrial chemicals. The republics have enjoyed only limited success in modifying the composition of their exports. Even as late as the postwar years they continued to export the same primary materials that they exported before World War II and a considerable portion of their foreign exchange earnings continued to come from a single commodity.

Foreign trade. To a greater extent than in the case of the countries that have reached a higher level of industrial development, the economies of the Latin-American republics have remained geared to overseas markets. Throughout the late 20th century it was common in many of the countries for the value of exports to contribute substantially to the gross national production. This situation, generally considered unfavourable by the leadership of the republics, has tended to increase Latin America's share of world trade.

The quite limited trade between the republics has given rise to a marked effort to expand their regional ties. The first major effort, the Central American Common Market (Cacom), encompassing El Salvador, Guatemala, Honduras, Nicaragua, and Costa Rica, created in 1957, was remarkably successful until civil wars and national rivalries in the 1980s halted progress.

LAFTA

The Latin American Free Trade Association (LAFTA), presently involving all the countries (except Guyana) in South America plus Mexico, went into effect in June 1961. LAFTA had many strong supporters and prospects for a successful future, as it succeeded in bringing about an increase of trade between the republics and in encouraging the private sectors. Many problems confront it, but none more serious than the need to increase its share of world trade, since foreign exchange is vital to the continued development of the republics.

Foreign investment. The disastrous experiences of the Depression and the conduct of nationalistic governments in the late 1930s made foreign investors most reluctant, after World War II, to send capital to Latin America in the form of portfolio investments. On the other hand, there has been since the war a relatively heavy flow of private capital into the area as a result of direct investments by foreign enterprises. Between 1945 and 1950 private capital went primarily into petroleum, but since 1950 investors have shown increased interest in manufactures and the extraction of minerals other than petroleum.

Latin-American governments in general have welcomed foreign investors since World War II but have insisted that since foreign investors will not put their capital into the development of those sectors basic to long-range growth, such as power and transportation, aid in these areas must come from international lending agencies.

Various agencies of the U.S. government have also been active in assisting the republics to develop their human and natural resources. The Export-Import Bank of Washington is the oldest of such agencies. After many years of agitation by the Latin-American republics, the U.S. government in 1959 approved an Inter-American Development Bank. This agency was originally capitalized at $1,000,000,000, of which $450,000,000 was contributed by the U.S. The bank approved its first loan in 1961. Loans and grants were made to the republics by the U.S. Agency for International Development (AID).

Urbanization. After World War II, three factors combined to produce a major urbanization movement: industrial and commercial expansion, a population explosion that was annually adding almost 3 percent to the total number of inhabitants, and the advantages afforded by the cities. In 1925 Latin America's population was 33 percent urban; in 1960 it was 45 percent urban and the percentage increased rapidly thereafter. Uruguay became the most urbanized of the republics, but nearly all the republics showed a pronounced trend toward urban concentration. During the decade after World War II Colombia's urban population increased 58 percent, Venezuela's 57 percent, Panama's 54 percent, and Mexico's 50 percent. Almost everywhere the tendency was for the largest cities to grow faster than the smaller ones.

ADMINISTRATIVE AND SOCIAL CONDITIONS

Centralization

One of the profound effects of state intervention in the social and economic fields has been the general strengthening of the already strong central government at the expense of the states and municipalities. In several of the smaller nations the state as a separate entity does not exist at all and the municipality thus serves as the only buffer between the central government and the individual. In many cases, notably Colombia, the states and municipalities have been largely stripped of their power to tax and are consequently dependent upon subsidies from the central authority.

The executive. Historically, the tendency in Latin America has been toward the concentration of power in the executive branch of government, a tendency that was not ordinarily deterred by any theoretical balance of power or by federalism. The strengthening of the central governments at the expense of the states and municipalities in most instances has encouraged the trend toward a strong president. Since World War II the legislative branches have not in general exercised their constitutional prerogatives, and the legislatures have been little more than rubber stamps. The chief executive, also, generally participates in, if he does not actually make, judicial appointments, and thus is able to exercise considerable influence over the judiciary. Moreover, programs of social legislation, which have tended to place social interests above the rights of individuals as private citizens, have been more closely linked with administrative acts than with private civil law. This innovation gives the executive branch power to regulate the rights of individuals by administrative decrees and thus to reduce the power of the regular courts.

The electorate. In a drive for general enfranchisement, property requirements have been removed in most instances; age and literacy requirements have been reduced and in some cases discontinued; and women have been granted the right to vote. These measures have been highly successful in broadening popular participation in politics.

Political parties. Personalism and the political influence that the family traditionally exercised have given the erroneous impression that organized political parties are either nonexistent or are of recent origin in the Latin-American area. It is true that in several of the republics major and even dominant parties date from World War II. But it is also true that by the mid-19th century two relatively homogeneous party traditions had emerged, represented by the Liberals and the Conservatives. The Liberal and Conservative parties of Colombia and Chile all date from before 1850. In the late 19th century nationalist parties arose with programs for national development. Parties with middle-class leaders and depending upon the electoral support of labour groups were active in Argentina, Chile, and Uruguay before 1920. These older parties usually were organized from the top down and consequently lacked local spontaneity.

Single-party and multiparty governments

After World War II all types of party systems were used. In the late 20th century a single party held an effective monopoly on public power in Mexico, Paraguay, Nicaragua, and Cuba. Multiparty arrangements existed in Argentina, Bolivia, Brazil, Chile, Costa Rica, Guatemala, Panama, Peru, and Venezuela.

Quasi-Fascist parties—Peronista in Argentina, Integralista in Brazil, Nacista in Chile, and Sinarquista in Mexico—have had large followings at times. The agrarian-populistic Aprista parties have indigenous roots. The Apristas have sought far-reaching social and economic reform and the integration of the lower classes into the political process. Acción Democrática, after World War II the predominant civilian party in Venezuela, is often considered to be an Aprista party. After 1959 a number of parties based on ideologies similar to that of Castro made their appearance, notably in Brazil and Venezuela.

The Roman Catholic Church. The Roman Catholic Church exerts a profound influence over the people of Latin America, 90 percent of whom consider themselves Catholic. Nevertheless, as indicated in the section dealing with the 19th century, the church's influence did not prevent it from coming under persistent and often violent attacks from anticlericals. After World War II, however, there was a notable lessening of tension, and in the late 20th century there was no major anti-church movement anywhere in Latin America, except in Cuba.

Three developments after World War I appear to have contributed significantly to the change. (1) National governments became stronger, which allowed them to be somewhat more tolerant of the opposition. (2) The middle class became politically powerful at the expense of the old allies of the church. In the light of this development the church reexamined the ideology of constitutional democracy that such groups advocated, and by 1960 the local churches had, in most instances, revised their position to agree with the church's official social doctrine of concern for the plight of the working and underprivileged classes. In giving practical application to this new position, the church cooperated with liberal democratic groups in the overthrow of the Argentine dictator, Juan Perón, the Colombian military chief, Gustavo Rojas Pinilla, and the Venezuelan tyrant, Marcos Pérez Jiménez. In 1961 the church went into open opposition against Fidel Castro in Cuba. (3) The Communists established their ability to create ideological confusion in the minds of the members of both the lower classes and the intellectual middle class. This development was of great concern to the church, which emphasized social and economic reform, including, at least in Colombia and Venezuela, land reform.

Education. The schools have been the stepchildren of the social and economic planners. The public neglect of schools accounts in large part for the fact that developments which might be expected eventually to produce basic changes in educational thinking have been slow in appearing, and the direction that some of them will finally take is not yet clear.

Except at the university level, where public institutions generally are superior, private schools continue to be preferred by those families who can afford to send their children to them. As has been the case historically, educational opportunities at every level are far greater in the urban centres than in the rural areas. Meanwhile, the advantages afforded in the cities serve to attract the best young minds from the farms and villages, and once in the cities the youths show little inclination to return to the backward areas from which they came. What education is available in the rural districts is often determined in the capital cities and may have little relevance to the needs of the students or, for that matter, of the nation. The final and perhaps most obvious tendency is for educational planning, administration, and financing to come under the control of the central governments, as have many other social and economic activities.

Summary. Certain broad generalizations may be drawn regarding Latin America in the late 20th century. Despite the rash of military coups that unseated constitutionally elected governments in Argentina, Peru, Guatemala, Ecuador, the Dominican Republic, Honduras, Bolivia, and Brazil, it was evident that the long-range trend in Latin America was toward more government by law and by the people. Appreciable progress had been made toward institutionalizing the electoral process. Issue-oriented political parties had grown in strength. These trends were in part counterbalanced by more demagoguery; the concentration of power in the central government at the expense of the states and municipalities; and the general failure to make inroads on the extended powers of the executive branch of government, a situation conducive to the continuance of dictatorship in the republics.

In the social-religious area the problems of the underprivileged had been given recognition; people of colour had penetrated the privileged classes without producing significant social clashes; and the Roman Catholic Church had found it easier to live at peace with the political leadership. However, little had been done to create a responsible labour movement; education had failed to keep pace with progress in other areas; and a large part of the lower classes continued to live marginal existences.

Industrial expansion had often been at the expense of agriculture; factories had failed to absorb all those entering the labour market; industry had not measurably improved the living levels of the working groups; and increased industrialization had, by increasing the need for raw materials, fuels, and capital goods, tied the republics ever closer to the world trading community.

The most recent outgrowth of these phenomena has been the emergence of a dynamic nationalism in the most advanced republics. The new nationalism is the instrument of the growing managerial and intellectual classes. It reflects the deep conviction among public figures that their nations can be developed only within a global framework of which they are a part. The new nationalism accepts the necessity for foreign aid but insists that such assistance must not mean economic submission and cultural dependence as it often has in the past. (J.J.Jo./Ed.)

BIBLIOGRAPHY

General works: CHARLES GIBSON, *Spain in America* (1966), the best short survey, incorporates the latest scholarship and has a valuable bibliographical essay; JOHN H. PARRY covers the same ground somewhat more amply in his well-written *The Spanish Seaborne Empire* (1966). SILVIO A. ZAVALA, *El mundo americano en la época colonial,* 2 vol. (1967), is a work of synthesis by a leading Mexican historian. STANLEY J. and BARBARA H. STEIN, *The Colonial Heritage of Latin America: Essays* *on Economic Dependence in Perspective* (1970), brief but insightful, shows the continuity of Latin-American economic patterns from colonial times to the present. Among older works, CLARENCE H. HARING, *The Spanish Empire in America* (1947, reprinted 1963), remains indispensable for colonial institutions. BAILEY W. DIFFIE, *Latin American Civilization: Colonial Period* (1945), is a work of formidable scholarship and sharply defined viewpoints on various controversial topics. For a comprehensive collection of source materials on the colonial period, see BENJAMIN KEEN (comp.), *Readings in Latin America Civilization, 1492 to the Present,* 2nd ed. (1967).

Spanish conquest of America: CARL O. SAUER, *The Early Spanish Main* (1966), critically examines the impact of the discovery on the Indian population of the Caribbean. WILLIAM H. PRESCOTT, *History of the Conquest of Mexico,* 3 vol. (1843, reprinted 1966), and *History of the Conquest of Peru,* 2 vol. (1908, reprinted 1963), remain classics, unsurpassed for breadth of conception and literary charm, but their romantic attitudes clearly reveal the books' age. JOHN HEMMING, *The Conquest of the Incas* (1970), supersedes all previous accounts.

Spain's colonial empire: PHILIP W. POWELL, *Soldiers, Indians, and Silver: The Northward Advance of New Spain, 1550–1600* (1952); and EUGENE H. KORTH, *Spanish Policy in Colonial Chile* (1968), examine Spanish–Indian relations. LEWIS U. HANKE, *The First Social Experiments in America* (1935), and *The Spanish Struggle for Justice in the Conquest of America* (1949), discuss the intellectual history of the Conquest; while his *Aristotle and the American Indians* (1959) studies the controversy between Las Casas and Juan Ginés de Sepúlveda over the nature and capacity of the Indians. For Messianic and Utopian influences in the Conquest, see JOHN L. PHELAN, *The Millenial Kingdom of the Franciscans in the New World,* rev. ed. (1969). For a reappraisal of Spain's Indian policy that questions some of Lewis Hanke's premises, see BENJAMIN KEEN, "The Black Legend Revisited: Assumptions and Realities," *Hispanic American Historical Review,* 49:703–719 (1969). On race relations in the colonial period, see the thoughtful survey of MAGNUS MORNER, *Race Mixture in the History of Latin America* (1967). Controversy surrounds the question of the size of pre- and post-Conquest Indian populations. S.F. COOK and WOODROW BORAH made an illuminating series of studies that indicate a very large Indian population in 1519, followed by a demographic catastrophe in the 16th and 17th centuries, consolidating their findings in *The Indian Population of Central Mexico, 1531–1610* (1960). For comparison, see the sharply divergent findings of ANGEL ROSENBLAT, *La población de América en 1492: Viejos y nuevos cálculos* (1967). FRANCOIS CHEVALIER, *La Formation des grands domaines au Mexique* (1952; Eng. trans., *Land and Society in Colonial Mexico: The Great Hacienda,* 1963), a landmark in the study of colonial land systems, traces the interplay of demographic and economic trends in the development of the hacienda. JAMES LOCKHART deftly analyzes the structure of Spanish society in colonial Peru in *Spanish Peru, 1532–1560* (1968).

The *encomienda* has been the subject of careful study. Two pioneer works are L.B. SIMPSON, *The Encomienda in New Spain,* rev. ed. (1950); and SILVIO A. ZAVALA, *La encomienda indiana* (1935). CLARENCE H. HARING, *Trade and Navigation Between Spain and the Indies in the Time of the Hapsburgs* (1918), remains a standard work. On land systems, see J.M. OTS CAPDEQUI, *España en América: El régimen de tierras en la época colonial* (1959). On mining, see MODESTO BARGALLO, *La minería y la metalurgía en la América Española durante la época colonial* (1955), for a general survey.

For the relations between church and state, see JOHN L. MECHAM, *Church and State in Latin America,* rev. ed. (1966); and WILLIAM E. SHIELS, *King and Church: The Rise and Fall of the Patronato Real* (1961).

Colonial Brazil: CAIO PRADO, *Formacão do Brasil Contemporañeo* (1942; Eng. trans., *The Colonial Background of Modern Brazil,* 1967), is an excellent introductory survey. See also CHARLES R. BOXER, *The Dutch in Brazil, 1624–1654* (1957), and *The Golden Age of Brazil, 1695–1750* (1962). DAURIL ALDEN, *Royal Government in Colonial Brazil* (1968), is a model monograph. GILBERTO FREYRE, *Casa Grande e Senzala,* 2 vol. (1943; Eng. trans., *The Masters and the Slaves,* 1946), a work of great literary charm, portrays Portuguese colonizers as almost free from colour prejudice and Brazilian slavery as relatively mild. For opposing points of view, see CHARLES R. BOXER, *Race Relations in the Portuguese Colonial Empire, 1415–1825* (1963); and MARVIN HARRIS, *Patterns of Race in the Americas* (1964). On the economics of colonial Brazil, see ALEXANDER MARCHANT, *From Barter to Slavery* (1942), which stresses the mixed feudal-capitalist character of early Brazilian economy; and CAIO PRADO, *op. cit.*

The Bourbon reforms and Spanish America: JOHN LYNCH, *Spanish Colonial Administration, 1782–1810* (1958), discusses colonial political reform. For the transmittal of Enlightenment ideas to Latin America, see the essays in ARTHUR P. WHITAKER (ed.), *Latin America and the Enlightenment,* 2nd ed. (1961).

Wars of independence: ROBIN A. HUMPHREYS, "The Fall of the Spanish American Empire," *History,* 37:213–277 (1952), is a perceptive interpretive essay, while Humphreys and JOHN LYNCH (eds.) bring together a variety of viewpoints in their anthology, *The Origins of the Latin American Revolutions, 1808–1826* (1965).

(B.K.)

Latin-American Literature

Latin-American literature consists of the national literatures of the Spanish-speaking countries of the Western Hemisphere and Portuguese-speaking Brazil. It also includes the literary expression of the highly developed Indian civilizations conquered by the Spaniards. Over the years Latin-American literature has developed into one of the finest literatures of the Western world, displaying a richness and diversity of themes, forms, and styles. A concise survey of its development is provided here.

The article is divided into the following sections:

THE COLONIAL YEARS (1492–1826)

Literature of the conquest (1492–1600). With the discovery of new lands beyond the ocean, Spain and Portugal embarked on a Christian crusade that was to stamp the colonial seal on vast areas of the Americas. This adventure was chronicled from the day Columbus set sail; his letters to King Ferdinand and Queen Isabella of Spain marked the beginnings of a rich body of colonial writings. The discovery and conquest are told in countless letters, chronicles, histories, polemical tracts, dictionaries, grammars, religious pieces, and epic poems. The great cultures discovered and conquered by the Spaniards also possessed a rich heritage of poetry, theatre, and mythicohistorical writing, the most poignant of which are their chronicles of the conquest and their defeat and destruction.

The thrill of the first contact and the adventures and problems that followed are recorded in various writings, including the five dispatches, or *Cartas de relación* (1519–26; *Five Letters*), sent by Hernán Cortés to his emperor, Charles V; the indignant account of Bernal Díaz del Castillo, who spoke for the common soldier in his *Verdadera historia de la conquista de la Nueva España* (1632; *The True History of the Conquest of New Spain*); the impassioned pages of the *Brevísima relación de la destrucción de las Indias* (1552; *The Tears of the Indian*) by the Dominican friar Bartolomé de las Casas, which became the cornerstone of the "black legend" of colonial Spain; and the observations on the tragic consequences of the struggle between cultures embodied in the *Comentarios reales que tratan del origen de los Incas* (1609–17; *First Part of the Royal Commentaries of the Yncas*) by Garcilaso de la Vega, a mestizo born of an Incan princess and a Spanish conqueror.

Epic beginnings

The conquerors did not chronicle their deeds in prose alone. Fired by the heroic fervour of their age and by the example of Ariosto, Tasso, and the Latin masters, they sang in epic measures their adventures from distant Antarctica to the upper reaches of the Río Grande. *La Araucana* (1569–89; *The Araucaniad*), the first and the best of these epics, was begun on scraps of paper and bark by the young captain and courtier Alonso de Ercilla y Zúñiga while he was serving with the Spanish armies fighting against the Araucanians of Chile. Its great attraction still is the immediacy of the experience and the balanced attitude toward the Indians. Enormously popular, *La Araucana* inspired similar efforts elsewhere: Juan de Castellanos, *Elegías de varones ilustres de Indias* (1588; "Elegies of the Illustrious Gentlemen of the Indies"); Martín del Barco Centenera, *La Argentina;* and Gaspar de Villagrá, *Conquista de la Nueva México* (1610). These later poems pale in poetic import as they gain in documentary significance. Only the *Arauco domado* (1596; *Arauco Tamed*) of Pedro de Oña, Chile's first outstanding native poet, approaches Ercilla's epic in artistic achievement. *La cristiada* (1611; "The Saviour"), written in Lima by the Dominican Diego de Ojeda, is often called the best sacred epic in the Spanish language. Finally there is Bernardo de Balbuena, whose work best represents the rich and varied literary expression of the dawning Baroque age. His epic of Spanish history, *Bernardo, o la victoria de Roncesvalles* (1624; "Bernard, or the Victory of the Roncesvalles"), and his eclogues are overshadowed by his *La grandeza mexicana* (1604; "The Grandeur of Mexico"), a paean to the attractions of the new metropolis of Mexico City.

Origin of Brazilian literature

The discovery and conquest of the tropical heartland of America produced no rich body of Brazilian counterparts to the spirited epics in prose and verse of the Spanish conquerors. The Portuguese found no centuries-old native civilizations upon which to build a new society. Indians were few, and, rather than resist, they retreated into the interior, leaving the invaders to settle at widely scattered points along the extended narrow coastal plain. There was, then, no epic clash, but there were the beautiful and bountiful coast and forest lands, and these set the tone even today for *brasilidade,* the love for the land of Brazil. Brazil's "literary baptism" is to be found in the letter of discovery sent to Dom Manuel I of Portugal by the scribe Pero Vaz de Caminha, who accompanied the explorer Pedro Álvares Cabral in 1500. The missionary labours were largely in the hands of the Jesuits, and one of their number, José de Anchieta, is hailed the father of Brazilian literature. For the period, however, there is only one epic, and this, except for some descriptive passages, sings of Portuguese exploits against the Moors in feeble imitation of Luís Vaz de Camões. The epic *Prosopopéa* (1601), by Bento Teixeira Pinto, is commonly regarded as the first book by a Brazilian-born writer.

Cultural influence of the homeland

The flowering of colonial letters (1600–1808). By 1600 the day of the conqueror was past, and the New World entered a less spectacular phase as colonial society stabilized. The first printing press in the Americas was established in Mexico City about 1539, another in Lima in 1584, and both cities were granted university charters in 1551. In Brazil no university was founded or printing permitted until the close of the colonial period. Everywhere in the Americas a growing leisure class devoted more time to intellectual and artistic pursuits, and close ties with the homeland encouraged the development of parallel literary patterns. Life became a reflection of trends across the Atlantic, and there was little in these two centuries that had originality, although it is possible to find the imprint of Indian traditions among even cultivated writers.

The theatre, emerging from medieval forms at the time of the conquest, served during the 16th century as a missionary medium in the Indian tongues for the conversion of the natives. There were also a few secular representations in the Indian languages of pre-Conquest memories. (Some of these were written by Creole authors.) For the bulk of the non-Indian population consisting of the Creoles and urbanized mestizos, however, the dramatic repertoire was mainly Spanish and Portuguese. Plays written in America were patterned after the drama of the Spanish Golden Age, and the greatest of the native dramatists, the Mexican Juan Ruiz de Alarcón, even lived and wrote in Spain.

Fiction, banned by the Spanish crown, only emerged with independence, leaving the field in prose to historical and biographical works. One of the best was *El lazarillo de ciegos caminantes* (*c.* 1773; *A Guide for Inexperienced Travelers*), a satire in the form of a travelogue of a journey between Buenos Aires and Lima. Its author, Alonso Carrió de la Vandera, was a Spanish postal official; he used the pseudonym Concolorcorvo to protect himself from official reprisal.

The writings of Sor Juana Inés de la Cruz

Poetry was the most popular form of literature, and a contest held in Mexico in 1585 attracted more than 300 mostly indifferent disciples of the Spanish fashion. Their poems are in the curious anthology *Ramillete de varias flores poéticas* (1675; "A Nosegay of Poetic Flowers"), gathered by Jacinto de Evia of Ecuador. One later poet stood out above all in the colonial world: the Mexican nun Sor Juana Inés de la Cruz. Her metaphysical poem "Primero sueño" ("First Dream") and, above all, her beautiful profane lyrics are among the greatest literary achievements of Latin America.

During the colonial period, there appeared a satirical tradition protesting against social and individual suffering: the Peruvian Juan del Valle y Caviedes and Gregório de Matos Guerra, the epigrammatic "devil's mouthpiece" of Brazil, both of whom were influenced by the Spanish satirist Francisco Gómez de Quevedo y Villegas. Their verse was widely circulated and avidly read. Toward the end of the colonial period, it developed popular forms that stirred the revolutionary spirit.

Literature of rebellion (1808–26). Political unrest spread in Latin America as the 18th century advanced. French ideas broke through the relaxed controls held by Spain and Portugal over New World thought. Early stirrings became more purposeful under the impact of the French and American revolutions. Printing presses and periodicals sprang up, and ideals quickened in literary societies founded by Latin America's young liberals.

One of the earliest fruits of contacts with foreign thought was an abortive Brazilian *inconfidência mineria* of 1789, a "conspiracy of poets" headed by Joaquim José da Silva Xavier and supported by a number of exceptional writers who were members of the Minas school of epic and Neoclassical poets, which had no equal in the Spanish colonies of that day. José Basílio da Gama's *Uraguai* (1769) and José de Santa Rita Durão's *Caramuru* (1781) were two native epics of Brazil. Love of country and the appearance of the Indian as a literary character stamped both works as forerunners of Brazilian intellectual independence as well as of incipient Romanticism. When, after a bloodless victory in 1822, Brazil emerged as an empire, only one literary figure, José Bonifácio de Andrade e Silva, stood out as a patriarch of Brazil's struggle for independence. Author of vigorous, passionate verse (*Poesias,* 1825), he is considered Brazil's first Romantic poet.

Francisco de Miranda, a Venezuelan leader of Spanish-American independence, left a remarkable journal that revealed the influence of his contacts in the United States with the "great American experiment." His compatriot Simón Bolívar was later christened "the thinker of the Revolution" for his prophetic analyses of the sociopolitical scene. Bolívar's writings exhibit some of the best of French thought, particularly that of Montesquieu and Rousseau. But the Mexican José Joaquín Fernández de Lizardi, referred to as *el pensador mexicano* ("the Mexican thinker"), is the only liberator remembered primarily as a man of letters. His fame rests largely on a picaresque tale, *El periquillo sarniento* (1816; *The Itching Parrot*), conceded to be the first Latin-American novel.

The revolution found popular expression in balladry and heroic verse. More enduring patriotic poetry came with

Patriotic poetry

Precursors of the Romantic movement

victory in the work of three outstanding poets. Of the three, only José Joaquín Olmedo, an Ecuadorean, limited his work almost exclusively to the themes and spirit of the revolutionary years. His best known poem, “La victoria de Junín, canto a Bolívar” (1825), is a fine example of heroic poetry in the classical style. In his Virgilian *Silva a la agricultura de la zona tórrida* (1826; *A Georgic of the Tropics*), Andrés Bello of Venezuela exhorted his fellow Americans to turn their swords into plowshares and to cultivate the natural riches of America. In later years Bello distinguished himself as a grammarian, critic, lawgiver, and educator and as the intellectual father of Chile's Romantic generation. José María Heredia of Cuba lived most of his life in political exile (Venezuela, New York City, Mexico), where nature's grander moods and the Indian past inspired his widely acclaimed poems *En el teocalli de Cholula* (1820) and *Oda al Níagara* (1824). He anticipated the new literary movement of Romanticism with which the young Latin-American nations were born to political independence.

THE FORMATIVE YEARS (1826–1910)

Emergence of gaucho literature

Romanticism. Political independence from Spain and Portugal did not bring freedom from political despotism and anarchy; economic and political stability for most new nations came late and with difficulty. American themes had fired the imagination of the liberators, but Neoclassic forms were still dominant. European Romanticism pointed the way to cultural independence also, even though that way lay largely along a route marked out by French, English, and Spanish writers. The controlled form and restraint of Neoclassicism yielded to the freedom, individualism, and emotional intensity of Romanticism, and the European cult of the medieval became in many cases a passion for the Indian—his present and past. The most illustrious early Romanticists were Argentine political refugees who fled from the dictator Juan Manuel de Rosas. Their leader was Esteban Echeverría, who, after a stay in France (1826–30) where Romanticism was at its height, showed the way in “La cautiva” (1837; “The Captive”), one of the earliest fusions of native themes and scenes with newer free verse forms. Domingo Faustino Sarmiento provided the first serious study of the great plain (or Pampas) and of gaucho (cowboy) lore in his *Facundo* (1845; *Life in the Argentine Republic in the Days of the Tyrants, or Civilization and Barbarism*), a novel written in passionate denunciation of Rosas. This emphasis on the national scene gave birth to an indigenous literary genre without European prototype, the gaucho literature of Argentina and Uruguay. The gaucho had long been the subject of folktale and ballad and soon figured in some of the best verse, as in Rafael Obligado's poem (1887) on the legendary minstrel Santos Vega, and the humorous *Fausto* (1866) by Estanislao del Campo, until finally he received epic treatment in *Martín Fierro* (1872–79; *The Gaucho, Martin Fierro*), by José Hernández.

This Romantic evocation of national themes and types reached its poetic climax while also pointing the way to the next period in the elegiac *Tabaré* (1886) by the Uruguayan Juan Zorrilla de San Martín. Zorrilla's epic poem related the fate of the aboriginal Charrúas, vanquished by Spanish invaders. In prose, the Colombian Jorge Isaacs wrote the popular lachrymose idyll *María* (1867), while Juan León Mera of Ecuador contributed *Cumandá* (1871) and Manuel de Jesús Galván of Santo Domingo added *Enriquillo* (1879–82) to a growing number of fictionalized portrayals of idealized Indian life. José Mármol gave a dramatic depiction of life in Argentina under the tyranny of Rosas in *Amalia* (1851–55). The *tradición*, patterned after the historical anecdote, was perfected by the Peruvian master of humorous prose, Ricardo Palma, whose *Tradiciones peruanas* (*The Knights of the Cape*) appeared between 1872 and 1910.

The Brazilian Romantics had no such “glorious” past to idealize and preferred to extol the natural beauties of their homeland and the simple Indian life. Domingo José Gonçalves de Magalhães, though still eclectic, launched the Romantic movement with *Suspiros Poéticos e Saudades* (1836; “Poetic Sighs and Longings”), but the best and most representative of Brazil's Romantic poets is Antônio Gonçalvez Dias. Later phases were exemplified in a poetry of doubt and despair by Manuel Antônio Alvares de Azevedo, author of *A Noite na Taverna* (*c.* 1851; “The Night in the Tavern”) and in the sociopolitical verse of Antônio de Castro Alves, author of *Os Escravos* (1876; “The Slaves”).

The theatre was not one of Latin America's strongest genres during the Romantic period. It consisted primarily of melodrama, regional comedy, and political pamphleteering. One exception was Cuba's Gertrudis Gómez de Avellaneda, who demonstrated that she was capable of serious psychological analysis and careful dramatic structure. She produced her plays in Spain, however, where she spent most of her life.

Cuadro de costumbres

Realism and Naturalism. The Romanticist's interest in the picturesque and unusual helped him discover evidence of a budding national way of life, and shortly after mid-century the *cuadro de costumbres* (sketch of contemporary customs) developed into a realistic novel of manners, often with an urban setting. From that time, the novel assumed a more commanding role in Latin-American letters, but it appeared almost concurrently in the several types representative of successive literary trends in Europe whose masters provided the molds into which Latin-American themes were poured. Alberto Blest Gana began producing a series of *costumbrista* novels on Chilean life, of which *Martín Rivas* (1862) was considered the best. Naturalism in the manner of Émile Zola made its appearance with the Argentine Eugenio Cambaceres. After mid-century several late-Romantic political writers, both Brazilian and Spanish-American, distinguished themselves in essay form. Among them were Juan Montalvo, Eugenio María de Hostos, Joaquim Nabuco, and Rui Barbosa. Manuel González Prada, an ironic experimental poet and essayist, was the chief figure, and his verse paved the way for the new poetry of a coming generation of rebels.

The true novel appeared first in Brazil in 1844 with *A Moreninha* (“The Little Brunette”) by Joaquim Manuel de Macedo. Still one of the most widely read of his country's novelists, José Martiniano de Alencar initiated a vogue of the Brazilian *Indianista* novel with *O Guarani* (1857; “The Guarani Indian”) and *Iracema* (1865). These romantic tales of love between Indian and white, however, represented only one aspect of Alencar's varied literary activity. He also turned to the life and customs of Brazil's backlands, and *O Gaúcho* (1870) and *O Sertanejo* (1876; “The Man of the Backlands”), though still markedly Romantic in spirit, were among the forerunners of a flourishing regional genre. Two other contributors to this transitional genre were Alfredo d'Escragnolle Taunay, whose *Inocência* (1872) became a universal favourite, and Bernardo Guimarães, whose abolitionist *Escrava Isaura* (1875) was a decisive step forward in the direction of the novel of social protest.

True Realism

True Realism, with a definite leaning toward Naturalism, was initiated by *Memórias de um Sargento de Milícias* (1854) by Manuel Antônio de Almeida, but it was not until the mid-1870s that the novel began to expose cankers of social and psychological maladjustments to a rapidly changing economic scene. Aluízio Azevedo, an early example of social protest in the manner of 20th-century novelists, wrote such favourites as *O Mulato* (1881) and *O Cortiço* (1890; *A Brazilian Tenement*). Less occupied with external aspects of Brazilian life, Joaquim Maria Machado de Assís pried into the psychological complex of the Brazilian and distinguished himself as his country's most original and gifted writer. His trilogy, *Bras Cubas* (1881; *Epitaph of a Small Winner*), *Quincas Borba* (1891; *Philosopher or Dog?*), and *Dom Casmurro* (1899), was a landmark in Latin-American letters.

Rubén Darío and the Modernists. In Spanish America, a measure of political and economic stability aided the emergence of a cosmopolitan awareness of life and letters that resulted in the revolt against the sentimental romantic writers who filled the literary pages of the newspapers and magazines. Young writers across the Americas immersed themselves in the mainstream of world thought and writing. Somewhat disparagingly labelled *modernistas* by the older generation, they wrote on exotic themes, often shutting themselves off from their immediate environment in artificial worlds of their own making—the ancient past, the distant Orient, and the lands of childhood fancy and sheer creation. Beauty was their goddess and "art for art's sake" their creed. Influenced by French movements, they followed no regular path; Symbolism, Parnassianism, Decadentism, and all the rest coexisted in any given individual or followed each other in any order.

Foremost among the early Modernists were the Mexican Manuel Gutiérrez Nájera, whose elegiac verse and restrained rhythmical prose sketches and tales best represented the transition from the excesses of Romanticism to the more filigreed Modernism; the Colombian José Asunción Silva, who wrote a small but influential body of savagely ironic and elegiac poems; the Cuban Julián del Casal, cultivator of the exquisite Parnassian sonnet; and his compatriot José Martí, martyr and symbol of Cuba's struggle for freedom from Spain, whose inspired prose style and deceptively simple, sincere verse set his work above and apart from all schools and movements.

The full flowering of Modernism, however, came under the leadership of one of the greatest poets in Spanish, Rubén Darío of Nicaragua. His collection of verse and prose, *Azul,* published in 1888, pointed the initial way, but *Prosas profanas* (1896; "Lay Hymns") represented the high point of the escapist, cosmopolitan phase of the movement. Darío blended the best of Modernist formal experimentation with an expression of inner despair or an almost metaphysical joy in *Cantos de vida y esperanza* (1905; "Songs of Life and Hope"). When Spain's empire crumbled in 1898 and mutual sympathy allayed the old distrust between Spain and its former colonies, he turned to Hispanic traditions as he had always turned to Hispanic forms; and in the face of U.S. imperialism, he spoke for Hispanic solidarity. Darío's imitators, particularly of his early experimental, escapist phase, were often slavish copiers who deserved the scornful name of *rubendaristas,* but Darío and his fellow Modernists brought about the greatest revitalization of language and poetic technique in Spanish since the 17th century. Many of his contemporaries were writers of considerable merit: Mexico's Amado Nervo, whose Orientally influenced mysticism was reflected in *Serenidad* (1914) and *Elevación* (1917); Peru's José Santos Chocano, whose exalted Americanism gave birth to *Alma América* (1906; "American Soul"); Bolivia's Ricardo Jaimes Freyre, who drew upon Scandinavian mythology for *Castalia bárbara* (1899; "The Barbarous Castalia"); Colombia's Guillermo Valencia, whose classic bent was manifest in *Ritos* (1898; "Rituals"); and Uruguay's philosopher and essayist José Enrique Rodó, whose *Ariel* (1900) distinguished him as the leading theoretician and exponent of Modernist ideals.

Modernist revitalization of the Spanish language and poetic technique

Even after Darío's death, the majority of Spanish-American Modernists continued to be spellbound by the verbal magic and brilliance of his *Prosas profanas.* There were, however, other gigantic figures: Leopoldo Lugones of Argentina underwent drastic shifts ranging from Laforguian irony through Baroque intensity to an intense nationalism expressing itself in poems based on popular folk songs; Enrique González Martínez of Mexico wrestled with social and ethical problems in Symbolist sonnets; and Julio Herrera y Reissig of Uruguay was perhaps the outstanding Symbolist of Modernism, finding new visions in a landscape represented in startling images.

In Portuguese-speaking Brazil, reaction against Romantic verse never produced the rich mosaic of Spanish-American Modernism. The Brazilian Parnassians with their formalistic, detached poetry were challenged by poets attracted to French Symbolism, but a Symbolist movement as such never materialized in Brazil. Parnassianism, as epitomized in the poetry of Raimundo Correia, Alberto de Oliveira, and Olavo Bilac, was unchanged until the developments of the 1920s altered Brazilian letters drastically.

Parnassianism in Brazil

LITERARY DEVELOPMENTS OF THE 20TH CENTURY

The horror and bloodshed of the Mexican Revolution (1910–17) shocked much of the complacent intellectual minority into a realization of the plight of their country's submerged masses: the Indian and mestizo (or person of European and Indian parentage) found able champions of their cause. The revolution had a similar effect almost everywhere throughout Latin America. Other events also played a significant role in altering the perspective and general orientation of Latin-American men of letters. World Wars I and II, along with the intervening worldwide economic depression of the 1930s and the Spanish Civil War, thrust their nations into the international scene. Given this situation, regionalistic preoccupations gave way to more universal concerns, a shift that was accompanied not only by new themes but also by new literary modes and stylistic techniques as well. The works that emerged during the second half of the century give testimony to the full maturing of Latin-American literature and its entry into the mainstream of Western letters.

Vanguard literature. Shortly after 1900 the Modernist leaders Darío and Lugones initiated a return from their formal and exotic innovations to more traditional forms and especially to themes dealing with the troubled external world. Their followers, however, never wholly rejected the very complex versification and language and countless new thematic sources with which Modernism had enriched Hispanic poetry. Prominent among them was an extraordinary group of women whose lyrics were more widely enjoyed than most of the work of male poets in the first half of the 20th century. Love in its impassioned and transcendental manifestations, maternal longing, and social protest were the themes of the Uruguayans Delmira Agustini and Juana de Ibarbourou and of the Chilean Gabriela Mistral, winner of the 1945 Nobel Prize for Literature. The Argentine Alfonsina Storni dealt with personal anguish and the difficulties of being a woman in a stern male world in a harsh, ironic idiom. Stemming from various aspects of the Modernist tradition were the allusive, interiorized lyrics of the Peruvian José María Eguren or the less complex subtleties of the Argentine Enrique Banchs; the idiosyncratic blend of novel imagery, Baudelairean struggle, and provincial themes of the Mexican Ramón López Velarde; or the brilliant sonnet sequence of the tropical scene in *Tierra de promisión* (1921; "Land of Promise") by the Colombian José Eustasio Rivera.

Women lyricists

Poetry in the modern period is of an extraordinary richness and complexity. Some groups, following the nihilistic waves of post-World War I "isms," experimented with free verse, often daring to use obscure imagery that gave a mistaken impression of a coldly intellectual mood. Many of these vanguard experimenters wrote out of a sociopolitical commitment as well. In the experiments of the Puerto Rican Luis Palés Matos, the Cuban mulatto poet Nicolás Guillén, and others, the voice and song of the African tradition were carried to a high artistic level.

Vicente Huidobro of Chile, who initiated the *creacionista* movement, is important for his insistence on the poet's total creation of an autonomous world, an approach that has been extremely influential on younger figures. Argentina's Jorge Luis Borges launched *ultraísmo* in Buenos Aires in 1921 but evolved from these avant-garde beginnings to a poetry reflecting a strong love for his city, a familiarity with numerous foreign literatures, and a preoccupation with metaphysical themes. These latter elements are also discernible in Borges' short stories, which have brought him international fame. César Vallejo of Peru fused social concerns with Surrealism and the heritage of Modernism to create an intensely subjective and often obscure but vital poetry. The Chilean Pablo Neruda, winner of the 1971 Nobel Prize for Literature, also blended Marxism with Surrealism in his earlier work; he attempted a poetic synthesis of the suffering of the Americas in the *Canto general* (1950; *General Song of Chile*). In his enormous production, Neruda made poetry of even the smallest aspects of the world he saw about him. It would be impossible to mention all the distinguished poets of the Post-Modernist period who were closely associated with such journals as *Martín Fierro* in Argentina, *Contemporáneos* in Mexico, and *Colónida* in Peru. Suffice it to say that the period from the beginnings of Modernism to the end of Post-Modernism rivals the Spanish Golden Age of the 16th and 17th centuries in wealth of poetry.

Borges and *ultraísmo*

The vanguard revolt in Brazil, usually referred to as Modernism (not at all the same as Spanish-American Modernism), broke away noisily from academicism and colonial cultural bondage at the noted Modern Art Week program in São Paulo in 1922. The Brazilian Modernists' primary aim was to modernize national thought and life, casting aside the persistent vestiges of the 19th century. This high-pitched, often theatrical, self-searching period of aesthetic reevaluation and analysis of the immediate Brazilian present served as a sorely needed purge and produced such important figures in Brazilian literature as the movement's high priest, Mário de Andrade, a gifted poet and musicologist; his lieutenant, Oswald de Andrade; Ronald de Carvalho, a critic and bard; and Manuel Bandeira, who has been acclaimed the country's greatest modern lyric poet. Preoccupation with social and metaphysical problems and an imperative urge toward untrammelled self-expression characterized the poetry of Modernist contemporaries or followers—namely, Jorge de Lima, Cecília Meireles, and Augusto Federico Schmidt.

Literature of social protest. Martí and González Prada were hailed as the intellectual progenitors of men aware of their responsibilities in guiding the Americas in a rapidly changing world. Rufino Blanco Fombona of Venezuela assailed his country's tyrants in *El hombre de hierro* (1907; "The Man of Iron") and *El hombre de oro* (1916; *The Man of Gold*). He was also among the first to attack "Yankee imperialism," abetted by a militant Argentine, Manuel Ugarte. The latter's *Porvenir de América latina* (1911; "The Future of Latin America") and *Destino de un continente* (1923; *The Destiny of a Continent*), together with the writings of the Peruvian Francisco García Calderón, envisioned Latin America as the future guardian of the Latin tradition. Ricardo Rojas, an Argentine literary historian and critic, and José Vasconcelos, a controversial Mexican philosopher and educator, were more concerned with racial and cultural aspects within the American family of nations. Alfonso Reyes, a Mexican poet, scholar, and critic, made the essay a vital, intimate force and raised it to a new level of artistic excellence.

It was in prose fiction that the grandeur of the American scene in all its drama was best described. The disheartening years following the abolition of slavery in 1888 and the establishment of a republic in 1889 made serious-minded Brazilians analyze their troubled homeland as an extraordinary amalgam of man, land, and climate. Euclides da Cunha revealed the bedrock of Brazilian life in the epic *Os Sertões* (1902; *Rebellion in the Backlands*); this work was the first written protest on behalf of Brazil's forgotten man, the emerging Brazilian of the backlands. In *Canaã* (1902; *The Canaan*), a novel of ideas, José Pereira da Graça Aranha focussed on the effects of recent European immigration upon this evolving Brazilian type. José Bento Monteiro Lobato's collection of short stories *Urupês* (1918; "Shelf Fungi") showed that intellectuals were still probing for native traits in a search that gave direction to the Modernist outburst of the 1920s.

Regionalist Brazilian literature

A new cultural regionalism of Brazil's "Northeastern school" that flowered after 1930 produced gifted prose writers, including a sociologist, Gilberto Freyre, whose *Casa Grande e Senzala* (1933; *The Masters and the Slaves*) was fundamental to an understanding of the region. José Lins do Rego, in a highly personal, evocative style, depicted the clash of the old and new way of life in his classic "Sugarcane" cycle and in *Pedra Bonita* (1938); Jorge Amado gave Brazil some of America's best proletarian literature in *Cacau* (1933), *Jubiabá* (1935), and *Terras do Sem Fim* (1942; *The Violent Land*). *Angústia* (1936), by Graciliano Ramos, attested to the fact that the individual inner struggle had also been adroitly plumbed by these new regionalists. Érico Veríssimo was one of Latin America's most distinguished cosmopolitan writers, as demonstrated in *Olhai os Lírios do Campo* (1938; *Consider the Lilies of the Field*) and *O Tempo e o Vento* (1950; *Time and the Wind*).

New trends in the Spanish-American novel

Contrary to its exceptional development in Brazil, the Spanish-American novel had been left largely to a few Modernist novelists, such as Manuel Díaz Rodríguez of Venezuela and Enrique Larreta of Argentina, and to the followers of the French Naturalist Émile Zola. Baldomero Lillo of Chile gave artistic dimension to the sufferings of oppressed miners in *Sub sole* (1906), and Federico Gamboa of Mexico, in *Santa* (1903), dealt with a prostitute reminiscent of Zola's protagonist in *Nana* from a Catholic point of view—the only version of Naturalism possible in the Hispanic world. Later novelists, essayists, and short-story writers developed new and more effective techniques under the influence of various foreign innovators, including Marcel Proust, James Joyce, Franz Kafka, and William Faulkner. The most widely acclaimed work that resulted from the Mexican Revolution was the novel *Los de abajo* (1915; *The Underdogs*) by Mariano Azuela, an army doctor of one of the bands of the revolutionary general Pancho Villa. Azuela chronicled the revolution from the point of view of the humble peasants who were its soldiers and its victims. From the late 1920s on, Martín Luis Guzmán, Gregorio López y Fuentes, and José Rubén Romero, among many others, gave further breadth and scope to this turbulent period without ever equalling Azuela's treatment.

The 20th-century Indian was not the uncompromising hero of the epic *La Araucana,* nor the symbol of colonial revolt against tyrannical Spain, and much less the "noble savage" of the untamed romantic wilderness. He was rather the victim of political and economic forces that kept the masses in abject bondage to colonial institutions. This new *indianista* literature had its roots in such novels as *Aves sin nido* (1889; *Birds Without a Nest*) by Clorinda Matto de Turner of Peru. The Indian's cause, moreover, was advanced by González Prada, a precursor of the militant pro-Indian, social reform party APRA (Alianza Popular Revolucionaria Americana) in 1923. The most extreme example of this committed literature was the brutally realistic school of Ecuadorean writers. Its most influential member, Jorge Icaza, produced mass-directed, vernacular novels such as *Huasipungo* (1934; *The Villagers*) and *En las calles* (1935; "In the Streets").

The effects of the tensions between the pampa and the city

The clash between the forces of nature and powerful economic pressures, between the land and the city, had by no means died with the passing of 19th-century local chiefs. The land and its resources were more zealously sought than ever before, and the struggle became more violent as man fought against man for the possession of these riches. In the growing urban centres, modern industrial economy exerted an even more insidious control over the destiny of the masses. The clash between the old and the new on the pampas of Argentina and Uruguay created the sombre descriptive pages of Uruguay's short-story writer Javier de Viana; the psychological portrayal of rural types in *El terruño* (1916; "The Native Country") by Carlos Reyles, also of Uruguay; the brilliant imagery of the mythic re-creation of the gaucho, *Don Segundo Sombra* (1926) by Ricardo Güiraldes of Argentina; and the tragic depths of the irreconcilable difference between the city and pampa in *El inglés de los güesos* (1924; "The English Archaeologist") by another Argentine, Benito Lynch. In *Doña Bárbara* (1929) Rómulo Gallegos gave a dramatic depiction of similar forces at work on the Venezuelan *llanos,* or "plains."

From the tropics appeared two artists who spoke for a growing number of younger writers who had discovered the *selva,* or "jungle": Horacio Quiroga of Uruguay, a consummate short-story artist, who excelled both in fantasy and in dramatic descriptions of the struggle for life in the jungle of Misiones, Argentina; and José Eustasio Rivera, a Colombian poet, whose sole prose work, *La vorágine* (1924; *The Vortex*), was a powerful denunciation of exploitation in the upper Amazon during the rubber boom of the early 1900s.

In *La maestra normal* (1914; "The Grade-School Teacher") Manuel Gálvez, an Argentine novelist, captured the pettiness and monotony of smaller provincial centres before modern mechanized manners shattered old colonial ways. Chile's underprivileged had two champions in the novelist Joaquín Edwards Bello and the short-story writer Manuel Rojas. Man's struggle with the deeper forces within and beyond himself was re-created in the psychological novels of the Chilean Eduardo Barrios and in the tales of the Cuban Alfonso Hernández Catá.

Major characteristics of contemporary Latin-American literature

Recent trends. The literature of the last half of the 20th century has been characterized by an increased preoccupation with man as the victim of alienating forces, solitude, identity, anguish, and evil and by a marked determination to create new forms and techniques. Above all, it has displayed a new language more responsive to the demands imposed by increasingly complex spiritual, social, and ideological concerns. These concerns found a direct expression in the essay, a form that has been cultivated with distinction by writers equally competent in other genres. Individual and collective preoccupation with analysis ran the gamut from the ruthless dissection of his country's ills by the Argentine Ezequiel Martínez Estrada in *Radiografía de la pampa* (1933; *X-Ray of the Pampa*) to the more social and psychological probings of the Mexican Octavio Paz (*El laberinto de la soledad* [1950; *The Labyrinth of Solitude*]). Paz is also notable as a poet; he has wedded the heritage of Surrealism with Indian and popular traditions and Oriental mysticism. Many poets veered from experimental and hermetic emphasis to seek answers to the same concerns in a more personalized style, often striving for a direct, conversational, and sometimes heavily ironic tone.

Experimentation in the theatre

The drama had enjoyed considerable popularity in the larger cities since the late 1800s, although relatively few plays were of real note. By the end of the century, Cuba and Argentina both had a flourishing satirical popular theatre based on regional types and language. In Argentina and Uruguay this led to an important regional realistic theatre anchored in social problems, particularly the complex impact of intense immigration. Its outstanding practitioner was the Uruguayan Florencio Sânchez. The late 1920s saw an outburst of experimental activity, reflecting influences ranging from Expressionism to Eugene O'Neill, Luigi Pirandello, and Jean Cocteau. Since that time, the Latin-American theatre has absorbed forces as varied as Arthur Miller, Tennessee Williams, Samuel Beckett, and Eugène Ionesco. Among the best of those leading the movement of renovation were the Brazilian Joracy Camargo (*Deus lhe Pague* [1932; "God Pays Them"]) and the Mexican Rodolfo Usigli (*El gesticulador* [1937] and *Corona de sombra* [1943; *Crown of Shadows*]), a caustic commentator of his compatriots' foibles and a seeker of a national self-comprehension. A younger generation, including Sebastián Salazar Bondy of Peru, Emilio Carballido of Mexico, Osvaldo Dragún of Argentina, Jorge Díaz of Chile, José Triana of Cuba, and Ariano Suassuna of Brazil won international recognition for its technical expertise and its humane responses to social problems. After the unrest of the late 1960s, the Latin-American theatre became increasingly politicized, and a series of groups under the inspiration of Enrique Buenaventura of Colombia and Augusto Boal of Brazil developed a theory and practice of theatre as a collective creation.

Predominance of prose fiction

Prose fiction has occupied the centre of the contemporary Latin-American literary scene. This new fiction has given full voice to social concerns through techniques that launched an unremitting attack on both the form of the novel and the structure of the language. The new narrative prose was already in evidence in the work of a small band of earlier writers, exemplified especially in the extraordinary tales of the Argentine Jorge Luis Borges (*El Aleph* [1949; *The Aleph and Other Stories, 1933–1969,* or *Labyrinths*]); in the terrifying portrait of tyranny, *El señor presidente* (1948; *The President*), of the Guatemalan Miguel Angel Asturias, winner of the 1967 Nobel Prize for Literature; in the Joycean examination of the social and psychological roots of the revolution of 1910 by the Mexican Agustín Yáñez (*Al filo del agua* [1947; *The Edge of the Storm*]); in the ideological and philosophical novels of the Argentine Eduardo Mallea (*La bahía de silencio* [1940; *The Bay of Silence*] and *Todo verdor perecerá* [1941; *All Green Shall Perish*]); in the vision of America as a new and different reality expressed in Baroque language by the Cuban Alejo Carpentier (*Los pasos perdidos* [1953; *The Lost Steps*]); in the earthy, enigmatic prose of the Brazilian João Guimarães Rosa (*Grande Sertão Veredas* [1956; *The Devil to Pay in the Backlands*]); and in the Rabelaisian romances of another Brazilian, Jorge Amado (*Gabriela, Cravo e Canela* [1958; *Gabriela, Clove and Cinnamon*]).

Principal among the creators of a new Latin-American literature was the Argentine Julio Cortázar, who explored interlocking realities in novels and short stories. His *Rayuela* (1963; *Hopscotch*) was a challenge to the whole concept of the structure of fiction. It was on the bedrock of such pioneers that the younger generation planted the invigorating and challenging contemporary novel. The leaders of this generation were the Colombian Gabriel García Márquez, winner of the 1982 Nobel Prize for Literature for his mythic re-creations of Spanish-American history and society, *Cien años de soledad* (1967; *One Hundred Years of Solitude*) and *Crónica de una muerte anunciada* (1981; *Chronicle of a Death Foretold*); the Peruvian José María Arguedas, preoccupied with the problem of the rural Indian and the linguistic interactions of Spanish and Indian tongues; the Mexican Carlos Fuentes, engaged in the effort to examine the interaction between the present and the still-living past in the Spanish-American psyche; the Peruvian Mario Vargas Llosa, author of massive re-creations of his homeland in structures learned from the romance of chivalry; and the Cubans Guillermo Cabrera Infante, Reinaldo Arenas, and José Lezama Lima and the Puerto Rican Luis Rafael Sânchez, each in his own way revolutionizing the structures of the language to re-create a highly personal vision of his nation and his people. Other leaders were Chile's José Donoso, who examines the decline of feudal society in novels that range from realistic through the bizarre; Manuel Puig of Argentina, who re-creates the impact of popular culture; or Juan Rulfo of Mexico, who transforms the arid highlands into complex metaphors of salvation and damnation.

BIBLIOGRAPHY. Several good anthologies of Latin-American literature in English translation are available: JOHN M. COHEN (ed.), *Latin American Writing Today* (1967), translations of prose and poetry from Argentina, Brazil, Chile, Colombia, Cuba, Mexico, Peru, and Uruguay; WILLIAM I. OLIVER (trans. and ed.), *Voices of Change in the Spanish American Theatre* (1971), a collection of six plays; GEORGE WOODYARD (ed.), *The Modern Stage in Latin America* (1971), a collection. Useful literary histories and critical studies include ISAAC GOLDBERG, *Brazilian Literature* (1922, reprinted 1978); LUIS HARSS and BARBARA DOHMANN, *Into the Mainstream: Conversations with Latin-American Writers* (1967, reprinted 1969); JEAN FRANCO, *An Introduction to Spanish American Literature* (1969); JOHN A. NIST, *The Modernist Movement in Brazil: A Literary Study* (1967); WILSON MARTINS, *The Modernist Idea: A Critical Survey of Brazilian Writing in the Twentieth Century* (1970, reprinted 1979; originally published in Spanish, 1969); DAVID P. GALLAGHER, *Modern Latin American Literature* (1973); JOHN S. BRUSHWOOD, *The Spanish American Novel: A Twentieth-Century Survey* (1975); DAVID WILLIAM FOSTER and VIRGINIA RAMOS FOSTER (eds.), *Modern Latin American Literature,* 2 vol. (1975), a critical commentary on more than 100 Latin-American writers; MARGARET SAYERS PEDEN (ed.), *The Latin American Short Story: A Critical History* (1983). Special topics are discussed in LUCÍA FOX-LOCKERT, *Women Novelists in Spain and Spanish America* (1979); RICHARD L. JACKSON, *Black Writers in Latin America* (1979); DAVID T. HABERLY, *Three Sad Races: Racial Identity and National Consciousness in Brazilian Literature* (1983); BRAULIO MUÑOZ, *Sons of the Wind: The Search for Identity in Spanish American Indian Literature* (1982). *The Handbook of Latin American Studies,* prepared by the Latin American, Portuguese, and Spanish Division of the Library of Congress, is an annual critical bibliography.

(J.E.E./F.N.D.)

Latin Literature

Latin literature was the product of the Roman Republic and the Roman Empire. When Rome fell, Latin remained the literary language of the Western medieval world until it was superseded by the Romance languages it had generated and by other modern languages. After the Renaissance the writing of Latin was increasingly confined to the narrow limits of certain ecclesiastical and academic publications. This article focuses primarily on ancient Latin literature. It does, however, provide a broad overview of the literary works produced in Latin by European writers during the Middle Ages and Renaissance.

The article is divided into the following sections:

Ancient Latin literature

Literature in Latin began as translation from the Greek, a fact that conditioned its development. Latin authors used earlier writers as sources of stock themes and motifs, at their best using their relationship to tradition to produce a new species of originality. They were more distinguished as verbal artists than as thinkers; the finest of them have a superb command of concrete detail and vivid illustration. Their noblest ideal was *humanitas,* a blend of culture and kindliness, approximating the quality of being "civilized" as the word is used today of individuals.

Little need be said of the preliterary period. Hellenistic influence came from the south, Etrusco-Hellenic from the north. Improvised farce, with stock characters in masks, may have been a native invention from the Campania region (the countryside of modern Naples). The historian Livy traced quasi-dramatic *satura* (medley) to the Etruscans. The statesman-writer Cato and the scholar Varro said that in former times the praises of heroes were sung after feasts, sometimes to the accompaniment of the flute, which was perhaps an Etruscan custom. If they existed, these *carmina convivalia,* or festal songs, would be behind some of the legends that came down to Livy. There were also the rude verses improvised at harvest festivals and weddings and liturgical formulas, whose scanty remains show alliteration and assonance. The nearest approach to literature must have been in public and private records and in recorded speeches.

STYLISTIC PERIODS

Ancient Latin literature may be divided into four periods: early writers, to 70 BC; Golden Age, 70 BC–AD 18; Silver Age, AD 18–133; and later writers.

Greek influence of Livius Andronicus

Early writers. The ground for Roman literature was prepared by an influx from the early 3rd century BC onward of Greek slaves, some of whom were put to tutoring young Roman nobles. Among them was Livius Andronicus, who was later freed and who is considered to be the first Latin writer. In 240 BC, to celebrate Rome's victory over Carthage, he composed a genuine drama adapted from the Greek. His success established a tradition of performing such plays alongside the cruder native entertainments. He also made a translation of the *Odyssey.* For his plays Livius adapted the Greek metres to suit the Latin tongue; but for his *Odyssey* he retained a traditional Italian measure, as did Gnaeus Naevius for his epic on the First Punic War against Carthage. Scholars are uncertain as to how much this metre depended on quantity or stress. A half-Greek Calabrian called Ennius adopted and Latinized the Greek hexameter for his epic *Annales,* thus further acquainting Rome with the Hellenistic world. Unfortunately his work survives only in fragments.

The Greek character thus imposed on literature made it more a preserve of the educated elite. In Rome coteries emerged such as that formed around the Roman consul and general Scipio Aemilianus. This circle included the statesman-orator Gaius Laelius; the Greek Stoic philosopher Panaetius; the Greek historian Polybius; the satirist Lucilius; and an African-born slave of genius, the comic playwright Terence. Soon after Rome absorbed Greece as a Roman province, Greek became a second language to educated Romans. Early in the 1st century BC, however, Latin declamation established itself, and, borrowing from Greek, it attained polish and artistry.

Plautus, the leading poet of comedy, is one of the chief sources for colloquial Latin. But Ennius sought to heighten epic and tragic diction, and from his time onward, with a few exceptions, literary language became ever more divorced from that of the people, until reaction came in the 2nd century AD.

The Ciceronian period

Golden Age, 70 BC–AD 18. The Golden Age of Latin literature spanned the last years of the republic and the virtual establishment of the Roman Empire under the reign of Augustus (27 BC–AD 14). The first part of this period, from 70 to 42 BC, is justly called the Ciceronian. It produced writers of distinction, most of them also men of action, among whom Julius Caesar stands out. The most prolific was Varro, "most learned of the Romans," but it was Cicero, a statesman, orator, poet, critic, and philosopher, who developed the Latin language to express abstract and complicated thought with clarity. Subsequently, prose style was either a reaction against, or a return to, Cicero's. As a poet, although uninspired, he was technically skillful. He edited the *De rerum natura* of the philosophic poet Lucretius. Like Lucretius, he admired Ennius and the old Roman poetry and, though apparently interested in Hellenistic work, spoke ironically of its extreme champions, the *neōteroi* ("newer poets").

After the destruction of Carthage and Corinth in 146 BC, prosperity and external security had allowed the cultivation of a literature of self-expression and entertainment. In this climate flourished the *neōteroi,* largely non-Roman Italians from the north, who introduced the mentality of "art for art's sake." None is known at first hand except Catullus, who was from Verona. These poets reacted against the grandiose, the Ennian tradition of "gravity," and their complicated allusive poetry consciously emulated the Callimacheans of 3rd-century Alexandria. The Neoteric influence persisted into the next generation through Cornelius Gallus to Virgil.

Virgil, born near Mantua and schooled at Cremona and Milan, chose Theocritus as his first model. The self-consciously beautiful cadences of the *Eclogues* depict shepherds living in a landscape half real, half fantastic; these allusive poems hover between the actual and the artificial. They are shot through with topical allusions, and in the fourth he already appears as a national prophet. Virgil was drawn into the circle being formed by Maecenas, Augustus' chief minister. In 38 BC he and Varius introduced the young poet Horace to Maecenas; and by the final victory of Augustus in 30 BC, the circle was consolidated.

The Augustan Age

With the reign of Augustus began the second phase of the Golden Age, known as the Augustan Age. It gave encouragement to the classical notion that a writer should not so much try to say new things as to say old things better. The rhetorical figures of thought and speech were mastered until they became instinctive. Alliteration and onomatopoeia (accommodation of sound and rhythm to sense), previously overdone by the Ennians and therefore eschewed by the *neōteroi,* were now used effectively with due discretion. Perfection of form characterizes the odes of Horace; elegy too became more polished.

The decade of the first impetus of Augustanism, 29–19 BC, saw the publication of Virgil's *Georgics* and the composition of the whole *Aeneid* by his death in 19 BC; Horace's *Odes,* books I–III and *Epistles,* book I; in elegy, books I–III of Propertius (also of Maecenas' circle) and books I–II of Tibullus, with others from the circle of Marcus Valerius Messalla Corvinus, and doubtless the first recitations by a still younger member of his circle, Ovid. About 28 or 27 BC Livy began his monumental history.

Maecenas' circle was not a propaganda bureau; his talent for tactful pressure guided his poets toward praise of Augustus and the regime without excessively cramping their freedom. Propertius, when admitted to the circle, was simply a youth with an anti-Caesarian background who had gained favour with passionate love elegies. He and Horace quarreled, and after Virgil's death the group broke up. Would-be poets now abounded, such as Horace's protégés, who occur in the *Epistles;* Ovid's friends, whom he remembers wistfully in exile; and Manilius, whom no one mentions at all. Poems were recited in literary circles and in public, hence the importance attached to euphony, smoothness, and artistic structure. They thus became known piecemeal and might be improved by friendly suggestions. When finally they were assembled in books, great care was taken over arrangement, which was artistic or significant (but not chronological).

Meanwhile, in prose the Ciceronian climax had been followed by a reaction led by Sallust. In 43 BC he began to publish a series of historical works in a terse, epigrammatic style studded with archaisms and avoiding the copiousness of Cicero. Later, eloquence, deprived of political influence, migrated from the forum to the schools, where cleverness and point counted rather than rolling periods. Thus developed the epigrammatic style of the younger Seneca and, ultimately, of Tacitus. Spreading to verse, it conditioned the witty couplets of Ovid, the tragedies of Seneca, and the satire of Juvenal. Though Livy stood out, Ciceronianism only found a real champion again in the rhetorician Quintilian.

Silver Age, AD 18–133. After the first flush of enthusiasm for Augustan ideals of national regeneration, literature paid the price of political patronage. It became subtly sterilized; and Ovid was but the first of many writers actually suppressed or inhibited by fear. Only Tacitus and Juvenal, writing under comparatively tolerant emperors, turned emotions pent up under Domitian's reign of terror into the driving force of great literature. Late Augustans such as Livy already sensed that Rome had passed its summit. Yet the title of Silver Age is not undeserved by a period that produced, in addition to Tacitus and Juvenal, the two Senecas, Lucan, Persius, the two Plinys, Quintilian, Petronius, Statius, Martial, and, of lesser stature, Manilius, Valerius Flaccus, Silius Italicus, and Suetonius.

Later writers. The decentralization of the empire under Hadrian and the Antonines weakened the Roman pride and passion for liberty. Romans began again to write in Greek as well as Latin. The "new sophistic" movement in Greece affected the "novel poets" such as Florus. An effete culture devoted itself to philology, archaism, and preciosity. After Juvenal, 250 years elapsed before Ausonius of Bordeaux (4th century AD) and the last of the true classics, Claudian (flourished about 400), appeared. The anonymous *Pervigilium Veneris* ("Vigil of Venus"), of uncertain date, presages the Middle Ages in its vitality and touch of stressed metre. Ausonius, though in the pagan literary tradition, was a Christian and contemporary with a truly original Christian poet, the Spaniard Prudentius. Henceforward, Christian literature overlaps pagan and generally surpasses it.

The *Meditations* of Marcus Aurelius

In prose these centuries have somewhat more to boast, though the greatest work by a Roman was written in Greek, the *Meditations* of the emperor Marcus Aurelius. *Elocutio novella,* a blend of archaisms and colloquial speech, is seen to best advantage in Apuleius (born about 125). Other writers of note were Aulus Gellius and Macrobius. The 4th century AD was the age of the grammarians and commentators, but in prose some of the most interesting work is again Christian.

THE GENRES

Comedy. Roman comedy was based on the New Comedy fashionable in Greece, whose classic representative was Menander. But whereas this was imitation of life to the Greeks, to the Romans it was escape to fantasy and literary convention. Livius' successor, Naevius, who developed this "drama in Greek cloak" (*fabula palliata*), may have been the first to introduce recitative and song, thereby increasing its unreality. But he slipped in details of Roman life and outspoken criticisms of powerful men. His imprisonment warned comedy off topical references, but the Roman audience became alert in applying ancient lines to modern situations and in demonstrating their feelings by appropriate clamour.

Plautus

Unlike his predecessors, Plautus specialized, writing only comedy involving high spirits, oaths, linguistic play, slapstick humour, music, and skillful adaptation of rhythm to subject matter. Some of his plays can be thought of almost as comic opera. Part of the fun consisted in the sudden intrusion of Roman things into this conventional Greek world. "The Plautine in Plautus" consists in pervasive qualities rather than supposed innovations of plot or technique.

Terence

As Greek influence on Roman culture increased, Roman drama became more dependent on Greek models. Terence's comedy was very different from Plautus'. Singing almost disappeared from his plays, and recitative was less prominent. From Menander he learned to exhibit refinements of psychology and to construct ingenious plots; but he lacked comic force, being uninterested in raising easy laughs. His pride was refined language—the avoidance of vulgarity, obscurity, or slang. His characters were less differentiated in speech than those of Plautus, but they talk with an elegant charm. The society Terence portrayed was more sensitive than that of Plautine comedy; lovers tended to be loyal and sons obedient. His historical significance has been enhanced by the loss of nearly all of Menander's work.

Though often revived, plays modeled on Greek drama were rarely written after Terence. The Ciceronian was the great age of acting, and in 55 BC Pompey gave Rome a permanent theatre. Plays having an Italian setting came into vogue, their framework being Greek New Comedy but their subject Roman society. A native form of farce was also revived. Under Julius Caesar, this yielded in popularity to verse mime of Greek origin that was realistic, often obscene, and full of quotable apothegms. Finally, when mime gave rise to the dumb show of the *pantomimus* with choral accompaniment and when exotic spectacles had become the rage, Roman comedy faded out.

Tragedy. Livius introduced both Greek tragedy (*fabula crepidata,* "buskined") and comedy to Latin. He was followed by Naevius and Ennius, who loved Euripides. Pacuvius, probably a greater tragedian, liked Sophocles, and heightened tragic diction even more than Ennius. His successor, Accius, was more rhetorical and impetuous. The fragments of these poets betoken grandeur in "the high Roman fashion," but they also have a certain ruggedness. They did not always deal in Greek mythology: occasionally they exploited Roman legend or even recent history. The Roman chorus, unlike the Greek, performed on stage and was inextricably involved in the action.

Classical tragedy was seldom composed after Accius, though its plays were constantly revived. Writing plays, once a function of slaves and freedmen, became a pastime of aristocratic dilettantes. Such writers had commonly no thought of production: post-Augustan drama was for reading. The nine extant tragedies of the younger Seneca probably were not written for public performance. They are melodramas of horror and violence, marked by sensational pseudo-realism and rhetorical cleverness. Characterization is crude, and philosophical moralizing obtrusive. Yet Seneca was a model for 16th- and early 17th-century tragedy, especially in France, and influenced English revenge tragedy.

Epic and epyllion. Livius' pioneering *Odyssey* was, to judge from the fragments, primitive, as was the *Bellum Punicum* of Naevius, important for Virgil because it began with the legendary origins of Carthage in Phoenicia and Rome in Troy. But Ennius' *Annales* soon followed. This compound of legendary origins and history was in Latin, in a transplanted metre, and by a poet who had imagination and a realization of the emergent greatness of Rome. In form his work must have been ill-balanced; he almost ignored the First Punic War in consideration of Naevius and became more detailed as he added books about his own times. But his great merit shines out from the fragments—nobility of ethos matched with nobility of language. On receptive spirits, such as Cicero, Lucretius, and Virgil, his influence was profound.

Virgil's *Aeneid*

Little is known of the "strong epic" for which Virgil's friend Varius is renowned, but Virgil's *Aeneid* was certainly something new. Recent history would have been too particularized a theme. Instead, Virgil developed Naevius' version of Aeneas' pilgrimage from Troy to found Rome. The poem is in part an Odyssey of travel (with an interlude of love) followed by an Iliad of conquest, and in part a symbolic epic of contemporary Roman relevance. Aeneas has Homeric traits but also qualities that look forward to the character of the Roman hero of the future. His fault was to have lingered at Carthage. The command to leave the Carthaginian queen Dido shakes him ruthlessly out of the last great temptation to seek individual happiness. But it is only the vision of Rome's future greatness, seen when he visits Elysium, that kindles obedient acceptance into imaginative enthusiasm. It was just such a sacrifice of the individual that the Augustan ideal demanded. The second half of the poem represents the fusing in the crucible of war of the civilized graces of Troy with the manly virtues of Italy. The tempering of Roman culture by Italian hardiness was another part of the Augustan ideal. So was a revival of interest in ancient customs and religious observances, which Virgil could appropriately indulge. The verse throughout is superbly varied, musical, and rhetorical in the best sense.

With his *Hecale,* Callimachus had inaugurated the short, carefully composed hexameter narrative (called epyllion by modern scholars) to replace grand epic. The *Hecale* had started a convention of insetting an independent story. Catullus inset the story of Ariadne on Naxos into that of the marriage of Peleus and Thetis, and the poem has a mannered, lyrical beauty. But the story of Aristaeus at the end of Virgil's *Georgics,* with that of Orpheus and Eurydice inset, shows what heights epyllion could attain.

Ovid's *Metamorphoses*

Ovid's *Metamorphoses* is a nexus of some 50 epyllia with shorter episodes. He created a convincing imaginative world with a magical logic of its own. His continuous poem, meandering from the creation of the world to the apotheosis of Julius Caesar, is a great Baroque conception, executed in swift, clear hexameters. Its frequent irony and humour are striking. Thereafter epics proliferated. Statius' *Thebaid* and inchoate *Achilleid* and Valerius' *Argonautica* are justly less read now than they were. Lucan's unfinished *Pharsalia* has a more interesting subject, namely the struggle between Caesar and Pompey, whom he favours. He left out the gods. His brilliant rhetoric comes close to making the poem a success, but it is too strained and monochromatic.

Didactic poetry. Ennius essayed didactic poetry in his *Epicharmus,* a work on the nature of the physical universe. Lucretius' *De rerum natura* is an account of Epicurus' atomic theory of matter, its aim being to free men from superstition and the fear of death. Its combination of moral urgency, intellectual force, and precise observation of the physical world makes it one of the summits of classical literature.

This poem profoundly affected Virgil, but his poetic reaction was delayed for some 17 years; and the *Georgics,* though deeply influenced by Lucretius, were not truly didactic. Country bred though he was, Virgil wrote for literary readers like himself, selecting whatever would contribute picturesque detail to his impressionistic picture of rural life. The *Georgics* portrayed the recently united land of Italy and taught that the idle Golden Age of the fourth *Eclogue* was a mirage: relentless work, introduced by a paternal Jupiter to sharpen men's wits, creates "the glory of the divine countryside." The compensation is the infinite variety of civilized life. Insofar as it had a political intention, it encouraged revival of an agriculture devastated in wars, of the old Italian virtues, and of the idea of Rome's extending its works over Italy and civilizing the world.

Ovid's *Ars amatoria* was comedy or satire in the burlesque guise of didactic, an amusing commentary on the psychology of love. The *Fasti* was didactic in popularizing the new calendar; but its object was clearly to entertain.

Satire. *Satura* meant a medley. The word was applied to variety performances introduced, according to Livy, by the Etruscans. Literary satire begins with Ennius, but it was Lucilius who established the genre. After experimenting, he settled on hexameters, thus making them its recognized vehicle. A tendency to break into dialogue may be a vestige of a dramatic element in nonliterary *satura.* Lucilius used this medium for self-expression, fearlessly criticizing public as well as private conduct. He owed much to the Cynic-Stoic "diatribes" (racy sermons in prose or verse) of Greeks such as Bion; but in extant Hellenistic literature he is most clearly presaged by the fragments of Callimachus' iambs. "Menippean" satire, which descended from the Greek prototype of Menippus of Gadara and mingled prose and verse, was introduced to Rome by Varro.

The satire of Horace and Juvenal

Horace saw that satire was still awaiting improvement: Lucilius had been an uncouth versifier. *Satires* I, 1–3 are essays in the Lucilian manner. But Horace's nature was to laugh, not to flay, and his incidental butts were either insignificant or dead. He came to appreciate that the real point about Lucilius was not his denunciations but his self-revelation. This encouraged him to talk about himself. In *Satires* II he developed in parts the satire of moral diatribe presaging Juvenal. His successor Persius blended Lucilius, Horace, diatribe, and mime into pungent sermons in verse. The great declaimer was Juvenal, who fixed the idea of satire for posterity. Gone was the personal approach of Lucilius and Horace. His anger may at times have been cultivated for effect, but his epigrammatic power and brilliant eye for detail make him a great poet.

The younger Seneca's *Apocolocyntosis* was a medley of prose and verse, but its pitiless skit on the deification of the emperor Claudius was Lucilian satire. The *Satyricon* of Petronius is also Menippean inasmuch as it contains varied digressions and occasional verse; essentially, however, it comes under fiction.

With Lucilian satire may be classed the fables of Augustus' freedman Phaedrus, the Roman Aesop, whose beast fables include contemporary allusions.

Iambic, lyric, and epigram. The short poems of Catullus were called by himself *nugae* ("trifles"). They vary remarkably in mood and intention, and he uses iambic metre normally associated with invective not only for his abuse of Caesar and Pompey but also for his tender homecoming to Sirmio. Catullus alone used the hendecasyllable, the metre of skits and lampoons, as a medium for love poetry.

Horace was a pioneer. In his *Epodes* he used iambic verse to express devotion to Maecenas and for brutal invective in the manner of the Greek poet Archilochus. But his primary aim was to create literature, whereas his models had been venting their feelings. In the *Odes* he adapted other Greek metres and claimed immortality for introducing early Greek lyric to Latin. The *Odes* rarely show the passion now associated with lyric but are marked by elegance, dignity, and the studied perfectionism of their craftsmanship.

Martial went back to Catullus for his metres and his often obscene wit. He fixed the notion of epigram for posterity by making it characteristically pointed. Occasionally his poems are touching.

Catullus' love poems

Elegy. The elegiac couplet of hexameter and pentameter (verse line of five feet) was taken over by Catullus, who broke with tradition by filling elegy with personal emotion. One of his most intense poems in this metre, about Lesbia, extends to 26 lines; another is a long poem of involved design in which the fabled love of Laodameia for Protesilaus is incidentally used as a paradigm. These two poems make him the inventor of the "subjective" love elegy dealing with the poet's own passion. Gallus, whose work is lost, established the genre; Tibullus and Propertius smoothed out the metre.

Propertius' first book is still Catullan in that it seems genuinely inspired by his passion for Cynthia: the involvement of Tibullus is less certain. Later Propertius grew more interested in manipulating literary conventions. Tibullus' elegy is constructed of sections of placid couplets with subtle transitions. These two poets established the convention of the "soft poet," valiant only in the campaigns of love, immortalized through them and the Muses. Propertius was at first impervious to Augustan ideals, glorying in his abject slavery to love and his naughtiness (*nequitia*), though later he became acclimatized to Maecenas' circle.

Tibullus, a lover of peace, country life, and old religious customs, had grace and quiet humour. Propertius, too, could be charming, but he was far more. He often wrote impetuously, straining language and associative sequence with passion or irony or sombre imagination.

Ovid's aim was not to unburden his soul but to entertain. In the *Amores* he is outrageous and amusing in the role adopted from Propertius, his Corinna being probably a fiction. Elegy became his characteristic medium. He carried the couplet of his predecessors to its logical extreme, characterized by parallelism, regular flow and ebb, and a neat wit.

OTHER LANGUAGE AND LITERARY ART FORMS

Cicero's influence on oratory

Rhetoric and oratory. Speaking in the forum and law courts was the essence of a public career at Rome and hence of educational practice. After the 2nd century BC, Greek art affected Latin oratory. The dominant style in Cicero's time was the "Asiatic"—emotional, rhythmical, and ornate. Cicero, Asiatic at first, early learned to tone down his style. Criticized later by the revivers of plain style, he insisted that style should vary with subject. But in public speaking he held that crowds were swayed less by argument than emotion. He was the acknowledged master speaker from 70 BC until his death (43 BC). He expounded the history of Roman oratory in the *Brutus* and his own methods in the *De oratore.*

The establishment of monarchy robbed eloquence of its public importance, but rhetoric remained the crown of education. Insofar as this taught boys to marshal material clearly and to express themselves cogently, it performed the function of the modern essay; but insofar as the temptations of applause made it strained and affected, it did harm.

In the *De oratore,* Cicero had pleaded that an orator's training should be in all liberal arts. Education without rhetoric was inconceivable; but what Cicero was proposing was to graft onto it a complete system of higher education. Quintilian, in his *Institutio oratoria,* went back to Cicero for inspiration as well as style. Much of that work is conventional, but the first and last books in particular show admirable common sense and humanity; and his work greatly influenced Renaissance education.

History. Quintus Fabius Pictor wrote his pioneering history of Rome during the Second Punic War, using public and private records and writing in Greek. His immediate successors followed suit. Latin historical writing began with Cato's *Origines.* After him there were as many historiasters, or worthless historians, as the poetasters disdained by Cicero. The first great exception is Caesar's *Commentaries,* a political apologia in the guise of unvarnished narrative. The style is dignified, terse, clear, and unrhetorical.

Sallust took Thucydides as his model. He interpreted, using speeches, and ascribed motives. In his extant monographs *Bellum Catilinae* and *Bellum Jugurthinum,* he displays a sardonic moralism, using history to emphasize the decadence of the dominant caste. The revolution in style he inaugurated gives him importance in an account of Latin literature.

Livy began his 40 years' task as Augustus came to power. His work consummated the annalistic tradition. If in historical method he fell short of modern standards, he had the literary virtues of a historian. He could vividly describe past events and interpret the participants' views in eloquent speeches. He inherited from Cicero his literary conception of history, his copiousness, and his principle of accommodating style to subject. Indeed, he was perhaps the greatest of Latin stylists. His earlier books, where his imagination has freer play, are the most readable. In the later books, the more historical the times become, the more disturbing are his uncritical methods and his patriotic bias. Livy's work now is judged mainly as literature.

The histories of Tacitus

Tacitus, on the other hand, stands higher now than in antiquity. Though his anti-imperial bias in attributing motives is plain, his facts can rarely be impugned; and his evocation of the terrors of tyranny is unforgettable. He is read for his penetrating characterizations, his drama, his ironical epigrams, and his unpredictability. His is an extreme development of the Sallustian style, coloured with archaic and poetic words, with a careful avoidance of the commonplace.

Suetonian biography apart, historiography thereafter degenerated into handbooks and epitomes until Ammianus Marcellinus appeared. He was refreshingly detached, rather ornate in style, but capable of vivid narrative and description. He continued Tacitus' account from Domitian's death to AD 378, more than half his work dealing with his own times.

Biography and letters. The idea of comparing Romans with foreigners was taken up by Cornelius Nepos, a friend of Cicero and Catullus. Of his *De viris illustribus* all that survive are 24 hack pieces about worthies long dead and one of real merit about his friend Atticus. The very fact that Atticus and Tiro decided to publish nearly 1,000 of Cicero's letters is evidence of public interest in people. Admiration of these fascinating letters gave rise to letter writing as a literary genre. The younger Pliny's letters, anticipating publication, convey a possibly rose-tinted picture of civilized life. They are nothing to his spontaneous correspondence with Trajan, where one learns of routine problems, for instance with Christians confronting a provincial governor in Bithynia. The letter as a verse form, beginning with striking examples by Catullus, was established by Horace, whose *Epistles* carry still further the humane refinement of his gentler satires.

Suetonius' biographies

Suetonius' lives of the Caesars and of poets contain much valuable information, especially since he had access to the imperial archives. His method was to cite in categories whatever he found, favourable or hostile, and to leave this raw material to the judgment of the reader. The *Historia Augusta,* covering the emperors from 117 to 284, is a collection of lives in the Suetonian tradition. Tacitus' *Agricola* was an admiring, but not necessarily overcoloured, biographical study.

Some of the most valuable autobiography was incidental, such as Cicero's account of his oratorical career in the *Brutus.* Horace's largely autobiographical *Epistles* I was sealed with a miniature self-portrait. Ovid, in exile and afraid of fading from Rome's memory, gave an invaluable account of his life in *Tristia* IV.

Philosophical and learned writings. The practical Roman mind produced no original philosopher. Apart from Lucretius the only name that demands consideration is Cicero's. He was trained at Athens in the eclectic New Academy, and eclectic he apparently remained, seeking a philosophy to fit his own constitution rather than a logical system valid for all. He used the dialogue form, avowedly in order to make people think for themselves instead of following authority. Essentially, he was a philosophic journalist, composing works that became one of the means by which Greek thought was absorbed into early Christian thinking. The *De officiis* is a treatise on ethics. The dialogues do not follow the Platonic, or dialectic, pattern but the Aristotelian, in which speakers expounded already formed opinions at greater length.

Nor were the Romans any more original in science. Instead, they produced encyclopaedists such as Varro and Celsus. Pliny's *Natural History* is a fascinating ragbag, especially valuable for art history, though it shows to what extent Hellenistic achievement in science had become confused or lost.

Literary criticism. Cicero's *Brutus* and the 10th book of Quintilian's *Institutio oratoria* provide examples of general criticism. Cicero stressed the importance of a well-stocked mind and native wit against mere handbook technique. By Horace's day, however, it had become more timely to insist on the equal importance of art. Some of Horace's best criticism is in the *Satires* (I, 4 and 10; II, 1), in the epistle to Florus (II, 2), and in the epistle to Augustus (II, 1), a vindication of the Augustans against archaists. But it was his epistle to a Piso and his sons (later called *Ars poetica*) that was so influential throughout Europe in the 18th century. It supported, among acceptable if trite theses, the dubious one that poetry is necessarily best when it mingles the useful (particularly moral) with the pleasing. Much of the work concerned itself with drama. The Romans were better at discussing literary trends than fundamental principles—there is much good sense about this in Quintilian, and Tacitus' *Dialogus* is an acute discussion of the decline of oratory.

Horace's *Ars poetica*

Fiction. Republican and early imperial Rome knew no Latin fiction beyond such things as Sisenna's translation of Aristides' *Milesian Tales*. But two considerable works have survived from imperial times. Of Petronius' *Satyricon*, a rambling picaresque novel, one long extract and some fragments remain. The disreputable characters have varied adventures and talk lively colloquial Latin. The description of the vulgar parvenu Trimalchio's banquet is justly famous. Apuleius' *Metamorphoses* (*The Golden Ass*) has a hero who has accidentally been changed into an ass. After strange adventures he is restored to human shape by the goddess Isis. Many passages, notably the story of Cupid and Psyche, have a beauty that culminates in the apparition of Isis and the initiation of the hero into her mysteries. (L.P.Wi./R.H.A.J.)

Medieval Latin literature

From about 500 to 1500 Latin was the principal language of the church, as well as of administration, theology, philosophy, science, history, biography, and belles lettres, and medieval Latin literature is therefore remarkably rich. Two themes dominate the linguistic and literary development of medieval Latin: its close and creative adaptation of the classical heritage from which it emerged and its changing relationship with the medieval vernacular languages. Within these two broad themes a number of subsidiary yet significant strains can be distinguished: the emergence of national characteristics in the Latin literature produced in different parts of Europe; the refinement of the polarity between popular and learned Latin by the clergy's use of a colloquialism intelligible to its audience as a lingua franca; and the effect of certain periods of special vigour and artistic self-awareness, such as the Carolingian revival of the 8th and 9th centuries and the new impulse given to learned and vernacular literature in the 12th.

THE 3RD TO THE 5TH CENTURY: THE RISE OF CHRISTIAN LATIN LITERATURE

The early history of medieval Latin literature is in part the story of the reception of the classical past by the Christians, to whom it represented secular culture. Old forms and genres were continuously renewed over the millennium following the entrance of Christians to the circle of literary production, dated for convenience to the conversion of Constantine to Christianity (in about AD 313). For example, the Latin epic persisted in recognizable form throughout the period, and its authors remained in continuous contact with the great classical exponents Lucan, Statius, and, above all, Virgil. From the 4th century, the degree of scholarly interpretation applied to these epic poets, especially Virgil, was intensified. Virgilian technique was imitated by many poets, among them the 4th-century Spaniard Juvencus, who versified a portion of the Bible, and the author of the epic poem *Waltharius* (probably 9th century), written in hexameters.

Persistence of the Latin epic

Even before the conversion of Constantine, Christians were developing new forms of literature, which persisted throughout the ensuing centuries. The production of hagiographical texts (lives of the saints) was widespread in the Middle Ages. The first Acts of the Martyrs in Latin were written during the 3rd century, and the flowering of the form after the end of the period of persecution of Christians shows the powerful appeal that it exercised at all levels of society. The *Passio Sanctarum Perpetuae et Felicitatis* (*The Passion of S. Perpetua*), written in a style that owes little to classical precedent, is a distinctive early example of the genre.

The 3rd and 4th centuries were above all an age of translation. Among the Greek patristic writings diffused to a wider audience in the West in Latin versions, the lives of the Desert Fathers occupied an important place. The Latin translation by Evagrius, bishop of Antioch, of Athanasius' *Life of Saint Antony* enjoyed the widest transmission, and its influence is as marked by contrast in the early Latin Lives of the Saints as it is by imitation. Sulpicius Severus' biography of St. Martin, an original Latin work, greatly influenced hagiography over many centuries. (A further, equally influential example of the genre was the *Dialogues* of Pope Gregory the Great, written in about 593.)

The most important work of translation appeared at the end of the 4th century: the Vulgate, completed by the monastic leader Jerome, replaced sporadic earlier attempts to render the Bible into Latin. The idiom and style of the Bible's original languages were apparent through the veil of Jerome's Latin, however, and provided a counterweight to the classical styles that continued to be taught and practiced through the schools in the West. Exegesis of the text occupied many of the greatest minds of the Middle Ages for the largest part of their careers, and the literary work of many major authors, from Augustine and Gregory to Bede, reflects their individual understanding of Scripture.

The early Christian liturgy also gave birth to new forms of literature. From the ancient practice of psalmody in the churches derives the hymn. Ambrose, bishop of Milan in the second half of the 4th century, wrote the earliest prosaic hymns, which incorporated nonliturgical texts into the mass to be sung by the congregation. These were rapidly imitated, notably by the Spanish poet Prudentius at the end of the century, and remained in continuous use in churches and monasteries for more than a millennium.

A major problem of Christian thinkers in these centuries was the integration of the history of the pagan empire with the history of salvation. Synthesis and epitome of biblical and classical history appeared in the *Historiarum adversus paganos libri VII* (*7 Books of Histories Against the Pagans*) of Orosius and the briefer *Chronica* (*c.* 402–404) of Sulpicius Severus. On a larger scale, Augustine's *De civitate Dei* (*The City of God*) offered a comprehensive view of past history, the present, and the world to come in the light of scriptural revelation. His spiritual autobiography, the *Confessiones* (*Confessions*), was an exploration of the philosophical and emotional development of an individual soul. The distinctive originality of this work owed little to classical autobiography and was unmatched by later imitations.

Writings of Augustine

The Gallic schools of the 5th century gave rise to a literary culture unique in this period. Versification of the Bible developed a new degree of exegetical and stylistic refinement, while the letters of Paulinus of Nola and Sidonius Apollinaris, bishop of Auvergne, display a picture of cultivated aristocratic and ecclesiastical society. Both men were also admired as poets, Sidonius in particular as an encomiast. On the secular side, at the beginning of the century in Rome the Egyptian poet Claudian produced the most elaborate examples of imperial verse panegyric to a succession of dignitaries. His *Raptus Proserpinae* (*c.* 400; *The Rape of Proserpine*) is one of the last examples of an extended narrative in verse that dwells wholly in the world of pagan mythology.

THE 6TH TO THE 8TH CENTURY

Gaul's literary history is interrupted by the Frankish invasions, though there are signs that abbots and bishops began to perceive the benefit of using literature to promote the cults of local saints. Two figures of note are Gregory of Tours and Venantius Fortunatus, bishop of Poitiers. In addition to a vast corpus of hagiography, Gregory produced the monumental *Historia Francorum* (605–664; *History of the Franks*), the most extensive history of a barbarian people that had yet been written. He set the arrival of the Franks in Gaul, and their recent past, in the perspective of universal history. An element of local patriotism is also discernible. Gregory was one of the many patrons who inspired the poet Fortunatus, whose astute and pliable talent achieved distinction in both secular panegyric and hymnody. His hagiography, in verse and in prose, also occupies a prominent place in his output. His style exercised a powerful appeal upon the poets of the Carolingian renaissance.

Three figures of encyclopaedic learning dominate the literature of the 6th and 7th centuries. In the course of his long retirement from a career in public service under the Ostrogothic kings in Italy, Cassiodorus combined zealous preservation of the literature of the classical past with an enormously influential educational plan. His late 6th-century compendium of sacred and secular learning, *Institutiones divinarum et humanarum lectionum* (*An Introduction to Divine and Human Readings*), was among the shaping influences upon monastic culture. The Roman Boethius, a Neoplatonist philosopher, wrote on arithmetic and music, but his most popular and influential work was *De consolatione philosophiae* (1882–91; *The Consolation of Philosophy*), written in about 524, when Boethius was imprisoned under sentence of execution. The Spaniard Isidore produced a series of encyclopaedic compilations that were used as repositories of diverse learning by later centuries. It was midway through the 6th century that the last major Latin work was produced in the Eastern Empire: the epic *Iohannis* of the African poet Corippus.

Writings of the Venerable Bede

The conversion of the Saxons began to bear literary fruit during the 7th and early 8th centuries. In an elaborate and allusive style, Aldhelm, bishop of Sherborne, wrote, first in prose and later in verse, a treatise on sainthood called *De Virginitate.* In the kingdom of Northumbria, particularly open to influence of Irish monastic learning, St. Bede the Venerable devoted his life to scholarship. The culmination of his work is the *Historia ecclesiastica gentis Anglorum* (*The Venerable Bede's Ecclesiastical History of England*), completed in 731. Synthesized from a variety of sources, literary and nonliterary, the work charts the involvement of God with the English people and the relation of the English church to the Christian world centred on Rome.

THE CAROLINGIAN RENAISSANCE

The revival of letters, accompanied by wide-scale copying of classical texts, to which the reign of Charlemagne (768–814) gave fresh impetus, produced some of the most brilliant literary achievements of the Latin Middle Ages. An international elite of scholars, among whom the most distinguished were the Anglo-Saxon Alcuin, the Visigoth Theodulf of Orléans, and the Italians Paulinus of Aquileia and Paul the Deacon, produced a body of lyric, epic, and didactic poetry (both sacred and secular, both religious and political) unmatched in the earlier period. The revival of epic, and the secularization of the sacred hero, occurred in the extant third book of a lost and larger Virgilian epic, anonymously transmitted but known by the title *Karolus Magnus et Leo Papa* ("Charlemagne and Pope Leo"). Its example was followed in the next generation by Ermoldus Nigellus, writing about the deeds of Louis the Pious, and the tradition of earlier Carolingian authors is extended by two major political poets, Walafrid Strabo and Sedulius Scottus (also the author of an uproarious mock epyllion). In prose the major achievements lie in the fields of biography, with Einhard's *Vita Karoli Magni* (*c.* 830; *Life of Charlemagne*); of religious controversy, with Theodulf's *Libri Carolini* (defenses written at Charlemagne's request); and of theology, with John Duns Scotus' metaphysical masterpiece, the *Periphyseon.*

THE 9TH TO THE 11TH CENTURY

The sequence and the liturgical drama

From the later 9th century on, the liturgy gave rise to two new literary forms: the sequence and the liturgical drama. Notker Balbulus, monk of St. Gall, was not the first to compose sequences, but his *Liber hymnorum* ("Book of Hymns"), begun about 860, is an integrated collection of texts that spans the whole of the church year in an ordered cycle. Performed between the biblical readings in the mass, each sequence is a free meditation upon scriptural themes, often drawing upon and synthesizing disparate texts. Among later exponents of the genre, Adam of St. Victor was the most distinguished, though the mystical sequences of Hildegard of Bingen exercise a potent appeal. During the same period the enormous expansion of the cult of the Virgin left a notable mark upon hymnody, the early 11th century seeing the composition of Marian hymns, including such ubiquitous texts as "Salve Regina" ("Hail, Queen") and "Alma Redemptoris Mater" ("Sweet Mother of the Redeemer").

Notker's sequences are alive with dramatic possibility, and at St. Gall the practice of troping, or embellishing, liturgical texts also took dramatic form. The *Quem quaeritis* trope from St. Martial, an abbey at Limoges, was one of the earliest such pieces to demand dramatic performance. From this beginning developed the long tradition of liturgical drama, which, like the sequence, is centred upon the major feasts of the church year.

Two narrative works stand out in this period. The *Waltharius* epic is set in the years of the invasions of Attila the Hun. The polished sophistication of its narrative technique contrasts delightfully with its Germanic subject matter. The *Ruodlieb*, a romance written perhaps in about 1050 in a language heavily influenced by vernacular usage, reveals a comparable narrative subtlety. Even in its fragmentary state, the variety and vigour of its episodes are apparent.

The ease with which religious forms such as the sequence are adapted for secular use is nowhere seen better than in the 11th-century compilation known as the *Cambridge Songs.* The blend of humorous contes, hymnody, and lyric testifies to a diverse taste in the unknown anthologist. Other lyric collections from the next century, such as the Ripoll and Arundel lyrics, may draw upon work of earlier provenance. To the chance survival of individual compilations such as these derives the bulk of knowledge of the secular lyric, which is one of the chief distinctions of the 12th and 13th centuries.

THE 12TH TO THE 14TH CENTURY

The *Carmina Burana*

The *Carmina Burana* ("Songs from Bavaria"), the largest and greatest collection of secular lyrics, comes from the Benediktbeuern, a Benedictine monastery in Bavaria. It was put together in the 13th century, though most of the songs are much older, and contains work by many of the finest poets of the age. The contents are divided by subject into moral and satirical verse, love poetry, drinking songs, and liturgical dramas. Walter of Châtillon and Philip the Chancellor are conspicuous among the authors of the satires, the force of their works deriving from learned and allusive use of Scripture. Peter of Blois is found in the section of satirical verse and the section of love poetry. His verse forms achieve a new degree of delicacy and sophistication, and his erotic poetry owes much to a close study of classical poets, particularly Ovid. Yet many of the forms in evidence, the pastourelle (a love debate between a knight and a shepherdess) for example, have no classical antecedent. In the complexity of its argument, and profusion of imagery, a poem such as "Dum Diane vitrea" ("While Shining Diane") far exceeds the imagination of any classical author. Among the drinking songs in the third section are works of the anonymous German "Archpoet" and of Hugh Primas of Orléans, a slightly earlier figure. Under the cover of a pointedly low-life persona, these poets, both prominent men in court society, practiced a robust form of satire in which much of the humour is deflected upon themselves. Grander forms of poetry are not neglected: Walter of Châtillon's foray into epic, the *Alexandreis* (written *c.* 1180), is one of the most distinguished products of the medieval fascination with the legends of Alexander the Great, and it exercised an immense influence on subsequent vernacular literature.

Works of Peter Abelard

The 12th century was an age of philosophical development, above all in the cathedral schools (as at Chartres) and new universities (as at Paris). Scholars such as Alain of Lille (Alanus de Insulis) and John of Salisbury returned to philosophical problems that had been posed in the days of Boethius. With Roger Bacon, Duns Scotus, and Robert Grosseteste, the first chancellor of Oxford University, a significant English contribution is discernible. Peter Abelard trained at Paris, where he taught John of Salisbury. Of Abelard's philosophical works, *Sic et non* (completed *c.* 1136; "Yes and No") is the most notable, probing critically the vast bulk of received authority. In three of his most original literary works, the relationship with Héloïse is a prominent feature. The *Hymnarius Paraclitensis* is a collection of hymns for Héloïse's convent, where the reading of Scripture is complex and shows the imprint of novel theological thought. The six *planctus* ("laments") are meditations on guilt and suffering, set in the mouths of biblical personages, while the correspondence between Abelard and Héloïse reflects themes found in both verse collections. Abelard's autobiographical work, the *Historia calamitatum* (written *c.* 1136; *The Story of Abelard's Adversities*), recounts the story of his tragic love affair and its theological consequences.

Liturgical and cultic innovation left its mark upon Latin literature during the 13th and 14th centuries. John of Garland's compilation of hymns to the Virgin is a late testimony to the force of Marian inspiration. From the early 13th century derive two of the latest sequences to feature in the liturgy in all countries, the "Dies irae" ("The Day of Wrath") and the "Stabat Mater" ("The Mother Stands"). The cults of the Holy Cross and of the Passion are the impetus to the poetry of two Franciscans, the Italian St. Bonaventura and John Pecham in England. Pecham's *Philomena praevia* is an extended lyrical meditation that blends the story of the Redemption with the liturgical course of a single day.

The theology of the 13th century is dominated in bulk and stature by the writings of St. Thomas Aquinas. The culmination of a career centred upon Paris and Rome is the *Summa theologiae* (written between 1265 and 1272), a systematic exposition of the essentials of faith, grounded in Aristotelian principles. The translation of Aristotle into Latin continued throughout the century. Aquinas' liturgical works also remained prevalent. (P.Go.)

Renaissance Latin literature

The term Renaissance Latin is associated, for 14th-century Italy, mainly with Dante, Petrarch, and Boccaccio, though mention should also be made of the Florentine historian Leonardo Bruni and the humanist scholars Albertino Mussato, Coluccio Salutati, and Aeneas Silvius Piccolomini (Pope Pius II). In verse there was a general return to classical models and elegance, while in prose Latin was still a necessary medium for the abundant humanistic, scientific, philosophical, and religious literature that was a mark of the new age.

In Italy there were three main centres of learning and literature in the 15th and 16th centuries: Florence, Rome, and Naples. Each of these centres had its own circle of writers and scholars. The Florentine group was chiefly noted for the Platonist philosophers Poggio Bracciolini, Marsilio Ficino, Giovanni Pico della Mirandola, and a poet and scholar, Angelo Poliziano. Rome was the centre for a grammarian, Pietro Bembo, and for Marco Vida, author of a Latin epic on the redemption, while Naples was the home of many poets and scholars, notably Giovanni Pontano, Jacopo Sannazzaro, Lorenzo Valla, and Girolamo Fracastoro.

Influence of the Brethren of the Common Life

Germany and the Low Countries also made a large contribution in prose and verse to Latin literature in the 15th and 16th centuries. Many humanists owed their early education to the Brethren of the Common Life, a Dutch Christian community that laid great emphasis on the classics. Among these was Desiderius Erasmus, the greatest figure of the northern Renaissance. Bred in the rhetorical tradition of literary humanism, he had little interest in the scientific premonitions of the age. As an editor and expositor of classical texts and the writings of the Church Fathers, as a commentator on the ecclesiastical conflicts of his time, and as a scholar, wit, and satirist, he was unsurpassed by any humanist in northern Europe. A German abbot, Johannes Trithemius, was a historian and scholar with an immense range of interests and knowledge; Conradus Celtis was conspicuous as a humanist and poet; while Petrus Lotichius wrote elegant verse.

Spanish humanism was best seen in the scholar and friend of Erasmus, Juan Vives, while in England the statesman and scholar Sir Thomas More was the outstanding figure. Polydore Virgil, an Italian, brought the new methods of historical writing into England, though a poet and historian, Tito Livio Frulovisi, had written a life of Henry V that influenced later English writers. Among many Latin poets should be mentioned George Buchanan and John Barclay, both Scots. The strong English tradition of classical verse composition in the schools was shown in the Latin poems of such 17th-century poets as John Milton, Henry Vaughan, Richard Crashaw, and Abraham Cowley.

In France, where, as in England, the Renaissance came late, some members of the group of writers known as La Pléiade wrote Latin verse. Despite the eventual triumph of the French vernacular, Latin poems continued to be written, and several hymns composed in classical forms were included in church services in the 17th and 18th centuries. (F.J.E.R.)

Until the early 18th century, Latin was recognized as the best medium for historical and scientific work if it were intended to reach a European audience. For this reason Marsilio Ficino and Pico della Mirandola, Erasmus and More, and later Francis Bacon, Hugo Grotius, René Descartes, Benedict Spinoza, and Sir Isaac Newton used what was still an international language.

(Ed.)

Lavoisier

A French chemist and the father of modern chemistry, Antoine-Laurent Lavoisier was a brilliant experimenter and many-sided genius who was active in public affairs as well as in science. He developed a new theory of combustion that led to the overthrow of the phlogistic doctrine, which had dominated the course of chemistry for more than a century. His fundamental studies on oxidation demonstrated the role of oxygen in chemical processes and showed quantitatively the similarity between oxidation and respiration. He formulated the principle of the conservation of matter in chemical reactions. He clarified the distinction between elements and compounds and was instrumental in devising the modern system of chemical nomenclature. Lavoisier was one of the first scientific workers to introduce quantitative procedures into chemical investigations. His experimental ingenuity, exact methods, and cogent reasoning, no less than his discoveries, revolutionized chemistry. His name is indissolubly linked to the establishment of the foundations upon which modern science rests.

Education and early work

Lavoisier was born in Paris on August 26, 1743. His father, an *avocat au parlement* (parliamentary counsel), gave him an excellent education at the Collège Mazarin, where, along with a solid classical grounding in language, literature, and philosophy, he received the best available training in the sciences, including mathematics, astronomy, chemistry, and botany. Following his family's tradition, he pursued the study of law, and he received his license to practice in 1764. His inquiring mind, however, continually drew him to science. In 1766 he received a gold medal from the Academy of Sciences for an essay on the best means of lighting a large town. Among his early work were papers on the Aurora Borealis, on thunder, and on the composition of gypsum. Pursuing an early interest in rocks and minerals, he accompanied the geologist J.-E. Guettard on a long geological trip and assisted him in preparing his mineralogical atlas of France. In 1768, after presenting a paper on the analysis of water samples, Lavoisier was admitted to the academy as *adjoint-chimiste* (associate chemist). He passed through all the grades in the academic structure and was made director in 1785 and treasurer in 1791.

Lavoisier, with his wife, oil painting by Jacques-Louis David, 1788. In the collection of Rockefeller University, New York City.

Through his family, Lavoisier became independently wealthy in his early 20s. In 1771 he married Marie Paulze, who would later assist him in his work by illustrating his experiments, recording results, and translating scientific articles from English. In accordance with a common practice among the wealthy bourgeoisie at the time, his father bought him a title of nobility in 1772, and a few years later Lavoisier purchased the country estate of Fréchines, near Blois.

Scientific achievements. Lavoisier's name gained wide recognition when, in 1770, he refuted the then prevalent belief that water is converted into earth by repeated distillation. By carefully weighing both the earthy residue and the distilling apparatus, he demonstrated that the solid matter came from the glass vessels and not from the water.

Study of combustion

Speculating on the nature of the traditional four elements—earth, water, air, and fire—Lavoisier began to investigate the role of air in combustion. On November 1, 1772, he deposited with the Academy of Sciences a note stating that sulfur and phosphorus when burned increased in weight because they absorbed "air," while the metallic lead formed when litharge was heated with charcoal weighed less than the original litharge because it had lost "air." The exact nature of the airs concerned in the processes he could not yet explain, and he proceeded to study the question extensively. In 1774 he published his first book, *Opuscules physiques et chimiques,* in which he presented the results of both his reading and his experimentation. That year Joseph Priestley prepared "dephlogisticated air" (oxygen) by heating "red precipitate of mercury." Lavoisier confirmed and extended Priestley's work. Perceiving that in combustion and the calcination of metals only a portion of a given volume of common air was used up, he concluded that the active agent was Priestley's new "air," which was absorbed by burning, and that "nonvital air," or azote (nitrogen), remained behind. He observed that birds lived longer in the new "eminently respirable air," as he described it, and he showed that this air combined with carbon to produce the "fixed air" (carbon dioxide) obtained by Joseph Black in 1754.

Recognition that the atmosphere is composed of different gases that take part in chemical reactions made it possible to identify the composition of many substances, particularly the acids. In a memoir presented to the academy in 1777, read in 1779 but not published until 1781, Lavoisier assigned to dephlogisticated air the name oxygen, or "acid producer," on the erroneous supposition that all acids were formed by its union with a simple, usually nonmetallic body. He explained combustion not as the result of the liberation of a hypothetical fire principle, phlogiston, but as the result of the combination of the burning substance with oxygen. On June 25, 1783, he announced to the academy that water was the product formed by the combination of hydrogen and oxygen; in this, however, he had been anticipated by the English chemist Henry Cavendish. As a member of a committee for finding ways to improve lighter-than-air flight with the newly invented balloons, he produced quantities of hydrogen, called "inflammable air," by decomposing water into its constituent gases. From his knowledge of the composition of water, Lavoisier was led to the beginnings of quantitative organic analysis. He burned alcohol and other combustible organic compounds in oxygen, and from the weight of water and carbon dioxide produced he calculated their composition.

Lavoisier published a brilliant attack on the phlogistic theory in 1786. Despite the opposition of Priestley and others, a growing number of scientists began to adopt his views. In 1787 a group of French chemists published the *Méthode de nomenclature chimique,* which classified and renamed the known elements and compounds. Reflecting Lavoisier's new discoveries and theories, the *Nomenclature* exerted a wide influence. Also influential was the revision in 1788 of Antoine-François de Fourcroy's popular *Élémens d'histoire naturelle et de chimie,* which was completely recast in terms of Lavoisier's views and according to the new chemical nomenclature. The following year Lavoisier and others established the *Annales de chimie,* a journal devoted to the new chemistry. Gradually the older approach based on the phlogistic theory lost adherents, and eventually Lavoisier's ideas were adopted universally.

The spread of Lavoisier's doctrines was greatly facilitated by the defined and logical form in which he presented them in his *Traité élémentaire de chimie* (1789). This classic book provided a concise exposition of his work and that of his followers and offered an introduction to the new approach to chemistry. In the prefatory "Discours préliminaire" Lavoisier set forth his views on the proper methods of scientific inquiry and scientific teaching, and he defended the new nomenclature. Those substances that could not be decomposed he termed *substances simples,* the elements out of which other matter was made. To a large extent the modern concept of an element, as against the ancient Greek idea, stems from Lavoisier. In the *Traité* he furnished a clear statement of his principle of the conservation of matter in chemical reactions. Nothing, he said, is created or destroyed; there are only alterations and modifications, and there is an equal quantity—an equation—of matter before and after the operation.

Other scientific work

In addition to his purely chemical work, Lavoisier, mostly in conjunction with the mathematician and astronomer Pierre-Simon Laplace, devoted considerable attention to physical problems, especially those connected with heat. The two carried out some of the earliest thermochemical investigations, devised an apparatus for measuring linear and cubical expansions, and employed a modification of Black's ice calorimeter in a series of determinations of specific heats. Regarding heat (*matière du feu*) as a peculiar kind of imponderable matter, Lavoisier held that the three states of aggregation—solid, liquid, and gas—were modes of matter, each depending on the amount of *matière du feu* with which the substances concerned were associated. He also worked at fermentation, respiration, and animal heat, looking upon the processes concerned as essentially chemical in nature. From measurements made in his pioneering biochemical experiments on animal heat and on the gases exchanged during respiration, he concluded that respiration was a type of oxidation reaction similar to the burning of carbon. A paper discovered many years after his death showed that he had anticipated later thinkers in explaining the cyclical process of animal and vegetable life.

Public service. Throughout Lavoisier's extraordinary career as a scientist, he carried on a simultaneous career as a public servant of remarkable versatility, contributing his talents in the areas of finance, economics, agriculture, education, and social welfare, among others. In 1768 he became an assistant in one of the revenue-collecting departments of the government, subsequently becoming a full titular member of the Ferme Générale, the main tax-collecting agency. The financial and organizational abilities he displayed as a farmer-general, along with his undoubted scientific and technical capacity, led in 1775 to his appointment as *régisseur des poudres* (a director of the gunpowder administration). With his customary energy he set about making improvements in the chaotic powder industry. He abolished the vexatious search for saltpetre in the cellars of private houses, increased the production of the salt, and improved the manufacture of gunpowder. The post enabled Lavoisier to move to the Arsenal of Paris, where he took up residence and equipped a superb laboratory. This establishment soon became a gathering place for the scientists and advanced thinkers of the day, and the dinners presided over by his wife became famous. After dinner the guests often would be escorted to the laboratory to witness or take part in a demonstration of some new experiment. Although an increasing number of public duties claimed Lavoisier's time, he regularly set aside one day a week for scientific investigations.

As his influence in the Academy of Sciences grew, so did his responsibilities. He was a member of numerous official committees to look into matters concerning the public. In 1781 the notorious Franz Anton Mesmer arrived in Paris, and Lavoisier (along with Benjamin Franklin) served on a committee to investigate his cures by "animal magnetism," pronouncing them a hoax. With another committee, he explored the hospitals and prisons of Paris and recommended remedies for their deplorable state. At Fréchines he started a model farm, where he demonstrated the advantages of scientific agriculture. In 1785 he was named to the government's committee on agriculture and as its secretary drew up reports and instructions on the cultivation of crops, promulgating various agricultural schemes. As a landowner in the province of Orléans, Lavoisier was chosen a member of the provincial assembly in 1787. There he devised measures for improving social and economic conditions in the area by such means as savings banks, insurance societies, canals, workhouses, and tax reforms. He advanced money without interest to the towns of Blois and Romorantin for the purchase of barley during the famine of 1788. He was associated with committees on hygiene, coinage, the casting of cannon, and public education. He was secretary and treasurer of the commission appointed in 1790 to secure uniformity of weights and measures throughout France, work that led to the establishment of the metric system.

Lavoisier's fate in the Revolution

A reformer and political liberal opposed to many aspects of the ancien régime, Lavoisier took an active role in the French Revolution. When the States General was reconvened in 1789, he became an alternate deputy and drew up the code of instructions for guidance of the deputies. He was elected to the commune of Paris and joined the moderate Society of 1789, a planning group. He became an administrator of the national treasury and published detailed analyses of the state of the nation's finances and its agriculture. But his membership in the unpopular Ferme Générale was alone sufficient to make him an object of suspicion to the authorities, and, despite his many services to the nation and his wide renown as a scientist, he came under increasingly severe attack from the more radical pamphleteers. In 1787, at Lavoisier's suggestion, a wall had been erected around Paris to halt the flow of contraband into the city. The extremist revolutionary Jean-Paul Marat accused him of putting Paris in prison and of stopping the circulation of air. In 1791 the Ferme Générale was abolished, and Lavoisier was subsequently removed from his position in the gunpowder administration and forced to leave his home and laboratory in the Arsenal. In 1793 the Reign of Terror commenced, and, in spite of strenuous efforts by Lavoisier, the Academy of Sciences, along with the other learned societies, was suppressed. At the end of the year the Revolutionary Convention ordered the arrest of the former members of the Ferme Générale, and in May 1794 they were tried by the revolutionary tribunal. The trial lasted less than a day. Lavoisier and 27 others were condemned to death. That same afternoon, May 8, he and his companions, including his father-in-law, were guillotined at the Place de la Révolution (now Concorde). His body was thrown into a common grave. (D.I.D.)

BIBLIOGRAPHY. ANTOINE-LAURENT LAVOISIER, *Oeuvres de Lavoisier,* 6 vol. (1862–93, reprinted 1965), is a collected edition that includes all of his principal works and memoirs from the academy volumes, as well as numerous letters, notes, and reports. DENIS I. DUVEEN and HERBERT S. KLICKSTEIN, *A Bibliography of the Works of Antoine Laurent Lavoisier, 1743–1794* (1955), with the *Supplement* (1965), is a definitive work that contains a description of Lavoisier's writings, together with annotations. DOUGLAS MCKIE, *Antoine Lavoisier: Scientist, Economist, Social Reformer* (1952, reissued 1962), is an authoritative biography. A good account of his life and career can be found in SARAH R. RIEDMAN, *Antoine Lavoisier: Scientist and Citizen* (1957, reissued 1967). A biography based on 20th-century research is LÉON VELLUZ, *Vie de Lavoisier* (1966). Lavoisier's place in the history of science is explored in KENNETH S. DAVIS, *The Cautionary Scientists: Priestley, Lavoisier, and the Founding of Modern Chemistry* (1966). HENRY GUERLAC, *Lavoisier: The Crucial Year* (1961), examines his first experiments on combustion in 1772, and his *Antoine-Laurent Lavoisier: Chemist and Revolutionary* (1975) is an illustrated reprint of the article from the *Dictionary of Scientific Biography.* ROGER HAHN, *The Anatomy of a Scientific Institution: The Paris Academy of Sciences, 1666–1803* (1971), includes information on Lavoisier's activities.

The Profession and Practice of Law

The primary function of the profession and practice of law is to apply the law in specific cases—to individualize it. This function is manifest in the work of the advocate and the judge in the process of trying and deciding cases. In Anglo-American systems a lawyer investigates the facts and the evidence by conferring with his client, interviewing witnesses, and reviewing documents. He may seek a summary dismissal because the opponent evidently has no case, or, through discovery proceedings he may force the other side to reveal more fully the issues and facts on which it relies. At the trial he introduces evidence, objects to improper evidence from the other side, and advances partisan positions on questions of law and of fact. In continental European countries the judge has greater responsibility for investigation of the facts. At trial he plays an active role in taking evidence, questioning witnesses, and framing the issues. Continental lawyers suggest lines of factual inquiry to the judge and, like their Anglo-American counterparts, advance legal theories and argue the law in accord with the interests of their clients. In either system, if a lawyer loses his client's case, he may seek a new trial or relief in an appellate court.

Even controversies that are not resolved in court require the aid of lawyers. Negotiation, reconciliation, compromise—in all of which lawyers have a large part—bring about the settlement of most cases without trial.

The profession also applies and utilizes the law in the less dramatic setting of the office. The lawyer as counselor and negotiator may aid in shaping a transaction so as to avoid disputes or legal difficulties in the future, or so as to achieve advantages for his client, such as the minimization of taxes. The law gives to private persons extensive but not unlimited power to arrange and determine their legal rights in many matters and in various ways, such as through wills, contracts, leases, or corporate bylaws. In structuring these arrangements the lawyer is helping to particularize the legal rights of the parties.

Another field of legal work, which has developed rapidly in the 20th century, is the representation of clients before administrative commissions, commissions of inquiry, and, in some countries, legislative committees. This development has been a result of the increase of government regulation of economic life.

A lawyer has several loyalties in his work, including loyalty to his client, to the administration of justice, to the community, to his associates in practice, and to himself—whether to his economic interests or to his ethical standards. These diverse and at times competing loyalties must be reconciled with wisdom. It is the purpose of the standards of the profession to effect the reconciliation. (M.A.Gl.)

This article is divided into the following sections:

Legal profession

One definition of the legal profession is "the vocation based on expertness in the law and its application." This simple definition may be best, despite the fact that in some countries there are several professions and even some occupations (*e.g.,* police service) that require this expertness but may not be considered to be within the "legal profession" at all.

HISTORY

Distinct legal systems emerged relatively early in history, but legal professions of size and importance are relatively modern. There is not the slightest trace in ancient times of a distinct legal profession in the modern sense. The earliest known legal specialist was the judge, and he was only a part-time specialist. The chief, prince, or king of small societies discharged the judicial function as part of the general role of political leader. As his power spread, he delegated the function, though not to legal specialists; in the secular stages of the early systems, legal duties were taken over by royal officials who were "generalists." In the wake of powerful religious or quasi-religious movements priests or wise men often judged or advised the judges, a situation that persisted in Muslim countries and in China until the 20th century AD. It may be suspected that in some of these cases specialized legal aid to the ordinary citizen did exist, but at levels of social status below the notice of chroniclers or tomb inscriptions and perhaps without benefit of official approval.

Classical beginnings of a legal profession. A distinct class of legal specialists other than judges first emerged in the Greco-Roman civilization, and as with the law itself, the main contribution was from Rome in the period from 200 BC to AD 600. In the early stages of both Greece and Rome, as later among the German tribes who overran the Roman Empire, there was a prejudice against the idea of specialists in law being generally available for fee. The assumption was that the citizen knew the customary law and would apply it in transactions or in litigation personally with advice from kinsmen. As the law became more complex, men prominent in public life—usually patricians—found it necessary to acquire legal knowledge, and some acquired a reputation as experts. Often they also spent periods serving as magistrates and in Rome as priests of the official religion, having special powers in matters of family law. Among the German tribes noble experts were allowed to assist in litigation, not in a partisan fashion but as interpreters (*Vorsprecher*) for those unready of speech who wished to present a case. The peculiar system of development of the early Roman law, by annual edict and by the extension of trial formulas, gave the Roman patrician legal expert an influential position; he became the jurisconsult, the first nonofficial lawyer to be regarded with social approbation, but he owed this partly to the fact that he did not attempt to act as an advocate at trial—a function left to the separate class of orators—and was prohibited from receiving fees.

The jurisconsult and his successors

The modern legal professional, earning his living by fee-paid legal services, first became clearly visible in the later Roman Empire when the fiction that a jurisconsult received only gifts was abandoned and when at the same time the permissible fees were regulated. Changes in the methods of trial and other legal developments caused the jurisconsult to disappear in time. The orator, who now was required to obtain legal training, became the advocate. A subordinate legal agent of the classical system, the procurator, who attended to the formal aspects of litigation, took on added importance because later imperial legal procedure depended largely on written documents drawn by procurators. The jurisconsults had been important as teachers and writers on law; with their decline this function passed to government-conducted law schools at Rome, Constantinople, and Berytus and to their salaried professors. There was also a humbler class of paid legal documentary experts, the *tabelliones,* useful in nonlitigious transactions.

Medieval Europe. This late Roman pattern of legal organization profoundly influenced the Europe that began to arise after the barbarian invasions from AD 1000 on; and even during the invasions the methods of Roman imperial administration never ceased to exist in some parts of southern France and in central Italy. The Christian Church, which became the official Roman imperial church after AD 381, developed its own canon law, courts, and practitioners and followed the general outline of later Roman legal organization. Because of its success among the invaders the church was in a position to establish its jurisdiction in many matters of family law and inheritance. Hence both the idea of a legal profession and the method of its operation retained sufficient force to offset Germanic and feudal objections to legal representation. After the revival of learning in the 12th century, in particular the revived study of Roman law at Bologna, the influence of the late Roman professional system was greatly strengthened.

Classes of legal practitioners

From then on every country in continental Europe acquired, by various stages and with numerous local variations, a legal profession in which four main constituents could be observed. Procurators attended to the formal and especially the documentary steps in litigation. Advocates, who usually were university graduates in Romanist learning, gave direct advice to clients and to procurators and presented oral arguments in court. Among a miscellany of legal scribes the notaries acquired importance because, in addition to being drafting experts, they also provided officially recognized document authentication and archives. University teachers of law took over the main task of explaining and of adapting the mixture of Roman law and Germanic custom that produced the modern laws of the major European countries and continued to dominate in the scholarly interpretation of the law even after the 19th-century codifications. The relative importance of these classes varied enormously from place to place and from century to century. At times the teaching doctors almost supplanted the advocates; in some courts the procurators swallowed up the advocates and in others the converse occurred; only the notaries managed to survive with little change.

England after the Conquest. England after the Norman Conquest also was influenced by Roman example, and the clerics who staffed the Norman and Plantagenet monarchies and who provided the earliest of their judges enabled the notion of a legal profession and especially of litigious representation to be accepted. Only in the ecclesiastical and admiralty courts, however, did procurators (proctors) and doctors of the civil and canon laws become established as practitioners. The native "common law" was developed by a specialized legal society, the Inns of Court in London; there, through lectures and apprentice training, men acquired admission to practice before the royal courts. More particularly, they could become serjeants—the most dignified of the advocates, from whom alone after about 1300 the royal judges were appointed. Various agents for litigation resembling procurators also became known. The "attorneys," authorized by legislation, at first shared the life of the Inns with the "apprentices" in advocacy, who themselves in time acquired the title of barristers. Indeed there were cases of men working as both barristers and attorneys. When in the 16th century the Court of Chancery was established as the dispenser of "equity," the appropriate agent for litigation was called a solicitor, but the common-law serjeants and barristers secured the right of advocacy in that court. It was not until the 17th century that the attorneys and solicitors were expelled from the Inns and the division between advocate and attorney became rigid, and not until the 18th century that the barristers accepted a rule that they would function only on the engagement of an attorney—not directly for the client. Other types of legal agents also developed in England, but in the 19th century all of the nonbarristers were brought under the one name, solicitor. The order of serjeants was wound up, leaving only barristers, of whom the most senior could be made Queen's (or King's) Counsel.

The English division

In its final development the English legal profession thus bore a resemblance to the European—particularly to that of northern France, where the *parlements* (courts) had a corporate life and apprentice training not unlike that of the Inns. But there were four significant differences between England and the Continent. No distinct class of university teachers and commentators on the national law developed in England. Development of the law took place chiefly through precedent based on the reported judgments of the courts, rather than through legislation. The continental monarchies also developed a system of career judicial office, in which the young university licentiate went straight into government service, whereas in England appointment of judges from the senior practicing profession remained the settled practice. In addition, the division between barristers and solicitors ultimately became much more rigid in England than did the division between the advocate and procurator in Europe, and Europe never adopted an equivalent of the English practice requiring a barrister to be employed by a solicitor; both the procurator and the advocate were separately and directly employed by the client. England never developed the profession of notary, so that the whole burden of transactional work fell on those who are now the solicitors, with legal advice from the bar.

Worldwide legal profession. The main patterns both of law and of legal practice were exported by the continental European powers and England to their overseas colonies and possessions, and most of the noncolonial countries of the rest of the world imitated one or the other system. Thus the Romano-Germanic practices (frequently called civil law) became the norm for Scandinavia, Scotland, Latin America, and most of the Muslim countries of the Middle East, for French-speaking areas and Portuguese and Spanish Africa, and for Japan, Thailand, and the former French parts of Southeast Asia. They have also influenced practice in what are now the socialist countries of eastern Europe. The English system provided the model for English-speaking North America, for most former English colonies in Africa, including South Africa, for most of the Indian subcontinent, and for Malaysia, Australia, and New Zealand. The original model has undergone considerable modification by both the countries of export and the countries of reception. In particular, the specialization of procurator–advocate and solicitor–barrister has tended to be replaced by a "fused" profession of legal practitioners qualified to perform both functions and usually doing so. Such a fusion occurred gradually in Germany between the 16th and 18th centuries. It has taken place more recently in France except before the courts of appeal and, while the division still formally exists in Italy, it is no longer of practical importance. In Latin America the fused profession is general. Notaries as a separate specialized branch of the profession exist, however, in most civil-law countries.

CHARACTERISTICS OF THE PROFESSION

Social role. The legal profession has always had an ambiguous social position. Leading lawyers have usually been socially prominent and respected—the sections of the profession so favoured varying with the general structure of the law in the particular community. The family status of early Roman jurisconsults may have been more important than their legal expertise in securing such a position, but by the time of the principate it was their legal eminence that made them respected. The English serjeants lived magnificently, especially in Elizabethan times, and the French Ordre des Avocats was established (14th century AD) by feudal aristocrats in circumstances reminiscent of early Rome—including an insistence on receiving gifts rather than fees. The early Italian doctors of the civil and canon law (12th–15th centuries) were revered throughout Europe. In England and the countries influenced by its system the highest prestige gradually came to be concentrated on the judges rather than on the order of serjeants, of which they were members, and the judges of high-level courts remain the only legal class in the liberal capitalist common-law countries of today to command great respect. In the Romano-Germanic systems it is the notaries and the advocates who have come to be most trusted or admired, the judiciary being more closely identified with the civil service.

The legal profession and social conflict

Yet along with this high repute, sustained over two millennia, lawyers have also been among the most hated and distrusted elements in society. In a few cases this has been the consequence of a general hostility to the whole idea of law, China being the most important example. Confucian teaching (6th century BC) opposed the use of civil law as a major means of social control, and this influence remained powerful there and in Japan until the 20th century. In the Soviet Union the early leaders (1917–22) imagined that law and lawyers were the instruments of the ruling classes and that law would soon wither away in classless Communism. This belief was revived in the early days of Chinese Communism (1947–55). Further experience persuaded these governments that there was room for "socialist legality" and for lawyers to serve it, but a degree of mistrust remains and the repute of the legal expert is lower than that of the political and technological expert.

Most lawyers are conservative because the law itself is predominantly intended to satisfy expectations arising from an inherited pattern of behaviour; in a particular social setting this tends to identify the lawyer with the established and successful classes and to make him seem an enemy to oppressed classes or "new men." Individual lawyers have, nevertheless, often been on the side of rebels: Robespierre and Lenin were both lawyers. But the dominant attitude of the legal profession is one of moderation. Thus many lawyers took the British side in the American Revolution, and even among the lawyers who took the other side the predominant influence was against any attempt to turn the political revolution into a social revolution.

Along with these ideological and political reasons for popular distrust, and even more deep-seated, are the inherent difficulties associated with law and with some of the legal functions. Most people would like law to be so certain that its application is of equal certainty in all cases and so simple that any person of sense can see how it applies. In a discipline sharing the imperfection and complexity of society itself, no such situation is attainable, and the lawyers are blamed for the basic difficulty of their craft—which in some instances they intensify needlessly themselves by multiplying obscurities, contradictions, and complexities. The legal function likely to be most distrusted by the average person, though it also produces some of the law's heroes, is litigious advocacy, particularly in the criminal law. Plato and Aristotle condemned the advocate as one who was paid to make the worse cause appear the better or endeavoured by sophisticated tricks of argument to establish as true what any person of common sense could see was false. The feeling against advocacy in the criminal law was so strong that, at least in the case of the more serious kinds of crime, a right to representation by a trained advocate was nowhere generally recognized until the 18th century AD.

Governments and the members of organized legal professions have from the infancy of the craft endeavoured to meet the basic problem of representation by a basic rule of professional ethics—that the dominant duty of the advocate is not to his client but to truth and the law. Since the later Roman Empire, advocates have been required to take oaths to this effect, and lawyers are often technically classed as "officers of court." The duty of the advocate is to fight for the rights of his client, but only up to the point where an honourable person could fairly put the case on his own behalf. He must not identify with his client's possible willingness to tell untruths or to misrepresent the relevant law. (See below *Legal ethics.*)

Private practice. Client-directed lawyers often are called counselors, but in the original sense of that word—giving advice as to how the law stands—this is rarely an independent function; it is an inseparable part of the other functions. In his client-directed activities the lawyer is concerned with how the law affects specific circumstances, which can for convenience be divided into two main types: transactional and litigious.

In the transactional type the lawyer is concerned with the validity or legal efficacy of a transaction independent of any immediate concern with the outcome of litigation. Such activities comprise the largest area of professional activity whether considered from the point of view of the number of lawyers involved, or of the time they have to spend on the task, or of the number of clients affected. If the events constituting the transaction in question happen before the lawyer is consulted, he can only advise on their legal significance and perhaps suggest methods of overcoming legal deficiencies in what has been done. If future conduct is involved, he is better placed to plan his client's course of conduct so as to secure the required end in the most economical fashion that the law permits and to minimize the chances of future litigation. Transactions may concern words and acts, but characteristically they require the drafting of documents. In the Romano-Germanic systems these often require notarization. Typical activities falling in this category today include the following: transferring interests in land; transmitting property on death; settling property within a family; making an agreement (especially if a commercial agreement of some complexity and duration is involved); incorporating or winding up a corporate entity; varying the terms on which a corporate entity is conducted (classes of shares, managerial rights, distribution of profits, etc.); and adjusting the ownership and control of property and income so as to comply with the requirements of taxation laws and minimize their impact on the property and income in question or so as to ensure the proper management of the assets and distribution of the proceeds among beneficiaries (estate planning) or both. In the Romano-Germanic systems many of these functions are discharged by notaries and in the English and similar divided systems by solicitors, though in difficult situations the opinions of advocates or barristers may be obtained. In the fused professions of North America some firms of attorneys, or departments within firms, specialize in business of this type and avoid, so far as they can, the litigious function.

Typical legal transactions

The litigious function is subdivided into three main stages. First is the preparation of the case—interviewing the client and investigating the circumstances in the light of the leads provided by the client, and attending to the formal requirements of the procedure in question, which may involve writs, summonses, filing of statements of claim or defense, and preparing for trial. Second is the trial proper, in which the facts and law are established and argued before the judge and a decision is made. Third is the execution of the judgment—obtaining payment of damages, delivery of property, or performance of obligation in civil cases; payment of fine or imprisonment, etc., in criminal matters. Similar stages arise on appeal. In the divided professions the sharing of these functions is intricate and varies between one system and another. The advocate or barrister is especially responsible for the second stage, but he may advise upon or draft many of the documents used in other stages. If incidental disputes concerning procedure have to be litigated, he is likely to conduct the proceedings; and if the procedure includes a pretrial conference, he is likely to represent the client. Otherwise the first and third stages are mainly the province of procurator or solicitor.

Public-directed practice. Many law graduates choose to enter public service rather than private practice. Of the public roles played by members of the legal profession that of judge is most visible, but the status of judge and the mode of entry into this branch of the profession vary considerably from country to country.

The traditional independence, power, creativity, and prestige of the Anglo-American judge contrasts with the rather ordinary civil servant status of most continental judges. In the countries of Anglo-American influence, at least until recently, appointment (or, in some U.S. states, election) to a judgeship has been viewed as the crown of a long and distinguished legal career. In the continental countries, by contrast, a law graduate who wishes to be a judge has merely to complete a training period and pass an examination to get a job deciding cases. The beginning civil-law judge can expect to start at the lowest level and, like any other civil servant, to rise in the hierarchy through a series of promotions. In continental Europe ordinarily only positions on the highest courts are open to distinguished practitioners or professors as well as to career civil servants. Lateral entry into the judiciary at any level is uncommon. It has frequently been observed that, because of their standardized training, continental judges tend to share a common outlook and that their concerns about advancement promote a civil service mentality which discourages initiative and independence. Any tendency toward individualism is apt to be further inhibited by the fact that continental judges, even at the lowest levels, usually sit in panels and that their decisions are presented in unsigned opinions. Except in a few courts, such as the West German Federal Constitutional Court, disagreement among the judges is not revealed, either in the form of a dissenting opinion or in a record of the judges' votes.

In the late 20th century, however, the contrast between continental and Anglo-American judicial roles has diminished. In the United States the prestige of judgeships, except at the higher levels, has declined somewhat. It is not unusual for judges to resign and return to private practice or for eminent lawyers to decline to be considered for judicial positions. Relatively low judicial salaries are often mentioned as a reason why lower court judgeships in the United States have ceased to attract the best candidates. Meanwhile, in some continental countries, such as West Germany, judges are being recruited from among the best law graduates. Because of the special training for their positions, continental judges are almost uniformly professional and competent.

Governments have always required a staff of legal specialists, and the scope for such employment today is enormous. There is usually a senior political officer—minister of justice, attorney general, solicitor general—who by convention needs to be a lawyer, and a government department concerned mainly with the legal problems of the government as client (in the English-derived systems usually the office of the attorney general). Increasingly, however, the great departments of state need their own legal subbranch. In some countries, West Germany for example, lawyers dominate the higher offices in the civil service, while in others, such as France, the various official bureaus are more likely to be staffed by nonlawyers who have been trained in a special school of administration. In the socialist countries of eastern Europe most lawyers tend to work for government or for collectivized industrial and farm organizations.

One of the oldest and still most difficult of the governmental legal functions is that of prosecutor in criminal cases. Prosecution is sometimes in part carried on by private persons acting through private lawyers, but the trend is to concentrate the function in government legal officers. In most Commonwealth countries the crown, or public, prosecutor is a specialized officer under the general control of the attorney general. England has an independent "director of public prosecutions" concerned only with the most serious types of crime, but most prosecutions have been conducted by private barristers briefed by him or by the police. A 1985 law, however, provides for the establishment of a body of official prosecutors, following the Scottish system, which relies on public prosecutors (procurators fiscal). In the United States this function has come to be mainly local, and prosecutors, whose most common title is district attorney, are elected for short terms.

In the Romano-Germanic systems prosecuting is a career service. In Italy and France the prosecutor is a member of the judiciary. Both prosecutors and judges receive the same training and both may move from one role to the other in the course of their advancement in the civil service. In West Germany, although the prosecutor is not technically a member of the judiciary, he is not strictly separate from it, and individuals move easily from one position to the other.

The prosecuting function is particularly delicate because criminal prosecution can be used as an instrument of oppression and political persecution, even where conviction is not obtained, and because in most systems prosecutors are expected to act with a degree of fairness and restraint not necessarily expected of the parties to civil litigation. Many Romano-Germanic systems employ officers who keep a general supervision over the working of the courts and especially their criminal jurisdiction. This is the office of the "prosecutor general," or "officer of justice"; and a similar service exists in most of the socialist countries of eastern Europe.

Another branch of government, the legislature, usually requires legal assistance. Legislation needs to be expressed in language readily comprehensible by judges and lawyers and to be framed in harmony with the existing body of law. This requires the service of parliamentary draftsmen who are expert lawyers. A further specialized branch of advisory activity associated with legislation has become prominent—the law reform commission or committee.

Teaching and scholarship. Since Roman times teaching and scholarship in the law have provided prominent roles in the legal profession. Until the 18th century, teaching of the English common law was vested exclusively in the Inns of Court, and a good deal of continental European teaching for professional practice—particularly in the case of notaries and procurators—was also professionally organized. Even university law teaching in Europe was rarely aloof from legal practice; there was usually a fruitful interchange between practitioner and teacher, exemplified in such great figures as the French 18th-century teacher, advocate, and judge Robert Joseph Pothier, whose commentaries provided the foundation for the Napoleonic Code of civil law. Much law teaching in the new university law schools that sprang up in the United States, the United Kingdom, and the Commonwealth in the 19th and 20th centuries was carried on part-time by attorneys, barristers, and judges, and some still is. Sir William Blackstone, the first Vinerian professor of English law at Oxford, came from the bar and became a judge. Law teaching in the late 20th century has tended to become a distinct, full-time profession, usually carried on at a university.

Teachers and practitioners in all countries contribute to an enormous professional literature, with students' texts, practical manuals, theoretical monographs, and a periodical literature whose bulk is coming to be almost as big a problem as the enormous bulk of reported judicial decisions that are consulted for guidance and precedent. Civil-law judges pay close attention to the views of legal scholars as expressed in general and specialized treatises, commentaries on the codes, monographs, law review articles and case notes, and expert opinions rendered in connection with litigation. Persistent scholarly criticism often prompts reexamination of a legal doctrine and sometimes even leads to the abandonment of an established judicial position. In the Anglo-American systems certain kinds of legal writing, such as leading treatises, have become highly influential, as evidenced by the measurable increase in citations to secondary sources in contemporary judicial opinions. But the degree of deference to academic opinion is in general much less than in the continental countries.

Trends in the profession. Beginning in the 1960s nearly everywhere the legal profession experienced unprecedented expansion, which began to slow down in the 1980s. Major elements in this expansion were the postwar baby boom, the opening of new university law faculties, and the entry of women into the profession in significant numbers for the first time. The growth of the profession has increased competitive pressures for jobs and business.

Trends toward specialization and bureaucratization are also clearly noticeable in the modern legal profession. Although formal divisions among lawyers based on functions have declined, there tends to be in most places a de facto division of labour between those lawyers who advise clients and those who appear and argue before tribunals as well as increasing specialization in various legal fields, such as tax law, estate planning, and labour law. Bureaucratization has affected both the practice of law and the judiciary. In all countries the ranks of those lawyers who work as salaried employees of government, business, or law firms are growing more rapidly than those of traditional independent professionals. Changes in the administration of justice in the United States, brought about by increased litigation and crowded dockets, have bureaucratized the roles of judges. Courts in the United States increasingly depend on large and layered staffs to perform many functions that were previously considered to be within the province of the independent judge. While judges in the United States are far from being civil servants in the continental European sense, their work is becoming more administrative in nature. (G.S./M.A.Gl.)

AUTONOMY AND CONTROL

Issues of judicial independence. At least since classical Greece a recurring political theme has been the need for a government of laws rather than of men. Actually, however, as the legal philosopher Julius Stone has said, society of necessity has a government both of laws and of men, and the demand for legal autonomy is often seen in practice as a demand for freedom of the lawyers from political dictation or influence. The main issue has been the independence of the judiciary, and democracies have been particularly assiduous in cultivating both a spirit and traditions that respect judicial independence. The details of their governmental structure or constitutional guarantees tend in that direction, offering obstacles to the ready dismissal of judges, charging their salaries on consolidated revenue, and prohibiting the vesting of judicial functions other than in duly constituted courts of law.

Political context of the judiciary

The special position of the judiciary in constitutional states is usually considered to be an aspect of the division of powers, but it should also be considered in its relation to the structure of the legal profession. Since the late Roman Empire admission to the practice of law and the regulation of the practicing profession have been habitually vested in the judiciary. Furthermore, the duty to speak fearlessly for his client has often required courage of the advocate in the face of political threats directed against him, and, when these threats were directed also against the court before which he appeared, judicial courage was also required. The legal profession as a whole is then seen defending "the rule of law" against the political regime.

The issue of judicial independence may sometimes, however, be seen in the context of tension between the judges and the advocates. In the Romano-Germanic systems the judges often are subject to a strong corporate discipline within their own craft, and differences can occur between them and the body of advocates and also between them and the university teacher-commentators. These differences may relate to questions of legal ethics, especially the limits of advocate identification with client, or to questions of legal doctrine; the judges are then apt to be considered as representing "the state" and the advocates and teachers the autonomy of the law. In the English-derived systems judges are much less subject to corporate discipline, and disputes with the bar are more likely to arise with individual judges and to be highly personal. Even in stable countries, where the rule of law and the independence of judiciary and profession are respected, there is a less dramatic tension between the standards and tone of the lawyers on the one hand and the political administration on the other. For the lawyers, policy is largely concealed in the propositions that constitute the normative system, and legal reasoning usually involves definitions and processes of inference from the body of such propositions themselves rather than directly from the policies that the norms subserve. There have often been revolts against such "logic" within the legal profession itself, especially in the 20th century, but it still remains the most common method of thinking among lawyers and it is doubtful whether one can speak of a "rule of law" at all unless a good deal of legal reasoning is conceptual in style. Politicians and administrators, on the other hand, are more likely to reason directly from policies and purposes and from the considerations relevant to their attainment. This divergence of approach is often illustrated by referring to the tension beween the police officer, confident that he has the guilty man and intent only on putting him in jail, and the lawyers and judge, who insist on the need for "conviction according to law," which may involve applying rules of evidence that seem artificial and even absurd to the police officer. In rigid constitutional systems, where there is judicial review of legislation, politicians may be affronted at the way in which political issues are transformed by the lawyers into legal issues. In many modern countries there has been a tendency to remove certain kinds of disputes both from the courts and from the lawyers and to vest their determination in administrative bodies before which lawyers are denied standing, so as to escape what has been regarded as the blight of legal reasoning; as often there have been reactions in favour of restoring the "rule of law" and the lawyers. In such disputes it is often difficult to distinguish between lawyer attitudes that reflect the necessary features of a rule of law from those that merely reflect the temporary self-interest of particular lawyers or their clients.

Professional associations: protection and control

Regulation by statutes and bar associations. Since about 1800 most countries have brought their legal professions under systems of statutory control with three main principles: admission to practice automatically and compulsorily makes the lawyer a member of an appropriate professional association; those associations are given substantial powers in relation to legal education, admission to practice, and the disciplining of the profession, but they are subject to overriding powers vested in the courts and/or (especially in the Romano-Germanic systems) in government legal departments; the practice of law for reward is prohibited—generally or as to particular functions—to persons not admitted under the system. In the United States about half of the states have such a system, which is known as the "integrated bar"; in the other states bar associations are voluntary and have few controlling powers. England has retained the traditional Inns of Court (in whose management the judges play a leading role) for barristers, but solicitors are subject to a statutory system as above. In some countries (*e.g.,* France) professional organization is regionalized to correspond with judicial organization, and in some federal countries (*e.g.,* the United States, Canada, and Australia) professional control is vested in the states; such situations create the problem of a national organization that is generally a voluntary federation of regional bodies and therefore lacking in compulsive authority. The American Bar Association, established in 1878, is a leading example. In other federal countries (*e.g.,* West Germany and India) the central government has created national law associations responding to the need for a system of control. The law associations, apart from the functions already mentioned, help their members to understand and apply professional ethics, and they develop canons of ethics to cover new problems. They are often active in the prohibition of legal practice by unqualified persons, which tends to bring them into dispute with other professions—*e.g.,* tax accountants and land salesmen—whose members wish to perform legal functions in relation to their tasks and often have considerable knowledge of the relevant law.

Where the profession is divided, it is usually possible to transfer from one branch to another, though sometimes after delay or additional training. In many of the Romano-Germanic systems, however, professional mobility is severely restricted by another factor—numerical limits on the numbers admitted to a branch of the profession.

There are usually limits to the numbers of procurators and notaries, and in some cases, notably the highest French courts, advocate and procurator functions have been combined in relation to a particular jurisdiction and a limit has been placed on numbers; otherwise the number of advocates is generally not restricted. In the restricted cases a person admitted to practice can actually work in the profession only as an employee of an existing practitioner or after buying out such a practitioner.

The actual ability to enter or pursue the profession can also be much influenced by the varying national rules as to legal partnerships. They are prohibited for English barristers and for most divided bars derived from that system and among some of the Romano-Germanic specialized advocates and notaries. In France law partnerships are permitted, and the proportion of lawyers practicing in this manner is constantly increasing. Incorporation of legal practitioners is almost universally prohibited. These restrictions result from the emphasis on personal responsibility of the individual lawyer to his client, to the court, and to the ethical system. In countries with fused professions, however, partnership is usually permitted. West German law firms tend to be quite small, and even in the United States, despite the fact that some very large firms have developed, particularly among the "corporation lawyers" of New York, single-person practices and small partnerships are still common. (G.S./M.A.Gl.)

Legal ethics

Sources of legal ethics

Legal ethics are the principles of conduct that members of the profession are expected to observe in the practice of law. They are an outgrowth of the development of the legal profession itself.

Practitioners of law emerged when legal systems became too complex for those affected by them to understand and apply the law. Certain individuals with the required ability mastered the law and offered their skills for hire. No prescribed qualifications existed, and these specialists were not subject to legal controls. The incompetent, unscrupulous, and dishonest charged exorbitant fees, failed to perform as promised, and engaged in delaying and obstructive tactics in the tribunals before which they appeared. Action to prevent such abuses was taken by legislation and by judicial and other governmental measures. The right to practice law came to be limited to those who met prescribed qualifications. Expulsion from practice and criminal penalties were introduced for various types of misconduct.

These measures did more than correct the abuses. They also gave recognition to the social importance of the functions performed by lawyers and identified those who were qualified to perform them. A consciousness developed within the profession of the need for standards of conduct. This became the core of legal, or professional, ethics.

Prior statutes, court rules, and other government directives remained in force along with the profession's self-imposed ethical standards. Taken together, they constituted the sum total of the restraints placed upon lawyers in regard to their professional conduct. This pattern has continued to the present time.

In many countries professional associations of lawyers have sought to commit the principles of ethical conduct to written form, but a written code is not essential. Ethical principles may exist by common understanding as well as in the literature and writings of the profession. This is the case in England. A code, however, makes ethically obligatory principles readily available to the practitioner and thus helps to assure greater observance of them. When such a code does exist, it usually contains both statements of general ethical principles and particular rules governing specific problems of professional ethics. But no code can foresee every ethical problem that may arise in the practice of law. Hence, codes are supplemented by opinions rendered and published by committees of bar associations.

DIFFERENCES AMONG COUNTRIES

Principles of legal ethics, whether written or unwritten, not only seek to control the conduct of legal practice but also reflect the basic assumptions, premises, and methods of the legal system within which the lawyer operates. They reflect as well the profession's conception of its own role in the administration of justice. In western European legal systems the role of the practitioner in both civil and criminal litigation differs from what it is in Anglo-American legal systems, and this is reflected in the ethics of their legal professions. Practitioners in countries having a Communist form of government are ordinarily salaried employees of the government, and their ethical obligations consequently have a focus different from that in countries where lawyers engage in independent practice or are employed by private firms. In England and to a certain extent in France, where the profession is divided into separate branches, the principles of professional ethics reflect the relationships incident to that division.

In western European and Anglo-American countries and others with similar systems of justice, such as Japan and India, in which the lawyer is not an employee of the state but engages in private practice to serve clients who employ him, professional ethics are addressed to two basic aspects of the lawyer's status. On the one hand, he is employed by clients to serve and represent their interests; on the other, he is participating in an important social function—the application of rules of law through advice, trial of cases, preparation of legal documents, and negotiation with others for his clients. Hence, the principles of legal ethics stress that the lawyer's chief interest lies in serving his client and in securing justice—not in increasing his own income. He is an agent of his client but deemed to retain a large measure of independent judgment as to the proper course to pursue. He represents his client's interests but may not engage in tactics that defeat the fair administration of justice. The lawyer is engaged, it is said, in a profession and not in a business.

Conflicting interests of client and society

Naturally the interests of client and society sometimes conflict, and the principles of legal ethics do not always indicate how these conflicts should be resolved. Should a lawyer cross-examine an adverse witness in such a way as to undermine or destroy his testimony when the lawyer believes the witness is actually telling the truth? May he invoke rules of evidence to exclude points that would weigh against his case but that he considers to be probably true? May he take advantage of the errors of an unskilled opponent? Should he demand a jury trial for purposes of delay when a jury trial has no advantage for his client? These questions may be answered differently in legal systems that operate on different premises. A system in which a lawyer presents his client's case in the most favourable light permitted by law and in which the court must decide the merits of the case may well produce different answers than those produced in a system that assigns a higher priority to the lawyer's duty to the state to assure proper administration of justice.

AREAS OF APPLICATION

Conflicting interests. A lawyer is at times faced with the question of whether or not he may represent two or more clients whose interests conflict. Quite aside from his ethical obligation, the legal systems of the world generally forbid a lawyer from representing a client whose interests conflict with those of another, unless both consent.

In the Anglo-American legal systems the prohibition has three aspects. First, the attorney is not permitted to concurrently represent two or more clients if, in order to further the interests of one, he must forego advancing the conflicting interests of another. In short, he cannot be both for and against a client. Second, he cannot subsequently accept employment from another for the purpose of undoing what he had earlier been retained to accomplish. Third, he may not accept subsequent employment from another if it involves the use, the appearance of use, or possible use of confidential information received from his former client. Such actions are forbidden by law and by legal ethics.

Obligations to the client

To illustrate, an attorney may not ordinarily prepare an instrument for both buyer and seller in which their respective rights are defined. He may not prepare an instrument or negotiate a settlement for a client and later accept employment from another to defeat that instrument or settlement. He may not represent both a driver and his passenger in recovering damages from another party charged with negligent driving in a collision since the passenger may have a claim against his own driver as well. He may not represent two or more defendants in a criminal prosecution if their respective defenses are inconsistent or, possibly, even when the case against one is stronger than the case against the other. The same principles apply with respect to interests of the attorney that may detract from the full and faithful representation of his clients. For example, he may not purchase property that he has been retained to acquire for his client, nor may he draw a will in which he is a beneficiary.

These conflict-of-interest prohibitions are not absolute. The client may consent to the representation after full disclosure of the actual or possible conflict. But the client's consent may not suffice if public interest is deemed to be adversely affected.

The practicing lawyer who is also a member of a legislature is confronted with a conflict of interest whenever his clients enlist his support to promote or oppose legislation or to secure favourable decisions from administrative agencies that are dependent on legislative financial support. The problem is an important one in the United States, where members of legislatures frequently maintain private law practices, but it has received insufficient consideration by the U.S. legal profession. (M.E.P.)

Confidential communications. In the Anglo-American countries judicial decisions, legislation, and professional ethics forbid a lawyer to testify about confidential communications between himself and his client unless the client consents. Similar provisions are found in such diverse legal systems as those of Japan, West Germany, and the Soviet Union. In countries in which the attorney's obligation to protect state interests is given relatively greater emphasis, there may be a duty to disclose information when it is deemed to be to the state's advantage. In Anglo-American law the obligation does not apply when the client seems about to commit a crime. An attorney also may disclose his client's communication when the client sues him; *e.g.,* for malpractice.

Dignity of the profession

Advertising and solicitation. Traditionally, advertising by lawyers was forbidden almost everywhere. It has been a long-standing principle of professional ethics in Anglo-American countries that an attorney must not seek professional employment through advertising or solicitation, direct or indirect. The reasons commonly given have been that seeking employment through these means lowers the tone of the profession, that it leads to extravagant claims by attorneys and to unrealistic expectations on the part of clients, and that it is inconsistent with the personal relationship that should exist between attorney and client. A more basic reason appears to have been the social necessity of restraining the motive of personal gain and of stressing the objective of service. Until 1977 the legal profession in all Anglo-American countries took the position that, with some exceptions, the prohibition must be complete. The situation changed in the United States in 1977 when the U.S. Supreme Court ruled that lawyers could not be barred from advertising fees. The American Bar Association subsequently revised its code of ethics to include provisions and guidelines for advertising and suggested that lawyers limit their advertising to basic information about services and fees. Within narrow limits the same trend has made itself felt in England.

Fees. Attorneys are ethically enjoined to keep fees reasonable, neither too high nor too low. Attempts to control fees range from mandatory fees fixed by statute in West Germany, minutely regulating compensation for legal services of all sorts, to mandatory fees set by courts for solicitors in contentious matters in England and Wales, to advisory fee schedules set by the profession in Canada, France, Spain, and Japan. In the United States local bar associations sometimes enforced minimum fee schedules through disciplinary proceedings, but the U.S. Supreme Court held in 1975 that such practices violated the antitrust laws.

The profession in the United States has assumed, in principle, the obligation to serve poor clients without compensation. The task, however, has become so enormous, especially in view of the expansion of the constitutional right to counsel in criminal cases, that ways of providing paid legal services for the poor have emerged, such as through legal aid societies and public defenders. The growth of legal aid has been a significant 20th-century development in many other countries. In West Germany legal insurance plans are widespread as well.

Fees that are contingent on the successful outcome of litigation or settlement are widely used in the United States, particularly in automobile-accident and other negligence cases, and they are accepted as ethical by the U.S. legal profession. The fee is usually an agreed percentage (typically 20 to 40 percent) of the recovery. The justification given is that this arrangement makes the courts accessible to persons who would otherwise be unable for financial reasons to press their claims. But contingent fees give the attorney a financial stake in the outcome of litigation—which is ordinarily frowned upon. The converse consideration may be that in this type of case, where the outcome is difficult to predict, the lawyer also assumes the risk of losing his fee. Furthermore, although free legal aid has removed the need for a poor person to enter into such a transaction, legal aid is not available to persons who are not poor but are not wealthy enough to engage in extended litigation. In countries other than the United States contingent fees are, nevertheless, generally prohibited. Nor are they permitted in the United States in criminal and divorce cases, in cases to secure a pardon, or in the enactment of legislation.

Honesty in court

Criminal cases. Both the prosecution and the defense of criminal cases raise special ethical issues. The prosecutor represents the state, and the state's concern is not only in convicting the guilty but also in acquitting the innocent. The prosecutor also has an ethical and, in considerable measure, a legal duty to disclose to the defense any information known to him and unknown to the defense that might exonerate the defendant or mitigate the punishment. He must not employ trial tactics that may lead to unfair convictions, nor should he prosecute merely to enhance his political prospects.

The defense counsel has different concerns. Under Anglo-American law an accused may compel the state to prove that he is guilty beyond a reasonable doubt. The defense counsel, therefore, becomes ethically obligated to require the state to produce such proof, whether or not the attorney believes his client to be guilty. His client's guilt is for the tribunal to determine. The attorney may not, however, deliberately resort to perjured or other false testimony. Similar principles hold in civil-law countries. When the client, against the attorney's advice, insists on testifying falsely, the ethical course to be pursued has not been fully settled. Some maintain that the attorney should withdraw, if possible, or else merely permit the client to testify without aiding him or asserting the truth of the testimony given. (M.E.P./M.A.Gl.)

Legal education

The rise of legal education

Schools of law are of comparatively recent origin. The ancient Romans had schools of rhetoric that provided training useful to someone planning a career as an advocate, but there was no systematic study of the law. During the 3rd century BC, Tiberius Coruncanius, the first plebeian *pontifex maximus* (chief of the priestly officials) gave public legal instruction, and a class of nonpriests (*jurisprudentes*) who acted as legal consultants emerged. A student, in addition to reading the few lawbooks that were available, might attach himself to a particular *jurisprudens* and learn the law by attending consultations and by discussing points with his master. Over the ensuing centuries a body of legal literature developed, and some *jurisprudentes* set themselves up as regular law teachers.

In the medieval universities of Europe, including England, it was possible to study canon law and Roman law but not the local or customary legal system. The study of national laws at universities is in most European countries a development that began in the 18th century; the study of Swedish law at Uppsala dates from the early 17th century.

On the continent of Europe the transition to the study of national law was facilitated by the fact that modern legal systems grew mostly from Roman law. In England, on the other hand, the national law, known as the common law, was indigenous. In medieval times education in the common law was provided for legal practitioners by the Inns of Court through reading and practical exercises. These methods fell into a decline in the late 16th century, mainly because students came to rely on printed books, and after the middle of the 17th century there was virtually no organized education in English law until the introduction of apprenticeship for solicitors in 1729. The famous jurist Sir William Blackstone lectured on English law at Oxford in the 1750s, but university teaching of the common law did not develop significantly until the 19th century. The Council of Legal Education for barristers was established in 1852. In the United States systematic legal education began with the founding of the Harvard Law School in 1817. (L.A.S.)

THE AIMS OF LEGAL EDUCATION

Legal education generally has a number of theoretical and practical aims, not all of which are pursued simultaneously. The emphasis placed on various objectives differs from period to period, place to place, and even from one teacher to another. One aim is to make the student familiar with legal concepts and institutions and with characteristic modes of reasoning. Like most intellectual disciplines the law has its technical concepts, frequently expressed in technical terms. All lawyers must become acquainted too with the processes of making law, settling disputes, and regulating the legal profession. They must study the structure of government and the organization of courts of law, including the system of appeals and other adjudicating bodies.

Another aim of legal education is the teaching of law in its social, economic, political, and scientific contexts. While law schools have never ignored the social context of their subject, Anglo-American legal education has always been less interdisciplinary than that of continental Europe. With the development of a more or less scientific approach to social studies in the 20th century, however, this is changing. Some law schools appoint economists, psychologists, or sociologists to their staffs, while others require or permit their students to take courses outside the law school as part of their work toward a degree. This awareness of the other social studies is thought to be more advanced in the United States than in Great Britain. Continental legal education (in both eastern and western Europe) tends to be highly interdisciplinary, with nonlegal subjects compulsory for students taking their first degree in law.

Traditionally, legal education included the teaching of legal history, which was once regarded as an essential part of any educated lawyer's equipment. While legal history has lost prestige in the sense that separate courses in the subject are offered in few law schools and, when optional, are not very popular among students, much legal history is, nonetheless, taught in the context of other courses. Since the corpus of the law is a constantly evolving collection of rules and principles, many teachers consider it necessary to trace the development of the branch of law they are discussing. In countries where most parts of the law are codified (as, for example, in continental Europe, Central and South America, the countries in the Mediterranean basin and in Africa that were formerly under French influence, Thailand, and Japan) it is not generally thought necessary to go back beyond the codes. On the other hand, in countries with a common-law system (England, most members of the British Commonwealth, and most parts of the United States), in which few branches of law are codified, knowledge of the law has traditionally depended to a great extent on the study of court decisions and statutes out of which common law evolved. This made the study of legal history of more immediate significance in such countries. But as the former case-law areas have increasingly come under statutory and administrative regulation, the practical importance of legal history has receded.

The graduating law student is not expected to have studied the whole body of substantive law. He is, however, expected to be familiar with the general principles of the main branches of law. To this end certain subjects are regarded as basic: constitutional law, governing the major organs of state; the law of contract, governing obligations entered into by agreement; the law of tort (or delict), governing compensation for personal injury and damage to property, income, or reputation; the law of real (or immovable) property, governing transactions with land; and criminal (or penal) law, governing punishment, deterrence, rehabilitation, and prevention of offenses against the public order. The chief materials are the same everywhere: codes (where these exist), reports of court decisions, legislation, government and other public reports, institutional books (in civil-law countries), textbooks, and articles in learned periodicals. The aim is not so much that the student should remember "the law" as that he should understand basic concepts and methods and become sufficiently familiar with a law library to carry out the necessary research on any legal problem that may come his way.

STUDY AND PRACTICE

To some extent all law courses are out of harmony with legal practice, for in real life a case is not presented as neatly by a client to his lawyer as it is in a textbook. The case usually begins as a statement, often jumbled, of facts and problems that cut across pedagogical categories. A story of a road accident, for example, may involve the lawyer in considering questions of the civil responsibility for the cause of the accident; of contract (in relation to insurance); of criminal law (in relation to a traffic offense); and of other branches of law as well. It is therefore important, while making divisions of law for convenience of study and examination, to guard students against the danger of thinking in compartments.

Lawyers must also contend in practice with branches of law in which they have received no formal education. More importantly, new social problems requiring legal attention and new legal structures come into existence during every lawyer's lifetime. His task may be eased if he has learned to look to the experience of other nations. A good law school produces a graduate who is not constricted by pedagogy but is trained to adapt himself to—and perhaps lead in bringing about—legal changes related to social, economic, and political developments.

The curriculum of the law school must also allow for the great diversity of careers followed by those who have been trained in the law. In most countries large numbers of persons with a legal training seek a career outside the practicing legal profession, commonly in the civil service, in municipal government service, in legal education, and in commerce and industry. Students' requirements and tastes differ; and most law schools, therefore, offer a choice. It is common to prescribe a certain number of compulsory subjects, which are regarded as essential to any law student's education, and leave a freedom of selection as to other subjects, stipulating only the number of courses to be studied. Except in the Soviet Union there is little uniformity from law school to law school within the same country as to which subjects are compulsory, and lists of optional subjects vary markedly.

The extent to which legal education aims to teach practice and procedure varies from place to place. Attention is always given to the methods of ascertaining the law from the books but not always to the ways of using this knowledge of the law in various roles, such as legal adviser or judge. Discussion of these matters tends to be more widespread in universities in the United States and in countries where the main qualification to practice the law is a university degree than it is in England and continental Europe, where professional training is provided outside the university and after graduation. In recent years clinical programs, in which students can have real or simulated experience in law practice, have become a staple part of the American law school curriculum. In the Soviet Union students are required to take one semester of clinical work. On the Continent such training is typically part of a postgraduate apprenticeship program (see below).

Courses on the rules and principles of court procedure are typically compulsory in university law schools. In England, however, few universities teach these, leaving them to the bar and solicitor's examinations, though the law of evidence (governing what facts may be proved in court, and how) is usually an optional subject; some knowledge of civil and criminal procedure may be picked up incidentally during the study of substantive law.

TEACHING METHODS

Methods of legal education are constantly changing, but the requirement of a university degree has become more or less uniform, coupled in many countries with the need to pass a qualifying examination organized by the profession. Apprenticeship, once a usual way of entering the profession in the common-law countries, has everywhere been increasingly displaced by university education, to which it has now become a supplement.

University law schools tend to differ along national lines in their methods of teaching. In the United States, following pioneer work by Christopher Columbus Langdell at Harvard in the latter half of the 19th century, the case method came to prevail, in which the student reads reported cases and other materials collected in a casebook and the class answers questions about them instead of listening to a lecture by the teacher. The casebook method has been adopted at some institutions in England and other common-law countries but has found scarcely any adherents elsewhere. Even in the United States most law schools now use seminars and lectures as well. The case method has the advantage of emphasizing the characteristic feature of the common law—the evolution of principles from decisions in actual cases—and thus of focusing the student's attention on the processes of analogy and distinction. It has the disadvantages, first, of being relatively time-consuming in relation to the amount of knowledge of legal principle that can be imparted and, second, of concentrating on a source of law that has become just one of many in modern statutory and regulatory legal systems. The traditional teaching techniques in English universities have been lectures and tutorials (or seminars).

In continental European countries the backbone of legal education is the formal lecture. Class sizes are typically very large compared with those in the United States and Britain, and lectures tend to be magisterial performances. Attendance is frequently voluntary, and those who stay away are usually able to secure the text of what they have missed. Seminars are given too, particularly for specialized subjects. Similar methods are used in other countries with large numbers of law students. In the Soviet Union, as in western Europe, the lecture method supplemented by smaller discussion groups is typical. But in the Soviet Union the lectures are well attended and participation in seminars is mandatory.

Teaching methods are not unrelated to the nature of the legal system. The methodology of continental legal education has grown out of and perpetuates a legal tradition heavily influenced by scholars, while the methods in England and the United States have emerged from and contribute to the maintenance of the tradition of judge-made law. Methods were influenced also by the fact that in England legal education was from early times in the hands of the bar, while on the Continent from the 12th century on it was the province of the universities. The fact that in common-law systems principles of law are largely derived by a process of inductive reasoning from many decisions of higher courts lay behind the development of the case method. In continental Europe the fact that law is found mainly in systematic legislation is one of the chief reasons for the lecture method, in which the subject can be approached through its philosophical background. A desire to systematically expound a body of principles rather than approaching facts and problems by the case-by-case method is met better by formal lectures and textbooks than by class discussion. This formal approach is reinforced in countries where published reports of local court decisions are scanty.

Much has happened in recent years, however, to diminish these contrasts. Law schools everywhere are seeking a better balance between theory and practice. American law professors increasingly consider the case method only one of several useful teaching techniques, while continental law faculties, particularly since the student unrest of the 1960s, have instituted various reforms designed to provide students with more opportunities for practical exercises and classroom discussion. The main obstacle faced by continental law faculties engaged in these efforts, however, is the unfavourable ratio of teachers to students.

EXAMINATIONS AND QUALIFICATIONS

The process of selecting members of the legal profession begins in the universities and law schools and continues afterward in the form of professional entrance requirements.

School examinations. In the United States, Great Britain, and other common-law countries students are generally required to pass an examination in each subject. Four or five subjects are studied simultaneously during the academic term, and students must take examinations in all of them at the end of the term or year. In France and Italy, too, students are required to pass a certain number of examinations in various subject matter areas in order to qualify for a degree.

In some continental European countries more comprehensive examinations are the rule. In West Germany the course work for the university law degree normally takes about five years, with a single comprehensive examination at the end of those five years (the First State Examination). Students are admitted to this examination if they produce certificates of satisfactory work in each subject, in a jurisprudence seminar, and in a course on economics and finance. The Netherlands has an intermediate system: the course for a first degree in law lasts five years, with an examination at the end of the second year and another at the end of the fifth. The Soviet Union combines the system of examinations in each course with a comprehensive examination at the end of the five-year period of study.

The method of subject-by-subject examination is less taxing on the memory than the system of comprehensive examination. It may well enable the student to do more detailed work on the problems of each subject. It has the disadvantage of encouraging him to think in terms of separate subjects, whereas the comprehensive examination leads him to consider legal problems in all their aspects. Being aware of the dangers of compartmentalized thinking, some law schools in the common-law world have introduced into their curricula "general" subjects, such as "common law," in place of separate courses in contract and tort, or they require the student to write papers about issues that relate to several of the subjects studied.

No formal test is wholly satisfactory as a method of screening potential lawyers. The type used most widely, in which students write answers to questions in an examination hall, has been criticized for placing too much emphasis on memory. This criticism is met to some extent in many universities by allowing candidates to consult books and reference materials during the examination, thus bringing the test a little closer to what a lawyer will do when confronted with a real problem. Another objection is that testing creates a situation of stress, in which a candidate does not necessarily demonstrate how he has benefited from his legal education, and also one in which the skill demonstrated in the examination hall is not all the skill required of a lawyer. In particular, the examination does not test capacity for patient research or the capacity for oral argument, which requires theses and oral examinations. Examinations to be done outside orthodox examination halls have thus been proposed.

Some universities in the United States, Great Britain, and the Commonwealth countries require one or more long essays or a short thesis or research paper as part of the work for a first degree in law (as opposed to the more substantial dissertation, or thesis, for a postgraduate law degree). This is commonly written during the final year with no restriction on the resources employed. A thesis in the last year of study is required in Soviet law schools and in some civil-law countries. Credit is also sometimes given for articles or notes published by students in law reviews. Such student publishing is more common in the

United States than elsewhere, partly because most U.S. law schools have their own legal journals and partly because American law students are nearly always college graduates. Such student work also enhances prospects of employment, particularly if the student becomes an editor of the law review.

Oral examinations are the rule in some countries, such as Italy and the Soviet Union. In the United States oral examinations are rare. French universities typically use both written and oral examinations. Some British and overseas Commonwealth universities hold oral examinations to confirm or resolve doubtful results on written papers or as a prerequisite to the award of first class honours. In Italy, where a law student must present a thesis after passing his other examinations, the thesis must be orally defended before examiners. The West German law student, after passing his written examination, has an oral one. In Japan, for professional qualification at the Legal Training and Research Institute (see below), there is an oral examination in each of the compulsory subjects after the written examination has been passed.

Qualifications for practice. *Common-law countries.* In England and Wales practicing lawyers must be either barristers (advocates and consultants) or solicitors (general legal advisers dealing with all kinds of legal business out of court and advocates in some of the lower courts). The former are organized in four Inns of Court (Lincoln's Inn, Inner Temple, Middle Temple, Gray's Inn) under the discipline of the Senate of the Inns of Court; the latter are under the jurisdiction of the Law Society. It is not necessary to hold a law degree or any university degree to qualify for the profession of law, but such a degree is usual. To become a barrister a candidate must pass a two-part examination in legal subjects, but university graduates may obtain partial or total exemption from the first part, depending on their degrees. A barrister's preparation also includes practical courses and a period of pupilage administered under the authority of the Senate of the Inns of Court. A barrister may not practice at all until he has undergone six months of pupilage in chambers and may not practice independently until he has been a pupil for a year. Pupilage causes some difficulty, partly because of the cost but mainly because of the increasing shortage of places in chambers. To qualify as a solicitor, the normal course is to serve as an articled clerk for two years and also pass law examinations in two parts. In Scotland and Ireland (both the republic of Ireland and Northern Ireland) there are similar requirements, though the arrangements differ in detail.

In the United States admission to the bar qualifies one for all types of legal work. The only formal requirements are the passing of state bar examinations after graduating from a law school; in a few states the law degree alone is sufficient.

In both England and the United States, as in many other common-law countries, becoming a judge or magistrate is a promotion (by appointment or election) from the ranks of the bar, and there is no special training for the exercise of judicial functions. But in some other common-law countries, especially in Africa and Asia, a newly qualified lawyer may enter the government legal service and find himself appointed in a short time to a junior magistracy. Even in these countries there is generally no special training for the job of adjudicating.

Civil-law countries. In continental European countries the qualifications to practice law typically depend on which of the various branches of the profession the university law graduate wishes to enter. Some countries place more emphasis on apprenticeship and others on examination. In France, for example, a legal practitioner may be an advocate, an *avoué,* a notary, or a judge. Each receives a different training, but all normally have gone through third- and fourth-year law degree courses. The advocate (roughly corresponding to the English barrister) must pass a bar examination and then serve as a probationary lawyer for three years, during which he takes further course work as well as acquiring practical experience. The *avoué* (something of a cross between a junior barrister and a senior solicitor) serves a period of articled clerkship and undergoes a professional examination by practicing lawyers. The notary (who does the noncontentious work performed in England by a solicitor) need not be a university graduate and can be a product of a professional school. His period of training lasts at least three years in a notary's office. He also takes a professional examination and if successful must wait for a vacancy since there is a limited number of notarial offices established by law.

In West Germany the graduate in law who seeks a legal career must embark upon a period of practical training as a *Referendar.* This is a uniform program involving two years of practical work in the courts, in the office of a lawyer in private practice, in the office of a public prosecutor, in the civil service, and sometimes in the legal department of a commercial concern. Upon its completion, he must pass a state examination (*Assessorexamen*).

A somewhat similar procedure is followed in Japan. Law graduates who seek careers as judges, public procurators, or lawyers in private practice must (with the exception of summary court magistrates and assistant procurators) pass the National Law Examination for entrance to the Legal Training and Research Institute. This is an organ of the Supreme Court. Like his German counterpart, the *Referendar* training to become an *Assessor,* the Japanese student at the institute is paid by the state. The period of training at the institute lasts two years. The bulk of the work consists of practical exercises and discussions, lectures on legal topics, and visits to institutions of concern to lawyers (such as prisons). The training is uniform, leads to a single examination, and qualifies the graduate for any branch of legal practice.

In some countries, such as France and Spain, there are special schools for training judges. In others, such as West Germany and the Nordic countries, judicial training is acquired in the post-law school practical internship period. In West Germany, for example, a law graduate may be appointed to a lower court after completing the *Referendarzeit* and passing the Second State Examination. After serving a three-year probationary period, he becomes eligible for an appointment for life. In France the first step to becoming a judge is to pass an annual competitive examination for which students prepare by taking a special program in their last year of law studies. Successful candidates then must undergo 28 months of training consisting of a period of formal study at the National School of the Judiciary in Bordeaux, followed by a series of short practical internships in such settings as police departments, law offices, prisons, and the Ministry of Justice in Paris. This training culminates in a judicial apprenticeship, during which the future judge participates on a daily basis in all the activities of a variety of courts. Upon completion of their training period, the students are ranked on the basis of their grades and the evaluations of supervisors and are then assigned to their first positions in the judicial system. Since the administrative law courts in France are not part of the judiciary but rather of the administration, most judges for these courts are drawn not from the lawyers trained in the National School of the Judiciary but from the civil servants trained in the National School of Administration.

LEVELS OF STUDY

Law degrees are undergraduate degrees in most countries. The student embarks upon the study of law at a university at about the age of 18. In France the universities offer a course of two years in duration that may be taken by anyone who has completed his secondary education. High marks in this entitle the candidate to enroll for the *licence-en-droit,* which is given at the end of the third year of study. Successful completion of a fourth year leads to a *maîtrise-en-droit,* which for all practical purposes has become the basic French law degree.

In the United States, by contrast, most law schools require the entrant to be a university graduate. Consequently, the U.S. student of law is generally in his early 20s. Other countries where legal education is organized on a graduate level include India and Pakistan.

University law schools in many countries accept all candidates with a certain level of prelegal education. One drawback of this open admissions system is a substantial failure rate in examinations. In countries where candidates are screened before admission to law school there is less attrition. In England, for example, each university imposes a quota on entry to its law school and selects among candidates on the basis, usually, of academic performance. In the United States candidates are selected on the basis of academic performance and the results of a test designed to demonstrate aptitude for the study of law. In both the United States and England entry requirements vary according to the prestige of the law school.

Most countries also provide for higher degrees in law. In common-law countries there is usually a series of steps, ascending through a degree of master of laws to a doctorate or senior doctorate. In civil-law countries it is normal to go straight from a first degree to a doctorate. Master's degrees are, as a rule, based on advanced examination after courses of instruction, though sometimes they are awarded for research or for a combination of examination and dissertation. Doctorates are awarded for theses expounding the results of original research and senior doctorates for published contributions to scholarship in the subject. In many countries there are also specialized postgraduate diplomas or certificates in particular subjects.

TRENDS IN LEGAL EDUCATION

Modern legal education is expanding both in quantity and scope, and formal university legal education has become dominant everywhere. The opportunities for university and professional education in law increased greatly after World War II. In England and Wales, for example, where before the war only the universities of Cambridge, Oxford, and London produced significant numbers of law graduates, there are now more than 50 academic law departments. A second wave of expansion took place, starting in the 1960s, when the numbers of law students, law instructors, and institutions teaching law grew dramatically almost everywhere. A particularly noteworthy development has been the increase in women law students, once a rarity but now constituting 30 to 40 percent of law students in most countries. The number of students enrolled in accredited law schools in the United States tripled between 1961 and 1980; thereafter demand for legal education began to level off and decline somewhat. A large increase in the teaching of law has occurred in Africa, where newly independent countries have established universities and professional schools concentrating on local laws and practice. Many governments have made provision, or greater provision, for the financial support of students, and legal education has been opened to a larger cross section of society in many places. The children of middle-class parents nevertheless continue to predominate in the field.

Since the late 1960s universities in several civil-law countries have departed from the rigidity of prescribed syllabi to allow a greater range of student choice in selecting subjects. In most countries, more attention is paid than formerly to foreign legal systems, transnational law, and to comparative law. In some countries nonlegal subjects have long been part of the syllabus; in others where law as a first-degree specialization has hitherto comprised only law studies, there has been a tendency to include nonlegal studies, joint courses in law and social sciences, or a more sociological approach to law.

Legal education has always had the problem of reconciling its aim of teaching law as one of the academic disciplines with its goal of preparing persons to become members of a profession. Most law schools are trying to find a middle path between being mere trade schools or citadels of pure theory. The criticism is often made that these efforts result in a type of education that is not practical enough to be really useful in resolving day-to-day legal problems but yet not as rigorously theoretical as a truly academic discipline ought to be. Animal Learning

That animals can learn seems to go without saying. The cat that runs to its food dish when it hears the sound of the cupboard opening; the rat that solves a maze in the laboratory; the bird that acquires the song of its species—these and many other common examples demonstrate that animals can learn. Yet what is meant by saying that animals can learn? What, in other words, is learning? This question proves exceedingly difficult to answer, and, in fact, some theorists propose that no single, all-encompassing definition of learning is possible. Moreover, a moment's reflection shows that there are different kinds of learning. The learning of number concepts, for example, surely seems to be of a different nature than the learning of the association between the sound of a cupboard door and the receipt of food. To explore animal learning, then, this article first considers what learning is and is not and then examines in detail some of the specialized types of learning that occur in animals.

The article is divided into the following sections:

The general nature of learning

Many animals live out their lives following fixed and apparently unvarying routines. Among numerous species of solitary insects, for example, the life cycle consists of the following unvarying events: the females lay their eggs on a particular plant or captured prey; the newly hatched larvae immediately start eating and then follow a standard sequence of developmental stages; the adults recognize appropriate mates by a set of fixed signs, perform a fixed sequence of mating responses, provision their eggs with suitable nourishment, and finally die before the next generation hatches. The same unchanging sequence is repeated generation after generation. And it is, of course, eminently successful. The same set of responses is invariably elicited by the same set of stimuli, because those responses were, and continue to be, adaptive. Where circumstances do not change, there is little need for an animal's behaviour to change. Even many aspects of the behaviour of mammals show a similar fixity. A dog withdraws its foot if it is pricked and a young child his hand if burned; both people and rabbits blink whenever an object is moved rapidly toward their eyes; the feeding behaviour of young infants of virtually all mammalian species consists of sucking elicited by contact with the lips.

Whenever the same response is always appropriate in a particular circumstance, there is little reason why an animal should need to learn what to do in that circumstance. But the world is not always so stable a place. The food supply that was plentiful yesterday may be exhausted today, and the foraging animal that always returns to the same spot will starve to death. Moreover, a particular food supply may be temporarily depleted but will be replenished if left long enough; the successful forager needs to remember where the supply was and when it was last visited, so as to time a return to advantage. In other words, circumstances may change, and the same response is not always appropriate to the same stimuli. Knowing what behaviour is appropriate may depend, therefore, on keeping track of past events.

POSSIBLE EXPLANATIONS OF BEHAVIORAL CHANGES

If an animal's behaviour toward a particular stimulus changes, one must look for an explanation of that change. One possible explanation is that the change is due to learning, but there are numerous other possibilities. If a definition of learning is to be provided, that definition must specify when to attribute the change to learning, and when to other causes.

At least two other major causes of behavioral change have been widely recognized. The first of these is motivation. A laboratory rat may pick up, chew, and swallow a pellet of food at one moment; half an hour later, after having eaten 20 grams of food, the rat will simply ignore any further pellets offered. Similarly, a male rat may mount and copulate with a receptive female introduced into his cage, but he will not repeat this pattern of behaviour endlessly even if offered the opportunity to do so. Some male territorial birds, such as chaffinches, will feed amicably beside other males at certain times of day or certain seasons of the year, but at other times they will launch an attack on any intruding male. In all these cases, it is more reasonable to attribute the change in behaviour not to anything the animal has learned but rather to a change in the creature's motivational state.

Changes due to motivation

It should not be thought, however, that just because all of these examples can be attributed to a single item—*i.e.,* motivation—that their detailed explanation will always be the same. The analysis of motivation is itself a large field of study, and it has proved to be more profitable to concentrate on the specific explanation of individual cases of changes in behaviour rather than to search for broad explanatory principles that end up being nearly vacuous. Nonetheless, it does seem possible to draw a contrast between motivational explanations for such changes and those that appeal to learning.

A second broad class of changes in behaviour can be attributed to maturation. We are inclined to ascribe the unfolding pattern of behaviour that emerges over the first few weeks of life to this ill-defined process. Newborn rat pups, for example, are relatively helpless; their eyes do not open for about two weeks, and their main sources of sensory input are probably touch and smell. As their sensory apparatus matures, the pups exhibit changed behavioral responses. The other obvious instance of a maturational change in behaviour is that which comes with sexual maturity: sexually mature adults of most species behave toward one another in ways quite different from those of

Changes due to maturation

younger members of the species. It is not only courtship and mating behaviour that change with sexual maturity; for instance, male puppies urinate in the same way as females, by squatting, and it is the onset of sexual maturity that produces the adult pattern of cocking a hind leg.

The concept of maturation is probably no better defined than that of motivation, and it is equally important to stress that it must cover a number of different processes. And, as with motivation, it is more profitable to analyze each case in detail, in order to uncover the precise mechanisms involved, than it is simply to label a change as an example of maturation. Indeed, at the level of physiological process, it seems probable that both motivational and maturational changes are often due to alterations in the hormonal state of the animal, and the distinction between the two is largely one between the unidirectional nature of the change in the case of maturation contrasted with the cyclical change common to short-term motivational states.

But how are these changes discerned from those that might be ascribed to learning? In many cases, of course, the answer is because a precise causal explanation has been provided: a great deal is known, at a physiological level, about the changes in brain and body associated with the motivational states of hunger and thirst. Even without any such detailed knowledge of the underlying mechanisms, it is possible to insist that certain changes in behaviour be attributed to motivation rather than to learning if the opportunity to learn anything relevant was lacking and the opportunity for a motivational change was present. If, for example, an animal that has been deprived of food for a long time behaves in one way toward food-related stimuli, but some hours later, after having been given ample opportunity to eat, it behaves differently toward those stimuli, the obvious interpretation is a motivational one. This interpretation would be strengthened if the animal had not come into contact with these stimuli during the intervening period and had been given, as far as one could judge, no other opportunity to learn anything about them. Learning, in other words, depends on certain kinds of opportunity, and a definition of learning may well turn out to be no more than a specification of the particular set of opportunities and experiences that produce it.

CIRCUMSTANCES THAT PRODUCE LEARNING

A particular change in behaviour is attributed to learning, then, because it is possible to specify the set of circumstances that produced it. What are those circumstances?

The role of practice

It is common to claim that learning depends on practice. (An older generation of experimental psychologists would have claimed that it depended on "reinforced" practice.) This definition can be misleading, however, if it causes one to attribute to learning all behavioral changes that follow what appears to be practice. In other words, it is not enough to show that an animal appeared to engage in practice and its behaviour subsequently changed. A temporal correlation of this sort does not establish a causal connection. Young birds, for example, are unable to fly, and their first attempts at flight are clumsy and ill-coordinated. Casual observation suggests that young birds improve with practice, gradually perfecting the set of skills they display as adults, but experimental analysis suggests that this practice may be unnecessary. Young birds have been brought up under restricted conditions that completely prevented their flying. When released at the age at which normally reared birds fly proficiently, the experimental subjects flew—without practice—as successfully as those that had spent their time in trial flight. The development of the skill appears to depend more on the maturation of strength and agility than on specific practice.

The notion that learning depends on practice also seems unduly restrictive and is, perhaps, an unnecessary legacy of an earlier version of behaviourism. It is not obvious that an animal should actually have to engage in a particular form of behaviour in order that this pattern of behaviour should be affected by learning. In many cases, indeed, no such practice seems necessary. The young of many songbirds must, it is quite clear, learn their species-typical song. There are several aspects to this learning process, one of which may indeed involve practicing the song at the beginning of the young bird's second season. But another critical aspect is simply exposure to the adult song at some point during the autumn of the young bird's first year, at a time when the young bird does not practice singing at all. Deprived of such experience, chaffinches and song sparrows produce an extremely impoverished version of the adult song; some finches may develop a song more characteristic of another species if that is what they heard during this period of their life. There are numerous other examples where learning appears to depend more on the opportunity to observe than on the opportunity for practice.

Broad versus narrow definitions of learning

This suggests that the definition of learning will have to refer to changes in behaviour that are attributable to particular kinds of experience. The danger now is that, as with motivation and maturation, the definition of learning will be so broad and vague as to be useless. As in those cases, it may be more profitable to concentrate on more detailed analysis of particular instances of learning. Such analysis has, for example, led to widespread agreement on the definition of classical conditioning, a particular type of learning whose study was pioneered by the Russian physiologist Ivan Petrovich Pavlov. In a typical experiment on classical conditioning, an experimenter might arrange a correlation between the ringing of a bell and the delivery of food to an animal. The animal predictably learns to direct food-related activity toward the sound of the bell. Analyses of such experiments have led to the definition of classical conditioning as a type of learning that occurs when there is a correlation between two stimuli and the animal's behaviour toward one of these stimuli changes in a predictable manner determined by the nature of the other. This definition, which will be expanded later in this article, is useful because it specifies both the circumstances responsible for learning (a temporal correlation between two stimuli) and the general way in which experience of those circumstances changes behaviour (the animal starts directing toward one stimulus responses that are related to those normally directed toward the other). Experimental psychologists and ethologists, however, have devised a tremendous range of procedures for studying learning in animals. The range and variety are such that it may be well-nigh impossible to formulate a meaningful definition of the circumstances that produce learning, for the definition either will be so restrictive that it clearly applies to only a fraction of the cases that should be regarded as instances of learning, or it will be so broad that it says nothing.

Rather than pursue any further the attempt to find an all-embracing, single definition of learning, it seems more useful to provide narrower definitions for particular cases, along the lines suggested above for classical conditioning. One consequence of this approach is that it may encourage the belief that learning consists of a large number of distinct processes that have nothing in common with one another. It is, of course, an open question as to whether this is true: it is certainly possible that, just as with the concept of motivation, the layman's concept of learning encompasses a large number of different cases whose underlying mechanisms are quite distinct. It is important not to prejudge this issue. Insistence on a single, global definition may well tend toward just such prejudgment by encouraging the belief that learning is a single, common process. To start by drawing some distinctions between types of learning does not rule out the possibility of seeing whether the various cases studied do have anything in common.

The interplay of theory and definition

In the final analysis, as is true of all scientific definitions, the definition of learning is a matter of theory. It has been said that a good scientific definition is the end product of good theory and experiment, not the starting point. Thus, there is a single process of learning if it turns out to be possible to devise a single theory that adequately accounts for the variety of cases in which learning is assumed to occur. Superficial appearances may be deceptive: just because the circumstances that produce learning in two cases, along with the consequences of that learning, appear quite different, it does not follow that the processes underlying learning are different. For instance, the phenomenon of filial imprinting, first seriously analyzed by the Austrian ethologist Konrad Lorenz, appears to be a highly specialized form of learning in which a newborn animal (*e.g.,* a chick, duckling, or gosling) rapidly learns to follow the first salient, moving object it sees. Normally this object will be the mother, but Lorenz discovered that the range of potential imprinting objects is large, extending from Lorenz himself to a bright red ball. There is no question but that some process of learning occurs here, and Lorenz assumed it to be highly specialized. Yet one theory seeks to explain imprinting in terms of simple classical conditioning. Whether or not the account of imprinting provided by this theory is correct, the point is made that how learning is defined and whether it is defined as a single, monolithic process or as many specialized processes are, in the end, questions of theory.

Types of learning

SIMPLE NONASSOCIATIVE LEARNING

When experimental psychologists speak of nonassociative learning, they are referring to those instances in which an animal's behaviour toward a stimulus changes in the absence of any apparent associated stimulus or event (such as a reward or punishment). Studies have identified two major forms of simple nonassociative learning, which are to some extent mirror images of one another: habituation and sensitization.

Habituation. A classic example of habituation is the following observation on the snail *Helix albolabris.* If the snail is moving along a wooden surface, it will immediately withdraw into its shell if the experimenter taps on the surface. It emerges after a pause, only to withdraw again if the tap is repeated. But continued repetition of the same tapping at regular intervals elicits a briefer and more perfunctory withdrawal response. Eventually, the stimulus, which initially elicited a clear-cut, immediate response, has no detectable effect on the snail's behaviour. Habituation has occurred.

Habituation can be defined in behavioral terms as a decline in responding to a repeatedly presented stimulus. As such, it is a very widespread phenomenon, one that can be observed in animals ranging from single-celled protozoans to humans. Most animals behave differently to novel and familiar stimuli: the former sometimes elicit startle responses, sometimes investigatory or exploratory responses; the latter often apparently are ignored. The suggestion that habituation is a simple form of learning, however, implies that it can be distinguished from some even simpler potential causes of this sort of change in behaviour. One reason why an animal might stop responding to a stimulus is that it no longer detects the stimulus; *i.e.,* some form of sensory adaptation might have occurred. Another potential cause is fatigue: perhaps some temporary refractory state is produced by repeated elicitation of the same response, making it impossible to perform that response again. Whether or not one would want to call either of these processes a form of learning is doubtful. But both behavioral and physiological evidence establishes that habituation cannot be explained in these terms.

Evidence that habituation is a form of learning

The critical behavioral evidence is that habituation can be disrupted by almost any change in the experimental conditions. If repeated presentation of one stimulus leads to habituation of a response, the same response can still be elicited by a different stimulus. Even if the experimenter presents a novel stimulus that does not itself elicit the response in question, its presentation may restore the response on the next trial in which the originally habituated stimulus is presented. This latter observation, usually referred to as an instance of dishabituation, seems to rule out any simple sensory adaptation; both observations rule out simple effector fatigue.

Neurophysiological analysis of habituation in various mollusks—for example, in the sea snail *Aplysia*—has confirmed that habituation need not depend on changes in the activity of sensory or motor neurons. In the case of *Aplysia,* researchers have studied the gill withdrawal reflex, a response that rapidly habituates to repeated stimulation of the snail's siphon or mantle shelf. But habituation still occurs even if it is elicited by direct, electrical stimulation of the motor nerve, bypassing the sensory receptors completely; and recording from the sensory nerve during normal habituation reveals no decline in its level of activity. These observations eliminate sensory adaptation as a possible cause of the animal's having ceased to respond to the stimulus. Effector fatigue can be ruled out by showing that direct stimulation of the motor neurons controlling the withdrawal response can still elicit a perfectly normal reaction even after the response has completely habituated. Research shows that habituation in *Aplysia* depends on changes in the activity of more central neurons. Repeated tactile stimulation of the siphon, leading to habituation of the withdrawal response, causes changes in the activity of the motor neurons innervating the response. Specifically, these motor neurons show a decline in excitatory postsynaptic potential, which is the electrical change that enables the nerve impulse to cross the gap (synaptic cleft) that separates one neuron in the pathway from the next. The decline in excitatory postsynaptic potential short-circuits the response. Moreover, the presentation of a novel stimulus, sufficient to dishabituate the behavioral response, restores the postsynaptic potential.

Habituation occurs even in animals without a central nervous system—probably in single-celled protozoans; certainly in animals such as the coelenterate *Hydra,* which have a diffuse nerve net and do not appear to be capable of associative learning. Among mammals, habituation of certain reflex responses can be observed even in "spinal" subjects, that is, those whose spinal cord has been severed from the brain. There can be little doubt, then, that habituation is not only widespread, but that it also can be a relatively simple phenomenon. There is, however, no guarantee that it is the same phenomenon wherever it appears. The waning response to a repeatedly presented stimulus admits of a number of different explanations. In principle, as we have already seen, it might be due to sensory adaptation, effector fatigue, or a more central neural change. These distinctions make rather little sense in the case of a single-celled animal. And one should not necessarily expect the habituation observed in a spinal mammal to involve precisely the same mechanisms as those responsible for comparable behavioral effects in an intact animal. Some psychologists have proposed theories of habituation that appeal to processes of classical conditioning. Such a theory is not likely to apply to the habituation observed in an animal that shows no capacity for classical conditioning.

Habituation is usually, as here, classified as an instance of simple, nonassociative learning. It is supposedly nonassociative because all that happens in the course of habituation is that a stimulus is repeatedly presented and the animal's behaviour changes; there is, on the face of it, no other event with which the stimulus can be associated. Habituation must therefore, it appears, be understood by reference to some change in the pathway between stimulus and response, and the work with *Aplysia* and other mollusks shows how this analysis may proceed at the physiological level. But if habituation is not always the same phenomenon, it is possible that different processes may underlie the habituation of the startle response to a loud noise in an intact mammal. And despite appearances to the contrary, those processes may involve some associative learning. One suggestion is that novel stimuli elicit a biphasic response: an initial increase in startle responses, which include components of emotion or anxiety, followed by a rebound in the opposite direction. Habituation occurs when the latter, rebound response becomes conditioned to the stimulus, occurring sooner and sooner with each repetition of the stimulus and thereby damping down and eventually canceling out the initial reaction. An alternative possibility is that long-term habituation depends on associating the repeatedly presented stimulus with the context in which it occurs, a suggestion that would explain why presentation of the stimulus in a different context sometimes leads to dishabituation.

Possible associative bases for habituation

The generality of habituation implies that this behavioral phenomenon has considerable adaptive significance; if true, it would be quite reasonable to expect that a number

Adaptive value of habituation

of different mechanisms might have evolved to produce the behavioral result. The adaptive value of habituation is not difficult to see. A novel stimulus may signify danger, and an animal should react to this stimulus either by withdrawing or at least by orienting toward it to see what will happen next. But if the same stimulus occurs again with no further consequence, it is probably safe: regular repetition of the same stimulus implies that it is part of the background, such as the waving of a branch in the wind or the shadow caused by a piece of seaweed floating with the waves. If the stimulus is not dangerous, time should not be wasted on it. Withdrawal, especially in the case of a snail into its shell, is a time-consuming effort, incompatible with such vital activities as searching for food. If it is important, therefore, for animals to be wary of novel stimuli, it is equally important that they should discriminate the novel and potentially dangerous from the familiar and probably safe.

Sensitization. The effect of habituation is to eliminate unnecessary responses, but the main function of learning has usually been thought to be the production of new responses. Traditional psychological theories of learning have assumed that the learning of new patterns of behaviour comes about through the association of a new response with a particular stimulus. Consequently, psychologists usually have either ignored the possibility that nonassociative processes might be sufficient to increase the probability of a new response or regarded it as a nuisance that interferes with the measurement of associative changes. They have rarely treated it as a subject worthy of study in its own right.

This is unfortunate, for the nonassociative phenomenon of sensitization is probably fairly widespread, and it provides a simple means of acquiring adaptive behaviour. Sensitization is said to occur when the repeated presentation of a particular significant stimulus (such as food or electric shock) lowers the threshold for the elicitation of appropriate behaviour to the point where a second stimulus, not normally capable of calling forth that behaviour, now does so. A typical example is provided by the behaviour of the marine worm *Nereis.* If the worm is kept in a small tube and fed at regular intervals, it becomes progressively more likely to respond to any novel stimulus, such as a change in illumination, by exploratory, food-seeking movements toward the open end of the tube. If, on the other hand, the worm receives mild electric shocks at regular intervals, it becomes progressively more likely to respond to a novel stimulus by withdrawal.

Relationship of sensitization to habituation

The first point to note about sensitization is its relationship to habituation. Habituation refers to a decline in the probability of responding to a repeatedly presented stimulus. Sensitization, by contrast, refers to an increase in the probability that behaviour appropriate to a repeatedly presented stimulus will occur, even in response to another stimulus. Although these two outcomes cannot be observed simultaneously, it is quite possible that the same operation—repeated presentation of a stimulus—can simultaneously engage two different processes, one causing a decline in the probability of responding to that stimulus, the other causing an increase. Experimental analysis suggests that both processes are real and may be engaged in the same experiment, so that the observed change in behaviour actually results from a mixture of the two. Typically, the process of habituation wins out, and what is observed is an overall decline in responding. But a common finding in habituation experiments is that responding initially increases before declining; the implication is that the initial presentations of a stimulus result in more sensitization than habituation, while further presentations produce more habituation than sensitization. A second factor influencing the relative importance of the two processes is the intensity or significance of the stimulus. A weak stimulus, or one with little intrinsic biological significance, will show relatively rapid habituation and little or no initial sensitization. A stronger stimulus, especially one, such as food or shock, that has substantial significance to the animal, may show marked sensitization and relatively little habituation.

The second point about sensitization is that it may mimic the effect of associative learning or conditioning. As has been mentioned, in a classical conditioning experiment a neutral stimulus, such as a change in illumination, is paired with the delivery of a significant stimulus, such as food or shock. Repeated pairing causes the neutral stimulus to elicit responses initially called forth by the significant stimulus; for example, a change in illumination that has been associated with an electric shock would come to elicit retreat or withdrawal. But in the case of the worm *Nereis,* experiments demonstrate that the light would come to elicit this change in behaviour whether or not it had been paired with shock: all that is needed is sufficient exposure to the shock. To attribute the change in behaviour toward the light to its association with food or shock, one must show that this change is greater than that which would have resulted from sensitization alone.

Relationship of sensitization to associative learning

The physiological processes underlying sensitization, like those underlying habituation, have been analyzed in experiments on such invertebrate species as *Aplysia.* Not surprisingly, the mechanisms involved appear to mirror one another. Whereas habituation is correlated with a decline in postsynaptic potentials, sensitization is correlated with an increase in the magnitude of postsynaptic potentials at the same locus.

Adaptive value of sensitization

Although sensitization has often been treated as a nuisance whose effects must be controlled in studies of habituation or associative learning, it remains a process worthy of study in its own right, for the behavioral changes it produces can have significant adaptive value. Without requiring the presumably more complex neural machinery necessary to subserve associative learning, sensitization enables animals to respond to local variations in the occurrence of significant events. If an animal's sources of food tend to occur together (that is, they are not distributed randomly in time or space), then it pays that animal, having once found food, to continue to behave in a food-gathering manner. Conversely, the animal that is increasingly wary after exposure to danger will have a better chance of evading a lurking predator. Sensitization thus enables an animal to take advantage of statistical regularities in the occurrence of significant events, without requiring it to detect other events that predict the significant ones. No doubt, further advantage accrues to the animal that can perform such calculations, for associative learning provides a powerful means of predicting the future. But there can be equally little doubt that such a process requires a more elaborate nervous system.

ASSOCIATIVE LEARNING: CONDITIONING

The study of animal learning in the laboratory has long been dominated by experiments on conditioning. This domination has been resisted by critics, who complain that conditioning experiments are narrow, artificial, and trivial, and, as such, miss the point of what animals are adapted to learn. From the critics' point of view, one unfortunate effect of their attacks has been the progressive refinement and elaboration of the theory of conditioning to the point where it can often explain the exceptions to which they drew attention. This is not to insist that associative learning is the sole, or even the most important, form of learning in vertebrates, but rather to introduce the idea that the processes underlying conditioning may be more interesting than older theories and an earlier generation of textbooks suggested.

Classical and instrumental conditioning. Pavlov was not the first scientist to study learning in animals, but he was the first to do so in an orderly and systematic way, using a standard series of techniques and a standard terminology to describe his experiments and their results. In the course of his work on the digestive system of the dog, Pavlov had found that salivary secretion was elicited not only by placing food in the dog's mouth but also by the sight and smell of food and even by the sight and sound of the technician who usually provided the food. Anyone who has prepared food for his pet dog will not be surprised by Pavlov's discovery: in a dozen different ways, including excited panting and jumping, as well as profuse salivation, the dog shows that it recognizes the familiar precursors of the daily meal. For Pavlov, at first, these "psychic secretions" merely interfered with the planned study of the digestive system. But he then saw that he had a tool for the objective study of something even more interesting: how animals learn. From about 1898 until 1930, Pavlov occupied himself with the study of this subject.

Pavlov's experiments

Pavlov's experiments on conditioning employed a standard, simple procedure. A hungry dog was restrained on a stand and every few minutes was given some dry meat powder, an event signaled by an arbitrary stimulus, such as the ticking of a metronome. The food itself elicited copious salivation, but, after a few trials, the ticking of the metronome, which regularly preceded the delivery of food, also elicited salivation. In Pavlov's terminology, the food is an unconditional stimulus, because it invariably (unconditionally) elicits salivation, which is termed an unconditional response. The ticking of the metronome is a conditional stimulus, because its ability to elicit salivation (now a conditional response when it occurs in reaction to the conditional stimulus alone) is conditional on a particular set of experiences. The elicitation of the conditional response by the conditional stimulus is termed a conditional reflex, the occurrence of which is reinforced by the presentation of the unconditional stimulus (food). In the absence of food, repeated presentation of the conditional stimulus alone will result in the gradual disappearance, or extinction, of its conditional response. In translation from the Russian, the terms "conditional" and "unconditional" became "conditioned" and "unconditioned," and the verb "to condition" was soon introduced to describe the experimental activity.

Thorndike's experiments

To the American psychologist Edward L. Thorndike must go the credit for initiating the study of instrumental conditioning. Thorndike began his studies as a young research student, at about the time that Pavlov—already 50 years old and with an eminent body of research behind him—was starting his work on classical conditioning. Thorndike's typical experiment involved placing a cat inside a "puzzle box," an apparatus from which the animal could escape and obtain food only by pressing a panel, opening a catch, or pulling on a loop of string. Thorndike measured the speed with which the cat gained its release from the box on successive trials. He observed that on early trials the animal would behave aimlessly or even frantically, stumbling on the correct response purely by chance; with repeated trials, however, the cat eventually would execute this response efficiently within a few seconds of being placed in the box.

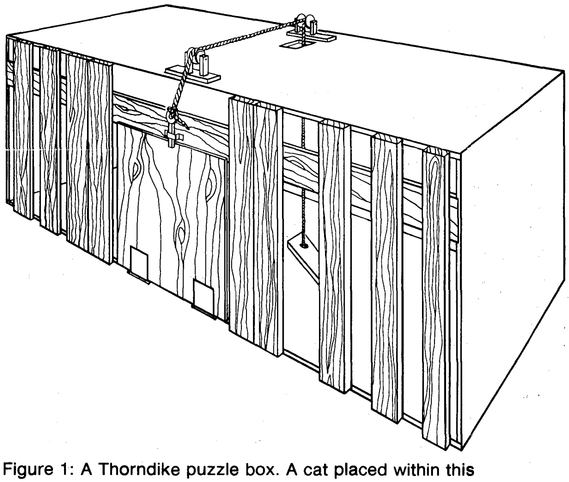

Figure 1: A Thorndike puzzle box. A cat placed within this apparatus could obtain its release by pressing a pedal inside the box.

Skinner's experiments

Thorndike's procedures were greatly refined by another U.S. psychologist, B.F. Skinner. Skinner delivered food to the animal inside the box via some automatic delivery device and could thus record the probability or rate at which the animal performed the designated response over long periods of time without having to handle the animal. He also adopted some of Pavlov's terminology, referring to his procedure as instrumental, or operant, conditioning; to the food reward as a reinforcer of conditioning; and to the decline in responding when the reward was no longer available as extinction. In Skinner's original experiments, a laboratory rat had to press a small lever protruding from one wall of the box in order to obtain a pellet of food. Subsequently, the "Skinner box" was adapted for use with pigeons, who were required to peck at a small, illuminated disk on one wall of the box in order to obtain some grain.

In experiments on both classical conditioning and instrumental conditioning, the experimenter arranges a temporal relation between two events. In Pavlov's experiment the food was always preceded by the conditional stimulus; in Skinner's original experiment the delivery of food was always preceded by the rat's pressing the lever. Conditioning, or associative learning, is inferred if the animal's behaviour changes in certain ways and if that change can be attributed to the temporal relationship between these events. If the dog started salivating to the ticking of a metronome just because it had recently received food, rather than because the delivery of food had been signaled by the metronome, this should be regarded as an instance of sensitization rather than associative learning. One of the simplest ways of establishing that the change in behaviour results from the temporal relationship between the conditional stimulus and the unconditional stimulus in a classical experiment, or between the response and the reinforcer in an instrumental case, is to impose a delay between the two. A gap of even a few seconds between the rat's pressing the lever and the delivery of food will seriously interfere with the animal's ability to learn the connection. And although in some classical experiments evidence of conditioning can be found in spite of relatively long gaps between the conditional stimulus and the unconditional stimulus, increasing this interval beyond a certain point invariably causes a decline in conditioning.

Laws of associative learning. The temporal relation between the conditional stimulus and the unconditional stimulus, or between the response and the reinforcer, was for a long time regarded as the primary determinant of conditioning. Conditioning is certainly a matter of associating temporally related events, but temporal contiguity is only one of several factors—and probably not the most important—that influences conditioning. A variety of experiments have shown that classical conditioning will occur only if the conditioned stimulus is the best predictor of the occurrence of the unconditional stimulus. In other words, it is the correlation between two events, just as much as their temporal contiguity, that establishes an association between them. A pigeon, for example, will learn by classical conditioning to peck an illuminated disk in a Skinner box if, whenever the disk is illuminated, food is delivered. This temporal relationship between the light and food can be preserved intact, but if the experimenter now arranges that food is equally available at other times (when the light is not on), the pigeon will not peck at the illuminated disk. Delivering food at other times destroys the correlation between light and food (although leaving the temporal relationship untouched) and abolishes conditioning.

Conditioning occurs to the best predictor

Although some conditioning will occur when the conditional stimulus is not perfectly correlated with the delivery of food (perhaps because on a proportion of trials the conditional stimulus is presented alone without food) or when the temporal relationship is less than perfect (there is a gap between the conditional stimulus and the delivery of food), this conditioning is abolished if the experimenter ensures that there is some better predictor always available. If a dog is conditioned to the ticking of a metronome paired with the delivery of food, the animal will salivate in response to the metronome even if the food is presented in no more than 50 percent of the trials. If, however, a light is illuminated on those trials when the metronome is accompanied by food, and not on the remaining 50 percent of the trials, the dog will become conditioned to the light and not to the metronome. Similarly, a pigeon will learn to peck at a disk illuminated with red light even if a gap of several seconds separates this response from the delivery of food. But if, during this interval, after the red light has been turned off and before food is delivered,

Figure 2: Effects on conditioning of various relationships between a conditioned stimulus (CS$_1$) and an unconditioned stimulus (US). (A) and (B) show that temporal contiguity of CS$_1$ and the US is not by itself sufficient to ensure conditioning; (C) and (D) demonstrate that conditioning occurs to the best predictor of the US (see text).

a green light is turned on, the pigeon will never learn to peck at the red light. It is as though the pigeon attributes the occurrence of food to the most recent potential cause (now the green light rather than the red), and the dog attributes food to the stimulus best correlated with its delivery (the light rather than the metronome). Conditioning, in other words, occurs selectively to better predictors of reinforcement at the expense of worse predictors. This same principle explains the earlier observation of the role of correlation in general. The pigeon will not associate the illumination of the disk with food if food is equally probable both when the light is on and when it is switched off; from the pigeon's point of view, food occurs whenever the animal is placed in the Skinner box. The illumination of the light signals no increase in the probability of food, and the best predictor of food is the mere fact of being in the Skinner box.

Built-in biases toward certain associations

Temporal contiguity, therefore, is not necessarily the most important factor in successful conditioning. Moreover, there is yet another factor that should be stressed. It will hardly have escaped the reader's attention that there is an astonishing artificiality to the typical conditioning experiment conducted by Pavlov or Skinner. An animal is placed in a bare, confined space; lights are flashed on and off; the animal is permitted to operate some mechanical contrivance; some meat powder or a pellet of food is delivered. How could one possibly suppose that the ways in which animals learn anything of importance in the real world will be illuminated by this contrived and restrictive kind of experiment? This question raises large issues, some of which will recur at later points in this article. But one point should be acknowledged right away: the more restricted the range of experimental manipulations employed, the greater the chance that the investigator will completely miss important principles. Experiments with lights and metronomes failed to reveal the following important principle of conditioning: animals appear to have built-in biases toward associating some classes of stimuli with certain classes of consequences. The most dramatic instance of this principle is provided by conditioned food aversions. If rats eat some novel-flavoured substance and shortly thereafter are made mildly ill (for example, by an injection of a drug such as apomorphine or lithium chloride), they afterward will show a marked aversion to the novel food. Because they will show an aversion even though an interval of several minutes, or sometimes even hours, intervenes between eating the food and the onset of the illness, there has been some question as to whether this should be regarded as an instance of conditioning at all. But the parallels between food aversions and other forms of conditioning are so extensive that it is hard to believe that some common processes are not involved. And there is no question but that the length of the interval is important; other things being equal, rats will form a stronger aversion to a food they have eaten recently than to one they have eaten several hours earlier.

The most interesting feature of such aversions is that they are, by and large, confined to foods. If rats suffer the unpleasant experience of being made ill, they are not likely to show an aversion to anything other than a novel-tasting food or drink they have recently ingested. As in other forms of conditioning, the novelty of the potential conditional stimulus is important. Rats will not show any marked aversion to a thoroughly familiar diet unless the experience of illness is repeatedly induced shortly after eating the daily ration, just as, in Pavlov's experiments, conditioning will proceed only slowly to the ticking of a metronome if the dog has heard this sound repeatedly before. The more striking restriction, however, is that it is the taste of the food or drink that is associated with illness. If rats drink plain tap water before being made ill, they will show little aversion to tap water (since there is no novelty here). But even if a novel buzzer is sounded while they are drinking and they are then made ill, they will not associate the buzzer with the illness. This is certainly not because rats are unable to associate the buzzer with an aversive consequence. If drinking water while the buzzer is sounded produces a mild electric shock, rats will rapidly learn to stop drinking whenever they hear the buzzer. In this case it is the flavour of the water that rats find difficult to associate with the shock; punishing rats with a mild shock whenever they drink sugar-flavoured water has little effect on their tendency to drink sugar-flavoured water. The flavour of food or drink is readily associated with subsequent illness, but only poorly associated with other painful consequences. Conversely, an external stimulus such as a buzzer or flashing light, which is readily established as a signal for shock, is only with great difficulty associated with illness. These relationships are summarized in the Table.

Occurrence of Conditioning to Certain Combinations of Conditional Stimulus and Unconditional Stimulus

conditional stimulus	unconditional stimulus	outcome
Water with novel flavour	Lithium-induced illness	Conditioned aversion to flavour
Water with novel flavour	Mild shock	No aversion to flavour
Water plus buzzer	Lithium-induced illness	No aversion to buzzer
Water plus buzzer	Mild shock	Conditioned aversion to buzzer

Adaptive value of biases

The full explanation of this finding remains uncertain. It is known that even very young rats show such selectivity, so it cannot depend solely on any prior experience. What is easy to see is that this behaviour makes biological sense. Internal malaise, such as that caused in the psychologist's experiment by an injection of lithium, will in the real world usually be a consequence of eating spoiled or poisonous food or of drinking tainted water. The most reliable sign of such food or drink will be its taste, and animals predisposed to associate the taste of what they have ingested with subsequent illness are likely to be better equipped to avoid potentially harmful food in the future. On the other hand, painful injury, mimicked in the laboratory by a brief electric shock, is hardly likely to be a consequence of eating food of a particular flavour; it will usually be caused by external circumstances, such as contact with a sharp or very hot object or a narrow escape from a predator. The natural suggestion is that the function of conditioning is to enable animals to find out what causes certain events of biological significance. If this is so, a built-in bias toward associating certain classes of events together makes adaptive sense. Conditioning is not just a matter of associating two events because one happens to follow the other; it is more profitably seen as the process whereby animals discover the most probable causes of events of consequence to themselves.

Laws of performance. Conditioning could have no function at all, however, if it did not involve changes in an animal's behaviour. Nor could scientists infer that conditioning has occurred unless they could observe, at some point, a change in an animal's behaviour attributable to certain conjunctions of events. So, although conditioning may involve the formation of associations between events or the attribution of particular events to their most probable antecedent causes, it must also include some mechanisms for translating these associations into changes in behaviour.

Stimulus–response theory

For an earlier generation of behaviourists, the fundamental fact about conditioning was precisely that it changed behaviour, and the theories they advanced were determined by this fact. The description of conditioning as the establishment of a new response to a stimulus that had not previously elicited that response naturally suggested that conditioning was a matter of forming new stimulus–response connections. This conceptualization led to the development of the stimulus–response theory, variations of which long provided the dominant account of conditioning. One version of the stimulus–response theory suggested that the mere occurrence of a new response to a given stimulus, as when Pavlov's dog started salivating shortly after the metronome had started ticking, is in itself sufficient to strengthen the connection between the two. Thorndike, however, argued that the probability that a particular stimulus will repeatedly elicit a particular response depends on the perceived consequences of this response. According to this view, new stimulus–response connections are strengthened only if the response is followed by certain kinds of consequences.

Thorndike's law of effect

There are several questions raised here, and it is important to keep them distinct. One is whether responses are sometimes (or even always) modified by their consequences. Although denied by some theorists, their denial seems distinctly paradoxical. A rat whose presses on a lever are followed by the delivery of a food pellet will press the lever again; if the only consequence of pressing the lever is the delivery of a painful shock, the rat will desist from this action. Thorndike's law of effect—which stated that a behaviour followed by a satisfactory result was most likely to become an established response to a particular stimulus—was intended to summarize these observations, and it is surely an inescapable feature of understanding how and why humans and other animals behave. In keeping with this understanding, parents reward children for good behaviour and punish them for bad. When this fails to produce the desired behaviour, we are inclined to argue that the child is finding other sources of reward or does not find the intended punishment particularly unpleasant, or that the parents' behaviour is hopelessly inconsistent. We are far less likely to question the assumption that, other things being equal, people (and other animals) repeat actions that have desirable consequences and avoid repeating those that have undesirable consequences.

Thorndike's law of effect was, however, also a theory of how reward and punishment modify behaviour. This theory, which states that behaviour normally is modified by changing the strength of stimulus–response connections, finds less general acceptance today. A simple experiment suggests one reason for this. A rat is trained to press a lever in a Skinner box, being rewarded with a small quantity of sucrose solution for each press of the lever. Once the response has been established, the rat is removed from the Skinner box. The next day, while in its home cage, the animal is given sucrose solution to drink and shortly thereafter is made ill by an injection of lithium. Once this treatment has established a strong aversion to the sucrose, the rat is returned to the Skinner box, where, despite the opportunity to do so, the animal does not press the lever again. The result is hardly surprising: there is no reason to expect the rat to perform a response whose sole consequence is the delivery of the now aversive sucrose solution. But this behaviour cannot be explained by Thorndike's theory, for according to Thorndike all that the rat learned in the first stage of the experiment was a new stimulus–response habit; stimuli from the Skinner box should, by Thorndike's reasoning, now elicit the response of pressing the lever. Thorndike's stimulus–response theory credits the rat with no acquired knowledge of the connection between pressing the lever and obtaining sucrose; the function of sucrose is merely to strengthen the stimulus–response connection.

That responses are modified by their consequences, therefore, need not call for Thorndike's theoretical account of this fact. It is probably more reasonable to suppose that animals learn about the relationship between their actions and consequences (just as they can also learn about the relationship between any other classes of events), and that they then modify their actions in accordance with the current value of these consequences. The next question to consider is whether this is an entirely general principle of performance, or whether it applies only to some classes of response in some kinds of situations. Why, for example, does Pavlov's dog start salivating to the ticking of the metronome? Is it because the response of salivating is followed by a rewarding consequence? The response is, at first, elicited by the sight of food and is shortly followed by the rewarding consequence of chewing and swallowing the food. But another simple experiment suggests that salivating to the metronome is not strengthened because it is followed by food. The experimenter can turn on the metronome for five seconds on each trial, at the end of which time the dog receives food—but only if it did not start salivating before the arrival of food. Now the response of salivating to the metronome is followed by an undesirable consequence, the cancellation of the food that would otherwise have been delivered on that trial, but the dog still cannot help salivating (at least sometimes) to the metronome. The implication is that salivating is not a response modified by its consequences, but one reflexly elicited by food and also by any stimulus associated with food. Voluntary responses can be modified by their consequences; involuntary responses (such as blushing when a person is embarrassed or the release of adrenalin when a person is angry or afraid) cannot. The reason Pavlov's dog starts salivating to the metronome is, just as Pavlov himself supposed, that the association between metronome and food means that the metronome can substitute for food. To put it another way, the metronome now produces activity in neural centres normally responsive to the delivery of food, activity that is reflexly connected to the salivary response.

It should not be thought that only autonomic, glandular responses are involuntary in this sense. If a small light is always illuminated for five seconds before the delivery of food to a hungry pigeon, the pigeon will learn, by classical conditioning, to approach and peck at the light. Exactly the same experiment as that described above can be undertaken, with food delivered only on those trials when the pigeon does not approach and peck the light during the initial five seconds. The pigeon cannot help doing so. Pavlovian conditioning appears to be a widespread phenomenon, applying to a relatively wide range of responses.

Functions of conditioning. The behaviour of the dog and pigeon in the above experiments seems maladaptive, precisely because it violates the law of effect. If the way to obtain food is to refrain from performing a particular response, then that is what the law of effect says the animal should do. The law of effect makes obvious adaptive sense; several writers, indeed, have pointed to the analogy between the law of effect and natural selection. Just as natural selection favours those variations that happen to increase fitness, so the law of effect selects those responses that happen to be followed by certain consequences.

Adaptive value of Pavlovian conditioning

The fact that Pavlovian conditioning may result in apparently maladaptive behaviour in the artificial confines of the experimental psychologist's laboratory, however, does not mean that it is not adaptive in the real world. The pigeon's behaviour provides a clue. In a normal classical conditioning experiment, where the illumination of a small light regularly precedes the delivery of food, the pigeon will rapidly learn to approach and direct pecks at the light. Approach and pecking are food-related activities: what is happening is that a simple process of Pavlovian conditioning is ensuring that responses related to food are being elicited by stimuli associated with food. It is not difficult to appreciate the adaptive significance of a process that results in animals approaching places where they have found food in the past, or in learning that a particular novel object is in fact an example of food, and directing food-related activity toward these stimuli in the future.

Pavlovian conditioning also affects other significant behaviours. For example, it probably provides the basic process by which animals learn to avoid poisonous foods. If a novel food is associated with illness, its taste will elicit responses of disgust or nausea, ensuring that the substance will subsequently be rejected after the first taste.

In territorial birds and fish, aggressive displays and attacks can become conditioned to stimuli that regularly precede the appearance of a rival male. A male already primed to threaten and attack an intruder, because he has learned that certain signs herald the appearance of the intruder, should be more successful in defense of his territory than the male that is unprepared. Experimental analysis has, in fact, nicely confirmed this expectation. In general, any pattern of defensive behaviour that is adaptive in response to an intruder or predator—such as displaying or fighting, fleeing or taking other evasive action, or freezing into immobility or feigning death—will be even more adaptive if performed in advance, at the first reliable signal of the predator's or intruder's appearance.

Adaptive value of instrumental conditioning

The process of Pavlovian conditioning thus often enables animals to behave appropriately in anticipation of events of biological significance, without involving any direct modification of that behaviour by its success or failure. But further modification must sometimes be of further advantage. For instance, it is not always enough just to approach a stimulus associated with food; if that stimulus is a prey species, it may take evasive action that will require much more elaborate behaviour on the part of the predator. This can be seen in the feeding behaviour of the oystercatchers, a group of birds that eat bivalve mollusks. Oystercatchers first catch their pray by probing down the hole made by the bivalve in the mud; the sight of the hole must be rapidly established as a conditional stimulus for food. But the birds must then perform a complex series of actions to get at the mollusk's flesh, and this skilled sequence of responses also must be learned, presumably in accordance with the law of effect. Similarly, many animals have a wide range of defensive behaviour patterns; in the laboratory, at least, which one eventually predominates in any given situation normally depends on which one successfully enables the animal to escape or to avoid aversive consequences. In all these cases, it appears that instrumental conditioning serves to modify, via the law of effect, initial responses that owed their origin to Pavlovian conditioning.

The adaptive value of instrumental conditioning is an area of research that has seen some fruitful collaboration among experimental psychologists, ethologists, and behavioral ecologists. From ecology has come the "optimal foraging theory," the idea that efficient foraging behaviour should maximize an animal's net rate of food intake. From ethology and experimental psychology has come the idea that an animal's instrumental behaviour in any given situation is a product of competition between various possible activities, a competition whose resolution depends on weighing the costs and benefits of increasing one activity at the expense of another. Both in the laboratory and in more natural settings, for example, the proportion of time spent searching for one kind of food depends not only on the probability of finding that food and on its value when found but also on the probability of the animal finding an alternative food if it looks elsewhere. There is also abundant evidence that animals improve their foraging efficiency with practice; this clearly must depend on learning which stimuli signal the availability of which kinds of food, the most efficient way of taking a given food, and the most effective distribution of time between alternatives.

SPATIAL LEARNING

One of the major problems many animals must confront is how to find their way around their world—for example, to know where a particular resource is and how to get to it from their present location, or what is a safe route home to avoid a predator. Such spatial learning may cover only the highly restricted confines of an animal's home range or territory, or it may embrace a migration route of several hundreds or even thousands of miles. Although some forms of navigational behaviour may be explicable in relatively simple terms, not necessarily requiring appeal to processes more complex than those of simple conditioning, others suggest some quite new principles.

Maze learning. In the psychologist's laboratory, the primary method of studying spatial learning has been to put a rat in a maze and watch how it finds its way to the goal box, where it is fed. As befits the analytic (some would say sterile) approach so popular in experimental psychology, the elaborate and complex mazes used in earlier studies (the very first published experiment used a scaled-down replica of the maze at Hampton Court, London) soon gave way to something very much simpler, a T-maze or Y-maze. A rat placed at the end of one arm must run to the central choice-point, from where it has to enter one of the two remaining arms. Although extremely simple, even this apparatus allows for a number of possible modes of solution. One possibility is that the rat learns to execute a particular response, a left turn or a right turn, at the choice-point, because that response is followed by food. A second possible solution is that the rat learns that the two alternative arms differ in some particular way and further learns to associate one of the arms with food and hence to choose it. The third and most interesting possibility is that the rat learns to define the rewarded arm not in terms of its own intrinsic characteristics but by its spatial relationship to an array of landmarks outside the maze. Thus the rat might learn that the correct arm is the one pointing to the left of a window and away from a table with a lamp on it. Experiments show that whenever such landmarks are available, this third solution mode is the one used.

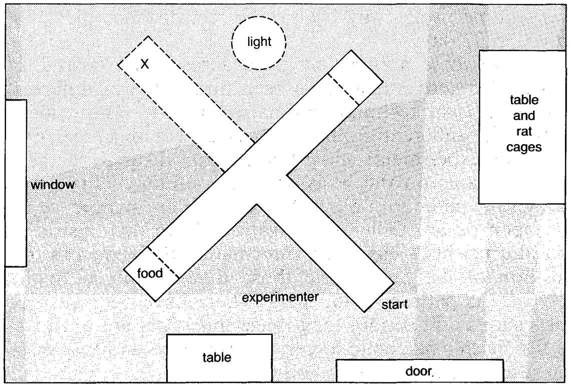

Figure 3: Diagram of a T-maze. Once a rat has learned to run to the arm that contains food, the maze can be flipped (so that the start-arm is in the position marked X) to determine if the rat has learned to reach the goal by making a left turn. If the rat turns right on this trial, the experimenter can rotate the maze 180° to see if the animal has learned to identify the goal-arm in terms of its intrinsic characteristics or, as is usually the case, by its relation to landmarks outside the maze.

Evidence of spatial learning in rats

Perhaps the most convincing demonstration that rats can find their way to a particular location—one defined solely in terms of its spatial relation to various external landmarks—has been provided by experiments in which the animals are placed in a large circular tank of water and must swim to a transparent platform submerged somewhere in the middle of the tank. They can rapidly learn to do this, regardless of where they are initially put into the tank and even though the platform itself is invisible. (The invisibility of the platform is shown by the following: if the platform is moved, the rat will swim straight past it, heading instead toward the position it used to occupy.)

Rats in these experiments are not simply approaching a single landmark; they locate their goal by reference to its spatial relationship with a whole series of landmarks, no one of which is necessary. This can be established by using half a dozen arbitrary but easily identified objects as landmarks during maze training. Removal of any one or two of them in no way disrupts the rat's behaviour. If all the landmarks are systematically rotated around the room, the rat will identify a new arm of the maze as correct (the one that has the same relationship to the landmarks as the initially correct arm). If, however, the landmarks are rearranged in such a way as to destroy their original spatial relationship to one another, the rat does not know which arm to choose.

The processes involved in this sort of learning are not well understood. Some psychologists have been sufficiently impressed by the rat's flexibility in these experiments to argue that the animal is constructing a map of its environment—not, obviously, a written map but an internal, maplike representation that encodes a complete set of spatial relationships between major landmarks. The best evidence for such a maplike representation would be if a rat could take an unfamiliar route when its original route to a goal is blocked. Unfortunately, there is little evidence of such performance in rats, except in the not especially critical case where the goal, or a stimulus very close to it, is clearly visible from the choice-point. On the other hand, studies of long-range navigation have shown that some animals can do just this.

Navigation. Salmon return from the ocean to spawn in the stream in which they were hatched; swallows return to the same nest sites in northern Europe each spring from wintering in southern Africa. These and other examples of large-scale migrations have long fascinated students of animal behaviour, and experimental intervention has produced some remarkable results. A Manx shearwater was taken in an airplane from its breeding site on the island of Skokholm, off south Wales, to Boston, Mass. It returned to Skokholm within 13 days of being released in Boston; the direct distance between these two points is 3,050 miles, which implies (assuming that the bird did not fly at night) a minimum average speed in excess of 20 miles per hour. An albatross flew from a release site in the Philippines to its home in Midway Island, a direct distance of 4,120 miles, in 32 days.

Navigational cues

How do these animals navigate across such great distances? Numerous cues have been implicated in different instances. Near to home, animals probably rely on local cues quite different from those used at a distance. For example, experiments show that salmon distinguish their home streams on the basis of smell, although this sense can hardly come into play while the fish are swimming in the open ocean. Other investigations have demonstrated that diurnal birds use visual information derived from the position of the Sun, while those that migrate at night rely on the pattern of the stars. There have been several suggestions that certain long-range migrators are sensitive to the Earth's magnetic forces; sensitivity to auditory cues has also been suggested in some cases.

The most intensive analysis of long-range navigation has been undertaken with homing pigeons. These birds are trained by being released from sites progressively further from their home loft. Just what the pigeons learn on these training flights is not entirely clear. In part, they obviously learn the visual landmarks immediately surrounding the home loft, but experimental evidence suggests that they use such landmarks only very close to home. Once some training has been given, however, a pigeon can be taken 100 miles or more in any direction from home, and it will, within a few minutes of its release, start flying in a homeward direction.

One general class of theory on homing behaviour postulates that the pigeon detects a discrepancy between a particular set of stimuli observed at the release site and its stored knowledge of what that set of stimuli should be like at home, and it then flies in such a direction as to reduce this discrepancy. Different versions of this theory appeal to different sets of stimuli that might be used to guide the pigeon home. At one time, a popular idea was that the pigeon used the Sun's height in the sky in combination with an internal clock. At any given season and time of day, the Sun's height in the sky—and, by extrapolation from its current rate of climb, its maximum height—are unique to a single place (in this case, the pigeon's home). Assuming that the pigeon's home loft and the release site are both in the Northern Hemisphere, then if the Sun's maximum height is lower at the release site, the release site is north of home; if higher, then the release site is south of home. If the Sun will reach its maximum height later than at home, the release site is west of home; if earlier, the site is east of home. If released at noon at a site in the Northern Hemisphere 200 miles northeast of home, the pigeon must fly so as to raise the maximum height of the Sun (*i.e.,* south), and so as to stop the Sun falling (*i.e.,* west).

This explanation is immensely ingenious and, although calling for some astonishingly fine sensory discriminations on the part of the pigeon, not impossible in principle. Unfortunately, it is probably wrong. Two critical experiments have produced results quite at variance with its predictions. The first suggested that pigeons do not rely on the height of the Sun to navigate at all. In this experiment, the pigeons were confined to a laboratory from which they could see the Sun for only a relatively short time around noon each day, and the apparent height of the Sun above the horizon was raised or lowered by allowing the birds to view the Sun only through a complex series of mirrors. This should have had drastic effects on their perception of the true position of their home; for instance, an increase of 70′ in the apparent height of the Sun at noon would correspond to an 80-mile southward relocation of the home. The pigeons were then taken from home and released 40 miles south, where they saw the real Sun for the first time in several weeks. If the Sun's height was indeed a critical stimulus in navigation, the pigeons would be expected to fly south rather than north. In fact, they correctly flew north.

Experiments on navigation in homing pigeons

The second experiment involved shifting the birds' internal clock, by confining them indoors and exposing them to a new light–dark cycle. Independent observations had shown that this procedure is entirely successful: if a bird is confined indoors for a few weeks with the lights switched on every day at midnight and switched off at noon, its clock soon will be entrained on this new cycle, so that 6:00 AM is regarded as the middle of the day. In the critical experiment, the bird was taken out of the laboratory and released at 6:00 AM (true time) from a site 50 miles south of home. The Sun, now seen for the first time in several weeks, was just rising; but, according to the pigeon's internal clock, the time at home was noon. This implied that the release site was a long way west of home, and if the pigeon were using the height of the Sun as a cue to guide it home, it should have flown east. In fact, the pigeon flew west.

Use of the Sun as a compass

The result of the second experiment indicates that the pigeon was using the position of the Sun in the sky, and that the clock shift had been effective (for the pigeon was not flying in the direction of home). This is readily explained by the hypothesis that the pigeon used the Sun as a compass. If we allow, for the sake of argument, that the pigeon knew that the release site was south of home, then it should have tried to fly north. In the Northern Hemisphere at noon, the Sun is due south; therefore, the pigeon—whose internal clock said it was noon—should fly away from the Sun. But although the pigeon's shifted clock said that it was noon, the true local time was 6:00 AM, and the Sun was in the east. Flying away from the Sun, the pigeon flew west. This experiment then suggests first, that the pigeon was not using the height of the Sun at all; second, that it used the Sun's horizontal position, or azimuth, to provide a compass bearing; and, third, and most important, that the pigeon had some other map that told it that the release site was south of home. In general, a compass is of no use without a map.

The role of experience in establishing an internal map

The basis for the map component of the pigeon's navigational skill remains extremely obscure. There is evidence from studies of many migratory birds that the compass component is in some sense innate, but that a map of the relative positions of the summer and winter habitats and of other places in between (or even not in between) develops only with the experience of migration. For example, starlings that breed around the Baltic Sea fly southwest in autumn to winter in southern England, northern France, and Belgium. When captured during this autumn migration and released in Switzerland (some 500 miles south of their normal route), experienced, adult birds flew back to northern France and Belgium—even though they had presumably never flown over any part of this route before. Young birds, however, for whom this was the first migration, flew southwest from Switzerland and ended up in southern France or northern Spain. They clearly had a compass that told them which direction was southwest; what they lacked was any knowledge of the spatial relationship between their present location in Switzerland and their goal in northern France.

PERCEPTUAL LEARNING

According to Thorndike's stimulus–response theory, learning, which is reducible to the strengthening and weakening of the tendency to perform a particular response in the presence of a particular stimulus, occurs only when that response is performed; learning, in other words, depends on trial and error. Even in the realm of simple conditioning, there are good reasons to question this restriction. Conditioning is better conceptualized as the acquisition of knowledge about temporal relationships between events rather than as the acquisition of behaviour. Spatial learning seems to be a matter of learning about spatial relationships between objects and places in one's environment and, apparently, the construction of some sort of map that will subsequently permit the animal to perform a new sequence of actions across unknown territory. This section considers other examples of learning, in which at least part of what an animal appears to acquire is the recognition of a more or less complex set of stimuli that subsequently can be used to guide its actions.

Imitation and observational learning. One reason why Thorndike adopted such a narrow, behavioral view of learning was that he looked for evidence of other forms of learning without success. Having taught one cat to escape from the puzzle box by operating a latch, he looked to see whether a second cat would acquire the correct solution simply by watching the first. A series of such experiments produced uniformly negative results, and Thorndike concluded that trial and error was the only form of learning available to animals other than humans.

Why Thorndike should have been so unsuccessful is something of a mystery, for later experiments have established quite convincingly that animals can often benefit from watching another member of their species perform a particular task. Casual observation in natural settings, for instance, reveals that young chimpanzees intently watch their elders perform intricate tasks; this certainly suggests that learning by observation is very common in some species.

Experimental analysis has revealed a number of important distinctions concerning the role of observation in behaviour. For example, domestic chickens that have eaten to satiation a particular source of food will start eating again if they observe other chickens feeding. Although the observation of conspecifics engaged in a particular activity has clearly affected the tendency of the satiated chicken to engage in that activity, it is not clear what they might have learned from this observation. They already know how to peck, and they already know that the grain before them is palatable food. It is probably more appropriate to regard this as an instance of "social facilitation" and to say that one of the stimuli that elicits feeding in chickens is the sight of other chickens feeding.

The basic nature of observational learning

The example above demonstrates the minimum requirement for establishing that an animal has learned by observation: in the absence of the opportunity to observe another, the animal must have been unlikely to have performed a particular response, and the reason for this must reside in lack of knowledge. An artificial, laboratory example of observational learning would be to allow an observer rat to watch a demonstrator rat pressing a lever for food. If the observer has never before pressed a lever and, given the opportunity, now does so much more rapidly than another rat denied the opportunity to observe the demonstrator, surely some genuine observational learning has occurred. But even here it remains difficult to establish exactly what it is that the observer has learned by watching the demonstrator, and more elaborate experiments may be required to elucidate this. An experiment with two monkeys showed how this may be done. The monkeys took turns acting as demonstrator and observer. The demonstrator's task was to choose between two objects, one of which contained some hidden food. Since the objects were changed on each new trial for the demonstrator, there was no way for the animal to know which choice was correct, and it necessarily picked one at random. The observer, however, could watch the demonstrator's trial and thus could find out which of the two objects in a particular set was correct. Given an opportunity to choose between the two, the observer more often than not chose correctly. That the observer was not simply watching the demonstrator, but was in fact looking to see the outcome of the choice, is established by the finding that the observer performed somewhat more accurately on those trials when the demonstrator's choice was wrong than on those when it was right.

The distinction between observation and imitation

This last finding points to a further distinction, that between observing the actions of another and imitating those actions. In this particular experiment, the monkeys clearly were not imitating one another, or they would have copied each other's choices even when these were wrong. A demonstration of imitation is provided by the behaviour of oystercatchers feeding on mussels. Having found a mussel, an adult oystercatcher obtains the food from within either by inserting its beak in the right place and cutting the muscle that holds the shell together or by pecking a hole in the weakest point of the shell. Young birds develop the method employed by their parents, but experiments in which chicks were fostered by adults with a different habit from that of the natural parents have established that this behaviour is not genetically determined. Rather, the young birds imitate the actions they observe being performed by their foster parents.

The best known natural example of such imitation was provided by a troop of macaques in Japan. In order to lure the monkeys out of the forest and into the open, where their behaviour could be better studied, scientists routinely left sweet potatoes and wheat on the beach. The monkeys ate this food but clearly disliked the fact that it had become liberally mixed with sand. A young female member of the troop, however, discovered that sweet potatoes could readily be washed free of sand, and that a handful of wheat and sand could be thrown into a pool, where the sand would sink, leaving the wheat floating behind. Both customs spread through the troop, first to the immediate family and young companions of the original inventor, and last of all (an interesting touch) to the old, conservative males. Other examples of observational learning are readily apparent in the behaviour of animals in the field, but in many cases, as in some of the laboratory studies cited above, it remains difficult to elucidate just what it is that has been learned.

Song learning. A special case of observational learning is that of young birds acquiring their species-typical song. Numerous species of animals, including many birds, produce species-typical calls or other vocalizations as adults; in many cases, however, there is little evidence that learning plays any significant role in their development. In many species of crickets, for example, the song is stereotyped, and the pattern of neural activity that produces the song can be detected even in young animals who neither sing nor apparently react to the adult song. But in most songbirds, there is reason to believe that learning has a significant effect on the development of the adult song.

The role of observation

The interesting feature of this learning is that it sometimes occurs in two distinct phases separated by several months. The first of these can be regarded as purely observational learning, the second as the perfection of the song through practice (*i.e.,* as imitation of a model). Song sparrows, for example, do not develop a normal adult song unless they have the opportunity to hear the song during their first autumn. There is thus a sensitive period during which they must hear their species' song if they are to develop normally, but it is important to note that they do not themselves sing at all during the first autumn. It is not until the next spring that they start practicing the song. At this point, they do not need to hear other sparrows singing, but they do need to hear themselves. If the bird is deafened before it starts practicing, only a very crude song emerges. The implication is that, during exposure in the first autumn, the sparrow learns to identify the detailed song and establishes a template of it; the following spring, the sparrow starts singing and needs practice to match its output to the stored template.

The song sparrow provides an example of a particularly clear separation between observation and imitation. In other species, such as the chaffinch, the young bird learns from exposure to song in the first autumn, but refinement of the song is produced by further exposure to other chaffinches singing during the following spring. In yet others, such as indigo buntings, the adult bird learns its song from territorial neighbours. But even where there is no temporal separation between the two aspects of learning, it still seems valid to distinguish between the learning involved in establishing the template and that involved in perfecting the motor skill.

If song learning consists solely of the young bird learning to reproduce the adult, species-typical song, one might wonder why any learning should be necessary at all. Why should the song not develop simply through maturation, or, in other words, why is not the template, at least, genetically laid down in the bird's brain? In fact, studies indicate that a relatively crude template is innately determined in most species. There are very strict limits to the range of songs that a bird of one species can learn. Moreover, among chaffinches and certain other species, even if a young bird hears no song at all it will still develop a crude song that has recognizable features of the full, species-typical one. The degree of this innate specification varies widely from species to species: at one extreme are such birds as cuckoos, which develop a standard call with no prior exposure at all; at the other extreme are such birds as marsh warblers, which develop idiosyncratic songs picked up, it seems, from any other species they come in contact with during the sensitive period.

Value of learned songs

Species whose song acquisition involves a great deal of individual learning are probably those in which individual birds develop slightly different songs. In some species, such as song sparrows, there are recognizable local "dialects" that the young birds learn from adults living in the same region. In other species, there is even more variation between individuals. If one function of the song is to attract a mate, then an interplay is called for between a song that simply advertises the singer's species and one that establishes his individual identity. The importance of individual learning, then, depends on the role of the song in the mating patterns of the species.

Value of imprinting

Imprinting. The young of many species are born relatively helpless: in songbirds, rats, cats, dogs, and primates, the hatchling or newborn infant is wholly dependent on its parents. These are altricial species. In other species, such as domestic fowl, ducks, geese, ungulates, and guinea pigs, the hatchling or newborn is at a more advanced stage of development. These are precocial species, and their young are capable, among other things, of walking independently within a few minutes or hours of birth, and therefore of wandering away from their parents. Since mammals are dependent on their mothers for nourishment, and even birds are still dependent on parental guidance and protection, it is important that the precocial infant not get lost in this way. The phenomenon of filial imprinting ensures that, in normal circumstances, the precocial infant forms an attachment to its mother and never moves too far away.

Although imprinting was first studied by the Englishman Douglas Spalding in the 19th century, Konrad Lorenz is usually, and rightly, credited with having been the first not only to experiment on the phenomenon but also to study its wider implications. Lorenz found that a young duckling or gosling learns to follow the first conspicuous, moving object it sees within the first few days after hatching. In natural circumstances, this object would be the mother bird; but Lorenz discovered that he himself could serve as an adequate substitute, and that a young bird is apparently equally ready to follow a model of another species or a bright red ball. Lorenz also found that such imprinting affected not only the following response of the infant but also many aspects of the young bird's later behaviour, including its sexual preferences as an adult.

Imprinting, like song learning, involves a sensitive period during which the young animal must be exposed to a model, and the learning that occurs at this time may not affect behaviour until some later date. In other words, one can distinguish between a process of perceptual or observational learning, when the young animal is learning to identify the defining characteristics of the other animal or object to which it is exposed, and the way in which this observational learning later affects behaviour. In the case of song learning, observation establishes a template that the bird then learns to match. In the case of imprinting, observation establishes, in Lorenz' phrase, a model of a companion, to which the animal subsequently directs a variety of patterns of social behaviour.

With imprinting, as with song acquisition, one can ask why learning should be necessary at all. Would it not be safer to ensure that the young chick or lamb innately recognized its mother? There are, in fact, genetic constraints on the range of stimuli to which most precocial animals will imprint. A model of a Burmese jungle fowl (the species whose domestication produced domestic chickens) serves as a more effective imprinting object for a young chick than does a red ball; there is even evidence that imprinting in the latter case involves different neural circuits from those involved in imprinting to more natural stimuli. Nonetheless, it is clear that the innate constraints are not very tight and that a great deal of learning normally occurs. The most plausible explanation, as in the case of song learning, is that imprinting involves some measure of individual identification. Lorenz argued that one of the unique characteristics of imprinting was that it involved learning the characteristics of an entire species. It is true that imprinting results in the animal directing its social and mating behaviour toward other members of its own species, and not necessarily toward the particular individuals to which it was exposed when imprinting occurred. But learning usually involves some generalization to other instances, and there does not seem to be anything peculiar to imprinting here. The primary function of imprinting, however, is to enable the young animal to recognize its own mother from among the other adults of its species. This no doubt is particularly important in the case of such animals as sheep, which live in large flocks. Only learning could produce this result.

There is also an important element of individual recognition in at least some cases of imprinting's effects on sexual behaviour. Experiments with Japanese quail have shown that their sexual preferences as adults are influenced by the precise individuals to whom they are exposed at an earlier age. Their preferred mate is one like, but not too like, the individuals on whom they imprinted. The preference for some similarity presumably ensures that they attempt to mate with members of their own species. The preference for some difference is almost certainly a mechanism for reducing inbreeding, since young birds will normally imprint on their own immediate relatives.

The possible role of rewards in imprinting

The difference between imprinting and song learning lies in the consequences of observational learning. The effect of imprinting is the formation of various forms of social attachment. But what mechanism causes the young chick or duckling to follow its mother? Lorenz thought that imprinting was unrewarded, yet the tendency of a young bird to follow an object on which it has been imprinted in the laboratory can be enhanced by rewarding the bird with food. Rewards also occur outside the laboratory: the mother hen not only scratches up food for her young chicks, she also provides a source of warmth and comfort. Moreover, following is also rewarded by a reduction in anxiety. As chicks develop over the first few days of life, they show increasing fear of unfamiliar objects; they allay this anxiety by avoiding novel objects and approaching a familiar one. This latter object must be one to which they have already been exposed—in other words, one on which they have imprinted. Imprinting works because newly hatched birds do not show any fear of unfamiliar objects, perhaps because something can be unfamiliar only by contrast with something else that is familiar. On the contrary, the newly hatched birds are attracted toward salient objects, particularly ones that move. Once, however, a particular object has been established as familiar and its features identified, different objects will be discriminated from it. These will be perceived as relatively unfamiliar, and hence they will provoke anxiety and the attempt to get as close as possible to the more familiar object. The imprinting of the young bird on one object necessarily closes down the possibility of its imprinting on others, as these will always be relatively less familiar. Thus, there is normally a relatively restricted period in the first few hours or days of life during which imprinting can occur. The only way to prolong this period is to confine the newly hatched bird to a dark box where it is exposed to no stimuli; prevented from imprinting during this period of confinement, the bird imprints on the first salient object it sees after emerging.

COMPLEX PROBLEM SOLVING

Experimental psychologists who study conditioning are the intellectual heirs of the traditional associationist philosophers. Both believe that the complexity of the human or animal mind is more apparent than real—that complex ideas are built from simple ideas by associating simple elements into apparently more complex wholes. According to this perspective, the only relationship between these ideas is their association, and the determinants of these associations are themselves relatively simple and few in number. Neither conditioning theorists nor associationist philosophers, however, have lacked for critics, who claim that intelligent problem solving cannot be reduced to mere association. Although allowing that the behaviour of invertebrates, and perhaps that of birds and fish, may be understood in terms of instincts and simple forms of nonassociative and associative learning, these critics maintain that the human mind is an altogether more subtle affair, and that the behaviour of animals more closely related to man—notably apes and monkeys, and perhaps other mammals as well—will share more features in common with human behaviour than with that of earthworms, insects, and mollusks.

Differing views of animal intelligence

The idea that animals might differ in intelligence, with those more closely related to humans sharing more of their intellectual abilities, is commonly traced back to Charles Darwin. This is because the acceptance of Darwin's theory of evolution was at the expense of the ideas of the French philosopher René Descartes, who held that there is a rigid distinction between man, who has a soul and can think and speak rationally, and all other animals, who are mere automatons. The Cartesian view had, in fact, been challenged long before Darwin's time by those who believed (as seems obvious from even the most casual observations) that some animals are notably more complicated than others, in ways that probably include differences in behaviour and intelligence. It was, however, the publication of Darwin's *Descent of Man* (1871) that stimulated scientific interest in the question of mental continuity between man and other animals. Darwin's young colleague, George Romanes, compiled a systematic collection of stories and anecdotes about the behaviour of animals, upon which he built an elaborate theory of the evolution of intelligence. It was largely in reaction to this anecdotal tradition, with its uncritical acceptance of tales of astounding feats by pet cats and dogs, that Thorndike undertook his studies of learning under relatively well-controlled laboratory conditions. Thorndike's own conclusions, already noted above, were distinctly Cartesian: animals ranging from chickens to monkeys all learned in essentially the same way, by trial and error or simple instrumental conditioning. Unlike man, none could reason.

This controversy actually involves two questions, which are worth keeping apart. The first is whether theories of learning based on the results of, say, simple conditioning experiments are sufficient to explain all forms of learning and problem solving in animals. The second question is whether new and more complex processes operate only in some animals, that is to say, whether some animals are more intelligent than others. The distinction between these questions is not always easy to preserve, for they are clearly related, and an answer to one usually has implications for the other. The remainder of this article is organized around the first question; in cases where the behaviour of an animal does, in fact, seem to indicate that more complex processes are involved, the second question is also considered.

Discrimination of relational and abstract stimuli. Laboratory studies of habituation and conditioning usually employ very simple stimuli, such as lights, buzzers, and ticking metronomes in Pavlov's experiments. Some of the other examples of learning considered earlier have already suggested that animals can actually respond to additional, more complex stimuli. Even the solution of simple spatial discriminations in the laboratory requires the animal to learn about spatial relationships between different landmarks; migration or navigation over hundreds of miles demands abilities at least as complex as this. Song learning requires the young bird to discriminate between different sequences of subtly varying notes and calls, and the individual recognition involved in imprinting requires response to elaborate configurations of features.

Transposition of relational discriminations

Thus, one way in which a problem may become more difficult is if its solution depends on response to more subtle changes in stimuli. Numerous laboratory studies have examined the abilities of a variety of animals to perform such discriminations. The phenomenon of transposition, first studied in chicks by the Gestalt psychologist Wolfgang Köhler, suggests that animals may solve even simple discriminations in ways more complex than the experimenter had imagined. Köhler trained his chicks to perform simple discriminations—say, to choose a large white circle (five centimetres in diameter) in preference to a small white circle (three centimetres in diameter). He then sought to discover whether the animal was responding to the relationship between the two stimuli or to the absolute characteristics of the stimuli. In other words, had the chick learned to select the larger of the two circles, or had it learned to pick the five-centimetre circle? If the former were the case, Köhler reasoned that given the choice between the five-centimetre circle and an even larger one (eight centimetres in diameter), the animal should transpose the relationship and choose the larger circle. This was indeed the result, demonstrating that the animal was responding in terms of the relationship between stimuli rather than, or at least in addition to, their absolute properties.

Counting as an example of an abstract discrimination

Transposition experiments show that animals can respond to relationships between stimuli varying along a particular continuum of physical characteristics: size, brightness, hue, etc. Another question is whether animals can respond to an abstract property of a stimulus array, independent of the actual physical stimuli making up that array. In experiments on counting, the animal must choose between an array containing, say, five stimuli and one containing three. The actual stimuli in the array vary from trial to trial, in order to rule out the possibility that the animal is responding in terms of other features, such as differences in total area or brightness, between the arrays. Counting experiments have been tried on birds more frequently than on any other class of animal, and several species, notably ravens, rooks, and jackdaws, have solved this type of problem. This success may not be entirely by chance, for there is reason to believe that the stimulus that controls when a female bird stops laying eggs is something to do with the number of eggs already laid and in the nest. Chimpanzees, however, have been trained to label pictures of various objects (*e.g.*, spoons, shoes, padlocks, and balls) with the numeral specifying the number of objects in the picture. Moreover, rats and other standard laboratory animals have solved similarly abstract discriminations, for example, of temporal duration. A rat can learn to perform one response after a stimulus has been turned on for two seconds and a different response after the stimulus has been turned on for five seconds. The nature of the actual stimuli employed can vary without disrupting the rat's discrimination, suggesting that it is the duration of the stimuli to which the rat responds.

Concept learning

Concept learning makes up another class of discriminations that may be solved by the abstraction of a particular property or set of properties from a very wide array of individual stimuli. In a typical experiment, a pigeon is shown a large number of colour photographs of natural scenes: half of these contain, somewhere within the scene, all or part of a tree or group of trees; the other half contain no tree (although there might be flowers, a climbing rose, or other plants). Responding to the pictures of trees is rewarded, but responding to the remaining pictures is not. Pigeons rapidly learn the discrimination. In one sense, perhaps this is not surprising: birds that roost in trees, one is inclined to argue, must be able to recognize them. But pigeons can learn other discriminations with almost equal facility; for example, they can be trained to distinguish between underwater scenes containing a fish and similar views with no fish present. In such cases, the class of stimuli in question is one for which their evolutionary history can hardly have prepared pigeons. The question, of course, is how the pigeons solve such problems. Are they, in some sense, abstracting a conceptual rule for categorizing the world into classes of stimuli? Or are they responding to what is no doubt a very large number of particular features that differentiate trees or fish from other objects in the world?

Pigeons, in common with most birds, rely more heavily on vision, and certainly have better developed colour vision, than most mammals—with the exception of primates. There is evidence that monkeys can solve the concept discriminations that have been set to pigeons, but there is no evidence that other mammals can. For extensive comparative analysis, therefore, it is necessary to turn to different kinds of tasks. One that has been studied almost to excess is discrimination reversal. In reversal tasks, an animal is first trained on a simple discriminative problem: for example, to choose the left-hand arm of a T-maze, where it is rewarded, rather than the right arm, where it is not. Once the animal has solved the problem, the experimenter reverses the reward assignments, so that the food is now in the right arm rather than the left. Training continues until the animal has learned this reversal, whereupon the assignment of reward is switched back to the left arm. And so on. Rats trained on this series of reversals eventually become extremely adept at the task. Although the initial reversal causes considerable problems, with animals making many more errors than on the original discrimination, after a few more reversals these difficulties vanish. Eventually, rats solve each new reversal in fewer trials than they took to solve the original discrimination, often with no more than a single error.

The learning of discrimination reversals

Similarly efficient performance has been observed in a relatively wide range of mammals. More interesting was the early suggestion that the few species of fish (goldfish, African mouthbreeders, and Paradise fish) trained on similar problems showed no evidence of the increase in efficiency displayed by mammals. The fish would learn the first reversal slowly and laboriously, and the 20th reversal equally slowly. Subsequent experiments have established that this was an unfairly pessimistic assessment, for improvements in experimental techniques have been accompanied by a significant improvement in the fish's performance, a finding that highlights the extreme difficulty of assessing the relative efficiency of widely differing animals on supposedly the same task. Nevertheless, it remains doubtful that goldfish are as adept at reversal tasks as rats are.

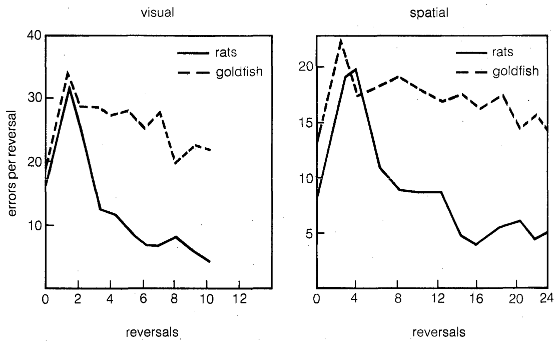

Figure 4: Learning of visual and spatial reversals by rats and goldfish. Although disrupted by the first few reversals of a discrimination, rats soon adjust and learn to reverse their choices with only a few errors. Goldfish also show some adjustment to repeated reversals (they learn later reversals significantly faster than earlier ones), but they do not seem to become as proficient as rats.

The theoretical question, however, is how rats attain such efficiency. What processes allow them eventually to learn the reversal of a discrimination faster than they originally learned the discrimination itself, and often with only a single error? The most plausible suggestion is that they develop a "win-stay, lose-shift" strategy. They learn, in other words, to characterize the alternatives between which they must choose not in terms of their physical features but in terms of whether or not they chose it on the previous trial. They then learn that, if the alternative they chose on the last trial was rewarded, choice of that alternative will be rewarded again on the current trial; while, if it was not, choice of the other alternative will now be rewarded. A variety of other experiments have shown that rats can rapidly learn to use the outcome of one trial to predict the outcome of the next, and hence keep track of regular sequential dependencies in the availability of food or other rewards.

The theoretical basis of reversal learning

Generalized rule learning. Second only to the reversal task in popularity as a tool for the comparative analysis of learning has been the learning set task. The latter is designed to measure the animal's ability "to learn to learn"—in other words, to discover whether after having learned a new behaviour the animal can then more readily learn other related behaviours. For example, an animal is trained on a simple discrimination between two objects, A and B. Once the problem has been solved, the experimenter substitutes a new pair of objects, C and D, for the original pair; when the animal has solved this new problem, yet another new pair, E and F, is substituted, and so on. Rhesus monkeys trained on such a series of problems become progressively more efficient at solving each new problem. Like rats trained on reversal tasks, the monkeys eventually solve each new problem after a single trial, choosing at random on the first trial with each new pair of stimuli but thereafter selecting with essentially perfect accuracy.

Learning set tasks

Performance on learning sets, as on reversals, was once thought to discriminate between more intelligent and less intelligent animals. Apes and rhesus monkeys were extremely efficient at such tasks, more so even than New World monkeys, who were, in turn, more efficient than any nonprimate mammals. Again, however, there are grave difficulties in the way of making valid comparisons. Primates have better developed visual systems than most other mammals, so it is not surprising that they should be better at solving a series of visual discrimination problems. Even the difference in performance between rhesus and cebus monkeys (Old World versus New World monkeys) turns out to be attributable to differences in colour vision more than anything else. Rats appear to solve learning set tasks very efficiently if olfactory stimuli are used.

Nevertheless, there may be important intellectual differences also underlying the differences in performance. One reason for thinking so arises from consideration of the processes probably involved in mastering learning sets. The win-stay, lose-shift strategy that explains the progressive improvement in reversal learning can also explain the same improvement in the learning set task—but only if the animal can generalize the strategy to novel stimuli. Successful performance requires that the animal learn that the alternative chosen on the last trial, and the outcome of that choice, predict which alternative will be rewarded on this trial, whatever the nature of the alternatives. Some evidence suggests that primates can generalize rules of this sort more readily than many other animals can. Monkeys trained on a series of reversals of a single discrimination will learn the reversal of any new discrimination with equal facility. By contrast, cats trained on comparable problems show little evidence of such transfer.

Matching-to-sample discriminations

A discriminative problem widely used in the study of transfer is the "matching-to-sample" discrimination. A pigeon, for example, is required to choose between two disks, one illuminated with red light and the other with green light. The correct alternative on any one trial depends on the value of a sample stimulus, which is also part of each trial. If this third light is red, then the red disk is correct; if green, then green is correct. The correct alternative is the one that matches the sample. Although naturally more difficult than the simple red–green discrimination, matching-to-sample discriminations are learned readily enough by a wide variety of animals; however, there appear to be differences among animals in their capabilities to transfer this learning to a new set of stimuli. Primates and dolphins have shown good evidence of such transfer, but pigeons have shown at best only limited transfer. If pigeons are trained with two or three colours to the point where they are responding with essentially no errors, a substitution of a new colour for one of the trained colours may result in a complete breakdown in the discrimination; there is even some question as to whether they can learn a new matching-to-sample discrimination with new stimuli any faster than pigeons with no prior experience of matching problems.

The abilities to respond in terms of certain relationships between stimuli, to abstract those relationships and invariant features from a complex and changing array of stimuli, and, above all perhaps, to transfer such learning to a completely novel set of physical stimuli seem to be some of the more important processes underlying the solution of complex discriminative problems. The fact that certain evidence suggests that animals may differ in some of these abilities has implications for studies of other forms of problem solving.

Köhler's examples of insight learning

Insight and reasoning. Köhler's best known contribution to animal psychology arose from his studies of problem solving in a group of captive chimpanzees. Like other Gestalt psychologists, Köhler was strongly opposed to associationist interpretations of psychological phenomena, and he argued that Thorndike's analysis of problem solving in terms of associations between stimuli and responses was wholly inadequate. The task he set his chimpanzees was usually one of obtaining a banana that was hanging from the ceiling of their cage or lying out of reach outside the cage. After much fruitless endeavour, the chimpanzees would apparently give up and sit quietly in a corner, but some minutes later they might jump up and solve the problem in an apparently novel manner—for example, by using a bamboo pole to rake in the banana from outside or, if one pole was not long enough, by fitting one pole into another to form a longer rake. Other chimpanzees reached the banana hanging from the ceiling by using a wooden box, or a series of boxes stacked precariously on top of one another, as a makeshift ladder.

Criticisms of Köhler's interpretation

Köhler believed that his chimpanzees had shown insight into the nature of the problem and the means necessary to solve it. According to Köhler's interpretation, the solution depended on a perceptual reorganization of the chimpanzee's world—seeing a pole as a rake, or a series of boxes as a ladder—rather than on forming any new associations. But subsequent experimental analysis has cast some doubts on Köhler's claims. The critical observation is that the sorts of solutions that Köhler took as evidence of insight quite clearly depend on relevant prior experience. Chimpanzees will not fit two poles together to form a rake or stack boxes up to form a ladder unless they have had a great deal of prior experience with those objects. This experience may well occur during play, when the young chimpanzee discovers that using a stick can extend the reach of an arm, or that standing on a box can put one within reach of high objects. Thus, what Köhler was studying, without knowing it, was probably the transfer of earlier instrumental conditioning to new situations. As we have already seen, the ability to transfer an old solution to a new stimulus situation is an important one, relevant to a wide range of problem-solving activities. This ability is not at all well understood, but it will not necessarily be greatly illuminated by describing it as insight. Certainly it is not a process unique to the great apes: if the component tasks are sufficiently well-structured, even pigeons can put together two independently learned patterns of behaviour to solve a novel problem.

Combining information from separate sources to reach a new conclusion is one form of reasoning. The paradigm case of reasoning is the solution of syllogisms; for example, when we conclude that Socrates is mortal given the two separate premises that Socrates is a man and that all men are mortal. Employing transitive inference, we can use the premises that Adam is taller than Bertram and that Bertram is taller than Charles to conclude that Adam must be taller than Charles. Reasoning has often been regarded as a uniquely human faculty, one of the few factors, along with the possession of language, that distinguishes us from the rest of the animal kingdom.

Examples of complex reasoning in nonhuman primates

But are humans the only animals that can reason? The unsatisfying answer must be that it depends on what is meant by reasoning. In a very general sense, most animals appear perfectly able to arrive at a conclusion based on combining information obtained on two separate occasions. A formal demonstration is provided by an experiment on instrumental conditioning discussed earlier. If rats learn that pressing a lever provides sucrose pellets and later learn that eating sucrose pellets makes them ill, they will subsequently put these two pieces of information together and refrain from pressing the lever. Monkeys and chimpanzees, however, have been trained to solve problems that appear more similar to transitive inference. They are first given discriminative training between pairs of coloured boxes, called, for example, A, B, C, D, E. Confronted with the choice between A and B, they learn that choice of A is rewarded and B is not. When B and C are the alternatives, they learn that B is correct; when C and D are the alternatives, C is correct; and so on. Although choice of A is always rewarded, and that of E never is, the remaining three boxes each are associated equally often with reward and with nonreward. Nonetheless, given a choice between B and D on a test trial, the animals choose B.

Syllogistic and transitive inference are not the only forms of reasoning: humans also reason inductively or by analogy. Indeed, analogical reasoning problems (black is to white as night is to __?) form a staple ingredient of some IQ tests. One chimpanzee, a mature female called Sarah, was tested by David Premack and his colleagues on a series of analogical reasoning tasks. Sarah previously had been extensively trained in solving matching-to-sample discriminations, to the point where she could use two plastic tokens, one meaning *same,* which she would place between any two objects that were the same, and another meaning *different*, which she would place between two different objects. For her analogical reasoning tasks, Sarah was shown four objects grouped into two pairs, with each pair symmetrically placed on either side of an empty space. If the relationship between the paired objects on the left was the same as the relationship between those on the right, her task was to place the *same* token in the space between the two pairs. Thus in one series of geometrical analogies, a simple problem would display a blue circle and a red circle on the left and a blue triangle and a red triangle on the right; the correct answer, of course, was *same.* But Sarah was equally correct on more complex problems, even when the relationships in question were functional rather than simply perceptual. For example, she correctly answered *same* when the two objects on the left were a tin can and a can opener and the two on the right a padlock and a key.

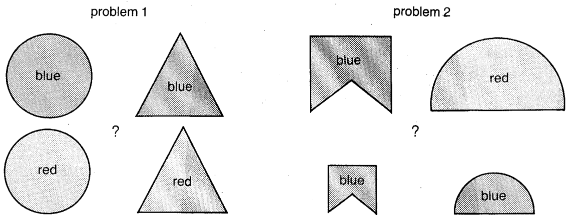

Figure 5: Example of problems in analogical reasoning solved by the chimpanzee Sarah. In each problem her task was to place the token for *same* or *different* between the two pairs of diagrams, depending on whether the relationship between those on the left was the same as, or different from, that between the pair on the right. The correct answer to the first problem is *same;* to the second, *different.*

Solution of analogies requires one to see that the relationship between one pair of items (whether they are words, diagrams, pictures, or objects) is the same as the relationship between a different pair of items. If simple matching-to-sample requires animals to see that one comparison stimulus is the same as the sample and another is different, solving analogies requires them to match relationships between stimuli. The difficulties encountered in training pigeons to generalize simple matching-to-sample discriminations does not encourage one to believe that they would find analogies very easy.

Language learning. The ability to speak was regarded by Descartes as the single most important distinction between humans and other animals, and many modern linguists, most notably Noam Chomsky, have agreed that language is a uniquely human characteristic. Once again, of course, there are problems of definition. Animals of many species undoubtedly communicate with one another. Honeybees communicate the direction and distance of a new source of nectar; a male songbird informs rival males of the location of his territory's boundaries and lets females know of the presence of a territory-owning potential mate; vervet monkeys give different calls to signal to other members of the troop the presence of a snake, a leopard, or a bird of prey. None of these naturally occurring examples of communication, however, contains all of the most salient features of human language. In human language, the relationship between a word and its referent is a purely arbitrary and conventional one, which must be learned by anyone wishing to speak that language; many words, of course, have no obvious referent at all. Moreover, language can be used flexibly and innovatively to talk about situations that have never yet arisen in the speaker's experience—or indeed, about situations that never could arise. Finally, the same words in a different order may mean something quite different, and the rules of syntax that dictate this change of meaning are general ones applying to an indefinite number of other sequences of words in the language.

Defining characteristics of human language

During the first half of the 20th century, several psychologists bravely attempted to teach human language to chimpanzees. They were uniformly unsuccessful, and it is now known that the structure of the ape's vocal tract differs in critical ways from that of a human, thus dooming these attempts to failure. Since then, however, several groups of investigators have employed the idea of teaching a nonvocal language to apes. Some have used a gestural sign language widely used by the deaf to communicate with one another; others have used plastic tokens that stand for words; still others have taught chimpanzees to press symbols on a keyboard. All have had significant success, and several apes have acquired what appears to be a vocabulary of several dozen, and in some cases 100 or 200, "words."

Language learning experiments with apes

Washoe, a female chimpanzee trained by Beatrice and Allan Gardner, learned to use well over 150 signs. Some apparently were used as nouns, standing for people and objects in her daily life, such as the names of her trainers, various kinds of food and drink, clothes, dolls, etc. Others she used as requests, such as *please, hurry,* and *more;* and yet others as verbs, such as *come, go, tickle,* and so on. Sarah, the chimpanzee trained by Premack to use plastic tokens as words, also apparently learned to use tokens for nouns, verbs (*give, take, put*), adjectives (*red, round, large*), and prepositions (*in, under*). But do these signs or tokens really function as words? Does the ape using them, or obeying instructions from a trainer who uses them, really understand their meaning? Or is the ape simply performing various arbitrary instrumental responses in the presence of particular stimuli because she had previously been rewarded for doing so?

There can be little doubt that chimpanzees do have some understanding of what their "words" refer to. Sarah responded appropriately with her token for *red* if asked the question "What colour of apple?" both when an actual red apple was shown as part of the question and when only the token for an apple (which happened to be a blue triangle) was presented. To Sarah, the blue triangle surely stood for, or was associated with, the red apple. In another study, after two chimpanzees had been taught the meaning of a number of symbols for different kinds of food and different tools, they were able not only to fetch the appropriate but absent object when requested to do so, but they could also sort the symbols into two groups, one for foods and one for tools. In another series of studies, a pygmy chimpanzee named Kanzi demonstrated remarkable linguistic abilities. Unlike other apes, he learned to communicate using keyboard symbols without undergoing long training sessions involving food rewards. Even more impressive, he demonstrated an understanding of spoken English words under rigorous testing conditions in which gestural clues from his trainers were eliminated.

As noted above, human language is more than a large number of unrelated words: in accordance with certain implicitly understood syntactic rules, humans combine words to form sentences that communicate a more or less complex meaning to a listener. Can apes understand or use sentences? Undoubtedly they can put together several gestures or tokens in a row. A chimpanzee named Lana, who was trained to press symbols on a keyboard, could type out "Please machine give Lana drink"; Washoe and other chimpanzees trained in gestural sign language frequently produced strings of gestures such as "You me go out," "Roger tickle Washoe," and so on. Skeptical critics, however, have raised doubts about the significance of these strings of signs and symbols. They have pointed out, for example, that when Lana pressed a series of coloured symbols on her keyboard, it was humans who interpreted her actions as the production of a sentence meaning "Please machine give Lana drink." Might it not be equally reasonable to say that she learned to perform an arbitrary sequence of responses in order to obtain a drink? Pigeons can be trained to press four coloured keys—red, white, yellow, and green—in a particular order to obtain food. Psychologists do not feel any temptation to interpret this behaviour as the production of a sentence. What is it about Lana's behaviour that requires this richer interpretation?

Critical interpretations of language experiments

In the case of apes trained to use sign language, two other doubts have been raised. First, there is some reason to believe that a disappointingly high proportion of the apes' gestures may be direct imitations of gestures recently executed by their trainers. Second, a sequence of gestures interpreted as a single sentence is often just as readily interpreted as a number of independent gestures, each prompted, in turn, by a gesture from the trainer. Both these conclusions are based on careful examinations of video recordings of interactions between trainers and apes. Whether they will turn out to be generally true remains an open, and heatedly debated, question.

Without any explicit training, apes have nevertheless learned to produce strings of two or three signs in certain preferred orders: "more drink" or "give me," for example, rather than "drink more" or "me give." Do the animals understand that a string of signs in one order means something different from the same signs in a different order? The following anecdote is suggestive. A chimpanzee called Lucy was accustomed to instructing her trainer, Roger Fouts, by gesturing "Roger tickle Lucy." One day, instead of complying with this request, Fouts signed back "No, Lucy tickle Roger." Although at first nonplussed, after several similar exchanges Lucy eventually did as asked. A simple instance of this sort proves little or nothing, but it may suggest what is needed—namely, that Lucy should understand that changing the order of a set of signs alters their meaning in certain predictable ways. She must generalize the rule that the relationship between the meanings of the signs A-B-C and C-B-A (the same signs in reverse order) is similar to the relationship between the meanings of certain other triplets of signs in her vocabulary when their order is reversed.

Conflicts in approach to the study of animal learning

The research on language in apes forcefully illustrates a conflict, or tension, that is common to many other areas of research on learning in animals. If the investigators are interested in language and communication, they can attempt to communicate as naturally and informally as possible with their apes. This approach involves treating an ape as a fellow social being, with whom one plays and interacts as far as possible as one would with a human child; it also, almost inevitably, results in a style of research where it is exceptionally difficult to control precisely the cues that the ape may be using and even hard to avoid an overly rich, anthropomorphic interpretation of the ape's behaviour. If, on the other hand, the researchers are interested in rigorous experimental control and economical interpretation of the processes underlying the ape's performances, they are likely to set the ape formal problems to solve, with rewards for correct responses and no rewards for errors. But such an approach, however scientific it may seem, must run the risk of missing the point. This is not language; the investigators are not communicating with the ape in the way they would communicate with a child. The very nature of the experimental problems ensures that the ape will not use its language in the way that a child does: to communicate shared interests, to attract a parent's attention to what the child has seen or is doing, to comment on a matter of concern to both.

There is no resolution to this conflict, for both approaches have their virtues as well as their dangers, and both are therefore necessary. In just the same way, the study of a rat pressing a lever in a Skinner box or of a dog salivating to the ticking of a metronome seems to many critics a sterile and narrow approach to animal learning—one that simply misses the point that, if the ability to learn or profit from experience has evolved by natural selection, it must have done so in particular settings or environments because it paid the learner to learn something. It would be foolish to deny this obvious truism: of course it pays animals to learn. Indeed, it may pay them to learn quite particular things in specific situations, and different groups of animals may be particularly adapted to learning rather different things in similar situations. None of this should be forgotten, and the study of such questions requires the scientist to forsake the laboratory for the real world, where animals live and struggle to survive. But few sciences can afford to miss the opportunity to manipulate and experiment under laboratory conditions where this is possible, and none can afford to forget the benefits of precise observation under controlled conditions.

Human Learning and Cognition

A common goal in defining any psychological concept is a statement that corresponds to common usage. Acceptance of that aim, however, entails some peril. It implicitly assumes that common language categorizes in scientifically meaningful ways; that the word learning, for example, corresponds to a definite psychological process. However, there appears to be good reason to doubt the validity of this assumption. The phenomena of learning are so varied and diverse that their inclusion in a single category may not be warranted.

Recognizing this danger (and the corollary that no definition of learning is likely to be totally satisfactory) a definition proposed in 1961 by G.A. Kimble may be considered representative: Learning is a relatively permanent change in a behavioral potentiality that occurs as a result of reinforced practice. Although the definition is useful, it still leaves problems.

The definition may be helpful by indicating that the change need not be an improvement; addictions and prejudices are learned as well as high-level skills and useful knowledge.

The phrase relatively permanent serves to exclude temporary behavioral changes that may depend on such factors as fatigue, the effects of drugs, or alterations in motives.

The word potentiality covers effects that do not appear at once; one might learn about tourniquets by reading a first-aid manual and put the information to use later.

To say that learning occurs as a result of practice excludes the effects of physiological development, aging, and brain damage.

The stipulation that practice must be reinforced serves to distinguish learning from the opposed loss of unreinforced habits. Reinforcement objectively refers to any condition—often reward or punishment—that may promote learning.

However, the definition raises difficulties. How permanent is relatively permanent? Suppose one looks up an address, writes it on an envelope, but five minutes later has to look it up again to be sure it is correct. Does this qualify as relatively permanent? While commonly accepted as learning, it seems to violate the definition.

What exactly is the result that occurs with practice? Is it a change in the nervous system? Is it a matter of providing stimuli that can evoke responses they previously would not? Does it mean developing associations, gaining insights, or gaining new perspective?

Such questions serve to distinguish Kimble's descriptive definition from theoretical attempts to define learning by identifying the nature of its underlying process. These may be neurophysiological, perceptual, or associationistic; they begin to delineate theoretical issues and to identify the bases for and manifestations of learning. (The processes of perceptual learning are treated in the article PERCEPTION.)

This article is divided into the following sections:

Theories of learning

THE RANGE OF PHENOMENA CALLED LEARNING

Even the simplest animals display such primitive forms of adaptive activity as habituation, the elimination of practiced responses. For example, a paramecium can learn to escape from a narrow glass tube to get to food. Learning in this case consists of the elimination (habituation) of unnecessary movements. Habituation also has been demonstrated for mammals in which control normally exercised by higher (brain) centres has been impaired by severing the spinal cord. For example, repeated application of electric shock to the paw of a cat so treated leads to habituation of the reflex withdrawal reaction. Whether single-celled animals or cats that function only through the spinal cord are capable of higher forms of learning is a matter of controversy. Sporadic reports that conditioned responses may be possible among such animals have been sharply debated.

At higher evolutionary levels the range of phenomena called learning is more extensive. Many mammalian species display the following varieties of learning.

Classical conditioning. This is the form of learning studied by Ivan Petrovich Pavlov (1849–1936). Some neutral stimulus, such as a bell, is presented just before delivery of some effective stimulus (say, food or acid placed in the mouth of a dog). A response such as salivation, originally evoked only by the effective stimulus, eventually appears when the initially neutral stimulus is presented. The response is said to have become conditioned. Classical conditioning seems easiest to establish for involuntary reactions mediated by the autonomic nervous system.

Conditioning of involuntary reactions

Instrumental conditioning. This indicates learning to obtain reward or to avoid punishment. Laboratory examples of such conditioning among small mammals or birds are common. Rats or pigeons may be taught to press levers for food; they also learn to avoid or terminate electric shock.

Chaining. In the form of learning called chaining the subject is required to make a series of responses in a definite order. For example, a sequence of correct turns in a maze is to be mastered, or a list of words is to be learned in specific sequence.

Acquisition of skill. Within limits, laboratory animals can be taught to regulate the force with which they press a lever or to control the speed at which they run down an alley. Such skills are learned when a reward is made contingent on quantitatively constrained performance. Among human learners complex, precise skills (*e.g.,* tying shoelaces) are routine.

Discrimination learning. In discrimination learning the subject is reinforced to respond only to selected sensory characteristics of stimuli. Discriminations that can be established in this way may be quite subtle. Pigeons, for example, can learn to discriminate differences in colours that are indistinguishable to human beings without the use of special devices.

Concept formation. An organism is said to have learned a concept when it responds uniquely to all objects or events in a given logical class as distinct from other classes. Even geese can master such concepts as roundness and triangularity; after training, they can respond appropriately to round or triangular figures they have never seen before.

Principle learning. A subject may be shown sets of three figures (say, two round and one triangular; next, two square and one round, and so on). With proper rewards, the subject may learn to distinguish any "odd" member of any set from those that are similar. Animals as low in the evolutionary scale as the pigeon can master the principle of this so-called oddity problem.

The oddity problem

Problem solving. Examples of human problem solving are familiar: finding the roots of a quadratic equation, solving a mechanical puzzle, and navigating by the stars. Among other animals, chimpanzees have been observed to solve problems requiring toolmaking.

This list only samples from the remarkable array of animal activities categorized as learning. Beginning with habituation, they range from the simple adjustments of single-celled animals up to the highest intellectual accomplishments of mankind. It would be wonderful indeed if a single theory of learning were enough to account for all this diversity. So far, however, no theory of learning adequately covers more than a small fraction of these phenomena.

THE STATE OF LEARNING THEORIES

Yet, at the start of the 20th century, vast psychological systems, such as behaviourism and Gestalt psychology, indeed were offered as explanations of learning (and of much wider ranges of behaviour as well). And as late as the 1940s, comprehensive theories of learning were still believed to be reasonably near at hand. But during the next three decades it grew clear that such theories are tenable only for very limited sets of data. By the late 20th century learning theory seemed to consist of a set of hypotheses of limited applicability.

Important earlier theorists. Beginning in the 1930s a number of general theories were advanced in attempts to organize most or all of the psychology of learning. The most influential of the contributing theorists are noted below.

E.R. Guthrie (1886–1959) wrote that learning requires only that a response be made in a changing situation. Any response was held to be linked specifically to the situation in which it was learned. Guthrie argued that learning is complete in one trial, that the most recent response in a situation is the one that is learned, and that responses (rather than perceptions or psychological states) provide the raw materials for the learning process.

For E.C. Tolman (1886–1959) the essence of learning was the acquisition by the organism of a set of what he called Sign-Gestalt-Expectations. These referred to propositions said to be made by the learner that his own specific response to given signs (or stimuli) would result in such and such circumstances later on. Tolman seemed to be saying that what the learner acquires is a specific knowledge of "what leads to what." In brief, his theory was that the learner develops expectations based on experience and that learning depends entirely on successions of events. Although less vocal on the point than others, Tolman implied that learning was a gradual process.

The theory offered by Clark L. Hull (1884–1952), over the period between 1929 and his death, was the most detailed and complex of the great theories of learning. The basic concept for Hull was "habit strength," which was said to develop as a function of practice. Habits were depicted as stimulus-response connections based on reward. According to Hull, responses (rather than perceptions or expectancies) participate in habit formation, the process is gradual, and reward is an essential condition.

Comparison of these theories yields major questions for empirical investigation. Is learning continuous or discontinuous; is it a gradual or sudden (one-trial) process? Is learning a matter of establishing stimulus–response (S–R) connections or does it depend on the learner's understanding of perceptual relationships? Is reward necessary for learning?

Are theories of learning necessary? Such major investigators of learning as B.F. Skinner and J.A. McGeoch maintained in the 1930s and 1940s that preoccupation with theory was misguided. For them the approach simply was to discover the conditions that produce and control learned behaviour. Beyond this, their interests diverged. Skinner studied instrumental conditioning (operant conditioning, as he called it) among rats; McGeoch specialized in human rote memory. Although study of rote verbal learning had become heavily theoretical by the 1970s, Skinner and his associates stuck to their empirical guns, guiding a variety of programs for the practical control of behaviour. Teaching machines and computer-aided instruction, behaviour modification (*e.g.,* the use of tokens to reward desired behaviour among psychiatric patients), and planned utopian societies (Walden II) all found scientific origins in Skinner's rejection of theory in favour of direct efforts to produce results.

Intervening variables and hypothetical constructs. Learning is a concept and not a thing, and the activity called learning is inferred only through behavioral symptoms. The distinction implicit here between behaviour and inferred process is one of Tolman's major contributions and serves to reconcile influential views that might seem completely at odds. Classical behaviourism, as developed by John B. Watson (1878–1958), rejected every mentalistic account and sought to limit analysis to such physiological mechanisms as reflexes. Watson argued that these are objective in a way that so-called thoughts, hopes, expectancies, and images cannot be. The opposing view holds that experiential (introspective) activity (exactly what Watson sought to dismiss) does require discussion.

Watson's reflex theory

Tolman called himself a behaviourist and ostensibly was bound by Watson's insistence on objectivity. But he also was interested in thinking, expectancy, and consciousness. Tolman found his solution to this problem of incompatible theories after his association with the Vienna Circle of Logical Positivists, whose deterministic teachings he brought to the attention of U.S. psychologists about 1920. He maintained that learning is inexorably produced (determined) by such independent (directly manipulable) variables as the organism's previous training and physiological condition and by the response the environment requires. According to Tolman, the development of learning is revealed through the changing probability that given behaviour (the dependent variable) will result. He held that learning itself is not directly observable; it is an intervening variable, one that is *inferred* as a connecting process between antecedent (independent) variables and consequent (dependent) behaviour.

An attractive possibility is that intervening variables may have discoverable physiological bases. Psychologists Paul E. Meehl and Kenneth MacCorquodale proposed a distinction between the abstractions advocated by some and the physiological mechanisms sought by others. Meehl and MacCorquodale recommended using the term *intervening variable* for the abstraction and *hypothetical construct* for the physiological foundation. To illustrate: Hull treated habit strength as an intervening variable, defining it as an abstract mathematical function of the number of times a given response is rewarded. By contrast, Edward L. Thorndike (1874–1949) handled learning as a hypothetical construct, positing a physiological mechanism: improved conduction of nerve impulses.

Intervening variables and hypothetical constructs need not be incompatible; Thorndike's hypothetical neural process could empirically be found to be the mechanism through which Hull's abstraction operates.

Miniature theories. With growing realization of the complexity of learning, the grand theories of Guthrie, Hull, and Tolman generally have been abandoned except as historic landmarks. Hope for any impending, comprehensive theory was almost dead in the 1970s. More modest miniature theories remain, many likely to be of temporary value. An account of their major themes and issues, however, should have more enduring interest.

MAJOR THEMES AND ISSUES

Association. A dominant ancient theme in theories of learning has been that of association. Although the concept was accepted by Aristotle, it was brought into the developing psychology of learning by British empiricist philosophers (Locke, Berkeley, Hume, the Mills, and Hartley) during the 17th, 18th, and 19th centuries. Popular acceptability of the notion of association was related to progress in the physical sciences. The physical universe had been shown to consist of a limited number of chemical elements that can combine in innumerable ways. By analogy, a science of "mental chemistry" seemed appealing. The theorized elements in this new "science" were called ideas, said to be based on what were named sensations. The synthesizing principles by which these posited ideas combined in conscious experience were expressed as so-called laws of association. It was suggested that such conditions as temporal and spatial contiguity, repetition, similarity, and vividness favoured the formation of associations, and each was called a law of association. Thus, there were "laws" of repetition, of similarity, and so on.

Rote learning

At the end of the 19th century the notion of association was widely accepted among psychologists. German psychologist Wilhelm Wundt (1832–1920) took a position nearly identical with that of the British empiricist philosophers. Also in Germany, Hermann Ebbinghaus (1850–1909) began to study rote learning of lists of nonsense verbal items (*e.g., XOQ, ZUN, ZIB*). He maintained that the association of each word with every succeeding word was the primary mechanism in learning these lists. Pavlov in Russia offered temporary associative connections in the nervous system as a hypothetical basis for conditioned reflexes.

These European influences coalesced in North America. Wundt's notions were introduced there when a student of his from England, Edward Bradford Titchener (1867–1927), came to teach at Cornell University in Ithaca, New York. Ebbinghaus' method and theory became standard in Canadian and U.S. studies of verbal learning; Watson and other behaviourists applied Pavlov's conceptions to their learning experiments. Experimental psychology in the Western Hemisphere came to be dominated by what seemed to be a search for laws of association.

What is associated? Investigators asked whether associations are formed between observable stimuli and responses (S–R) or between subjective sensory impressions (S–S). One group that included Hull, Guthrie, and Thorndike took the relatively objective S–R position, while Tolman and others favoured the more introspective, perceptual S–S approach. For a time S–R theorists held popularity; behavioral responses are readily observable evidence of learning, and many included them in the associative process itself.

But the reduction of learning to mere external stimuli and overt responses raised discordant theoretical objections that the inner activities of the organism were being ignored. S–R theories failed to account for a host of learned phenomena. For example, people could be trained to say they heard sounds even when such auditory stimuli were absent. They said they dreamed about what they had learned, too; yet there need be no immediate external stimulus, nor does the dreamer always make the responses he dreams about.

Physiological psychologists and biologists found ways of delivering electrical stimulation directly to the brain; this eliminated the sensory stimuli and vocal or motor responses on which S–R theories hinge. Direct neural stimulation was found to be an adequate signal and the electrical response of the brain itself proved susceptible to conditioning. At this level of the nervous system, distinctions between stimulus and response mean less than at the periphery, and the S–S versus S–R controversy is no longer such a burning issue.

Direction of association. Classical conditioning dependably has been shown to proceed only forward in time. Bell must precede food if a conditioned reaction is to be established. If it had any effect, the reverse procedure (food before bell) would be called backward conditioning; but at most it only inhibits other reactions. There seems to be a relatively brief optimal interval in classical conditioning at which associations are most easily made. For quick reflexes such as the eyeblink, this interval is about one-half second; longer or shorter intervals are less effective. For slower reactions such as salivation the interval is longer, perhaps two seconds or so.

Forward and backward association; context association

In learning verbal associations the situation appears to be quite different. When one learns the Russian–English forward association *da*–"yes," he also learns the English–Russian backward association "yes"–*da.* Moreover, timing is much less critical than in classical conditioning. Verbal pairs are learned with almost equal ease whether presented simultaneously or separated by several seconds.

In what is called context association, the general environment may begin to elicit a response that is being conditioned to a specific stimulus. Thus, a dog may salivate simply on being brought into the experimental room—before any bell rings. Verbal associations also can be weakened by changes in the general situation.

Repetition. A major theoretical issue concerns whether associations grow in strength with exercise or whether they are fully established all at once. Evidence is that learning usually proceeds gradually; even when a problem is solved insightfully, practice with similar tasks tends to improve performance. Some (perhaps most) learning theorists have concluded that repetition gradually enhances some underlying process in learning.

Stimulus sampling, a statistical learning theory

The view that associations develop at full strength in a single trial leads to a typical question. How can the gradual nature of most learning be explained if all-or-nothing is the rule? One possible answer suggested by Guthrie has led to so-called stimulus-sampling theory. The theory assumes that associations indeed are made in just one trial. However, learning *seems* slow, it is said, because the environment (context) in which it occurs is complex and constantly changing. Given a changing environment, the sample of stimuli will differ from trial to trial. Thus, it is reasoned, it should take many trials before a response is associated with a relatively complete set of all possible stimuli.

In this light, the strength (or probability) of a response should increase with practice even if the elementary associative process occurs in a single trial.

These stimulus-sampling notions translate easily into mathematical form; they are an example of statistical learning theory, a more general development in the quantitative treatment of learning.

Reinforcement. Repetition alone does not ensure learning; eventually it produces fatigue and suppresses responses. An additional process called reinforcement has been invoked to account for learning, and heated disputes have centred on its theoretical mechanism.

Objectively reinforcement refers to the use of stimuli that have been found to facilitate learning. Under appropriate conditions, these include praise, food, water, opportunity to explore, sexual stimuli, money, electric shock, and direct brain stimulation.

More theoretically, the term reinforcement expresses various theoretical hunches about some specialized subjective quality all such stimuli might share. Food for a hungry animal is a well-established reinforcer, conceivably through its distinctive appearance and odour. It tends to elicit a set of responses: approaching, chewing, tasting, swallowing; these may produce additional perceptual activities that reduce the drive or desire for food (*e.g.,* by halting stomach contractions that are experienced as hunger pangs). But no single subjective quality imagined by theorists seems invariably effective in reinforcement studies. Perhaps some combination of introspective influences is critical, or it may be that perceptual processes apply differently from one learning situation to another.

Anti-associationistic positions. Not all psychologists have accepted the general validity of association theories; many have suggested that considerations other than association are crucial to learning.

Organization. Major critics of association theory included such Gestalt psychologists as Wolfgang Köhler (1887–1967), who held that learning often entails a perceptual restructuring of environmental relationships. Köhler cited his own studies of insightful learning by a chimpanzee. The animal learned to join two sticks (akin to a jointed fishing pole) as a tool to pull in a banana that was out of arm's reach and of either short stick alone. The ape was described as sitting quietly (as if in thought), and then suddenly fitting the sticks together to rake in the fruit. It was argued that the ability to perceive new ways of relating the sticks to the banana was essential in solving the problem.

Learning as perceptual organization

Similar organizational processes in perceiving can be demonstrated in serial verbal learning. Memorizing the list *thick, wall, it, tea, of, myrrh, seize, knots, trained* should demand some rehearsal. Yet, notice the phonetic resemblance to Shakespeare's famous line from *The Merchant of Venice*: "The quality of mercy is not strained. . . ." With that kind of perceptual organization, learning can become quick and easy.

A powerful argument also was made by psycholinguists who criticized what they took to be the associationistic account of language learning. Even assuming one-trial acquisition, it was held that such individually learned associations could not account for all combinations of words people use; there are simply too many. They suggested that learning a language requires some general organizing structure on which words are hung. Some proponents of this position hold that this structure does not depend on learning, being transmitted genetically from parent to child.

Inhibition. Gestalt interpretations often reject the associationistic hypothesis wholesale. Other theorists endorse the notion of association, but hold it to be less important than is a process of inhibition through which errors in learning are eliminated. Such theorists find support in evidence for the development of learning sets (what is called learning to learn).

For example, a monkey may learn a long series of discriminations; *e.g.,* red versus green, black versus white, round versus square, large versus small, triangle versus ellipse. After solving several hundred such problems, some monkeys learn to master each new one in a single trial, as if insightfully. The animal is said to have learned to learn such discriminations.

Learning to learn: error-factor theory

Evidence clearly shows that the monkey gradually abandons erroneous tendencies as learning proceeds. At first it might be prone to choose stimuli that are red, black, round, large, or triangular. Correct choices do not always correspond to the animal's initial biases, and their suppression (inhibition, extinction) eventually permits single-trial learning. Theoretically, organisms learn to learn by inhibiting erroneous behaviour; thus, Harry F. Harlow, a proponent of this view, called it an error-factor theory.

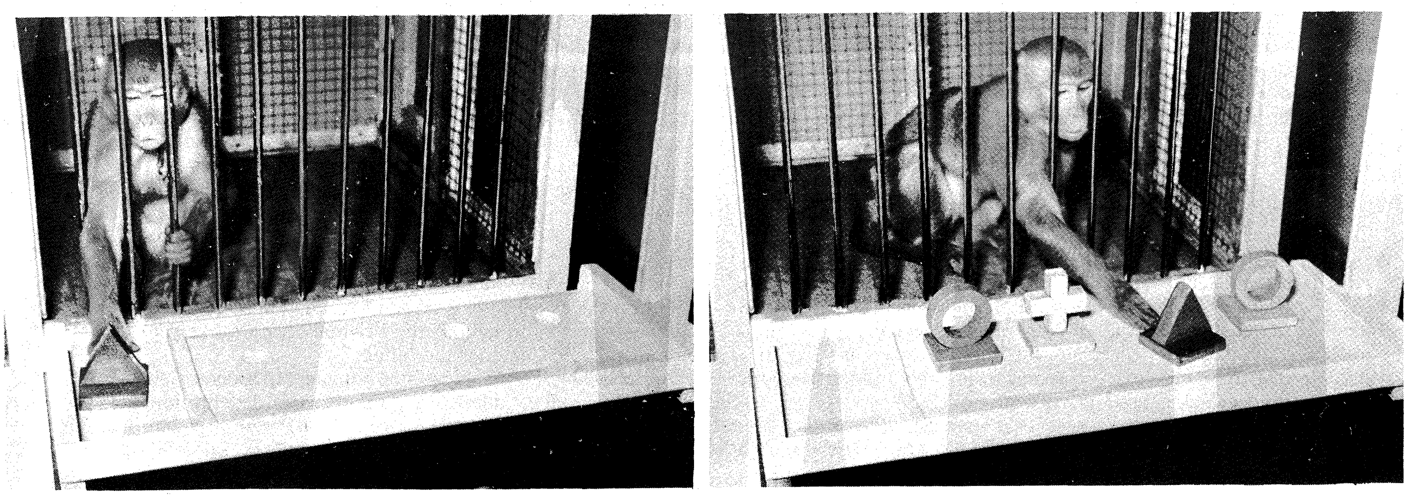
Motivation in learning. Motivation popularly is thought to be essential to learning. Yet many theorists suggest that motives make little or no direct contribution—that they simply tend to promote practice.

Motivation and performance. Learning was defined above as a change in a behavioral potentiality. Realization of such potential seems to be related to the learner's level of motivation. A pupil who has learned the names of all members of the British Commonwealth of Nations would be expected to recite them with particular energy under some sort of incentive (reward or punishment). The incentive is said to raise his level of motivation.

Incentives do seem to invigorate performance up to a point; however, when motivation seems particularly intense, some studies show performance to deteriorate. From such data some theorists conclude that the effect of drive intensity on performance follows a U-shaped course, first helping and later hindering.

Greatly increased motivation also may change performance qualitatively by introducing new inefficient modes of behaviour. A student may be so tautly driven to do well on an examination that his tension, fear of failure, and his visceral and muscular discomfort interfere with performance.

Motivation and learning. To show that motivation af-



Learning-to-learn experiment by Harry F. Harlow.
The monkey has been trained to expect food after lifting an object. In the first picture, the monkey lifts the triangle after having been shown a sample triangular form. In the second picture, taken several minutes later, the monkey selects the triangle from among other forms. The process is repeated with the circle and the cross.

fects performance of what has been learned is not the same as demonstrating its effect on the process of learning itself. This would require that individuals learn under various levels of motivation and be tested under the same incentive levels. (This is to control for the effects of motivation on performance alone.) And, indeed, the best-controlled experiments of this design indicate learning effects to be the same under different levels of motivation.

Varieties of learning. It is debated whether all forms of learning represent the same process. This question applies even to relatively primitive phenomena such as classical and instrumental conditioning.

Classical and instrumental conditioning

In instrumental conditioning reinforcement is contingent on the learner's response; a rat receives food only if it presses the lever. In classical conditioning there is no such contingency; a dog is fed whether or not it salivates. But this is a distinction in experimental procedure. Whether the underlying process of learning is the same for both is quite another question.

Classical conditioning usually has been reported for glandular, autonomically mediated, involuntary responses (*e.g.,* salivation, heart rate). By contrast, voluntary movements of skeletal muscles more typically have been found to be conditionable instrumentally. However, to theorize that classical conditioning is exclusively effective for one class of responses while instrumental conditioning is uniquely applicable to others seems to be a mistake.

Evidence that seems to demolish such theorizing comes from a series of experiments directed by Neal E. Miller at the Rockefeller University in New York City. Rats were immobilized with curare; this drug blocks the junction between muscle and nerve to paralyze the skeletal muscles. However, a curarized individual still can show autonomic, involuntary signs of emotional activity such as a rapidly beating heart.

Electrical stimulation of selected parts of the brain seems to be rewarding; animals behave as if they seek such stimulation and will learn to press a switch for it (voluntary muscle function). Using curarized animals, Miller and others made the rewarding stimulation contingent on such typically *involuntary* responses as changes in heart rate, blood pressure, contractions of the bowel, and salivation. Their research has shown such instrumental conditioning to be effective for all these responses. The evidence appears to destroy the once-popular hypothesis that involuntary autonomic reactions are subject only to classical conditioning. In this sense the two primitive forms of learning seem to be the same.

Stages of learning. Should the basic process prove to be the same for all varieties of learning, there would still be reason to believe that it operates differently from one stage of practice to another. For example, in coping with painful stimuli (*e.g.,* electric shocks) laboratory animals seem to learn in two successive, distinguishable phases. Apparently they first learn to fear the situation, *then* to avoid it.

For example, when an animal learns to avoid painful shock (by turning a paddle wheel or by running away), a warning signal can be given; *e.g.,* with a flash of light or a buzzer. The two stages of learning then can be studied separately. The animal first is subjected to pairings of signal and unavoidable shock to establish (by classical conditioning) signs of fear in response to the signal. In the second stage it is allowed to stop the frightening signal by making an appropriate response. Preconditioned members of the many animal species have learned to avoid the signal itself, even though shock never was presented again.

The role of fear

Theoretically, the classically conditioned signs of fright in response to the initially neutral signal have a motivating function. Termination of that stimulus is seen as instrumental—that is, as rewarding the animal by reducing learned experiences of fear.

Classical conditioning. A two-stage process has been suggested even for classical conditioning. One theory is that in the first stage the subject learns that a neutral stimulus (a ringing bell) is to be presented along with another stimulus (food) whether or not it exhibits a reaction (salivation). Conditioning of any reaction is held to constitute the second stage of learning. The skimpy supporting evidence points to the first stage as a prerequisite, suggesting that responses can only be conditioned after the sensory conditions are recognized.

Verbal learning. Theories that interpret verbal learning as a process that develops in stages also have been worked out. In one variety of rote learning the subject is to respond with a specific word whenever another word with which it has been paired is presented. In learning lists that include such paired-associates as *house–girl, table–happy,* and *parcel–chair,* the correct responses would be *girl* (for *house*), *happy* (for *table*), and *chair* (for *parcel*). By convention the first word in each pair is called the stimulus term and the second the response term. Paired-associate learning is theorized to require subprocesses: one to discriminate among stimulus terms, another to select the second terms as the set of responses, and a third to associate or link each response term with its stimulus term. Although these posited phases seem to overlap, there is evidence indicating that the first two (stimulus discrimination and response selection) precede the associative stage.

Remembering and forgetting. Learning, remembering, and forgetting often have been considered separate processes. Yet these distinctions seem to blur in the face of contemporary research and theory.

Transient and enduring memory. Evidence for stages of learning comes from observations of learners over relatively extended series of trials (or comparatively long periods). The empirical data suggest that several alterations in memory function occur even during a single trial. The process that commits information to memory also seems to have several stages.

Immediate, short-term, and long-term memory

Most theorists attribute at least three stages to memory function: immediate, short-term, and long-term. Immediate memory seems to last little more than a second or so. For example, subjects may be asked to remember where specific objects are located within a complex array they have just seen. Their performance shows that considerable information is retained only briefly, rapidly fading unless it is given special attention.

Short-term memory lasts about 15–30 seconds, as after looking up a telephone number. One makes the call, discovers he has forgotten the number (perhaps in the midst of dialing), and has to look it up again. Nevertheless, such short-term retention does make information available long enough to be rehearsed; if the learner repeats it to himself, the number can be transferred to some sort of longer term storage.

Thus, rehearsal seems to facilitate transfer of data from short-term to long-term memory. Once committed to long-term memory, the results of learning tend to endure but can be abruptly abolished when specific parts of the brain are injured or removed; they also are vulnerable to interference from other learning. Nevertheless, conditioned responses may undergo little or no forgetting over periods of months or years. And electrical stimulation of the surgically exposed brain while a person is awake can make him remember experiences long thought forgotten. Recall is reported to be similarly enhanced during hypnosis.

Retrieval. The amount of information one readily can retrieve from what is stored in memory is prodigious. In locating an item in memory, he apparently activates a system that stores a set of related data; then he searches for the item within that system. For example, a person is shown a long, randomly mixed list of words that belong to different categories (*e.g.,* names of animals, plants, professions, tools). When asked to remember as many words as he can, he spontaneously will tend to group them by category; this is called clustering of recall. Thus, names of animals (spread throughout the original list) are likely to be remembered one after the other.

Clustering; tip-of-the-tongue phenomenon

Studies of the familiar tip-of-the-tongue experience yield analogous results. College students who heard definitions (of this sort: a small, open Chinese boat) were asked to supply the right word (in this case it would be sampan). Those who said they might have it somewhere on the tip of the tongue were significantly accurate in guessing the first letter and the number of syllables. Their tendency also to recall words that sounded the same or that had similar meanings is reminiscent of clustering.

Considerable evidence of this kind supports the theory that the process of retrieval first locates stored data in some sort of associative network and then selects an item with specific characteristics.

Forgetting. Whether immediate and short-term data simply decay or are lost through interference is a matter of controversy. However, evidence is clearer that interference affects retention of information in long-term storage. Retention of the word *happy* (learned as a paired associate of *table*) seems to be subject to the interference of a strong tendency to associate *table* with *chair.* Thus, the paired associate *table–happy* becomes more readily forgotten when followed by *parcel–chair* as the very next item in a list; this seems to help *chair* reassert its old tendency to be associated with *table.* In general, it is found that associations tend to interfere with or to inhibit one another. Interference deriving from earlier (and later) associations is called proactive inhibition (and retroactive inhibition). These two forms of inhibition commonly are accepted as major processes in forgetting, proactive inhibition being assigned greater importance.

Contemporary trends in learning theory. In the early 1930s the distinction between learned and inherited behaviour seemed clearer than it does now. The view that any bit of behaviour either was learned or simply developed without learning seemed straightforward. Studies based on these expectations led investigators to conclude that rat-killing behaviour among cats is learned rather than instinctive, that human fears are all acquired, or that intelligence is completely the result of experience. Learning theorists were saying then that most behaviour is learned and that biological factors are of little or no importance.

Forty years later this position seemed grossly untenable. The once-implied sharp distinction between learned and inherited behaviour had become badly blurred. For example, it has been found that the young of many animal species automatically will learn to follow the first large, moving, noisy object presented (as if it were their mother). This special form of learning is called imprinting and seems to occur only during a critical early stage of life. Among mallard ducklings imprinting is most feasible about 15 hours after hatching. During this period a duckling will imprint as easily on an old man or on a rubber ball as it will on a mother duck. Is this instinctive or learned behaviour? Manifestly it is both. The instinctive tendency to be imprinted is part of the duckling's biological heritage; while the object on which it is imprinted is a matter of experience. What is significant for learning theory is that the contribution of biology cannot be ignored.

Imprinting, a special form of learning

Learning theorists once ruled a number of concepts out of court on the ground that they seemed objectively unclean. Image, cognition, awareness, and volition, all are concepts that were denied acceptance on this basis. They sounded mentalistic, subjective, introspective, and unverifiable. Yet, in the late 20th century these were being given more serious scientific consideration.

For example, the concept of image in learning has begun to show real viability. It has long been reported that the more meaningful a list of words is, the easier it will be to learn. Degree of meaningfulness for a word may be defined by the objectively observed probability that people quickly can give another word in response. Using such empirical scales of meaningfulness, a reliable and substantial relationship has been found between meaningfulness and ease of learning. However, meaningful words also may evoke vivid images that subjects can describe when asked. When they do evoke such imagery, they seem to be learned and remembered even more easily. Thus, learning theory seems to be enriched when introspective data are used.

A final fault in much learning theory stems from earlier tendencies to use the laws of physics as a model. Theorists once sought general laws of wide applicability that tended to obscure differences among individuals. For example, so complete was Hull's faith in universal "laws" of animal behaviour, that he based his hypothesis about the optimal interval for classical conditioning in humans, other mammals, and birds on the pattern of nerve conduction in the optic nerve of the horseshoe crab. There was little concern even for species differences. Within the same species, individual differences were viewed as a mere nuisance; it was believed that, by studying many subjects and by computing averages, basic laws of learning could be found. However, so-called laws were developed in this way that failed to represent even one individual whose behaviour contributed to the average. More than any other consideration, this has led learning theorists to take a belated look at the importance of individual differences and species differences in learning.

(G.A.K.)

Psychomotor learning

Human psychomotor skills are organized patterns of muscular activities guided by changing signals from the environment. Driving a car and eye–hand coordination tasks such as drilling a tooth, throwing a ball, typing, operating a lathe, and playing a trombone are behavioral examples. Also called sensorimotor and perceptual-motor skills, they are studied as special topics in the experimental psychology of human learning and performance. In research concerning psychomotor skills, particular attention is given to the learning of coordinated activity of the arms, hands, fingers, and feet; the role of verbal processes (see below *Concept formation)* is not emphasized.

THE RANGE OF SKILLS

The term "skill" denotes a movement that is reasonably complex and the execution of which requires at least a minimal amount of practice. Thus skill excludes reflex acts. One does not become skilled at sneezing or at blinking the eyes when an object approaches. At the same time, it has become increasingly apparent to scientists investigating the performance and acquisition of motor acts that the performance of complex skills is closely linked to sensations arising from the things the performer looks at, sensations from the muscles that are involved in the movement itself, as well as stimuli received by other sensory end organs. Thus the term "sensorimotor skill," denoting the close relationship between movement and sensation in the acquisition of complex acts, is found within the research literature with increasing frequency.

Simple components of bodily skills. Most of life's skills are continuous and complex and contain a multitude of integrated components; however, these complex skills may be analyzed by examination of their component parts.

Reception of stimulus and selection and initiation of response

The performance of a skill may be broken down into several time intervals. Initially the performer must be attentive and alert enough to be receptive to some kind of sensory information, which may in turn lead toward some kind of motor act. For this to occur the performer usually becomes aware of some kind of stimulus that is intense or distinctive enough to be perceived as different from other sensory information.

As this cue occurs the performer then must make a decision to act or not to act; and this is generally dependent upon his past experience within similar situations and with similar stimuli, as well as upon his feelings about his personal capabilities. If he decides to act, the next thing that occurs is the selection of an appropriate motor response from the entire "collection" of motor responses that he has acquired.

In the laboratory, a subject's reaction time is the time between the presentation of some kind of stimulus and the performer's initiation of response. The individual's speed of reaction in such situations is dependent upon a number of variables, including the intensity of the stimuli; for example, a person will initiate a movement more quickly to increasingly louder sounds until a limit is reached. If too loud a sound is presented it will delay the onset of the movement and result in a longer reaction time. Similarly, a longer reaction time will be recorded in such experiments if the subject is aware that he will have to initiate a complex movement or if the subject must choose from among a number of stimuli before initiating a movement (*e.g.,* if he must move only if one of a number of various coloured lights is turned on).

Factors that affect quality of motor response

The quality of the movement then initiated is dependent upon a number of other factors, the precision of the act required, the past experience of the performer in similar skills, the speed of the movement, the force of the motor act, as well as body part or parts to be moved.

The efficient performance of many types of extremely simple motor skills may be limited by inherent response capacities built into the human nervous system. Finger tapping at more than ten times per second for example is not usually possible. A person's ability to keep a body part relatively steady may be disturbed by natural, regular, and rather predictable oscillation rates of the limbs, fingers, and of the total body (evidenced in measures of body sway).

Individuals vary greatly in their ability to exercise force with various body parts. At the same time, there are limits beyond which it is not realistic to expect humans to go when evidencing strength in various tasks.

Careful experimentation reveals that because of the complexity of the human motor system it is unlikely that an individual ever repeats an apparently similar movement in precisely the same way. Thus the acquisition of skill in a given task involves the performance of a reasonably consistent response pattern, which varies, within limits, from trial to trial.

Basic abilities that contribute to motor skills

It is a common observation that there seem to be a number of basic motor abilities that may underlie the performance of a number of life's activities. This subject was investigated rather extensively during the 1950s and 1960s. The intercorrelation of performance scores elicited from thousands of young adult subjects who participated in these investigations revealed that there are in fact a number of basic abilities that contribute to the efficient performance of both fine and gross motor skills. Although a detailed examination of these abilities is not possible here, in general it was revealed that there are five components of what might be broadly referred to as "manual dexterity," including fine finger dexterity, arm-wrist speed and aiming ability. Similar research has explored the manner in which performance scores group themselves in skills in which larger muscles are involved. It was found, for example, that there are several kinds of strengths, including static strength (pressure measured in pounds exerted against an immovable object); this is independent of what was termed "dynamic strength" (moving the limbs with force). Muscular flexibility and balancing ability were similarly dissected into several components. Thus discussion of a single quality in human movement is inaccurate. Rather, one should refer to several specific types of ability.

Other classifications of motor skills

Motor skills may also be classified by reference to the more general characteristics of the tasks themselves rather than by measuring and intercorrelating the scores elicited by human subjects. It is common, for example, to find the dichotomy "fine" and "gross" motor skill, in which the latter label is applied to acts in which the larger muscles are commonly involved, while the former classification denotes actions of the hands and fingers. One researcher has proposed a three-way classification system, separating human movements into "body transport movements," in which the total body moves in space; limb movements; and manual (hand) actions. In general, however, most skills incorporate precise movements of both larger and smaller muscle groups working in harmony. The basketball player must use his larger skeletal muscles to run and jump but at the same time must employ a fine "touch," evidencing accurate finger control, when dribbling the ball. On the other hand, when a person sits at a desk and writes, the large postural muscles that contribute to the writer's stability are invariably active.

Complex, integrated skills. Most of life's skills are not simple ones. They are rhythmic at times and almost always are composed of several integrated parts. Such skills are often controlled by the organization of visual information available to the performer, particularly during the early stages of learning. At the same time, the individual's ability to analyze the mechanics of a motor task, his verbal ability, and other intellectual and perceptual attributes may influence his acquisition of a skill.

Although psychomotor skills are widely distributed—*e.g.*, in military, athletic, musical, and industrial settings—such complex situations typically do not lend themselves to rigorous experimental research. Most scientists have found it more analytically useful to study psychomotor learning under controlled laboratory conditions. Measures of proficiency obtained in the laboratory reflect increasing accuracy and decreasing variability in a learner's performance as training progresses. If there is sufficient genetic aptitude, a person's mastery of a skill depends on his motivation to improve, on his receiving continuous information or sensory feedback about the adequacy of his performance during training, and on such factors as the rewarding effects of corrections made during successive practice periods. Skills are susceptible to inhibitory influences. The full extent of gains in proficiency often is masked by temporary losses and emerges only later, without additional practice sessions.

Factors in performance

Psychomotor habits are mediated primarily by the sensory and motor cortex of the brain and by the neural fibres (commissures) that connect the two cerebral hemispheres. According to the majority of theoreticians, learning proceeds (habit strength develops) as a mathematical function of the amount or duration of rewarded (reinforced) practice. The effects of associative and motivational factors are believed to combine mathematically by multiplying one another, while inhibitory and oscillation (variability) factors are thought to have subtractive effects. Despite theoretical and empirical progress, much remains to be discovered about the learning and performance of psychomotor skills, especially about the interrelationships among training variables, feedback contingencies, and human-factor variables.

(C.E.N./B.J.C.)

LABORATORY RESEARCH IN PSYCHOMOTOR LEARNING

Devices and tasks. Hundreds of electrical and mechanical instruments have been developed for research in psychomotor learning, but those commonly used number less than two dozen. In operating a device called a complex coordinator, the learner is instructed to make prompt, synchronized adjustments of handstick and foot-bar controls to match different combinations of stimulus lights. Another device, a discrimination reaction timer, requires that one of several toggle switches be snapped rapidly in response to designated distinctive spatial patterns of coloured signal lamps. In performing on a manual lever, a blindfolded subject must learn how far to move the handle on the basis of numerical information provided by the experimenter. With a so-called mirror tracer, a six-pointed star pattern is followed with an electrical stylus as accurately and quickly as possible, the learner being guided visually only by a mirror image. The operator of an instrument called a multidimensional pursuitmeter is required to scan four dials and to keep their indicators steady by making corrections with four controls of the type found in an airplane cockpit. On a rotary pursuitmeter the trainee's task is to hold a flexible stylus in continuous electrical contact with a small, circular metal target set into a revolving turntable.

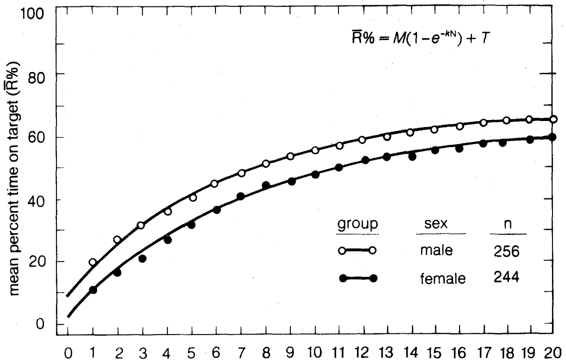
The pursuitmeter and the mathometer

Also employed in such research is a selective mathometer, on which the subject's problem is to discover, with cues provided by a signal lamp, which of 19 pushbuttons should be pressed in response to each of a series of distinctive images projected on a screen. While using a star discrimeter, a person receives information about his errors through earphones; his task is to learn to selectively position one lever among six radial slots in accordance with signals from differently coloured stimulus lights. A trainee on a two-hand coordinator has to manipulate two lathe crank handles synchronously to maintain contact with a target disk as it moves through an irregular course.

Measurements. The tasks required by the above devices produce a substantial range of psychomotor difficulty. The elements of skilled behaviour are expressed as numerical scores; *e.g.*, correct response and error percentages, amplitude and speed of movement, hand or foot pressures exerted, time on target, reaction time, rate of response, and indices of time-sharing activity. Most of the behaviour thus recorded lends itself readily to mathematical treatment. Laboratory devices for studying psychomotor learning characteristically exhibit high reliability (*i.e.*, intra-task consistency) and yield scores of useful validity (extra-task correlation) in predicting such behaviour as performance in factory work and the operation of motor vehicles and aircraft. In other words, it would appear that perceptual-motor devices reliably measure what they are designed to measure, and they also tap a significant proportion of the abilities required in real-life situations (see also PSYCHOLOGICAL TESTS AND MEASUREMENT). When properly maintained and used under standardized conditions, and when the resulting measurements are treated by statistical methods, the above devices are prime choices for many applied and basic research programs.

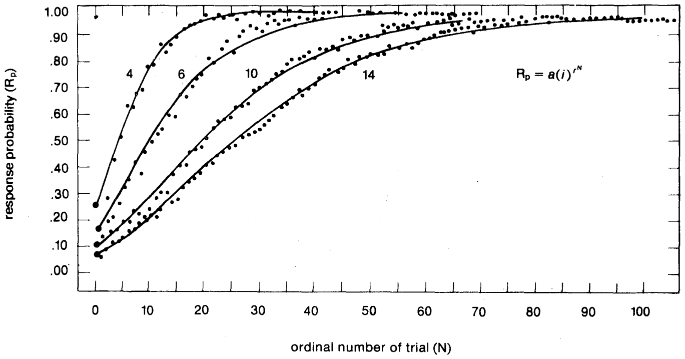
PHENOMENA OF PSYCHOMOTOR LEARNING

Acquisition. Speed and accuracy in the majority of psychomotor tasks studied are typically acquired very rapidly during the early stages of reinforced practice, the average rate of gain tending to drop off as the number of trials or training time increases (Figure 1). Curves based on such measures as reaction time or errors reflect the learner's improvement by a series of decreasing scores, giving an inverted picture of Figure 1. Tracking scores from the two sexes are seen in Figure 1. Other devices have yielded more complicated functions—*e.g.,* S-shaped curves for complex multiple-choice problems on the selective mathometer (Figure 2). Most acquisition curves obey a law of diminishing returns as high levels of skill are approached.



From Clyde E. Noble, "Acquisition of Pursuit Tracking Skill Under Extended Training as a Joint Function of Sex and Initial Ability," *Journal of Experimental Psychology,* vol. 86, pp. 360–373 (1970); Copyright (1970) by the American Psychological Association, and reproduced by permission

Figure 1: *Rotary pursuit acquisition curves.*
Average percent of response time on target ($\bar{R}\%$) while using a rotary pursuitmeter is plotted as a mathematical function of the number of successive 5-trial blocks of practice (N), with sex as the distinguishing factor, for 500 subjects. Both curves are predicted by the exponential equation shown in the figure, where *T, k,* and *M* represent origin, rate, and limit of theoretical response time, respectively.



From Clyde E. Noble, "The Length-Difficulty Relationship in Compound Trial-and-Error Learning," *Journal of Experimental Psychology,* vol. 54 (1957), pp. 246–252 (1957); Copyright (1957) by the American Psychological Association, and reproduced by permission

Figure 2: *Selective mathometer acquisition curves.*
Response probability (R_p), or relative frequency of correct multiple choices, in a selective mathometer learning experiment is plotted as a mathematical function of the number of successive practice trials (N), with task length (4,6,10, or 14 units) as the experimental condition, for 192 male subjects. All four curves are predicted by the double-exponential equation shown in the figure, where *I, r,* and *a* represent origin, rate, and limit of theoretical response probability, respectively.

Data such as those from tracking and multiple-choice tasks can be explained by rational mathematical equations derived from theoretical models (see formulas and captions in Figures 1 and 2). Between them, these two equations describe psychomotor acquisition curves from a wide variety of learning situations and of trainees with less than a 2 percent average error of prediction. Contrary to lay opinion, stepwise plateaus of proficiency are seldom seen, not even in learning Morse code. The "natural plateau" is a phantom.

Similarity and performance

Generalization and transfer. The occurrence of the phenomenon of generalization is seen in the tendency of laboratory subjects (conditioned to respond to a particular stimulus—*e.g.,* a light) to respond as well to similar stimuli beyond the original conditions of training. As differences along a physical continuum (*e.g.,* brightness) between the stimuli used in training and those encountered on test trials increase, the effects of generalization decrease until there may be no transfer from one situation to another. Alternatively, the more the two situations have in common, the greater is the amount of predictable transfer. Generalization (or transfer) may be based on temporal patterns of stimuli (*e.g.,* rhythms), spatial cues (*e.g.,* triangularity), or other physical characteristics (see below *Transfer of training.*).

The measured effects of prior training on the performance of a subsequent task define the transfer of psychomotor learning. Although similar, the latter task usually differs measurably from that originally practiced. A common example is the ability required of many automobile drivers to change easily from, say, a three-speed transmission with a horizontal gear lever on the steering wheel to a four--speed mechanism with a vertical floor-mounted gearshift. In laboratory tasks the amount and direction of transfer effects are accurately predicted. In practical skills, transfer is more likely between tennis and badminton than between swimming and football, between cornet and trumpet than between piano and tuba. Similarity is not the only correlate of transfer, however, and empirical studies must take account of such factors as the amount of practice and the sequence of events in previous training.

Transfer effects may be positive, negative, or zero; *i.e.,* learning one task may facilitate, hinder, or have no observable influence upon performance of the next task. Flight simulators are designed to maximize the amount of positive transfer, often by ensuring high levels of behavioral similarity. Negative transfer effects (*e.g.,* reaching for the floor to shift gears when the lever is on the steering wheel) appear occasionally but tend to be easily overcome. Since transfer necessarily involves retention, the best schedules minimize forgetting by the inclusion of short time intervals between training and transfer.

The degree and amount of transfer are contingent upon such factors as number of common elements or principles, stimulus and response similarity, amount of predifferentiation training, the variety of learning-to-learn experiences, part–whole relationships, differences in intertask complexity, use of mnemonic aids, and the extent of proactive or retroactive interference. Transfer equations usually assume that the basic indices of performance for experimental and control groups will increase with practice, that the possible measures range from negative 100 percent through zero to positive 100 percent, and that the groups have been equated in aptitude or initial ability to learn before the experimental treatments are begun. Retroactive interference designs typically employ a sequence of original learning, interpolated learning, and relearning.

Effects of rest intervals

Retention. Learning is to acquisition as memory is to retention. Psychomotor retention scores indicate the percentage or degree of originally learned skill that is remembered or recalled as a function of elapsed time. Alterations of motor memory are reflected by changes in means, variances, and correlations between test results. In contrast to verbal behaviour, which is notoriously susceptible to forgetting through interference within a matter of seconds, mean scores for tracking and coordination skills recorded over periods ranging from two days to two years diminish scarcely at all. Yet, when intervals of three minutes to six weeks are interpolated between discrete responses on a manual lever device, performance remains stable for about two days and then becomes inconsistent; variabilities increase and correlations decrease as the subjects mis-recall more and more of their original skill. In the light of this evidence, motor memory may be viewed as a phenomenon of persistence, while forgetting is a case of inconsistence.

One hypothesis advanced to account for the greater retentivity of psychomotor behaviour, as compared to that of newly acquired verbal behaviour, is that nonverbal striped-muscle responses are more often overlearned and are less susceptible to proactive interference (*i.e.,* competition arising from things learned in the past). Distinctions between immediate, short-term, and long-term memory are also less prominent in studies of motor learning, possibly because of the devotion of skills specialists to efficient practice and feedback methods that ensure permanent storage of habits in the brain. This is not to say that motor skills are unforgettable; studies of short-term memory suggest that psychomotor forgetting can be swift indeed. Regardless of theoretical differences, however, psychologists generally agree that psychomotor behaviour is best remembered (and least forgotten) when overlearning is high, interference is low, reinforcing feedback is optimal, and interpolated activities are unrelated to the task being learned. Time is less important in the degradation of memory than are the events that fill the time (see also MEMORY).

Reminiscence. The phenomenon of reminiscence is a gain in performance without practice. Thus, when subjects performing trial after trial without rest (massed practice) are given a short break, perhaps midway through training, scores on the very next trial will show a significant improvement when compared with those of a massed group given no break. Reminiscence effects are most prominent in tasks demanding continuous attending and responding; they are least often observed with discrete-responding apparatus. The theoretical importance of this concept derives from its role in testing a hypothesis of reactive inhibition that asserts that a decremental process cumulates in the organism as a positive function of responding to stimulation and a negative function of resting time. That the phenomenon of reminiscence also manifests bilateral transfer of skill (*e.g.,* from the left to the right hand) suggests that the locus of the decrement is in the central nervous system rather than in the peripheral effector organs. Indeed, merely watching another subject practicing on a rotary pursuitmeter has an inhibitory effect on a person's performance; yet the cause is neither boredom nor fatigue.

Warm-up. Athletes and musicians often report that they get "cold" during a layoff (even for a rest period of a mere five minutes); when practice is resumed, the decrement in performance requires a warm-up before it is overcome. Similarly, on a rotary pursuitmeter, it is necessary to regain the optimal posture, grip the stylus correctly, begin the coordinated movements of eyes and hand, and recapture the proper whole-body rhythm. Warm-up produces a further gain in proficiency following the initial reminiscence effect. Mean scores continue to rise for several trials, reach a peak at the level found for distributed practice, and then fall more gradually until they merge with the curve for massed practice. When the duration of rest is extended, the amount of warm-up decrement first increases rapidly and then decreases; similar findings obtain for a succession of work and rest periods. Investigators who have tried to substitute warm-up activities other than actual pursuitmeter practice to offset or reduce the magnitude of the decrement have not been successful. At least for continuous psychomotor tasks of this sort, the need for proper, task-specific warm-up appears to be an intrinsic requirement of efficient performance. Wherever reminiscence goes, warm-up seems to follow; yet the converse does not always hold. The connection between warm-up and forgetting is uncertain.

Warm-up as a practice factor

Refractory period and anticipation. When required to make quick, discrete responses to two stimuli separated in time by one-half second or less, an operator's reaction time (latency) for executing the second response is typically longer than that of his first response. This difference in reaction time is called the psychological refractory period. At one time, it was thought possible that sensory feedback from the first response might stack up in the nerve centres to make the system refractory for a brief time, thereby delaying the processing of the second stimulus. Research findings that erroneous reactions could be corrected within one-tenth second would seem to negate the hypothesis. An alternative suggestion is that corrective movements are facilitated by feedback from the incorrect ones, and controlled observations appear to confirm that error-correcting responses have shorter latencies than those that are either correct or erroneous. Apparently, a false movement can be stopped on the basis of internal cues more promptly than on that of external stimuli.

Expectancy is a collateral factor with which researchers have had to reckon; *i.e.,* a subject may learn to accommodate himself to expect a delay between the first and second stimulus and thus be relatively unprepared should the second arrive earlier than usual. Further, people learn to be more expectant for particular kinds of stimuli than for others. When a person is uncertain about whether regularly occurring stimuli will be auditory or visual, or when their spatial direction is uncertain, performance is significantly degraded. This would suggest the possibility of divided attention; indeed, when pairs of stimuli are made perfectly predictable as to time and type, no impairment of response is observed.

Learning to divide attention

If a subject can acquire suitable expectancies via training and experience, then he can improve the skill of dividing his attention and, within physiological limits, simultaneously handle an increased range of stimuli without loss of proficiency. Results from extended practice on a task requiring successive choice and dual reaction indicate that, with learning, people can reduce the psychological refractory period. The ability to develop anticipatory responses to regularly occurring stimulus cues is well established. A military gunner scanning a distant fixed target for azimuth and elevation, for example, is engaging in a preview of receptor anticipation to maximize his score. An operatic tenor who rehearses covertly the opening notes of his cadenza while the orchestra finishes the introduction is employing perceptual anticipation to optimize his rendition. Anticipatory timing is learned, and reinforcing feedback is necessary.

FACTORS AFFECTING PSYCHOMOTOR SKILL

Amount of practice. It has been noted above (Figure 1) that the practice of sensorimotor tasks usually produces changes in scores that reflect diminishing returns. A major influence in learning generally, repetition is the most powerful experimental variable known in psychomotor-skills research. But practice alone does not make perfect; psychological feedback is also necessary. The consensus among theoreticians is that feedback must be relevant and reinforcing to effect permanent increments of habit strength. Once developed, habit never dies; it does not even fade away.

The effects of feedback and four other important performance variables (*i.e.,* task complexity, work distribution, motive-incentive conditions, and environmental factors) remain to be summarized.

Psychological feedback. Ranking prominently among experimental variables are so-called feedback contingencies (aftereffects, knowledge of results) that may be controlled by the experimenter so as to occur concurrently with or soon after a subject's response. A learner appears to improve by knowing the discrepancy between a response he has made and the response required of him; but, in experimental practice, the investigator manipulates behaviour by transforming functions of error. Since transformations are usually numerical or spatial, sensory returns from one's action may be informative, motivating, or reinforcing. Response-produced stimulation is intrinsic to most skeletal–muscular circuits; the neural consequences of bodily movement are fed back into the central nervous system to serve the organism's regulatory and adaptive functions. When this normal feedback is interrupted or delayed, psychomotor skill is often seriously degraded. Experimentally delayed auditory feedback of a subject's oral reading produces stuttering and other speech problems; delayed visual feedback in simulated automobile steering is a greater hazard under emergency conditions than is the driver's reaction time.

Generalizations about psychomotor learning

Laboratory investigations have supported the following generalizations about psychomotor learning: (1) without some kind of relevant feedback, there is no acquisition of skill; (2) progressive gains in proficiency occur in the presence of relevant feedback; (3) performance is disrupted when relevant feedback is withdrawn; (4) delayed feedback in continuous (but not discrete) tasks is typically decremental; (5) augmented or supplementary feedback usually results in increments; (6) the higher the relative frequency of reinforcing feedback, the greater is the facilitation of skill; and (7) the more specific the feedback (*e.g.,* in designating location, direction, amount), the better is the performance.

Experiments with a manual lever device, for example, suggest that when feedback is introduced and withdrawn at four stages of practice, the effect on error scores is profound. Knowledge of results given early and late has effects similar enough to reject any hypothesis that learning arises merely from repetition. These experiments indicate that practice makes perfect only if reinforced; the result of unreinforced practice is extinction of the correct response and a proliferation of errors. Studies employing a complex mirror-tracking apparatus have clarified the role of reinforcing feedback. Targeting performance was facilitated by presenting distinctive supplementary visual feedback cues previously associated with aversive (electrical shock) and nonaversive consequences. Moreover, the amount of facilitation grew curvilinearly with the number of cue conditioning trials. Work on human incentive learning thus demonstrates that the rate of gain in psychomotor proficiency can be regulated by stimuli that have been accompanied by positive or negative aftereffects. Persistence of the acquired reinforcing effects, considered with their cumulative quantitative properties, enhances the attractiveness of theoretical interpretations that emphasize continuity and reinforcement as contrasted with theories based on discontinuity and contiguity alone. Clark Hull's system (1943) is the classic model.

Human incentive learning

Task complexity. The complexity of discrete psychomotor tasks may be specified either as the number of response sequences a subject can make or as some measure of a subject's uncertainty about choices among stimuli. Still other factors that have been investigated as instances of complexity include variations in the number of possible responses at each choice point, different lengths of series, and regular versus unpredictable stimulus sequences.

Experimental procedures involving an increase of complexity produce more errors, require more trials to reach proficiency, and result in longer latencies per trial. Difficulty in psychomotor learning, therefore, generally increases with the complexity of the task to be mastered. An example of this phenomenon appears in Figure 2. Subjects exhibit continually altered probabilities of response during training sessions, and an average person with enough practice on a discrete sensorimotor task can learn to perceive, select, and react as fast to ten stimuli as he can to two. Apparently, it is not the number of choices among stimuli as much as it is the number of choices among responses that slows up a subject's processing activities and complicates his decision problems. Indeed, by limiting response alternatives (*e.g.,* circumscribing the physical range of a trainee's movements or providing supplementary auditory and visual indicators of error), a training device can facilitate the acquisition or transfer of skill.

Work distribution. Hazardous though generalizations about work and rest in psychomotor learning may be, a few guiding principles are notable: (1) massed practice is usually superior to distributed practice for simple discrete-trial tasks; (2) distributed practice is usually superior for complex continuous-action tasks; (3) short practice sessions are generally superior to long practice sessions; (4) long rest periods are generally superior to short rest periods, although forgetting must be counteracted; (5) for continuous-tracking tasks practiced under constant work sessions and variable rest periods, the final proficiency level grows curvilinearly as the intertrial interval is lengthened; (6) gains in proficiency under distributed practice, or with interpolated rest periods during massed practice, are usually in terms of performance rather than of learning; (7) losses in proficiency under massed practice, or with increased work load, usually pertain to inhibitory rather than motivational decrements; (8) under certain conditions (*e.g.,* "cramming" for examinations) it may be most efficient to mass practice as long as adequate rest can be obtained before criterion performance is demanded; (9) reminiscence increments and warm-up decrements are intimately related to schedules of work and rest; (10) decrement is not the same as fatigue.

Quite apart from the practical question of the optimal management of training programs (*e.g.,* in coaching oarsmen in racing shells), the aversive inhibitory consequences of sustained action that are recognized as subjective fatigue and behavioral decrement are clearly adaptive. By a reflex negative-feedback mechanism, inhibitory impulses may prevent an organism from working itself to exhaustion. With few exceptions, the presumption in favour of spaced practice can safely be taken out of the psychomotor-skills laboratory and applied in the gymnasium, lake, and playing field. Research on the skills involved in, for example, archery, badminton, basketball, golf, javelin throwing, juggling, marksmanship, rowing, and tennis supports the notion of distributing training by means of short workouts and frequent breaks.

Distributed practice applications

Motive-incentive conditions. Motivational processes are states of the organism that serve to activate reaction tendencies. Such states are classified as primary (innate) or secondary (acquired, learned) motivation. Though common physiological needs (*e.g.,* for food, water, avoidance of pain) may evoke psychological drives (*e.g.,* hunger, thirst, pain), the concepts of need and drive are not perfectly correlated. Some needs (*e.g.,* oxygen demand) seem to have no specific behavioral drive, and for some drives, clear-cut biological needs remain to be identified (*e.g.,* curiosity). Despite this apparent discrepancy, there is a theoretical consensus that psychological drive arouses the body to action, energizes its latent responses, and supports its behaviour over time. Most theorists believe that motivation (drive) and learning (habit) interact (in a multiplicative—drive times habit equals action—manner) in generating response. In other words, to produce action both are theoretically indispensable, but neither is sufficient alone. A person is not likely to perform a skill if he does not want to and cannot do so if he does not know what to do. The multiplicative theory implies that the same level of psychomotor proficiency may arise from quite different combinations of learning and motivation. Moreover, the organism's temporary drive state seems clearly to affect the adequacy of reinforcing feedback (*e.g.,* offers of monetary reward do little to arouse one who is already trying his level best). While these theoretical interpretations often apply well to laboratory animals, their application to human acquisition of skill is complicated because incentive learning in man can become very abstract.

Physiological explanations of human behaviour that depend on the concept of primary motives (derived from research with rats and dogs) run into difficulties in view of the fact that primary motivation and reward do not appear to be critical in most studies of human skill acquisition. Thus, instead of giving food pellets (as to a rat), an experimenter delivers praise to a human subject; rather than receiving feedback by electric shock, the human can be guided by a needle moving on a dial or a buzzer signalling an error. At any rate, despite efforts to distinguish such motivational factors as general drives from selective incentives, attempts to demonstrate significant motivational effects in human psychomotor learning have met with only modest success. Among exceptions to the above are a few studies with standard apparatus (*e.g.,* the complex coordinator) and with special devices that have indicated that such incentives as money, verbal threats, electric shock, exhortations, and social competition may be relevant. Significant effects frequently fail to appear in experiments, and findings are often contradictory, so it has been suggested that the intrinsic challenge of the

Contradictory findings about motivation

gadgetry, coupled with the subjects' already high preexperimental motivation, leaves human volunteers unaffected by such weak laboratory manipulations of motive-incentive conditions as the foregoing (see also EMOTION AND MOTIVATION).

Environmental factors. Many practical skills must be executed outside the laboratory under unfavourable conditions of temperature, humidity, illumination, and motion. It is generally found that below the limiting levels of extreme stress, such conditions affect psychomotor performance to a greater extent than they affect psychomotor learning. Representative findings have included the following: (1) isolation and sensory deprivation cause dramatic reductions in vigilance and monitoring skills within an hour; (2) environmental temperatures above or below 70° ± 5° F tend to lower scores on tracking apparatus but do not impair learning; (3) lack of oxygen slows reaction time, especially when the atmosphere corresponds to altitudes of 20,000 feet or higher; (4) accelerations of the body in a centrifuge or rotating platform disrupt postural coordination and produce systematic shifts in the perception of the vertical; (5) although such people as acrobats, dancers, pilots, and skaters can adapt well to high accelerations, even they lose equilibrium if deprived of the customary visual frame of reference; (6) rather mild centrifugal effects of slow, constant rotation may induce acute motion sickness and associated degradation of psychomotor proficiency in normal persons; (7) while some controlled work-rest schedules of crews during confinement in a small cabin upset daily sleep rhythms and lead to decrements in watchkeeping, memory, and procedural skills, a schedule of four-hours-on versus four-hours-off duty can be maintained for several months without significant impairment; (8) faulty identifications of visual displays on an eye–hand matching task have been produced in volunteer subjects exposed to controlled infectious diseases (*e.g.*, respiratory tularemia, phlebotomus fever, viral encephalitis).

Other environmental stress variables found to exert negative influences are vibration, low illumination, high atmospheric pressure, noise, glare, toxic gases, ionization, and subgravity. Certain drugs have positive effects on psychomotor performance (*e.g.*, amphetamines, magnesium pemoline, methyl caffeine, pipradrol); some have deleterious effects (*e.g.*, alcohol, barbiturates, diphenhydramine hydrochloride, lysergic acid, meprobamate, phenothiazines, scopolamine, tetrahydrocannabinol, tripelennamine); and others are either neutral or have inconsistent effects (*e.g.*, caffeine, nicotine).

INDIVIDUAL AND GROUP DIFFERENCES

Statistical indices of psychomotor ability (*e.g.*, means, variances, correlations) not only differ among individuals but may also serve to distinguish from each other groups of persons classified by such traits as age, sex, race, personality, and intelligence. Comparative psychological studies of monozygotic (identical, one-egg) and dizygotic (fraternal, two-egg) twins have indicated that high coefficients of heritability—measured as a ratio of genotypic to phenotypic variance—exist for perceptual, spatial, and motor abilities.

Types of changes with age

Age. The most pervasive differences in human performance on psychomotor apparatus are associated with chronological age, and scores obtained from nearly all the devices mentioned above are sensitive to age differences. Researchers generally report a rapid increase in psychomotor proficiency from about the age of five years to the end of the second decade, followed by a few years of relative stability and then by a slow, almost linear decrease as the ninth decade is approached. For simple hand or foot reactions, complex discrimination-reaction time, and coordinated automobile steering, the peak of skill is attained between ages 15 and 20 on the average, and then performance at age 70 declines to about the level of age 10. This is a two-stage process: first, a developmental phase (*e.g.*, through maturation), followed by the more gradual deterioration of aging. Common athletic skills (*e.g.*, balancing, catching, gripping, jumping, reaching, running, and throwing) also improve through childhood, and it is well known that most athletes reach their prime before the end of the third decade. Olympic events requiring great muscular strength or stamina (*e.g.*, swimming) are dominated by athletes in their teens and 20s, whereas practitioners of more refined technical skills (*e.g.*, gymnastics) tend to be older. Self-paced, leisurely sports (*e.g.*, golf) are favoured over opponent-paced, combative activities (*e.g.*, tennis) as the aging process continues. Hereditary potentialities require several years to become established. It is probable that the genetic factors that underlie growth rates, and the age sequence in which different kinds of behaviour first appear, affect learning as well as performance.

Sex. Although the assessment of sexual differences in perceptual and reactive abilities is complicated by a number of factors (*e.g.*, age, race, and personality), girls and women tend to be more proficient than boys and men in such psychomotor skills as finger dexterity and inverted-alphabet printing. On the other hand, males generally do better than females at pursuit tracking, repetitive tapping, maze learning, and reaction-time tasks. On rotary pursuitmeter tests, women are not only less accurate but more variable than men of the same age and race (Figure 1). Although males appear to be superior to females in aptitude and capacity, these advantages disappear when subgroups are carefully matched for initial ability. In contrast, speed scores on discrimination-reaction tests reveal clearly diverging trends for college men and women trained intensively for several days (960 trials). This seems to be a genuine sex difference rather than an element of measurement or selection. Though both groups were equated for intelligence and had similar error scores, females began to suffer cumulative impairment on the fourth day of practice, whereas males kept improving. Sizable average differences in reaction latency as well as in movement time are characteristic of the sexes on other tasks.

Athletic skills

Whereas girls tend to attain their maximum proficiency in speeded tasks earlier in life than boys do, males continue to gain over a longer period and maintain their superiority over females for about half a century of the lifespan. After puberty, boys excel at most athletic skills demanding stamina and strength (*e.g.*, jumping, running, throwing). Thus, female Olympic swimming and track-and-field records are inferior to those of males and are achieved by girls who are noticeably younger than male champions in the same events. Sex has also been implicated in experiments employing complex coordinators, mirror tracers, and selective mathometers, with boys and men typically surpassing girls and women. Not all psychomotor differences associated with sex are intrinsically biological; unequal opportunities, distinctive social learning, role playing, and other culturally conditioned influences undoubtedly modulate the learning and execution of skills by males and females.

Race. All mankind is of one species. Zoologically, human races are all mutually interfertile subspecies—*i.e.*, breeding populations that differ in the relative frequencies of one or more genes. Although the variety of possible traits is practically limitless, random mating is not the case. Because of historical inbreeding tendencies, it is statistically improbable that any two human races have the same means and variances for all psychological traits. Not surprisingly, therefore, significant differences in psychomotor behaviour are found among ethnic groups throughout the world.

In one classic set of data (1904) on form-board skill (fitting nine geometric forms into correct holes), the average time in seconds for completing the task varied for different races—*e.g.*, seven African Pygmies (82.20), 12 Philippine Negritos (63.30), 55 American Indians and Eskimos (34.24), and 74 U.S. whites (27.80). Average error scores fell in the same order and, consistent with a genetic hypothesis, hybrid groups were appropriately ranked in between. These small samples were, however, not necessarily representative; *i.e.*, no effort was made to equate for differences in cultural values and psychomotor experiences found in different societies. Furthermore, since these were average differences, no conclusions about individual persons were warranted. It is interesting that the rankings were found to change for other psychomotor tasks; *e.g.*, on a test of tapping and aiming skill, Eskimos surpassed all others, followed by Filipinos, who were in turn trailed by

Caucasians. A more recent study (1967) discovered that a sample of Mongoloid Chamorro people from Saipan and another of Indians from the U.S. exceeded white norms on a test of maze-tracing ability. In both studies, people of mixed races tended to make intermediate scores, a fact consistent with contemporary research in behavioral genetics and physical anthropology.

Absence of a superior race

No particular race is found to be uniformly superior in all psychomotor aptitudes and capacities, but environmental causes seem to be inadequate to explain differences in rate of acquisition and final level of performance on standard apparatus. For some tasks (*e.g.,* on the rotary pursuitmeter) psychologists report that the degree of initial hereditary determination seems to reach 90 percent, thus leaving little room for sociological variables to operate. Teams conducting research with infant tests have noted that Congoid babies in both Africa and the United States are more precocious in sensorimotor maturation than are Caucasoid babies in Africa, the United States, or Europe, and that this precocity lasts about three years, after which whites outperform the blacks. By adolescence, Negro subjects score significantly less well than whites on complex coordinator, rotary pursuitmeter, discrimination reaction, selective mathometer, and two-hand coordinator tasks. On the other hand, Chinese- and Japanese-American infants lag behind Caucasians in motor development but perform better than both whites and blacks on certain eye–hand coordination and dexterity tasks at later ages.

Many research workers believe that social, economic, educational, and attitudinal variables that might unequally influence minority groups are of little consequence in the psychomotor field. They point out, for instance, that Chinese, Jewish, Negro, and Puerto Rican children, when tested by members of their own cultures, show distinctive patterns of basic perceptual and motor abilities, and their particular skill profiles are unaffected by differences in socio-economic level. Malnutrition (*e.g.,* protein deficiency) is not believed to be a plausible explanation unless there has been severe deprivation during the perinatal period. According to much of the literature, blacks generally do better than whites on chemical taste tests, rhythmic discrimination, visual acuity, colour perception, and resistance to special optical illusions; Mongoloids show better taste sensitivity and less colour blindness than Caucasoids; and on certain physical-fitness tests male Afro-American athletes are not only superior to their white countrymen but their relative proficiency is inversely correlated with the degree of Caucasoid admixture.

Genetic behavioral differences among human populations—just as those of morphology—appear to be the rule rather than the exception. Tarahumara Indians far surpass other races in endurance at long-distance running contests; Andeans and Tibetans are superbly adapted to working at high altitudes; Eskimos excel on psychomotor tasks performed under low-temperature stress. It is plausible that the inherited factors underlying behavioral aptitudes and capacities have evolved from different selective pressures in different ecological niches. As is true for age and sex, however, hereditary and environmental variables are complexly intertwined in racial studies. Nevertheless, genetic determinants seem to be far more powerful in the etiology of original psychomotor aptitudes. It does not follow that learnability is weak. Quantitative experiments demonstate that heritabilities can be systematically altered by controlled practice; this is a theoretical discovery of broad implications for practical training programs. At the same time, it would appear that the hereditary control of several psychomotor abilities tends to be less pronounced at the end of training than at the beginning.

Other factors. A number of other personal characteristics have been found to be of significance in psychomotor behaviour. For instance: (1) speed scores in reaction-time tasks are positively correlated with body temperature in adults, one of the many indices of variation within the individual; (2) psychotics show longer reaction times and poorer tracking scores than do people of normal personality; (3) right-handed operators are favoured on the rotary pursuitmeter, while left-handed persons tend to do better on the complex coordinator; (4) left-handed people are more variable in finger-dexterity and paper-cutting skills and also are more prone to show signs of ambidexterity; (5) intelligence quotients (IQ) are weakly related to physical strength or endurance yet are strongly associated with performance in such psychomotor activities as running the 35-yard dash, balancing on one foot, discrimination reaction, rotary pursuit, and selective mathometry—these correlations are especially high when based on groups that comprise a full range of IQs (from retardates to college students); (6) typically one's body build (somatotype) is associated with his athletic skills—the best fencers, oarsmen, and basketball players, for example, tend to be tall and lean (ectomorphic); top swimmers, divers, and pole-vaulters are likely to be broad-shouldered and slim-hipped (mesomorphic); champion wrestlers, shot putters, and weight lifters are apt to be thick-trunked and short-limbed (endomorphic). While these genetically determined somatotypes do not guarantee athletic prowess, they definitely do favour success in certain sports rather than others. Similar considerations apply to vocal and instrumental musical aptitudes wherein unique combinations of such anatomical structures as lips, teeth, larynx, tongue, eyes, ears, hands, and arms can facilitate the attainment of virtuoso skill.

IQ correlations

In short, psychomotor abilities and learning underlie some of the most fundamental human activities, contributing to the full spectrum of work, play, creativity, love, and the very survival of individual and species. (C.E.N.)

Concept formation

Concept formation refers to the process by which one learns to sort his specific experiences into general rules or classes. One is observed to meet a given person, to lift a particular stone, and to drive a specific car. When he seems to *think* about things, however, he often appears to deal with classes; apparently he knows that stones (in general) sink, that automobiles (as a class) are powered by engines. He behaves as if he thinks of them in a general sense beyond any particular stone or automobile. Awareness of such classes can help guide behaviour in new situations. Thus two people in a bakery may never have met before; yet, if one can be classified as customer and the other as clerk, they tend to behave appropriately. Similarly, many people seem able to drive almost any automobile by knowing about automobiles in general.

Concepts as rules

Concept formation is a term used to describe how one learns to form classes; conceptual thinking refers to one's subjective manipulations of those abstract classes. A concept is a rule that may be applied to decide if a particular object falls into a certain class. The concept "citizen of the United States" refers to such a decision rule, meaning any person who was born in U.S. territory or who is a child of a U.S. citizen or who has been legally naturalized. The rule suggests questions to ask in checking the citizenship of any particular individual. As most concepts do, it rests on other concepts; "U.S. citizen" is defined in terms of the concepts "child" and "territory." Many scientific or mathematical concepts cannot be understood until the terms in which they are defined have been grasped. Concept formation builds on itself.

Conceptual classification may be contrasted with another type of classification behaviour called discrimination learning. In discrimination learning, objects are classified on the basis of directly perceived properties such as physical size or shape. The usual explanation for discrimination learning is that the sensory features of any stimulus are matched to what is already remembered of these features, and that the learner's response becomes associated with them. The response thus classifies the stimulus. In discrimination learning subjective representations of immediate and past stimuli seem directly to indicate concrete, physical features (in contrast to the more abstact nature of concept formation). When a stimulus is perceived to match several different past experiences, the response may be a compromise; an object need not bear an all-or-none relation to a set of others in discrimination learning—for example, there is no absolute distinction between tall and short people.

While human beings popularly are called abstract thinkers, many of the classifications people make clearly seem to be concrete discriminations. Indeed, people may use the same term either in a discriminative or conceptual way. A child uses the term policeman in discriminating a man in distinctive uniform, while a lawyer may have a concept of a civil servant charged with enforcing criminal codes.

In practice, people seem to think in many ways that combine abstractness and concreteness. They also may blend class membership with assignment along a scale; *e.g.,* such concepts as leadership, an abstract quality that people are said to exhibit in varying degrees. The same applies to vivacity, avarice, and other personality classifications.

People seem to develop more complex sets of classes than do other animals, but this need not mean that human modes of learning are qualitatively unique. It may be that all animals have the same basic biochemical machinery for learning, but that human animals exhibit it in greater variety. Yet, it seems no more appropriate to account for human concept formation in terms of discrimination learning alone than it does to reduce the functions of a piston engine to chemical reactions.

EXPERIMENTAL STUDIES

Since careful observation of informal, everyday behaviour is difficult, most evidence about human concept formation comes from laboratory subjects. For example, each subject is asked to learn a rule for classifying geometric figures (see the Table).

Geometric Patterns of the Type Used in Studying Concept Formation

object number	size	colour	shape
1	big	green	triangle
2	big	green	circle
3	big	red	triangle
4	big	red	circle
5	small	green	triangle
6	small	green	circle
7	small	red	triangle
8	small	red	circle

The experimenter may concoct the rule that all green objects are called GEK. The subject is shown some of the figures, told which are named GEK, and asked to infer the rule or to apply it to other figures. This is roughly akin to teaching a young child to identify a class of barking animals with the name DOG. In both cases a general rule is derived from specific examples.

The problem of discovering that GEK = GREEN is almost trivial when four GEK and four NOT GEK figures are presented at once; it becomes surprisingly difficult if they are presented one at a time and need to be remembered. When two concepts are to be learned together (*e.g.,* JIG = TRIANGLE and GEK = GREEN) memory for each concept tends to be mixed, and it becomes a formidable task to solve either problem. This is evidence that short-term memory functions in concept learning, and that it often is a limiting factor in performance. Efficiency in more complex concept learning often depends on providing enough time for examples of a rule to be fixed in memory for longer periods.

Concept identification

Most such experiments involve very simple rules. They properly concern concept identification (rather than formation) when the learner is asked to recognize rules he already knows. Adult subjects tend to focus on one stimulus attribute after another (*e.g.,* shape or colour) until the answer is found. (This is problem solving with a minimum of thinking; they simply keep guessing until they are right.) People tend to avoid repeating errors but seem to make surprisingly little use of very recent, short-term experience.

Most people are orderly in trying out attributes, first considering such striking features as size, shape, and colour, only later turning to the more abstract (*e.g.,* number of similar figures, or equilateral versus isosceles triangles). This characteristic progression is reminiscent of the quantitative distinction between discrimination learning (relatively concrete) and concept formation (more abstract); there seems to be no sharp, qualitative division. If pairs of arrays are shown in which the same geometric figure is repeated (the rule being that all GEK arrays have exactly 10 figures), people first are apt to react to directly perceivable characteristics (*e.g.,* the extent to which the figures fill the space). They are likely to discriminate most grossly different NOT GEK patterns in this way quickly but to be troubled by arrays of 9 or eleven. Eventually most adults should discover a solution by counting figures. Ordinarily more difficult, higher-order abstractions (*e.g.,* GEK arrays have an even number of figures) become easy to learn if the distinction is directly perceivable; for example, if even-numbered arrays are drawn symmetrically and all others are not.

Concept learning; conjunctive and disjunctive rules

Study can shift from concept identification to concept learning by requiring combination of previously learned rules. A conjunctive concept (in which the rule is based on the joint presence of 2 or more features; *e.g.,* GEK patterns now are LARGE and GREEN) is fairly easy to learn when the common characteristics stand out. But learning a disjunctive rule (*e.g.,* GEK objects now are either LARGE or GREEN but not both) is quite difficult; there is no invariant, relatively concrete feature on which to rely.

Concept learning in adults may be understood as a two-step process: first the discovery of *which* attributes are relevant, then the discovery of *how* they are relevant. In the conjunctive illustration used here, the learner first is likely to notice that size and colour have something to do with the answer and then to determine what it is. This two-step interpretation presupposes that he already has learned rules for colour, size, shape, or similar dimensions.

In an example of what is called intradimensional shift, initially the subject learns that GEK = GREEN; then, without warning, the experimenter changes the rule to GEK = RED. The same attribute or dimension (colour) is still relevant, but the way in which it is used has been changed. In extradimensional shift the relevant dimension is changed (*e.g.,* from GEK = GREEN to GEK = TRIANGLE) but the classification of some objects does not change (GREEN TRIANGLE is a GEK under both rules). The relative ease with which a subject handles such problems suggests something about how he learns. If he tends to learn simply by associating GEK with specific figures without considering the selected attribute, then he should find extradimensional-shift problems easier, since only some of his associations need be relearned. But if he has learned stepwise in terms of relevant attributes (*e.g.,* to say "What is the colour? . . . Ah, *that* colour means it is GEK"), intradimensional shift should be easier, since only the *how* phase of the two-step process need be relearned.

College students tend to find intradimensional-shift problems easier, indicating that they are prone to use the two-step process. On the other hand, suppose a rat initially is rewarded when it runs into the right-hand side of a maze for food, then a change is made by rewarding entries to the left (intradimensional shift) or by rewarding entries to any brightly lighted alley regardless of location (extradimensional shift). The rat will perform best on the extradimensional-shift problem. Among children, performance depends substantially on age; preschool children are likely to do best with extradimensional shifts (as rats do) but beyond kindergarten age they tend to find the intradimensional shift easiest. Perhaps these differences are related to how children learn to apply language in problem solving.

Concepts as models of change

Concepts need not be defined as limited to simple classification but also can be interpreted as models or rules that reflect crucial possibilities for change. To take a simple case, an adult is not apt to think that the volume of water changes when it is poured into a container of different shape. (Young children may claim that it does.) In the adult's concept, volume is not synonymous with the shape of a container but is based on a model of how fluids behave. The concept of "heat" does not serve simply to sort objects as hot or cold; it implies a rule or model of energy transfer that can be used widely (*e.g.,* to explain how water boils at a lower temperature when pressure drops). Concepts can be understood as models on which to decide if particular changes will have significant effects. This also implies classification (of sets of equivalent situations), but the way people learn to make this sort of classification may be quite different from the processes described so far.

AGE AND CONCEPTUAL BEHAVIOUR

Piaget's observations. The provocative clinical observations of Swiss psychologist Jean Piaget (1896–1980) have initiated considerable study of how young children learn concepts for coping with their physical surroundings. As models for defining feasible change, concepts are at least as important in such contexts as they are for classification. Piaget stressed that an infant normally first must learn that he is a thing apart from his external environment; next that he must form enough concepts of physical invariances (*e.g.,* that objects fall) to let him explore his world. Later in the preschool period the child typically grasps the concept of spatial localization (of objects separated in space). Piaget characterized the child during this period as classifying objects only on the basis of perceptually attractive, concrete physical features (in agreement with laboratory studies of intradimensional and extradimensional shift).

He and others who used his methods reported that preschool children are apt to explain external change in terms of their own needs; *e.g.,* a four-year-old is likely to say that a cloud moves "because the sun is in my eyes." Other distinctions between cause and effect emerge among children in early primary grades, who may say a moving cloud "wants to hide the sun." In later primary grades, volitional and passive movement usually become conceptually distinct.

Ability to deal analytically with objects apart from their immediate perceptual characteristics is reported typically to become effective only just before adolescence. At that time the concept of hierarchies of subclasses within more general classes commonly develops. A normal child of eleven applies the properties of all living things to the class called birds.

The role of learning

Progressive use of abstract concepts seems to reflect both maturation and learning. Given proper information, by the age of six many children display impressive concept-forming abilities. They ordinarily have considerable linguistic competence, using (though often not being able to explain) such abstract transformations as present and past tense. Rules of formal logic can be taught in the elementary grades; the so-called new mathematics reflects efforts to improve the order in which such concepts are introduced.

The role of instruction in concept formation remains poorly understood, yet practically all cultural heritage is explicitly taught. How many people would develop the concept of number (let alone that of odd and even) if left to themselves? Human societies have existed for thousands of years without these concepts. Better knowledge of how to instruct and of the role of imitation in transmitting cultural concepts is needed.

Aging. It is generally reported that potential for learning new abstractions decreases in old age. In such extreme cases as senility, severe alcoholism, or brain injury, the deficit is dramatic. Much less is known, however, about changes in conceptual ability during the active period of adult life, and what evidence there is is conflicting. Perhaps such adults are too busy to serve as research subjects.

People deemed gifted as children tend to retain superior ability into their later years in grasping new abstractions. However, among more typical people, little correlation is found between conceptual ability evaluated in the early teens and the same ability measured ten or more years later. Very gifted youngsters are likely to be given special scholastic challenges and opportunities that may enhance their skill in abstract thinking.

In such abstract pursuits as pure mathematics or theoretical physics there is a tendency for creative scientists and writers to be most productive in their late 20s and early 30s, but there are many exceptions. Among people in general, there probably is a slight decrease in ability to form new concepts starting from the late 20s. At the same time, as people get older they have more learned concepts that they can apply to a problem, so the net change in ability is hard to predict. Deterioration in learning new concepts is likely to be more rapid past 60, its severity varying markedly from person to person. Deterioration may be associated with illness or injury rather than with mere age in years.

LANGUAGE

Language, as a system of symbols abstracted from experience, provides an important vehicle for thinking. Some theorists treat linguistic concept formation as being a complex type of discrimination learning. The U.S. psychologist B.F. Skinner, for example, held that linguistic concept formation is based on the same principles that describe how a rat learns to push a bar in response to a specific signal. This seems to account for name learning (*e.g.,* that some objects are called horse and others dog). Other aspects of language learning, however, do not seem to fit Skinner's discrimination-learning model; its adequacy in explaining how one learns the concept of grammatically equivalent sentences has been challenged. Considering concepts as specifications of feasible transformations, sentences are equivalent if one can be derived from another by allowable change (*e.g.,* from active to passive tense). It is hard to see how learning to handle transformations could be based on the learning of primitive discriminations.

Genetic theories

Another explanation of language acquisition favoured by some linguists and biologists lays less stress on learning. It could be that humans are genetically prepared to acquire some language at an early age, much as some birds show readiness to learn any song pattern to which they are exposed when they reach a certain age. In humans, this period seems to stretch from about age one to six. If this explanation holds, all human languages should obey constraints established by the linguistic limits of genetic endowment. Should language prove to be a relatively independent biological function, the high linguistic competence of many young children with poor ability for abstract reasoning would appear less paradoxical.

Perhaps some rudimentary bases for language among other animals can be learned by methods appropriate for discrimination learning; even very young children are among the best discrimination learners in the animal kingdom. Once basic linguistic discriminations have been grasped, they can be used as tools with which the remainder of any language is learned. This suggests a theoretical position that falls between strictly cognitive accounts of language learning and Skinner's ideas. Nevertheless, biological bases for language learning remain to be identified and incorporated in such theories.

At any rate, such an array of theories is a sign of how little is known of the way people learn the concepts of a language.

CONCEPT FORMATION IN ANIMALS

Rats learn to enter lighted or unlighted alleys to get food, and goldfish can be taught to swim toward or away from an object. In such discrimination learning the animal is said to associate a physical property of the stimulus with its response, and with some contingency of reward or punishment. Thus, while a dog can be trained to come when called, it need not mean that he knows his name in the same sense that a man apparently does. But how can one prove that the dog does not know his name, or even that another person has a deeper concept of his name?

Most animals show classification behaviour that clearly seems to be discrimination learning. A crow will respond to the danger call of a bird of another species, but, only if that call physically resembles the crow's. Chimpanzees, however, have been observed using sticks as primitive tools; they behave as if they have a concept of things that extend reach. On considerable evidence of this sort, many are reluctant to say flatly that the animals are incapable of abstract thinking.

The oddity problem

Most studies aimed at evidence of concept formation among laboratory animals have involved primates, although there are reports of abstract behaviour among such animals as dogs, dolphins, and pigs. Monkeys have been taught to solve the oddity problem: presented with two objects of one kind and one of another, they can be trained to select the discrepant one. This behaviour persists even for sets of objects that have never been presented to them before. The animals behave as if they grasp the general concept of similarity, an abstraction rather than a simple discrimination. With great effort chimpanzees have been taught to speak and to use correctly a very few words. A much more successful attempt has been made to teach a chimpanzee the sign language used by deaf people, gestures apparently being more appropriate to the anatomic structure of chimpanzees. (Human beings ordinarily seem more prepared to learn spoken language.) The chimpanzee learned to use the signs for hat, dog, food, yes, me (self), sorry, funny, go, come, and many others. This work was reported in 1967 by R.A. Gardner and B.T. Gardner.

CONCEPT FORMATION BY MACHINE

Computers can be programmed to process information and to develop classification rules (*e.g.,* they can play chess and make decisions about business or military problems). Essentially such devices are programmed to mimic the process of problem solving required of subjects in laboratory experiments on concept learning. In this sense, machines have formed concepts; but their functions remain relatively impoverished. Efficient linguistic behaviour has proven particularly difficult to produce in a machine, despite numerous attempts. Yet there is no evidence that human concept formation is based on any mode of handling information that in principle could not be built into a machine. It is almost an article of faith among many investigators that human thinking can be explained mechanistically in physiological terms, but the scientists themselves do not yet seem to have developed concepts adequate for producing machines that can approach the full range of human talent. (E.B.H.)

Transfer of training

Will one's knowledge of English help him learn German? Are skillful table-tennis (Ping-Pong) players generally good court-tennis players? Can a child learn to multiply if he does not known how to add? These questions represent the problems of transfer of training: the influence the learning of one skill has on the learning or performance of another.

KINDS OF TRANSFER

Basically three kinds of transfer can occur: positive, negative, and zero. The following examples from hypothetical experiments, purposely uncomplicated by distracting detail, illustrate each. Suppose a group of students learn a task, B, in 10 practice sessions. Another group of equivalent students, who previously had learned another task, A, is found to reach the same level of performance on task B in only five practice sessions. Since the average number of practice sessions required to learn B was reduced from 10 to five, transfer of training from task A to task B is said to be positive (10 − 5 = +5). Many successful training aids, such as those that simulate the cockpit of an airplane and that are applied to teach people how to use instruments for flying blind without leaving the ground, produce positive transfer; when students who have preliminary training in such trainers are compared to those who do not, those with preliminary training almost invariably require less practice in achieving the desired level of skill.

Positive, negative, and zero transfer

Sometimes the effect of transfer of training is to hamper effectiveness in subsequent activity. If after learning task A a group of people need 15 practice sessions to learn task B whereas only 10 sessions are required for those without any previous training in task A, then task A is said to lead to negative transfer of training on task B (10 − 15 = −5). Having learned to drive on the right side of the road often is observed to produce negative transfer for the tourist from Japan or continental Europe or North America when he is travelling in Great Britain, where cars are to be driven on the left-hand side of the road.

The degree to which transfer of training occurs between two different tasks is often minimal and may be so small that it is called zero transfer. If learning task B with or without previous training in task A requires 10 practice sessions, then the amount of transfer from one task to the other is said to be zero (10 − 10 = 0). Learning to knit Argyle socks is apt to produce zero transfer of training in learning to sing an operatic aria in French.

Although in contemporary psychology transfer of training is a distinct topic of investigation with its own experimental designs and procedures for measurement, its implications pervade practically all of psychology, from conditioning to personality development. Ivan P. Pavlov discovered that when a dog is conditioned to salivate in response to a sound wave of 1,000 cycles per second, it will also salivate if it is next exposed to a tone of 900 cycles per second, although typically the volume of saliva will be slightly reduced. In this case, transfer of training occurs between two similar auditory stimuli; in general, phenomena of this sort are called stimulus generalization. At the very root of modern theories of personality development is the assumption that what a person learns during his childhood will show a pervasive degree of transfer to his adult behaviour. In some cases stimulus generalization mediates this transfer. Some cases of excessive fears may have their origins in unpleasant experiences during early life.

EDUCATION AND TRANSFER

The experimental study of transfer of training has historical roots in problems of educational practice. Educators in Western countries at the end of the 19th century widely endorsed the doctrine of formal discipline, contending that psychological abilities, called "mental faculties" by such philosophers as Thomas Aquinas (1225–74), could be strengthened, like muscles, through exercise. By learning geometry, one was expected to improve his ability to reason; studying Latin was held to "strengthen" the so-called faculty of memory, and so on. Although what contemporary educators have demoted from the doctrine to the theory of formal discipline once seemed reasonable to many, experimental tests have refuted it. When the reasoning abilities of groups of mathematics students in secondary schools were compared with those of other equally talented students who had not had the same mathematical training, no differences in general logical effectiveness were observed between the groups.

An alternative theory of identical elements was proposed in which it was postulated that transfer between activities would take place only if they shared common elements or features. Thus it was predicted that one's training in addition would transfer to his ability to learn how to multiply. It was reasoned that both tasks share identical features, multiplication basically requiring a series of successive additions, and that both tasks demand the individual's concentration.

But the identical-elements formulation soon came under attack when experimental results suggested that one's understanding of general principles, rather than the presence of identical task elements, has substantial effects on transfer of training. In one notable experiment, two groups of boys practiced throwing darts at a target placed under about a foot of water. Only one group, however, was instructed about the principle that water bends (refracts) light. According to this principle, the apparent position of the target should vary with the depth of the water. When the target depth was reduced to four inches, the group that had been taught the general principle of refraction adjusted rapidly to the change and exhibited substantial positive transfer; the other boys showed comparative difficulty in learning to hit the target at the shallower level.

Theories of transfer

These formulations (formal discipline, identical elements, and general principles), when considered carefully, might be recognized as points of view rather than as rigorously specified theories that could lead to unequivocal predictions of the results of new experiments in transfer of training. For example, failure to demonstrate positive transfer between mathematical training and general reasoning ability could be attributed to ineffective teaching of mathematics; in such case, the results need not be interpreted as refuting the theory of formal discipline. If the then-traditional manner of teaching mathematics could be changed to emphasize logical thinking (rather than routinized application of formulas), it was argued that perhaps mathematical training could improve reasoning ability in general. Some theorists also suggested that the positive transfer observed to result when boys learned the principle of refraction was consistent with the hypothesis of identical elements; these theorists observed that a general principle may be considered an element common to many tasks. According to this line of reasoning, the group of boys who exhibited positive transfer with the shift to a new target depth shared the principle of refraction as an element in common with the previous task, along with those of aiming and throwing. By contrast, the youngsters who performed without the benefit of knowing about refraction were held to have gained positive transfer from throwing but to have suffered negative transfer as a result of aiming incorrectly.

EXPERIMENTAL ANALYSIS OF TRANSFER OF TRAINING

The indeterminate character of the broad theoretical formulations offered to account for transfer of training and the often unsuccessful ways in which they were applied to the practical problems of classroom teaching led some psychologists to retreat to the laboratory in the hope of identifying more clear-cut, fundamental processes in transfer of training. As a result, a number of different transfer-of-training phenomena were discovered, several of which may be reviewed as follows.

Stimulus and response similarity. The method of paired-associate learning, in which a person is asked to learn to associate one syllable or word with another (*e.g., complete–hot, safe–green, wild–soft*), encouraged the investigation of the influence of stimulus and response similarity on transfer of learning. Typically these pairs of verbal items are presented to the laboratory subject so that the first, or stimulus, member (*e.g., complete*) is exposed alone, followed after a short interval by the second, or response, member (*e.g., hot*). The subject's task is to respond to the stimulus term before the response term appears, as when an English-speaking student in learning French is supposed to respond to *le livre* with *the book.*

When two successive lists of paired associates are learned in which the stimulus elements are the same but the response terms are changed (*e.g., complete–hot* in the first list and *complete–new* in the second), negative transfer typically results. Apparently, in learning the second list the subject tends to respond to the stimulus term (*e.g., complete*) with the previously learned correct response term (*e.g., hot*), the result being interference with new learning to produce negative transfer. If he were learning the second list without having learned the first, the subject would not be so handicapped.

Another question concerns the sort of transfer that results when response terms are different and stimulus elements are similar but not identical; for example, *entire* is similar to *complete.* After one has learned *complete–hot,* the experimental evidence is that his ability to learn *entire–new* becomes definitely more difficult. Both *entire* and *complete* seem to have a tendency to evoke the response *hot* and to be incompatible with subsequently learning the association of *entire* with *new.* The principle that appears to operate in such situations is that the greater the similarity in stimulus elements, the greater the degree of negative transfer.

The influence of response (rather than stimulus) similarity on transfer of training is more complex; in paired-associate learning, the subject needs to learn the response term of each pair (response learning) and then to remember that it is linked with its appropriate stimulus partner (associative learning). When response terms are relatively difficult to learn (as in the case of unfamiliar or foreign words), the subject tends to profit considerably from learning the first list. But when response terms already have been learned (or are easy to learn), little if any positive transfer is likely to occur. The degree of transfer between lists that contain similar response terms depends both on how similar they are and on their level of difficulty; increasing the similarity between response terms is most likely to increase positive transfer when the response terms are relatively difficult to learn.

Although attempts have been made to formulate an all-embracing theory that would account for the effects of similarity among paired associates on transfer of training, a major obstacle that has prevented fully satisfying results is that the degree of positive or negative transfer is typically a product of many interacting influences beyond those of stimulus and response similarity. For example, the amount of training that the subject receives also has significant effects on transfer. When initial training is given on a simulated task (*e.g.,* learning to operate a set of dummy controls in preparation for a second task of acquiring a complicated skill, such as flying an airplane), negative transfer effects frequently appear during the initial stages of learning the second task and then give way with further training to generally positive transfer effects.

Obstacles to a unified theory of similarity in transfer

Another stumbling block in developing theoretical explanations has to do with the meaning of the central concept of similarity. In such experiments as those in which the salivary reflex is conditioned to different auditory stimuli, similarity is measured in terms of physical stimulus properties (*e.g.,* pitch or loudness); in other studies, as in paired-associate learning, similarity typically is expressed in terms of verbal meaning. In neither case has a universally adopted method yet been devised to measure similarity in a reliable and precise way; perhaps none can be, simply since there are so many different aspects of physical and linguistic or semantic similarity. Despite these difficulties, efforts to analyze transfer experimentally in terms of the properties of stimulus and response events have been productive in identifying conditions that can be varied to alter the direction and the degree of transfer of training.

Retroactive and proactive inhibition. Closely related to stimulus and response similarity are phenomena called retroactive inhibition and proactive inhibition; these demonstrate how forgetting seems to result from interfering activities.

In a study of retroactive inhibition, both the experimental and control groups of people learn task A (for example, a list of adjectives) and are tested for their ability to recall A after a specified time interval. The groups differ in what they are asked to do during the interval; the experimental group learns a similar task B (say, another list of words), while the control group is assigned some unrelated activity (for example, naming a series of coloured chips) designed to prevent them from rehearsing task A. The results of numerous studies of retroactive inhibition show that the experimental subjects typically are poorest in recalling information from task A. The interpolated activity, particularly a comparable one such as memorizing a second list of adjectives, apparently interferes with one's ability to recall words from the first list. Habit competition, or what is sometimes called interference, between the items of the original and the interpolated word lists at the time of recall is considered to be one of the major sources of the negative transfer exhibited in retroactive inhibition.

Interference theory

Experimental designs for demonstrating proactive inhibition differ from those used for showing retroactive inhibition in that the experimental group learns task B before, instead of after, task A. Whereas B was a task that was interpolated between the learning and the recall of task A in the retroactive inhibition study, B is a task that precedes the learning of task A in the proactive inhibition study. To evaluate the effects on the experimental subjects of their having learned B prior to A, the control people are instructed to relax during the time the experimental group is learning B. Typically an experimental subject's ability to recall from task A is inferior to that of a control person, the degree of inferiority depending in part on how similar the two tasks are; the greater the similarity, the poorer the recall tends to be. Although proactive inhibition, so called to indicate that it acts forward from the first-learned task to the second, produces appreciably less forgetting than does retroactive inhibition, they both support the theory that interference can produce forgetting (see MEMORY).

Stimulus predifferentiation. Educational films can be considered as everyday examples of stimulus predifferentiation, in which the individual gets preliminary information to be used in subsequent learning. The student who sees a film describing the various parts of a microscope is likely to be better prepared to learn the requisite skills when confronted with the instrument itself. In laboratory studies of stimulus predifferentiation, the subject is given experience with a particular stimulus situation ahead of time; later he is asked to learn new responses in the same situation. In one illustrative study, subjects first practiced labelling four different lights and then later were asked to learn to press selectively one of four switches, each connected to one light. The rate at which they learned the appropriate pressing reactions was related to how well they had learned to label the lights.

The results of a large number of experiments covering a variety of stimulus predifferentiation techniques suggest that when a learner has an opportunity to become generally acquainted with an environment, he retains some information about its different components that prepares him for learning to make new responses to them. Various explanations have been offered to account for this facilitation; some investigators suggest that the process of labelling enhances the distinctiveness of environmental stimuli for the labeller; others hold that perceptual acquaintance can more sharply differentiate an environment into its component parts for the perceiver or that it may encourage appropriate responses of observing or attending. Nevertheless, no single process has been identified as fundamental in stimulus predifferentiation. Perhaps a number of these processes operate in different combinations from one stimulus-predifferentiation transfer experiment to another, each process representing a different method by which a learner can become familiar with the details of his environment.

Transposition. Another phenomenon that has received considerable attention in theories of transfer of training is called transposition. An initial report of transposition came from a study in which chickens were trained by rewards to respond to the darker of two gray squares. After this discrimination task was learned, the chickens were shown the originally rewarded gray square along with one that was still darker. They seemed to prefer the darkest gray to the square that had been previously rewarded. This finding was interpreted to support the hypothesis that the birds had initially learned to respond to a relationship (what a human being would call the concept "darker") and that this response to a relationship had been transposed or transferred to the new discrimination. This relational interpretation later was challenged by theorists who offered a formulation to show, on the basis of principles of stimulus generalization, how a response to a relational stimulus could be explained by assuming that organisms do indeed respond to the absolute properties of the stimuli. Both explanations were found to be too simple for the variety of findings obtained with transposition studies. As a result, the interest of many investigators shifted away from demonstrating the relative merits of absolute versus relational interpretations to identifying conditions that seem to influence transposition behaviour. Within this context, newer, more sophisticated formulations have been proposed that consider both the absolute and relational characteristics of the stimuli in transposition studies.

Transfer among animals

Learning to learn. When people are asked to learn successive lists of words, their performance tends to improve from one task to another so that much less time is commonly required to learn, say, the tenth list than was needed for mastering the first list. This improvement suggests that information beyond the specific content of lists of words is also learned. It would seem as if the subjects are learning how to learn; that is, they seem to be acquiring learning sets, or expectancies, that transfer from list to list to produce continually improving performance.

Some of the most intensive work on learning sets has been carried out with monkeys that were learning how to solve several hundred discrimination problems in succession. In each problem, the monkey learned which one of two objects (for example, a bottle cap and a cookie cutter) consistently contained a piece of food. Although the solution of each successive problem required the animals to discriminate between two previously unfamiliar objects, performance tended to improve on successive tasks; the monkeys made increasing numbers of correct choices on the second trial of each problem as the process continued. Manifestly there was no cue to indicate the correct choice on the first trial of any specific problem. If the animal responded correctly on the first trial, then on the second trial it would only have to choose the same object to be correct thereafter; if the monkey made an error on the first trial, then the other object would inexorably be the one that should be chosen next. During their efforts to solve the first few problems the monkeys were correct approximately half the time on the second attempt to solve each problem. This success increased to an average of 80 percent correct after each animal had solved 100 problems, to 88 percent after 200 correct solutions, and eventually to 95 percent after 300. Thus, after a long series of separate tasks, all of the same type, the monkey's first response to the next problem usually provided sufficient information for the animal to make the correct choice.

Since each of the successive discrimination problems was different, what actually was being transferred from problem to problem? In these discrimination problems, the monkeys seemed to have several items of information to learn in addition to which one of the two objects contained the rewarding bit of food. The animals apparently had to learn to pay attention to that part of their environment where the objects were placed. To make the correct choice, it would seem that a monkey would have to learn to abandon any preference it might exhibit for objects on either the left or the right; indeed, the animals usually did show such preferences. (The correct object was shifted from side to side in a random sequence to control for these preferences.) Ostensibly, the monkeys also had to learn that one object consistently contained food while the other was always empty. Although these learning sets by themselves would not serve to identify the correct object in each new discrimination problem, it seems likely that they could help the animal locate the reward very rapidly by eliminating initially unprofitable responses.

Reversal learning. In reversal learning, the individual first learns to make a discrimination, such as choosing a black object in a black–white discrimination problem, and then is supposed to learn to reverse his choice—*i.e.,* to choose the white object. Such reversals tend to be difficult for most learners since there are negative transfer effects; *e.g.,* the individual tends to persist in responding to the black object that was originally correct. Eventually, however, one's tendency to make the originally learned selection typically becomes weaker, and he makes the competing response (*e.g.,* to white) more frequently until a point is reached where it is almost consistently evoked. Reversal learning can be accomplished very rapidly when a laboratory animal, such as a monkey, is presented with a series of reversal-learning problems in which the same sequence of shifts is repeated (as when black is initially correct, then white, then black, then white, and so on). After extended reversal training, some animals are able to make the next reversal in the sequence in one trial. They behave as if they have mastered the abstract concept of alternation or of regular sequence.

Evolution and transfer

The speed with which representatives of a given species of animal, including human beings, can be taught to make a reversal of this kind seems to be related to the place biologists assign them in a hierarchy of evolutionary development. On first being exposed to a reversal-learning problem, normally competent adult humans who can use language are likely to achieve a solution with great rapidity. Monkeys can learn to perform equally well after a relatively longer series of reversal-learning tasks; but isopods such as pill bugs or sow bugs, small relatives of crabs and shrimp, have such primitive brains that they seem to be unable to improve their performance at all during a series of reversal-learning tasks.

DEVELOPMENTAL PROCESSES AND TRANSFER

The manner in which a problem is learned seems to have an effect on what is transferred. This conclusion is supported by experiments in which comparisons are made of the relative ease with which children of different ages execute reversal and so-called extradimensional shifts (see above *Concept formation*). In performing both kinds of shift, experimental subjects learn two successive discriminations between two pairs of objects that vary simultaneously in two aspects or dimensions—*e.g.,* white triangle versus black square, and black triangle versus white square. In training subjects initially, discrimination of only one dimension (for example, black–white) is made relevant, with the child's selection of one of the cues (for example, white) being rewarded, while the other (black) is incorrect. After they have learned this, the children are shifted to the second discrimination. In the case of a reversal shift, the same stimulus dimension (black–white) remains relevant, but the child is now to learn to reverse his initial choice; black choices are now rewarded, and white selections become incorrect. For an extradimensional shift, the initially irrelevant dimension (square–triangle) is given relevance by rewarding selection of one of its alternatives and by failing to reward choices for the other.

The relative ease with which human beings learn to make extradimensional and reversal shifts is related to how old they are. Reversal shifts are relatively difficult for young children to learn and are relatively easy for adults to master. As people gain maturity, the relative ease with which they execute a reversal shift tends to increase in comparison with their ability to achieve an extradimensional shift.

Age and transfer

Explanations for these developmental changes seem to be found in the manner in which the individual solves a discrimination problem. Very young children and laboratory animals tend to learn simple habits when faced with a discrimination problem for the first time; for example, they are most likely to learn simply to approach black objects and to avoid white. Reversal shift is often extremely difficult for them, and negative transfer effects are substantial. Subjects who primarily learn simple habits are faced with the task of eliminating one habit (*e.g.,* to choose black) that has been rewarded and then of developing another habit (*e.g.,* to choose white) that previously has not been rewarded.

Human adults, on the other hand, generally find a reversal shift relatively easy; they do not behave as if they simply associate their choices to the relevant stimuli (*e.g.,* white and black) but instead appear symbolically (or conceptually) to react to both of them in terms of their common characteristic (brightness). A similar kind of symbolic or logical response is appropriate in solving reversal-shift problems; since the relevant dimension remains the same, this kind of shift tends to be easier to make than is one involving extradimensional shift, which requires the individual to switch to a new symbolic response (*e.g.,* from brightness to size). In short, when they respond concretely, learners favour their potentials for achieving extradimensional transfer; those who tend to respond symbolically enhance the probability for reversal transfer.

Whatever the validity to be found in theoretical explanations of this sort, review of how transfer phenomena may be influenced suggests that no single principle or simple theory thus far put forward accounts for all of the observed data. Instead, the evidence is that several interacting processes underlie transfer of training and that their relative influence depends both on the nature of the tasks between which transfer takes place as well as on the characteristics of the learning organism. If one seeks to control the degree of transfer, as one does in educational settings, it seems useful to analyze transfer behaviour in terms of a number of component processes—*e.g.,* stimulus and response similarity, stimulus predifferentiation and response learning, and the symbolic abilities of the learner.

THE PHYSIOLOGY OF TRANSFER OF TRAINING

Although available evidence for a physiological basis of transfer of training is limited, some impressive data already are recorded. Some central (brain and spinal-cord) mechanisms seem to control transfer of training. A long-established transfer phenomenon is cross education, in which there is positive transfer of a skill learned with one part of the body to another, untrained part. For example, a person who learns to throw a dart with his preferred hand exhibits positive transfer to his non-preferred hand. Since different muscles are involved in the equivalent action of opposite limbs, positive transfer resulting from cross education cannot be attributed simply to common muscular movements; instead it would seem that cross education depends on central processes that control the actions of both limbs.

Cross education

Among highly evolved animals, transfer of training between limbs from opposite sides of the body evidently is mediated through a massive system of neural fibres, known as the corpus callosum, that connects the two hemispheres of the brain. One of the many ways in which the validity of this principle may be demonstrated is first to train blindfolded cats to discriminate with one paw between two different pedals (by feeling raised horizontal lines on one pedal and by detecting raised vertical lines on the other). Since each eye sends some of its nerve impulses to both hemispheres of the cat's brain while each paw only directs impulses to the hemisphere of the brain on the same side of the animal's body, this procedure feeds the sensory information to just one hemisphere. After learning to make the discrimination with one paw (*e.g.,* reward being given only for the pedal with the horizontal pattern), a cat that is confronted with making the same discrimination with the other front paw, which has its connections with the ostensibly "untrained" brain hemisphere, will nevertheless exhibit positive transfer. Indeed, even when the corpus callosum is surgically severed immediately after learning (to "disconnect" the two hemispheres), positive transfer will take place from one front paw to the other; manifestly, transfer of training takes place between connected hemispheres while the animal is learning. If the cat's corpus callosum is severed before it initially learns to discriminate the two pedals, however, no transfer occurs between the animal's limbs; the untrained paw fails to exhibit any benefit from what has been learned with the other paw. In other words, by severing the cat's corpus callosum, the surgeon splits the brain into two independently functioning units. The same kinds of behaviour are observable among other split-brain animals, including chimpanzees and people.

The physiological foundations of transfer of training are not limited merely to the anatomical considerations of the central nervous system. To better understand how physiological processes mediate transfer of training means also to be able to specify more fully the anatomic, electrical, and chemical basis of learning in general, a goal that remains incompletely achieved. Many physiologists and psychologists hold that the search for the neurophysiological foundations of learning can be pursued most profitably by measuring physical and chemical changes that influence the transmission of nerve impulses. It has long been established that chemical changes are part of the process of neural transmission; and it is widely agreed that, in some way, biochemical activities also are responsible for all forms of learning, including transfer of training.

One popular theory in the 1960s was that learning and remembering depend on changes in the molecular structure of such chemicals as ribonucleic acid (RNA) and peptides that are incorporated in the cells of the body, including nerve cells. Some researchers have theorized that memory traces are physically coded within the molecules of cells.

Reports of experiments have been published offering evidence that skills have been transferred from one individual to another by injecting materials taken from the brains (or even other parts of the body) of trained animals into the bodies of untrained organisms (*e.g.,* flatworms, rats, hamsters). These reports have encouraged many to hope that someday one might be able to learn a foreign language, for example, by simply taking a pill instead of through the usual time-consuming practice. Subsequent efforts to repeat such experiments sometimes have given positive results but more often have yielded no evidence of chemical transfer of training from one individual to the next. In view of such inconsistent findings, this question became a matter of considerable controversy. Many investigators seemed inclined to dismiss the notion that organisms can learn by swallowing chemicals or through injection as another of those oversimplified interpretations that continue to be offered in efforts to account for complex psychophysiological phenomena. (H.H.K.)

BIBLIOGRAPHY

General works: J.F. HALL, *The Psychology of Learning* (1966), provides a comprehensive account of the empirical data that theories of learning are designed to integrate. E.R. HILGARD and G.H. BOWER, *Theories of Learning*, 3rd ed. (1966), is the standard reference on this subject. G.A. KIMBLE (ed.), *Hilgard and Marquis' Conditioning and Learning*, 2nd ed. (1961), describes theoretical issues as they apply to simple learning. The separate articles reproduced in KIMBLE, *Foundations of Conditioning and Learning* (1967), develop some of these arguments in more detail and also present synopses of the theoretical positions of Hull, Guthrie, and Tolman. G.A. KIMBLE and N. GARMEZY, *Principles of General Psychology*, 3rd ed. (1968), is a general textbook that covers several theoretical issues and should be particularly useful on the topics of memory and retrieval.

Psychomotor learning: A.L. IRION, "A Brief History of Research on the Acquisition of Skill," in E.A. BILODEAU (ed.), *Acquisition of Skill* (1966), an excellent historical survey; R.S. WOODWORTH and H. SCHLOSBERG, *Experimental Psychology*, rev. ed. (1954), one of the best standard reference works; C.E. NOBLE, "S-O-R and the Psychology of Human Learning," *Psychol. Rep.*, 18:923–943 (1966), a brief introduction to human learning; A.W. MELTON (ed.), *Apparatus Tests* (1947), a classic volume on psychomotor devices used in aviation psychology. Periodic reviews of the psychomotor field include: E.A. and I.MCD. BILODEAU, "Motor-Skills Learning," *A. Rev. Psychol.* 12:243–280 (1961); J.A. ADAMS, "Motor Skills," *ibid.*, 15:181–202 (1964); and C.E. NOBLE, "The Learning of Psychomotor Skills," *ibid.*, 19:203–250 (1968). C.L. HULL, *Principles of Behavior* (1943); and K.W. SPENCE, *Behavior Theory and Conditioning* (1956), are two of the most influential books on general behaviour theory from the reinforcement viewpoint. C.E. NOBLE, "A Theory of Psychomotor Skill: Derivation and Data," *Psychonomic Sci.* 21:344 (1970), makes a specific application to psychomotor learning. Two volumes presenting detailed information-processing analyses of skill are P.M. FITTS and M.I. POSNER, *Human Performance* (1967); and A.T. WELFORD, *Fundamentals of Skill* (1968). E.A. BILODEAU (ed.), *Principles of Skill Acquisition* (1969), provides an eclectic, simplified treatment of current topics by several authors. R.N. SINGER, *Motor Learning and Human Performance* (1968), is oriented mainly toward athletic proficiency and physical education. Articles of specialized interest, as indicated by their titles, are J.A. ADAMS, "Response Feedback and Learning," *Psychol. Bull.*, 70:486–504 (1968); C.E. NOBLE, "Acquisition of Pursuit Tracking Skill Under Extended Training As a Joint Function of Sex and Initial Ability," *J. Exp. Psychol.*, 86:360–373 (1970); and R.B. PAYNE, "Functional Properties of Supplementary Feedback Stimuli," *J. Motor Behav.*, 2:37–43 (1970).

Concept formation: L.E. BOURNE, *Human Conceptual Behavior* (1966), a well-organized review of laboratory studies; J.S. BRUNER, J.J. GOODNOW, and G.A. AUSTIN, *A Study of Thinking* (1956), a classic, well-written description of some experiments in the field; J.H. FLAVELL, *The Developmental Psychology of Jean Piaget* (1963), a competent explanation of Piaget's controversial and provocative ideas; E.B. HUNT, *Concept Learning: An Information Processing Problem* (1962), a comprehensive review and theoretical presentation of major approaches; B.F. SKINNER, *Verbal Behavior* (1957), a challenging proposal for applying laboratory psychology.

Transfer of training: Introductory psychology texts that discuss transfer of training as an experimental phenomenon and its implications for a wide variety of behaviour are H.H. KENDLER, *Basic Psychology*, 2nd ed. (1968); and H.H. and T.S. KENDLER, *Basic Psychology: Brief Edition* (1971). H.C. ELLIS, *The Transfer of Learning* (1965), presents a general analysis of transfer and includes reprints of important journal articles on the topic. Undergraduate texts that review theories and experimental evidence concerning transfer of training are J. DEESE and S.H. HULSE, *The Psychology of Learning*, 3rd ed. (1967); and J.F. HALL, *The Psychology of Learning* (1966). H.W. REESE, *The Perception of Stimulus Relations: Discrimination Learning and Transposition* (1968); and D.A. RILEY, *Discrimination Learning* (1968), are accounts of how transfer of training influences discrimination learning.

Lebanon

The Republic of Lebanon (al-Jumhūrīyah al-Lubnānīyah), a predominantly mountainous country of great scenic beauty, is an Arab republic situated on the eastern shore of the Mediterranean Sea. Consisting of a narrow strip of land about 135 miles (215 kilometres) long from north to south and 20 to 55 miles wide from east to west, it is bounded to the north and east by Syria and to the south by Israel. With an area of 3,950 square miles (10,230 square kilometres), Lebanon is one of the world's smaller sovereign states. The capital is Beirut.

Though Lebanon, particularly its coastal region, was the site of some of the oldest human settlements in the world—the Phoenician ports of Tyre (modern Ṣūr), Sidon (Ṣaydā), and Byblos (Jubayl) were dominant centres of trade and culture in the 3rd millennium BC—it was not until 1920 that the contemporary state came into being. In that year France, which administered Lebanon as a League of Nations mandate, established the state of Greater Lebanon. Lebanon then became a republic in 1926 and achieved independence in 1943.

As an Arab republic, Lebanon shares many of the cultural characteristics of the Arab world, yet it has attributes that differentiate it from many of its Arab neighbours. Its rugged, mountainous terrain has served throughout history as an asylum for diverse religious and ethnic groups and for political dissidents. Lebanon is one of the most densely populated countries in the Mediterranean area. It has one of the highest rates of literacy. Although its prosperity is unevenly distributed, having bypassed large segments of its population, wealth and privilege appear to be evenly distributed among its middle-income group. Notwithstanding its meagre natural resources, Lebanon long managed to serve as a busy commercial and cultural centre for the Middle East.

This outward image of vitality and growth nevertheless disguised serious problems. Not only did Lebanon have to grapple with internal problems of social and economic organization, but also it had to struggle to define its position in relation to Israel, to its Arab neighbours, and to Palestinian refugees living in Lebanon. The Lebanese pluralistic communal structure eventually collapsed under the pressures of this struggle. Communal rivalries over political power became so exacerbated by the complex issues that arose from the Palestinian question that a breakdown of the governmental system resulted from an extremely damaging civil war that began in 1975.

This article is divided into the following sections:

Physical and human geography

THE LAND

Relief. As in any mountainous region, the physical geography of Lebanon is extremely complex and varied. Landforms, climate, soils, and vegetation undergo some sharp and striking changes within short distances. Four distinct physiographic regions may be distinguished: a narrow coastal plain along the Mediterranean Sea, the Lebanon Mountains (Jabal Lubnān), al-Biqāʿ (Beqaa) valley, and the Anti-Lebanon and Hermon ranges running parallel to the coastal mountains.

Physiographic regions

The coastal plain is narrow and discontinuous, almost disappearing in places. It is formed of river-deposited alluvium and marine sediments, which alternate suddenly with rocky beaches and sandy bays, and is generally fertile. In the far north it expands to form the ʿAkkār Plain.

The snowcapped Lebanon Mountains are the most prominent feature of the country's landscape. The range, rising steeply from the coast, forms a ridge of limestone and sandstone, cut by narrow and deep gorges. It is approximately 100 miles long and varies in width from 35 to six miles. Its maximum elevation is at Qurnat as-Sawdā' (10,138 feet [3,090 metres]) in the north, where the renowned cedars of Lebanon grow in the shadow of the peak. The range then gradually slopes to the south, rising again to a second peak, Jabal Ṣannīn, northeast of Beirut. To the south the range gives way to the hills of Galilee, which are lower. The limestone composition of the mountains provides a relatively poor topsoil. The lower and middle slopes, however, are intensively cultivated, the terraced hills standing as a scenic relic of the ingenious tillers of the past. On the coast and in the northern mountains reddish topsoils with a high clay content retain moisture and provide fertile land for agriculture, although they are subject to considerable erosion.

Al-Biqāʿ valley lies between the Lebanon Mountains in the west and the Anti-Lebanon Mountains in the east; its fertile soils consist of alluvial deposits from the mountains on either side. The valley, approximately 110 miles long

LEBANON

and from six to 16 miles wide, is part of the great East African Rift System. In the south, al-Biqā' becomes hilly and rugged, blending into the foothills of Mt. Hermon (Jabal ash-Shaykh) to form the upper Jordan Valley.

The Anti-Lebanon range (al-Jabal ash-Sharqī) starts with a high peak in the north and slopes southward until it is interrupted by Mt. Hermon (9,232 feet).

Drainage. Lebanese rivers, though numerous, are mostly winter torrents, draining the western slopes of the Lebanon Mountains. The only exception is the Līṭānī (90 miles long), which rises near the famed ruins of Baalbek (Ba'labakk) and flows southward in al-Biqā' to empty into the Mediterranean near historic Tyre. The two other important rivers are the Orontes (Nahr al-'Āṣī), which rises in the north of al-Biqā' and flows northward, and the Kabīr.

Climate. There are sharp local contrasts in climatic conditions. Lebanon is included in the Mediterranean climatic region, which extends westward to the Atlantic Ocean. The winter storms formed over the ocean move eastward through the Mediterranean, bringing rain at that season; in summer the Mediterranean receives no rain. The climate of Lebanon is generally subtropical and is characterized by hot, dry summers and mild, humid winters. Mean daily maximum temperatures on the coast and in al-Biqā' range from 90° F (32° C) in July to 60° F (16° C) on the coast and 50° F (10° C) in al-Biqā' in January. Mean minimum temperatures in January are 50° F (10° C) on the coast and 35° F (2° C) in al-Biqā'. At 5,000 feet, the altitude of the highest settlements, these are reduced by about 15° F (8° C).

Nearly all precipitation falls in winter and averages 30 to 40 inches (750 to 1,000 millimetres) on the coast, rising to more than 50 inches in higher altitudes. Al-Biqāʿ is drier and receives 15 to 25 inches. On the higher mountaintops, this precipitation falls as heavy snow that remains until early summer.

Cedar trees

Plant and animal life. Lebanon was heavily forested in ancient and medieval times, and its timber—particularly its famed cedar—was exported for building and shipbuilding. The natural vegetation, however, has been grazed, burned, and cut for so long that little of it is regenerated. What survives is a wild Mediterranean vegetation of brush and low trees, mostly oaks, pines, cypresses, firs, junipers, and carobs.

Few large wild animals survive in Lebanon, though bears are occasionally seen in the mountains. Among the smaller animals, deer, wildcats, hedgehogs, squirrels, martens, dormice, and hares are found. Numerous migratory birds from Africa and Europe visit Lebanon. Flamingos, pelicans, cormorants, ducks, herons, and snipes frequent the marshes; eagles, buzzards, kites, falcons, and hawks inhabit the mountains; and owls, kingfishers, cuckoos, and woodpeckers are common.

Settlement patterns. Most of the population live on the coastal plain, and progressively fewer people are found farther inland. Rural villages are sited according to water supply and the availability of land, frequently including terraced agriculture in the mountains. Northern villages are relatively prosperous and have some modern architecture. Villages in the south have been generally poorer and less stable; their agricultural land is less fertile and, because of their proximity to Israel, many have been subject to frequent dislocation, invasion, and destruction since 1975. Most cities are located on the coast; they have been inundated by migrants and displaced persons, and numerous, often poor, suburbs have been created as a result. Before 1975 many villages and cities were composed of several different religious groups, usually living together in harmony, and rural architecture reflected a unity of style irrespective of religious identity. Since the civil war began, a realignment has moved thousands of Christians north of Beirut along the coast and thousands of Muslims south or east of Beirut, so that settlement patterns reflect the chasms separating sections of the Lebanese people from each other.

THE PEOPLE

Lebanon has a heterogeneous society composed of numerous ethnic, religious, and kinship groups. Primordial attachments and local communalism antedate the creation of the present territorial and political entity and continue to survive with remarkable tenacity.

Ethnic and linguistic groups. Ethnically, the Lebanese compose a mixture in which Phoenician, Greek, Armenian, and Arab elements are discernible. Arabic is the official language, but French and English are widely spoken. A small percentage of the population is Armenian-speaking, and Syriac is used in some of the churches of the Maronites (Roman Catholics following an Eastern rite).

Religious groups. Perhaps the most distinctive feature of Lebanon's social structure is its varied religious composition. Since the 7th century Lebanon has served as a refuge for persecuted Christian and Muslim sects. The population is estimated to consist of a majority of Muslims and a large minority of Christians. Shīʿite Muslims are the most numerous group. Among the Christians, Maronites form the largest group, and Greek Orthodox and Greek Catholics are the next largest groups. Among the three Muslim denominations, the Shīʿites are followed closely by the Sunnites; the Druzes constitute a small percentage. There is also a very small minority of Jews.

Demography. One of the most salient demographic features of Lebanon is the uneven distribution of its population. The country's overall density is much lower than that of Bayrūt *muḥāfaẓah* (Beirut governorate) but much higher than that of the most sparsely populated, al-Biqāʿ governorate.

Before the civil war began, the movement of people from rural areas was a major factor in the country's soaring rate of urbanization. Most of the internal migration was to Beirut, which accounted for the great majority of Lebanon's urban population. The civil war and postwar fighting led to a substantial return of people to their villages and to a large migration abroad, primarily to the United States, Europe, Latin America, Australia, and the oil states of the Middle East.

THE ECONOMY

Until 1975 Lebanon had an economy characterized by a minimum of government intervention in private enterprise. Since the civil war, the weak central government has exercised little power in economic matters, and local militias have dominated public decision making.

Werner Braun—Camera Press

Cedars of Lebanon on the slopes of the Lebanon Mountains.

The services sector generated the overwhelming proportion of national income before the civil war and employed the largest proportion of the labour force; industry generated the second largest proportion of income and of employment. Agriculture accounted for a smaller proportion of income. The growth of services was related mainly to international transport and trade and to the position of Beirut as a centre of international banking and tourism.

Economic losses after 1974

The war of 1975–76, the Israeli invasion of 1982, and the continuing violence have left deep scars and have led to chaos in the economy. There has been extensive destruction in all sectors, but especially in housing, trade, and public services, and the country's productive capacity has been drastically reduced. The greatest reduction in productive capacity seems to be in services, followed by industry and agriculture.

Resources. The mineral resources of Lebanon are few. There are deposits of high-grade iron ore and lignite; building-stone quarries; high-quality sand, suitable for glass manufacture; and lime. The Līṭānī River hydroelectric project generates electricity and also has increased the amount of irrigated land for agriculture.

Agriculture. Arable land is scarce, but the climate and the relatively abundant water supply from springs favour the intensive cultivation of a variety of crops on mountain slopes and in the coastal region. On the irrigated coastal plain market vegetables, bananas, and citrus crops are grown. In the foothills the principal crops are olives, grapes, tobacco, figs, and almonds. At higher altitudes (about 1,500 feet) peaches, apricots, plums, and cherries are planted, while apples and pears thrive at an altitude of about 3,000 feet. Sugar beets, cereals, and vegetables are the main crops cultivated in al-Biqāʿ. Poultry is a major source of agricultural income, and goats, sheep, and cattle are also raised.

As a result of the continued violence many small farmers have lost their livestock, and there has been a noticeable decrease in the production of many agricultural crops. The production of hemp, the source of hashish, has flourished in al-Biqāʿ valley, however, and the hashish is exported illegally through ports along the coast.

Industry. The majority of the country's industry survived the civil war unscathed. Beirut's industrial belt was razed, but some of the country's large complexes were unharmed. Manufacturing recovered to more than half of the still existing capacity, restrained by limited labour mobility, difficulty in acquiring supplies, insufficient working capital, and difficulty in obtaining credit. The Israeli invasion of 1982, however, with its heavy bombardment of some of Lebanon's major cities and subsequent sabotage by local warring factions, caused further damage to industry and infrastructure.

Beirut's well-developed seaport and airport and the country's free economic and foreign exchange systems, favourable interest rates, and banking secrecy law (modeled upon that of Switzerland) all contributed to the traditional preeminence of trade and services. Prior to the civil war, the country's scenery, its biblical and other historic sites, its hotels, bars, nightclubs, and restaurants, its seaside and mountain resorts, its outdoor sports facilities, and its international cultural festivals made tourism a year-round industry. As the war progressed, the prosperous hotel district in Beirut became the scene of some of the fiercest fighting, and bombing in 1982 caused heavy damage. The closures of Beirut airport, the heavy destruction of the port, and the continued political unrest greatly damaged the service industry.

Finance. The finance sector of Lebanon's economy, including banking and insurance, showed an impressive expansion before the war, and the monetary reserves of Lebanon continued to rise despite political uncertainties. During the two years of civil war and the extended period of domestic instability and economic inflation following that, reserves, which included a considerable portion of gold, nevertheless continued to rise.

Capital inflows

The balance of payments has traditionally shown a surplus. The strength of the Lebanese pound and of the balance-of-payments position reflected large inflows of capital, mostly from Lebanese living abroad (whose numbers rose considerably during and after the civil war) and from the high level of liquidity of commercial banks. By 1983, however, inflows from Lebanese living abroad had begun to decrease, and the value of the Lebanese pound fell dramatically.

Trade. Widespread smuggling, covert foreign aid to armed groups, and illegal drug production have disguised the pattern of trade since 1975. Exports, chiefly vegetable products, textiles, and nonprecious metals are sent mainly to Middle Eastern countries. Imports such as consumer goods, machinery and transport equipment, petroleum products, and food come mostly from western Europe. A huge trade deficit has been partly covered by "invisible" items such as foreign remittances and government loans.

Trade unions. Lebanon is one of the few countries in the Middle East with a comparatively well-developed labour movement. Trade unions have secured some tangible gains, such as fringe benefits, collective bargaining contracts, and better working conditions. During the civil war divisions in many of the trade unions weakened their normal functions, and many of their members joined the warring factions. Many others emigrated.

Transportation. As in antiquity, Lebanon's situation makes it a vital crossroads between East and West. The road network traversing Lebanon includes international highways, which form part of major land routes connecting Europe with the Arab countries and the East. There are also national highways, paved secondary roads, and unpaved roads. The railway system, which includes lines along the coast and up al-Biqāʿ valley and a cog railway across the Lebanon Mountains, connects with the rail system of Syria. In the past the system was linked with rail systems of other Arab countries and with Europe and was used mainly for long-distance bulk transport.

Port of Beirut

There are numerous ports along the Lebanese seacoast. Berths for oil tankers have been built offshore at Tripoli and at az-Zahrānī, near Sidon, where pipeline terminals and refineries also are located. The principal cargo and passenger port is that of Beirut, which has a free zone and storage facilities for transit shipments. The port has been expanded and deepened, and a large storage silo (for wheat and other grains) has been built there, but port facilities were severely damaged during the civil war and the postwar fighting. The harbour at Jūniyah has grown in importance.

Beirut International Airport was one of the busiest airports in the Middle East before the civil war. Its runways were built to handle the largest jet airplanes in service, and a number of international airlines used Beirut regularly.

GOVERNMENT AND SOCIAL CONDITIONS

Parliament

Government. *The constitutional framework.* Modern Lebanon is a republic with a parliamentary system of government. Its constitution, promulgated in 1926 during the French mandate and modified by several subsequent amendments, provides for a unicameral Chamber of Deputies (renamed National Assembly in 1979) elected, for a term of four years, by universal adult suffrage (women attained the right to vote and eligibility to run for office in 1953). Parliamentary seats are apportioned on a religious basis in the ratio of six Christians to five Muslims, making the total number always a multiple of 11. This sectarian distribution is also to be observed in administrative appointments for public office.

The president of the republic is elected by a two-thirds majority of the National Assembly for a term of six years and is eligible for reelection only after the lapse of a further six years. By an unwritten convention, the president must be a Maronite, the premier a Sunnite Muslim, and the speaker of the National Assembly a Shīʿite. The president, who is constitutionally invested with the power of chief executive, calls upon a Sunnite Muslim to form a Cabinet, and the Cabinet members' portfolios must reflect the sectarian balance. The Cabinet, to remain in power, requires a vote of confidence from the Assembly. A vote of no confidence, however, is a constitutional right that is rarely exercised in practice. A Cabinet usually falls because of internal dissension or because the president withdraws his support.

Local government. For administrative purposes Lebanon is divided into *muḥāfaẓāt* (governorates): Bayrūt (Beirut), Jabal Lubnān, ash-Shamāl, al-Janūb, al-Biqāʿ, and an-Nabaṭīah. These are administered by the *muḥāfiẓ* (governor), who represents the central government. The *muḥāfaẓāt* are further divided into *qaḍāʾ*s (districts), each of which is presided over by a *qāʾim-maqām* (district chief), who, along with the *muḥāfiẓ*, supervises local government. Municipalities (communities with at least 500 inhabitants) elect their own councils, which in turn elect mayors and vice mayors. Villages and towns (more than 50 and fewer than 500 inhabitants) elect a *mukhṭār* (headman) and a council of elders, who serve on an honorary basis. All officers of local governments serve four-year terms.

The political process. The political system in Lebanon remains a curious blend of secular and traditional features. Until 1975 the country appeared to support liberal and democratic institutions, yet, in effect, it had hardly any of the political instruments of a civil polity. Its political parties, parliamentary blocs, and pressure groups were so closely identified with parochial, communal, and personal loyalties that they often failed to serve the larger national purpose of the society. The National Pact of 1943, a sort of Christian–Muslim entente, sustained the national entity (*al-kiyān*), yet this sense of identity was neither national nor civic.

National Pact of 1943

In April 1975 the political process collapsed. The war that had engulfed the Lebanese exposed the vulnerability of the political system. The legitimate authority continues to maintain the facade of continuity, while the process on which it is based was destroyed by the contending forces in the conflict that has continued to ravage Lebanon. Real power rests in the sectarian militias, who are not under the control of the official central government.

Justice. The system of law and justice is mostly modeled on French concepts. The judiciary consists of courts of the first instance, courts of appeal, courts of cassation, and a Court of Justice that handles cases affecting state security. The Council of State is a court that deals with administrative affairs. In addition, there are religious courts that deal with matters of personal status (such as inheritance, marriage, and property matters) as they pertain to autonomous communities. Despite the country's well-developed legal system and a very high proportion of lawyers, significant numbers of disputes and personal grievances are resolved outside the courts. Justice by feud and vendetta continues.

Armed forces. The armed forces consist of an army, air force, and navy. Lebanon also has a paramilitary gendarmerie and police force. During the civil war the army practically disintegrated as splinter groups joined the different warring factions. Reconstruction of the Lebanese armed forces has been attempted, particularly with the assistance first of the United States and then of Syria, but to very little effect. Responsibility for maintaining security and order has fallen to the various political and religious factions and to foreign occupiers.

Education. A well-developed system of education reaches all levels of the population. Literacy is among the highest in the Middle East. Education was once almost exclusively the responsibility of religious communities or foreign groups, but the number of students in public schools has risen to about two-fifths of the total school enrollment.

The compulsory five-year primary school program is followed either by a seven-year secondary program (leading to the official baccalaureate certificate) or by a four-year program of technical or vocational training. Major universities include the American University of Beirut, the Universitê Saint-Joseph (subsidized by the French government and administered by the Jesuit order), the Lebanese University (Universitê Libanaise), and the Beirut Arab University (an affiliate of the University of Alexandria).

Universities

Health and welfare. Public health services are largely concentrated in the cities, although the government increasingly directs medical aid into rural areas. As in the field of social welfare, nongovernmental voluntary associations—mostly religious, communal, or ethnic—are active. The Lebanese diet is generally satisfactory, and the high standard of living and the favourable climate have served to reduce the incidence of many diseases that are still common in other Middle Eastern countries.

Lebanon has a large number of skilled medical personnel, and hospital facilities are also adequate under normal circumstances. The thousands of casualties and deaths caused by almost constant warfare since 1975 have overburdened the country's health and medical facilities and hampered the treatment of routine illnesses.

The National Social Security Fund, which is not fully implemented, provides sickness and maternity insurance, labour accident and occupational disease insurance, family benefits, and termination-of-service benefits.

Housing. In response to the need for low-cost housing, the Popular Housing Law was enacted, providing for the rehabilitation of substandard housing. Prior to the civil war a substantial percentage of homes were without bathrooms, and thousands of families, including Palestinian refugees, were living in improvised accommodations. When an economic boom attracted villagers to the capital, the housing shortage worsened considerably. The civil war drastically increased the problem. Thousands of homes in battle zones were destroyed, and entire villages were evacuated and others occupied. The result was chaos in which property rights were violated as a matter of course. The government, in an attempt to remedy the situation, set up a Housing Bank to make housing loans.

Housing Bank

Wages and cost of living. A minimum wage is set by the Labour Code, and legislation provides for cost-of-living increases. The cost of living increased sharply prior to, during, and after the civil war, mainly because of a substantial rise in the cost of rent, education, food, and petroleum products.

Social and economic division. Lebanese society was able for a long time to give a semblance of relative economic stability. The existence of a large middle-income group, in addition to the political and social legitimacy that kinship ties and religious and communal attachments had, reinforced the false veneer that masked the growing socioeconomic dislocations. The interaction of these factors covered up the growing class polarization, especially around the industrial belt that encircled Beirut. The eruption of civil conflict in 1975 and the ensuing state of chaos is attributable in part to the fact that the system of government was unresponsive to the acute social problems and grievances.

CULTURAL LIFE

The cultural milieu. Historically, Lebanon is the heir of a long succession of Mediterranean cultures—Phoenician, Greek, and Arab. Its cultural milieu continues to show clear manifestations of a rich and diverse heritage. As an Arab country, Lebanon shares more than a common language with neighbouring Arab states; it also has a similar cultural heritage and common interests.

In the 19th century Lebanese linguists were in the vanguard of the Arabic literary awakening. In more recent times, writers of the calibre of Khalil Gibran, Georges Shehade, and Michel Chiha have been widely translated and have reached an international audience.

While for a time cultural life in Lebanon was predominantly centred around universities and affiliated institutions, there has been an impressive proliferation of cultural activities under other auspices. Beirut has several museums and a number of private libraries, learned societies, and research institutions.

The state of the arts. Lebanon's antiquities and ruins have provided not only inspiration for artists but also magnificent backdrops for annual music festivals, most notably the Baalbek International Festival. At one time, international opera, ballet, symphony, and drama companies, of nearly all nationalities, competed to enrich the cultural life of Beirut. Lebanon has produced a number of gifted young artists who have shown a refreshing readiness to experiment with new expressive forms. Some Lebanese are active in European opera and theatre companies, while others are intent on creating a wider audience for classical Arabic music and theatre.

Music festivals

The cultural awakening encouraged the revival of national folk arts, particularly song, *dabkah* (the national dance), and *zajal* (folk poetry), and the refinement of traditional crafts. Although the Baalbek International Festival was suspended during the civil war, popular theatre and radio satires continued to flourish in the war-ridden country.

The communications media. In addition to the wide variety of foreign newspapers and magazines that can be found in Beirut, Lebanon has registered publications in Arabic, English, French, and Armenian, including a number of daily newspapers.

Because of the wide choice of films, comfortable surroundings, and low prices, going to view motion pictures emerged as a popular form of entertainment among the Lebanese. Moviegoing has been supplanted to some extent, however, by private viewing of videocassettes.

Television programming is offered by Beirut's private companies, and Egyptian and Syrian broadcasts are received. With the advent of the transistor, Lebanon became virtually saturated with radios. The government-run radio station broadcasts Arabic, French, English, and Armenian programs, and clandestine radio stations broadcast the news and views of the warring parties.

For statistical data on the land and people of Lebanon, see the *Britannica World Data* section in the BRITANNICA WORLD DATA ANNUAL. (S.G.K./C.F.M./W.L.O.)

History

PHOENICIA

Origins and relations with Egypt. The evidence of tools found in caves along the coast of Lebanon shows that the area was inhabited from the Paleolithic through the Neolithic periods. Village life followed the domestication of plants and animals (the Neolithic Revolution, after about 10,000 BC), with Byblos (modern Jubayl) apparently taking the lead. At this site also appear the first traces in Lebanon of pottery and metallurgy (first copper, then bronze, an alloy of tin and copper) by the 4th millennium BC. The Phoenicians, indistinguishable from the Canaanites of Palestine, probably arrived in the land that became Phoenicia (a Greek term applied to the coast of Lebanon) in about 3000 BC. Herodotus and other Classical writers preserve a tradition that they came from the coast of the Erythraean Sea (*i.e.*, the Persian Gulf), but in fact nothing certain is known of their original homeland.

Arrival of the Phoenicians

Except at Byblos, no excavations have produced any information concerning the 3rd millennium in Phoenicia before the advent of the Phoenicians. At Byblos, the first urban settlement is dated *c.* 3050–2850 BC. Commercial and religious connections, probably by sea, with Egypt are attested from the Egyptian 4th dynasty (*c.* 2613–*c.* 2494 BC). The earliest artistic representations of Phoenicians are found in a damaged relief at Memphis of Pharaoh Sahure of the 5th dynasty (early 25th century BC). This shows the arrival of an Asiatic princess to be the Pharaoh's bride; her escort is a fleet of seagoing ships, probably of the type known to the Egyptians as "Byblos ships," manned by crews of Asiatics, evidently Phoenicians.

Byblos was destroyed by fire about 2150 BC, probably by the invading Amorites. The Amorites rebuilt on the site, and a period of close contact with Egypt was begun. Costly gifts were given by the pharaohs to those Phoenician and Syrian princes, such as the rulers of Ugarit and Katna, who were loyal to Egypt. Whether this attests to Egypt's political dominion over Phoenicia at this time or simply to strong diplomatic and commercial relations is not entirely clear.

In the 18th century BC new invaders, called Hyksos, destroyed the Amorite rule in Byblos and, passing on to Egypt, brought the Middle Kingdom to an end (*c.* 1720 BC). Little is known about the Hyksos' origin, but they seem to have been ethnically mixed, including a considerable Semitic element, since the Phoenician deities El, Baal, and Anath figured in their pantheon. The rule of the Hyksos in Egypt was brief and their cultural achievement slight, but in this period the links with Phoenicia and Syria were strengthened by the presence of Hyksos aristocracies throughout the region. Pharaoh Ahmose I expelled the Hyksos in about 1567 BC and instituted the New Kingdom policy of conquest in Palestine and Syria. In his annals Ahmose records capturing oxen from the Fenkhw, a term here perhaps referring to the Phoenicians. In the annals of the greatest Egyptian conqueror, Thutmose III (*c.* 1504–1450 BC), the coastal plain of Lebanon, called Djahy, is described as rich with fruit, wine, and grain. Of particular importance to the New Kingdom pharaohs was the timber, notably the cedar, of the Lebanese forests. A temple relief at Karnak depicts the chiefs of Lebanon felling cedars for the Egyptian officers of Seti I (*c.* 1300 BC).

Fuller information about the state of Phoenicia in the 14th century BC comes from the Amarna Letters, diplomatic texts belonging to the Egyptian foreign office, written in cuneiform and found at Tell el-Amarna in Middle Egypt. These archives reveal that the Land of Retenu (Syria–Palestine) was divided into three administrative districts, each under an Egyptian governor. The northernmost district (Amurru) included the coastal region from Ugarit to Byblos; the central (Upi) included the southern al-Biqāʿ valley and Anti-Lebanon; and the third district (Canaan) included all of Palestine from the Egyptian border to Byblos. Also among the letters are many documents addressed by the subject princes of Phoenicia and their Egyptian governors to the pharaoh. It was a time of much political unrest. The Hittites from central Anatolia were invading Syria; nomads from the desert supported the invasion, and many of the local chiefs were ready to seize the opportunity to throw off the yoke of Egypt. The tablets that reveal this state of affairs are written in the language and script of Babylonia (*i.e.*, Akkadian) and thus show the extent to which Babylonian culture had penetrated Palestine and Phoenicia; at the same time they illustrate the closeness of the relations between the Canaanite towns (*i.e.*, those in Palestine) and the dominant power of Egypt.

The Hittite invasion

After the reign of Akhenaton (Amenhotep IV; 1379–*c.* 1362), that power collapsed altogether; but his successors attempted to recover it, and Ramses II reconquered Phoenicia as far as the Nahr el Kelb. In the reign of Ramses III (1198–66) many great changes began to occur as a result of the invasion of Syria by peoples from Asia Minor and Europe. The successors of Ramses III lost their hold over Canaan; the 21st dynasty no longer intervened in the affairs of Syria. In *The Story of Wen-Amon,* a tale of an Egyptian religious functionary sent to Byblos to secure cedar around 1100 BC, the episode of the functionary's inhospitable reception shows the extent of the decline of Egypt's authority in Phoenicia at this time. Sheshonk (Shishak) I, the founder of the 22nd dynasty, in about 928 BC endeavoured to assert the ancient supremacy of Egypt. His successes, however, were not lasting, and, as is clear from the Old Testament, the power of Egypt thereafter became ineffective.

Phoenicia as a colonial and commercial power. Kingship appears to have been the oldest form of Phoenician government. The royal houses claimed divine descent, and the king could not be chosen outside their members. His power, however, was limited by the powerful merchant families, who wielded great influence in public affairs. Associated with the king was a council of elders; such at least was the case at Byblos, Sidon, and perhaps Tyre. During Nebuchadrezzar II's reign (605–562 BC) a republic took the place of the monarchy at Tyre, and the government was administered by a succession of suffetes (judges); they held office for short terms, and in one instance two ruled together for six years. Much later, in the 3rd century BC, an inscription from Tyre also mentions a suffete. Carthage was governed by two suffetes, and these officers are frequently named in connection with the Carthaginian colonies. But this does not justify any inference that Phoenicia itself had such magistrates. Under the Persians a federal bond was formed linking Sidon, Tyre, and Aradus. Federation on a larger scale was never possible in Phoenicia, for the reason that no sense of political unity existed to bind the different states together.

Colonies. By the 2nd millennium BC the Phoenicians had already extended their influence along the coast of the Levant by a series of settlements, some well known, some virtually nothing but names. Well known throughout history are Joppa (Tel Aviv–Yafo) and Dor (later Tantura, modern Nasholim) in the south. The earliest site, however, outside the Phoenician homeland known to possess important aspects of Phoenician culture is Ugarit (Ras Shamra), about six miles north of Latakia. The site was already occupied before the 4th millennium BC, but the Phoenicians only became prominent there in the Egyptian 12th dynasty (1991–1786 BC).

Evidence remains of two temples dedicated to the Phoenician gods Baal and Dagon, although the ruling family appears to have been of different, non-Phoenician stock. The 15th century BC shows strong cultural influences already established there from Cyprus and the world of Mycenaean Greece. A splendid archive of literary and administrative documents found at Ugarit from this period provides evidence of an early form of alphabetic script, arguably the most important Phoenician contribution to Western civilization. In the latter part of the 13th century BC, a flood of land and sea raiders (the Sea Peoples) descended on the Levant coast, destroying many of the Phoenician cities and rolling onward to the frontier of Egypt, from which they were beaten back by the Pharaoh Ramses III. Ugarit was destroyed, together with Aradus and Byblos, though the latter were afterward rebuilt. Though Sidon was destroyed only in part, its inhabitants fled to Tyre, which from this time was regarded as the principal city of Phoenicia and began its period of prosperity and expansion.

Phoenician expansion

Tyre's first colony, Utica in North Africa, was founded perhaps as early as the 10th century BC. It is likely that the expansion of the Phoenicians at the beginning of the 1st millennium BC is to be connected with the alliance of Hiram of Tyre with Solomon of Israel in the second half of the 10th century BC. In the following century, Phoenician presence in the north is shown by inscriptions at Samal (Zincirli Hüyük) in eastern Cilicia, and in the 8th century at Karatepe in the Taurus Mountains, but there is no evidence of direct colonization. Both these cities acted as fortresses commanding the routes through the mountains to the mineral and other wealth of Anatolia.

Cyprus had Phoenician settlements by the 9th century BC. Citium, known to the Greeks as Kition (biblical Kittim), in the southeast corner of the island, became the principal colony of the Phoenicians in Cyprus. Elsewhere in the Mediterranean, several smaller settlements were planted as stepping-stones along the route to Spain and its mineral wealth in silver and copper: at Malta, early remains go back to the 7th century BC, and at Sulcis and Nora in Sardinia and Motya in Sicily, perhaps a century earlier. According to Thucydides, the Phoenicians controlled a large part of the island but withdrew to the northwest corner under pressure from the Greeks. Modern scholars, however, disbelieve this and contend that the Phoenicians arrived only after the Greeks were established.

In North Africa the next site colonized after Utica was Carthage (near Tunis). Carthage in turn seems to have established (or, in some cases, reestablished) a number of settlements in Tunisia, Algeria, Morocco, the Balearic Islands, and southern Spain, eventually making this city the acknowledged leader of the western Phoenicians.

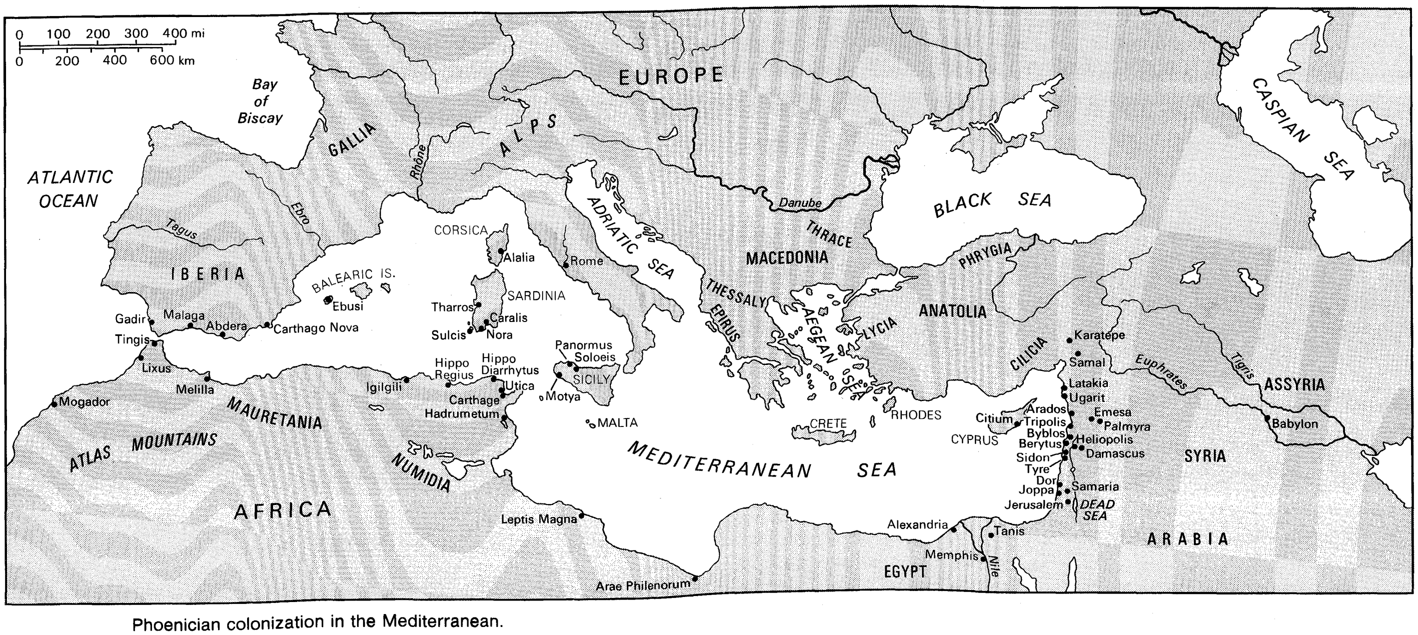
There is little factual evidence to confirm the presence of any settlement in Spain earlier than the 7th century BC, or perhaps the 8th century, and many of these settlements should be viewed as Punic (Carthaginian) rather than Phoenician, though it is likely that the colonizing expeditions of the Carthaginians were supported by many emigrants from the Phoenician homeland. It is very probable that the tremendous colonial activity of the Phoenicians and Carthaginians was stimulated in the 8th to 6th centuries BC by the military blows that were wrecking the trade of the Phoenician homeland in the Levant. Also, competition with the synchronous Greek colonization of the western Mediterranean cannot be ignored as a contributing factor.

In the 3rd century BC Carthage, defeated by the Romans, embarked on a further imperialistic phase in Spain to recoup its losses. Rome responded, defeated Carthage a second time, and annexed Spain. Finally, in 146 BC, after a third war with Rome, Carthage suffered total destruction. It was rebuilt as a Roman colony in 44 BC. The ancient Phoenician language survived in use as a vernacular in some of the smaller cities of North Africa at least until the time of St. Augustine, bishop of Hippo (5th century AD).

Commerce under Egyptian protection

Commerce. The role that tradition especially assigns to the Phoenicians as the merchants of the Levant was first developed on a considerable scale at the time of the Egyptian 18th dynasty. The position of Phoenicia, at a junction of both land and sea routes, under the protection of Egypt, favoured this development, and the discovery of the alphabet and its use and adaptation for commercial purposes assisted the rise of a mercantile society. A fresco in an Egyptian tomb of the 18th dynasty depicted seven Phoenician merchant ships that had just put in at an Egyptian port to sell their goods, including the distinctive Canaanite wine jars in which wine, a drink foreign to the Egyptians, was imported. *The Story of Wen-Amon* recounts the tale of a Phoenician merchant, Werket-el of Tanis in the Nile Delta, who was the owner of "50 ships" that sailed between Tanis and Sidon. The Sidonians are also famous in the poems of Homer as craftsmen, traders, pirates, and slave dealers. The prophet Ezekiel (chapters 27 and 28), in a famous denunciation of the city of Tyre, catalogs the vast extent of its commerce, covering most of the then-known world.

The exports of Phoenicia as a whole included particularly cedar and pine wood from Lebanon, fine linen from Tyre,



Phoenician colonization in the Mediterranean.

Byblos, and Berytos, cloths dyed with the famous Tyrian purple (made from the snail *Murex*), embroideries from Sidon, metalwork and glass, glazed faience, wine, salt, and dried fish. They received in return raw materials, such as papyrus, ivory, ebony, silk, amber, ostrich eggs, spices, incense, horses, gold, silver, copper, iron, tin, jewels, and precious stones.

In addition to these exports and imports, the Phoenicians also conducted an important transit trade, especially in the manufactured goods of Egypt and Babylonia (Herodotus, i, 1). From the lands of the Euphrates and Tigris regular trade routes led to the Mediterranean. In Egypt the Phoenician merchants soon gained a foothold; they alone were able to maintain a profitable trade in the anarchic times of the 22nd and 23rd dynasties (*c.* 945–*c.* 730 BC). Though there were never any regular colonies of Phoenicians in Egypt, the Tyrians had a quarter of their own in Memphis (Herodotus, ii, 112). The Arabian caravan trade in perfume, spices, and incense passed through Phoenician hands on its way to Greece and the West (Herodotus, iii, 107).

Caravan trade

The Phoenicians were not mere passive peddlers in art or commerce. Their achievement in history was a positive contribution, even if it was only that of an intermediary. For example, the extent of the debt of Greece alone to Phoenicia may be fully measured by its adoption, probably in the 8th century BC, of the Phoenician alphabet with very little variation (along with Semitic loan words); by "orientalizing" decorative motifs on pottery and by architectural paradigms; and by the universal use in Greece of the Phoenician standards of weights and measures.

Navigation and seafaring. For the establishment of commercial supremacy, an essential constituent was the Phoenician skill in navigation and seafaring. The Phoenicians are credited with the discovery and use of Polaris (the Pole Star). Fearless and patient navigators, they ventured into regions where no one else dared to go, and always, with an eye to their monopoly, they carefully guarded the secretş of their trade routes and discoveries and their knowledge of winds and currents. Pharaoh Necho II (610–595 BC) organized the Phoenician circumnavigation of Africa (Herodotus, iv, 42). Hanno, a Carthaginian, led another in the mid-5th century. The Carthaginians seem to have reached the island of Corvo in the Azores; and they may even have reached Britain, for many Carthaginian coins have been found there.

Assyrian and Babylonian domination of Phoenicia. Between the withdrawal of Egyptian rule in Syria and the western advance of Assyria there was an interval during which the city-states of Phoenicia owned no suzerain. Byblos had kings of its own, among them Ahiram, Abi-baal, and Ethbaal (Ittobaʿal) in the 10th century, as excavations have shown. The history of this time period is mainly a history of Tyre, which not only rose to a hegemony among the Phoenician states but also founded colonies beyond the seas. Unfortunately, the native historical records of the Phoenicians have not survived, but it is clear from the Bible that the Phoenicians lived on friendly terms with the Israelites. In the 10th century Hiram, king of Tyre, built the Temple of Solomon at Jerusalem in return for rich gifts of oil, wine, and territory. In the following century Ethbaal of Tyre married his daughter Jezebel to Ahab, king of Israel, and Jezebel's daughter in turn married the King of Judah.

The Assyrian intrusion

In the 9th century, however, the independence of Phoenicia was increasingly threatened by the advance of Assyria. In 868 BC Ashurnasirpal II reached the Mediterranean and exacted tribute from the Phoenician cities. His son, Shalmaneser III, took tribute from the Tyrians and Sidonians and established a supremacy over Phoenicia, at any rate in theory, which was acknowledged by occasional payments of tribute to him and his successors. In 734 BC Tiglath-pileser III in his western campaign established his authority over Byblos, Arados, and Tyre. A fresh invasion, by Shalmaneser V, took place in 725 when he was on his way to Samaria, and in 701 Sennacherib, facing a rebellion of Philistia, Judah, and Phoenicia, drove out and deposed Luli, identified as king of both Sidon and Tyre. In 678 Sidon rebelled against the Assyrians, who marched down and annihilated the city, rebuilding it on the mainland. Sieges of Tyre took place in 672 and 668, but it resisted both, only submitting in the later years of Ashurbanipal.

During the period of Neo-Babylonian power, which followed the fall of Nineveh in 612 BC, the pharaohs made attempts to seize the Phoenician and Palestinian seaboard. Nebuchadrezzar II, king of Babylon, having sacked Jerusalem, marched against Phoenicia and besieged Tyre, but it held out successfully for 13 years, after which it capitulated, seemingly on favourable terms.

Persian period. Phoenicia passed from the suzerainty of the Babylonians to that of their conquerors, the Persians, in 538 BC. Not surprisingly, the Phoenicians turned as loyal supporters to the Persians, who had overthrown their oppressors, and reopened to them the trade of the Orient. Lebanon, Syria–Palestine, and Cyprus were organized as the fifth satrapy (province) of the Persian Empire. At the time of Xerxes I's invasion of Greece, the city of Sidon was considered to be the principal city of Phoenicia, and the ships of Sidon were considered the finest part of Xerxes' fleet, its king ranking next to Xerxes and before the king of Tyre. (Phoenician coins have been used to supplement historical sources on the period. From the reign of Darius I [522–486 BC], the Persian monarchs had allowed their satraps and vassal states to coin silver and copper money. Arados, Byblos, Sidon, and Tyre therefore issued a coinage of their own.) In the 4th century Tyre, and later Sidon, revolted against the Persian king. The revolt was suppressed in 345 BC.

Greek and Roman periods. In 332 BC Tyre resisted Alexander the Great in a siege of eight months. Alexander finally captured the city by driving a mole into the sea from the mainland to the island. As a result Tyre, the inhabitants of which were largely sold into slavery, lost all importance, soon being replaced in the leadership of the Oriental markets by Alexandria, the conqueror's newly founded city in Egypt. In the Hellenistic period (323–30 BC) the cities of Phoenicia became the prize for the competing Macedonian dynasties, controlled first by the Ptolemies of Egypt in the 3rd century BC and then by the Seleucids of Syria in the 2nd and early decades of the 1st century BC. The Seleucids apparently permitted a good measure of autonomy to the Phoenician cities. Tigranes II of Armenia brought an end to the Seleucid dynasty in 83 BC and extended his realm to Mt. Lebanon. The Romans eventually intervened to restore Seleucid sovereignty, but when anarchy prevailed they imposed peace and assumed direct rule in 64 BC.

Phoenicia was incorporated into the Roman province of Syria, though Aradus, Sidon, and Tyre retained self-government. Berytus (Beirut), relatively obscure to this point, rose to prominence by virtue of Augustus' grant of Roman colonial status and by the lavish building program financed by Herod the Great (and in turn by his grandson and great-grandson). Under the Severan dynasty (AD 193–235) Sidon, Tyre, and probably Heliopolis (Baalbek) also received colonial status. Under this dynasty the province of Syria was partitioned into two parts: Syria Coele ("Hollow Syria"), comprising a large region loosely defined as north and east Syria; and Syria Phoenice in the southwestern region, which included not only coastal Phoenicia but also the territory beyond the mountains and into the Syrian desert. Under the provincial reorganization of the Eastern Roman emperor Theodosius II in the early 5th century AD, Syria Phoenice was expanded into two provinces: Phoenice Prima (Maritima), basically ancient Phoenicia; and Phoenice Secunda (Libanesia), an area extending to Mt. Lebanon on the west and deep into the Syrian desert on the east. Phoenice Secunda included the cities of Emesa (its capital), Heliopolis, Damascus, and Palmyra.

During the period of the Roman Empire the native Phoenician language died out in Lebanon and was replaced by Aramaic as the vernacular. Latin, the language of the soldiers and administrators, in turn fell before Greek, the language of letters of the eastern Mediterranean, by the 5th century AD. Lebanon produced a number of important writers in Greek, most notably Philo of Byblos (64–141), and in the 3rd century Porphyry of Tyre and Iamblichus of Chalcis in Syria Coele. Porphyry played a key role in disseminating the Neoplatonic philosophy of his master Plotinus, which would influence both pagan and Christian thought in the later Roman Empire.

In many respects, the two most important cities of Lebanon during the time of the Roman Empire were Heliopolis and Berytus. At Heliopolis the Roman emperors, particularly the Severans, constructed a monumental temple complex, the most spectacular elements of which were the Temple of Jupiter Heliopolitanus and the Temple of Bacchus. Berytus, on the other hand, became the seat of the most famous provincial school of Roman law. The school, which probably was founded by Septimius Severus, lasted until the destruction of Berytus itself by a sequence of earthquakes, tidal wave, and fire in the mid-6th century. Two of Rome's most famous jurists, Papinian and Ulpian, both natives of Lebanon, taught as professors at the law school under the Severans. Their judicial opinions constitute well over a third of the Pandects (Digest) contained in the great compilation of Roman law commissioned by the emperor Justinian I in the 6th century AD.

In 608–609 the Persian king Khosrow II pillaged Syria and Lebanon and reorganized the area into a new satrapy, excluding only Phoenicia Maritima. Between 622 and 629 the Byzantine emperor Heraclius mounted an offensive and restored Syria–Lebanon to his empire. This success was short-lived; in the 630s Muslim Arabs conquered Palestine and Lebanon, and the old Phoenician cities offered only token resistance to the invader.

LEBANON IN THE MIDDLE AGES

The Maronites

The population of Lebanon did not begin to take its present form until the 7th century AD. At some time in the Byzantine period, a military group of uncertain origin, the Mardaites, established themselves in the north among the indigenous population. From the 7th century onward another group entered the country, the Maronites, a Christian community adhering to the Monothelite doctrine. Forced by persecution to leave their homes in northern Syria, they settled in the northern part of the mountain and absorbed the Mardaites and indigenous peasants to form the present Maronite Church. Originally Syriac-speaking, they gradually adopted the Arabic language although keeping Syriac for liturgical purposes. In south Lebanon Arab tribesmen came in after the Muslim conquest of Syria in the 7th century and settled among the indigenous people. In the 11th century many were converted to the Druze faith, an esoteric offshoot of Shīʿite Islām. South Lebanon became the headquarters of the faith. Groups of Shīʿite Muslims settled on the northern and southern fringes of the mountain and in al-Biqāʿ. In the coastal towns the population became mainly Sunnite Muslim, but in town and country alike there remained considerable numbers of Christians of various sects. In course of time, virtually all sections of the population adopted Arabic, the language of the Muslim states in which Lebanon was included.

Beirut and Mt. Lebanon were ruled by the Umayyads (661–750) as part of the district of Damascus. Despite the occasional rising by the Maronites, Lebanon provided naval forces to the Umayyads in their interminable warfare with the Byzantines. The 8th-century Beirut legist al-Awzāʿī established a school of Islāmic law that heavily influenced Lebanon and Syria. From the 9th to the 11th century coastal Lebanon was usually under the sway of independent Egyptian Muslim dynasties, although the Byzantine Empire attempted to gain portions of the north.

At the end of the 11th century Lebanon became a part of the crusaders' states, the north being incorporated in the county of Tripolis, the south in the kingdom of Jerusalem. The Maronite Church began to accept papal supremacy, while keeping its own patriarch and liturgy.

Despite the strong fortresses of the crusaders, a Muslim reconquest of Lebanon, under the leadership of Egypt, began with the fall of Beirut in 1187. Mongol raids against al-Biqāʿ valley were defeated. Lebanon became part of the Mamlūk state of Egypt and Syria in the 1280s and 1290s and was divided among several provinces. Mamlūk rule, which allowed limited local autonomy to regional leaders, encouraged commerce. The coastal cities, and especially Tripoli, flourished, and the people of the interior were left largely free to manage their own affairs.

OTTOMAN PERIOD

Ottoman expansion began in the area under Selim I (1512–20). He defeated the Mamlūks in 1516–17 and added Lebanon (as part of Mamlūk Syria and Egypt) to his empire. Between the 16th and 18th centuries Ottoman Lebanon evolved a social and political system of its own. Ottoman Aleppo or Tripoli governed the north, Damascus the centre, and Sidon (after 1660) the south. Coastal Lebanon and al-Biqāʿ valley were usually ruled more directly by Istanbul, while Mt. Lebanon enjoyed semiautonomous status. The population took up its present position: the Shīʿites were driven out of the north but increased their strength in the south; many Druze moved from south Lebanon to Jebel Druze (Jabal ad-Durūz) in southern Syria; Maronite peasants, increasing in numbers, moved south into districts mainly populated by Druze. Monasteries acquired more land and wealth. In all parts of the mountains there grew up families of notables, who controlled the land and established a feudal relation with the cultivators; some were Christian, some Druze, who were politically dominant. From them arose the House of Mʿan, which established a princedom over the whole of Mt. Lebanon and was accepted by Christians and Druze alike. Fakhr ad-Dīn II ruled most of Lebanon from 1593 to 1633 and encouraged commerce. When the House of Maʿn died out in 1697, the notables elected as prince a member of the Shihāb family who were Sunnite Muslims but with Druze followers, and this family ruled until 1842. Throughout this period European influence was growing. European trading colonies were established in Saïda and other coastal towns, mainly to trade in silk, the major Lebanese export from the 17th to the 20th century. French political influence was great, particularly among the Maronites, who formally united with the Roman Catholic Church in 1736.

European influence

The 19th century was marked by economic growth, social change, and political crisis. The growing Christian population moved southward and into the towns, and toward the end of the century many of these Christians emigrated to North America, South America, and Egypt. French Catholic and U.S. Protestant mission schools, as well as schools of the local communities, multiplied: in 1866 the American mission established the Syrian Protestant College (later the American University of Beirut), and in 1881 the Jesuits started the Université Saint-Joseph. Such schools produced a literate class, particularly among the Christians, that found employment as professionals. Beirut became a great international port, and its merchant houses established connections with Egypt, the Mediterranean countries, and England.

The growth of the Christian communities upset the traditional balance of Lebanon. The Shihāb princes inclined more and more toward them, and part of the family indeed became Maronites. The greatest of them, Bashīr II (reigned 1788–1840), after establishing his power with the help of Druze notables, tried to weaken them. When the Egyptian troops of Ibrāhīm Pasha occupied Lebanon and Syria in 1831, Bashīr formed an alliance with him to limit the power of the ruling families and to preserve his own power. But Egyptian rule was ended by Anglo-Ottoman intervention, aided by a popular rising in 1840, and Bashīr was deposed. With him the princedom virtually ended; his weak successor was deposed by the Ottomans in 1842, and from that time relations grew worse between the Maronites, led by their patriarch, and the Druze, trying to retain their traditional supremacy. The French supported the Maronites and the British supported a section of the Druze, while the Ottoman government encouraged the collapse of the traditional structure, which would enable it to impose its own direct authority. The conflict culminated in the massacre of Maronites by the Druze in 1860. The complacent attitude of the Ottoman authorities led to direct French intervention on behalf of the Christians. The powers jointly imposed the Organic Regulation of 1861 (modified in 1864), which gave Mt. Lebanon, the axial mountain region, autonomy under a Christian governor appointed by the Ottoman sultan, assisted by a council representing the various communities. Mt. Lebanon prospered under this regime until World War I, when the Ottoman government placed it under strict control, similar to that already established for the coast and al-Biqāʿ valley.

French intervention

FRENCH MANDATE

At the end of the war Lebanon was occupied by Allied forces and placed under a French military administration. In 1920 Beirut and other coastal towns, al-Biqāʿ, and certain other districts were added to the autonomous territory Mt. Lebanon as defined in 1861, to form Greater Lebanon (Grand Liban; subsequently called the Lebanese Republic). In 1923 the League of Nations formally gave the mandate for Lebanon and Syria to France. The Maronites, strongly pro-French by tradition, welcomed this, and during the next 20 years, while France held the mandate, the Maronites were favoured. The expansion of prewar Lebanon into Greater Lebanon, however, changed the balance of the population. Although the Maronites were the largest single element, they no longer formed a majority. The population was more or less equally divided between Christians and Muslims, and a large section of it wanted neither to be ruled by France nor to be part of an independent Lebanon, but rather to form part of a larger Syrian or Arab state. To ease tensions between the communities, the constitution of 1926 provided that each should be equitably represented in public offices. Thus by convention the president of the republic was normally a Maronite, the prime minister a Sunnite Muslim, and the speaker of the chamber a Shīʿite Muslim.

French administration was reasonably efficient. Public utilities and communications were improved, and education was expanded (although higher education was left almost wholly in the hands of religious bodies). Beirut prospered as a centre of trade with surrounding countries, but agriculture was depressed by the decline of the silk industry and the worldwide economic depression. As the middle class of Beirut grew and a real if fragile sense of common national interest sprang up alongside communal loyalties, there grew also the desire for more independence. A Franco-Lebanese treaty of independence and friendship was signed in 1936 but was not ratified by the French government. Lebanon was controlled by the Vichy authorities after the fall of France in 1940 but was occupied by British and Free French troops in 1941. The Free French representative proclaimed the independence of Lebanon and Syria, which was underwritten by the British government. Because of their own precarious position, however, the Free French were unwilling to relax control. In 1943, however, they held elections, which resulted in victory for the Nationalists. Their leader, Bishara al-Khuri, was elected president. The new government passed legislation introducing certain constitutional changes that eliminated all traces of French influence, to which the French objected. On Nov. 11, 1943, the President and almost the entire government were arrested by the French. This led to an insurrection followed by British diplomatic intervention; the French restored the government and transferred powers to it. After another crisis in 1945, agreement was reached on a simultaneous withdrawal of British and French troops. This was completed by the end of 1946, and Lebanon became wholly independent; it had already become a member of the United Nations and the Arab League. (R.D.B./W.L.O.)

LEBANON AFTER INDEPENDENCE

For many years Lebanon maintained its parliamentary democracy, despite serious trials. The main problem for Lebanon was to implement the unwritten power-sharing National Pact of 1943 between the Christians and Muslims. In the early years of independence, so long as no urgent call for pan-Arab unity came from outside, the National Pact faced no serious strains.

The Khuri regime, 1943–52. The Maronite president Bishara al-Khuri closely cooperated with the Sunnite leader Riad as-Sulh, who was premier most of the time. A temporary amendment of the constitution permitted the president, in 1949, a second six-year term. The parliamentary elections of 1947 were blatantly rigged to produce a Parliament favourable to the amendment. This, together with the open favouritism of the President toward his friends and the gross corruption he allegedly condoned, made Khuri increasingly unpopular after his reelection in 1949.

The military coup that overthrew the Kuwatli regime in Syria in March 1949 encouraged the opponents of Khuri in Lebanon. In July 1949 the Syrian Social Nationalist Party (PPS) tried to overthrow the regime by force. The coup failed and its leaders were seized and shot. The PPS took its revenge by securing the assassination of Khuri's premier in 1951. The mounting opposition to the Khuri regime culminated in September 1952 in a general strike that forced his resignation. Camille Chamoun was elected by the Parliament to succeed him.

Lebanon's difficult position

The Chamoun regime and the 1958 crisis. The presidency of Camille Chamoun coincided with the rise of Nasser in Egypt. During the Suez war (October–December 1956), Chamoun earned Nasser's enmity by refusing to break off diplomatic relations with Britain and France, which had joined Israel in attacking Egypt. Chamoun was accused of seeking to align Lebanon with the Western-sponsored Baghdad Pact.

Matters came to a head following the parliamentary elections of 1957, which allegedly were manipulated to produce a Parliament favourable to the reelection of Chamoun. When Syria entered into a union with Egypt, as the United Arab Republic, in February 1958, the Muslim opposition to Chamoun in Lebanon hailed the union as a triumph for pan-Arabism, and there were widespread demands that Lebanon be associated in the union. In May a general strike was proclaimed, and the Muslims of Tripoli rose in armed insurrection. The insurrection spread, and the army was asked to take action against the insurgents. The commanding general, Fuad Chehab, refused to attack them for fear that the army, which was composed of Christians and Muslims, would split apart. The Chamoun government took the issue of external intervention to the United Nations, accusing the United Arab

Republic of intervention, and UN observers were sent to Lebanon. When in July the pro-Western regime in Iraq was toppled in a coup, President Chamoun immediately requested U.S. military intervention, and on the following day U.S. marines landed outside Beirut. The presence of U.S. troops had little immediate effect on the internal situation, but the insurrection slowly faded out. Parliament turned to the commander of the army, General Chehab, to succeed Chamoun as his term ended; Rashid Karami became the new premier.

National unity of the Lebanese people

The Chehab, Hélou, and Franjieh regimes, 1958–76. The crisis had been resolved by compromise, and the Chehab regime was successful in maintaining the compromise and promoting the national unity of the Lebanese people. By his refusal as army commander to take offensive action against the insurgents in 1958, Chehab had earned the confidence of the Muslims. Once in power, he proceeded to allay long-standing Muslim grievances by associating Muslims more closely in the administration and by attending to neglected areas of Lebanon where Muslims predominated. Internal stability was further promoted by the maintenance of good relations with the United Arab Republic, which, even after the Syrian secession in 1961, remained highly popular with the Muslim Lebanese. The economic boom that had begun under the Chamoun regime as the result of the flight of capital from the unstable Arab world into Lebanon continued under the Chehab regime.

Charles Hélou, a former journalist and member of Khuri's Constitutional Bloc, was elected to succeed Chehab in 1964. His government, essentially a weaker version of the Chehab regime, was followed in 1970 by the troubled regime of Suleiman Franjieh.

Despite the apparent calm of the years 1958–69, events in Lebanon moved toward the outbreak of one of the most destructive civil wars in modern history. The essential issues were separate but strongly and immediately affected one another. First came the fact that the political structure of Lebanon was based on a sort of floating consensus—an agreement among leaders of the various religious and ethnic minorities over their respective roles in the state. Under the regimes of Chehab and Hélou, the personal and group ambitions of the various sectors of society were held in check, and the organs of the state, especially the army and the security police, were employed to prevent recourse to violence.

Lebanese social change

During that period, major changes took place in Lebanese society, most significantly urbanization, which brought 40 percent of the Lebanese population to the city of Beirut. But the city, like the country, failed to make its people homogeneous; Beirut became a reflection of Lebanon as a whole. Each quarter took on a religious affiliation, with virtually every village having an enclave established in one suburb or more. And the newcomers suffered from deep and growing social and economic contrasts with their more affluent neighbours. Those who remained in the rural areas lost even more ground, relatively speaking. By the early 1970s, agriculture, in which nearly half of the population was employed, accounted for less than 11 percent of the country's gross domestic product, while the share of urban commerce was rising. An already existing schism was deepened between the groups, which increasingly took on an urban Christian versus rural Muslim coloration.

A second factor, the role of Lebanon in the Arab world, was also a complex issue. Many Syrians still felt that the French decision to separate Lebanon from Syria in 1920 was invalid; many in Lebanon agreed. Lebanon's noninvolvement in the Arab–Israeli wars of 1967 and 1973, its strong and often heavy-handed security policies, and rumours of its secret understandings with Israel all directed attention on this issue.

Palestinian radicalization

Third, the Palestinians thought of Lebanon, after the ruinous Jordanian campaign against them in September 1970, as their last refuge, and by 1973 roughly one person in each 10 in Lebanon was a Palestinian. Yet the Palestinians were constantly made aware of their separate and inferior status; landless and mostly poor, they were exploited as a source of cheap labour. Increasingly their politics became radicalized, and they found common cause with those Lebanese who were poor, rural, and mainly Muslim. As they acquired structure, motivation, and arms during the period after the fall of their base in Jordan, they were sought out as allies by groups in Lebanon. Faced in September 1975 by an Egyptian–Israeli interim agreement on Sinai, the Palestinians concluded that they were being deserted by the Arab states and would shortly be suppressed in Lebanon.

The civil war, 1975–76. *Beginning of the war.* Toward the end of the presidency of Charles Hélou, the Palestinians began to clash with Lebanese security forces. The situation was increasingly complicated by the inability of the Palestine Liberation Organization (PLO) to control the more radical of the factions into which the Palestinians were divided. Under an agreement announced in Cairo on Nov. 3, 1969, the Lebanese government gave the Palestinians virtually a free hand in the refugee camps and at forward posts in the south along the Israeli frontier. In return, the PLO promised not to intervene in Lebanese politics; this was impossible for the Palestinians and not desired by the Lebanese left. When the Lebanese failed to restrain the Palestinians, the Israelis began to raid the south with increasing severity, and this encouraged the Lebanese Christian right, particularly the militant Phalangist Party (with discreet army backing), to attack the Palestinians with its well-organized and well-armed militia.

Franjieh election

It was in this atmosphere that Suleiman Franjieh was elected president, by only one vote in the Parliament, on Aug. 17, 1970. Franjieh was known as a man of personally violent tendencies, and the Lebanese right looked to him to suppress the left and their Palestinian allies. Economic events, however, soon got out of control. Lebanon was caught in a severe inflation that enriched those on one side of the social chasm while it exacerbated the distress and bitterness of those on the other side. The government appeared incapable of addressing this problem; in its attempt to make an appearance of reform, it discarded or destroyed the strong instruments of state control that it had inherited from the aftermath of the civil war of 1958. The more radical of the guerrilla groups, angered by failure of the Lebanese to prevent Israeli incursions and encouraged by the vacillation of the regime, determined upon a series of dramatic attacks. When their plots were foiled, they retaliated by abducting several Lebanese soldiers. Heavy fighting then broke out between the army and the armed refugees in May 1973, and thereafter, despite a series of truces, events moved rapidly toward civil war. By early 1974 the Palestinians were providing the force for the Lebanese National Movement led by Kamal Jumblatt. Into this arena then stepped the relatively deprived Shīʿite Muslims, especially those of the rural al-Biqāʿ valley, under the leadership of a Muslim *imām,* Musa as-Sadr; his Movement of the Deprived was based on a call for Shīʿite political rights, economic justice, and defense against Israeli raids in the mainly Shīʿite south.

Hardly a day passed after the beginning of full civil war in April 1975 without a battle somewhere in Lebanon. The country was torn apart, and the central government virtually ceased to exist. The army, long the mainstay of the government, was immobilized by the nature of the conflict. And the combatants, amply supplied by various foreign groups, turned upon one another with a ferocity—and firepower—almost unequaled in such a small area of the world.

Syrian reversal of position

Final phases of the war. During the early phases of the civil war, the Christians had received encouragement from Pres. Anwar el-Sādāt of Egypt, while President Assad of Syria had encouraged and aided the left and the Palestinians. Gradually the left and the Palestinians began to win the war. By the early months of 1976, it seemed clear that the Christians were losing and that either they would be defeated (so that Lebanon would be reconstituted as a left-dominated, Palestine-oriented state) or Lebanon would be partitioned. Either case appeared to the Syrians likely to bring Israeli intervention. This realization forced a reversal of Syrian policy, first toward restraint on the left and then toward support for the Christians. Ironically, both the Syrians and the Israelis, so opposed to one another on other issues, took up the cause of the Lebanese Christians with essentially the same tools. Syria supplied arms and prevented the Palestinians from taking strategic points, while Israel blockaded Sidon and Tyre (through which arms to the left and the Palestinians had arrived), trained a large military contingent of Lebanese in Israel and supplied it with tanks, and shipped equipment to the Christian sector. During the summer of 1976 the Israeli Army occupied sizable parts of southern Lebanon; from the east, beginning in early June, Syrian military units entered the country with about 450 tanks and 20,000 soldiers.

This realignment led to two new developments. First, the non-Syrian left, represented by Iraq and Libya, resumed close contacts with the PLO, which earlier it had denounced as conservative and ineffectual, and this, in turn, caused President Sādāt of Egypt to seek closer relations with the PLO leader Yāsir ʿArafāt in order to win Palestinian support for his claim to Arab leadership and to prevent attacks on the Egyptians' separate disengagement agreement (September 1975) with the Israelis. Second, the Christians, with strong support from Syrian tanks and soldiers, began to win the civil war. In late June 1976, Christian forces launched attacks on the two Palestinian refugee camps of Jisr al-Bāshā, which fell after one week, and Tall az-Zaatar, which, becoming a symbol of Palestinian resistance, withstood a tragic and bloody siege until mid-August.

In April President Franjieh had signed a constitutional amendment to permit the Parliament to elect a new president. Elias Sarkis was elected on May 8 with the support of Syria but was not inaugurated until September 23. Meanwhile, Lebanon was effectively partitioned along the "Green Line," which passed through the centre of Beirut (east–west) and along the main road to Damascus: to the north was a Christian government, to the south a leftist (Druze–Muslim–Palestinian) government led by Kamal Jumblatt until he was murdered in March 1977. Repeated attempts were made to bring the fighting to an end, until finally a formal "summit" meeting, held on Oct. 25–26, 1976, established an Arab League peacekeeping force of 30,000 troops, mostly Syrian, under the overall command of President Sarkis. By the end of November, despite continued minor clashes, the civil war came to a close.

Postwar fighting

Continued fighting among the Lebanese factions led to the loss of prestige of the former political elite except for that of the Phalangist Party, whose successful leadership of the Christian-rightist coalition so alarmed the Syrian army of occupation that it once again began to support the Muslim–leftist–Palestinian groups in 1978. The destruction and violence had caused hundreds of thousands of Lebanese to flee their homes, particularly from southern Lebanon, where the threat of Israeli intervention stopped Syria from imposing a peace. Israel invaded the area with 20,000 troops on March 14–15, 1978, to destroy Palestinian military bases and to force Lebanon to curb future raids by the PLO into Israel. A small contingent of UN forces replaced the Israelis by June; however, Israel continued to supply arms, money, and troops to the Christians in the south, while the Palestinians soon returned to the same region.

Consequences of the war. The civil war was a catastrophe for the Lebanese, whose country lay in ruins. There seemed to be no compromise acceptable to both the Muslims, who numbered more than one-half of the population, and the Christians, who were determined to keep their control of key government institutions. Foreign intervention merely restrained open, full-scale warfare. Economic destruction was massive, but the chief political problem was the bitterness caused by the thousands of deaths and the ensuing hatreds that promised to destroy the possibility of Lebanese living together again in one nation with one government.

For the Palestinians the war cost perhaps 20,000 killed and twice that many wounded. The Syrians appeared stronger than before, but having got into Lebanon, they faced the problem of extricating themselves. Only Israel among the states of the Middle East appeared to have "won," and the unity of its enemies appeared to be shattered. The Palestinians lost their major bid; Syria acted, apparently, out of fear of Israeli intervention and against its fellow Arabs; and the Lebanese Christians, likely to regain much of their former power, were in Israel's debt. More important, the revulsion and horror of the war had caused Arabs everywhere to question, as never before, the very dream of pan-Arabism.

The Israeli invasion of 1982. The political disintegration of Lebanon led directly to intensified external intervention. Bashir Gemayel, the leader of the Phalangist militia, whose strength derived in part from extensive Israeli aid, forcibly united under his control all the Maronite private armies and thereby created a ministate in East Beirut and the northern coastal sector of Lebanon. The Syrian army was dominant in most of the rest of Lebanon, but a jumble of factions, many of which were armed and paid by outsiders, disputed Syria's power and wreaked havoc because of their internecine quarrels.

Israeli forces bombed PLO headquarters in West Beirut on July 17, 1981, causing in the process more than 300 civilian deaths. This attack led the United States to arrange a cease-fire between the Israelis and the PLO, which, it was hoped, would end raids into northern Israel and would provide the opportunity for President Sarkis of Lebanon to try once again for national reconciliation. The government was again unable to exert its authority, and Palestinian attacks and Israeli counterattacks intensified. The situation erupted on June 6, 1982, when an estimated 60,000 Israeli troops invaded Lebanon.

Although the stated goal of Israel was only to secure the territory north of its border with Lebanon so as to stop PLO raids, Israeli Prime Minister Menachem Begin sought to destroy the PLO and establish in power a Lebanese government that would conclude a peace treaty with Israel along the lines of the Egyptian–Israeli peace of 1979. The invasion was successful: Syrian forces were defeated, the PLO retreated to West Beirut, and Egypt and the other Arab states did little but protest. From late June to August, Israel hesitated to attack PLO and leftist Muslim troops in densely populated West Beirut. Instead, Israel shelled, bombed, and blockaded the area to pressure the PLO and Syrian garrisons to evacuate their forces.

Under supervision by an international (U.S., French, and Italian) force, PLO leaders and troops left Beirut for a number of Arab countries in late August. Because Syria supported the PLO forces remaining in northern Lebanon and in al-Biqāʿ valley, the forces could not be compelled by Israel to leave, but the Syrian backing was used to foster a PLO leadership that opposed Arafat. (In heavy fighting near Tripoli, Arafat was forced into exile in December 1983 for a second time, on this occasion at the instigation of the Syrians.) The Israeli victory in the south and centre was shared by the Phalangists, who then had no barrier to electing their leader president of Lebanon. Bashir Gemayel, however, was assassinated before his inauguration. The Phalangists then secured the election of Bashir's brother, Amin Gemayel, to replace the exhausted and ineffectual Sarkis as president. After West Beirut was occupied by the Israelis, Phalangist militiamen massacred perhaps as many as 1,000 Palestinians in two refugee camps in Beirut in revenge for the death of Bashir Gemayel.

On May 17, 1983, Israel and Lebanon concluded what was very nearly a peace treaty. It called for the withdrawal of Israeli forces and the establishment of bilateral relations. Israel's power in Lebanon deteriorated and Israeli casualties mounted; in September 1983 Israel began withdrawing its forces, first from central Lebanon and then from the south. The international peacekeeping force left Beirut in February 1984 after suffering heavy casualties, and in March Syria and Lebanese Muslims and leftists forced Pres. Amin Gemayel to abrogate the Lebanon–Israel agreement. By June 1985 Israel had withdrawn most of its military from Lebanon, leaving Gemayel and the central government dependent on the dominant Syrians.

This abrupt reversal among the intervening foreign states exacerbated political instability inside Lebanon. The Christian and rightist movement, the Shīʿite–Druze alliance, and the PLO all split asunder over the question of accepting or rejecting Syria's leadership. The cabinet announced on April 30, 1984, represented all Lebanese factions, but it was unable to bring about substantial political reforms or the permanent disarming of private militias, despite intense Syrian pressure to do so. Although the interminable quarrels of the Lebanese continued, with deadly consequences for themselves, external intervention lessened, as Syria attempted to resolve the basic issues that had led to the first outbreak of civil war in 1975.

For later developments in the political history of Lebanon, see the *Britannica Book of the Year* section in the BRITANNICA WORLD DATA ANNUAL. (W.L.O.)

The Evolution of Modern Western Legal Systems

The three great law families of modern Western civilization are civil law (also called Romano-Germanic law), common law (also called Anglo-American law), and Socialist law. They are descended from ancient Roman law and ancient Germanic tribal law and have been altered by various customary, ecclesiastical, feudal, commercial, and modern sociopolitical influences.

Most of the laws of the legal systems of continental Europe are traditionally classified as civil law. This type of law spread to Latin America and, later, to those countries of Asia and Africa that found it necessary to westernize their laws, such as Japan (in which American law has also had great influence), Thailand, Turkey, and Ethiopia. It also prevails, supplemented by religious or customary laws, in those regions that were colonies, protectorates, or trust territories of France, Belgium, The Netherlands, Spain, Portugal, and Italy, including Morocco, Algeria, Zaire, Indonesia, and Somalia, as well as in some dependencies or outlying parts of European countries, such as Martinique and Curaçao in the West Indies. Civil law, supplemented increasingly by Islāmic law, has come to prevail in several countries of the Middle East and North Africa.

Common law is, essentially, the law of England and the law of those countries in which the law of England has been received or implanted. Although common law was often transformed in certain respects or supplemented by local or religious traditions, its principal features have been preserved. Common-law countries that have remained closest to the English tradition include Canada, Australia, New Zealand, the Republic of Ireland, and the present and former British areas of the West Indies. Common law also prevails in India, Pakistan, Burma, Malaysia, and Singapore, where it is supplemented in matters of personal status by religious laws. In Liberia and in most of those parts of Africa and Oceania that were British colonies, protectorates, or trust territories, common law is supplemented by native customs. The United States has developed a type of common law that differs in many respects from the English.

Civil law and common law have merged in the legal systems of several countries (Scotland, Puerto Rico, the Philippines, Israel, South Africa, Zimbabwe, Sri Lanka, Mauritius, and the Seychelles) and in other localized regions (Quebec, in Canada, and Louisiana, in the United States). In most of these places private law still follows a civil-law pattern. The laws of the Nordic countries (Sweden, Finland, Denmark, Norway, and Iceland) are also closer to civil law than to common law.

In the Soviet Union and the other Socialist countries of eastern Europe, all law is permeated with the collectivist spirit, and the aim of law is seen as assisting in the creation of a new social order. These systems have diverged from their Romano-Germanic roots in important respects, but many concepts of civil law are still used in Socialist legal thinking.

This article is divided into the following sections:

The Western legal heritage

ROMAN LAW

In its strictest sense the term Roman law denotes the law of the city of Rome and of the Roman Empire that was in force during the period from the foundation of the city (traditional date 753 BC) until the fall of the Western Empire in the 5th century AD and the fall of the Eastern Empire in 1453. The term Roman law today, however, often refers to more than the laws of Roman society. The legal institutions evolved by the Romans had influence on the laws of other peoples in times long after the disappearance of the Roman Empire and in countries that were never subject to Roman rule. To take the most striking example, in a large part of Germany, until the adoption of a common code for the whole empire in 1900, the Roman law was in force as "subsidiary law"; that is, it was applied unless excluded by contrary local provisions. This law, however, which was in force in parts of Europe long after the fall of the Roman Empire, was not the Roman law in its original form. Although its basis was indeed the Corpus Juris Civilis—the codifying legislation of the emperor Justinian I—this legislation had been interpreted, developed, and adapted to later conditions by generations of jurists from the 11th century onward and had received additions from non-Roman sources.

The range of influence of Roman law

Development of the jus civile and jus gentium. In the great span of time during which the Roman Republic and Empire existed, there were many phases of legalistic development. During the period of the republic (753–31 BC), the *jus civile* (civil law) developed. Based on custom or legislation, it applied exclusively to Roman citizens. By the middle of the 3rd century BC, however, another type of law, *jus gentium* (international law), was developed by the Romans to be applied both to themselves and to foreigners. *Jus gentium* was not the result of legislation, but was, instead, a development of the magistrates and governors who were responsible for administering justice in cases in which foreigners were involved. The *jus gentium* became, to a large extent, part of the massive body of law that was applied by magistrates to citizens, as well as to foreigners, as a flexible alternative to *jus civile.*

Roman law, like other ancient systems, originally adopted the principle of personality—that is, that the law of the state applied only to its citizens. Foreigners had no rights and, unless protected by some treaty between their state and Rome, they could be seized like ownerless pieces of property by any Roman. But from early times there were treaties with foreign states guaranteeing mutual protection. Even in cases in which there was no treaty, the increasing commercial interests of Rome forced it to protect, by some form of justice, the foreigners who came within its borders. A magistrate could not simply apply Roman law because that was the privilege of citizens; even had there not been this difficulty, foreigners would probably have objected to the cumbersome formalism that characterized the early *jus civile.*

The law that the magistrates applied probably consisted of three elements: (1) an existing mercantile law that was used by the Mediterranean traders; (2) those institutions of the Roman law that, after being purged of their formalistic elements, could be applied universally to any litigant, Roman or foreigner; and (3) in the last resort, a magistrate's own sense of what was fair and just. This system of *jus gentium* was also adopted when Rome began to acquire provinces so that provincial governors could administer justice to the *peregrini* (foreigners). This word came to mean not so much persons living under another government (of which, with the expansion of Roman power, there came to be fewer and fewer) as Roman subjects who were not citizens. In general, disputes between members of the same subject state were settled by that state's own courts according to its own law, whereas disputes between provincials of different states or between provincials and Romans were resolved by the governor's court applying *jus gentium.* By the 3rd century AD, when citizenship was extended throughout the empire, the practical differences between *jus civile* and *jus gentium* ceased to exist. Even before this, when a Roman lawyer said that a contract of sale was *juris gentium,* he meant that it was formed in the same way and had the same legal results whether the parties to it were citizens or not. This became the practical meaning of *jus gentium.* Because of the universality of its application, however, the idea was also linked with the theoretical notion that it was the law common to all peoples and was dictated by nature—an idea that the Romans took from Greek philosophy.

Written and unwritten law. The Romans divided their law into *jus scriptum* (written law) and *jus non scriptum* (unwritten law). By "unwritten law" they meant custom; by "written law" they meant not only the laws derived from legislation but, literally, laws based on any written source.

Types of written law

There were various types of written law, the first of which consisted of *leges* (singular *lex*), or enactments of one of the assemblies of the whole Roman people. Although the wealthier classes, or patricians, dominated these assemblies, the common people, or plebeians, had their own council in which they enacted resolutions called *plebiscita.* Only after the passage of the Lex Hortensia in 287 BC, however, did *plebiscita* become binding on all classes of citizens; thereafter, *plebiscita* were generally termed *leges* along with other enactments. In general, legislation was a source of law only during the republic. When Augustus established the empire in 31 BC, the assemblies did not at once cease to function, but their assent to any proposal became merely a formal ratification of the emperor's wishes. The last known *lex* was passed during the reign of Nerva (AD 96–98).

The earliest and most important legislation, or body of *leges,* was the Twelve Tables, enacted in 451–450 BC during the struggle of the plebeians for political equality. It represented an effort to obtain a written and public code that patrician magistrates could not alter at will against plebeian litigants. Little is known of the actual content of the Twelve Tables; the text of the code has not survived, and only a few fragments are extant, collected from allusions and quotations in the works of authors such as Cicero. From the fragments it is apparent that numerous matters were treated, among them family law, delict (tort, or offense against the law), and legal procedure.

A second type of written law consisted of the *edicta* (edicts), or proclamations issued by a superior magistrate (praetor) on judicial matters. The office of praetor was created in 367 BC to take over the expanding legal work involving citizens; later, a separate praetor was created to deal with foreigners. Upon taking office, a praetor issued an edict that was, in effect, the program for his year in office. The curule aediles, who were the magistrates responsible for the care and supervision of the markets, also issued edicts. During the later stages of the republic, these praetorian and magisterial edicts became an instrument of legal reform, and *leges* ceased to be a major source of private law.

Law-making power of magistrates

The Roman system of procedure gave the magistrate great powers for providing or refusing judicial remedies, as well as for determining the form that such remedies should take. The result of this magisterial system was the development of a new body of rules that existed alongside, and often superseded, the civil law. The *edicta* remained a source of law until about AD 131, when the emperor Hadrian commissioned their reorganization and consolidation and declared the resulting set of laws to be unalterable, except by the emperor himself.

A third type of written law was the *senatus consulta,* or resolutions of the Roman senate. Although these suggestions to various magistrates had no legislative force during the republic, they could be given force by the magistrates' edicts. In the early empire, as the power of the assemblies declined and the position of the emperor increased, *senatus consulta* became resolutions that endorsed the proposals of the emperor. As the approval of the Senate became increasingly automatic, the emperor's proposals became the true instrument of power. Consequently, emperors ceased referring proposals to the Senate and, not long after the early imperial period, ended the practice of legislating through the Senate.

A fourth type of written law consisted of the *constitutiones principum,* which were, in effect, expressions of the legislative power of the emperor. By the middle of the 2nd century AD, the emperor was, essentially, the sole creator of the law. The chief forms of imperial legislation were edicts or proclamations; instructions to subordinates, especially provincial governors; written answers to officials or others who consulted the emperor; and decisions of the emperor sitting as a judge.

The last type of written law was the *responsa prudentium,* or answers to legal questions given by learned lawyers to those who consulted them. Although law, written and unwritten, was originally a rather secretive monopoly of the college of pontiffs, or priests, a recognizable class of legal advisers, *juris consulti* or *prudentes,* had developed by the early 3rd century BC. These legal advisers were not professionals as such but men of rank who sought popularity and advancement in their public careers by giving free legal advice. They interpreted statutes and points of law, especially unwritten law, advised the praetor on the content of his edict, and assisted parties and judges in litigation. Augustus empowered certain jurists to give *responsa* with the emperor's authority; this increased their prestige, but the practice lapsed as early as AD 200.

During the early empire, numerous commentaries were written by the great jurists on individual *leges,* on civil law, on the edict, and on law as a whole. In the 5th century a law was passed stipulating that only the works of certain jurists could be cited. Legal scholarship declined in the postclassical period.

The law of Justinian. When the Byzantine emperor Justinian I assumed rule in AD 527, he found the law of the Roman Empire in a state of great confusion. It consisted of two masses that were usually distinguished as old law and new law.

Old law and new law under Justinian

The old law comprised (1) all of the statutes passed under the republic and early empire that had not become obsolete; (2) the decrees of the Senate passed at the end of the republic and during the first two centuries of the empire; and (3) the writings of jurists and, more particularly, of those jurists to whom the emperors had given the right of declaring the law with their authority. These jurists, in their commentaries, had incorporated practically all that was of importance. Of these numerous records and writings of old law, many had become scarce or had been lost altogether, and some were of doubtful authenticity. The entire mass of work was so costly to produce that even the public libraries did not contain complete collections. Moreover, these writings contained many inconsistencies.

The new law, which consisted of the ordinances of the emperors promulgated during the middle and later stages of the empire, was in a similarly disorganized condition. These ordinances or constitutions were extremely numerous and contradictory. Because no complete collection existed (earlier codices were not comprehensive), other ordinances had to be obtained separately. It was thus necessary to collect into a reasonable corpus as much of the law, both new and old, as was regarded as binding and to purge its contradictions and inconsistencies.

Immediately after his accession, Justinian appointed a commission to deal with the imperial constitutions. The 10 commissioners went through all of the constitutions of which copies existed, selected those that had practical value, cut all unnecessary matter, eliminated contradictions by omitting one or the other of the conflicting passages, and adapted all the provisions to the circumstances of Justinian's own time. The resulting Codex Constitutionum was formally promulgated in 529, and all imperial ordinances not included in it were repealed. This Codex has been lost, but a revised edition of 534 exists as part of the so-called Corpus Juris Civilis.

The success of this first experiment encouraged the Emperor to attempt the more difficult enterprise of simplifying and digesting the writings of the jurists. Thus, beginning in 530, a new commission of 16 eminent lawyers set about this task of compiling, clarifying, simplifying, and ordering; the results were published in 533 in 50 books that became known as the Digest (Digesta) or Pandects (Pandectae). After enacting the Digest as a lawbook, Justinian repealed all of the other law contained in the treatises of the jurists and directed that those treatises should never be cited in the future, even by way of illustration; at the same time, he abrogated all of the statutes that had formed a part of the old law. An outline of the elements of Roman law called the Institutes of Justinian (or simply Institutiones) was published at about the same time.

Between 534 and his death in 565, Justinian himself issued a great number of ordinances that dealt with many subjects and seriously altered the law on many points. These ordinances are called, by way of distinction, new constitutions (Novellae Constitutiones Post Codicem); in English they are referred to as the Novels.

Corpus Juris Civilis: the civil-law code of Justinian

All of these books—the revised Codex Constitutionum (the original work was revised four and a half years later), the Digest, the Institutes, and the Novels—are collectively known as the Corpus Juris Civilis. This Corpus Juris of Justinian, with a few additions from the ordinances of succeeding emperors, continued to be the chief lawbook in what remained of the Roman world. In the 9th century a new system known as the Basilica was prepared by the emperor Leo VI the Wise. It was written in Greek and consisted of parts of the Codex and parts of the Digest, joined and often altered in expression, together with some material from the Novels and imperial ordinances subsequent to those of Justinian. In the western provinces, the law as settled by Justinian held its ground.

Categories of Roman law. *The law of persons.* "The main distinction in the law of persons," said the 2nd-century jurist Gaius, "is that all men are either free or slaves." The slave was, in principle, a human chattel who could be owned and dealt with like any other piece of property. As such, he was not only at the mercy of his owner but rightless and (apart from criminal law) dutiless. Even though the slave was in law a thing, he was in fact a man, and this modified the principle. A slave could not be a party to a contract nor own property, but he could be given a de facto patrimony, which could be retained if he were freed; if he made a "commitment," it could ultimately be enforced against his master. A manumitted slave became, in most instances, not only free but also a citizen.

The definition of citizenship was important for the purposes of private law because certain parts applied only to citizens (*jus civile*). Noncitizens could be either Latini, inhabitants of Roman settlements that had the rights of members of the original Latin League, or *peregrini,* who were members of foreign communities or of those territories governed but not absorbed by Rome. The great extension of the citizenship by the emperor Caracalla in AD 212 reduced the importance of this part of the law.

Patria potestas: the power of the paternal head of the Roman family

Family. The chief characteristic of the Roman family was the *patria potestas* (paternal power in the form of absolute authority), which the elder father exercised over his children and over his more remote descendants in the male line, whatever their age might be, as well as over those who were brought into the family by adoption—a common practice at Rome. Originally this meant not only that he had control over his children, even to the right of inflicting capital punishment, but that he alone had any rights in private law. Thus, any acquisitions made by a child under *potestas* became the property of the father. The father might indeed allow a child (as he might a slave) certain property to treat as his own, but in the eye of the law it continued to belong to the father.

By the 1st century AD there were already modifications of the system: the father's power of life and death had shrunk to that of light chastisement, and the son could bind his father by contract with a third party within the same strict limits that applied to slaves and their masters. Sons also could keep as their own what they earned as soldiers and even make wills of it. In Justinian's day, the position regarding property had changed considerably. What the father gave to the son still remained, in law, the father's property, but the rules concerning the son's own earnings had been extended to many sorts of professional earnings; and in other acquisitions (such as property inherited from the mother), the father's rights were reduced to a life interest (usufruct). Normally, *patria potestas* ceased only with the death of the father; but the father might voluntarily free the child by emancipation, and a daughter ceased to be under her father's *potestas* if she came under the *manus* of her husband.

Marriage with and without *manus,* or husbandly authority

There were two types of marriage known to the law, one with *manus* and one without, but the *manus* type of marriage was rare even in the late republic and had disappeared long before Justinian's day. *Manus* was the autocratic power of the husband over the wife, corresponding to *patria potestas* over the sons.

Marriage without *manus* was by far the more common in all properly attested periods. It was formed (provided the parties were above the age of puberty and, if under *potestas,* had their father's consent) simply by beginning conjugal life with the intention of being married, normally evidenced by the bringing of the bride to the bridegroom's house. The wife remained under her father's *potestas* if he were still alive; if he were dead, she continued (as long as guardianship of women continued) to have the same guardian as before marriage. Both spouses had to be citizens, or if one was not, he or she must have *conubium* (the right, sometimes given to non-Romans, of contracting a Roman marriage). In marriage without *manus,* the property of the spouses remained distinct, and even gifts between husband and wife were invalid.

Divorce was always possible at the instance of the husband in cases of marriage with *manus;* in marriage without *manus,* either party was free to put an end to the relationship at will. A formal letter was usually given to the spouse, but any manifestation of intention to end the relationship—an intention made clear to the other party and accompanied by actual parting—was all that was legally necessary. The Christian emperors imposed penalties on those who divorced without good reason, but the power of the parties to end the marriage by their own act was not taken away.

Concubinage was recognized in the empire as a "marriage" without a dowry, with a lower status for the woman, and with provisions that the children were not legally the father's heirs. A man could not have both a wife and a concubine. In the 4th century the emperor Constantine first enacted a law enabling the children of such unions to be legitimated by the subsequent marriage of their parents. Medieval civil law extended this rule to all illegitimate children.

Guardianship

Persons under the age of puberty (14 for males, 12 for females) needed *tutores* if they were not under *patria potestas.* Such tutors could be appointed under the will of the father or male head of the household. Failing such an appointment, the guardianship went to certain prescribed relatives; if there were no qualified relations, the magistrates appointed a tutor. Originally, children were considered adults at the age of puberty; but, after a long development, it became usual for those between the ages of puberty and 25 to have guardians who were always magisterially appointed. Originally, all women not under *patria potestas* or *manus* also needed *tutores,* appointed in the same way as those for children. By the early empire, this provision was little more than a burdensome technicality, and it disappeared from Justinian's law.

Corporations. The Romans did not develop a generalized concept of juristic personality in the sense of an entity that had rights and duties. They had no terms for a corporation or a legal person. But they did endow certain aggregations of persons with particular powers and capacities, and the underlying legal notion hovered between corporate powers, as understood in modern law, and powers enjoyed collectively by a group of individuals. The source of such collective powers, however, was always an act of state.

Four types of corporation were distinguished:

1. *Municipia* (the citizen body, originally composed of the conquered cities and later of other local communities) possessed a corporateness that was recognized in such matters as having the power to acquire things and to contract. In imperial times, they were accorded the power to manumit slaves, take legacies, and finally—though this

became general only in postclassical law—to be instituted as an heir.

2. The *populus Romanus,* or the "people of Rome," collectively could acquire property, make contracts, and be appointed heir. Public property included the property of the treasury.

3. *Collegia*—numerous private associations with specialized functions, such as craft or trade guilds, burial societies, and societies dedicated to special religious worship—seem to have carried on their affairs and to have held property corporately in republican times. The emperors, viewing the *collegia* with some suspicion, enacted from the beginning that no *collegium* could be founded without state authority and that their rights of manumitting slaves and taking legacies be closely regulated.

4. Charitable funds became a concern of postclassical law. Property might be donated or willed—normally, but not necessarily, to a church—for some charitable use, and the church would then (or so it appears from the evidence) have the duty of supervising the fund. Imperial legislation controlled the disposition of such funds so that they could not be used illegally. In such cases ownership is thought to have been temporarily vested in the administrators.

The Roman concept of absolute ownership

The law of property and possession. In Roman law (today as well as in Roman times), both land and movable property could be owned absolutely by individuals. This conception of absolute ownership (*dominium*) is characteristically Roman, as opposed to the relative idea of ownership as the better right to possession that underlies the Germanic systems and English law.

Mancipatio, or formal transfer of property, involved a ceremonial conveyance needing for its accomplishment the presence of the transferor and transferee, five witnesses (adult Roman citizens), a pair of scales, a man to hold them, and an ingot of copper. The transferee grasped the object being transferred and said, "I assert that this thing is mine by Quiritarian [Roman] law; and be it bought to me with this piece of copper and these copper scales." He then struck the scales with the ingot, which he handed to the transferor "by way of price." Clearly, this was a symbolical sale and the relic of a real sale.

In jure cessio was a conveyance in the form of a lawsuit. The transferee claimed before the magistrate that the thing was his, and the transferor, who was the defendant, admitted the claim. The magistrate then adjudged the thing to the transferee. (The sham-lawsuit theory, however, is not acceptable to all modern scholars, principally because the judgment of ownership was valid against any possible private claimant, not merely against the defendant, as in a true lawsuit.)

Usucapio referred to ownership acquired by length of possession. In early Roman law, two years of continuous possession established title in the case of land, one year in the case of movables. In the developed law, possession must have begun justifiably in good faith, and the thing must not have been stolen (even though the possessor himself may have been innocent of the theft) or acquired by violence.

In terms of *occupatio,* ownerless things that were susceptible to private ownership (excluding such things as temples) became the property of the first person to take possession of them. This applied to things such as wild animals and islands arising in the sea. In some views, it also applied to abandoned articles.

Accessio worked in this manner: if an accessory thing belonging to A was joined to a principal one belonging to B, the ownership in the whole went to B. For example, if A's purple were used to dye B's cloth, the dyed cloth belonged wholly to B. By far the most important application of this rule asserted that whatever is built on land becomes part of the land and cannot be separately owned.

Specificatio was somewhat different. If A made a thing out of material belonging to B, one school of thought held that ownership went to A, and another held that it remained with B. Justinian adopted a "middle opinion": B retained ownership if reconversion to the original condition was possible (a bronze vase could be melted down); A obtained ownership if it was not (wine cannot be reconverted into grapes).

According to *thesauri inventio,* or treasure trove, the final rule was that if something was found by a man on his own land, it went to him; if it was found on the land of another, half went to the finder, half to the landowner.

Traditio was the simple delivery of possession with the intention of passing ownership and was the method of conveyance of the *jus gentium.* If A sold and merely delivered a slave to B, under the *jus civile,* A remained the owner of the slave until a specified length of time had elapsed. The praetors, however, devised procedural methods of protecting B's possession in such a way that A's title became valueless, and B was said to own the thing *in bonis.* This was a remarkable triumph for informality in the granting of title. From the phrase *in bonis,* later writers coined the expression "bonitary ownership." Justinian abolished the theoretical distinction between civil and bonitary ownership.

The ordinary leaseholder had no protection beyond a contractual right against a landlord and could not assign tenancy. But there were certain kinds of tenure that did provide the tenant protection and that were assignable: agricultural and building leases granted for a long term or in perpetuity often enabled leaseholders to enjoy rights hardly distinguishable from ownership.

Servitudes: rights to specific, limited use or enjoyment of another's property

There were also servitudes, in which one person enjoyed certain rights in property owned by another. Rights of way and water rights were rustic servitudes; rights to light or to view were urban servitudes. *Ususfructus* was the right to use and take the fruits (such as crops) of a thing and corresponded to the modern notion of life interest. A more restricted right, likewise not extending beyond the life of the holder, *usus* permitted merely the use of a thing; thus, a person could live in a house but could not let it, as that would be equivalent to "taking the fruits."

Since ownership was absolute, it was sharply distinguished from possession, which the civil law did not protect as such. Any owner wishing to interfere with an existing possessor, however, had to bring legal action to prove his title. If he interfered on his own authority, the praetor would see that the original state of affairs was restored before adjudicating the title.

Delict and contract. Obligations were classified by classical jurists into two main categories, according to whether they arose from delict or contract. Justinian's law recognized two further classes of obligation, termed quasi-delict and quasi-contract.

As early as the 6th and 5th centuries BC, Roman law was experiencing a transition from a system of private vengeance to one in which the state insisted that the person wronged accept compensation instead of vengeance. Thus, in the case of assault (*injuria*), if one man broke another's limb, *talio* was still permitted (that is, the person wronged could inflict the same injury as he had received); but in other cases, fixed monetary penalties were set. Theft involved a penalty of twice the value of the thing stolen, unless the thief was caught in the act, in which case he was flogged and "adjudged" to the person wronged.

By the early empire, reforms had substituted a fourfold penalty in the case of a thief who was caught in the act, and the court assessed all penalties for *injuria* (which by then included defamation and insulting behaviour). The law of damage to property was regulated by statute (the Lex Aquilia), which in turn was much extended by interpretation. Additionally, there were situations in which a person could be held liable for damages even though he was not personally responsible.

In the early republic, a law of contract hardly existed. There was, however, an institution called *nexum,* of which little can be said with certainty except that it was a kind of loan so oppressive in character that it could result in the debtor's complete subjection to the creditor. It was obsolete long before imperial times. The contracts of classical law were divided into four classes: literal, verbal, real, and consensual. The literal contract was a type of fictitious loan formed by an entry in the creditor's account book; it was comparatively unimportant and was obsolete by Justinian's day. The verbal contract, or *stipulatio,* was of great importance, for it established a form in which any agreement (provided it was lawful and possible) could be made binding by the simple method of reducing it to question and answer: "Do you promise to pay me 10,000 sesterces?" "I promise." Originally it was absolutely necessary that the words be spoken, but by Justinian's day a written memorandum of such a contract would be binding, even though, in fact, nothing at all had been spoken.

Enforceable contracts

If an agreement was not clothed in the form of a stipulation, it must, to be valid, fall under one of the types of real or consensual contracts. A real contract was one requiring that something should be transferred from one party to the other and that the obligation arising should be for the return of that thing. Real contracts included loans of money, loans of goods, deposits, and pledges. Consensual contracts needed nothing except verbal or written agreement between the parties, and though there were only four such contracts known to the law, they were the most important in ordinary life—sale, hire of things or services, partnership, and mandate (acting upon instructions). In Justinian's day there was a further principle that in any case of reciprocal agreement, such as an agreement for exchange (but not sale), if one party had performed, he could bring an action to enforce performance by the other. In addition to the foregoing contracts, a few other specific agreements were recognized as enforceable, but the general recognition of all serious agreements as binding was never achieved by the Romans.

Quasi-delict covered four types of harm, grouped together by no clearly ascertainable principle. They included the action against an occupier for harm done by things thrown or poured from his house into a public place and the action against a shipowner, innkeeper, or stablekeeper for loss caused to customers on the premises through theft or damage by persons in his service.

Quasi-contract embraced obligations that had no common feature save that they did not properly fall under contract, because there was no agreement, or under delict, because there was no wrongful act. The most noticeable examples were, first, *negotiorum gestio,* which enabled one who intervened without authority in another's affairs for the latter's benefit to claim reimbursement and indemnity, and second, the group of cases in which an action (*condictio*) was allowed for the recovery by A from B of what would otherwise be an unjustified enrichment of B at A's expense, such as when A had mistakenly paid B something that was not due (*condictio indebiti*). This notion of unjust enrichment as a source of legal obligation was one of the most pregnant contributions made by Roman law to legal thought.

The law of succession. The first requirement of any Roman will of historical times was the appointment of one or more heirs. An heir, in the Roman sense of the term, was a universal successor; that is, he took over the rights and duties of the deceased (insofar as they were transmissible at all) as a whole. On acceptance, the heir became owner if the deceased was owner, creditor if he was creditor, and debtor if he was debtor, even though the assets were insufficient to pay the debts. It was thus possible for an inheritance to involve the heir in a loss. Until Justinian's day this consequence could be avoided only by not accepting the inheritance, but Justinian made one of his most famous reforms by providing that an heir who made an inventory of the deceased's assets need not pay out more than he had received. Freedom of testation, furthermore, was not complete: a man was obliged to leave a certain proportion of his property to his children and in some cases to ascendants and brothers and sisters.

With regard to intestate succession, or succession without a will, those first entitled in early times were the deceased's own heirs—that is, those who were in his *potestas* or *manus* when he died and who were freed from that power at his death. Failing these heirs, the nearest agnatic relations (relations in the male line of descent) succeeded, and, if there were no agnates, the members of the gens, or clan, of the deceased succeeded. Later reforms placed children emancipated from *potestas* on an equal basis with those under *potestas* and gradually gave the surviving spouse (in marriage without *manus*) greater rights of succession. By Justinian's day the system had evolved as follows: descendants had the first claim, and failing these heirs, came a composite class consisting of ascendants, brothers and sisters of full blood, and children of deceased brothers and sisters. Next came brothers and sisters of the half blood and, finally, the nearest cognates (relations in the female line). Husband and wife were not mentioned, but their old rights were kept alive in the absence of any of the preceding categories. Justinian also gave a "poor" widow a right to one-quarter of her husband's estate unless there were more than three children, in which case she shared equally with them. If, however, the heirs were her own children by the deceased, she received only a *ususfructus* (life interest) in what she took.

The law of procedure. The earliest forms of procedure had two stages: a preliminary one before the jurisdictional magistrate, in which the issue was developed; and then the actual trial before the *judex,* or judge. The system required that set forms of words be spoken by the parties and, sometimes, by the magistrate. The parties making an assertion of ownership, for instance, would grasp the thing in dispute and lay a wand on it, after which the magistrate would intervene and say, "Let go, both of you." So formal was the procedure that a plaintiff who made the slightest mistake lost his case. Under the system the plaintiff was also responsible for physically producing the defendant in court and, often, for carrying out the sentence of the court.

Instructions to the judge

Under new procedures developed in the 2nd and 1st centuries BC, the issue at the magisterial stage was formulated in written instructions to the *judex,* couched in the form of an alternative: "If it appears that the defendant owes the plaintiff 10,000 sesterces, the *judex* is to condemn the defendant to pay the plaintiff 10,000 sesterces; if it does not so appear, he is to absolve him." A draft of these written instructions was probably prepared for the plaintiff before he came into court, but there could be no trial until it was accepted by the defendant, for there was always a contractual element about a lawsuit under both the new and the old systems. Pressure, however, could be exercised by the magistrate on a defendant who refused to accept instructions that the magistrate had approved, just as a plaintiff could be forced to alter instructions that the magistrate had disapproved, by the magistrate's refusal to otherwise give the order to the *judex* to decide the case.

In late republican times, still another system developed, first in the provinces, then in Rome. Under the new system the magistrate used his administrative powers, which were always considerable, for the purpose of settling disputes. He could command: thus if one person brought a complaint against another before him, he could investigate the matter and give the order he thought fit. As imperially appointed officers superseded republican magistrates, this administrative process became more common. The result was that the old contractual element in procedure disappeared as did the old two-stage division. Justice was now imposed from above by the state—not, as originally, left to a kind of voluntary arbitration supervised by the state.

(H.F.J./R.Po./M.A.M./M.A.Gl.)

GERMANIC LAW

Germanic law is a designation that covers the laws of the various peoples of Germanic stock from the time that the earliest "barbarian" tribes came into contact with the Romans until their tribal laws developed into national territorial laws—a development that occurred at different times with different peoples. Thus some of the characteristics of Scandinavian legal collections of the 12th century are similar to those in the Visigothic laws of the 6th century.

Knowledge of the early Germanic period is derived mainly from the observations of tribal life contained in Julius Caesar's *Gallic War* and Tacitus' *Germania.* The first written collections of Germanic law are the so-called Leges Barbarorum, which date from the 5th century until the 9th century. They are written in Latin and show Roman influence by their use of the technical terms of Roman law. The Anglo-Saxon laws and the laws of the North Germanic group, on the other hand, are in the vernacular and owe their written form largely to the advent of Christianity.

For all of the Germanic peoples, law (West German, *reht* and *êwa;* High German, *wizzôd;* North German, *lagh,* from which the English word *law* is derived) was basically not something laid down by a central authority, such as the king, but rather the custom of a particular nation (tribe). It was essentially unwritten, being derived from popular practices, and was not sharply distinguished from morality; it was personal in the sense that it applied only to those who belonged to the nation. Thus each man followed his own law, a notion appropriate to a nomadic people who originally did not live in a clearly defined territory. When, after the fall of the Roman Empire in the West, Germanic tribes took over former Roman provinces, they did not attempt to apply their laws to their Roman subjects, for whom Roman law remained applicable.

Visigothic laws

Thus the earliest Germanic code, that of Euric, king of the Visigoths in Spain and southwestern Gaul in the late 5th century, applied exclusively to Visigoths. The Lex Romana Visigothorum, or Breviary of Alaric, was issued in AD 506 for their Roman subjects. It was a compilation of "vulgar law"—Roman law adapted to fit the social and economic conditions of the late Roman Empire—and was later the main source of Roman law in the Frankish kingdom. Only in the 7th century was Visigothic law applied to Visigoths and Romans alike, the two peoples by then having substantially fused. The Lex Burgundiorum and the Lex Romana Burgundiorum of the same period had similar functions, while the Edictum Rothari (643) applied to Lombards only.

The Leges Barbarorum, then, were not legislation in the modern sense but rather the records of customs that were first collected and then declared as law. The prologue to the Salic Law (the law of the West, or Salic, Franks) recounted how four chosen men collected the original practices in particular cases, having first discussed them with the presidents of the local popular assemblies. The Leges Barbarorum did not seek to set out all of the main rules of law as modern codes do. They were not concerned with what everyone took for granted but concentrated on matters that, perhaps as a result of migration or conquest, had become doubtful and needed authoritative exposition. They dealt with specific situations rather than general rules and focused particularly on court procedure, monetary compensation for acts of violence, and succession on death.

The initiative for declaring law usually came from the king, but the resulting laws normally required approval by the popular assemblies. Because of this collaboration between king and people, a compilation was sometimes referred to as an "agreement," or *pactus.* The Visigothic laws were an exception; they always appear to have been formulated by the king and chief landowners without popular participation. Gradually, first the Lombard and then the Frankish kings overcame their people's aversion to central government and began to legislate unilaterally. The Lombards, who invaded Italy in 568, had no single code of custom, but their kings issued edicts from the mid-7th century onward. In the Frankish kingdom the Merovingian kings called their legislation *edicta* or *praecepta,* but the succeeding Carolingians characterized them as *capitularia; i.e.,* royal ordinances divided into articles (*capitula*). These included modifications of the *leges* of the Franks or other nations in the Frankish kingdom, administrative orders to officials, and independent legislation. Like the Roman emperors before them, Charlemagne and his successors claimed the power to make laws for all their subjects, irrespective of nation, and without the consent of any assembly. The validity of the law depended solely on the oral act of the king who promulgated it.

Tribal Germanic institutions. Germanic law recognized a distinction between free and unfree persons. Only the former had legal capacity, and they were subdivided into nobles and ordinary freemen. The nobles enjoyed a larger share in land distribution, were preferentially chosen for public office, and were protected by a larger monetary compensation if they were injured. Certain west Germanic tribes recognized an intermediate status of half-free persons, who could enter into legal transactions and marry but had no political rights.

Basically a Germanic tribe was a league of clans. Its main institutions of government were the king, his council, and the tribal assembly (*mallus, witan, mot, ding,* or *thing*). The king was military leader, chief priest, and president of the assembly, and he was assisted in the routine business of government by his council of elders and higher nobles. The assembly was composed of all free members of the tribe grouped into clans. It elected kings, declared war, outlawed freemen, and generally controlled the membership of the tribe by its supervision of the manumission of slaves, the emancipation of minors, and the adoption of strangers.

Role of the king

The dominant social institution was the "sib" (*sippe*), a term that meant both a clan—the extended family composed of all those related by blood, however remotely, and subject to a clan chief—and also a household or narrow family, whose members were under the *mund* (guardianship) of the family head. A boy remained in his father's *mund* until he was emancipated on attaining physical maturity; a girl remained until she married, when she passed into the *mund* of her husband. Marriage commonly took the form of the sale of the bride to her groom for a price, which developed into a fund held by the husband for the wife's benefit. A husband could divorce his wife at will but risked being penalized financially.

Laws of property

The main notion in the law of property was *gewere,* or the power exercised by the owner, which did not clearly distinguish between legal title and physical control. Various forms of limited ownership were recognized. Land was treated differently from movables; originally it had belonged to each family collectively. Family ownership gradually developed into the private ownership of the family head, but for a long time he could alienate land only with the consent of the nearest heirs. Land transfer required much formality, and among the west Germanic peoples a glove or spear was handed over as a symbol of *gewere.*

At the death of the family head, his property passed to his descendants in the nearest degree of proximity, with a preference for males. (The declaration in the Salic Law that daughters could not inherit land was used by 16th-century French lawyers as additional support for the long-standing practice of excluding women or their descendants from succeeding to the crown.) In the absence of descendants, several *leges* provided that property deriving from the father's side should return to that side and property from the mother's side to her side. The order of succession could not be altered by will.

When trade was still on a cash or barter basis, there was little need for formal contract law. A family could obligate itself to another either by pledging a thing as security (*wadium, gage*) or by surrendering a hostage (*gijzel, born*).

Later, a debt was guaranteed by a formal oath accompanied by the surrendering of a staff to the creditor (*effestucatio*). Contractual obligation was then constituted either by oath (enforced by an action for perjury) or by delivery of a thing (enforced by an action for theft).

Laws to control crime

Offenses against the community, such as treason, secret killing, and secret theft, were punished by outlawry, which was pronounced by the tribal assembly. The convicted person could then be killed by anyone. Offenses against individuals, including open killing and open robbery, became the subject of a blood feud if the criminal and victim belonged to different family groups. Peace could be bought by the payment of compensation, known as *wergild* in homicide cases and *bot* in others. Payment was voluntary at first; only later did it become obligatory. Even in the 7th century, Visigothic law still allowed retaliation in kind for all injuries except those to the head. The *leges* contained elaborate tariffs of compensation for different kinds of injury, the amount varying according to the social status of the victim. Private feuds were eventually restricted by the growth of royal authority in the Frankish period and the notion of the king's peace, the breach of which was punishable by the king's court.

When parties appeared before a court and stated their cases, the court decided on an acceptable method of proof, which could be by oath of the parties, supported by *compurgatores* (literally "oath-helpers"), the number required depending on the gravity of the case, by ordeal, or by battle. A successful claimant had to enforce judgment himself on the person or property of the defendant.

Rise of feudal and monarchial states. With the disintegration of the Frankish kingdom in the late 9th century, government became highly decentralized. Already the pattern of landholding, which determined the more important legal relationships, had begun to take on the characteristics of feudalism. Before the end of the Roman Empire much of the land had been concentrated in the hands of magnates, secular and ecclesiastical. But, unlike their predecessors under the Romans, the holders of secular land in the Germanic states became largely independent of the central government. By the 9th century, many lords had become strong enough to challenge the power of the Carolingian kings of the Frankish Empire and to make the inhabitants of their own areas their vassals. These vassals held their land from the lords as tenants of a so-called feud, or fee. Each feudal lord held a court for his tenants in which he applied the same law to all of the tenants, irrespective of their racial or national origin. Thus the old Germanic personal principle was abandoned in favour of the territorial principle, or the application of the custom of the region. This type of feudal law usually was based partly on Germanic law and partly on the Roman law of the Lex Romana Visigothorum, adapted in the interests of the feudal lords.

Influence of canon law

During the same period the Roman Catholic Church became the main unifying force in western Europe and began to claim jurisdiction over many matters that earlier had been considered secular rather than ecclesiastical. Church courts had existed since the Roman Empire, and their power in matters of faith was recognized by the secular authorities. The personal law of the church as an institution was always Roman, and indeed the law of the Ripuarian Franks on the Rhine expressly declared that "the church lives by Roman law." The canon law applied in the church courts was largely influenced by Roman law and contained very few Germanic elements. As the power of the church grew, the church courts applied this law to matters that had previously been dealt with by the secular courts, such as marriage, adultery, wills, and succession. In many countries these matters remained withdrawn from Germanic law and subject to church law even after the Reformation.

Merchants also found that the old Germanic customary law was inadequate to cope with the problems created by the rapid growth of commerce that had occurred by the 12th century. A special commercial law, based mainly on Roman law as developed by the Mediterranean seaborne traders, was developed to settle disputes between merchants, without regard to their nationality or place of residence.

These developments reduced the range of cases that were subject to the jurisdiction of the local county courts. In Germany some of the earlier codifications of customary law were forgotten, partly because the local judges were unable to understand the Latin in which they were written and partly because the rules that they contained were unsuited to the new social and economic conditions. The local courts applied an unwritten customary law based on the dominant tribal law of the area, and it was this that formed the basis of such codifications as the *Sachsenspiegel* ("Mirror of the Saxons") in the 13th century.

Regional variations

In France the legal development in the north differed from that in the south. The regional customs in the north were made up of Germanic and Roman law, the Carolingian capitularies, and canon law, but Germanic elements predominated. In the south, the so-called *pays de droit écrit* ("land of written law"), where Gallo-Romans had been far more numerous than Franks, the custom of each district was based mainly on the vulgar law of the Lex Romana Visigothorum. In Italy this law existed side by side with Lombard law. In the 7th and 8th centuries that law was subjected to a relatively sophisticated codification, whose form showed Roman influence.

In England the Norman conquerors continued the movement toward legal unity begun by the Anglo-Saxons by imposing on the country a centralized form of government more powerful than any on the Continent. In the 12th century Henry II made the king's court a permanent court of professional judges with jurisdiction over many matters that earlier had been dealt with by other courts. The common law developed by this court was largely Germanic law. (P.G.S./M.A.Gl.)

Civil-law systems

THE HISTORICAL RISE OF CIVIL LAW

In the 5th and 6th centuries western and central Europe were dominated by Germanic peoples, especially those who had overrun the Roman Empire. Among them were the Anglo-Saxons of England, the Franks of western Germany and northern France, the Burgundians, the Visigoths of southern France and Spain, and the Lombards of Italy. Although Roman law traditions lingered on for some time, the Germanic customs came to prevail in most regions. In the Middle Ages these customs underwent vigorous growth in an effort to satisfy the complex needs of a society that encompassed changing feudalism, chivalry, growing cities, Eastern colonization, increasing trade, and a constantly refined culture. Among the many strands that went into the weaving of the complex pattern of medieval law, the customs of the merchants and the canon law of the Roman Catholic Church were of special significance. It was through the canon law that the concepts and ideas of ancient Rome continued to make their presence felt, even when, as a whole, Roman law had been forgotten. In the late 11th century Roman law was rediscovered and made the subject matter of learned study and teaching by scholars in northern Italy, especially at Bologna. With the increasing demand for trained judges and administrators, first by the Italian city-republics, then by princes in other localities, students flocked to Bologna from all over Europe, until the study and teaching of law were gradually taken over by local universities. As a result of this process, Roman law penetrated into the administration of justice north of the Alps, especially in Germany and the Netherlands, where the Roman-law influence became particularly strong.

Revival of Roman law

In the Holy Roman Empire of the German Nation the reception of Roman law was facilitated because its emperors cherished the idea of being the direct successors of the Roman Caesars; Roman law, collected in the Corpus Juris Civilis by the emperor Justinian I between 527 and 565, could be regarded as still being in effect simply because it was the imperial law. Decisive for the reception, however, was the superiority of the specialized training of Roman-law jurists over the empiricist methods of lay judges and practitioners of the local laws. Equally decisive was the superiority of the Roman-canonical type of procedure, with its rational rules of evidence, over the local forms of procedure involving proof by ordeal, battle, and other irrational methods. Nowhere, however, did Roman law completely supplant the local laws, and, as far as the content of the law was concerned, various amalgams developed. Roman law strongly influenced the law of contracts and torts; canon law achieved supremacy in the field of marriage; and combinations of Germanic, feudal, and Roman traditions developed in matters of property and succession. The conceptual formulations in which the norms and principles of the law were expressed, as well as the procedural forms in which justice was administered, were also strongly Roman. The system that thus emerged was called the *jus commune.* In actual practice it varied from place to place, but it was nevertheless a unit that was held together by a common tradition and a common stock of learning. Although the law of the Corpus Juris Civilis (especially its main part, the Digest, the writings of the jurists) was, as such, in effect nowhere, it constituted the basis of study, training, and discourse everywhere. In spite of all local variety, the civil-law world experienced a sense of unity that corresponded to the strongly felt unity of European civilization.

National codifications

This unity was undermined by the religious split of the Reformation and Counter-Reformation and by the rise of nationalism that accompanied the unification and stabilization of the European nations and their struggle for hegemony. In the field of law the split found expression in the national codifications, through which the law was unified within each nation but simultaneously was set apart from that of all others. In Denmark codification occurred in 1683, in Norway in 1687, in Sweden-Finland in 1734, and in Prussia in 1794. Because of the personality of their promoter and the novel technique applied, great fame and influence were achieved by the Napoleonic codifications of the private and criminal law of France, especially their central piece, the Civil, or Napoleonic, Code (Code Civil or Code Napoléon) of 1804.

Codification continued after the Napoleonic era. In Belgium and Luxembourg, which had been incorporated into France under Napoleon, his codes were simply left in effect. The Netherlands, Italy, Spain, Portugal, and numerous countries of Latin America followed the French model not only by undertaking national codification but also by using the same techniques and arrangements. Naturally, their courts and legal scholars were, at least in the early 19th century, inclined to pay great attention to French legal learning.

In Germany national codification came considerably later than in France. Only a commercial code had been uniformly created by the independent German states shortly after the revolution of 1848. The unification of the criminal law took place almost simultaneously with the political unification of the country, which occurred in 1871. Codification of the organization of the courts and of civil and criminal procedure came in 1879. But the Civil Code (Bürgerliches Gesetzbuch für das deutsche Reich) was not completed until 1896, and it did not take effect until Jan. 1, 1900.

Throughout the 19th century the vigorous German science of law exercised much influence in Austria (which as early as 1811 had codified its law in a technique different from that of France), in Switzerland, in the Nordic countries, and, later, in most of eastern Europe. When Swiss law was codified in 1907–12, it became the model for the Turkish codification of 1926 and strongly influenced that of China, which is still in effect in Taiwan.

Due to the different dates of codification and the different style and attitude of legal learning, the civil-law family of laws is thus divided into the French, or Romanist, branch and the German, or Germanic, branch. Their main features are determined by those of their prototypes. The legal system of Japan essentially belongs to the German branch, but it presents important features of its own.

THE FRENCH SYSTEM

Changes induced by the French Revolution

In France the revolutionary period was one of extensive legislative activity, and long-desired changes were enthusiastically introduced. A new conception of law appeared in France: statute was deemed the basic source of law. Customs remained only if they could not be replaced by statutes. The Parlements, the major courts of the nation, were dismantled and replaced by a unified system of courts that were merely supposed to apply the law and never to lay down general rules.

The main ideas embodied in the revolutionary legislation were to be found in the motto of the Revolution (which is still that of France), "*Liberté, égalité, fraternité.*" The passionate desire for liberty and equality aroused by the 18th-century philosophers inspired the changes that took place.

The system that had come to be called feudal, although it had little to do with the feudalism of the High Middle Ages, was hated by the peasants and the bourgeoisie for its unbalanced distribution of privileges—especially those exempting the nobles and clergy from taxation. These privileges were abolished early in the Revolution. The revolutionaries detested organized groups of any kind, for it was thought that only one authority should exist over the citizens—that of the state. As a result the guilds, which demanded compulsory membership and regulated every profession, were suppressed, and freedom of commerce was established. The old-style universities were dissolved; in the same spirit the property of the Roman Catholic Church was secularized, and the priests and bishops were made state employees, a situation that most of them did not accept.

Family relations were deeply transformed according to the principles of liberty and equality. Marriage was organized merely as a civil act, divorce was permitted, paternal authority was limited, and parents' consent was not required for marriages of children over 21 years of age. A short experiment was made with "family courts" that were permitted to overrule paternal decisions, and the wife was declared equal to her husband. In matters of succession, equal parts were given to all children, and the testator's right to dispose of property by will was limited in order to prevent the reestablishment of inequalities by this device.

Throughout the revolutionary period, successive governments were committed to consolidating the legal changes in a set of codes. Drafts were made, but time and authority were lacking, and none was enacted until society was restabilized under Napoleon.

The concept of codification. From a practical point of view, the Civil Code achieved the unification of French civil law. This was not, however, the only concern of its drafters. They shared with most of their contemporaries and with most modern French lawyers the belief that the law should be written in clear language so that it would be accessible to every citizen. This view implied that the new code must be complete in its field, setting forth general rules and arranging them logically. Finally, it must not unnecessarily break with tradition.

The Civil Code was organized as a series of short articles because it was assumed, first, that legislators could not foresee all circumstances that might arise in life and, second, that only conciseness could make the code flexible enough to adapt old principles to new circumstances. The general rules contained in the code have since been applied to concrete circumstances without much difficulty. When an interpretation has been required, the courts have had the responsibility to give it, taking into consideration the "spirit" of the code in an effort to apply to each case the solution that would have been desired by the legislator.

Logic and experience in the codification

The drafters of the code strove toward inner consistency in their work, so that reliance on logic might ensure satisfactory application of it. They saw no contradiction between logic and experience. Since the 17th-century beginnings of the Age of Reason, abstract reasoning had characterized the French approach to law and to life in general. For this reason articles of the code were not regarded as narrow rulings. If no one article was found to apply exactly to a given situation, it was proper to consider several articles and to draw from them a more general rule that could either itself be applied to the case or be combined with others to reach a solution.

Although the code was a work of logic, it relied mainly on experience. Its drafters were exceptionally well qualified in this respect: they had lived the first half of their lives under the laws of ancient France and had also known the Revolution. Their purpose was not so much to create new laws as to restate existing laws, subject to choice when revolutionary enactments varied from previous ones and when previous laws differed from one another. They were ready to adopt any rules that seemed best suited to the French people on the basis of experience; they recognized that laws could not be inflexible "but must be adapted to the character, the habits, and the situation of the people for whom they are drafted."

Later changes and adaptations. No important changes were made in the Civil Code from 1804 to 1880, except the repeal of divorce in 1816, when a Catholic monarchy was restored. The political and legislative power was held by the bourgeoisie, and they were entirely satisfied with the basic principles of the code, which favoured individualism and free will. In fact, from 1804 until the enactment of the constitution of the Third Republic in 1875, the Civil Code remained the law of France despite several changes in political regimes. Jurisprudence was centred upon it; in both teaching and writing, scholars discussed it article by article. The courts fulfilled the role that the drafters had stressed for them; imbued with the spirit of the code, they applied its general rules to particular cases.

Changes during the Third Republic

The social atmosphere changed during the Third Republic when universal suffrage gave the labouring class an influence on legislation. Faith in liberalism was shaken, and the idea grew that the state should intervene to protect the weak. Statutes increased in number. This movement was accentuated by World Wars I and II, when a mass of emergency regulations had to be passed, and the power of the state to encroach on private interests for the sake of the community was increased.

Subsequent amendments to the code revealed two trends: first, greater individualism in family law; second, qualification of individual rights for the sake of social interests—what has been called "socialization" of the law.

Adaptation of the law to new social needs was not made by statute alone: the courts, to a certain extent, adjusted the law to modern circumstances. They did this, however, while maintaining a consciousness of their subordinate position. They recognized that, as a general rule, basic changes were the province of the legislature and not of the judge, though this did not prevent them from gradually adapting the law to the modern conditions of life.

Legal learning also had a role. A number of important statutes were drafted by commissions that included judges, professors, and lawyers; and authors often suggested to the courts new developments in the application of rules of law. Although most of the statutes passed during the 19th and 20th centuries were left outside the code, they continued to be published with the new editions of the code.

By the middle of the 20th century, it had become apparent that the code should be revised. This task was entrusted to a commission, which produced several important drafts. The effort to replace the old code with a completely new one was halted when Charles de Gaulle came to power in 1958. Revision has since occurred only on a sporadic, piecemeal basis, except for the sections concerning family law, which have been thoroughly reformulated. The continuing development of multinational institutions such as the European Communities may require readjustments on a broad scale. This seems particularly likely in the field of commercial law, where company law has become the first target for harmonization, and perhaps even in contract law.

The main categories of French private law. The French Civil Code uses many of the categories that were developed in ancient Rome, but its law is that of its own time.

Marriage viewed as basic to civilized society

Marriage and family. The drafters of the French Civil Code regarded marriage as the basic institution of a civilized society. Taking into account the variety of religious attitudes in France, they decided that only marriage ceremonies celebrated before secular officials should be legally valid. This did not deprive ministers of the various faiths of the right to celebrate religious marriage ceremonies, but these were devoid of any legal effect and had to take place after the secular ceremony in order to avoid any risk of confusion. Parental control over children's marriages was partially restored; consent was required for sons under 25 and daughters under 21. After 1900 the formalities of marriage were lessened and parental control over it curtailed. Twentieth-century statutes gradually reestablished the revolutionary rule that the consent of the parents was not necessary when the parties were over 21. In 1974 the age of majority for this and other purposes was reduced to 18.

In France under the ancien régime the family had been centred upon the husband, whose strong authority and powers were inherited from the Roman paterfamilias (head of family). Although the Revolution proclaimed women to be equal in rights with men, it did little to implement this view in law. The drafters of the code saw no reason to modify the traditional situation, and Napoleon himself favoured subordination of the wife to the husband. The code expressly stated that she owed him obedience. With very few exceptions, she had no legal capacity to act. Without the written consent of her husband, the wife could not sell, give, mortgage, buy, or even receive property through donation or succession. Statutes in the 20th century, however, severely diminished the authority of the husband over his wife and endowed her with full legal capacity. In 1970 the old language stating that "the husband is the head of the family" was abandoned in favour of a new principle of joint family decision-making power, which did not, however, extend to the management of community property.

Rights of husband and wife

In recent years matrimonial property regimes have been revised in numerous countries, the tendency being toward a partnership in property acquired after the marriage, with each party retaining control over the property he or she had before the marriage. Although the Napoleonic Code provided for a statutory regime (if no particular marriage contract had been made), under which all chattels and earnings of the spouses would be community property to be shared equally between them or their heirs at the dissolution of the marriage, the husband was vested with all active powers, even over his wife's property. In 1965 movables owned by either spouse before marriage were excluded from the community fund, which now, in the absence of an agreement to the contrary, consists only of the fruits of the spouses' work or frugality during marriage. With the acquisition of legal capacity in the early part of the century, a French wife was free to manage and dispose of her own earnings and property, but it was not until 1985 that the long predominance of the husband in the management of the couple's common property was replaced by a system of equal comanagement.

Divorce. Divorce was first introduced into France after the Revolution. It was made very easy and was even allowed by mutual agreement.

The drafters of the code decided that since many persons were not prevented by religious conviction from seeking divorce, it was not for the legislator to prevent unhappy spouses from terminating their marriages and from entering new legal unions. Divorce, therefore, was allowed, but only within strict limits, so that "the most sacred of contracts should not become the toy of caprice." The only grounds for divorce were adultery, sentences for the most serious crimes, excesses such as gambling habits and expenditures, cruel treatment, or serious insult. Mutual agreement was added under the personal pressure of Napoleon, already intent on divorcing his first wife, by whom he had no child. But the procedure of divorce by mutual agreement was extremely long, complicated, and costly, and no second marriage could take place within six years thereafter.

Divorce was repealed in 1816 after Napoleon's fall and the restoration of the monarchy, and it was not reintroduced until 1884. From 1884 to 1975, divorce was permitted only on the grounds of adultery, conviction of a serious crime, and cruelty. Divorce by mutual agreement was not reinstated until 1975, when a comprehensive reform of the divorce law permitted a marriage to be terminated by consent or by petition of one spouse unopposed by the other, or when the marriage had broken down after six years of separation or after six years of mental illness of one spouse, in addition to the traditional grounds of fault.

Succession and gifts. The Napoleonic Code adopted many of the ideas of the Revolution concerning succession. But its formulators tempered them with exceptions and combined them with ideas from the ancien régime.

The revolutionary law on intestate succession (succession without a valid will) relied upon two basic principles: (1) that no distinctions be made within the estate of the deceased, land and chattels being treated in the same way and no account being taken of the origin of landed property; and (2) that equal parts be given to all heirs of the same degree of kindred, the advantages accruing through some customs to the firstborn or to male children being abolished. Using these two principles, the code provided that an estate should devolve first of all upon the children and other descendants. If heirs of one degree died before others of the same degree and left children, representation (the principle that the children of a deceased heir inherit his share) applied. In other cases distribution was made per capita, with equal shares going to those heirs of equal degree. Illegitimate children could inherit from their parents, but they received less than legitimate children and could not cut out either the deceased's own parents or his brothers and sisters. Through reforms in the 1970s, the rights of illegitimate children to succeed to their parents have largely been assimilated to those of legitimate offspring.

Rights of heirs and surviving spouse

According to the code, the spouse could succeed only if there were no persons who were related to the deceased up to a degree specified by law. A surviving wife was, thus, in a poor position if no gift or legacy had been made to her, though under the statutory matrimonial regime she received half of the community property into which all chattels of both spouses fell. The rights of the surviving spouse have been increased at various times during the 20th century. Today the surviving spouse is entitled to at least the usufruct (similar to a life interest) of one-quarter of the property left by the deceased. The survivor inherits half of the estate if there are no children and if there are surviving ascendants on only one side of the deceased's family. If the decedent leaves no blood relatives within a certain degree of kindred, the surviving spouse receives the entire estate.

Wills may be formal or informal. Unwitnessed wills are valid, provided that they are written throughout, and dated and signed, by the testator's own hand. Wills are effective upon the death of the testator and do not need to be probated. Freedom to dispose of property by will or by gift is limited in order to protect children and other descendants as well as parents and grandparents, who have to be allowed a certain proportion.

Property. The intricate system of obligations and rights inherited by the ancien régime from feudalism was rejected by the Revolution, which restored a system patterned on that of Roman law.

Concept of movables and immovables

The only classification of goods is the basic one of immovables (which are defined as having a fixed place in space) and movables (which include all goods that are not immovables). In contrast to the "feudalist" complexities in common law, the normal relationship between persons and things is ownership, which is defined as a complete, absolute, free, and simple right. But, as in the law of other modern nations, the use of property is subject to many kinds of restrictions imposed in the public interest. Usufructs, or servitudes, are possible, but rights in an estate never require the person in whom they are vested to do anything. The code states that a servitude "is a charge laid on an estate for the use and utility of another estate belonging to another owner," and it emphasizes that "servitudes do not establish any pre-eminence of one estate over another." Title in land may be acquired within 10 or 20 years if the possessor believed, in good faith, that he was the real owner. Furthermore, the bona fide purchaser of movable property immediately becomes its owner, and nobody can prove a better title against him unless the property has been lost or stolen.

The section on mortgages in the Civil Code was weak. An excellent statute of the revolutionary period was developed in 1798 to set up a system of registration for all transfers of land titles and real estate mortgages. It enabled a buyer of land to ascertain whether he was buying from a regular owner and whether the land was mortgaged; if it was, the buyer could clear his title by offering the price to the mortgagee.

The drafters of the code maintained this system of compulsory registration, but only for gifts and for contractual mortgages. Sales of real estate and a number of legal mortgages were not subject to registration. This gap left prospective creditors or buyers with insufficient information. It was only after reforms were made in 1855, 1935, 1955, and 1967 that there was a comprehensive, but still not fully reliable, system of publicity for mortgages and conveyances of immovable property.

Contracts and torts. The French Revolution brought no changes into the law in this relatively nonpolitical field. The drafters of the code merely restated the law that had developed during the course of centuries and that authors already had analyzed.

Informality and freedom of contract

The basic principles of contract law are informality and freedom; the latter is limited, however, when demanded by public policy. The code states that "agreements legally entered into have the effect of laws on those who make them." The entire matter of torts is dealt with in only five short articles. The general basis for liability is the following: "Any act of a person that causes injury to another obligates the person through whose fault the injury occurred to give redress." The subsequent articles in the code regulate liability for damages caused by things, animals, children, and employees. It was left to the courts to work out a complete system of tort law based on these few articles.

THE GERMAN SYSTEM

Roman law, as embodied in the Corpus Juris Civilis, was "received" in Germany from the 15th century onward, and with this reception came a legal profession and a system of law developed by professionals (*Juristenrecht*). Roman law provided the theoretical basis for legal progress that culminated in the work of the scholars of the 19th century. Under this tradition, the legal process has been viewed in Germany as the application of more or less generally formulated rules to individual cases. German courts traditionally have not been as dominant in developing the law as have their counterparts in the common-law countries. Roman law provided tools to strengthen sovereignty, as well as the correlative ideas that the legislative function is a state monopoly and that the responsibility for the development of law rests with a legally trained, state-controlled bureaucracy rather than—as in 18th- and 19th-century England—with a combination of gentry and leaders of the bar. German judges traditionally have been university-trained experts under the authority of the state and the anonymity of the court. In the post-World War II period, however, West German judges have steadily assumed a more active role, especially in constitutional law.

Contrasts between the German and French codes

The German Civil Code. Because the German Civil Code of 1896 came almost 100 years later than the code of France, its draftsmen profited from the intensive efforts of German scholars who had systematized, clarified, and modernized the law during the 19th century. As a result, the German code is markedly different from its French predecessor: its arrangement is more orderly, its language more precise, and its use more exacting.

The appeal of the German code is from lawyers to lawyers; the matter-of-fact, neutral tone contrasts with the livelier mood in which the French Civil Code was written. It does not try to teach men in a broad sense, but it emphasizes ethical imperatives. Good faith and fair dealing are to be observed in all affairs. Breaches of good morals, abuses of rights, and underhanded legal transactions are deprived of legal effect. The code was meant to fit the society of the turn of the century, but through the use of general clauses that leave the elaboration of specific norms to the judges, it has demonstrated an adaptability to new economic, cultural, and sociopolitical postulates.

Modern law in West Germany assumes that the proper form of society is that of a social democracy, which not only confers individual rights but also holds the state responsible for social welfare and individuals responsible for behaving in a socially responsible way. The former concern of German law with abstract concepts has given place to a more pragmatic approach that attempts to apply the scale of values of a pluralistic society, containing strong elements of a welfare state, while emphasizing civil liberties.

The main categories of German private law. The German Civil Code begins with the proposition that at birth every person acquires the capacity to exercise rights and to fulfill duties. A minor's interests are protected by a representative who acts in his name, and although certain legal transactions may be entered into at age seven, full legal capacity is not acquired until age 18 (formerly 21). Every person possesses the right, protected by an action in court, to freedom from personal injury and from attacks on individual dignity.

Marriage and family. Since 1875 marriage has required civil celebration by a registrar, who cannot be a priest. Celebration in church may follow the civil ceremony. Marriage can be declared null and void on application by one of the spouses or by the public prosecutor on various grounds, such as lack of form or affinity, but the consequences of such nullity approximate those of divorce: the children are not necessarily illegitimate. Since 1976, the sole ground for divorce has been the breakdown of the marriage, which is presumed if the spouses have lived apart for a year and are in agreement on the divorce, or if the spouses have lived apart for three years.

Rights of husband and wife

The provisions of the German Civil Code concerning the rights of women in marriage were less restrictive than those of the French Civil Code. After World War II nearly all rules contravening the principle of equality of men and women were repealed. The ordinary statutory marital-property regime, with the husband administering and using the wife's estate, was replaced in 1957 by a system of separate management and equal sharing in the value of acquisitions made during the marriage. Upon the death of one spouse the surviving spouse is entitled to a generous share in the estate. Care for the person and property of the children belongs to both spouses.

Succession. In contrast to Anglo-American law, the assets of the decedent pass directly to the heirs, who are determined by the rules of intestacy or by testamentary disposition. As a general rule, the estate does not pass through a stage of administration by an administrator or executor. The heirs are liable for the debts of the decedent with their own property but by taking appropriate steps may limit their liability to the assets of the estate. A testator may appoint an executor to perform certain functions in the settlement. A will may be unwitnessed, but then it must be entirely in the testator's handwriting. Public wills are either made orally before a public official, who records them, or set down in a document that the testator hands to the official with a declaration that it is his last will. Descendants and other close relatives, including the surviving spouse, cannot be deprived of more than one-half of their intestate shares.

Property. Property is declared to entail obligations of the owner to the community. This is particularly important in terms of farmland, which can be pooled and redistributed to make better use of machinery and to increase production. Every creation, transfer, encumbrance, or cancellation of a right in immovable property requires, in addition to the agreement of the parties, registration with the district court. A person who, in good faith, acquires an interest in land from the person registered is protected. In order to obtain title to a chattel from a person who does not own it, the transferor must have had possession, the transferee must have been in good faith, and the owner must not have lost possession involuntarily. But neither in the case of land nor in that of chattels is it required that the transfer to the transferee be for value. Even if the transferee acquires a title, he may be required to surrender the asset or to pay its value if the acquisition appears to be a legally unjustified enrichment.

Contract and delict. Parties are free to regulate their relations by contract, within limits set by express statutory prohibitions and by good morals. Strict limits are set to eliminate fraudulent practices by one of the contracting parties. In the case of a valid contract, the parties must observe the requirements of good faith, with ordinary usage taken into consideration. The determination of "ordinary usage" is left to the courts. This has been particularly advantageous given the rapidly changing conditions of the 20th century.

Compensations for breach of contract and injury

Unless the promisor can prove that a breach of contract has been caused in a way entirely outside his sphere of risk, he is liable for damages. But if the promisee chooses to do so, he may have the promisor ordered to complete the contract as long as it is not shown that this is impossible. The principle that "anyone who through an act performed by another or in any other way acquires something at the expense of that other without legal justification is bound to return it to him" is stated in broad terms, but it is cautiously applied by the courts.

In terms of delict, the German Civil Code provides that any person who intentionally or negligently injures unlawfully the life, body, health, property, or any other absolute right of another person is bound to compensate him for any damage arising therefrom. Damages also are due for harm caused by the violation of a statute meant to protect others and for harm caused intentionally and immorally. If a public officer violates his statutory duty, court remedies are readily available against the government.

OTHER SIGNIFICANT CODIFICATIONS

Swiss and Italian codes

Swiss law. Shortly after German law was codified, Switzerland followed suit. Its Civil Code of 1907, together with a separate Code of Obligations, went into effect in 1912. These new federal codes superseded the earlier codes of the separate cantons (which had generally been patterned after the Austrian or the French model). The Swiss draftsmen took advantage of earlier experiences with codification technique—drawing especially upon both the Code ,Napoléon and the German code. The Swiss Civil Code, which exists in German, French, and Italian versions of equal authority, is a masterly attempt at summarizing and systematizing civil law and has influenced codification in countries as diverse as Brazil and Turkey.

Italian law. The French code was introduced into parts of Italy during the Napoleonic conquests. Even after the collapse of Napoleon's empire, when French law was abrogated, the Code Napoléon still served as the model for the new codes of several Italian states. The new Civil Code for the Kingdom of Italy was enacted in 1865 while the peninsula was being united politically. Its structure and content were reproductions of the French Civil Code. Unlike France and Germany, which have occasionally tried to draft new codes but still have not replaced their original ones, Italy succeeded in introducing a reformed code in 1942, during the Fascist era. This code remains in force, with its only amendments due mainly to changes in political regimes. In comparison with the Civil Code of 1865, Italy's code of 1942 appears inspired by less individualist views—for example, in property law and in labour legislation the social aspects of the law are stressed.

The Japanese code

Japanese law. After the Meiji Restoration of 1868, which abolished feudal privileges and restored titular power to the emperor, the leaders of the new government sought to construct an economic, political, and legal structure capable of commanding respect internationally. The introduction of Western law was one element of a wholesale importation of things Western. In legal matters, the Japanese took for models the systems of continental Europe, especially the German. The drafters of the Japanese Civil Code of 1898 surveyed many legal systems, including the French, Swiss, and common-law, and they took something from each. Their final product was, however, best characterized as following the first draft of the German Civil Code. In subsequent developments, the Japanese legal system remained true to these sources. In 1947 revisions of code provisions dealing with family law and succession, which had reflected traditional Japanese attitudes, completed the transition of Japanese civil law to the continental European family of laws.

In several respects, however, Japanese law is closer to that of the United States than to European models, especially in matters of public and constitutional law. This is largely a result of the post-World War II occupation and of subsequent contacts with U.S. legal thinking and education. From the perspective of the rules and institutions of private law, the Japanese legal system remains closer to the civil law of Europe than to the common law of the United States. In many ways, nevertheless, the Japanese legal order differs markedly from all Western legal orders.

The fact that Japanese law is not the product of organic evolution suggests that the role of law in modern Japanese society differs markedly from its role in Western societies. In Japan, law plays a far less pervasive role in the resolution of disputes and in the creation and adjustment of rules regulating conduct. The size of the Japanese bar is small, and extralegal methods of resolving disputes continue in large measure.

For many purposes the Japanese family transcends husband, wife, and dependent children. The notion that a business is analogous to a family unit also persists and colours all labour relations, especially in small and middle-sized firms. In the relatively homogeneous Japanese society, social status carries heavy obligations, and community pressure is extremely powerful.

Thus, although Japan early adopted a version of the German Civil Code, it did not adopt the Germans' strong consciousness of legal rights. In many areas of Japanese life it is still difficult to predict whether a dispute will be settled under legal standards, and it is often impossible to know whether a person will enforce those rights that are legally available to him. The concepts pervasive in Western law—that the legal consequences of a particular conduct should be predictable before the conduct has occurred, that in any dispute the courts should give full effect to claims (a plaintiff receiving all or nothing), and that individual disputes should be resolved without considering the parties' social and economic background—have not penetrated deeply into Japanese law. In contrast, facilities for conciliation are used to promote adjustment in terms of nonlegal considerations: local police stations provide conciliation rooms; elders act as go-betweens. Compromise based on legally irrelevant considerations is encouraged, and disputes are often resolved by techniques that fall outside formal law.

Alternatives to legal action

Despite deliberate governmental efforts to limit the number of legal professionals, the continuing westernization of Japan may force Japanese law to play a role fully comparable to the role of law in the West; the sociological supports essential to the continued vitality of the traditional Japanese conception of law are clearly being undercut by Japan's shift to a highly urban, mechanized society.

(M.Rh./M.A.Gl.)

Common-law systems

THE HISTORICAL RISE OF COMMON LAW

English common law, or the body of customary law embodied in reports of decided cases, originated in the early Middle Ages in the decisions of local courts, which applied what Blackstone called "the custom of the realm from time immemorial" and practical reason to everyday disputes with the aid of but few formal enactments. Until the late 19th century, English common law continued to be developed primarily by judges rather than legislators.

The common law of England is in fact largely a Norman creation. The Anglo-Saxons, especially after the accession of Alfred the Great (871), developed a body of rules resembling those being used by the Teutonic peoples of northern Europe. Local customs governed most matters, while the church played a large part in government. The concept of crimes originated in this era, but they were treated as wrongs for which compensation was made to the victim.

The Norman Conquest of 1066 brought a practical end to the Saxon laws, except for some local customs. All of the land was allocated to Norman feudal vassals of the king. Serious wrongs were regarded mainly as public crimes rather than as personal matters, and the perpetrators were punished by death and forfeitures of property. Government was centralized, a bureaucracy built up, and written records maintained. Royal officials roamed the country, inquiring into the administration of justice. Church and state were separate and had their own law and court systems. This led to centuries of rivalry over jurisdiction, especially since appeals from church courts, before the Reformation, could be taken to Rome. Some elements of Saxon practice lingered, including trial by ordeal (by burning the hand, for example), which was retained until 1215. Outlawry, a Saxon procedure whereby a fugitive was placed outside the protection of the law, was retained for centuries to deal with people who fled from justice. Gradually, however, new procedures took the place of these crude devices.

Remnants of Saxon law

The Normans spoke French and had developed a customary law in Normandy. They had no professional lawyers or judges; instead, they used "clerks," or literate clergymen, to act as administrators. Some of the clergy were familiar with Roman law and the canon law of the Christian Church. Canon law was adopted by the English church, but the Normans resisted any attempt to introduce Roman law, which was applied only to certain claims under wills in the church courts, to marine disputes in the admiralty courts from the 14th century, and to military law. Norman custom was not simply transplanted to England, and a new body of rules, based on local conditions, grew up.

The feudal land law. At the critical formative period of common law, the English economy depended largely on agriculture. Wages and profits were important only in commercial centres such as London, Norwich, and Bristol. Political power was rural and based on landownership. Landowners voted at elections as Parliament evolved, and they acted as sheriffs and magistrates and sat on juries.

Land was held under a chain of feudal relations. Under the king came the aristocratic "tenants in chief," then strata of "mesne," or intermediate tenants, and finally the tenant "in demesne," who actually managed the property. Each piece of land was held under a particular condition of tenure; that is, in return for a certain service or payment. An armed knight, for example, might have to be provided to serve in the king's armies for a certain period each year. Nonmilitary service, such as making deliveries of grain, was often substituted for the uncertain obligations of knight service. Periodic services tended to be commuted into fixed annual payments, which ceased, under the impact of inflation, to have much value. The "incidents," or contingency rights, however, such as the right of the feudal lord to take the land if the tenant died without heirs and his rights regarding wardship and marriage of the tenant's infant heirs (that is, his rights to compensation for exercising wardship or granting permission to marry) were assessed at current land values and remained important.

Conditions of tenure

Succession to tenancies was regulated by a system of different "estates," or rights in land, which determined the duration of the tenant's interest. Land held in "fee simple," for example, meant that any heirs could inherit (that is, succeed to the tenancy), whereas land held in "fee tail" could pass only to direct descendants. Life estates (tenancies that lasted only for one person's lifetime) could also be created. Title to land was transferred by a formal ritual rather than by deed because the population was largely illiterate. Few elaborate rules regulating the terms by which land was held could be agreed upon in such circumstances, so statutes were passed to regulate matters of detail. The life tenant, for example, was forbidden in the 13th century to use the property in such a way as to damage it or to cause it to deteriorate unless the grant specifically allowed it, and the tenant "in tail" was forbidden to ignore the system of descent laid down for his property. The common-law judges devoted themselves to working out the proper rules to apply to all of these estates and tenures.

Primogeniture—*i.e.*, the right of succession of the eldest son—became characteristic of the common law. It was designed only for knight-service tenures but was inappropriately extended to all land. This contrasted with the widespread practice on the Continent, whereby all children inherited equal shares.

Development of a centralized judiciary. The unity and consistency of the common law were promoted by the early dominant position acquired by the royal courts. A single royal court, the King's Court (Curia Regis), was set up for most of the country at Westminster, near London. Whereas the earlier Saxon *witan*, or king's council, dealt only with great affairs of state, the new Norman court assumed wide judicial powers. Its judges (clergy and statesmen) "declared" the common law.

By straining the interpretation of a statute, royal judges greatly reduced the jurisdictions of local courts. With their increased powers, royal judges went out to provincial towns "on circuit" and took the law of Westminster everywhere with them, both in civil and in criminal cases. Local customs received lip service, but the royal courts controlled them and often rejected them as unreasonable or unproved: common law was presumed to apply everywhere until a local custom could be proved. This situation contrasted strikingly with that in France, where a monarch ruled a number of duchies and counties, each with its own customary law, or of the situation in lands such as Germany and Italy, which were divided into independent kingdoms and principalities with their own laws.

Dissemination of common law by itinerant judges

This early centralization also removed the need for England to import a single advanced foreign system of law, a need that led to the reception of Roman law in Europe after the decline of feudalism. The expression common law, devised to distinguish the general law from local or group customs and privileges, came to suggest to citizens a universal law, founded on reason and superior in type.

In the 13th century the common central court split into three courts—Exchequer, Common Pleas, and King's Bench. Although the same law was applied in each, they vied in offering better remedies to litigants in order to increase their fees.

The court machinery for civil cases was built around the writ system. Each writ was a written order in the king's name issued at the instance of the complainant and ordering the defendant to appear in the King's Court or ordering some inferior court to see justice done. It was based on a form of action (*i.e.,* on a particular type of complaint, such as trespass), and the right writ had to be selected to suit that form. Royal writs had to be used for all actions concerning title to land.

Bracton and the influence of Roman law. Under Henry III, who reigned from 1216 to 1272, an assize judge (*i.e.,* an itinerant judge of the periodical local assize courts), Henry de Bracton (originally Bratton), prepared an ambitious treatise known as "Bracton." It was modeled on the order of the 6th-century Roman legal classic, the Institutes of Justinian, and shows some knowledge of Roman law. Its English character derived from the space it devoted to actions and procedure, to the reliance on judicial decisions as declaring the law, and to the statements limiting absolute royal power. Bracton abstracted several thousand cases from court records (plea rolls) as the raw material for his book. The plea rolls formed an almost unbroken series from 1189 and included the writ, pleadings, verdict, and judgment of each civil action.

Early statute law. Edward I has been called the English Justinian because his enactments had such an important influence on the law of the Middle Ages. Edward's civil legislation, which amended the unwritten common law, remained for centuries as the basic statute law. It was supplemented by masses of specialized statutes that were passed to meet temporary problems.

Major statutory enactments of Edward I

Four of Edward's statutes deserve particular mention. The first Statute of Westminster (1275) made jury trial compulsory in criminal cases and introduced many changes in the land law. The Statute of Gloucester (1278) limited the jurisdiction of local courts and extended the scope of actions for damages. The second Statute of Westminster (1285), a very long enactment, confirmed the estate tail in land, which had often been linked with the maintenance of titles of honour; made land an asset for purposes of paying judgment debts (debts judged to exist by a court); liberalized appeals to high circuit courts; improved the law of administration of assets on death; and created a new form of action, action on the case, that gave broad approval to the creation of new remedies for new types of contract and tort cases. The Statute of 1290 (Quia Emptores) barred the granting of new feudal rights, except by the crown, and made all land held in fee simple freely transferable by denying interference by relatives or feudal lords.

In modern times the statutes issued prior to 1285 are sometimes treated as common law rather than statute law. This is because these laws tended to restate existing law or give it a more detailed expression. They explained what the law was, but they did not make an entirely new law; some authorities, in fact, doubted whether governments had the right to change ancient customs at all. In addition, judges did not always adhere closely to the words of the statute but tried to interpret it as part of the general law on the subject. Prior to the rise of the House of Commons in the 13th century, it also was difficult to distinguish acts of Parliament from the less binding decisions or resolutions of the royal council, the executive authority. Some statutes were passed but never were put into force, while others seem to have been quietly ignored.

The second Statute of Westminster, however, clearly made new law and allowed time for citizens to study its provisions before it came into force. Even so, this statute was freely interpreted by the courts, who read into it things that were not in the text.

Growth of Chancery and equity. Since legal rules cannot be formulated to deal adequately with every possible contingency, their mechanical application can sometimes result in injustice. In order to remedy such injustices, the law of equity (or, earlier, of "conscience") was developed. The principle of equity was as old as the strict common law, but it was hardly needed until the 14th century, since the law was still relatively fluid and informal. As the law became firmly established, however, its strict rules of proof began to cause hardship. Visible factors of proof, such as the open possession of land and the use of wax seals on documents, were stressed, and secret trusts and informal contracts were not recognized.

Power to grant relief in situations involving potential injustices lay with the king and was first exercised by the entire royal council. Within the council, the lord chancellor, a leading bishop, led the meetings and, by 1474, dealt personally with petitions for relief. Eventually the chancellor's jurisdiction developed into the Court of Chancery, whose function was to administer equity. Much of the work concerned procedural delays and irregularities in local courts, but gradually the power to modify the operation of the rules of common law was asserted.

Early grounds for equitable relief

The chancellor decided each case on its merits and had the right to grant or refuse relief without giving reasons. Common grounds for relief, however, came to be recognized. They included fraud, breach of confidence, attempts to obtain payment twice, and unjust retention of property.

Proceedings began with bills being presented by the plaintiff in the vernacular language, not Latin; the defendant was then summoned by a writ of subpoena to appear for personal questioning by the chancellor or one of his subordinates. Refusal to appear or to satisfy a decree was punished by imprisonment. Because the defendant could file an answer, a system of written pleadings developed.

Inns of Court and the Year Books. During Edward I's reign (1272–1307) the office of judge was transformed from a clerical position into a full-time career. Admission to the bar (*i.e.,* the right to practice as a barrister before a court) was made conditional on the legal knowledge of the applicant so that law began to emerge as a profession which required permanent institutions and some kind of organized education.

As the legal profession grew, the more experienced barristers were admitted to the dignity of serjeant-at-law and later banded together with the judges, who were appointed from their ranks, at Serjeants' Inns, in London. There, burning legal problems were informally discussed, and guidance was given to all concerning the decisions of actual or likely cases. The four Inns of Court (Gray's Inn, Lincoln's Inn, Inner Temple, and Middle Temple) evolved from the residential halls of junior barristers to become the bodies officially recognized as having the right to admit persons to the bar. Education consisted of attending court, participating in simulated legal disputes (moots), and attending lectures (readings) given by senior lawyers.

Bracton's work was adapted for purposes of study for a time, but it soon became outdated. Bar students therefore had to make notes in court of actual legal arguments in order to keep abreast of current law practices. These notes varied widely in quality, depending on the ability of the notetaker and the regularity of his attendance, and from about 1290 they seem to have been copied and circulated. In the 16th century they began to be printed and arranged by regnal year, coming to be referred to as the Year Books.

The Year Book reports were written in highly abbreviated law French. They did not always distinguish between the judges and barristers and often simply referred to them by name. The actual judgment also was often omitted. Previous decisions were not generally binding, but great attention was paid to them, and it appears that the judges and barristers referred to earlier Year Books in preparing their cases. Thus, case law became the typical form of English common law.

Effects of feudal conflict on the law

The dynastic Wars of the Roses in the latter part of the 15th century led to a practical breakdown of the legal order. Powerful hereditary aristocrats in the country, backed by private armies, and dominant commercial families in the towns were beyond the effective reach of the royal writ. When legal proceedings were possible, they were often manipulated or frustrated by the crown's "overmighty subjects," who intimidated and corrupted justices, sheriffs, juries, and witnesses.

Thus the years preceding the Tudor period were a time of insecurity and stagnation, a "Gothic age" in which lawyers tried to consolidate the law but made no new advances. Parliamentary authority also was weakened, and the royal council was called on more and more to rule the country and try to maintain order.

The rise of the prerogative courts. The accession of Henry VII in 1485 was followed by the creation of a number of courts that stood outside the common-law system that Henry II and his successors had instituted. These newer courts were described as prerogative courts because they were identified with the royal executive power, although some of them had a statutory origin. Thus, the Council of the North at York was set up by statute in 1537, and the Council of Wales and the Marches at Ludlow was confirmed by statute in 1543, though both had been preceded by older prerogative courts in those "frontier" regions. The Court of Requests (see below) was given regular status by an administrative action in 1493. The Court of Star Chamber, once thought to have been given its authority by a statute of 1487, is now believed to have evolved from the royal council, which began acting as a judicial committee in the early 16th century. All these courts rested on the comparative authority and efficiency of the council in times when regular courts were unable to operate properly.

The Court of Requests

In the Court of Requests, which had counterparts in France, the costs of procedure were lower than in common-law proceedings; it was designed to accommodate small civil claims by the poor. The judges of the court were styled masters of requests, and they had many other duties, which often caused delays. The court flourished in the 17th century until the Civil War (1642–51), when the procedure by which it operated was abolished. Its example of offering a simple, cheap procedure was imitated by several statutory courts that were set up in towns in later times, also known as courts of requests.

Whereas the common-law courts punished "hanging crimes," such as murder and robbery, the Star Chamber dealt with more sophisticated offenses, such as forgery, perjury, and conspiracy. Fines and sentences of imprisonment were the usual punishment. Common-law judges, lay peers, and bishops sat on this court, which also exercised civil jurisdiction. It lost its original popularity when the early Stuart kings used it to stifle political opposition, and its name eventually became synonymous with repression. It was abolished in 1641, and most of its jurisdiction was absorbed by the common-law courts in 1660.

The rather specialized High Court of Admiralty developed under royal prerogative in the 14th century; a statute of 1391 prohibited it from meddling in cases not arising at sea. In Tudor and early Stuart times, however, it exercised a wide commercial jurisdiction. After the Civil War it was confined exclusively to trying maritime disputes.

Further Roman-law influences. As described above, the common law had begun to break down in the 15th century. Abroad, law was in a state of flux. The customs of northern France were codified in 1453, and modified Roman law became a main source of imperial German law in 1495 and of Scots law in 1532. At the same time, the scope of canon and Roman law in England was increasing. Admiralty law, for example, drew on Greek, Roman, and Italian law and used documents drawn up in continental form, and the crimes of forgery and libel tried in Star Chamber were based on Roman models. Ecclesiastical courts applied canon-law rules based on Roman law, for example, to wills and marriages. The Councils of Wales and the North also used Roman law. All of these bodies competed with common-law courts for jurisdiction over the same cases and followed a written procedure modeled after that still being used on the Continent. Roman law and canon law, furthermore, were taught at Oxford and Cambridge, which gave doctorates to the practitioners in these courts.

One of the accusations reportedly made against Thomas Cardinal Wolsey, who fell from favour in 1529, was that he planned to introduce Roman law into England; Wolsey did appoint many clergy to the Council of the North and as justices of the peace. The 19th-century English legal historian F.W. Maitland discussed this legal crisis in a famous essay on English law and the Renaissance. Maitland ascribed the survival of the common law, in part, to the solid front presented by the Inns of Court, which trained lawyers practically and not theoretically. The English law tradition did not depend on abstract scholarly commentaries but on detailed judicial rulings about specific points of law arising in practice.

The influence of Roman-law ideas, however, was probably greater than generally admitted. The actions of trespass and disseisin (dispossession) had Roman analogies, and the estate tail was clearly influenced by a law made by Justinian. The equitable remedy of injunction had analogies in canon law, and the law of redemption of mortgages may have been related to the usury laws, which forbade making excessive profits from loans. The law of trusts and deceit resembled the breach of faith of the church courts. Continental mercantile law, which contained Roman-law elements, was absorbed into English law as it stood. Continental law also contributed to some of the rules of contract, such as the effect of mistake, and the Roman concept of fault played a part in the law of negligence. Many old European legal ideas, in fact, survived longer in England, where they escaped being eliminated in codifications, than in Europe.

Coke as a champion of the common law

An account of the development of common law in the Tudor-Stuart period would be incomplete without mention of Sir Edward Coke. Coke, who combined a distinguished career as a barrister and a judge, produced a wealth of legal writings. In 1606 he risked removal from the office of chief justice by challenging the exaggerated claims of the royalist party to prerogative powers outside of the common law. He disapproved of legislation by proclamation, of dispensation from the law in individual cases, and of the mushrooming jurisdictions of the prerogative courts. He helped draft the Petition of Right in 1628.

Coke's 11 volumes of *Reports* appeared between 1600 and 1615, and two posthumous volumes followed. Coke commented, rather than reported, but he was careful to supply a copy of the court record of each case. As the only formal series of collected law cases available at the time, his reports formed the main source for the citation of cases for many years. His four volumes of *Institutes of the Lawes of England,* published between 1628 and 1644, dealt with the law of real property (*Coke on Littleton*), the medieval statutes, the criminal law (pleas of the crown), and the jurisdiction of the courts.

Coke was no objective historian but an open advocate of the common law. Though he was old-fashioned and at times in error, his greatest works restated the common law in acceptable form and did much to save it.

Further growth of statute law. The Tudors made use of proclamations by the king to invoke emergency measures, to establish detailed regulations, especially on economic matters, and to grant royal charters to trading companies. Parliament passed laws of a political character, such as those enforcing the king's supremacy over the new established church. Statutes also regulated imports and exports, farming, and unfair competition. A law of 1562–63 regulated apprenticeships and provided for annual wage fixing by magistrates in accordance with the cost of living.

Among other statutory innovations were the Statute of Monopolies of 1623, which confirmed that monopolies were contrary to common law but which made exceptions for patentable inventions; a statute of 1601 that became the basis of the privileges enjoyed by charitable trusts; and the series of Poor Laws, which were enacted in the late 16th century to remedy the neglect of the poor caused by the dissolution of the monasteries.

In 1540 legal actions to recover land were subjected to time limits, and in 1623–24 the principle of limitation of actions by lapse of time was introduced into the law of contract and tort.

During the Commonwealth (1649–60) many reform projects were drafted; although they anticipated 19th-century reforms, none of them was carried out. These reforms included supplying counsel to prisoners, modernizing the land and law procedure, and permitting civil marriages.

The outstanding enactment of the later Stuart period was the Statute of Frauds of 1677. As a response to the growth of literacy and the prevalence of perjury and fraud, wills and contracts for sale of land or goods (of more than a certain amount) were required to be in writing. Though drafted by eminent judges, the statute was to require endless interpretation.

Further development of equity. Although one eminent contemporary observer, the legal historian John Selden, regarded the fate of a lawsuit in Chancery as varying with the chancellor's personality, the types of suits that would be granted relief had eventually become fairly clear. Precedent was being followed, and law reports of equity decisions and books on equity began to be published.

In 1615 the King declared that the Chancery was to retain its traditional superiority over the common-law courts but only in areas in which its authority was well recognized. If the applicability of equity was in doubt, the common law was to be followed.

Developments in the law of trusts

The main development in this period was in the law of trusts (see PROPERTY LAW). In medieval England, from the 14th century, most land was held "to uses"; *i.e.,* by nominees for the true owners. This situation may have been partly due to devices used to evade taxation, but it also enabled wills of land to be made. "Death duties" were payable if a man died while he was the legal proprietor; by transferring the land to another person, these could be avoided. Wills of land were not allowed before 1540, but the use of land could be transferred to another person while the owner was still alive, as long as the transferee observed the owner's wishes regarding the land while the owner lived. The beneficiary of such a trust usually stayed on the land as apparent owner, though the trustee held the legal title. A statute of Richard III, however, allowed the beneficiary to transfer the property, and in 1535–36 the Statute of Uses eliminated the middleman and revested the legal title in the beneficiary. The device of the use was exploited to create new and complicated legal interests in land. The old use was revived as the modern trust in Chancery, first for trusts involving money and leases and finally for trusts of land itself. The spur was the desire to separate the legal and beneficial titles, especially when the beneficiary was young or inexperienced. But the trust was adapted to many other ends, such as giving property to clubs and other unincorporated bodies and to churches.

THE MODERNIZATION OF COMMON LAW IN GREAT BRITAIN

Influence of Blackstone. Of extraordinary influence in the development of common law and in its dissemination to other parts of the world was the most famous of English jurists, Sir William Blackstone. Born in 1723, he entered the bar in 1746 and in 1758 became the first person to lecture on English law at an English university.

His most influential work, the *Commentaries on the Laws of England,* was published between 1765 and 1769 and consisted of four books: "Persons" dealt with family and public law; "Things" gave a brilliant outline of real-property law; "Private Wrongs" covered civil liability, courts, and procedure; and "Public Wrongs" was an excellent study of criminal law.

Blackstone was far from being a scientific jurist and was criticized for his superficiality and lack of historical sense. The shortcomings of the *Commentaries* in these respects, however, were offset by its style and intelligibility, and lawyers and laymen alike came to regard it as an authoritative exposition of the law. In the following century the fame of Blackstone was even greater in the United States than in his native land. After the Declaration of Independence the *Commentaries* became the chief source of knowledge of English law in the New World.

Reform in the 19th and 20th centuries. *Bentham.* Following the social turmoil of the French Revolution and the economic upheaval of the Industrial Revolution, there were many demands for reforms to modernize the law. The most significant figure in the reform movement was the English Utilitarian philosopher Jeremy Bentham, who was prepared to reform the whole law along radical lines. A brilliant student, Bentham disliked the picture of the law that was presented in Blackstone's lectures. In 1769 he entered the bar, but since he was living on an inheritance, he never found it necessary to enter practice. He worked to make law less technical and more accessible to the people, but he was slow to complete or publish his writings, and not until 1789 did his basic work, *An Introduction to the Principles of Morals and Legislation,* appear.

Bentham attacked legal fictions and other historical anomalies. He advocated two basic changes in the legal system: in order to achieve the greatest happiness for the greatest number, legislators, rather than courts, should make the law; and the aims of law should vary with time and place.

The fame of the *Principles* spread widely and rapidly. Bentham was made a French citizen in 1792, and his advice was respectfully received in most of the states of Europe and America. Although he wanted most of all to be allowed to draw up a legal code for his own or some foreign country, his practical influence was far more indirect and derived largely from the diffusion of Utilitarian ideas during the 19th century.

Increased protection of the rights of the accused

Changes in procedure and criminal law. In England the restrictive framework of the separate forms of action in civil cases was replaced in 1852 by a new system of uniform writs of summons, and liberal amendment of pleadings was permitted. Fixed dates were established for trials. In 1933 jury trial was ended in civil cases, except in libel and a few other actions. Evidence acts of 1938, 1968, and 1972 simplified civil proof. A major trend in criminal procedure since the early 19th century has been better protection of the rights of the accused. Since 1836 the accused has been entitled to counsel and since 1898 has been allowed to testify on his own behalf. In 1903 provision for the state to pay for defense was made and since expanded, and in 1907 the right of appeal against criminal convictions was created. In 1967 verdicts by a majority of the jury were made possible, and restrictions were imposed on press coverage of preliminary hearings.

The 19th century saw the enactment of a series of statutes that codified the part of criminal law dealing with individual crimes, apart from homicide. Basic ideas have changed little, other than the fact that some modern statutes have imposed responsibility without fault and that corporations can now be held responsible for the acts of their management.

The rules of legal insanity were laid down in the 19th century and supplemented in 1957 by the limited defense of "diminished responsibility." Capital punishment was gradually ended for most felonies and was finally eliminated for murder by the Homicide Acts of 1957–65. In 1968 a new Theft Act replaced the rather crude medieval idea of larceny by a broader concept that resembles the Roman delict (offense) of theft. Experimentation has led to new remedies, one of these being the suspended sentence, which only has to be served if a further crime is committed.

Reorganization of the judiciary. The lay jurisdiction of the church courts ended in 1857, when the divorce and probate courts were set up. These merged into the High Court of Justice in 1875 as a result of the Judicature Acts of 1873–75, which reformed the civil courts. The Judicature Acts were much more than a regrouping and renaming of courts; they attempted to fuse law and equity by making available legal and equitable remedies in all divisions of the High Court and by providing that the equitable rule should prevail when conflicts arose. Common law and equity nevertheless preserved their separate identities, partly because of the different subject matter with which they often dealt and partly because lawyers persisted in maintaining the distinction.

In the late 19th century the three central courts of common law were amalgamated as the Queen's Bench Division, which to this day continues to try suits for damages. Since 1875 cases have been tried by a single judge (before 1933 with a jury), not by a full bench of judges.

After it became a division of the High Court in 1875, the Chancery not only dealt with equity suits but also administered the voluminous legislation on property, bankruptcy, succession, copyrights, patents, and taxation. Contested probate cases were transferred to the Chancery by the Courts Act of 1971.

Before the Courts Act criminal cases were tried two or three times a year at assizes or four times a year at quarter sessions in the provinces. As of January 1972 a system of provincial crown courts replaced these. Civil assizes were replaced by allowing the High Court to sit at certain cities.

Small civil cases, tried at statutory county courts since 1846, are now regulated by an act introduced in 1984.

A remarkable feature of English criminal justice, as compared with most European systems, has been the continuing role of lay justices of the peace, who remain important despite the appointment of paid, legally trained magistrates in London and some of the larger cities, of barristers as recorders at borough quarter sessions, and of legally qualified chairmen at county quarter sessions. An important aspect of the magistrates' work has been their jurisdiction over young offenders, for whom special juvenile courts were first set up in 1908. The report of a royal commission on justices of the peace in 1948 strongly defended the position of lay justice against public criticism; its cautious recommendations as to the appointment of justices and as to the organization of their courts were largely put into effect by the Justices of the Peace Act (1949) and the Magistrates' Courts Act (1980). The Criminal Justice Administration Act (1962) extended the power of justices of the peace to try indictable offenses summarily. A series of statutes in 1972, 1973, 1977, 1981, and 1982 rendered the procedure more flexible, made detailed provision for penalties and their execution, and added a number of new offenses. In 1964 elementary judicial training for lay justices was introduced. These developments since 1948 show both the persistence in English law of ancient institutions and a preference for reforming rather than totally abolishing them.

Routes of appeal

A modern appellate court for civil cases in the High Court was set up in 1830 but was replaced in 1875 by a Court of Appeal consisting of special appellate judges. In 1907 a Court of Criminal Appeal was established, but it was merged into the Court of Appeal in 1966. A divisional court hears appeals from magistrates on points of law. A final appeal, subject to conditions, can be made to the House of Lords from all lower courts.

Reform in private law. Property law has been changed often. Wills are regulated mainly by a statute of 1837 (amended in 1982), and the freedom to disinherit has been curtailed by family provision acts of 1938, 1952, 1966, and 1975. Title to land is subject to a system of registration that has been gradually introduced under an act of 1925. Succession on intestacy (*i.e.,* in the absence of a valid will) for all kinds of property was unified in the same year. The law of leases has been modified by social legislation such as the numerous Rent (control) Acts, which protect residential tenants. The terms of trusts can be modified by the Chancery (since 1958), and a wider range of trustee investments has been allowed since 1961.

Grounds for divorce have been enlarged by a number of 20th-century statutes, culminating in the broad "breakdown of marriage" approach of the Divorce Reform Act of 1969, now the Matrimonial Causes Act of 1973 (as amended in 1984). Under this legislation a marriage may be terminated not only on traditional fault grounds but also when the parties have lived apart for at least two years and consent to divorce or when the parties have been separated for at least five years.

After several piecemeal laws addressed trade (labour) unions, a more comprehensive, but controversial, Industrial Relations Act was passed in 1971, requiring registration of unions and arbitration of disputes. This statute was repealed in 1974, but aspects of it were revived with considerable modification in 1980 and 1982.

In the field of tort, manufacturers' liability to consumers was established by case law in 1932 and later strengthened by legislation. Liability in libel has been cut down by many statutes. A law of 1945 introduced the Roman principle of apportioning damages when both parties are at fault.

Commercial law, with the Bills of Exchange Act (1882), Sale of Goods Act (1893 and 1979), the Unfair Contract Terms Act (1977), and consumer protection statutes in 1965 and 1974, has become primarily the domain of legislation. Arbitration, too, is regulated by statute.

THE DEVELOPMENT OF COMMON LAW IN THE UNITED STATES

The first English settlers on the Atlantic Seaboard of North America brought with them only elementary notions of law. Colonial charters conferred on them the traditional legal privileges of Englishmen, such as habeas corpus and the right to trial before a jury of one's peers, but there were few judges, lawyers, or lawbooks, and English court decisions were slow to reach them. Each colony passed its own statutes, and governors or legislative bodies acted as courts. Civil and criminal cases were tried in the same courts, and lay juries enjoyed wide powers. English laws passed after the date of settlement did not automatically apply in the colonies, and even presettlement legislation was liable to adaptation. English cases were not binding precedents. Several of the American colonies introduced substantial legal codes, such as those of Massachusetts in 1648 and of Pennsylvania in 1682.

The reception of English law

By the late 17th century, lawyers were practicing in the colonies, using English lawbooks and following English procedures and forms of action. In 1701 Rhode Island legislated to receive English law in full, subject to local legislation, and the same happened in the Carolinas in 1712 and 1715. Other colonies, in practice, also applied the common law with local variations.

Many legal battles in the period leading up to the War of Independence were fought on common-law principles, and half of the signatories of the Declaration of Independence were lawyers. The U.S. Constitution itself uses traditional English legal terms.

After 1776 anti-British feeling led some Americans to advocate a fresh legal system, but European laws were diverse, couched in foreign languages having unfamiliar turns of thought, and unavailable in textbook form. Blackstone's *Commentaries,* reprinted in America in 1771, was widely used, even though new English statutes and decisions were officially ignored.

In the 1830s two great judges, James Kent of New York and Joseph Story of Massachusetts, produced important commentaries on common law and equity, emphasizing the need for legal certainty and for security of title to property. These works followed the common-law tradition, which has never been fundamentally altered in the United States, except in Louisiana, where French civil law has survived.

American innovations. The American states saw law as a cementing force, and they used it to facilitate cooperation in the face of the hazards of nature and other difficulties arising in the development of the new continent. Special laws were developed to deal with timber, water, and mineral rights. Simple procedures were followed. Dogma was rejected in favour of personal experience and experiment, and old decisions soon became outdated. The pioneer spirit favoured freedom and initiative and distrusted central authority and a paternal government. Homespun local justice was preferred, as was the common sense of the local jury. For a time some of the colonies even tried to base their law on the Bible. But, even when English law reasserted itself, many of its institutions were rejected. On death intestate, for example, all of the children inherited land in America and not just the eldest son, as in England. Freehold title was the rule, not long leases under landlords. Church courts did not exist.

Growth of statute law and codes. After the War of Independence a drive to replace judge-made law by popular legislation was revived. In 1811 Jeremy Bentham proposed a national civil code to Pres. James Madison, but his proposal was premature. In the mid-19th century, the legal reformer David Dudley Field presided over the drafting of several codes and campaigned vigorously for the systematic, rational codification of U.S. law. Except for a code of civil procedure, which was widely copied, Field's codes found little acceptance in state legislatures. Field's civil code was adopted by five states, including California and New York, but the common-law tradition was so strong in these jurisdictions that the civil code became just another statute; it was read against the background of, and supplemented by, existing case law, rather than seen as a complete set of authoritative starting points for legal reasoning as were the continental civil codes. Louisiana, whose legal system is a hybrid of civil- and common-law elements, is the only American state that has a code in the civil-law sense. Despite the failure of the codification

Codes of David Dudley Field

movement, U.S. law became increasingly statutory, so that by the late 20th century legislation predominated over judge-made law.

U.S. statutes are not construed so narrowly as those in England, and there is less reluctance to change the older law. Statutes are also regularly revised; for example, New York state has had a Law Revision Commission since 1934.

Equity and probate. In 18th-century England the Court of Chancery administered equity and the church courts handled the probate of wills. In the American colonies the governor and his council acted as a court of equity. For a time after independence, equity was suspect as a remnant of royal prerogative, but it has come to be generally applied by the same court as the regular law. Although U.S. common law is more flexible than English law, and the need for equity is less, important remedies have nevertheless been developed within the system. Probate, with a few exceptions, is usually a matter for the regular courts.

Federal and state judicial systems. State courts try 90 percent of all civil and criminal cases. Local magistrates may sit on county or district courts. One appeal is always given, and two levels of appeals exist in many states. The highest court is usually called the supreme court of the state, but this varies. In New York state, for example, the Supreme Court is a trial court, and the highest court is the Court of Appeals.

The Constitution of 1789 set up a federal Supreme Court, and the 1789 Judiciary Act provided for federal district courts and circuit courts. The plan for inferior courts has undergone changes from time to time, notably in 1891, when circuit courts of appeal were established, and in 1911, when the old circuit courts were abolished.

Most federal law is statutory and enforced by federal courts. Laws concerning tax, labour, securities regulations, admiralty, interstate commerce, antitrust, patent, and copyright matters fall into this category. By a decision of 1803, the Supreme Court became the ultimate authority for determining the conformity of all legislation with the federal Constitution, which guarantees many fundamental rights.

To ensure the fair treatment of out-of-state citizens or of corporations incorporated elsewhere, federal courts can try cases involving a diversity of citizenship. In such cases they act as if they were state courts, however, being bound by state statutes since 1842 and by state interpretations of common law and equity since 1938. Federal procedure is followed, but state rules on vital matters, such as statutes of limitations, are enforced.

Federal courts also try claims by and against the United States, such as cases undertaken to protect federal assets. In the absence of statutory provisions for such cases, a "federal common law" is applied.

Personal and property rights. The guarantees of due process of law given in Magna Carta in 1215 and the English Bill of Rights of 1689 are reflected in the first ten amendments to the federal Constitution, which were passed in 1791 and are known as the Bill of Rights. Since the passage of the Fourteenth Amendment in 1868, the rights of life, liberty, and property have been protected from deprivation by both the states and the federal government without due process of law; this has tended to shield private property from government regulation and private contracts from government interference. The use of property, however, is increasingly restricted by zoning laws and health and safety measures, and the acquisition of property for public purposes may be justified under the doctrine of eminent domain (power of the government to take private property for public use without the owner's consent upon payment of compensation).

The 1929 Depression was followed by the rejection by the Supreme Court of many welfare measures. Since 1937, however, the power of the Congress to regulate the economy under its authority to oversee interstate commerce has generally been upheld by the Supreme Court. State legislation is, as a rule, also held to be constitutional in this area. Minimum-wage laws and the right to collective bargaining in industry are recognized as well.

Human rights in the Supreme Court

Since the 1950s the emphasis in constitutionality cases has shifted to human rights. The requirement of "equal protection of the laws" and the Civil Rights Act of 1866 led to the ruling in 1954 that public schools must be racially integrated and to later rulings against using public funds for segregated private schools. The Federal Civil Rights Act of 1964 applies not only to official laws and actions but also to the conduct of private citizens. Thus, no discrimination on the basis of race, sex, religion, or national origin is allowed in places of public entertainment or resort or in employment practices by larger firms.

Since 1962 the Supreme Court has insisted on a regular redrawing of electoral districts to give each vote roughly the same value (seat reapportionment). It has also interpreted the constitutional prohibition of the establishment of a state religion to render school prayers and religious instruction illegal. In 1971 freedom of the press was held to justify *The New York Times* in publishing confidential political material.

COMPARISONS OF ENGLISH, AMERICAN, AND COMMONWEALTH LAW

The legal systems rooted in the English common law have diverged from their parent system so greatly over time that in many areas the legal approaches of common-law countries differ as much among themselves as they do with the civil-law countries. Indeed, England and the United States have so many legal differences that they are sometimes described as "two countries separated by a common law." The most striking differences are found in the area of public law: England has no written constitution and no judicial review, whereas every court in the United States possesses the power to pass judgment on the conformity of legislation and on other official actions to constitutional norms. Throughout the 20th century, many areas of U.S. law have been "constitutionalized" by the increasing exercise of judicial power. Other factors that account for much of the distinctiveness of public law in the United States are its complex federal system and its presidential, as distinct from parliamentary, form of government. In the area of private law, however, family resemblances among the common-law systems are much greater. Yet even there, despite broad basic similarities, the common-law countries have developed distinctive variations over time.

Personal law. The law of personal status (nationality, capacity, domicile, and so on) has been transformed by the advancement of the principle of equality of the sexes. In the area of divorce law, the intense legislative activity of the 1960s and 1970s left most common-law countries with systems of "mixed grounds" for divorce: one can obtain a divorce either for the fault of the other spouse or upon some no-fault ground such as separation or breakdown of the marriage. A minority of U.S. states have eliminated fault grounds entirely. The major differences among common-law systems appear in the legal treatment of the economic consequences of divorce: most common-law countries follow the English model that permits judges to use their own discretion in reallocating the property and income of the spouses in the way that seems fair; a minority of U.S. states adhere to the principle of equal rather than discretionary division of assets.

Property and succession. The basic principles of property and succession are much the same everywhere, but the newer countries have special laws on forests, mines, and water rights. In Australia, for example, the crown reserves all mineral rights to itself. The transfer of land in England is governed by a system of title registration. In Canada and the United States the separate deeds are recorded, and title insurance is widely used to protect the purchaser.

Succession on intestacy is broadly similar throughout common-law countries but varies everywhere in detail. The widow, for example, may get more in one country and the children more in another. All children of both sexes generally take equal shares. In regard to testate succession, nearly all U.S. states protect the surviving spouse against disinheritance by securing to him or her a fixed indefeasible share of the decedent's estate. In England, and most of the former Commonwealth countries, however, not only the spouse but also children and certain other dependents of the deceased are permitted to petition the court for discretionary financial provision out of an estate if, in the judgment of the court, the testator did not make reasonable provision for them.

In most U.S. states and some Canadian provinces there are homestead laws, which protect the family house or a certain minimum sum of money from the claims of creditors.

Extensions of tortious liability

Tort law. Tort law (*i.e.,* the law relating to private civil wrongs) is largely common law in England, Canada, and the United States. Several major reforms have been introduced along the same lines in different countries. Allowing claims by dependents of persons tortiously killed and removing the immunity of the crown or government or charitable institutions from tort claims provide examples. The liability of manufacturers to the ultimate consumer was first laid down by U.S. and then by English judges.

In the field of libel, U.S. practice is less strict than the English, and in the United States a public figure cannot sue for honest but unfair and untrue criticisms of his activities, whereas in England published facts must be true and comment fair. In some Australian states truth is not necessarily a defense to an action.

A notable U.S. tort is interference with privacy, examples being a stranger using one's photograph for advertising without permission, using "bugging" (*i.e.,* electronic eavesdropping devices) in one's home or searching it, or taking photographs of persons in embarrassing situations.

Contracts. Contract law is basically similar in the common-law countries. The most interesting difference relates to the question of enforcement of contracts by third parties who are not actually parties to the contract but who are persons for whose benefit the contract was made. English law excludes such rights, except in an occasional statute. The Indian Contract Code of 1872 generally allows it, as does U.S. state law.

English law still requires the use of a seal on a gratuitous contract (such as one agreeing to make a gift) but has largely repealed the laws requiring written evidence of ordinary contracts. Written evidence is often called for in the United States.

The various areas of special contracts, such as those applying to employment, sale of land, and agency, are broadly similar everywhere but are regulated by local legislation and by a wealth of labour legislation.

Criminal law and procedure. As regards criminal law and procedure, the substance of the law is much the same throughout the common-law countries. More important differences appear in the rules of criminal procedure. This rests in England on modern legislation, whereas the old procedure bore heavily on the accused. Accused persons may now testify at the trial or not, as they wish; they are entitled to legal counsel; and they are assisted out of public funds when they are accused of serious crimes and are unable to afford to pay the costs themselves.

Canada has a Dominion Criminal Code, which covers major crimes. It also has a Canadian Bill of Rights and provincial laws such as the Ontario Human Rights Code. India has an overriding Bill of Rights.

Developments in the United States are the most interesting. Criminal procedure has become a constitutional matter, with a kind of federal common law of criminal procedure overriding state law in many instances. Thus, "due process of law" under the Fourteenth Amendment to the federal Constitution and the Federal Rules of Criminal Procedure confer wide protection on accused persons—too wide, some think, for public safety.

Different approaches to the admissibility of evidence

English courts are reluctant to admit tape recordings unless supported by direct evidence of persons present, and this is generally the position taken in the United States, although, with the permission of a court, emergency wiretapping is permitted. English and U.S. law exclude confessions unless they are made freely and spontaneously. If evidence is found by unlawful means, such as by searching a house without a warrant, English law permits such evidence to be used, but U.S. law does not.

The main difference between English and U.S. safeguards is that English protections rest on statute or case law and may be changed by ordinary statute, whereas U.S. safeguards are constitutional and cannot be relaxed unless the Supreme Court later reverses its interpretation or the Constitution is amended.

The future of the common law. In the past the law performed the function of a referee in a free economy and was called in to apply generally accepted ideas of right and wrong to individual disputes. Today, law often forms an instrument of governmental policy or results from social pressures on the government. Law, therefore, is increasingly administrative.

Another tendency, and one that is likely to be reinforced, is an increasing reliance on statute law and codification as instruments of legal development. At one time the English Law Commission considered drafting a contract code, and the law of tort has been the subject of several statutes. When Britain entered the European Economic Community it was thought that there might be pressures to make English law more accessible by codifying it along the lines of the continental model. Harmonization of the laws of the member states, however, has not thus far required this. In the United States the legal sovereignty of the states impedes such a radical change, but uniform state laws are becoming more common.

In view of the general tendency in modern society of shielding the individual as fully as possible from the consequences of chance accidents, the judge-made law of tort may in time be replaced, as it has been in New Zealand, by a comprehensive system of official or private insurance, similar to the present compulsory third-party risk insurance available for motor vehicles. Public law is also gaining on private law in other fields—in real-property development, for example, public zoning or town-planning rules are already more important than the traditional restrictions imposed by individual neighbouring landowners. In family law, public-welfare laws on child care and adoption, pensions, and social security are often more important than the older private law based on the rights of spouses and children. (A.R.Ki./M.A.Gl.)

Comparison of civil law and common law

Between the 11th and 15th centuries the law of England was strongly influenced by Roman-law learning, and, in the 16th century, experts trained in Roman law were welcomed as administrators as much by the kings of England as by continental rulers. In contrast to the countries of the Continent, however, where justice was administered locally, the English judicial system had, as a result of the Norman Conquest, been centralized. There had grown up at the king's courts of Westminster a profession of practitioners expert in the law and procedure of the centralized court system, strongly organized and unwilling to yield its position, power, and income to a new group of specialists of Romanist learning. In its resistance to royal innovation, the organized bar allied itself with the parliamentary party in the great constitutional struggle of the 17th century. Thus, a reception of Roman law, such as had developed on the Continent, was prevented in England. At the same time a strong connection was established between the principles of constitutionalism and individual freedom on the one side and the common law on the other, which over time fostered the image of the common law as the legal system of freedom, in contrast to the civil law, in which the state is exalted over the individual. This image gained additional support from the fact that free political institutions were developed earlier and have been maintained more firmly in countries of the common law than in countries of the civil law.

Legal procedure in free societies

Political institutions are one thing, however, and techniques of dealing with civil litigation and criminal prosecution are another. Intimate connections exist, of course, between the two; a society is not free if civil cases are not handled impartially and if persons accused of crimes are not safeguarded against injustice. In both of these respects, however, neither of the two great legal systems lags behind the other. The ways of argumentation and procedure differ, but each of the two systems has developed its own guarantees and safeguards, and neither can be shown to be superior to the other. The view frequently found in

England and the United States, that in civil-law criminal procedure the accused is presumed guilty until he has proved his innocence, is as unfounded as the view widely held on the Continent that trial by jury is tantamount to a lawless appeal to passion and emotion.

If one compares countries having firmly established institutions of constitutional government, such as the United Kingdom and the United States, to civil-law countries, such as Belgium, The Netherlands, Switzerland, the Federal Republic of Germany, or France, it appears that the protection of the individual against illegal actions by executive agencies is generally about the same. In some respects individual protection is even more elaborate in civil-law countries than in the United States and the United Kingdom. In general, it also may be said that it is less expensive for citizens on the Continent to seek legal protection of their private rights than it is in the common-law countries.

It is difficult to define what constitutes the real difference between common law and civil law. It would be erroneous simply to identify civil law with codified or even statutory law and common law with judge-made or case law. For one thing, the contrasts between the two systems existed long before the civil-law countries began to enact their codes. In addition, large parts of Anglo-American law are also contained in statutes or even codes, while in France, West Germany, and other civil-law countries parts of the law have never been reduced to statute at all but have been developed by the courts. Also, many of the statutes and code provisions have come to be overlaid by so many judicial opinions and interpretations that, in effect, they are dominated by judge-made law.

Role of judicial precedent

No essential difference can be found, either, in the role of judicial precedent. In theory, common-law courts are bound by precedent in the sense that once a legal question has been decided a certain way by a court, it must be decided in the same way by courts of inferior rank in the same jurisdiction until a higher court or the legislature sees fit to change the rule. Though higher courts are not "bound" by their previous decisions, they habitually follow them in the absence of a strong justification for overruling. In civil-law countries, on the other hand, courts are, in official theory, free to consider anew any legal question irrespective of how often it may have been determined before by other courts. In practice, however, common-law courts, especially those in the United States, have developed techniques for distinguishing new cases from older ones so that observable adherence to precedent is less a matter of strict obligation and more an acknowledgement of the importance of maintaining reasonable predictability in the law and of supporting the principle that like cases ought to be decided alike. Civil-law courts, for their part, have tended to follow precedent, not only for the sake of continuity and evenhandedness, but also in accord with the inclination of courts everywhere to save time and effort and to avoid reversal by a higher court.

The main difference between the systems consists of the ways in which the norms of the law are articulated and in which new rules are derived from older ones in novel cases. Though law cannot remain static, adaptation to new circumstances should be orderly and gradual so as not to unduly undermine predictability and stability in human affairs. In the common law, the role of adapting the law to changing conditions has traditionally belonged to judges. Because the administration of justice has been centralized, English judges have been well situated to assume this responsibility. In civil-law countries, where the multiplicity of courts has prevented this task from being performed by the judges, it has been professors who have taken the leading role.

Role of the professors

This difference in the identity of the influential lawmakers has had far-reaching consequences in the development of the law. Since courts must proceed from case to case, and cases arise in isolation and without prearrangement, a judge's opportunities for systematic theorizing are limited. Professors, by contrast, often deal with hypothetical cases as well as actual ones. They can develop comprehensive ideas and principles, and they are impelled for pedagogical reasons toward systematization and conceptualization. The civil law, as a professorial product, has thus tended to become more theoretical and consistent in its propositions and terminology than the judge-made common law, which has tended, for its part, to be closer to life and perhaps more detailed.

These traditional differences may diminish, however, for in the civil-law countries judicial power has increased with the national centralization of the administration of justice and with the assumption of a more active role by the judiciary, while in most of the common-law parts of the world the centralized English courts long ago lost their supremacy to a multiplicity of supreme courts in the United States and in the Commonwealth. The role of maintaining the internal coherence of the law is thus increasingly shared by the courts with that group of professionals—the professors—who traditionally have performed this function in the civil-law world. Gradual assimilation of the legal methods of the two great systems of law may thus well be expected.

Role of the adversary system

What is likely to continue, however, is the marked difference between the two great families of legal systems that exists in the field of procedure and, to some extent, in the personnel by whom justice is administered. All civil-law countries have adopted the adversary type of procedure that for centuries was peculiar to the common law, and they have abandoned the canonical procedure in which the evidence was presented to the judge in the form of a written record made up by a public officer, mostly in the absence of the parties. In modern adversary procedure, lawyers address their arguments directly to the court in both the civil-law and the common-law systems. Certain differences, however, are striking. In common-law systems the parties and their lawyers gather and present factual evidence in each case; in civil-law systems greater responsibility for investigation of facts is placed upon the judge, and it is generally the judge who plays the leading role in examining witnesses and who summons experts when needed. In general, the civil-law judge plays a much more active role in directing the course of a lawsuit than does his common-law counterpart.

Many differences between civil-law and common-law procedures and rules of evidence seem attributable to the absence of a jury in civil cases in the continental systems. During the 19th century, several civil-law countries experimented with the use of a jury for criminal cases. During the 20th century, however, the criminal jury has been abandoned in favour of a system having a mixed bench, on which professional, legally trained judges sit with a jury of laymen or lay judges to decide not only questions of fact (as in the common law) but also those of law.

(M.Rh./M.A.Gl.)

Variant and hybrid legal systems

Some Western legal systems cannot clearly be classified as belonging to the civil-law, common-law, or Socialist law traditions. Some developed in relative isolation from other systems, such as those in the Nordic countries; more often, variant legal systems arose from a confluence of influences, such as those that occurred when one colonial power succeeded another. Notable among these variants and hybrids are the Scandinavian, Roman-Dutch, and Scottish systems. Scandinavian law, though Germanic in origin and influenced by a revival of Roman law, is generally classified as sui generis and is set apart from the civil law by several distinctive features. Roman-Dutch law, an amalgam of Roman *jus commune* and the law of early modern Holland, survives in several former Dutch colonies in an altered form and in combination with several other legal influences. In Scotland, Roman law and common law have combined to form a hybrid system.

(M.A.Gl.)

SCANDINAVIAN LAW

Scandinavian law in medieval times constituted a separate and independent branch of early Germanic law and in modern times, in the form of codifications, became the basis of the legal systems of Norway, Denmark, Sweden, Iceland, and Finland.

Historical development of Scandinavian law. Before the Scandinavian states emerged as unified kingdoms in the 9th century, the several districts and provinces were virtually independent administratively and legally. Although social organization in the main was the same, and legal developments followed similar lines, there came into existence a number of separate legal systems, or "laws." Originally there were no written laws; the legal system consisted of customary law that was conserved, developed, and vindicated by the people themselves at the so-called *things,* or popular meetings of all free men. Between the 11th and 13th centuries the provincial customary laws were recorded in writing (invariably in the vernacular). These writings were most often private compilations but were occasionally instructions from the king. The best known laws of this period are the Gulathing's law (written in the 11th century, Norwegian); the law of Jutland (1241, Danish); and the laws of Uppland (1296) and Götaland (early 13th century), both Swedish. Other Scandinavian communities and states followed suit.

The early laws or codes did not have the character of civil codes as they are understood today. In addition to the subjects of private law (matrimony, inheritance, property, and contract), they contained constitutional and administrative law, criminal law, and laws of procedure. Ecclesiastical law was usually excluded and treated separately. In the main, the codes represented collections of customary law; influences from abroad were negligible except for some traces of canon law. Whereas the provincial laws, in common with other early Germanic laws, had tolerated and regulated blood feuds (setting up detailed tariffs for manslaughter and offenses against the body), the codes are, in several respects, more progressive. Thus, King Magnus' Swedish code (1350) abolished private vengeance, declaring that the king's officials should initiate criminal proceedings and provide for the punishment of wrongdoers. Furthermore, presumably under the influence of Christianity, legal provisions were introduced to assist paupers and the helpless. Rules concerning landed property (*e.g.,* the right of redemption belonging to the family) were markedly original.

In 1380 Norway and Denmark were united under a common king (Olaf IV), but the two countries retained their separate laws. During the next 300 years, before the acquisition of absolute royal power by Frederick III (1660), supplementary laws were issued by the king in conjunction with an assembly of nobles. Finally, during the reign of Christian V, a comprehensive work of codification was accomplished, and the earlier and often obsolete law was replaced by Christian V's Danish Law (1683) and Norwegian Law (1687). The new codes were mainly based on the existing national laws of the two countries, and the influences of German, Roman, and canon laws were comparatively slight. Like the early codes, the newer codes consisted of public as well as private law and purported to treat exhaustively all more or less permanent legal rules and institutions. They were excellent codes for their times, drafted in a plain and popular style and inspired by respect for individual rights and the idea of equality before the law. The provisions of criminal law were relatively humane when compared with legislation in other European countries.

Codification under Christian V

In Sweden a revised edition of the original code, issued by King Christopher (1442), was expressly confirmed by Charles IX (1608). The need for more modern legislation, however, made itself increasingly felt, and following the Danish-Norwegian example a royal commission was entrusted with the task of drafting a new code. The result, commonly called "the Law of 1734," was promulgated by Frederick I.

Finland, annexed by Sweden in the 13th century and made subject to Swedish law, came under the Swedish code of 1734, which was translated into Finnish as "Law of the Realm of Finland."

Modern Scandinavian law. The old codes have been all but completely displaced by modern parliamentary statutes. In Sweden the law of 1734 has been conserved as a formal framework. Elsewhere, plans for new and all-embracing codes are no longer entertained, but an extensive codification of important parts of the public and private law has taken place.

An interesting feature of Scandinavian law is the organized legislative cooperation that was begun in 1872 and has steadily increased in importance. In this way the Nordic states, including Iceland and Finland, have to a considerable degree obtained uniform legislation, especially regarding contracts and commerce, as well as in such fields of law as those concerned with family, the person, nationality, and extradition.

While conserving their national character, the Scandinavian legal systems have adopted certain conceptions of civil law (mainly German and French), chiefly through the influence of the law schools; commercial law and the laws of shipping and of companies, for example, conform more or less to common European patterns. Modern social welfare legislation, which has reached a high standard, also has strong international connections. Scandinavian law is pliable and close to life, less dogmatic than other European legal systems, and relatively free of formal rules and exigencies. Great attention is paid to rules and principles that have evolved in practice, especially in the courts. Much of the law is judge-made; and because the principle of stare decisis (*i.e.,* being bound by precedent) does not obtain, the courts have been free to meet the demands of changing social conditions. The extensive participation of laymen in both civil and criminal proceedings may have contributed in some measure to the pragmatic and flexible character of modern Scandinavian law. (F.Hi.)

ROMAN-DUTCH LAW

Roman-Dutch law is the system of law produced by the fusion of early modern Dutch law, chiefly of Germanic origin, and Roman, or civil, law. It existed in the Netherlands province of Holland from the 15th to the early 19th century and was carried by Dutch colonists to the Cape of Good Hope, where it became the foundation of modern South African law. It also influenced the legal systems of other countries that had once been Dutch colonies, such as Sri Lanka (formerly Ceylon) and Guyana.

Today Roman-Dutch law is in force throughout the Republic of South Africa and South West Africa/Namibia, and in Lesotho, Swaziland, Botswana, and Zimbabwe. In Sri Lanka it is present to a lesser degree, and in Guyana was from 1917 largely superseded by the common law of England. Reservation is made in favour of indigenous law and custom, so far as these are recognized; moreover the general law of these countries has in many respects departed from its original type.

Development of Roman-Dutch law in the Netherlands. In the 15th and 16th centuries the Roman law was "received" in the province of Holland (as it was sooner or later in the Netherlands generally), although general and local customs held their ground. These were based ultimately on Germanic tribal law—Frankish, Frisian, Saxon—supplemented by privileges and by-laws (*keuren*) and were themselves affected by an earlier infiltration of Roman law. The resulting mixed system, for which Simon van Leeuwen in 1652 invented the term "Roman-Dutch law," remained in force in the Netherlands until it was superseded in 1809 by the Code Napoléon, which in its turn in 1838 gave place to the Dutch civil code. The old law was also abrogated in the Dutch colonies. The Dutch civil code of 1838 has since been extensively revised.

There is, however, a third element in the Roman-Dutch system, namely the legislative acts of the Burgundian and Spanish periods, the most important of which were passed during the 16th century. Although a large quantity of legislation was later passed in the 17th and 18th centuries, it had little effect on the general character of the legal system. Roman-Dutch law can also be studied in collections of decided cases and of opinions (commonly termed *consultatien* or *advijsen*) and in the rich juristic literature of the system. The first attempt to reduce the Roman-Dutch civil law to a system was made by Hugo Grotius in his *Introduction to the Jurisprudence of Holland,* written while he was in prison in 1619–20 and published in 1631; this short treatise, a masterpiece of condensed exposition, remains a legal classic. Grotius' commentaries

The commentaries of Grotius

were followed by those of Johannes Voet and Simon van Groenewegen van der Made. Toward the end of the 18th century Dionysius Godefridus van der Keessel, professor at Leiden, lectured on the *jus hodiernum* ("law of today"), of which he published a summary in *Select Theses on the Laws of Holland and Zeeland* . . . (1800). The lectures, commonly known as the *Dictata,* still circulate as manuscript copies and have been cited in judgments by South African courts.

Survival and growth abroad of Roman-Dutch law. The law of the province of Holland was followed in the colonial empire, supplemented by local ordinances of the governors in council and, in the East Indies, by laws of the governors-general established at Batavia in Java (now Jakarta, Indon.). The ultimate legislative authority in the colonies was vested in the states general.

After the colonies passed to the British crown the old law underwent profound modifications, owing partly to changed social and economic conditions and partly to the incursion of rules and institutions derived from English common law.

The influence of English law (which was operative even during the period of the republics of the Transvaal and Orange Free State) has been most marked in criminal law and procedure, civil procedure, evidence, constitutional law, and, particularly, the commercial field of companies, bills of exchange, maritime law, and insurance. The law of tort or delict has also been considerably affected by English doctrines. On the other hand, the laws relating to property, persons, succession, and, to a lesser extent, contract still preserve their predominantly Roman-Dutch character. It is, for example, settled in both South Africa and Sri Lanka that "consideration" is not necessary for the validity of a contract.

The South Africa Act (1909) provided for the continuance of all laws in force in the several colonies at the establishment of the union until repealed by the Union Parliament or by the provincial councils within the sphere assigned to them. But thereafter, the Union Parliament and the appellate division of the Supreme Court of South Africa were active in consolidating, amending, and explaining the law and in making it more uniform. Many rules of the old law were pronounced obsolete by reason of disuse.

South African law

Modern South African law is a mixture of Roman-Dutch and English law. Constitutional law and administrative law have developed along English lines. The law of procedure and evidence is almost wholly English, as is most law relating to business associations and such areas as patents, trademarks, copyright, insurance, and maritime operations. On the other hand, criminal law is a combination of elements from Roman-Dutch and English common-law sources. In the law of succession, the rules governing the making of wills are English, whereas the substantive law of testamentary and intestate succession is largely Roman-Dutch. The law of persons and the law of property are almost purely Roman-Dutch, and the principles of the law of contract and of the law of delict are Roman-Dutch, only mildly influenced by common law.

(R.W.L./D.V.Cn.)

SCOTS LAW

At the union of the parliaments of England and Scotland in 1707, the legal systems of the two countries were very dissimilar. Scotland, mainly in the preceding century, had adopted as a guide much of the Roman law that had been developed by the jurists of Holland and France. But it is a fallacy to suppose that the law of Scotland is founded on the law of Rome: the Scots only turned to Roman, or civil, law when there was a gap in their own common or customary law. There is, however, a considerable infusion of civil law, not least in legal nomenclature and in the emphasis on principle rather than precedent. Perhaps the most important distinction is that Scotland, unlike England, did not separate the administration of equity and law. The Scottish conception of equity differs from the English system, which is parallel to the common law. The Scottish conception instead consists of a few fairly simple rules aimed at supplementing the law in order to prevent hardship. It also relegates certain remedies to the class of equitable remedies, of which the court has a large discretion to grant or withhold. The word equity in the law of Scotland has always retained its original meaning. The Scottish outlook upon this whole topic places Scots law clearly alongside the continental civil law and not the English system.

Scots notion of equity

Historical development of Scots law. The period following the union has been characterized by the merging of Scots and English law. One main cause of the merger is that much of the existing law of Scotland depends on statutes applicable to both countries. The House of Lords, consisting in its legal aspect until 1876 exclusively of English lawyers acting as the supreme court of appeal from Scotland, had a tendency to apply English law in Scottish appeals, and, in some cases, it ignored the distinction between its legislative and judicial functions. Another reason for the merging of systems is the influence of Scottish legal text writers, some of whom have tended to treat English law as though it were the law of their own country. The citation of English authorities in court has also had considerable effect. Not surprisingly the most complete merger of the systems has occurred in the field of mercantile law. In other fields the systems are still widely separated.

Courts of law. The system of Scottish courts is completely different from that of the English and again is closer to the continental pattern. The supreme Scottish court (the House of Lords not being a native court) is the Court of Session, instituted by King James V in 1532, probably upon a French model. The court has two main functions. It has original jurisdiction in a very wide range of cases, which is exclusive in a few matters; in its appellate capacity it hears appeals (by reclaiming petition) from the nine Court of Session courts of first instance (called compendiously the Outer House), each presided over by a lord ordinary, and also from the sheriff courts. The appellate court (Inner House) sits in two divisions, the first and second, presided over, respectively, by the lord president of the Court of Session and the lord justice clerk. All the judges have the courtesy title of "lord" but are not on that account peers.

While the judges of the Court of Session are traditionally judges of both fact and law, in the early 19th century the civil jury was introduced, less because it was wanted in Scotland than because the House of Lords was weary of the great number of appeals it had to hear. Because the decision of a jury cannot in the ordinary sense be appealed, the House of Lords determined that caseloads would be drastically reduced by the change. From the Inner House appeal lies in many cases to the House of Lords by right and not, as in England, by leave. The right of audience in the Court of Session is possessed exclusively by members of the Faculty of Advocates (the Scottish Bar).

The lower civil courts are the justice of the peace courts and the sheriff courts, which are ancient courts distributed by counties, having administrative as well as judicial functions. In civil matters the courts consist of an appellate judge only, who hears appeals from the sheriff of his jurisdiction. The position of sheriff is of great importance, and, except in a few matters, his jurisdiction almost exactly coincides with that of the Court of Session. As a local and comparatively inexpensive court the sheriff court is more popular than the Court of Session. The sheriff court, which has also a wide criminal jurisdiction, cannot be compared with the English County Court, with its very limited civil jurisdiction and complete lack of criminal jurisdiction. The justice of the peace court has a limited jurisdiction in small debt actions. The dean of Guild Court has a quaestorial jurisdiction in questions of building in the towns.

The Court of Session has absorbed the functions of certain ancient courts—the Court of Exchequer, the Admiralty Court, the Teind (or Tithe) Court, and the Commissary Court—which dealt with questions of marriage law and executry, while the judges have by statute been given separate duties in a Lands Valuation Appeal Court, a Registration Appeal Court, and an Election Petition Court.

The Scottish Land Court, established in 1911, has jurisdiction in a wide range of matters relating to agriculture.

Disputes between landlords and tenants of agricultural holdings may be brought before it by judicial process or, by agreement of the parties, in lieu of arbitration. It also deals with questions referred to it by the secretary of state for Scotland. (A.D.G./J.I.S.)

Socialist law systems

Socialist law derives from the system of public order devised by early Soviet leaders after the Russian Revolution in 1917. The Soviet model has subsequently been emulated in those parts of the world where Communist parties have become dominant, ranging from eastern Europe to Central and Southeast Asia and from the Caribbean to some parts of Africa. Socialist law has taken somewhat different forms in these countries because of differences in their prerevolutionary legal systems, which in the newer Socialist states were typically an amalgam of religious, customary, and received or imposed civil law. The immediate legal background of Socialist law in the Soviet Union and the eastern European Socialist countries was the Romano-Germanic system. For this reason and because Soviet law itself was much influenced by the civil-law tradition, some legal scholars classify Socialist law as a subdivision of civil law. They point out that while the rules of substantive law in Socialist countries have been influenced in varying degrees by the principles of Marxism and Leninism, the rules of civil and criminal procedure, the conceptual apparatus of the law, and the legal methodology are still essentially civilian. Guyana and Tanzania are notable exceptions because they are the only Socialist countries to have had a common-law background.

Other scholars, including Socialist jurists, claim an independent status for Socialist law. In their view, Socialist systems are distinguished from other legal systems by the influence of state ownership of the principal means of production, the special role that the Communist Party plays in the legal system, the close relationship between the legal system and national economic planning, the denial of any distinction between public and private law, and, perhaps above all, by a conception of the role of law as an instrument for restructuring society, shaping the new order, and dismantling the old. The claim that Socialist law is a separate legal family was recognized in practice after World War II when judges representing the Soviet legal system were elected to the International Court of Justice in accordance with requirements of the International Court's statute (article 9) that the court must include judges who are representative of the main forms of civilization and of the principal legal systems.

THE HISTORICAL DEVELOPMENT OF SOVIET LAW

Since Karl Marx and Friedrich Engels never prescribed a particular system of law for a state organized to achieve the aims set forth in their *Communist Manifesto* of 1848, it was left for V.I. Lenin and his colleagues in the Russian Communist Party after the Bolshevik Revolution of 1917 to improvise a legal system. General guidelines provided by Marx and Engels stated that law should be regarded as an instrument of the state, not as a limitation upon those who make policy, and that it should enunciate rules of public order to facilitate the transition to Socialism and ultimately to Communism. It was to have two major tasks: (1) elimination of the political power of the bourgeoisie (the property-owning middle class) by depriving them of their ownership of productive resources; and (2) education of citizens in the disciplined pattern of life claimed to be requisite for the achievement of the social order they desired. Completion of these two tasks was expected to assure both the abundant production necessary to realize the aim of distribution according to need and also the self-discipline of citizens necessary to eliminate coercion as the method of preserving order. The police, the army, and courts would become unnecessary, and law would, in Marxist terminology, "wither away." Citizens would perform social obligations, expressed in morals and unsanctioned administrative regulations, because they believed them to be desirable, not because they feared punishment for violating them.

The new principles were embodied in the first constitution of the Russian Soviet Federated Socialist Republic (R.S.F.S.R.), promulgated on July 10, 1918 (article 9), as follows:

> The basic task placed during the present transitional moment on the constitution of the R.S.F.S.R. is the establishment of the dictatorship of the city and village proletariat and of the poorest peasantry in the form of a powerful all-Russian Soviet authority with the objective of complete suppression of the *bourgeoisie,* the exploitation of man by man and the installation of socialism, under which there will be neither division into classes nor a State authority.

Early implementation. Lacking any precise pattern for a legal system designed to achieve the purposes stated in the first constitution, the new government issued only a few decrees designed to establish a framework for the new society and then set up a primitive institutional structure to enforce them. The decrees deprived private individuals of the ownership of land, banks, insurance companies, merchant fleets, and large-scale industry as an implementation of the policy of expropriation of the bourgeoisie. They also created restrictions on the employers of labour and secularized marriage and divorce. The enforcement instruments, called "people's courts," operated without benefit of professional prosecutors or a bar.

"Revolutionary conscience" as a guide

To permit regulation of the multitudinous social relationships for which no new law was prescribed, judges were directed at the start to apply Russian imperial laws, but only to the extent that they had not been revoked by the Revolution and were not contrary to the revolutionary conscience of the judges. Perhaps because Lenin and his colleagues were too busy to do otherwise, or perhaps because they preferred to let develop in practice a new legal order, no all-inclusive systematized body of law was prescribed until 1922. Local judges were guided during the first years, apart from the basic decrees indicated, only by suggestions issuing from the people's commissar of justice in the form of instructions, procedural manuals, and journal articles praising some court decisions as the proper application of revolutionary conscience and denouncing others as improper.

Political enemies of the Communists were not brought before the courts but were condemned by political bodies created at the same time as the people's courts and called revolutionary tribunals, or they were arrested and imprisoned without public hearings by the political police (Cheka). Lenin and his jurists professed that the treatment of opponents outside the regular court system was only a temporary measure. Nevertheless, the conduct of revolutionary tribunals and of the Cheka greatly influenced the course of Soviet law long after their formal abolition in 1922, for they stimulated a lack of respect for formality and strict adherence to law even among those charged with enforcing and administering the law.

After 1924 new agencies emerged within the People's Commissariat of Internal Affairs (NKVD), now the Committee for State Security (KGB), which enabled Lenin's successor, Joseph Stalin, to rid himself of opponents. Following Stalin's death in March 1953, the Communist Party's first secretary, Nikita S. Khrushchev, disclosed that many innocent persons had been convicted and sentenced to long prison terms and even to death by special boards of the secret police. The Soviet method of preserving order was revealed officially to have been dual, with courts on one side dealing publicly with nonpolitical offenses and social disputes, while, at the same time, administrative boards and the security police were secretly punishing Stalin's enemies.

Dual system

Codification. The New Economic Policy of 1921 reintroduced a strictly controlled private enterprise system in limited areas of the economy to speed reconstruction and to overcome the devastating effects of world and civil war. This reintroduction necessitated, in the Communist view, a stabilization of law to induce capitalists to invest in the country. Lenin's commissar of justice, Dmitry I. Kurskii, considered these measures retrogressive but necessary, while Nikolay V. Krylenko, later to become federal commissar of justice, called them the natural evolution of five years of Soviet law. Stabilization efforts resulted in the first systematic codification of Socialist law and led to the construction of a complex institutional framework of courts.

On Oct. 31, 1922, a judiciary act established within the Russian republic a three-tiered system of general courts with civil and criminal jurisdiction:

1. The name "people's court" was retained for the lowest level, but the institution was less primitive than that of 1917. Its bench comprised a full-time judge appointed annually and two lay judges selected from a panel of intelligent and politically trustworthy citizens, each serving for a few days. Lay judges shared responsibility with the professional judge in deciding issues of law and fact.

2. Appeals from this court were handled by a new provincial court that evolved from the Congress of People's Judges, which, under the prior rules, had gathered periodically in each province to survey the work of the local courts. The provincial courts also had jurisdiction to try offenses against the security of the regime and other serious civil and criminal cases. As an appellate court the provincial court consisted of a bench of three professional judges. As a trial court it resembled the people's court, except that the lay judges were selected from a more experienced panel of politically sound citizens.

3. The Supreme Court of the republic was created to coordinate policy in all provinces. Evolving from a control department established earlier in the Commissariat of Justice, this court was authorized not only to hear appeals from cases tried in provincial courts but also to discipline lower courts, to issue rulings interpreting the codes, and to try cases of an unusually important nature.

To provide specialized treatment for crimes relating to military matters and to the disruption of transport, then deemed critical to the success of the regime, special courts that had evolved earlier were continued by the judiciary act and subordinated to the Supreme Court. Following experiments that used non-professionals to conduct prosecution and defense, an office of public prosecutor and a college of defenders, who performed the functions of a bar, were established to aid the judges.

The substantive law and procedure applied by the new courts were established by codes enacted in 1922 and 1923; included were criminal, civil, family, land, and labour codes as well as codes of criminal and civil procedure. The drafters of these codes essentially followed patterns similar to those of the Romanist states of the European continent. The codes survived, with amendments, until the 1960s and '70s.

Soviet federal system

Patterns of legal institutions and the substantive and procedural law enacted by the R.S.F.S.R. were copied with little variation by the Soviet-type republics that emerged in peripheral regions of the old Russian Empire. The only change caused by the federation of the Soviet republics into the Union of Soviet Socialist Republics on Dec. 30, 1922, was the establishment, as a coordinator of all practice, of a Supreme Court of the U.S.S.R. The first federal constitution, adopted provisionally on July 6, 1923, and permanently on Jan. 31, 1924, extended to the federal government the authority to enact general principles of law that would be followed by the republics in maintaining their codes. While this development might have caused a change in the Soviet legal system, it did not; the first federal judiciary act of Oct. 29, 1924, confirmed the system of courts that already existed in each of the republics, and no change was made in substantive or procedural law. The sole innovation was the placing of the military and transport courts under the control of the Supreme Court; thus was created a self-contained system of federal courts, with lower branches functioning throughout the republics but beyond the reach of republic officials. A sharp line was thus drawn between courts that dealt with matters vital to the security of the regime and those concerned with social disputes.

The pattern established for Soviet courts and codes of law in 1922 and 1923 continued until Stalin's death, although the second federal constitution of Dec. 5, 1936, transferred authority to the federal level to enact codes of law to replace those of the republics. Although a second federal judiciary act was issued on Aug. 16, 1938, new codes were not enacted. On Feb. 11, 1957, the constitution was amended to restore the original relationship between individual republics and the federation, namely that they enact their own codes but conform to the general principles established federally. The first of the new general principles were enacted for criminal law and procedure on Dec. 25, 1958, and for civil law and procedure on Dec. 8, 1961. Others later were enacted at intervals, and codes for the republics were subsequently revised. The major innovation of the 1958 enactments was the requirement that punishment be ordered only by a court in accordance with the rules of the procedural code. This provision was heralded by Soviet jurists as a means of preventing the return to extralegal procedures such as those exercised by the secret police during Stalin's dictatorship.

Applications to other Communist states. The application of the pattern of law that had evolved within the Soviet Union was first exported to other areas when Outer Mongolia declared the establishment of a "people's government" on July 11, 1921. Its provisions for courts and prosecutors were like those of the Soviet Union, and the subsequently adopted law on land use of Feb. 6, 1942, provided the same formula of state ownership of land allocated for use gratis and in perpetuity by the nomadic herdsmen for their privately owned cattle. A labour law of Feb. 14, 1941, followed the Soviet pattern, as did a social insurance law of June 22, 1942.

The extension of Soviet law

The major opportunity to install the Soviet legal system outside the Soviet Union came only after World War II, when Soviet-type governments were created in the European states that were occupied by the Soviet army. The system was also established in China, North Korea, and North Vietnam when military victories placed the Communists in power. In each country there was some variation, related in part to the degree of national economic development, from the Soviet pattern evolved in the Soviet Union.

Throughout all of the Communist states, law was given the functions previously established in the Soviet Union. Thus, the first constitution of the Hungarian People's Republic of Aug. 20, 1949, declared (article 41):

> Courts of the Hungarian People's Republic punish enemies of the working people, defend and secure the state, economic and social structure of the people's democracy, its offices and the rights of the toilers, educate the toilers in the spirit of observance of the rules of socialist intercourse.

Regulations governing the organization of the people's courts in the People's Republic of China, promulgated on Sept. 3, 1951, specified that courts were "to consolidate the people's democratic dictatorship, uphold the new democratic social order and safeguard the fruit of the people's revolution." The People's Republic of Bulgaria was even more outspoken than the Soviet Union in clarifying the function of law; in its first constitution, enacted on Dec. 4, 1947, it granted the right to citizens to create associations, but (article 87) only "if they are not directed against state and public order established by the present constitution," and then it stated:

> It is forbidden and will be punished by law to form organizations having as their purpose taking from the Bulgarian people the rights and freedoms won by the people's uprising of September 9, 1944, and guaranteed by the present constitution, or to limit these rights and freedoms, to place under threat the national independence and state sovereignty of the country or to propagate open or concealed fascist or anti-democratic ideology, or to facilitate imperialist aggression, and also to participate in these organizations.

The first constitution of the People's Republic of China, promulgated on Sept. 20, 1954, nearly five years after proclamation of the People's Republic on Oct. 1, 1949, fixed a system of courts that emulated the judicial system in the Soviet Union. There were to be lay assessors, full-time professional judges, Soviet-type prosecutors, and three levels of courts; judges were "independent and subject only to the law," as they had been declared to be in the U.S.S.R. constitution.

Judicial power in Chinese law

The Chinese government, among its first actions, had abrogated all legal codes of the previous government. A commission to draft new codes was established in 1950, but little major legislation was enacted in China until the 1970s. In the interim, the courts were guided by governmental decrees, a few basic statutes, and the program of the Communist Party.

The Socialist states in eastern Europe moved more rapidly toward codification than had China, and, in contrast, confirmed their prewar civil codes, although with modifications. Poland adopted a General Statute on Civil Law with 119 articles on July 18, 1950. Before the expulsion of the Yugoslav Communist Party from the Cominform on June 28, 1948, Yugoslavia, under the constitution of Jan. 31, 1946, had followed the Soviet legal pattern. Under Tito, Yugoslavia accepted the concept of a monopoly of power in the Communist Party and the necessity for state ownership of productive resources. Tito, however, refused to accept the dictates of the Soviet Union on every detail, especially on the centralization of industrial control and the speed of implementing collectivization. The Yugoslav government experimented with bringing workers into the managerial process of public corporations. The government also broadened the autonomy of local government councils. Yugoslav legal philosophers rejected the view that the state could not begin to wither away until full achievement of Communism; they wanted to start relaxing coercion immediately. Stalin's attempts to unseat Tito failed, and after Stalin's death his successors attempted a reconciliation with Tito by indicating an acceptance of the idea that there could be many roads to Socialism.

Changes after the death of Stalin

Post-Stalin developments. Stalin's death in 1953 and his subsequent vilification by the Communist Party of the Soviet Union at its 20th congress three years later opened a new era in the law of Communist states. The people's democracies sought to be relieved of Soviet tutelage. Uprisings in Hungary and Poland forced Soviet leaders to accept the evolution of divergent Socialist legal systems. Polish jurists, including Communists, demanded humanistic attitudes toward legal procedure, greater flexibility within the system, and an increased regard for the individual; other eastern European states followed their lead. In 1958 Soviet legal philosophers formally endorsed a new humanism and declared that it was always fundamental to Lenin's thought.

Only Chinese Communists resisted the trend toward strengthened legal procedures, denouncing Soviet policies of humanism and legality in an open letter published in 1963. After 1957 Chinese leaders abandoned their policy of copying Soviet legal patterns and ceased their efforts to draft codes of law, declaring that they wanted flexibility in court. They evolved a legal system seemingly inspired by relics of traditional Chinese attitudes as modified by their own guerrilla experience before 1949 and by their study of Soviet practices during the period before 1921.

During the Cultural Revolution, which lasted from 1966 to 1976, the Chinese political leadership adopted the attitude that law was dispensable and an obstacle to political progress. In the post-Mao period, a major reevaluation of the role of law in a Socialist state took place, and in 1978 a long-range plan was adopted to enact legislation, reestablish the legal profession, improve court procedures, expand legal education, and make legal consciousness a part of the popular culture. In accordance with this program, China adopted the Constitution of 1982 as well as several important statutes, including election laws, a criminal code, codes of criminal and civil procedure, a marriage law, tax laws, and several laws on the organization of government, the courts, and the procuracy.

Concurrently with revival of concern for humanistic values, most Communist states revised their constitutions and law codes to give formal support to their claim that they had passed beyond capitalism and arrived at Socialism. New civil codes designed for Socialist economies were introduced in Poland and Czechoslovakia in 1964, the latter incorporating terminology that departed sharply from Romanist tradition.

Several features, however, remained unchanged in the law of these states, even after the introduction of variations. Most notable was the continuation of Lenin's principle that after the Russian Revolution no basis remained for the Romanist division of law into public and private spheres. To Lenin the concern of the Soviet state with every detail of social intercourse required the state to maintain the right and opportunity of intervention in any matter at any time. Consequently, he held that in the Soviet system all law must be public; that is, it must reflect the state's vital concern with the social relationships governed by the law. This principle, sometimes called *dirigisme* by French scholars, remains a characteristic of Socialist law.

CHARACTER OF SOVIET LAW

Montesquieu's concept of the separation of powers as embodied in the Constitution of the United States was rejected by the founders of the Soviet legal system. The legislature was made supreme over the executive and the judiciary. In principle only the enactments of the legislature were a source of law.

In reality, however, the executive became a source of law because the Council of Ministers often acted without convening the legislature. The second federal constitution of the Soviet Union, adopted in 1936, attempted to stop this practice, which violated the constitution of 1924, but the executive again soon usurped legislative authority. Post-Stalin reformers again sought to restore the monopoly of lawmaking power to the legislature. In practice, however, it was not the full assembly of the legislature but its derivative body, the presidium, elected from its membership to legislate during intervals between full sessions, that created the day-to-day changes in law. Although subsequent ratification from the full body was sought, it was extremely difficult in practice for the legislature to revoke presidium actions that had already gone into effect. The presidium thus became the most important source of law, except for proclamations of state economic plans and budgets and for the enactment of general principles for republic codes.

Legislative domination

Communist Party orders, except for certain decrees issued jointly by the party and a state agency, are not in the technical sense sources binding on courts. Still, the party provides the initiative for legislative action. Some vital laws, such as those reforming agriculture or industry, are given preeminent status if they are signed by the party secretary as well as by the chairman of the presidium when they are published as law.

Having embraced the principle of legislative supremacy and rejected the notion that judges can make law, the Soviet Union accepts no concept of judicial precedent like that of the Anglo-American common law. Nevertheless, the Supreme Court of the U.S.S.R., during the exercise of its authority to enunciate principles of interpretation, has proclaimed such far-reaching principles as to make of them de facto sources of law. Even individual decisions of the Supreme Court, although lacking the binding force of precedent, are given careful attention by lower courts, since they are published as guides. The Soviet approach to precedent is, in practice, generally similar to that of Romano-Germanic systems.

The Supreme Court of the U.S.S.R., being subordinate to the legislature, has no right to declare a law unconstitutional or to create any limitation upon the legislature or the executive on the ground that some higher or general principles of law have been violated. The legislature controls the judiciary at all levels above the people's court by exercising appointive and recall power through the soviet operating at the level of the court. Only people's judges are elected by the people. Elections follow the pattern established by Stalin for all representative bodies in the Soviet Union: the ballot consists of one candidate who is chosen by local professional groups with the guidance of the Communist Party members in the groups. In practice, judicial decisions have to generally agree with Communist Party policy or the judge risks recall.

The constitutional provision that "judges are independent and subject only to the law" (article 154) has to be understood as a means of denying local officials the right to intervene in the formation of an individual decision on personal grounds, but not as a means of prohibiting Communist Party intervention when such intervention is properly formulated in criticism of a line of decisions out of keeping with party wishes.

Judges are not entirely deprived of initiative by the rule of legislative supremacy or by the leading role played by the Communist Party. In both the civil and criminal codes adopted in 1922 there was authorization to depart from the rigid provisions of the code under special circumstances. The Civil Code opened with article 1, which reads, "Civil rights are protected by law except in cases where they are exercised contrary to their social and economic purpose." The exception permitted judges to apply their concept of state policy, when it was not specifically stated, to achieve an appropriate result in an individual situation, but the decision created no rule of law for future cases. The article was used frequently to justify judicial refusal to protect the rights of capitalists during the period of reconstruction (1922–28), but after 1930 it fell into disuse. Soviet jurists argued that it should be deleted from the code as being unrelated to a stable society from which all capitalist elements already had been eradicated, but it was retained in the civil-law general principles of 1961 (article 5).

Civil rights and state policy

The Criminal Code of 1922, revised in 1926, permitted the judge to exercise discretion in withholding a conviction despite the fact that a crime had clearly been committed, provided that the case posed no social danger. The judge also had the power to punish a citizen who had committed an "apparent" crime even though it was not defined as such by the code; the formula for such judicial initiative was that the act be found socially dangerous in a manner analogous to another act specifically defined as a crime. This provision, which led to unpredictability in the application of the law, was eliminated from the criminal law by the general principles adopted in December 1958.

SUBSTANTIVE LEGAL PROVISIONS

Soviet jurists and their colleagues in eastern Europe and other Communist states claim uniqueness for their system because of its constitutionally defined function of promoting Socialism. The end, in their view, transforms the means. While the novelty of the system is, therefore, primarily its philosophical base, the substantive law has been revised to introduce some novel institutions.

Property. The *Communist Manifesto*'s interpretation of property ownership as the source of political power was accepted by all Communist parties as the guiding principle to be followed in their revisions of the law. Consequently, private ownership of productive wealth was abolished everywhere, to some degree, as soon as state officials felt competent to administer production efficiently. The federal constitutions of the Soviet Union (1936 and 1977) set forth the ideal, denying to private individuals the right to employ labour in productive enterprise and reaffirming Lenin's decree of Feb. 19, 1918, which nationalized all land.

The ideal achievement of the goal was not realized everywhere. Polish and Yugoslav Communists continue to permit peasants to own farmlands and also allow private citizens to conduct service trades, although with limited numbers of employees. China alone permits the private ownership of factories to continue, but these are subject to the limitations that owners retain no financial link to foreign capitalists and that they share their ownership with the state as a partner.

The various legal codes reflect the preponderant importance given to state-owned productive property. For example, severer penalties are prescribed by the criminal code for the theft of state property than of private property. In the Soviet Union labour codes are concerned solely with state employment. The provisions of civil codes related to sales, contracts, property damage, and inheritance govern only consumer goods in traditional Romanist legal fashion, while new forms have been developed to govern transactions involving state property. Title to state property is subject to restrictions: no sales or leases are permitted, with limited exceptions for land allocated to peasant households that have been temporarily disrupted by military service or by relocation for industrial employment.

The ownership of land and personal property

Land has been declared state property only in the Soviet Union and the Mongolian People's Republic (constitution of 1924). In all Marxian Socialist states except Poland and Yugoslavia, land has increasingly been brought under the administration of cooperative-type associations structured on the model of the Soviet collective farm. Peasants have been induced, often under strong pressure, to assign to these associations the use of plots originally owned by or assigned to them. A variation introduced in China (1958) is called a "commune," and it unites both local government and land administration into one administrative unit that supervises "brigades" (groups of villages) and their subordinate "teams" (individual villages). By law, land ownership in China is not placed in the state as it is in the Soviet Union but in the "team" as a means of stimulating peasant initiative in land development.

The Soviet model collective farm places the ownership of machinery, tools, commonly used farm buildings, and crops in the cooperative; but member families are declared the owners of their family homestead, which also includes hand tools and barnyard animals. Small plots of state-owned land are assigned to each family for private use as a household garden. Farm government is carried out by a membership assembly that elects managers who are usually introduced to the members by central government authorities. Remuneration is in the form of a share of the produce that is graduated according to the value of work performed, computed by an accounting unit called a "labour day."

Agricultural cooperatives, generally regarded as transitional structures designed to guide peasants toward the superior type of organization patterned on industry, enable peasants to become farm employees and receive wages and social insurance benefits. Only China rejects this ultimate goal, preferring instead to perfect the "commune" as its model for rural productive units.

Nonproductive property and the tools of artisans are left to private ownership and are labeled "personal property" to distinguish them from income-producing "private property." Early efforts to equalize the ownership of consumer goods were abandoned by Stalin in 1930, and egalitarianism was denounced as a petty bourgeois utopian idea. The shortage of goods forced this change in attitude, and wages were adjusted to individual work performance as a means of stimulating production. This differentiation in wages led progressively to the weakening of restraints on inheritance and the ownership of luxury items.

Restrictions on personal property

The federal constitutions of the Soviet Union have entrenched the systems of property incentives by guaranteeing inheritance and the private ownership of savings accounts. To preclude reversion to capitalist practices, various restrictions are placed on the use of personal property. Thus, dwellings are limited in size to satisfy only family needs; sales of dwellings and apartments can occur only after long intervals; members of a family sharing a joint household may own only one dwelling and may lease excess space only temporarily and at rentals not exceeding those charged for occupancy of state-owned premises. Property purchased with income gained illegally can be expropriated. Neglected property can be expropriated if repairs are not made following a warning.

The determination to eliminate income resulting from the investment of private funds has been weakened by various paramount state pressures. Thus, interest is paid on state savings bank accounts to stimulate deposits as a means of accumulating funds available for state investment and to reduce the threat of an inflation of currency. Investment in state bonds also is encouraged, but returns are not paid in conventional interest but rather as lottery winnings. Inheritance from abroad is paid to heirs within the Soviet Union.

Marxian Socialist states outside the Soviet Union have established comparable restrictions, and Czechoslovakia has gone as far as requiring that the source of personal ownership be "honest"; *i.e.,* derived mainly from work for the benefit of society. China, under Mao Zedong, took the strict position, opposing extensive use of property incentives among individuals and espousing asceticism.

Communal ownership is reserved in Marxian Socialist states, except in China, for the distant future when abundance has been achieved, money is no longer used as a medium of exchange, and the state has "withered away," in accordance with the prophecy of Marx and Engels in the *Communist Manifesto.* Until that time, the state represents the community and therefore seeks to enlarge its segment of productive property.

Yugoslav Communists have rejected the Soviet model of state ownership of industry. Since 1950 they have used a system based on the "social ownership" of factories, under which the title to industrial property does not reside with the state but instead with the employees of each factory, who are organized into a "workers' council." Management is appointed not by a central ministry, as in other Marxian Socialist states, but by the workers' council, which acts in concert with the local government and an industry-wide chamber that represents all of the workers' councils in the republic in the same branch of industry. The primary aim of the Yugoslav system is to overcome the evils thought to be inherent in a centralized bureaucracy.

Economic planning. Production is planned in all Marxian Socialist states, although to varying degrees and through different types of institutions. Stalin favoured detailed planning and the centralized decisions of the Council of Ministers, who were advised by the State Planning Commission (Gosplan). The Yugoslav opposition to a centralized bureaucracy places an emphasis on planning by local government and workers' councils; these groups, however, are subject to influences exerted by the central government, which allocates major capital investment and establishes national goals.

After 1957 Stalin's successors experimented with forms of decentralized decision making; regional economic councils (Sovnarkhoz) were established for industries not directly related to national defense in the hope of stimulating managerial initiative. Most centralized industrial ministries were abolished from 1957 to 1965, but Gosplan and specialized financial and technical institutions retained control over the allocation of key resources. With the abolition of the Sovnarkhoz and the reconstitution of industrial ministries, in 1965 the Soviet Union returned to centralization—but in a form differing from Stalin's model. Under the new organization the responsibilities of the authorities of the republics were heightened, and plant managers were directed to search out local sources of supplies and markets.

The encouragement of local initiative went further in some Marxian Socialist states: Czechoslovak specialists even proposed to dramatize the change in emphasis by declaring that the public corporations administering state-owned property were the "owners" of the buildings and tools rather than only the administrators. This extreme experimentation was terminated by the Soviet intervention in 1968, although the Yugoslav Communists continue to rely on their system of local ownership and direction subject to indicative plans having no force of law.

Contracts as tools for economic planning

An interesting legal feature connected with production in all Marxian Socialist states is the system of contracts that are executed by plant managers for implementing production plans. These contracts prescribe quantity, design, technical specifications, price, and delivery date, and they use plan requirements as a basis for negotiation. After 1957 elements of consumer choice were also considered. These contracts are often used by permanent state tribunals, called State Arbitration, to settle disputes. The tribunals also may require a contract to be executed to implement the plan if the parties cannot agree on terms. China alone provides a variation by eschewing a permanent tribunal and opting for mediation through ad hoc committees established by local economic commissions that are linked to the planning apparatus.

Labour. While production and distribution in the Soviet Union are subject to compulsory orders, labour remains free to move as it wishes, although exceptions occurred during the emergency conditions of World War II. Although the Soviet labour supply is regulated by monetary and other inducements, it continues to be subject to the centralized determination of job classifications, hours, and wages.

The role of collective labour agreements has changed throughout the years as the central authorities increasingly have prescribed details of employment. The agreements fell into disuse in the mid-1930s but were restored after World War II to mobilize the labour force for production. Since job classifications, wages, and hours were established by law, the agreements concentrate on bettering local working conditions and on indicating the labour union's preferences regarding the use of bonuses that are collectively earned as incentives for exceeding planned production.

Strikes and grievances

Since production is planned and, therefore, is by definition rational, strikes are given no place in Marxian Socialist states. Remedies sought by management or labour unions against apparent injustices are supposed to take the form of petitions to higher authority for legislative or administrative rectification. Collective agreements are enforced primarily through moral suasion, but they are strengthened by provisions of the penal code that apply to state managers who violate the code, the collective agreement, or legal activity of labour unions, and to labour union officials who disrupt production so severely as to commit the crime of "wrecking." Work stoppages do occur in Socialist countries, however. Major strikes took place in Poland and Hungary in 1956 when Communist influence weakened, and reforms had to be instituted to enable the Communist Party to maintain power. In the 1980s, strikes in Poland and Yugoslavia became a significant de facto element of industrial relations.

The "right to work" has been established by all constitutions of Marxian Socialist states, but no system has implemented it by court orders that force an employment office to provide a job. The concept has come to require only the elimination of discrimination on the basis of race, sex, age, or domicile in filling such jobs as exist.

Individual employment contracts reflect the statutory provisions that govern employment and its termination. Since there is no individual bargaining in establishing the terms of employment, written contracts are often omitted in practice. A grievance procedure under labour union supervision is the established means by which aggrieved parties appeal to the courts for review of managerial decisions concerning payment and dismissal. Labour that becomes redundant with the advance of automation is to be retrained for other employment by state centres.

The "workers' self-government" of Yugoslavia presents a variation in the theory of employment relationships since workers can be said to employ themselves, being both owners and workers. Their activity is regarded as a social duty rather than a labour relationship, but in practice standards of employment are established to which management is required to adhere, these being generally the same as in other Marxian Socialist states.

Social insurance. Social insurance has been introduced in all Marxian Socialist states to protect employees who are injured on the job or elsewhere. No coverage was offered to collective farmers until 1966, or to housewives and children; the only means of recovery for these groups were suits based on the Civil Code's provisions on obligations. These rules conform to traditional Romanist legal models with some variation. Thus, the first Russian Civil Code (1922) required no fault for recovery, but this provision became conventional through court practice and later legislation. Fault is now necessary for liability, except in cases in which the instrument causing injury is classified as particularly hazardous. The list of such instruments includes automobiles.

The social utility of negligence suits

Social insurance benefits originally were inadequate because of the impoverishment of the state treasury. Consequently, victims of accidents were encouraged to sue for the difference between social insurance payments and total losses. Soviet policy makers later concluded that it was desirable to continue this practice even when social insurance funds were increased, the argument being that state managers would be prompted to exercise care because of the threat of suits, which would likely reduce profit margins and their eventual chances for promotion. Social insurance benefits thus continue to be set at levels lower than damages suffered.

Damages are generally limited to the loss of wages or anticipated wages for unemployed victims. Poland and Czechoslovakia also continue the ancient practice of allowing recovery for pain and suffering. No capitalization of damages is permitted, in part to avoid the transfer of large sums to irresponsible persons and in part to discourage an accumulation of wealth that might provoke capitalist speculation.

No personal liability insurance is made available to individuals in the Soviet Union, except to foreigners, in the belief that its availability would reduce the deterrent effect created by civil suits for accidents. Czechoslovak and Hungarian civil codes, however, retain pre-World War II provisions that created the opportunity of purchasing liability insurance. State insurance provides the state enterprises in all Marxian Socialist states with protection from suits by employees injured by hazardous equipment, unless charges of fault are made. The burden of proving absence of fault is on the defendant.

Liability for injury is attached to all state activities, even those not of an economic character, such as with ministries and local government, although until 1961 in the Soviet Union sovereign immunity for governmental functions had to be waived explicitly by statute to permit a suit. Thereafter, liability was extended to all types of state administration unless immunity was claimed by specific law. The Czechoslovak Civil Code (1964) established an approach to state liability by drawing no distinction between types of state activities in its rule of liability to suit.

The Chinese penchant for mediation over litigation developed after 1957 to eliminate possibilities of suits for injury in accidents, but in cases of reprehensible conduct the police were authorized to impose administrative sanctions for minor infringements of citizens' personal or property rights, or to require payment of medical expenses and property damage under the Security Administration Punishment Act of 1957.

A duty to protect state property (article 131) and to observe rules of Socialist conduct (article 130) was created by the second Soviet federal constitution (1936). It initiated judicial practice establishing an obligation of a state enterprise whose property had been protected to pay damages to a victim injured while attempting to perform his duty. This principle was written into the Fundamentals of Civil Law in 1961. No implementation was provided, however, for failure to rescue another in performance of the obligation to observe the rules of social conduct. Soviet authors concluded that this duty was moral and not legal, and violation could create no civil liability in favour of a citizen or his heirs if no rescue was attempted.

Artistic creation and invention. The legal rights that protect authors, artists, and inventors present problems in socialized economies unless such persons are employed by the state. Practice indicates that authors, artists, and inventors are most imaginative when they are unimpeded by state supervision. To provide the requisite freedom coupled with the stimulation of initiative, Soviet codifiers have created a status for innovators that stands midway between Western concepts and those of the Socialist ideal, in which wages are paid only for production. This status is referred to as "a law of personal relationships rather than of property relationships."

Inventors in the Soviet Union are offered two alternatives: an "author's certificate," or a patent. The first is granted after proof of novelty is submitted to the state patent office. It qualifies the inventor to receive payments computed on the savings that will accrue to the state from the use of the invention, with the computation being based on the best of the first five years of use. Additional benefits include tax exemption on a portion of the receipts, priority in the allocation of scarce living space, and acceptance into a technical school. The patent form is traditional, except that restrictions on private enterprise limit its use to assignment to state enterprises. In practice only foreigners choose patents, and their patent rights are protected under an international convention that was ratified by the Soviet Union in 1965.

Although other Marxian Socialist states in eastern Europe also offered a form similar to the "author's certificate," patents remained in common use until 1963, when the trend toward the Soviet model became marked. All states, however, retain the patent form for local inventions that are likely to have appeal abroad so as not to discourage potential foreign licensees.

Protection of artists' rights

Authors and artists are provided a more conventional protection than inventors, but they also are deprived of some of the traditional rights of a copyright owner. They cannot bargain for royalties or sell their work to foreign publishers except through a state trading enterprise. Royalties are paid in accordance with a state tariff that is based on the type and size of the edition. In addition to monetary rewards, which are payable for life and to heirs for a term of years, moral protection is offered in the form of the rights to control editorial changes and the use of the manuscript. Community interests are exerted against an individual author's will if the work is regarded as a national treasure. In such a case, it may be translated or published continuously after the first disclosure by the author. Royalties are paid, except when the language of translation is other than Russian—the reasoning behind this being that minority peoples need culture, but they may not be able to afford it. Nonmonetary inducements, including medals and honorary titles, are also used to stimulate innovation.

In 1973 the Soviet Union joined the Universal Copyright Convention, of which the United States and more than 70 other countries are members. Several other eastern European Marxian Socialist states are also members of the convention, and some belong to the Berne Convention.

Family law. Under the 1977 Soviet constitution, the family is placed under the protection of the state. This protection is manifested by the express constitutional obligation of the state to establish an extensive network of child-care institutions, to organize and improve services to families, and to provide allowances and benefits to families with children. Soviet family policy is closely allied with population and labour policy, aiming simultaneously at raising the birthrate while enabling mothers to remain in the labour force.

Equality of the sexes, a major aim of the Russian Revolution, is not understood as being inconsistent with the special protection offered in Socialist countries to women, especially to those with children. The 1977 Soviet constitution provides that women shall have equal rights with men, but that the state shall ensure the exercise of these rights by protecting the health of women; by providing material support for mothers, which includes paid maternity leaves and other benefits; and by aiding unmarried mothers.

Another goal of the Revolution in the area of family relationships was the secularization of marriage. Before 1926 Soviet family law presented little variation from western European models, but the 1926 code introduced unregistered marriage and divorce. Marriage could be recognized as legally constituted if cohabitation were proved orally. Divorce could be registered at the request of one party after the termination of marital relationships had been proved.

A trend toward the discouragement of promiscuity emerged in the mid-1930s after evidence linked increasing juvenile delinquency to the breakup of homes. A law enacted in 1936 required both parties to appear for divorce if the care and maintenance of children was an issue and sought to discourage repeated divorces by establishing a system of graduated fees for each suceeding divorce. The 1926 provisions, which accepted proof of marriage or divorce other than by registration, were revoked by law in 1944. Thereafter registration was compulsory to establish a marriage, and courts were given sole jurisdiction over divorce. Judges were required, however, to attempt reconciliation and to grant divorce only when they were convinced that the restoration of the family would be impossible.

The compromise on marriage and family

Hostility to the system grew during the succeeding years until a compromise position was formulated and adopted by law in 1968. While the registration of a marriage remains a requirement, divorce may be registered without prior court decision if both parties consent and if there are no offspring. In other circumstances court proceedings are compulsory.

While other Marxian Socialist states generally follow the Soviet model, all have introduced variations to preserve national cultural patterns. None but China has adopted the early attitudes espoused in the Soviet Union concerning unrestrained divorce, and even China discourages the use of its simple procedure of granting divorce at the request of either party. All Marxian Socialist states seek to preserve the conjugal family against gratuitous decisions to separate. The formula establishes no precise grounds for divorce; instead it authorizes divorce only in the event of a complete and permanent breakdown of the marital relationship. In practice marriages are considered to be broken if cohabitation has ceased. Children born out of wedlock generally are accorded the same rights as those born legitimate.

The marital property regime in the Soviet Union was established after early experimentation with individually owned property. The system that was finally chosen in 1926 incorporates the concept of community of acquests; that is, property owned individually by the spouses before marriage remains their separate property, but property acquired during marriage is co-owned, unless it was received by one spouse as a gift from outside or by inheritance. The Soviet model is that which is favoured by civil-law systems in general and has been adopted elsewhere among the Marxian Socialist states.

Criminal law. Novel definitions of crime have emerged in Marxian Socialist states to reflect Socialist principles. To the traditional crimes against the person and property, the Soviet Union has added "economic crimes." This development occurred in 1932 and coincided with the termination of the private enterprise system in favour of a system of state monopoly of large-scale production and state planning. Under these altered priorities, merchandising became a crime.

The constitutional prohibition of all private employment of labour for purposes of production is reflected in the Criminal Code, which penalizes employers for those practices. Even artisans employing no labour are forbidden to engage in various production activities unless their customers provide the raw materials. The leasing of unused space in small private dwellings at rates exceeding those established for tenants of state-owned apartment buildings is also a crime.

Crimes against the state

Fear of opposition to Communist Party leadership prompted the early introduction in the Soviet system of penalties for "counterrevolutionary" crimes. This phrase has been replaced in modern Socialist criminal codes by the term "crimes against the state." Although all legal systems punish attempts to subvert state authority, the definitions and practices under Stalin exceeded the norms of Western democracies in their vagueness of expression and in the severity of penalties they prescribed. After Stalin's death a decade ensued in which punishments for these crimes were lessened, but a new epoch was initiated in 1966 when authors were prosecuted for publishing allegorical manuscripts abroad that had been rejected by Soviet censors. The ground given for these prosecutions was that the authors should have anticipated the hostile use to which their writings would be put by enemies of the Soviet Union.

To implement Marxist attitudes that describe religion as an intolerable superstition to be discouraged, the conduct of religious schools and of social activities related to religious worship is prohibited in the Soviet Union. Strong measures were adopted during the 1920s when the religious hierarchies opposed Communist programs; although these were relaxed during World War II to gain the support of peasants, basic policies remained unchanged. An order in 1966 prescribed punishment for religious activities that are deemed harmful to health, and in practice the law is interpreted broadly in order to hamper worship by minority sects.

While other Marxian Socialist states have introduced less restrictive laws, their leaders have sought to discourage religion. Chinese Communists have expressed the belief that monks and priests should be reeducated. Eastern European leaders initially were militant in prosecuting clergy, but they have relaxed their vigilance as religious institutions have become more tractable. Poland is relatively liberal with respect to religion and religious practices, and Yugoslavia even went so far as to sign a concordat with the Vatican in 1966.

Procedural law. Romanist influence is strong in the Soviet codes of criminal and civil procedure, which resemble the French codes in their main features, except that they allow for more possibilities of control by the state. Soviet procedural law has in turn influenced all of the other Socialist systems.

Emphasis in criminal procedure is placed on investigation before trial, as in French practice. The examiner has to establish more than the prima facie case required of the grand jury in the traditional common-law system. The suspect has to be given an opportunity to testify and to produce witnesses and evidence in his defense. The examiner is authorized to bring the case to trial only if he becomes convinced of the suspect's guilt, so that the public trial consists primarily of verifying the examiner's work rather than hearing the defendant's case for the first time. Contrast with the French model is provided by the fact that the examiner is not a magistrate but a subordinate to the office of prosecutor, and until 1958 in the Soviet Union the defendant was not permitted to have an attorney during the preliminary investigation. Even now, only juveniles and certain special classes of defendants, such as deaf and mute persons, are given an absolute right to an attorney.

The "inquisitorial" system

Trial procedure follows the French model closely in that the judges are instructed to establish their personal conviction of guilt. To do so they may go beyond the evidence that is presented by the prosecution and defense. The court may call witnesses, seek its own experts, examine material evidence, and visit places connected with the crime. In practice, the judges do most of the interrogating in the courtroom and rely on the prosecutor and the defense only to bring out points that may have been overlooked. No rule of evidence of any kind binds the court, except for the requirements that evidence be relevant, probative, and not unduly repetitious.

Civil procedure requires the observance of rules of evidence only for certain formalities as established by the civil codes, such as for contracts or wills. Otherwise, the judges are as free in civil cases as they are in criminal matters to seek or hear what they feel they need to establish personal conviction. As in certain Romano-Germanic legal systems, the prosecutor has the authority to intervene in civil cases when intervention is deemed necessary to protect broader social interests.

Appellate courts that find violations of procedural requirements or of substantive law or that find evidence unconvincing are required to remand for a new trial. Revision of a sentence or of a decision without a retrial in a court in the original jurisdiction is permitted only when the original court had no jurisdiction, where an amnesty had been improperly applied, or where there had been no basis for trial. A penalty cannot be increased on the defendant's appeal.

Protest of decisions

A singular feature of Soviet procedure is the authority given to Supreme Court presidents and to the prosecutors of the republics and of the Soviet Union to protest a civil or criminal decision, after it has become final on appeal or in the absence of appeal. This procedure permits the reopening of convictions or even of acquittals if the highest legal authorities find grave errors in their periodic audits of inferior-court activities. Prosecutors frequently request such reopenings, even of convictions obtained by inferior prosecutors. This creates an opportunity of petition to superior prosecutors or to court presidents after all other remedies have been exhausted. At the same time it gives state authorities a second chance, not given to the convict or to the party of a civil suit, to change an otherwise final decision.

Socialist law in perspective. The industrialization that has been characteristic of the 20th century requires legal systems in all states to accept increasing state intervention in social relationships. Employers are no longer free to execute labour contracts as they wish; property owners are subject to increasing restraints on use (in some countries farms or dwellings may be lost if they are not used productively); nationalization or extensive regulation in banking, industry, and transport has become widespread; compulsory insurance against injury to third parties has become commonplace, as has social insurance against industrial accidents; and the secularization of marriage and divorce nearly everywhere prevents citizens from conducting their marital relationships solely within religious rules.

Socialist law, in reflecting the pervasive presence of the state in human affairs, appears to be an extreme extension of the trends common to all modern legal systems. Yet, with its sense of historic mission to advance society toward Socialism and ultimately to Communism, and with its educational ambition to help create the "new Socialist man" purged of selfish bourgeois propensities, Socialist law is closer to the religious legal systems of the world than it is to the civil or common law. Thus, despite its many common features with the Romano-Germanic systems, the conclusion seems justified that Socialist law differs in more than degree from other legal systems and therefore requires separate categorization. (J.N.H./M.A.Gl.)

BUCHNER, *Die Rechtsquellen,* published as a supplement to W. WATTENBACH and W. LEVISON, *Deutschlands Geschichtsquellen im Mittelalter: Vorzeit und Karolinger,* vol. 2 (1953); and EDWARD JENKS, *Law and Politics in the Middle Ages: With a Synoptic Table of Sources,* 2nd ed. (1913, reprinted 1970). For substantive law, see HEINRICH BRUNNER, *Deutsche Rechtsgeschichte,* 2nd ed., vol. 1 (1906, reprinted 1961), the classic treatment; H. CONRAD, *Deutsche Rechtsgeschichte: Ein Lehrbuch,* vol. 1, *Frühzeit und Mittelalter,* 2nd ed. (1962, reprinted 1982); and C. VON SCHWERIN, *Grundzüge der deutschen Rechtsgeschichte,* 4th ed. prepared by HANS THIEME (1950). For very early law, see MARCO SCOVAZZI, *Le origini del diritto germanico: fonti, preistoria, diritto pubblico* (1957).

For Visigothic and Burgundian law, see E.A. THOMPSON, "The Barbarian Kingdoms in Gaul and Spain," *Nottingham Mediaeval Studies,* 7:3–33 (1963); and P.D. KING, *Law and Society in the Visigothic Kingdom* (1972). For Anglo-Saxon law, see F.W. MAITLAND, "The Laws of the Anglo-Saxons," *The Collected Papers of Frederic William Maitland,* ed. by H.A.L. FISHER, vol. 3, pp. 447–473 (1911, reprinted 1981); and H.G. RICHARDSON and G.O. SAYLES, *Law and Legislation from Aethelberht to Magna Carta* (1966). For north Germanic law, see L.B. ORFIELD, *The Growth of Scandinavian Law* (1953).

Modern comparative law: The world's legal systems are comparatively presented in KONRAD ZWEIGERT and HEIN KÖTZ, *An Introduction to Comparative Law,* 2 vol. (1977; originally published in German, 1969–71), which contains in its second volume comparative studies of selected topics of the law of contracts, torts, and restitution; and in RENÉ DAVID and JOHN E.C. BRIERLEY, *Major Legal Systems in the World Today: An Introduction to the Comparative Study of Law,* 3rd ed. rev. (1985; originally published in French, 1966). Both works contain extensive bibliographies. See also MARY ANN GLENDON, MICHAEL WALLACE GORDON, and CHRISTOPHER OSAKWE, *Comparative Legal Traditions: Text, Materials, and Cases on the Civil Law, Common Law, and Socialist Law Traditions, with Special Reference to French, West German, English, and Soviet Law* (1985). For a historical discussion explaining the origins, the essential values, and the unifying features of the Western legal heritage, see HAROLD J. BERMAN, *Law and Revolution: The Formation of the Western Legal Tradition* (1983). JOHN P. DAWSON, *The Oracles of the Law* (1968, reprinted 1978), is a penetrating analysis of the methods of legal thought in the Anglo-American, French, and German systems, as developed through the different roles played in them by judges and scholars. The *International Encyclopedia of Comparative Law* (1971–), is a compendium of articles by an international group of scholars that compares legal systems on a wide variety of topics. Current materials and articles are published in the *American Journal of Comparative Law* (quarterly); and the *International and Comparative Law Quarterly.* A continuing list of all books and articles published in English since 1790 on the subject of civil law can be found in CHARLES SZLADITS (comp.), *A Bibliography on Foreign and Comparative Law* (1953–), with supplements in the *American Journal of Comparative Law.*

Civil law: ARTHUR TAYLOR VON MEHREN and JAMES RUSSELL GORDLEY, *The Civil Law System,* 2nd ed. (1977), is a rich collection of cases and other source materials from France and Germany. A useful introduction for general readers as well as for those with legal training is JOHN HENRY MERRYMAN, *The Civil Law Tradition: An Introduction to the Legal Systems of Western Europe and Latin America,* 2nd ed. (1985). Helpful guides to the legal systems of particular countries are: F.H. LAWSON, A.E. ANTON, and L. NEVILLE BROWN (eds.), *Introduction to French Law,* 3rd ed. (1967); OTTO KAHN-FREUND, CLAUDINE LÉVY, and BERNHARD RUDDEN, *A Source Book on French Law: System, Methods, Outlines of Contract,* 2nd ed. (1979); F.H. LAWSON, *A Common Lawyer Looks at the Civil Law* (1955, reprinted 1977), primarily concerned with French law; E.J. COHN, *Manual of German Law,* 2nd rev. ed., 2 vol. (1968–71), a book written for lawyers; NORBERT HORN, HEIN KÖTZ, and HANSI G. LESER, *German Private and Commercial Law: An Introduction,* trans. from German (1982); MAURO CAPPELLETTI, JOHN HENRY MERRYMAN, and JOSEPH M. PERILLO, *The Italian Legal System: An Introduction* (1967); and ARTHUR TAYLOR VON MEHREN (ed.), *Law in Japan: The Legal Order in a Changing Society* (1963).

Common law: A.K.R. KIRALFY, *The English Legal System,* 7th ed. (1984); and PHILIP S. JAMES, *Introduction to English Law,* 11th ed. (1985), are general outlines. There are numerous general historical works, such as EDWARD JENKS, *A Short History of English Law: From the Earliest Times to the End of the Year 1939,* 6th ed. (1949); A.K.R. KIRALFY, *Potter's Historical Introduction to English Law and Its Institutions,* 4th ed. (1958); THEODORE F.T. PLUCKNETT, *A Concise History of the Common Law,* 5th ed. (1956); J.H. BAKER, *An Introduction to English Legal History,* 2nd ed. (1979); and S.F.C. MILSOM, *Historical Foundations of the Common Law,* 2nd ed. (1981), a difficult but classic text.

For the United States, see E. ALLAN FARNSWORTH, *An Introduction to the Legal System of the United States,* 2nd ed. (1983), a broad study of the American legal system. A good historical treatment is LAWRENCE M. FRIEDMAN, *A History of American Law,* 2nd ed. (1985).

General studies of other common-law nations include G.W. PATON (ed.), *The Commonwealth of Australia: The Development of Its Laws and Constitution* (1952); BORA LASKIN, *The British Tradition in Canadian Law* (1969); E. MCWHINNEY (ed.), *Canadian Jurisprudence: The Civil Law and Common Law in Canada* (1958); and M.C. SETALVAD, *The Common Law in India,* 2nd ed. (1970).

Socialist law: For a comprehensive survey of the Soviet legal system, see WILLIAM E. BUTLER, *Soviet Law* (1983). HAROLD J. BERMAN, *Justice in the U.S.S.R.: An Interpretation of Soviet Law,* rev. ed. (1963), is a study of Soviet law to the end of the Khrushchev era against the backdrop of Russian legal history and Marxist philosophy. The relationship of Soviet law to other

Socialist legal systems is treated in JOHN N. HAZARD, *Communists and Their Law: A Search for the Common Core of the Legal Systems of the Marxian Socialist States* (1969). The effect of sociopolitical change on Soviet legal developments is discussed in JOHN N. HAZARD, *Managing Change in the U.S.S.R.* (1983). JOHN N. HAZARD, WILLIAM E. BUTLER, and PETER B. MAGGS, *The Soviet Legal System: The Law in the 1980's* (1984), presents original source materials and contains an extensive bibliography. Current documentary materials are available in a looseleaf service, WILLIAM E. BUTLER, *Collected Legislation of the Union of Soviet Socialist Republics and the Constituent Union Republics* (1979–), major enactments from which are collected in WILLIAM E. BUTLER (comp.), *Basic Documents on the Soviet Legal System* (1983). The constitutions of Socialist legal systems are translated with introductions in WILLIAM B. SIMONS (ed.), *The Constitutions of the Communist World* (1980, reissued 1984).

Lenin

Militant Marxist, founder of the Russian Communist Party (Bolsheviks), inspirer and leader of the Bolshevik Revolution, Lenin was the architect, builder, and first head of the Soviet state. He was the founder of the organization known as Comintern (Communist International) and posthumous source of "Leninism," the doctrine codified and conjoined with Marx's works by Lenin's successors to form Marxism-Leninism, the Communist world view. If the Bolshevik Revolution is—as some people have called it—the most significant political event of the 20th century, then Lenin must for good or ill be regarded as the century's most significant political leader. Not only in the Soviet Union but even among many non-Communist scholars, he is regarded as both the greatest revolutionary leader and revolutionary statesman in history, as well as the greatest revolutionary thinker since Marx.

Tass—Sovfoto

Lenin, 1918.

EARLY LIFE

The making of a revolutionary. It is difficult to find anything in his childhood that might have turned him onto the path of a professional revolutionary. Vladimir Ilich Ulyanov was born in Simbirsk (renamed Ulyanovsk) on April 22 (April 10, old style), 1870. (He adopted the pseudonym Lenin in 1901 during his clandestine party work after exile in Siberia.) He was the third of six children born into a close-knit, happy family of highly educated and cultured parents. His mother was the daughter of a physician, while his father, though the son of a serf, became a schoolteacher and rose to the position of inspector of schools. Lenin, intellectually gifted, physically strong, and reared in a warm, loving home, early displayed a voracious passion for learning. He was graduated from high school ranking first in his class. He distinguished himself in Latin and Greek and seemed destined for the life of a classical scholar. When he was 16, nothing in Lenin indicated a future rebel, still less a professional revolutionary—except, perhaps, his turn to atheism. But, despite an ideal upbringing, all five of the Ulyanov children who reached maturity joined the revolutionary movement. This was not uncommon in tsarist Russia, where even the highly educated and cultured intelligentsia were denied elementary civil and political rights.

In adolescence Lenin suffered two blows that unquestionably impelled him to take the path of revolution. First, his father was threatened shortly before his untimely death with premature retirement by a reactionary government grown fearful of the spread of public education. Second, in 1887 his beloved eldest brother, Aleksandr, a student at the University of St. Petersburg (now Leningrad State University), was hanged for conspiring with a revolutionary terrorist group that plotted to assassinate Emperor Alexander III. Suddenly, at age 17, Lenin became the male head of the family, which was now stigmatized as having reared a "state criminal."

Execution of Lenin's brother

Fortunately his mother's pension and inheritance kept the family in comfortable circumstances, despite the frequent imprisonment or exile of her children. Moreover, Lenin's high school principal (the father of Aleksandr Kerensky, who was later to lead the Provisional government deposed by Lenin in November [October, O.S.] 1917) did not turn his back on the "criminal's" family. He courageously wrote a character reference that smoothed Lenin's admission to a university.

In autumn 1887 Lenin enrolled in the faculty of law of the imperial Kazan University (now Kazan [V.I. Lenin] State University), but within three months he was expelled, accused of participating in an illegal student assembly. He was arrested and banished from Kazan to his grandfather's estate in the village of Kokushkino, where his older sister Anna had already been ordered by the police to reside. In the autumn of 1888, the authorities permitted him to return to Kazan but denied him readmission to the university. During his enforced idleness, he met exiled revolutionaries of the older generation and avidly read revolutionary political literature, especially Marx's *Das Kapital.* He became a Marxist in January 1889.

Formation of a revolutionary party. In May 1889 the Ulyanov family moved to Samara (now Kuybyshev). After much petitioning, Lenin was granted permission to take his law examinations. In November 1891 he passed his examinations, taking a first in all subjects, and was graduated with a first-class degree. After the police finally waived their political objections, Lenin was admitted to the bar and practiced law in Samara in 1892–93, his clients being mainly poor peasants and artisans. In his experience at law he acquired an intense loathing for the class bias of the legal system and a lifelong revulsion for lawyers, even those who claimed to be Social-Democrats.

But law was an extremely useful cover for a revolutionary activist. He moved to St. Petersburg (now Leningrad) in August 1893 and, while working as a public defender, made contact with revolutionary Marxists. In 1895 his comrades sent him abroad to make contact with Russian exiles in western Europe, especially with Russia's most commanding Marxist thinker, Georgy Plekhanov. Upon his return in 1895, Lenin and other Marxists, including L. Martov, the future leader of the Mensheviks, succeeded in unifying the Marxist groups of the capital in an organization known as the Union for the Struggle for the Liberation of the Working Class. The Union issued leaflets and proclamations on the workers' behalf, supported workers' strikes, and infiltrated workers' education classes to impart the rudiments of Marxism. In December 1895, the leaders of the Union were arrested. Lenin was jailed for 15 months, then exiled to Shushenskoye, in Siberia, for a term of three years. He was joined there in exile by his fiancée, Nadezhda Krupskaya, a Union member, whom he had met in the capital. They were married in Siberia, and she became Lenin's indispensable secretary and comrade. In exile they conducted clandestine party correspondence and collaborated (legally) on a Russian translation of Sidney and Beatrice Webb's *Industrial Democracy.*

Exile in Siberia

Upon completing his term of exile in January 1900, Lenin went abroad and was joined later by Krupskaya in Munich. His first major task abroad was to join Plekhanov, Martov, and three other editors in bringing out the newspaper *Iskra* ("The Spark"), which they hoped would unify the Russian Marxist groups scattered throughout Russia and western Europe into a cohesive Social-Democratic party.

Up to the point that Lenin joined the *Iskra,* his writings had focussed on three problems: first, he had written a number of leaflets that aimed to shake the workers' traditional veneration of the tsar by showing them that their harsh life was caused, in part, by the support tsarism rendered the capitalists; second, he attacked those self-styled Marxists who urged Social-Democrats and workers to concentrate on wage and hour issues, leaving the political struggle for the present to the bourgeoisie; third, and ultimately most important, he addressed himself to the peasant question.

The principal obstacle to the acceptance of Marxism by many of the intelligentsia was their adherence to the widespread belief of the Populists (Russian pre-Marxist radicals) that Marxism was inapplicable to peasant Russia, in which a proletariat was almost nonexistent. Russia, they held, was immune to capitalism, owing to joint ownership of peasant land by the village commune. This view had been first attacked by Plekhanov in the 1880s. Plekhanov had argued that Russia had already entered the capitalist stage, as evidenced by the rapid growth of industry. Despite the denials of the Populists, the man of the future in Russia was the proletarian, not the peasant. Applying the Marxist scheme of social development to Russia, Plekhanov had come to the view that the revolution in Russia must pass through two discrete stages: first, a bourgeois revolution that would establish a democratic republic and full-blown capitalism; and second, a proletarian revolution after mature capitalism had generated a numerous proletariat that had attained a high level of political organization, socialist consciousness, and culture, enabling them to usher in full Socialism.

It was this view that Lenin adhered to after he read Plekhanov's work in the late 1880s. But, almost immediately, Lenin went a step beyond his former mentor, especially in the peasant question. In an attack on the Populists published in 1894, Lenin charged that, even if they realized their fondest dream and divided all the land among the peasant communes, the result would not be Socialism but capitalism spawned by a free market in agricultural produce. The "Socialism" of the Populists would favour the growth of small-scale capitalism; hence the Populists were not Socialists but "petty bourgeois democrats." Outside of Marxism, which aimed ultimately to abolish the market system as well as the private ownership of the means of production, Lenin concluded, there could be no Socialism.

The peasant question

Even while in exile in Siberia, Lenin had begun research on his investigation of the peasant question, which culminated in his magisterial *Development of Capitalism in Russia* (published legally in 1899). In this work he argued that capitalism was rapidly destroying the peasant commune. The peasantry, for the Populists a homogeneous social class, was in actuality rapidly stratifying into a well-off rural bourgeoisie, a middling peasantry, and an impoverished rural "proletariat and semi-proletariat." In this last group, which comprised half the peasant population, Lenin found an ally for the extremely small industrial proletariat in Russia.

Iskra's success in recruiting Russian intellectuals to Marxism led Lenin and his comrades to believe that the time was ripe to found a revolutionary Marxist party that would weld together all the disparate Marxist groups at home and abroad. An abortive First Congress, held in 1898 in Minsk, had failed to achieve this objective, for most of the delegates were arrested shortly after the congress. The organizing committee of the Second Congress decided to convene the congress in Brussels in 1903, but police pressure forced it to transfer to London.

The congress sessions wore on for nearly three weeks, for no point appeared too trivial to debate. But the main issues quickly became plain: eligibility for membership and the character of party discipline; but, above all, the key issue focussed on the relation between the party and the proletariat, for whom the party claimed to speak.

In his *What Is To Be Done?* (1902), Lenin totally rejected the view that the proletariat was being driven spontaneously to revolutionary Socialism by capitalism and that the party should merely coordinate the struggle of the proletariat's diverse sections on a national and international scale. Capitalism, he contended, predisposed the workers to the acceptance of Socialism but did not spontaneously make them conscious Socialists. The proletariat by its own efforts in the everyday struggle against the capitalist could achieve "trade-union consciousness." But the proletariat could not by its own efforts grasp that it could win complete emancipation only by overthrowing capitalism and building Socialism, unless the party from without infused it with Socialist consciousness.

In his *What Is To Be Done?* and in his other works on party organization, Lenin created one of his most momentous political innovations, his theory of the party as the "vanguard of the proletariat." He saw the vanguard as a highly disciplined, centralized party that worked unremittingly to suffuse the proletariat with Socialist consciousness and served as mentor, leader, and guide, constantly showing the proletariat where its true class interests lie.

The "vanguard of the proletariat"

At the Second Congress the *Iskra* group split, and Lenin found himself in a minority on this very issue. Nevertheless, he continued to develop his view of "the party of a new type," which must be guided by "democratic centralism," or absolute party discipline. The party must be a highly centralized body organized around a small, ideologically homogeneous, hardened core of experienced professional revolutionaries, who were elected to the central committee by the party congress and who led a ramified hierarchy of lower party organizations that enjoyed the support and sympathy of the proletariat and all groups opposed to tsarism. "Give us an organization of revolutionaries," Lenin exclaimed, "and we will overturn Russia!"

Lenin spared no effort to build just this kind of party over the next 20 years, despite fierce attacks on his conception by some of his closest comrades of the *Iskra* days, Plekhanov, Martov, and Leon Trotsky. They charged that his scheme of party organization and discipline tended toward "Jacobinism," suppression of free intraparty discussion, a dictatorship *over* the proletariat, not *of* the proletariat, and, finally, establishment of a one-man dictatorship.

Lenin found himself in the minority in the early sessions of the Second Congress of what was now proclaimed to be the Russian Social-Democratic Workers' Party (RSDWP). But a walkout by a disgruntled group of Jewish Social-Democrats, the Bund, left Lenin with a slight majority. Consequently, the members of Lenin's adventitious majority were called Bolsheviks (majoritarians), and Martov's group were dubbed Mensheviks (minoritarians). The two groups fought each other ceaselessly within the same RSDWP and professed the same program until 1912, when Lenin made the split final at the Prague Conference of the Bolshevik Party.

The Bolsheviks and the Mensheviks

CHALLENGES OF THE REVOLUTION OF 1905 AND WORLD WAR I

The differences between Lenin and the Mensheviks became sharper in the Revolution of 1905 and its aftermath, when Lenin moved to a distinctly original view on two issues: class alignments in the revolution and the character of the post-revolutionary regime.

The outbreak of the revolution, in January 1905, found Lenin abroad in Switzerland, and he did not return to Russia until November. Immediately Lenin set down a novel strategy. Both wings of the RSDWP, Bolshevik and Menshevik, adhered to Plekhanov's view of the revolution in two stages: first, a bourgeois revolution; second, a proletarian revolution (see above). But the Mensheviks argued that the bourgeois revolution must be led by the bourgeoisie, with whom the proletariat must ally itself in order to make the democratic revolution. This would bring the liberal bourgeoisie to full power, whereupon the RSDWP would act as the party of opposition. Lenin defiantly rejected this kind of alliance and post-revolutionary regime. Hitherto he had spoken of the need for the proletariat to win "hegemony" in the democratic revolution. Now he flatly declared that the proletariat was the driving force of the revolution and that its only reliable ally was the peasantry. The bourgeoisie he branded as hopelessly counterrevolutionary and too cowardly to make its own revolution. Thus, unlike the Mensheviks, Lenin henceforth banked on an alliance that would establish a "revolutionary democratic dictatorship of the proletariat and the peasantry."

Nor would the revolution necessarily stop at the first stage, the bourgeois revolution. If the Russian revolution should inspire the western European proletariat to make the Socialist revolution, for which industrial Europe was ripe, the Russian revolution might well pass over directly to the second stage, the Socialist revolution. Then, the Russian proletariat, supported by the rural proletariat and semi-proletariat at home and assisted by the triumphant industrial proletariat of the West, which had established its "dictatorship of the proletariat," could cut short the life-span of Russian capitalism.

Years of discouragement

After the defeat of the Revolution of 1905, the issue between Lenin and the Mensheviks was more clearly drawn than ever, despite efforts at reunion. But, forced again into exile from 1907 to 1917, Lenin found serious challenges to his policies not only from the Mensheviks but within his own faction as well. The combination of repression and modest reform effected by the tsarist regime led to a decline of party membership. Disillusionment and despair in the chances of successful revolution swept the dwindled party ranks, rent by controversies over tactics and philosophy. Attempts to unite the Bolshevik and Menshevik factions came to naught, all breaking on Lenin's intransigent insistence that his conditions for reunification be adopted. As one Menshevik opponent described Lenin: "There is no other man who is absorbed by the revolution twenty-four hours a day, who has no other thoughts but the thought of revolution, and who even when he sleeps, dreams of nothing but revolution." Placing revolution above party unity, Lenin would accept no unity compromise if he thought it might delay, not accelerate, revolution.

Desperately fighting to maintain the cohesion of the Bolsheviks against internal differences and the Mensheviks' growing strength at home, Lenin convened the Bolshevik Party Conference at Prague, in 1912, which split the RSDWP forever. Lenin proclaimed that the Bolsheviks were the RSDWP and that the Mensheviks were schismatics. Thereafter, each faction maintained its separate central committee, party apparatus, and press.

When war broke out, in August 1914, Socialist parties throughout Europe rallied behind their governments despite the resolutions of prewar congresses of the Second International obliging them to resist or even overthrow their respective governments if they plunged their countries into an imperialist war.

Denunciation of pro-war Socialists

After Lenin recovered from his initial disbelief in this "betrayal" of the International, he proclaimed a policy whose audacity stunned his own Bolshevik comrades. He denounced the pro-war Socialists as "social-chauvinists" who had betrayed the international working-class cause by support of a war that was imperialist on both sides. He pronounced the Second International as dead and appealed for the creation of a new, Third International composed of genuinely revolutionary Socialist parties. More immediately, revolutionary Socialists must work to "transform the imperialist war into civil war." The real enemy of the worker was not the worker in the opposite trench but the capitalist at home. Workers and soldiers should therefore turn their guns on their rulers and destroy the system that had plunged them into imperialist carnage.

Lenin's policy found few advocates in Russia or elsewhere in the first months of the war. Indeed, in the first flush of patriotic fervour, not a few Bolsheviks supported the war effort. Lenin and his closest comrades were left an isolated band swimming against the current.

Lenin succeeded in reaching neutral Switzerland in September 1914, there joining a small group of anti-war Bolshevik and Menshevik émigrés. The war virtually cut them off from all contact with Russia and with like-minded Socialists in other countries. Nevertheless, in 1915 and 1916, anti-war Socialists in various countries managed to hold two anti-war conferences in Zimmerwald and Kienthal, Switzerland. Lenin failed at both meetings to persuade his comrades to adopt his slogan: "transform the imperialist war into civil war!" They adopted instead the more moderate formula: "An immediate peace without annexations or indemnities and the right of the peoples to self-determination." Lenin consequently found his party a minority within the group of anti-war Socialists, who, in turn, constituted a small minority of the international Socialist movement compared with the pro-war Socialists.

Lenin's theory of imperialism

Undaunted, Lenin continued to hammer home his views on the war, confident that eventually he would win decisive support. In his *Imperialism, the Highest Stage of Capitalism* (1917), he set out to explain, first, the real causes of the war; second, why Socialists had abandoned internationalism for patriotism and supported the war; and third, why revolution alone could bring about a just, democratic peace.

War erupted, he wrote, because of the insatiable, expansionist character of imperialism, itself a product of monopoly finance capitalism. At the end of the 19th century, a handful of banks had come to dominate the advanced countries, which, by 1914, had in their respective empires brought the rest of the world under their direct or indirect controls. Amassing vast quantities of "surplus" capital, the giant banks found they could garner superprofits on investments in colonies and semi-colonies, and this intensified the race for empire among the great powers. By 1914, dissatisfied with the way the world had been shared out, rival coalitions of imperialists launched the war to bring about a redivision of the world at the expense of the other coalition. The war was therefore imperialist in its origins and aims and deserved the condemnation of genuine Socialists.

Socialist Party and trade-union leaders had rallied to support their respective imperialist governments because they represented the "labour aristocracy," the better paid workers who received a small share of the colonial "superprofits" the imperialists proffered them. "Bribed" by the imperialists, the "labour aristocracy" took the side of their paymasters in the imperialist war and betrayed the most exploited workers at home and the super-exploited in the colonies. The imperialists, Lenin contended, driven by an annexationist dynamic, could not conclude a just, lasting peace. Future wars were inevitable so long as imperialism existed; imperialism was inevitable so long as capitalism existed; only the overthrow of capitalism everywhere could end the imperialist war and prevent such wars in the future. First published in Russia in 1917, *Imperialism* to this day provides the instrument that Communists everywhere employ to evaluate major trends in the non-Communist world.

LEADERSHIP IN THE RUSSIAN REVOLUTION

By 1917 it seemed to Lenin that the war would never end and that the prospect of revolution was rapidly receding. But in the week of March 8–15, the starving, freezing, war-weary workers and soldiers of Petrograd (until 1914, St. Petersburg) succeeded in deposing the Tsar. Lenin and his closest lieutenants hastened home after the German authorities agreed to permit their passage through Germany to neutral Sweden. Berlin hoped that the return of anti-war Socialists to Russia would undermine the Russian war effort.

First return to Petrograd. Lenin arrived in Petrograd

The Provisional Government

on April 16, 1917, one month after the Tsar had been forced to abdicate. Out of the revolution was born the Provisional Government, formed by a group of leaders of the bourgeois liberal parties. This government's accession to power was made possible only by the assent of the Petrograd Soviet, a council of workers' deputies elected in the factories of the capital. Similar soviets of workers' deputies sprang up in all the major cities and towns throughout the country, as did soviets of soldiers' deputies and of peasants' deputies. Although the Petrograd Soviet had been the sole political power recognized by the revolutionary workers and soldiers in March 1917, its leaders had hastily turned full power over to the Provisional Government. The Petrograd Soviet was headed by a majority composed of Menshevik and Socialist Revolutionary (SR), or peasant party, leaders who regarded the March (February, O.S.) Revolution as bourgeois; hence, they believed that the new regime should be headed by leaders of the bourgeois parties.

On his return to Russia, Lenin electrified his own comrades, most of whom accepted the authority of the Provisional Government. Lenin called this government, despite its democratic pretensions, thoroughly imperialist and undeserving of support by Socialists. It was incapable of satisfying the most profound desires of the workers, soldiers, and peasants for immediate peace and division of landed estates among the peasants.

Only a soviet government—that is, direct rule by workers, soldiers, and peasants—could fulfill these demands. Therefore, he raised the battle cry, "All power to the Soviets!"—although the Bolsheviks still constituted a minority within the soviets and despite the manifest unwillingness of the Menshevik–SR majority to exercise such power. This introduced what Lenin called the period of "dual power." Under the leadership of "opportunist" Socialists, the soviets, the real power, had relinquished power to the Provisional Government, the nominal power in the land. The Bolsheviks, Lenin exhorted, must persuade the workers, peasants, and soldiers, temporarily deceived by the "opportunists," to retrieve state power for the soviets from the Provisional Government. This would constitute a second revolution. But, so long as the government did not suppress the revolutionary parties, this revolution could be achieved peacefully, since the Provisional Government existed only by the sufferance of the soviets.

Initially, Lenin's fellow Bolsheviks thought that he was temporarily disoriented by the complexity of the situation; moderate Socialists thought him mad. It required several weeks of sedulous persuasion by Lenin before he won the Bolshevik Party Central Committee to his view. The April Party Conference endorsed his program: the party must withhold support from the Provisional Government and win a majority in the soviets in favour of soviet power. A soviet government, once established, should begin immediate negotiations for a general peace on all fronts. The soviets should forthwith confiscate landlords' estates without compensation, nationalize all land, and divide it among the peasants. And the government should establish tight controls over privately owned industry to the benefit of labour.

Rise of the Bolsheviks

From March to September 1917, the Bolsheviks remained a minority in the soviets. By autumn, however, the Provisional Government (since July headed by the moderate Socialist Aleksandr Kerensky, who was supported by the moderate Socialist leadership of the soviets) had lost popular support. Increasing war-weariness and the breakdown of the economy overtaxed the patience of the workers, peasants, and soldiers, who demanded immediate and fundamental change. Lenin capitalized on the growing disillusionment of the people with Kerensky's ability and willingness to complete the revolution. Kerensky, in turn, claimed that only a freely elected constituent assembly would have the power to decide Russia's political future—but that must await the return of order. Meanwhile, Lenin and the party demanded peace, land, and bread—immediately, without further delay. The Bolshevik line won increasing support among the workers, soldiers, and peasants. By September they voted in a Bolshevik majority in the Petrograd Soviet and in the soviets of the major cities and towns throughout the country.

Decision to seize power. Lenin, who had gone underground in July after he had been accused as a "German agent" by Kerensky's government, now decided that the time was ripe to seize power. The party must immediately begin preparations for an armed uprising to depose the Provisional Government and transfer state power to the soviets, now headed by a Bolshevik majority.

Lenin's decision to establish soviet power derived from his belief that the proletarian revolution must smash the existing state machinery and introduce a "dictatorship of the proletariat"; that is, direct rule by the armed workers and peasants which would eventually "wither away" into a non-coercive, classless, stateless, Communist society. He expounded this view most trenchantly in his brochure *The State and Revolution,* written while he was still in hiding. The brochure, though never completed and often dismissed as Lenin's most "Utopian" work, nevertheless served as Lenin's doctrinal springboard to power.

Until 1917 all revolutionary Socialists rightly believed, Lenin wrote, that a parliamentary republic could serve a Socialist system as well as a capitalist. But the Russian Revolution had brought forth something new, the soviets. Created by workers, soldiers, and peasants and excluding the propertied classes, the soviets infinitely surpassed the most democratic of parliaments in democracy, because parliaments everywhere virtually excluded workers and peasants. The choice before Russia in early September 1917, as Lenin saw it, was either a soviet republic—a dictatorship of the propertyless majority—or a parliamentary republic—as he saw it, a dictatorship of the propertied minority.

Lenin therefore raised the slogan, "All power to the Soviets!", even though he had willingly conceded in the spring of 1917 that revolutionary Russia was the "freest of all the belligerent countries." To Lenin, however, the Provisional Government was merely a "dictatorship of the bourgeoisie" that kept Russia in the imperialist war. What is more, it had turned openly counterrevolutionary in the month of July when it accused the Bolshevik leaders of treason.

From late September, Lenin, a fugitive in Finland, sent a stream of articles and letters to Petrograd feverishly exhorting the Party Central Committee to organize an armed uprising without delay. The opportune moment might be lost. But for nearly a month Lenin's forceful urgings from afar were unsuccessful. As in April, Lenin again found himself in the party minority. He resorted to a desperate stratagem.

Around October 20, Lenin, in disguise and at considerable personal risk, slipped into Petrograd and attended a secret meeting of the Bolshevik Central Committee held on the evening of October 23. Not until after a heated 10-hour debate did he finally win a majority in favour of preparing an armed takeover. Now steps to enlist the support of soldiers and sailors and to train the Red Guards, the Bolshevik-led workers' militia, for an armed takeover proceeded openly under the guise of self-defense of the Petrograd Soviet. But preparations moved haltingly, because serious opposition to the fateful decision persisted in the Central Committee. Enthusiastically in accord with Lenin on the timeliness of an armed uprising, Trotsky led its preparation from his strategic position as newly elected chairman of the Petrograd Soviet. Lenin, now hiding in Petrograd and fearful of further procrastination, desperately pressed the Central Committee to fix an early date for the uprising. On the evening of November 6, he wrote a letter to the members of the Central Committee exhorting them to proceed that very evening to arrest the members of the Provisional Government. To delay would be "fatal." The Second All-Russian Congress of Soviets, scheduled to convene the next evening, should be placed before a *fait accompli.*

Overthrow of the Provisional Government

On November 7 and 8, the Bolshevik-led Red Guards and revolutionary soldiers and sailors, meeting only slight resistance, deposed the Provisional Government and proclaimed that state power had passed into the hands of the Soviets. By this time the Bolsheviks, with their allies among the Left SR's (dissidents who broke with the pro-Kerensky SR leaders), constituted an absolute majority of the Second All-Russian Congress of Soviets. The delegates therefore voted overwhelmingly to accept full power and elected Lenin as chairman of the Council of People's Commissars, the new Soviet Government, and approved his Peace Decree and Land Decree. Overnight, Lenin had vaulted from his hideout as a fugitive to head the Revolutionary government of the largest country in the world. Since his youth he had spent his life building a party that would win such a victory, and now at the age of 47 he and his party had triumphed. "It makes one's head spin," he confessed. But power neither intoxicated nor frightened Lenin; it cleared his head. Soberly, he steered the Soviet government toward the consolidation of its power and negotiations for peace.

Saving the Revolution. In both spheres, Lenin was plagued by breaks within the ranks of Bolshevik leaders. He reluctantly agreed with the right-wingers that it would be desirable to include the Menshevik and Right SR parties in a coalition government—but on Lenin's terms. They must above all accept the soviet form of government, not a parliamentary one; they refused. Only the Left SR's agreed, and several were included in the Soviet government. Likewise, when the freely elected Constituent Assembly met in January 1918, the Mensheviks and Right SR majority flatly rejected sovietism. Lenin without hesitation ordered the dispersal of the Constituent Assembly.

The Allies refused to recognize the Soviet government; consequently it entered alone into peace negotiations with the Central Powers (Germany and her allies Austro-Hungary and Turkey) at the town of Brest-Litovsk. They imposed ruinous conditions that would strip away from Soviet Russia the western tier of non-Russian nations of the old Russian Empire. Left Communists fanatically opposed acceptance and preached a revolutionary war, even if it imperilled the Soviet government. Lenin insisted that the terms, however ruinous and humiliating, must be accepted or he would resign from the government. He sensed that peace was the deepest yearning of the people; in any case, the shattered army could not raise effective resistance to the invader. Finally, in March 1918, after a still larger part had been carved out of old Russia by the enemy, Lenin succeeded in winning the Central Committee's acceptance of the Treaty of Brest-Litovsk. At last Russia was at peace.

Treaty of Brest-Litovsk

But Brest-Litovsk only intensified the determination of counterrevolutionary forces and the Allies who supported them to bring about the overthrow of the Soviet government. That determination hardened when, in 1918, Lenin's government repudiated repayments of all foreign loans obtained by the tsarist and Provisional governments and nationalized foreign properties in Russia without compensation. From 1918 to 1920 Russia was torn by a Civil War, which cost millions of lives and untold destruction. One of the earliest victims was Lenin himself. In August 1918 an assassin fired two bullets into Lenin as he left a factory in which he had just delivered a speech. Because of his robust constitution, he recovered rapidly.

The Soviet government faced tremendous odds. The anti-Soviet forces, or Whites, headed mainly by former tsarist generals and admirals, fought desperately to overthrow the Red regime. Moreover, the Whites were lavishly supplied by the Allies with materiel, money, and support troops that secured White bases. Yet, the Whites failed.

It was largely because of Lenin's inspired leadership that the Soviet government managed to survive against such military odds. He caused the formation and guided the strategy of the Workers' and Peasants' Red Army, commanded by Trotsky. Although the economy had collapsed, he managed to mobilize sufficient resources to sustain the Red Army and the industrial workers. But above all it was his political leadership that saved the day for the Soviets. By proclaiming the right of the peoples to self-determination, including the right to secession, he won the active sympathy, or at least the benevolent neutrality, of the non-Russian nationalities within Russia, because the Whites did not recognize that right. Indeed, his perceptive, skillful policy on the national question enabled Soviet Russia to avoid total disintegration and to remain a huge multinational state. By making the industrial workers the new privileged class, favoured in the distribution of rations, housing, and political power, he retained the loyalty of the proletariat. His championing of the peasants' demand that they take all the land from the gentry, church, and crown without compensation won over the peasants, without whose support the government could not survive.

Because of the breakdown of the economy, however, Lenin adopted a policy toward the peasant that threatened to destroy the Soviet government. Lacking funds or goods to exchange against grain needed to feed the Red Army and the towns, Lenin instituted a system of requisitioning grain surpluses without compensation. Many peasants resisted—at least until they experienced White "liberation." On the territories that the Whites won, they restored landed property to the previous owners and savagely punished the peasants who had dared seize the land. Despite the peasants' detestation of the Soviet's grain requisitioning, the peasants, when forced to choose between Reds and Whites, chose the Reds.

The New Economic Policy

After the defeat of the Whites, the peasants no longer had to make that choice. They now totally refused to surrender their grain to the government. Threatened by mass peasant rebellion, Lenin called a retreat. In March 1921 the government introduced the New Economic Policy, which ended the system of grain requisitioning and permitted the peasant to sell his harvest on an open market. This constituted a partial retreat to capitalism.

From the moment Lenin came to power, his abiding aims in international relations were twofold: to prevent the formation of an imperialist united front against Soviet Russia; but, even more important, to stimulate proletarian revolutions abroad.

In his first aim he largely succeeded. In 1924, shortly after his death, Soviet Russia had won de jure recognition of all the major world powers except the United States. But his greater hope of the formation of a world republic of soviets failed to materialize, and Soviet Russia was left isolated in hostile capitalist encirclement.

Formation of the Third International. To break this encirclement, he had called on revolutionaries to form Communist parties that would emulate the example of the Bolshevik Revolution in all countries. Dramatizing his break with the reformist Second International, in 1918 he had changed the name of the RSDWP to the Russian Communist Party (Bolsheviks), and in March 1919 he founded the Communist, or Third, International. This International accepted the affiliation only of parties that accepted its decisions as binding, imposed iron discipline, and made a clean break with the Second International. In sum, Lenin now held up the Russian Communist Party, the only party that had made a successful revolution, as the model for Communist parties in all countries. One result of this policy was to engender a split in the world labour movement between the adherents of the two internationals.

The Communist International scored its greatest success in the colonial world. By championing the rights of the peoples in the colonies and semi-colonies to self-determination and independence, the International won considerable sympathy for Communism. Lenin's policy in this question still reverberates through the world today. And it offers another example of Lenin's unique ability to find allies where revolutionaries had not found them before. By taking the side of the national liberation movements, Lenin could claim that the overwhelming majority of the world's population, then living under imperialist rule, as well as the European proletariat, were the natural allies of the Bolshevik Revolution.

Thus Lenin's revolutionary genius was not confined to his ability to divide his enemies; more important was his skill in finding allies and friends for the exiguous proletariat of Russia. First, he won the Russian peasants to the side of the proletariat. Second, while he did not win the workers to make successful Communist revolutions in the West, they did compel their governments to curtail armed intervention against the Bolshevik Revolution. Third, while the Asian revolutions barely stirred in his lifetime, they did strengthen the Soviet Communists in the belief that they were not alone in a hostile world.

By 1921 Lenin's government had crushed all opposition parties on the grounds that they had opposed or failed to support sufficiently the Soviet cause in the Civil War. Now that peace had come, Lenin believed that their opposition was more dangerous than ever, since the peasantry and even a large section of the working class had become disaffected with the Soviet regime. To repress opponents of Bolshevism, Lenin demanded the harshest measures, including "show" trials and frequent resort to the death penalty. Moreover, he insisted on even tighter control over dissent within the party. Lenin's insistence on merciless destruction of the opposition to the Bolshevik dictatorship subsequently led many observers to conclude that Lenin, though personally opposed to one-man rule, nevertheless unwittingly cleared the way for the rise of Joseph Stalin's dictatorship.

Suppression of dissent

By 1922 Lenin had become keenly aware that degeneration of the Soviet system and party was the greatest danger to the cause of Socialism in Russia. He found the party and Soviet state apparatus hopelessly entangled in red tape and incompetence. Even the agency headed by Stalin that was responsible for streamlining administration was, in fact, less efficient than the rest of the government. The Soviets of Workers' and Peasants' Deputies had been drained of all power, which had flowed to the centre. Most disturbing was the Great Russian chauvinism that leading Bolsheviks manifested toward the non-Russian nationalities in the reorganization of the state in which Stalin was playing a key role. Moreover, in April 1922 Stalin won appointment as general secretary of the party, in which post he was rapidly concentrating immense power in his hands. Soviet Russia in Lenin's last years could not have been more remote from the picture of Socialism he had portrayed in *State and Revolution.* Lenin strained every nerve to reverse these trends, which he regarded as antithetical to Socialism, and to replace Stalin.

Illness and death. In the spring of 1922, however, Lenin fell seriously ill. In April his doctors extracted from his neck one of the bullets he had received from the assassin's gun in August 1918. He recovered rapidly from the operation, but a month later he fell ill, partially paralyzed and unable to speak. In June he made a partial recovery and threw himself into the formation of the Union of Soviet Socialist Republics, the federal system of reorganization he favoured against Stalin's unitary scheme. But in December he was again incapacitated by semi-paralysis. Although no longer the active leader of the state and party, he did muster the strength to dictate several prescient articles and what is called his political "Testament," dictated to his secretary between December 23, 1922, and January 4, 1923, in which he expressed a great fear for the stability of the party under the leadership of disparate, forceful personalities such as Stalin and Trotsky. On March 10, 1923, another stroke deprived him of speech. His political activity came to an end. He suffered yet another stroke on the morning of January 21, 1924, and died that evening at Gorky, near Moscow.

The last year of Lenin's political life, when he fought to eradicate abuses of his Socialist ideals and the corruption of power, may well have been his greatest. Whether the history of the Soviet Union would have been fundamentally different had he survived beyond his 54th birthday, no one can say with certainty. (Al.Re.)

MAJOR WORKS

BOOKS: *Chto Takoye "Druzya Naroda," kak oni voyuyut protiv Sotsial-Demokratov?* (hectographic editions from 1894, printed from 1920; *What the "Friends of the People" Are, and How They Fight the Social-Democrats,* 1946); *Razvitiye kapitalizma v Rossi* (1899; augmented ed., 1908; *The Development of Capitalism in Russia,* 1956); *Chto delat?* (1902; *What Is To Be Done?,* 1929, 1933, 1950, 1963); *Shag vperyod, dva shaga nazad* (1904; *One Step Forward, Two Steps Back,* 1941); *Dve taktiki Sotsial-Demokraty v demokraticheskoy revolyutsi* (1905; *Two Tactics of Social-Democracy in the Democratic Revolution,* 1935, 1947); *Agrarny vopros i "Kritiki Marksa"* (1908, first chapters already published in periodicals from 1901); *Agrarnaya programma Sotsial-Demokratyi v pervoy russkoy revolyutsi 1905–1907 godov* (1908, 1917; *The Agrarian Programme of Social-Democracy in the First Russian Revolution,* 1954); *Imperializm, kak noveyshy etap kapitalizma* (1917, later retitled *Imperializm, kak vysshaya stadiya kapitalizma; Imperialism: The Latest Stage in the Development of Capitalism,* 1924; and *Imperialism, the Highest Stage of Capitalism,* 1933, 1939, 1947); *Gosudarstvo i revolyutsiya* (1917; *The State and Revolution,* 1919); *Proletarskaya revolyutsiya i renegat Kautsky* (1918; *The Proletarian Revolution and Kautsky the Renegade,* 1920); *Detskaya bolezn "levizny" v kommunizme* (1920; *"Left Wing" Communism: An Infantile Disorder,* 1920, 1934, 1961).

MARXIST PERIODICALS EDITED OR CONTROLLED BY LENIN: *Iskra,* 51 numbers (1900–03); *Zarya,* 4 numbers (1901–02); *Vperyod,* weekly, 18 numbers (1905); *Novaya Zhizn,* daily, 28 numbers (1905); *Proletary,* weekly, 26 numbers (1905); *Volna,* daily, 25 numbers (1906); *Vperyod,* daily, 17 numbers (1906); *Ekho,* daily, 14 numbers (1906); *Proletary,* 50 numbers (1906–09); *Sotsial-Demokrat,* 58 numbers (1908–17; wholly Leninist from 1911); *Zvezda,* at first weekly, then more frequent, 69 numbers (1910–12); *Rabochaya Gazeta,* 9 numbers (1910–12); *Prosveshcheniye,* monthly, 31 numbers (1911–14; and 1 final number, 1917); *Pravda,* daily (1912–14 and from 1917 with numerous changes of name 1913–14 and July-October 1917); *Kommunist,* 1 double number (1915); *Sbornik Sotsial-Demokrata,* 2 numbers (1916).

JOURNALISM AND PARTY THESES: "O zadachakh proletariata v dannoy revolyutsi" (*The April Theses,* 1951), "O dvoevlasti," and "Uroki revolyutsi" (*Lessons of the Revolution,* 1918), all in *Pravda,* 1917; "Ocherednye zadachi Sovietskoy vlasti," *Pravda* (1918; *The Soviets at Work,* 1918; and *The Immediate Tasks of the Soviet Government,* 1951).

BIBLIOGRAPHY

Editions: The fifth and most complete collection of Lenin's works was published in Moscow in 55 vol. (1958–65; with index, 1966; reference volume in two parts, 1967–70). The *Collected Works,* 45 vol. (1960–70, reprinted 1980), is a Soviet English translation of the 4th Russian edition of Lenin's works, enriched by editorial notes from the 5th edition. *Selected Works,* 3 vol. (1970–71), includes most of the works mentioned in this article and many more. Other selections published in the Soviet Union include all the major works, as well as shorter writings, correspondence, and speeches, for the most part taken from the English translation of the 4th edition of the *Collected Works.* C. LEITEIZEN and J.S. ALLEN (eds.), *Lenin on the United States: Selected Writings* (1967, reprinted 1975), includes material from the period 1905–22. Western publications of Lenin's works in English are scarce. They include *The Essentials of Lenin,* 2 vol. (1947, reprinted 1973), which follows the Soviet edition; and ROBERT TUCKER (ed.), *The Lenin Anthology* (1975), with interpretive comments.

Biographical and critical studies: LOUIS FISCHER, *The Life of Lenin* (1964), a major, detailed work, enlivened by the author's own reminiscences of Moscow in Lenin's time; MOSHE LEWIN, *Lenin's Last Struggle* (1968, reprinted 1978; originally published in French, 1967), a brief but incisive account of Lenin's effort to mobilize party forces to curb Stalin and remove him from power; ALFRED MEYER, *Leninism* (1957, reissued 1972), analysis of Lenin's political philosophy; DAVID SHUB, *Lenin,* rev. ed. (1966, reprinted 1977), readable and informative; ADAM B. ULAM, *The Bolsheviks: The Intellectual and Political History of the Triumph of Communism in Russia* (1965, reprinted 1973), a learned political biography of Lenin; BERTRAM D. WOLFE, *Three Who Made a Revolution: A Biographical History,* 4th rev. ed. (1964, reprinted 1978), a pioneering work (biographies of Lenin, Trotsky, and Stalin) that demolishes many myths, and *The Bridge and the Abyss: The Troubled Friendship of Maxim Gorky and V.I. Lenin* (1967, reprinted 1983); NADEZHDA KRUPSKAYA, *Reminiscences of Lenin* (1970; originally published in Russian, 1924, 2nd ed., 1968), reticent, impersonal recollections by Lenin's widow; LEON TROTSKY, *Lenin: Notes for a Biographer* (1971; originally published in Russian, 1924), an appreciation of Lenin of the *Iskra* period and 1917–18, the periods of Trotsky's closest collaboration with Lenin, and *The Young Lenin* (1972, trans. from Russian); NIKOLAI VALENTINOV, *Encounters with Lenin* (1968; originally published in Russian, 1953), and *The Early Years of Lenin* (1969), revealing observations on Lenin's personality by a former associate; DIETRICH GEYER, *Lenin in der Russischen Sozialdemokratie* (1962), a scholarly study of Lenin and the origins of the Bolshevik–Menshevik split. Later studies include LEONARD SCHAPIRO and PETER REDDAWAY (eds.), *Lenin: The Man, the Theorist, the Leader: A Reappraisal* (1967), a collection of essays; E. VICTOR WOLFENSTEIN, *The Revolutionary Personality: Lenin, Trotsky, Gandhi* (1967, reprinted 1971); MICHAEL C. MORGAN, *Lenin* (1971, reprinted 1973), a sympathetic biography; TONY CLIFF, *Lenin,* 4 vol. (1975–79), a political biography, largely hagiographic; and GERDA WEBER and HERMANN WEBER, *Lenin: Life and Works* (1980; originally published in German, 1974).

Lenin is the subject of many historical studies, including HAROLD SHUKMAN, *Lenin and the Russian Revolution* (1967, reprinted 1977), and, with GEORGE KATKOV, *Lenin's Path to*

Power: Bolshevism and the Destiny of Russia (1971); HELMUT GRUBER, *International Communism in the Era of Lenin: A Documentary History* (1967, reissued 1972); BRANKO LAZITCH and MILORAD M. DRACHKOVITCH, *Lenin and the Comintern* (1972); ALFRED ROSMER, *Moscow Under Lenin* (1972; originally published in French, 1953), an insider's account of the period 1920–24, exploring the role of Lenin in the international movement; ALEXANDER RABINOWITCH, *The Bolsheviks Come to Power: The Revolution of 1917 in Petrograd* (1976); THOMAS H. RIGBY, *Lenin's Government: Sovnarkom; 1917–1922* (1979); and HÉLÈNE CARRÈRE D'ENCAUSSE, *Lenin: Revolution and Power* (1982), a study of economic, social, political, and ideological issues.

Interpretive studies include PAUL M. SWEEZY and HARRY MAGDOFF (eds.), *Lenin Today: Eight Essays on the Hundredth Anniversary of Lenin's Birth* (1970), an example of non-Soviet Marxist–Leninist thinking; GEORG LUKÁCS, *Lenin: A Study on the Unity of His Thought* (1971; originally published in German, 1924), an evaluation by a Hungarian Marxist philosopher; DAVID LANE, *Leninism: A Sociological Interpretation* (1981); ALAIN BESANÇON, *The Rise of the Gulag: Intellectual Origins of Leninism* (1981; originally published in French, 1977), a highly critical work aiming to prove the continuity between Leninism and Stalinism; and NEIL HARDING, *Lenin's Political Thought,* 2 vol. (1977–81, reprinted 1983). Official Soviet interpretation of Lenin's role is provided by BORIS N. PONOMAREV, *Lenin and the Revolutionary Process* (1980, trans. from Russian). NINA TUMARKIN, *Lenin Lives!: The Lenin Cult in Soviet Russia* (1983), explores the veneration of Lenin. For bibliography, see DAVID R. EGAN, MELINDA A. EGAN, and JULIE A. GENTHNER, *Lenin: An Annotated Bibliography of English-Language Sources to 1980* (1982).

Leningrad

The second largest city of the Soviet Union and one of the world's major cities, Leningrad has played a vital role in Russian history—for two centuries as capital of the Russian Empire—and it maintains today outstanding importance as an industrial and cultural centre and as a seaport. Founded by Peter I the Great in 1703 as St. Petersburg (Russian Sankt Peterburg), it was renamed Petrograd in 1914 and, finally, Leningrad in 1924. The city is particularly renowned as the scene of the February and October revolutions in 1917, as the besieged and fiercely defended city of World War II, and, architecturally, as one of the most splendid and harmonious cities of Europe. Leningrad lies in the far northwestern corner of the Soviet Union, about 398 miles (640 kilometres) northwest of Moscow and is situated only about 7° south of the Arctic Circle.

This article is divided into the following sections:

Physical and human geography

THE LANDSCAPE

Floods

The city site. Leningrad is located on the delta of the Neva River, at the head of the Gulf of Finland. The city spreads across nearly 42 islands of the delta and across adjacent parts of the mainland floodplain. The very low and originally marshy site has made the city subject to recurrent flooding, especially in the fall, when strong cyclonic winds drive gulf waters upstream, and also at the time of the spring thaw. Exceptionally severe inundations occurred in 1777, 1824, and 1924, the last two being the highest on record and flooding most of the city. To control the destructive floodwaters, the city began construction in the 1980s of an 18-mile-long dike across the Gulf of Finland. A number of canals have also been cut to assist drainage. These, together with the many natural channels, make Leningrad a city of waterways and bridges and have earned it the nickname "Venice of the North."

Greater Leningrad, the city itself with its satellites, forms a horseshoe shape around the head of the Gulf of Finland and includes the island of Kotlin in the gulf. On the north it stretches westward along the shores for nearly 50 miles to include Zelenogorsk. This northern extension is an area of dormitory towns, resorts, sanatoriums, and children's camps set among extensive coniferous forests and fringed by fine beaches and sand dunes. Some influential citizens also have summer cottages, or dachas, in this area. On the southern side of the gulf the metropolitan limits extend westward to include Petrodvorets and Lomonosov. Eastward, Greater Leningrad stretches up the Neva River to Ivanovskoye.

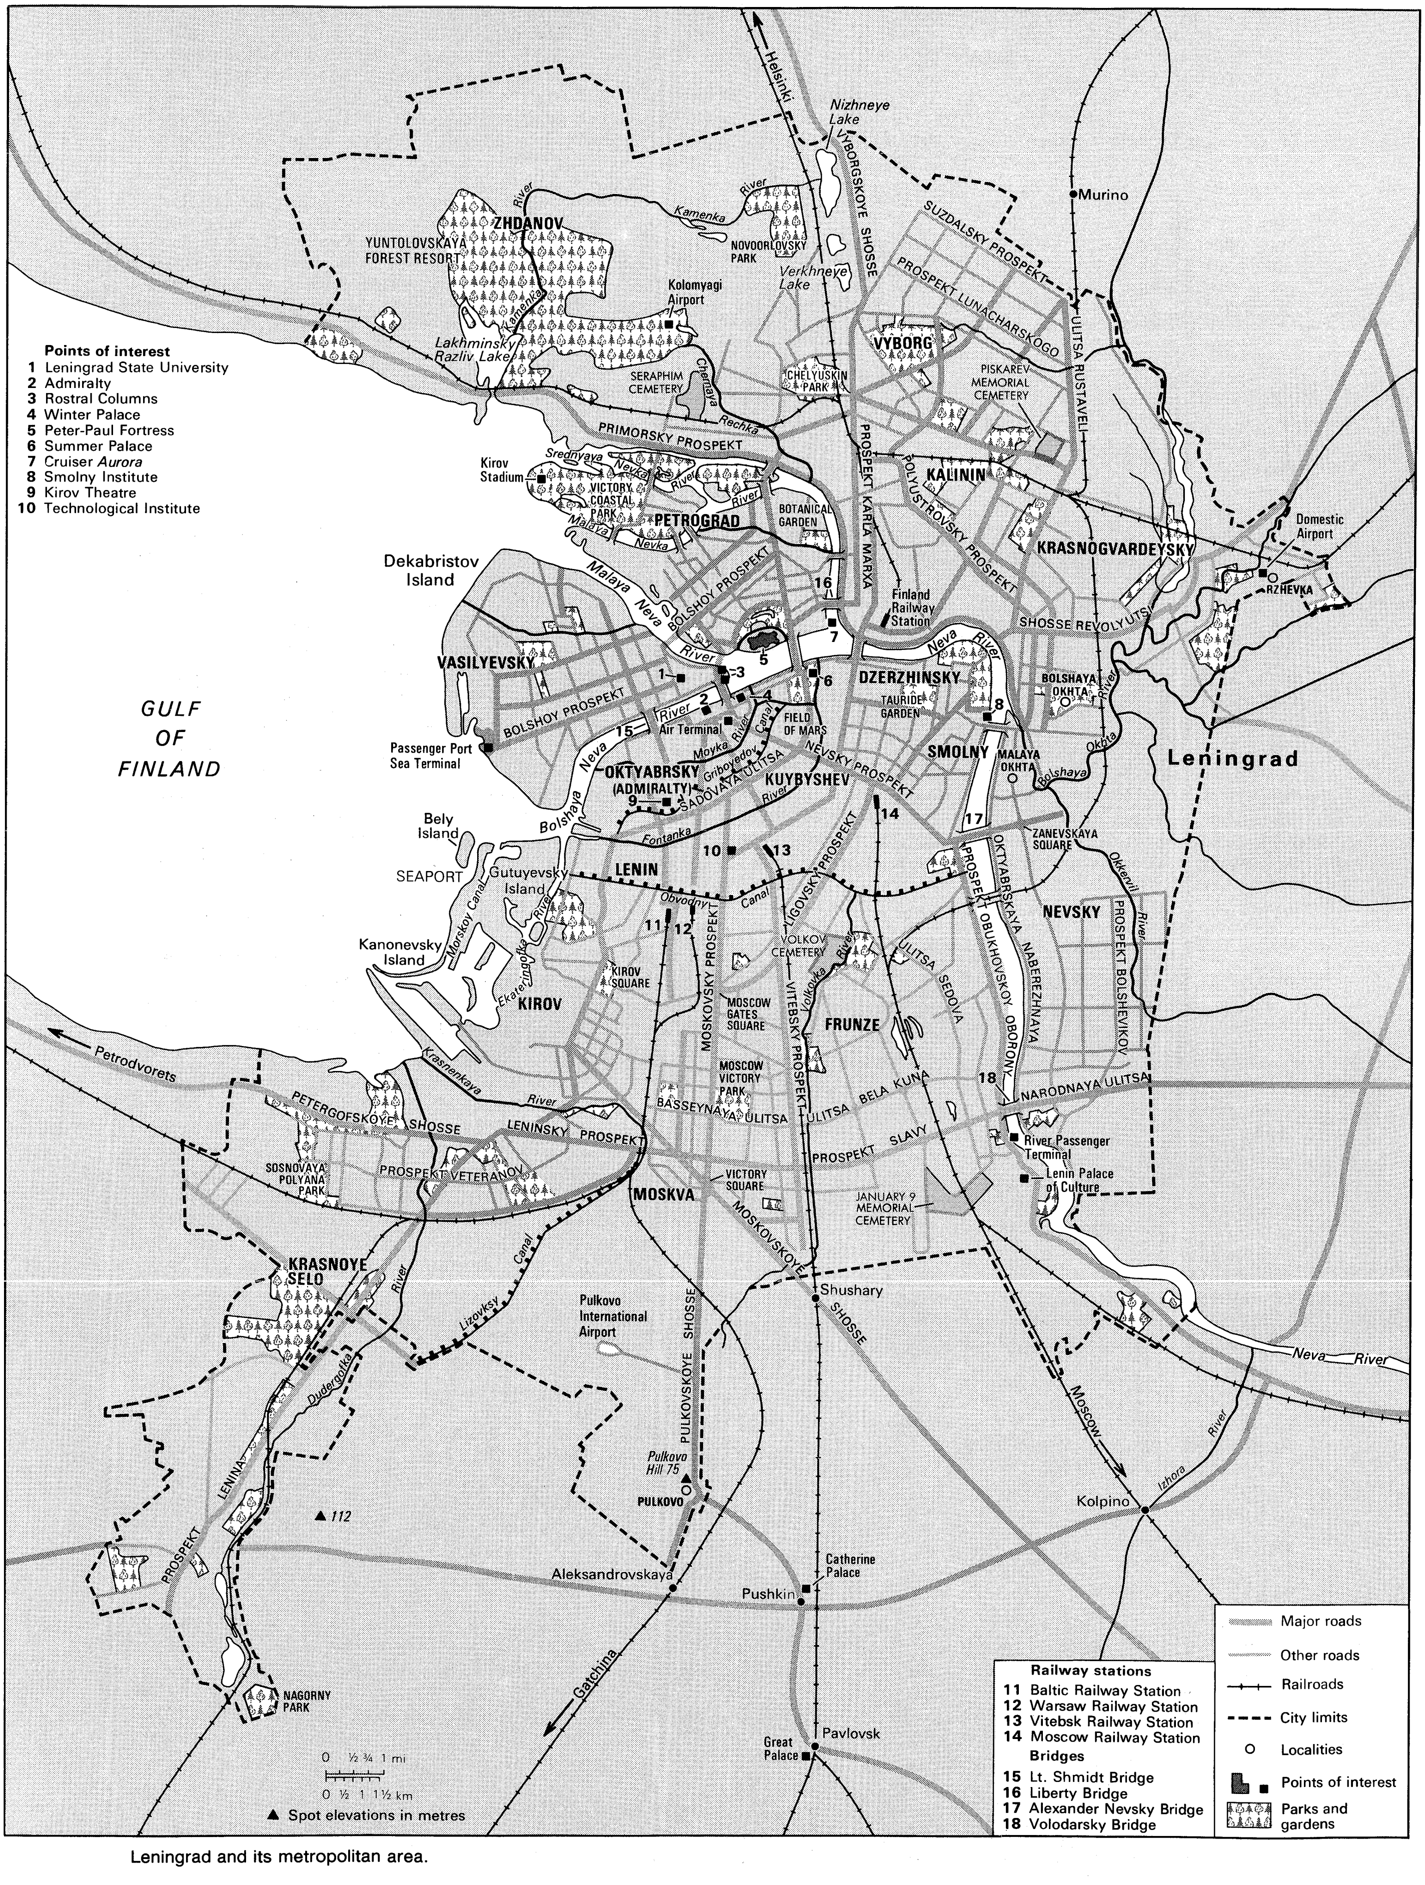
Climate. The mitigating effect of the Atlantic Ocean provides Leningrad with a milder climate than might be expected for its far northern site. Nevertheless, winters are rather cold, with a mean January temperature of about 18° F (−8° C), which is a few degrees warmer than Moscow. Winter temperature, however, can drop below −40° F (−40° C). Snow cover lasts on the average about 132 days. The Neva begins to freeze normally about mid-November, and the ice is solid by the start of December; breakup begins in mid-April and is usually completed by the end of the month. Icebreakers prolong the navigation season. Summers are moderately warm, with an average temperature in July of 64° F (18° C). The mean annual precipitation amounts to about 23 inches (584 millimetres), the maximum coming in summer. Because of Leningrad's northerly location it has long winter nights; in early summer, on the other hand, the city enjoys the half-light "white nights," one of its most renowned features.

The city layout. Central Leningrad is divided by distributaries of the Neva River into four sections. The Admiralty Side lies along the left (south) bank of the Neva itself. Between the two major arms of the Neva, the Bolshaya (Great) Neva and the Malaya (Little) Neva, is Vasilyevsky Island. The Malaya Neva and the distributary known as the Bolshaya Nevka enclose a group of islands known as the Petrograd Side, while east of the Bolshaya Nevka and north of the Neva lies the Vyborg Side.

The Admiralty

The Admiralty Side. Much of Leningrad's historical and cultural heritage is concentrated on the Admiralty Side. The district centres on the Admiralty. This, the nucleus of Peter's original city, was reconstructed in 1806–23 by Andreyan D. Zakharov, as a development of the earlier building of Ivan K. Korobov, remodeled in 1727–38, but retaining the layout of the original. Its elegant spire, topped by a weather vane in the form of a ship, is one of the principal landmarks of the city. The building today houses a naval college.

Just to the east lies the great Palace Square, the city's oldest. The 600-ton granite monolith of the Alexander



Leningrad and its metropolitan area.

Column (1830–34), the tallest of its kind in the world and so finely set that its base is not fastened, thrusts up for 165 feet (50 metres) near the centre of the square.

Between the square and the river rises the huge and massive rectangle of the Winter Palace, the former principal residence of the tsars. The present structure, the fifth to be built, was the Baroque masterpiece of Bartolomeo F. Rastrelli and was built in 1754–62. Both the exterior and the interior of the palace were designed in dazzlingly luxurious style. In 1837 the building was destroyed by fire, and only the adjoining Hermitage survived; the Winter Palace was recreated in 1839 almost exactly according to Rastrelli's plans. The striking appearance of the palace is highlighted by white columns against a green background, with golden stucco moldings; 176 sculptured figures line the roof. The whole complex, now called the Hermitage, or State Hermitage Museum, is a treasure-house of fine art of worldwide significance that originated in 1764 as the private collection of the tsarina Catherine II.

Opposite the Winter Palace, the great crescent of Carlo Rossi's General Staff building (1811–29) dominates the square. The two wings of the building are joined by a huge triumphal arch, topped by heroic figures and crowned by a chariot carrying a figure representing Glory, expressing the Russian victory in the campaign of 1812.

Decembrists' Square

On the western (downstream) side of the Admiralty stretches the expanse that was called Senate Square when the Senate moved there in 1763; it is now called Decembrists' (or Dekabrists') Square in commemoration of the revolt in 1825. The buildings of the former Senate and Synod (now housing archives) dominate the western side of the square, their decorated facades dating from the 1830s and representing the last great work of Rossi. They are separated by an arch looking across to the centre of the square where stands the equestrian statue of Peter the Great, known as the "Bronze Horseman" and created in 1782 by Étienne Falconet. Near the Senate and Synod buildings to the south rises the classical front of the Horse Guards Riding School, or Manezh (1804–07); beyond, dominating the south side of St. Isaac's Square, is the cathedral of the same name. An outstanding monument of late classical Russian architecture built by Auguste Montferrand (1818–58), St. Isaac's is one of the largest domed buildings in the world; its golden cupola, gilded with about 220 pounds (100 kilograms) of pure gold, soars to 331 feet in height and is visible all over Leningrad. It is now a museum.

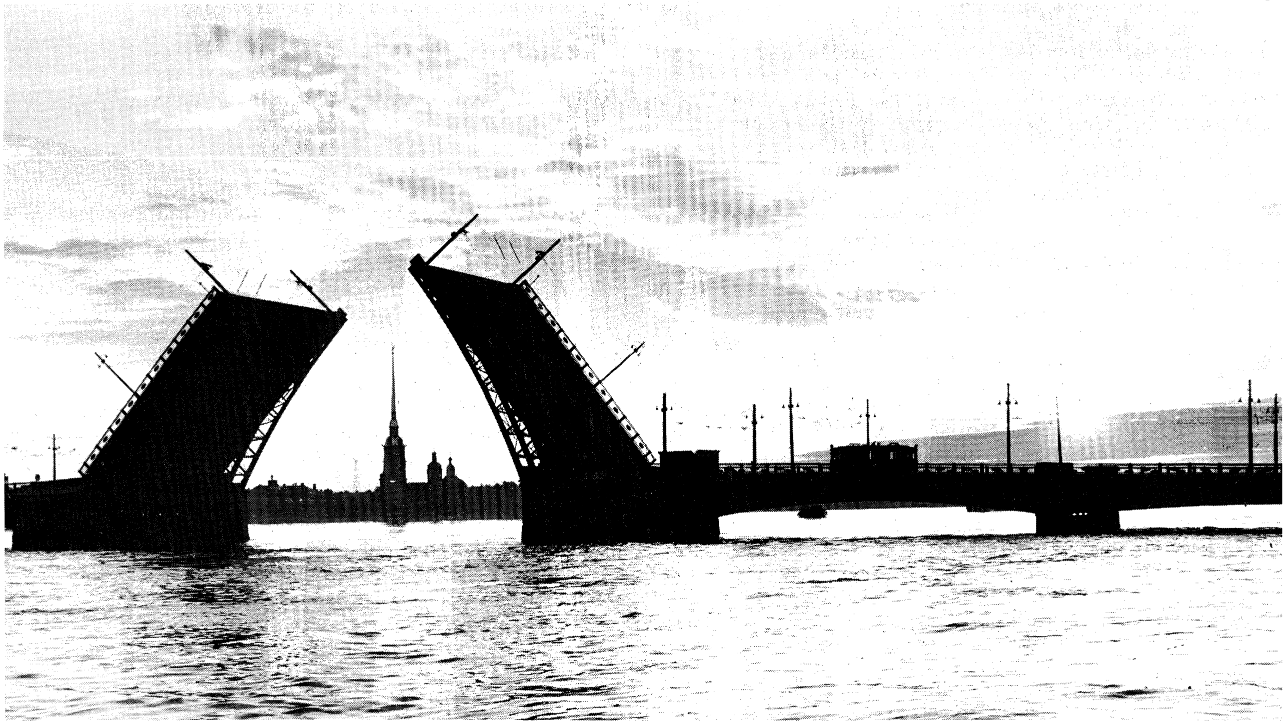
Nevsky Prospekt

From the Admiralty and its surrounding squares radiate three great avenues, of which the most important and best known is the Nevsky Prospekt. One of the world's great thoroughfares, the Nevsky Prospekt cuts southeastward across the peninsula formed by the northward loop of the Neva to the vicinity of the Alexander Nevsky Abbey, crossing the smaller Moyka and Fontanka rivers. The Anichkov Bridge across the latter is graced by four sculptured horses. The street has a special beauty; the architecture is majestic, the buildings are graceful and finely proportioned, the construction is complex. On the Nevsky Prospekt stand the Stroganov, Shuvalov, and Anichkov palaces (former private residences of the nobility) and several churches, of which the most prominent are St. Peter's Lutheran Church (1833–38), St. Catherine's Roman Catholic Church (1763–83), and the Kazan Cathedral (1801–11). The latter edifice, undoubtedly the street's finest feature, was designed by Andrey Voronikhin in Russian classical style and has an interior rich in sculptures and paintings behind a magnificent semicircular frontal colonnade. Another interesting building is the department store Gostiny Dvor (1761–85), originally designed by Jean-Baptiste M. Vallin de la Mothe. This building forms an irregular square and opens onto four streets; formerly it was a mercantile centre. Other department stores line the Nevsky Prospekt, as do many theatres—most notably the Pushkin Academic Drama Theatre—restaurants, and cafés.

At the eastern end of the Nevsky Prospekt, Alexander Nevsky Square fronts the main entrance to the abbey of the same name and its surrounding gardens. Beyond the square's main entrance lie, on the left and right, respectively, monuments and sculptures of the 18th-century Lazarus Cemetery (where Mikhail V. Lomonosov and many of the city's architects are buried) and the 19th-century Tikhvin Cemetery (containing the graves of such writers and composers as Dostoyevsky, Mussorgsky, and Tchaikovsky). Behind rise the spires and cupolas of the Church of the Annunciation (1720, designed by Domenico Trezzini), which is now a museum, and Holy Trinity Cathedral (1778–90, designed by Ivan Starov).

Through the Admiralty Side and intersecting the radial avenues cut the natural channels and canals that so characterize the city. The most important, in outward order

Novosti Press Agency—E. Ettinger



Drawbridge rising over the Neva River, Leningrad. In the background on the right embankment is the Cathedral of St. Peter and St. Paul.

from the Admiralty, are the Moyka and Fontanka rivers and the Griboyedov and Obvodny (Bypass) canals. Downstream from the northern entrance of the Fontanka into the Neva lies the Field of Mars, one of the city's beautiful open spaces. Begun under Peter the Great (when it was known as the Field of Amusement), it was intended for popular festivities and fireworks. It was a favourite haunt of the 18th-century nobility, but its present name derives from a monument erected in 1801 and portraying the great Russian military leader Aleksandr V. Suvorov (buried in the Church of the Annunciation) as the god of war. In the 19th century the space was used for military parades and exercises. The fallen of the 1917 February Revolution and defenders of the city during the civil war and foreign military intervention (1918–20) were buried there. They are commemorated by an eternal flame.

Summer Palace

Just to the east lies the Summer Garden. Founded on an island in 1704, it has parks and gardens that, by the end of the 18th century, contained more than 250 statues and busts, mostly the work of Venetian masters. The Summer Palace, Peter's first in the city, erected 1710–14 in early Russian Baroque style and designed by Trezzini, stands in the northeastern portion. The Neva embankment is fronted by a fence (1784), the iron grille of which is reputed to be among the world's finest examples of wrought iron work. So light and delicate is its design that the grillwork seems almost to be suspended in air.

At the extreme eastern side of the central city, within the sharp bend of the Neva itself, lies the Smolny complex of buildings; these include the former convent, with the five-domed cathedral, designed by Rastrelli and begun in 1748, and the classical building of the Smolny Institute, constructed by Giacomo Quarenghi in 1806–08. The institute was used as Lenin's headquarters in 1917.

The Strelka

Vasilyevsky Island. One of the first areas of Leningrad to be developed because of its defendable position, Vasilyevsky Island forms the northwestern corner of the central city. Opposite the Admiralty and Winter Palace, at the island's eastern tip, is the remarkable architectural complex known as the Strelka (literally, "Pointer"), facing the bifurcation of the Neva. Behind the two great Rostral Columns, decorated by carved ships' prows, and across Pushkin Square, the point rises majestically to the former Exchange building (Thomas de Thomon, 1805–10), the city's finest example of early 19th-century style and reminiscent of a classical Greek temple in appearance; it now houses the Central Naval Museum.

Farther back, the Twelve Colleges building (Trezzini, 1722–42), originally intended to house the supreme governmental bodies of Peter the Great, is now the home of Leningrad A.A. Zhdanov State University. The building is divided into 12 identical but independent sections and runs at right angles to the Neva embankment, which is fronted at that point by the facades of the main building of the Academy of Sciences, the Menshikov Palace, and the Academy of Arts. On the far, or northern, side of the Exchange is the Customs House (now the literary museum and the Institute of Russian Literature known as Pushkin House), designed by Giovanni Luchini (1829–32).

Cathedral of St. Peter and St. Paul

The Petrograd Side. Upstream of the bifurcation of the Neva is the Petrograd Side, where the great Peter–Paul Fortress faces the Strelka across the Malaya Neva. Founded in 1703, this fortification, the city's first structure, initially had earthen walls, but these were soon replaced by stone walls 40 feet high and 12 feet thick, with 300 cannon mounted on the bastions. Above the squat horizontal lines of the fortress's massive walls soars the slender, arrowlike spire of the Cathedral of St. Peter and St. Paul, a golden landmark for the city. The cathedral was built in 1712–33 by Trezzini, and the tsars and tsarinas of Russia from the time of Peter the Great (except for Peter II and Nicholas II) are buried in it. Trezzini also designed St. Peter's (Petrovsky) Gate (1718) as the eastern entrance to the fortress. The Neva Gate, designed by Nikolay A. Lvov, dates from 1787. From the early 19th century the fortress was used as a prison, chiefly for political prisoners. Today it is a museum. At noon each day a cannon is fired from its battlements.

Just to the east of the Peter–Paul Fortress, at the beginning of the distributary known as the Bolshaya Nevka River, the cruiser *Aurora* is permanently moored as a museum and training vessel for the Naval College. It was the *Aurora* that, in 1917, fired a blank shot as a signal to storm the Winter Palace.

Finland Railway Station

The Vyborg Side. The northeastern part of the central city had by the late 19th century developed into an industrial suburb, which in 1917 became a centre of Bolshevik support. One of its most famous features is the Finland Railway Station, which faces the Admiralty Side across the Neva. Lenin returned to Russia in April 1917 via this station, and there he made his initial pronouncement of a new course that would bring the Bolsheviks to power. Honouring that moment is the Statue of Lenin, the first major statue of the Soviet leader, which stands near the station. A major street of the Vyborg Side is the Prospekt Karla Marksa, along which stand such buildings as the modern Leningrad Hotel and the Cathedral of St. Sampson.

The outer region. Leningrad now extends well to the north and south of the original delta site, with arms of growth extending westward along the banks of the Gulf of Finland. The newer outer suburbs include extensive open areas, which help to reduce the overall population density, and parts of the periphery are designated as greenbelt. However, the multiplicity of large housing blocks containing numerous two- or three-room apartments means that population densities in the built-up areas remain extremely high. As in virtually all modern cities, commuting over long distances is the price paid for more living space and the cleaner air of the suburbs. Among the suburbs noteworthy for their historic and cultural value are Petrodvorets, Pushkin, Pavlovsk, and Gatchina.

The Great Palace

Petrodvorets. The most famous of the communities around Leningrad is Petrodvorets (Peterhof before 1944), whose unique garden-park setting, stretching in terraces rising above the Gulf of Finland, contains representative works from two centuries of Russian architectural and park styles. The Great Palace, the former residence of Peter the Great, stands at the edge of the second terrace, its bright yellow walls contrasting with white stucco decorations and the gilt domes of its lateral wings. Built in the Baroque style (1714–28), it was reconstructed and expanded by Rastrelli from the mid-1740s to the mid-1750s. On the north, the building commands a view of the Grand Cascade, a grandiose structure including a grotto, 64 fountains, and two cascading staircases, which lead to an enormous semicircular basin that contains a giant statue of Samson wrestling with a lion. This statue, symbolizing the military glory of Russia, is a copy of the original statue by Mikhail I. Kozlovsky, which was carried off by the Nazis in World War II. In fact, much of the town's treasure was plundered and this magnificent vista becomes all the more remarkable when it is remembered that much of it is a post-World War II restoration.

The Catherine Palace

Pushkin. The town of Pushkin (before 1917 Tsarskoye Selo; called Detskoye Selo in 1918–37) arose in the beginning of the 18th century as one of the tsarist residences. The Catherine Palace (1717–23; enlarged by Aleksey V. Kvasov and Savva I. Chevakinsky, 1743–48; rebuilt by Rastrelli, 1752–57) is notable for its dimensions, the beauty and majesty of its form, and the wealth of its sculptural decoration. The golden suite of splendid halls (including the Amber Room) exemplifies Russian Baroque at its peak. The community also is the site of the Chinese Village (1782–96) in Alexander Park and the gallery (1780–90) named after its architect, Charles Cameron, the terraces of which contain more than 50 busts of figures from ancient Greek and Roman history. The Lycée, a school for the offspring of the nobility, had the great Aleksandr Pushkin as a student, and a famous statue of the poet stands near the town's Egyptian Gates. The town suffered severe destruction during the German onslaught but has been restored to its former glory.

Pavlovsk. Pavlovsk, a southern suburb, is the site of a late 18th- and early 19th-century palace and park in the classical style that was created as a country residence for Tsar Paul I. The central Great Palace (1782–86; Cameron) is crowned by a dome supported by 64 columns. It was severely damaged by the Nazis and has been restored.

Gatchina. Another southern suburb, Gatchina, is noted for the palace built in 1766–81 by Antonio Rinaldi for Count Grigory Orlov, a favourite of Catherine II. Gatchina Park was created at the same time. Its monuments, sculptures, and gardens, like those of all Leningrad, are under state supervision that provides for protection and restoration.

THE PEOPLE

The population of Leningrad is overwhelmingly Russian. Before the Revolution the city had sizable Polish, Baltic, and German and smaller Tatar, Jewish, and Chinese communities. In the interwar period it continued to act as a magnet for Russian peasant labour, and, even in the more homogeneous postwar city, newcomers have tended to outnumber native Leningraders. Nevertheless, observers have commonly ascribed certain traits to the people—politeness, a sophistication, a slight reserve—that have seemingly passed from generation to generation. The old intelligentsia is no more, but many Leningraders, living in a city designed as a cultural centre, consider themselves to be the most cultivated of Russians.

THE ECONOMY

Industry. Leningrad is one of the major industrial centres in the Soviet Union, with more than half of its working population employed in factories and the building trades; its products are distributed throughout the Soviet Union. The city also makes important contributions in scientific and technical research.

Engineering industries

Engineering accounts for more than half of the city's industrial output. Special emphasis is placed on those branches of engineering that require a skilled labour force and relatively small quantities of metal. Even so, Leningrad uses about 10 percent of all steel made in the Soviet Union. Leningrad's original industry, shipbuilding, is still important and remains one of the largest of its kind in the Soviet Union; it produces icebreakers (some atomic-powered), tankers, timber carriers, and fishing vessels. Other sectors of heavy engineering make armaments and rolling stock. Of national importance are a plant producing nuclear reactors and others that manufacture electrical and power machinery, such as steam, hydraulic, and gas turbines, armatures, and generators. Precision engineering includes tools and instruments, refrigerators, radios, televisions, and other electrical and electronic goods. Machinery is produced for automated factories and for the knitwear and footwear industries.

Chemical-based industries rank second to engineering in importance. These make a wide range of items, such as superphosphate fertilizers (using apatite from the Kola Peninsula), tires and other synthetic rubber goods, plastics and plastic goods, artificial and synthetic fibres, paints, and pharmaceutical preparations. There are industries producing a wide range of consumer goods, with the city itself as their principal market. These include the production of cotton and woolen textiles, clothing, footwear, tobacco products, beer, and foodstuffs. Leningrad has a long-established and sizable printing industry.

Power sources

Electrical power for these industries comes from hydroelectric plants on the Volkhov, Svir, and Vuoksa rivers, and, more recently, from nuclear power stations. Natural gas is piped to Leningrad from the southern regions of European Russia and Soviet Central Asia.

Waterways

Transportation. Leningrad is one of the Soviet Union's most important hubs of transportation. Its port, the nation's largest, is of international significance. The main harbour is protected by breakwaters and is reached by a dredged channel from Kronshtadt. Imports include metal pipes, factory equipment, chemicals, sugar, cotton, and fruit, while machinery, timber, coal, potassium salts, and pyrites form the bulk of exports. Passenger liners maintain regular summer services to Stockholm and to Tilbury in Britain. Smaller seagoing ships have access by way of the Neva to Lake Ladoga and thence throughout the inland waterway system of European Russia. From Lake Ladoga the Svir River, Lake Onega, and the White Sea Canal (Belomor Kanal) lead to the White Sea and the Soviet Arctic coast. From Lake Onega the Lenin Volga–Baltic Waterway system leads to the Volga Basin and Caspian Sea and, via the Volga–Don Canal, to the Black and Azov seas. The main airfield, Pulkovo International Airport, is located 11 miles south of the city.

Local transport

The city is a focus of rail routes, with trunk lines radiating to Helsinki and Warsaw as well as to Moscow and other major cities of the Soviet Union. There are five principal passenger rail terminals—the Moscow, Vitebsk, Warsaw, Baltic, and Finland stations. A network of suburban electric services connects the outer parts of Leningrad and its satellite towns. Internal city traffic is carried by a subway system (opened in 1955) and a well-developed network of bus, streetcar, and trolleybus lines.

ADMINISTRATION AND SOCIAL CONDITIONS

Government. Since 1931 Leningrad has been designated a "city of republican subordination"—that is, its City Council (Soviet) is directly subordinate to the government of the Russian Soviet Federated Socialist Republic. The council members are elected for two-year terms. The city itself is divided into 16 administrative wards. In addition to these, there are five towns in the outer part of Greater Leningrad administered by the local government, which have status equivalent to that of the administrative wards; these include Kolpino, Petrodvorets, Pushkin, Sestroretsk, and Kronshtadt, on the island of Kotlin. Two other towns, Zelenogorsk and Pavlovsk, and 17 urban districts are subordinate to the administrative ward councils. Leningrad is also the administrative centre of Leningrad *oblast* (region). As a residue of the city's former status as capital, certain organizations still maintain their national headquarters in Leningrad, among them the all-union geographical, chemical, and medical societies.

Services and health. Much of the housing in Leningrad was destroyed during World War II and was replaced by massive postwar building programs. As a result a large proportion of the people live in relatively new and modern apartments, some in high-rise buildings. Virtually all housing has central heat and is tied to the city's sanitation and power services.

Leningrad is fully equipped with the health services of a modern city. There are several hundred clinics providing medical and dental care and maternity and nursing services for the residential regions and suburbs. Medical care also is provided by more than 150 general and specialized hospitals. As in the rest of the Soviet Union, health care in Leningrad is free.

Education. Leningrad is one of the most important centres for education and scientific research in the Soviet Union; a sizable proportion of the employed population is engaged in education, the arts, and the sciences. Heading the educational establishments is the Leningrad A.A. Zhdanov State University, founded in 1819. No less renowned and even older are the Academy of Arts, founded in 1757, the Institute of Mines (1773), and the Military Medical Academy (1798). The Leningrad M.I. Kalinin Polytechnic Institute (1899) is also noteworthy. The city has numerous other higher educational establishments and also a large number of general schools, as well as specialist and technical secondary schools.

Library of the Academy of Sciences

A focus for research is the library of the Academy of Sciences of the U.S.S.R., which remained in Leningrad when the academy's headquarters moved back to Moscow after the Revolution. The research establishments of the Academy of Sciences in the city include the Botanical, Geological, Forestry, and Zoological institutes and the Pulkovo Observatory. The city is the principal Soviet centre for arctic research, notably at the Arctic and Antarctic Research Institute and at the Institute for the Study of Permafrost.

CULTURAL LIFE

Leningrad evolved as a city of culture, and the number and quality of its cultural institutions remains one of its enduring attractions. It has many large and grand theatres and auditoriums. The Kirov State Academic Theatre of Opera and Ballet, formerly the Mariinsky Theatre, has long enjoyed an international reputation, and its resident company is frequently on tour abroad. Other important

Museums

theatres are the Maly (Little), Gorky, Pushkin, and Musical Comedy theatres. The largest of several concert halls is the October Great Concert Hall, which seats 4,000 people. Notable museums include the Hermitage and the State Russian Museum, which specializes in Russian painting. Leningrad is a significant centre of the Soviet motion-picture industry. There are a large number of libraries in the city, headed by the Saltykov–Shchedrin Public Library on the Nevsky Prospekt, established in 1795; among libraries in the Soviet Union, it is second only to Moscow's Lenin Library. Another important specialized collection is in the Pushkin House literary museum on Vasilyevsky Island.

Leningraders have abundant recreational facilities at their disposal. Among the stadiums in the area are the Kirov Stadium, the largest, seating about 100,000, and a 25,000-seat stadium in the Lenin sports complex. Other opportunities for outdoor recreation are provided by the Kirov Park of Culture and Rest, the zoo, the botanical gardens, and numerous other smaller parks and gardens.

History

THE EARLY PERIOD

Foundation and early growth. Settlement of the region around the head of the Gulf of Finland by Russians began in the 8th or 9th century AD. Known then as Izhorskaya Zemlya, or more commonly as Ingermanland, or Ingria, the region came under the control of Novgorod, but for long it remained thinly populated. In the 15th century the area passed, with Novgorod, into the possession of the grand princes of Moscow. Sweden annexed Ingria in 1617 and established fortresses along the Neva. During the Second Northern War of 1700–21, Peter the Great, seeking a sea outlet to the West, constructed a fleet on the Svir River (which connects Lakes Onega and Ladoga) and, sailing across Lake Ladoga, launched an attack on the fortress of Noteburg (now Petrokrepost), where the Neva flows out of Ladoga. In 1703 Noteburg fell to Peter; afterward he captured the Swedish fortress of Nienshants on the lower Neva, thus gaining control of the delta.

Peter–Paul Fortress

On May 16 (May 27, new style), 1703, shortly after the fall of Nienshants, Peter himself laid the foundation stones for the Peter–Paul Fortress on Zayachy Island. This date is taken as the founding date of St. Petersburg. In the spring of the following year Peter established the fortress of Kronshlot, later Kronshtadt, on Kotlin Island in the Gulf of Finland, to protect the approaches to the delta. At the same time he founded the Admiralty shipyard on the riverbank opposite the Peter–Paul Fortress; in 1706 its first warship was launched. Around the fortress and shipyard Peter began the building of a new city to serve as his "window on Europe." Just upstream of the Peter–Paul Fortress, the first small house, built for Peter himself in the early days of the city's construction, is preserved as a museum.

Capital of Russia

Although the first dwellings were single-storied and made of wood, it was not long before stone buildings were erected. The first stone palace, still preserved, was completed in 1714 for Prince Aleksandr Danilovich Menshikov, first governor of the city. From the start the city was planned as an imposing capital, on a regular street pattern, with spacious squares and broad avenues radiating out from the Admiralty. Architects, craftsmen, and artisans were brought from all over Russia and from many foreign countries to construct and embellish the new town. In 1712 the capital of Russia was transferred there from Moscow, although it was not until 1721 that Sweden, in the Treaty of Nystad, formally ceded sovereignty of the area to Russia. Members of the nobility and merchant class were compelled by Peter to move to the new capital and to build houses for themselves. Government buildings and private palaces and houses arose swiftly; among the earliest buildings were the Merchants' Exchange (now the Naval Museum), Customs House (now the Museum of Literature), and marine hospital, together with the Summer Palace. Canals for drainage were cut through the marshy left bank of the Admiralty Side. The first floating bridge over the Neva was constructed in 1727, and soon more than 370 bridges had been built across the many canals and river channels. Marshy, flood-prone land and an inhospitable climate made construction expensive in terms of human life; St. Petersburg, it was later suggested, rested on a swamp of human bones.

A harbour was constructed, and Peter took measures to curtail traffic through Arkhangelsk on the White Sea, previously Russia's major port. In consequence, as early as 1726 St. Petersburg was handling 90 percent of Russia's foreign trade. In 1703 work began on the Vyshnevolotsky Canal in the Valdai Hills, the first link in a chain that by 1709 gave the capital a direct water route to central Russia and all of the Volga Basin. Industry soon began to develop. The original and flourishing Admiralty shipyard was joined by enterprises to supply its needs and those of the growing fleet—a foundry to produce cannon, a gunpowder factory, and a tar works. Merchantmen as well as warships were built, and before the end of the 18th century papermaking, printing, and food, clothing, and footwear industries had been established; as early as the 1740s a factory was set up to make china. By 1765 the population numbered 150,300 and by the end of the century it had reached 220,200, of whom more than a third were in the armed forces or the administration.

Russian Baroque architecture

The rise to splendour. The growing city displayed a remarkable richness of architecture and harmony of style. Initially the style was one of simple but elegant restraint, represented in the cathedral of the Peter–Paul Fortress and in the Summer Palace. In the mid-18th century an indelible stamp was put on the city's appearance by the architects Bartolomeo F. Rastrelli, Savva I. Chevakinsky, and Vasily P. Stasov, working in the Russian Baroque style, which combined clear-cut, even austere lines with richness of decoration and use of colour. To this period belong the Winter Palace, the Smolny Convent, and the Vorontsov and Stroganov palaces, among others; outside the city were built the summer palaces of Peterhof and of Tsarskoye Selo. After a transitional period, dominated by the architecture of Jean-Baptiste M. Vallin de la Mothe and Aleksandr Kokorinov, toward the end of the 18th century a pure classical style emerged under the architects Giacomo Quarenghi, Carlo Rossi, Andrey Voronikhin, and others. The Kazan and St. Isaac's cathedrals, the Smolny Institute, the new Admiralty, the Senate, and the Mikhaylovsky Palace (now the State Russian Museum) are representative of the splendid buildings of this period.

Within this grand architectural setting cultural life developed and flourished. In 1773 the Institute of Mines was established. The University of St. Petersburg (now Leningrad State University) was founded in 1819. Many of the most celebrated names in Russia in the spheres of learning, science, and the arts are associated with the city: Mikhail V. Lomonosov, Dmitry I. Mendeleyev, Ivan Pavlov, Aleksandr Pushkin, Leo Tolstoy, and Fyodor Dostoyevsky, among others. Dostoyevsky's *Crime and Punishment* was set in the city, and the buildings described in the novel are a focus of tourism. As early as 1738 the first ballet school in Russia was opened in St. Petersburg; in the 19th century, under Marius Petipa, the Russian ballet rose to worldwide renown and produced such dancers as Vaslav Nijinsky, Tamara Karsavina, and Anna Pavlova. In 1862 the first conservatory of music in Russia opened its doors, and there the premieres of works by Tchaikovsky, Rimsky-Korsakov, Rachmaninoff, and other composers were performed. Over all, as focus and patron of the city's cultural life, stood the imperial court; its ostentatious splendour and wealth were legendary throughout Europe.

EVOLUTION OF THE MODERN CITY

New lines of communication

The road to revolution. The imperial magnificence, centred on the tsarist autocracy, was in sharp contrast to the other side of St. Petersburg's development, the growth of its industrial proletariat. During the 19th century there was much industrial growth in the city, accelerated by improvements in communications and extension of trade. Navigation was opened on the Mariinsky (1810) and Tikhvin (1811) canal systems, which replaced an old and inadequate system. In 1813 the first Russian steamship was built in St. Petersburg, and in 1837 the first Russian railway was constructed from the city to the Summer Palace in Tsarskoye Selo (now Pushkin). Five years later work started on the railway to Moscow, opened to traffic in 1851. A line to Warsaw was built in 1861–62, followed by still others. In particular, the cotton textile and metalworking industries flourished, the former using imported raw materials. By the 1840s more than 60 percent of Russian imports were entering by way of St. Petersburg. In 1885, a channel was dredged to give larger ships access to the port. City growth and industrialization were stimulated by the emancipation of the Russian serfs in 1861, which allowed far greater mobility of labour. From 539,400 inhabitants in 1864 the population rose to about 1,500,000 in 1900, largely by migration from rural areas (as late as 1910 only one-third of the population had been born in the city). By 1917 the total had risen to about 2,500,000.

Politicized work force

The factory environment in Leningrad became a breeding ground for revolution. With the development of metalworking and engineering as the primary industries, there arose a skilled labour force, increasingly alert politically. Moreover, the factory workers, who numbered nearly 250,000 in 1914, tended to be concentrated in plants of far larger size than was usual in Russia; the Putilov (now Kirov) armaments works alone employed about 13,000. It was thus easier for revolutionaries to spread their ideas and for workers' groups to organize than it was elsewhere in Russia. At the same time the growth of the city was characterized by a belated and slow development of public transport, making it necessary for workers to live close to their place of work, in conditions of appalling overcrowding (more than 180,000 per square mile in the centre), squalor, and lack of sanitation. Throughout the period before 1917 the city administration was lacking in efficiency and often in funds, and the provision of all public services—even a water supply—was inadequate. Outbreaks of serious epidemics were commonplace, and St. Petersburg became notorious for its unhealthy conditions.

Decembrist insurrection

The first serious revolutionary outbreak in St. Petersburg came on Dec. 14 (Dec. 26, N.S.), 1825, the Decembrist insurrection, organized largely by liberal aristocrats and army officers seeking a liberal constitution and an end to serfdom. It was ruthlessly suppressed. During the rest of the 19th century, workers' revolutionary activity and unrest steadily increased, with ever more frequent strikes and outbreaks of violence. These culminated in the general strike of January 1905, when some 150,000 workers took part. On what became known as Bloody Sunday, January 9 (22, N.S.), a mass march to the Winter Palace, bearing a petition to the Tsar, was met by troops, who opened fire; more than 100 people were killed and hundreds more wounded. The situation developed into revolution, spreading throughout Russia. Although it was again crushed, underground revolutionary activity continued.

Return of Lenin

The outbreak of World War I in 1914 brought an upsurge of patriotic fervour centred on the Tsar. The Germanic form of the city's name was changed to its Russian version, Petrograd. The military disasters of the war and the worsening economic situation, however, revived and intensified discontent. Transport inefficiencies led to severe shortages of food and other supplies. On Feb. 26 (March 11, N.S.), 1917, with a general strike in effect, disorders broke out. The authorities were slow to act and lost all control. The Petrograd Soviet of Workers' and Soldiers' Deputies was formed on February 27 (March 12, N.S.). On March 2 (15, N.S.) the Tsar abdicated. A provisional government was set up, eventually under the premiership of Aleksandr Kerensky. On April 3 (16, N.S.) Lenin returned to Petrograd from Switzerland and set about organizing the overthrow of the provisional government. Demonstrations in July were suppressed, but on October 25 (November 7, N.S.) Bolshevik-led workers and sailors stormed the Winter Palace, deposing the provisional government and establishing the Bolshevik Party in power.

The Russian Revolution of 1917, which changed the course of history, was spearheaded by the Petrograd proletariat and the sailors from Kronshtadt. In January 1918 a Constituent Assembly met in Petrograd, but the Bolsheviks, who had won only a minority of seats, dispersed it and consolidated their authority.

The Soviet period. Civil war reigned in Russia from 1918 to 1920, during which the Bolsheviks successfully defended their government against various Russian and foreign elements. In March 1918 the capital of the young Soviet state had been moved back to Moscow. The years of the civil war after the Revolution had a disastrous effect on the city's economy. Industry came very nearly to a standstill. The population fell sharply to 722,000 in 1920, a mere third of the pre-Revolutionary size. Many died of starvation. Recovery began when the war ended. In 1924, following Lenin's death, the city was renamed Leningrad. When in 1928 the era of five-year plans began, much of the initial burden of developing the national economy fell on Leningrad and its established industrial plant and work force, especially in the provision of power equipment and machinery. This stimulated further growth, and by 1939 the city was responsible for 11 percent of all Soviet industrial output and its population had passed 3,000,000.

The 900-day siege

Then once again Leningrad was struck by a period of loss and destruction. It was one of the initial targets of the German invasion in 1941; by September of that year German troops were on the outskirts of the city and had cut off communication with the rest of the Soviet Union, while Finnish troops advanced from the north. Many of the inhabitants and nearly three-quarters of the industrial plant were evacuated eastward ahead of the German advance. The remainder of the population and the garrison then began to endure what has become known as the 900-day siege; the German blockade in fact lasted 872 days, from Sept. 8, 1941, to Jan. 27, 1944. Leningrad put up a desperate and courageous resistance in the face of many assaults, constant artillery and air bombardment, and appalling suffering from shortages of supplies. An estimated 660,000 people died, a very high proportion from scurvy and starvation. In particular the exceptionally bitter winter of 1941–42, when temperatures fell to −40° F (−40° C), was one of extreme hardship and loss of life. The only route for supplies was the "road of life" across the ice of Lake Ladoga; later an oil pipeline and electric cables were laid on the lake bed. The blockade proper was broken in January 1943, but it was another year before the Germans had been driven back from the outskirts. Enormous damage had been caused by the bombardment, and before retreating the Germans destroyed the palaces at Petrodvorets and Pushkin. For its role in the war Leningrad was honoured with the title of Hero City, a special defense medal, and the Order of Lenin. Not until the 1960s did the city regain its prewar size of 3,000,000; by the 1980s the population had passed 4,000,000.

In Leningrad, the first postwar Five-Year Plan was devoted to reconstruction of the city's industry and restoration of its architectural heritage. In the late 1950s a program of housing construction in the new suburbs got under way; renovation of highly sought after inner-city apartments began in the 1970s. In the face of continuing construction and expansion, maintenance of the old city and modernization of the infrastructure have become major problems. In response the city planners have pioneered new forms of industrial administration, drawing on the city's strength as a scientific and technical centre and emphasizing the need to preserve its unique cultural heritage.

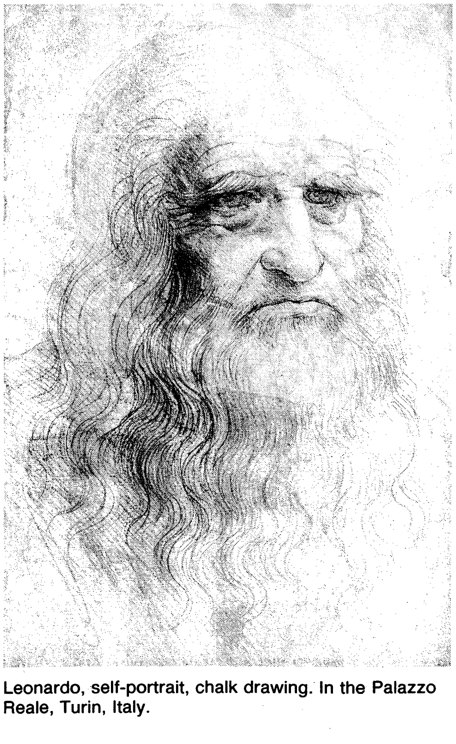
Leonardo da Vinci

The unique fame that the Florentine artist and scientist Leonardo da Vinci enjoyed in his lifetime and that, filtered and purified by historical criticism, has remained undimmed to the present day is based on the equally unique universality of his spirit. Leonardo's universality is more than many-sidedness. True, at the time of the Renaissance and the period of Humanism, many-sidedness was a highly esteemed quality; but it was by no means rare. Many other good artists possessed it. Leonardo's universality, on the other hand, was a spiritual force, peculiarly his own, that generated in him an unlimited desire for knowledge and guided his thinking and behaviour. An artist by disposition and endowment, he found that his eyes were his main avenue to knowledge; to Leonardo, sight was man's highest sense organ because sight alone conveyed the facts of experience immediately, correctly, and with certainty. Hence, every phenomenon perceived became an object of knowledge. *Saper vedere* ("knowing how to see") became the great theme of his studies of man's works and nature's creations. His creativity reached out into every realm in which graphic representation is used: he was painter, sculptor, architect, and engineer. But he went even beyond that. His superb intellect, his unusual powers of observation, and his mastery of the art of drawing led him to the study of nature itself, which he pursued with method and penetrating logic—and in which his art and his science were equally revealed.

LIFE AND WORKS

Early period: Florence. The illegitimate son of Ser Piero, a Florentine notary and landlord, Leonardo was born in 1452 on his father's family estate in Vinci, near Empoli. His mother, Caterina, was a young peasant woman who shortly thereafter married an artisan from that region. Not until his third and fourth marriages did Ser Piero's wives have children, the first one in 1476, when Leonardo was already an adult. Thus, Leonardo grew up in his father's house, where he was treated as a legitimate son and received the usual elementary education of that day: reading, writing, and arithmetic. As for Latin, the key language of traditional learning, Leonardo did not seriously study it until much later, when he acquired a working knowledge of it on his own. Not until he was 30 years old did he apply himself to higher mathematics—advanced geometry and arithmetic—which he studied with diligent tenacity; but here, too, he did not get much beyond the beginning stages.

Alinari—Art Resource/EB Inc.



Leonardo, self-portrait, chalk drawing. In the Palazzo Reale, Turin, Italy.

Leonardo's artistic inclinations must have appeared early. When he was about 15, his father, who enjoyed a high reputation in the Florence community, apprenticed him to Andrea del Verrocchio. In Verrocchio's renowned workshop Leonardo received a many-sided training that included not only painting and sculpture but the technical-mechanical arts as well. He also worked in the next-door workshop of Antonio Pollaiuolo, where he was probably first drawn to the study of anatomy. In 1472 Leonardo was accepted in the painters' guild of Florence but remained five years more in his teacher's workshop. Then he worked independently in Florence until 1481. In the few extant works of this early period one may clearly trace the development of the artist's remarkable talent. Keenness of observation and creative imagination stand out. His early mastery is revealed in an angel and a segment of landscape executed by him in Verrocchio's painting the "Baptism of Christ" (Uffizi, Florence) and in two Annunciations (Uffizi, as well as the Louvre, Paris), both of them done in Verrocchio's workshop, as were the "Madonna with the Carnation," the "Madonna Benois," and the "Portrait of Ginevra de' Benci." This mastery reached its peak in two paintings that remained unfinished: "St. Jerome" and a large panel painting of "The Adoration of the Magi." In addition to these few paintings there are a great many superb pen and pencil drawings, in which Leonardo's mastery blazed new trails for this graphic art. Among the drawings are many technical sketches—for example, pumps, military weapons, mechanical apparatus—evidence of Leonardo's interest in and knowledge of technical matters at the outset of his career.

Evidence of early mastery

Unfolding of Leonardo's genius: first Milanese period (1482–99). In 1482 Leonardo entered the service of the Duke of Milan—a surprising step when one realizes that the 30-year-old artist had just received his first substantial commissions from his native city of Florence: the above-mentioned unfinished panel painting of "The Adoration of the Magi" for the monastery of S. Donato a Scopeto (1481) and an altar painting for the St. Bernard Chapel in the Palazzo della Signoria, which was never fulfilled. That he gave up both projects despite the commitments he had undertaken—not even starting on the second named—seems to indicate deeper reasons for his leaving Florence. It may have been that the rather sophisticated spirit of Neoplatonism prevailing in the Florence of the Medici went against the grain of his experience-oriented mind and that the more realistic academic atmosphere of Milan attracted him. Moreover, there was the fascination of Ludovico Sforza's brilliant court and the meaningful projects awaiting him there.

Leonardo spent 17 years in Milan, until Ludovico's fall from power in 1499. He was listed in the register of the royal household as *pictor et ingeniarius ducalis* ("painter and engineer of the duke"). Highly esteemed, Leonardo was constantly kept busy as a painter and sculptor and as a designer of court festivals. He was also frequently consulted as a technical adviser in the fields of architecture, fortifications, and military matters, and he served as a hydraulic and mechanical engineer.

In this phase of his life Leonardo's genius unfolded to the full, in all its versatility and creatively powerful artistic and scientific thought, achieving that quality of uniqueness that called forth the awe and astonished admiration of his contemporaries. At the same time, in the boundlessness of the goals he set himself, Leonardo's genius bore the mark of the unattainable so that, if one traces the outlines of his lifework as a whole, one is tempted to call it a grandiose "unfinished symphony."

The six paintings completed in the Milanese years

Painting and sculpture. As a painter Leonardo completed only six works in the 17 years in Milan: portraits of Cecilia Gallerani ("Lady with an Ermine") and a musician, an altar painting of "The Virgin of the Rocks" (two versions), a monumental wall painting of the "Last Supper" in the refectory of the monastery of Sta. Maria delle Grazie (1495–97), and the decorative ceiling painting of the Sala delle Asse in the Milan Castello Sforzesco (1498). Three other pictures that, according to old sources, Leonardo was commissioned to do have disappeared or were never done: a "Nativity" said to have belonged to Emperor Maximilian; a "Madonna" that Ludovico Sforza announced as a gift to the Hungarian king Matthias Corvinus; and the portrait of one of Ludovico's mistresses, Lucrezia Crivelli.

Also unfinished was a grandiose sculptural project that seems to have been the real reason Leonardo was invited to Milan: a monumental equestrian statue in bronze to be erected in honour of Francesco Sforza, the founder of the Sforza dynasty. Leonardo devoted 12 years—with interruptions—to this task. Many sketches of it exist, the most impressive ones discovered only in the mid-20th century, when two of Leonardo's notebooks came to light again in Madrid. They reveal the sublimity but also the almost unreal boldness of his conception. In 1493 the clay model of the horse was put on open display on the occasion of the marriage of Emperor Maximilian with Bianca Maria Sforza, and preparations were made to cast the colossal figure, which was to be 16 feet (five metres) high—double the size of Verrocchio's equestrian statue of Bartolomeo Colleoni! But, because of the imminent danger of war, the metal, ready to be poured, was used for cannon instead, and so the project came to a halt. Ludovico's fall in 1499 sealed the fate of this abortive undertaking, which was perhaps the grandest concept of a monument in the 15th century. The ravages of war left the clay model a heap of ruins.

As a master artist Leonardo maintained an extensive workshop in Milan, employing apprentices and students. The role of most of these associates is unclear. Their activity involves the question of Leonardo's so-called apocryphal works, in which the master collaborated with his assistants. Scholars have been unable to agree in their attributions of these works, which include such paintings as "La Belle Ferronnière" in the Louvre, the so-called "Lucrezia Crivelli" in the Pinacoteca Ambrosiana, Milan, and the "Madonna Litta" in the Hermitage, Leningrad. Among Leonardo's pupils at this time were Giovanni Antonio Boltraffio, Ambrogio de Predis, Bernardino de' Conti, Francesco Napoletano, Andrea Solari, Marco d'Oggiono, and Salai.

Art and science: the notebooks. The Milan years also saw Leonardo's decided turn toward scientific studies. He began to pursue these systematically and with such intensity that they demanded more and more of his time and energy and developed into an independent realm of creative productivity. Within him there arose now a growing need to note and write down in literary form every one of his perceptions and experiences. It is a unique phenomenon in the history of art. Undoubtedly, the several treatises on art that appeared or were made available during those decades provided an external stimulus. Leon Battista Alberti's *De re aedificatoria* (*Ten Books on Architecture*) was first printed in 1485; Francesco di Giorgio's treatise on architecture was available in its first manuscript versions, and Leonardo had received a copy from the author as a gift. Moreover, Piero della Francesca in his *De prospectiva pingendi* ("On Perspective in Painting") had provided for his contemporaries a model text on the theory of perspective. Finally, there was the mathematician Lucas Pacioli, who had become an acquaintance of Leonardo's. In 1494 Pacioli published his *Summa de arithmetica geometria proportioni et proportional ità,* followed by his *Divina proportione* ("On Divine Proportion"), for which Leonardo drew figures of symmetrical bodies.

Stimulus for Leonardo's scientific studies

In this ambience Leonardo began to nourish the desire to write a theory of art of his own, and there arose in him the far-reaching concept of a "science of painting." Alberti and Piero della Francesca had already offered proof of the mathematical basis of painting in their analysis of the laws of perspective and proportion and thereby buttressed painting's claim to being a science. But Leonardo's claims went much further. Proceeding from the basic conviction that sight is the human being's most unerring sense organ, yielding immediate, accurate, and reliable data of experience, Leonardo—equating "seeing" with "perceiving"—arrived at a bold conclusion: the painter, doubly endowed with subtle powers of perception and the complete ability to pictorialize them, was the prime person qualified to achieve knowledge by observing and to reproduce that knowledge authentically in a pictorial manner. Hence, Leonardo conceived the staggering plan of observing all objects in the visible world, recognizing their form and structure, and pictorially describing them exactly as they are. Thus, drawing became the chief instrument of his didactic method.

In the years between 1490 and 1495 the great program of Leonardo the writer (author of treatises) began. In it, four main themes, which were to occupy him for the rest of his life, could be discerned and gradually took shape: a treatise on painting, a treatise on architecture, a book on the elements of mechanics, and a broadly outlined work on human anatomy. His geophysical, botanical, hydrological, and aerological researches also belong to this period and constitute parts of the "visible cosmology" that loomed before Leonardo as a distant goal. Against speculative book knowledge, which he scorned, he set irrefutable facts gained from experience—from *saper vedere.*

The notebooks

All these studies and sketches were written down in Leonardo's notebooks and on individual sheets of paper. Altogether they add up to thousands of closely written pages abundantly illustrated with sketches—the most voluminous literary legacy any painter has ever left behind. Of more than 40 codices mentioned in the older sources—often, of course, rather inaccurately—21 have survived; these in turn sometimes contain notebooks originally separate and now bound together so that 31 in all have been preserved. To these should be added several large bundles of documents: an omnibus volume in the Biblioteca Ambrosiana, Milan, called Codex Atlanticus because of its size, was collected by the sculptor Pompeo Leoni at the end of the 16th century; its sister volume, after a roundabout journey, fell into the possession of the English crown and was placed in the Royal Library, Windsor Castle. Finally there is the Arundel Manuscript (British Museum, MS. 263), which contains a number of Leonardo's fascicles on various themes.

It was during his years in Milan that Leonardo began the earliest of these notebooks. He would first make quick sketches of his observations on loose sheets or on tiny paper pads he kept in his belt; then he would arrange them according to theme and enter them in order in the notebook. Surviving are a first collection of material for the painting treatise (MSS. A and B in the Institut de France, Paris), a model book of sketches for sacred and profane architecture (MS. B, Institut de France, Paris), the treatise on elementary theory of mechanics (MS. 8937, Biblioteca Nacional, Madrid), and the first sections of a treatise on the human body (Anatomical MS. B; Windsor Castle, Royal Library).

Two special features make Leonardo's notes and sketches unusual: his use of mirror writing and the relationship between word and picture.

Leonardo was left-handed; so mirror writing came easily and naturally to him. It should not be looked upon as a secret handwriting. Though somewhat unusual, his script can be read clearly and without difficulty with the help of a mirror—as his contemporaries testified. But the fact that Leonardo used mirror writing throughout, even in his fair copies drawn up with painstaking calligraphy, forces one to conclude that, although he constantly addressed an imaginary reader in his writings, he never felt the need to achieve easy communication by using conventional handwriting. Yet occasional examples of normal handwriting (drafts of letters, notes, and comments to be submitted to third parties) show that Leonardo was completely at home in it. In the overwhelming majority of his notes in mirror writing, therefore, one gets the strong impression of "monologues in writing." Finally, then, his writings must be interpreted as preliminary stages of works destined for eventual publication, which Leonardo never got around to completing. In a sentence in the margin of one of his late anatomy sketches, he implores his followers to see that his works are printed.

Function of Leonardo's illustration vis-à-vis text

The second unusual feature in Leonardo's writings is the new function given to illustration vis-à-vis the text. Leonardo strove passionately for a language that was clear yet expressive. The vividness and wealth of his vocabulary were the result of intense self-study and represented a significant contribution to the evolution of scientific prose in the Italian vernacular. On the other hand, in his teaching method Leonardo gave absolute precedence to the illustration over the written word; hence, the drawing does not illustrate the text; rather, the text serves to explain the picture. In formulating his own principle of graphic representation—which he himself called *dimostrazione* ("demonstrations")—Leonardo was a precursor of modern scientific illustration.

Thus, during Leonardo's years in Milan the two "action fields"—the artistic and the scientific—developed and shaped his future creativity. It was a kind of "creative dualism," with mutual encouragement but also mutual pressure from each field.

Second Florentine period (1500–06). In December 1499 or at the latest January 1500—three months after the victorious entry of the French into Milan—Leonardo left that city in the company of Lucas Pacioli. He stopped first at Mantua, where, in February 1500, he drew a portrait of his hostess, Marchioness Isabella d'Este, and then proceeded to Venice (in March), where the Signoria (governing council) sought his advice on how to ward off a threatened Turkish incursion in Friuli. Leonardo recommended that they prepare to flood the menaced region. From Venice he returned to Florence, where, after a long absence, he was received with acclaim and honoured as a renowned native son. In that same year he was appointed an architectural expert to a committee investigating damages to the foundation and structure of the church of S. Francesco al Monte. A guest of the Servite order in the cloister of SS. Annunziata, Leonardo began there a cartoon for a painting of the "Virgin and Child with St. Anne," the composition of which won admiration from artists and art lovers of the city. He also painted (1501) a "Madonna with the Yarn-Winder," which has survived only in copies and which he probably never finished. Mathematical studies seem to have kept him away from his painting activity much of the time, or so Isabella d'Este, who sought in vain to obtain a painting done by him, was informed by Fra Pietro Nuvolaria, her representative in Florence.

Service with Cesare Borgia

Only his omnivorous "appetite for life" can explain Leonardo's decision, in the summer of the following year (1502), to leave Florence and enter the service of Cesare Borgia as "senior military architect and general engineer." Borgia, the notorious son of Pope Alexander VI, had, as commander in chief of the papal army, sought with unexampled ruthlessness to gain control of the Papal States of Romagna and the Marches. Now he was at the peak of his power and, at 27, was undoubtedly the most compelling and at the same time most feared person of his time. Leonardo, twice his age, must have been fascinated by his personality. For 10 months he travelled across the condottiere's territories and surveyed them. In the course of his activity Leonardo sketched some of the city plans and topographical maps that laid the groundwork for modern cartography. At the court of Cesare Borgia, Leonardo also met Niccolò Machiavelli, temporarily stationed there as a political observer for the city of Florence.

In the spring of 1503 Leonardo returned to Florence to make an expert survey of a project for diverting the Arno River behind Pisa so that the city, then under siege by the Florentines, would be deprived of access to the sea. The plan proved unworkable, but Leonardo's activity led him to a much more significant theme, one that served peace rather than war; the project, first advanced in the 13th century and now again under consideration, was to build a large canal that would bypass the unnavigable stretch of the Arno and connect Florence by water with the sea. Leonardo developed his ideas in a series of studies; with panoramic views of the river bank, which are also landscape sketches of great artistic charm, and with exact measurements of the terrain, he produced a map in which the route of the canal (with its transit through the mountain pass of Serravalle) was shown. The project, considered time and again in subsequent centuries, was never carried out, but centuries later the express highway from Florence to the sea was built over the exact route Leonardo chose for his canal.

That same year (1503), however, Leonardo also received a prized commission: to paint a mural for the Hall of the Five Hundred in Florence's Palazzo Vecchio; a historical scene of monumental proportions (at 23 × 56 feet [7 × 17 metres], it would have been twice as large as the "Last Supper"). For three years he worked on this "Battle of Anghiari"; like its intended complementary painting, Michelangelo's "Battle of Cascina," it remained unfinished. But the cartoon and the copies showing the main scene of the battle, the fight for the standard, were for a long time, to quote the sculptor Benvenuto Cellini, "the school of the world." These same years saw the portrait of "Mona Lisa" and a painting of a standing "Leda," which was not completed and has survived only in copies.

Scientific study during the Florentine period

The Florentine period was also, however, a time of intensive scientific study; Leonardo did dissections in the hospital of Sta. Maria Nuova and broadened his anatomical work into a comprehensive study of the structure and function of the human organism. He made systematic observations of the flight of birds, concerning which he planned a treatise. Even his hydrological studies, "on the nature and movement of water," broadened into research on the physical properties of water, especially the laws of currents, which he compared with those pertaining to air. These were also set down in his own collection of data, contained in the so-called Leicester Codex in Holkham Hall, Norfolk, England.

Second Milanese period (1506–13). Thus, during these years in Florence, Leonardo's productivity was also marked by his "creative dualism." Only sporadically did he work at his paintings. When, in May 1506, Charles d'Amboise, governor of the King of France in Milan, asked and was granted permission by the Signoria in Florence for Leonardo to go for a time to Milan, the artist had no hesitation about accepting the invitation. But what was originally a limited period of time became a permanent move under the stress of political circumstances. Florence let Leonardo go, and the monumental "Battle of Anghiari" remained unfinished. Unsuccessful technical experiments with paints seem to have impelled Leonardo to stop working on the mural. One cannot otherwise explain his abandonment of this great work—great both in conception and in realization.

Leonardo spent six years in Milan, interrupted only by a six-month stay in Florence in the winter of 1507–08, where he helped the sculptor Giovanni Francesco Rustici execute his bronze statues for the Florence Baptistery but did not resume work on the "Battle of Anghiari." Honoured and admired by his patrons Charles d'Amboise and King Louis XII, who gave him a yearly stipend of 400 ducats, Leonardo never found his duties onerous. They were limited to advice in architectural matters, tangible evidence of which are plans for a palace–villa for Charles d'Amboise and perhaps also sketches for an oratory for the church of Sta. Maria alla Fontana, which Charles funded. Leonardo also looked into an old project revived by the French governor: the Adda canal that would link Milan with Lake Como by water.

In Milan he did very little as a painter: two Madonnas, which he promised the King of France, were never painted. He continued to work on the paintings of the "Virgin and Child with St. Anne" and "Leda," which he had brought with him from Florence, as copies from the Lombard school of that period attest. Again Leonardo gathered pupils around him. With Ambrogio de Predis he completed a second version of "The Virgin of the Rocks" (1508), in the course of which protracted litigation between the purchasers and the artists had a happy ending. Of his older disciples, Bernardino de' Conti and Salai were again in his studio; new pupils came, among them Cesare da Sesto, Giampetrino, Bernardino Luini, and the young nobleman Francesco Melzi, Leonardo's most faithful friend and companion until his death.

The tomb sculpture for Trivulzio

An important commission in sculpture came his way. Gian Giacomo Trivulzio had returned victoriously to Milan as marshal of the French army and a bitter foe of Ludovico Sforza. He commissioned Leonardo to sculpt his tomb, which was to take the form of an equestrian statue and be placed in the mortuary chapel donated by Trivulzio to the church of S. Nazaro Maggiore. But after years of preparatory work on the monument, for which a number of significant sketches have survived, the Marshal himself gave up the plan in favour of a more modest one; so this undertaking, too, remained unfinished. Leonardo must have felt keenly this second disappointment in his work as a sculptor.

Compared with his almost cursory work in art, Leonardo's scientific activity flourished. His studies in anatomy achieved a new dimension in his collaboration with a famous anatomist from Pavia, Marcantonio della Torre. He outlined a plan for an overall work that would include not only exact, detailed reproductions of the human body and its organs but would also include comparative anatomy and the whole field of physiology. He even thought he would finish his anatomical manuscript in the winter of 1510–11. Beyond that, his manuscripts are replete with mathematical, optical, mechanical, geological, and botanical studies that must be understood as data for his "perceptual cosmology." This became increasingly actuated by a central idea: the conviction that force and motion as basic mechanical functions produce all outward forms in organic and inorganic nature and give them their shape and, furthermore, the recognition that these functioning forces operate in accordance with orderly, harmonious laws.

Last years (1513–19). In 1513 political events—the temporary ouster of the French from Milan—caused the now 60-year-old Leonardo to move again. At the end of the year he went to Rome, accompanied by his pupils Melzi and Salai as well as by two studio assistants, hoping to find employment there through his patron, Giuliano de' Medici, brother of the new pope Leo X. Giuliano gave him a suite of rooms in his residence, the Belvedere, in the Vatican. He also gave him a considerable monthly stipend, but no large commissions came to him. For three years Leonardo remained in the Eternal City, off to one side, while Donato Bramante was building St. Peter's, Raphael was painting the last rooms of the Pope's new apartments, Michelangelo was struggling to complete the tomb of Pope Julius, and many younger artists such as Peruzzi, Timoteo Viti, and Sodoma were active there. Drafts of embittered letters betray the disappointment of the aging master who worked in his studio on mathematical studies and technical experiments or, strolling through the city, surveyed ancient monuments. A magnificently executed map of the Pontine Marshes (Royal Library, Windsor Castle; 12684) suggests that Leonardo was at least a consultant for a reclamation project that Giuliano de' Medici ordered in 1514. On the other hand, there were sketches for a spacious residence for the Medici in Florence, who had returned to power there in 1512. But this did not go beyond the stage of preliminary sketches and never came to pass. Leonardo seems to have resumed his friendship with Bramante, but the latter died in 1514. And there is no record of Leonardo's relations with any other artists in Rome.

Service with King Francis I of France

In a life of such loneliness, it is easy to understand why Leonardo, despite his 65 years, decided to accept the invitation of the young king Francis I to enter his service in France. At the end of 1516 he left Italy forever, together with his most devoted pupil, Francesco Melzi. Leonardo spent the last three years of his life in the small residence of Cloux (later called Clos-Lucé), near the King's summer palace at Amboise on the Loire. *Premier peintre, architecte et méchanicien du Roi* ("first painter, architect, and mechanic of the King") was the proud title he bore; yet the admiring King left him complete freedom of action. He did no more painting or at most completed the painting of the enigmatic, mystical "St. John the Baptist," which the Cardinal of Aragon, when he visited Amboise, saw in Leonardo's studio along with the "Mona Lisa" and the "Virgin and Child with St. Anne."

For the King he drew up plans for the palace and garden of Romorantin, destined to be the widow's residence of the Queen Mother. But the carefully worked-out project, combining the best features of Italian-French traditions in palace and landscape architecture, had to be halted because the region was threatened with malaria.

Leonardo still made sketches for court festivals, but the King treated him in every respect as an honoured guest. Decades later, Francis I talked with the sculptor Benvenuto Cellini about Leonardo in terms of the utmost admiration and esteem. Leonardo spent most of his time arranging and editing his scientific studies. The final drafts for his treatise on painting and a few pages of the anatomy appeared. Consummate drawings such as the "Floating Figure" (Royal Library, Windsor Castle; 12581) are the final testimonials to his undiminished genius. In the so-called "Visions of the End of the World," or "Deluge" (Royal Library, Windsor Castle), he depicts with overpowering pictorial imagination the primal forces that rule nature.

On May 2, 1519, Leonardo died at Cloux. He was laid to rest in the palace church of Saint-Florentin. But the church was devastated during the French Revolution and completely torn down at the beginning of the 19th century. Hence, his grave can no longer be located. Francesco Melzi fell heir to his artistic and scientific estate.

ANALYSIS AND EVALUATION OF LEONARDO'S ACHIEVEMENT

Painting. Leonardo's total output in painting is really not large; only 17 of the paintings that have survived can be definitely attributed to him, and several of them are unfinished. Two of his most important works—the "Battle of Anghiari" and the "Leda," neither of them completed—have only survived in copies. Yet these few creations have established the unique fame of a man whom Vasari, in his *Lives,* dividing art history into three ages, placed in the last "golden age of the arts." His works, unaffected by all the vicissitudes of aesthetic doctrines in subsequent centuries, have stood out in all periods and all countries as consummate masterpieces of painting.

Leonardo's art of expression

The many testimonials to Leonardo, ranging from Vasari to Peter Paul Rubens, Johann Wolfgang von Goethe, and Eugène Delacroix, make it unmistakably clear that it has been, above all, Leonardo's art of expression that has called forth the utmost admiration. It is, in fact, the core of his formation as a painter—from his earliest beginnings to his last work. This expression was nurtured by his power of invention but also by every technical means: drawing, colour, use of light and shadow. To Leonardo, expression became a key concept of art; it also included the basic demands of truth, beauty, and accuracy in everything depicted.

What Leonardo was striving for was already revealed in his angel in Verrocchio's "Baptism of Christ" (*c.* 1474–75): in the natural structuring of the angel's body based on movement in several directions, in the relaxation of his attitude, and in his glance, which takes in what is occurring but at the same time is directed inward. In his landscape segment in the same picture, Leonardo also found a new expression for "nature experienced," in reproducing the forms he perceived as if through a veil of mist. The landscape study (Uffizi, Florence) dated 1473, a pen drawing, foreshadows in its treatment of transparent atmosphere by a 21-year-old his telling ability to transform perceived phenomena into convincing graphic forms.

In the "Madonna Benois" (1478) Leonardo succeeded in giving an old traditional type of picture a new, unusually charming, and expressive mood by showing the child Jesus reaching for the flower in Mary's hand in a sweet and tender manner.

His "Portrait of Ginevra de' Benci" (*c.* 1475–78) opened new paths for portrait painting with his singular linking of nearness and distance.

The emaciated body of his "St. Jerome" (*c.* 1480) is presented with realistic truth based on his sober and objective studies in anatomy; gesture and look give Jerome an unrivalled expression of transfigured sorrow.

The interplay of mimicry and gesture—"physical and spiritual motion," in Leonardo's words—is also the chief concern of his first large creation containing many figures, "The Adoration of the Magi" (1481). Never finished, the painting nevertheless affords rich insight into the master's subtle methods of work. The various aspects of the scene are "built up" from the base with very delicate, paper-thin layers of paint in chiaroscuro (the balance of light and shadow) relief. The main treatment of the Virgin and Child group and the secondary treatment of the surrounding groups are clearly set apart with a masterful sense of composition; yet thematically they are closely interconnected: the bearing and expression of the figures—most striking in the group of praying shepherds—depict all degrees and levels of profound amazement.

The two versions of "The Virgin of the Rocks"

"The Virgin of the Rocks" in its first version in the Louvre is the work that reveals Leonardo's painting art at its purest. The painting, according to Leonardo's first contract with the Confraternity of the Immaculate Conception, was to be the central panel of a large work for their chapel in the church of S. Francesco and was done in the years *c.* 1483–85. It never arrived, however, at the place it was originally destined for. It seems to have been prematurely taken from the Confraternity, perhaps by some highly placed interested party who removed it from Leonardo's workshop. Instead of this first painting, Leonardo and Ambrogio de Predis painted a second, slightly revised version, probably begun around 1494. This one gave rise to a 10-year litigation between the artist and the Confraternity regarding the price, a dispute that was not settled until 1506 in favour of Leonardo; whereupon, two years later, the painting was delivered as per contract. This second version remained in the chapel of S. Francesco until the Confraternity was dissolved (1781), and then, after changing owners frequently, it came finally in 1880 to the National Gallery in London.

"The Virgin of the Rocks" depicts the apocryphal legend of the meeting in the wilderness between the boy John and the equally young Jesus returning home from Egypt. Leonardo's artistry makes of this theme a vision that the true believer experiences when he contemplates the devotional picture. In the visionary character of the picture lies the secret of its effect: it presents not a "reality" but a "manifestation." Leonardo uses every artistic means at his disposal to emphasize the visionary nature of the scene. The soft colour tones (his famous sfumato), the dim light of the cave from which the figures emerge bathed in light, their quiet attitude, the meaningful gesture with which the angel (the only one facing the viewer) points to John as the intercessor between the Son of God and humanity—all this combines, in a patterned and formal way, to achieve an effect of the highest expressiveness.

The "Last Supper"

Leonardo's "Last Supper" is among the most famous paintings in the world. In its monumental simplicity, the composition of the scene is masterful; the power of its effect comes from the striking contrast in the attitudes of the 12 disciples as counterposed to Christ. Leonardo did not choose the portrayal of the traitor Judas customary in the iconographic tradition; he portrayed, rather, that moment of highest tension as related in the New Testament, "One of you which eateth with me will betray me." All of the Apostles—as human beings who do not understand what is about to occur—are agitated, whereas Christ alone, conscious of his divine mission, sits in lonely, transfigured serenity. Only one other being shares the secret knowledge: Judas, who is both part of and yet excluded from the movement of his companions; in this isolation he becomes the second lonely figure—the guilty one—of the company.

In the profound conception of his theme, in the perfect yet seemingly simple arrangement of the individuals, in the temperaments of the Apostles highlighted by gesture and mimicry, in the drama and at the same time the sublimity of the treatment, Leonardo attained a height of expression that has remained a model of its kind. Untold painters in succeeding generations, among them great masters such as Rubens and Rembrandt, marvelled at Leonardo's composition and were influenced by it. The painting also inspired some of Goethe's finest pages of descriptive prose. It has become widely known through countless reproductions and prints, the most important being those produced by Raffaello Morghen in 1800. Thus, the "Last Supper" has become part of humanity's common heritage and remains today one of the world's outstanding paintings.

Technical deficiencies in the execution of the work have not lessened its fame. Leonardo was uncertain about the technique he should use. He bypassed fresco painting, which, because it is executed on fresh plaster, demands quick and uninterrupted painting, in favour of another technique he had developed: tempera on a base mixed by himself on the stone wall. This procedure proved unsuccessful, inasmuch as the base soon began to be loosened from the wall. Damage appeared by the beginning of the 16th century, and deterioration soon set in. By the middle of the century the work was called a ruin. Later, inadequate attempts at restoration only aggravated the situation, and not until the most modern restoration techniques were applied after World War II was the process of decay halted.

In the Florence years between 1500 and 1506, four great creations appeared that confirmed and heightened Leonardo's fame: the "Virgin and Child with St. Anne" (Louvre); "Mona Lisa," "Battle of Anghiari," and "Leda." Even before it was completed, the "Virgin and Child with St. Anne" won the critical acclaim of the Florentines; the monumental plasticity of the group and the calculated effects of dynamism and tension in the composition made it a model that inspired Classicists and Mannerists in equal measure.

The "Mona Lisa"

The "Mona Lisa" became the ideal type of portrait, in which the features and symbolic overtones of the person painted achieved a complete synthesis. The young Raphael sketched the work in progress, and it served as a model for his "Portrait of Maddalena Doni." Similarly, the "Leda" became a model of the *figura serpentinata* ("sinuous figure")—that is, a figure built up from several intertwining views. It influenced such classical artists as Raphael, who drew it, but it had an equally strong effect on Mannerists such as Jacopo Pontormo.

In the "Battle of Anghiari" (1503–06) Leonardo's art of expression reached its high point. The preliminary drawings—many of which have been preserved—reveal Leonardo's lofty conception of the "science of painting"; the laws of equilibrium that he had probed in his studies in mechanics were put to artistic use in this painting. The "centre of gravity" lies in the group of flags fought for by all the horsemen. For a moment the intense and expanding movement of the swirl of riders seems frozen; this passing moment, the transition from one active movement to the next, is uniquely interpreted.

On the other hand, Leonardo's studies in anatomy and physiology influenced his representation of human and animal bodies, particularly when they were in a state of excitement. He studied and described extensively the baring of teeth and puffing of lips as signs of animal and human anger. On the painted canvas, rider and horse, their features distorted, are remarkably similar in expression.

The highly imaginative trappings take the event out of the sphere of the historical into a timeless realm. Thus, the "Battle of Anghiari" became the standard model for a cavalry battle. Its composition has influenced many painters: from Rubens in the 17th century, who made the most impressive copy of the scene from Leonardo's now-lost cartoon, to Delacroix in the 19th century.

After 1507—in Milan, Rome, and France—Leonardo did very little painting. He did resume work on the Leda theme during his years in Milan and sketched a variation, the "Kneeling Leda." The drawings he prepared—revealing examples of his late style—have a curious, enigmatic sensuality. Perhaps in Rome he began the "St. John the Baptist," which he completed in France. Bursting all the boundaries of usual painting tradition, he presented Christ's forerunner as the herald of a mystic oracle; his was an "art of expression" that seemed to strive consciously to bring out the hidden ambiguity of the theme.

Last manifestation of Leonardo's art of expression

The last manifestation of Leonardo's art of expression was in his "Visions of the End of the World," a series of pictorial sketches that took the end of the world as its theme. Here Leonardo's power of imagination—born of reason and fantasy—attained its highest level. The immaterial forces in the cosmos, invisible in themselves, appear in the material things they set in motion. What Leonardo had observed in the swirling of water and eddying of air, in the shape of a mountain boulder and in the growth of plants now assumed gigantic shape in cloud formations and rainstorms. The framework of the world splits asunder, but even its destruction occurs—as the monstrously "beautiful" forms of the unleashed elements show—in accordance with the self-same laws of order, harmony, and proportion that presided at its creation and that govern the life and death of every created thing in nature. Without any model, these "visions" are the last and most original expressions of Leonardo's art—an art in which his perception based on *saper vedere* seems to have come to fruition.

Sculpture. That Leonardo worked as a sculptor from his youth on is borne out by his own statements and those of other sources. In the introduction to his *Treatise on Painting* he gives painting precedence over sculpture in the hierarchy of the arts; yet he emphasizes that he practices both arts equally. A small group of generals' heads in marble and plaster, works of Verrocchio's followers, are sometimes linked with Leonardo because a lovely drawing on the same theme from his hand suggests such a connection. But the inferior quality of this group rules out an attribution to the master. Not a trace has remained of the heads of women and children that, according to Vasari, Leonardo modelled in clay in his youth.

The two great sculptural projects to which Leonardo devoted himself wholeheartedly stood under an unlucky star; neither the huge, bronze equestrian statue for Francesco Sforza, on which he worked until 1494, nor the monument for Marshal Trivulzio, on which he was busy in the years 1506–11, were brought to completion. Leonardo kept a detailed diary about his work on the Sforza horse; it came to light with the rediscovery of the Madrid MS. 8936. Text and drawings both show Leonardo's wide experience in the technique of bronze casting but at the same time reveal the almost utopian nature of the project. He wanted to cast the horse in a single piece, but the gigantic dimensions of the steed presented insurmountable technical problems. Indeed, Leonardo remained uncertain of the problem's solution to the very end.

The greatness of Leonardo's concept of sculpture

The drawings for these two monuments reveal the greatness of Leonardo's concept of sculpture. Exact studies of the anatomy, movement, and proportions of a live horse—Leonardo even seems to have thought of writing a treatise on the horse—preceded the sketches for the monuments. Leonardo pondered the merits of two types, the galloping or trotting horse, and in both cases decided in favour of the latter. These sketches, superior in the suppressed tension of horse and rider to the achievements of Donatello's Gattamelata and Verrocchio's Colleoni sculptures, are among the most beautiful and significant examples of Leonardo's art. Unquestionably—as ideas—they exerted a very strong influence on the development of equestrian statues in the 16th century.

A small bronze of a galloping horseman in Budapest is so close to Leonardo's style that, if not from his own hand, it must have been done under his immediate influence (perhaps by Giovanni Francesco Rustici). Rustici, according to Vasari, was Leonardo's zealous student and enjoyed his master's help in sculpting his large group in bronze of "St. John the Baptist Teaching" over the north door of the Baptistery in Florence. There are, indeed, discernible traces of Leonardo's influence in John's stance, with the unusual gesture of his upward pointing hand, and in the figure of the bald-headed Levite. Moreover, an echo of Leonardo's inspiration is unmistakable in the much-discussed and much-reviled wax bust of "Flora" in Berlin. It may have been made in France, perhaps in the circle of Rustici, who entered Francis I's service in 1528.

Architecture. Leonardo, who in a letter to Ludovico Sforza applying for service described himself as an experienced architect, military engineer, and hydraulic engineer, was concerned with architectural matters all his life. But his effectiveness was essentially limited to the role of an adviser. Only once—in the competition for the cupola of the Milan cathedral (1487–90)—did he actually consider personal participation; but he gave up this idea when the model he had submitted was returned to him. In other instances, his claim to being a practicing architect involved sketches for representative secular buildings: for the palace of a Milanese nobleman (around 1490), for the villa of the French governor in Milan (1507–08), and for the Medici residence in Florence (1515). Finally, there was his big project for the palace and garden of Romorantin in France (1517–19). Especially in this last named, Leonardo's pencil sketches clearly reveal his mastery of technical as well as artistic architectural problems; the view in perspective (at Windsor Castle) gives an idea of the magnificence of the site.

Activity as a military engineer

Leonardo was also quite active as a military engineer, beginning with the years of his stay in Milan. But no definite examples of his work can be adduced. Not until the discovery of the Madrid notebooks was it known that in 1504, sent probably by the Florence governing council, he stood at the side of the Lord of Piombino when the city's fortifications system was repaired and that Leonardo suggested a detailed plan for overhauling it. Finally, his studies for large-scale canal projects in the Arno region and in Lombardy show that he was also an expert in hydraulic engineering.

But what really characterizes Leonardo's architectural studies and makes them stand out is their comprehensiveness; they range far afield and embrace every type of building problem of his time. Furthermore, there frequently appears evidence of Leonardo's impulse to teach: he wanted to collect his writings on this theme in a theory of architecture. This treatise on architecture—the initial lines of which are in MS. B (Institut de France, Paris), a model book of the types of sacred and profane buildings—was to deal with the entire field of architecture as well as with the theory of forms and construction and was to include such items as urbanism, sacred and profane building, and a compendium of the important individual elements (for example, domes, steps, portals, and windows).

In the fullness and richness of their ideas, Leonardo's architectural studies offer an unusually wide-ranging insight into the architectural achievements of his epoch. Like a seismograph, his observations sensitively register all themes and problems. For almost 20 years he was associated with Bramante at the court of Milan and again met him in Rome in 1513–14; he was closely associated with such other distinguished architects as Francesco di Giorgio, Giuliano da Sangallo, Giovanni Antonio Amadeo, and Luca Fancelli. Thus, he was brought in closest touch with all of the most significant building undertakings of the time. Since Leonardo's architectural drawings extend over his whole life, they span precisely that developmentally crucial period—from the 1480s to the second decade of the 16th century—in which the principles of the classical style were formulated and came to maturity. That this genetic process can be followed in the ideas of one of the greatest men of the period lends Leonardo's studies their distinctive artistic value and their outstanding historical significance.

Science. *Science of painting.* Notwithstanding Leonardo's abundant scientific activity, one must never lose sight of the fact that it was the intellectual output of a man who proudly and consciously felt himself an artist throughout his life. And he described himself as such. He first came in contact with science as an artist, in the task he set himself of writing a treatise on painting.

Treatise on Painting

Leonardo's famous book on painting, in the form known and read today, is not an original work by the master but a compilation of texts from various manuscripts by Leonardo, collected and arranged with loving care by his disciple and heir, Francesco Melzi. It is the Codex Urbinas Latinus 1270, now in the Vatican Library. It was prepared around 1540–50, but from its form one can see that it was still an unfinished rather than a completed manuscript. Many original texts known to exist are missing; whole sections of Leonardo's overall plan are not included.

The first printed edition of the treatise in Melzi's version, omitting the long introductory chapter concerning the "pecking order" among the arts, appeared in a luxurious binding in 1651 in Paris, published by Raffaelo du Fresne with illustrations after drawings by Nicolas Poussin. The first complete edition of Melzi's text did not appear until 1817, published by Guglielmo Manzi in Rome. The two standard modern editions are that of Emil Ludwig, three volumes, Vienna, 1882 (with German translation); and that of A. Philip McMahon, Princeton, 1956, two volumes (facsimile of the Codex Urbinas and English translation).

Leonardo's plan envisaged a much broader treatment of the theme, as his own allusions to it indicate. For, in addition to detailed practical instructions for painting and drawing, the treatise was to deal with every area involving the artist's perception and experience, which he could then convey as acquired criteria. Three main problems form the keynote of the work: the definition of painting as a science, which is briefly outlined above; the theory of the mathematical basis of painting—that is, geometry, perspective, and optics—with the systematic study of light and shadow, colour, and aerial perspective; and the theory of forms and functions in organic and inorganic nature, as they are explained and made comprehensible to the painter trained in *saper vedere.* This theory of the forms and functions of the visible world sought first of all to describe the animal world, including man; next it sought to include the plant world; finally it endeavoured to explain how such phenomena of inorganic nature as water and earth, air and fire came into being.

Drawings for the *Treatise*

In the drawings for the *Treatise on Painting,* extending from the earliest Milan period to the final years of Leonardo's life in France, the progressive broadening and deepening of the theme can be followed. Many drawings were placed by the side of the text, and some of them were coloured; many studies of nature that are admired as art works, such as the famous rain landscape (Windsor Castle; 12409) or the "Foliage" (Royal Library, Windsor Castle; 12431), can be identified as illustrations for the treatise. Manuscript C in the Institut de France, Paris, with its diagrams of the blending of lights and shadows, likewise represents a segment of this textbook. Leonardo's so-called grotesque heads are also closely linked with the treatise. They have often been erroneously described as caricatures; but actually, for the most part, they represent types and only occasionally individuals. They are variations of the human face in its gradations between the poles of the beautiful and ugly, the normal and abnormal, the dignified and vulgar. They are also related to anatomical-physiological studies, in which old age—with wrinkled skin and bulging tendons—is contrasted with youth. Representation of the human being was to be treated at length: his body, his proportions, his organs and their functions but also his attitudes in physical and spiritual movement. Here Leonardo's artistic and scientific aims intertwine.

Anatomical studies and drawing. Leonardo's anatomical studies are perhaps the best way of revealing the process by which, in Leonardo's mind, an increasing differentiation set in among his diverse spheres of interest; but it was a differentiation in which the seemingly divergent areas of study—likewise on a higher level—always remained interrelated. Thus, Leonardo's study of anatomy, originally pursued for his training as an artist, quickly grew into an independent area of research. As his sharp eye uncovered the structure of the human body, Leonardo became fascinated by the *figura istrumentale dell' omo* ("man's instrumental figure"), and he sought to probe it and present it as a creation of nature. The early studies dealt chiefly with the skeleton and muscles; yet even at the outset Leonardo combined anatomical with physiological researches. From observing the static structure, Leonardo proceeded to study the functions exercised by the individual parts of the body as they bring into play the organism's mechanical activity. This led him finally to the study of the internal organs; among them he probed most deeply into the brain, heart, and lungs as the "motors" of the senses and of life. He did practical work in anatomy on the dissection table in Milan, then in the hospital of Sta. Maria Nuova in Florence, and again in Milan and Pavia, where he received counsel and inspiration from the physician-anatomist Marcantonio della Torre. By his own admission he dissected 30 corpses in his lifetime, thus acquiring an astonishing range of experience on his own. This experience was distilled in the famous anatomical drawings, which are among the most significant achievements of Renaissance science. These drawings, among his *dimostrazione,* are based on a curious connection between natural and abstract representation; sections in perspective, reproduction of muscles as "strings" or the indication of hidden parts by dotted lines, and finally a specifically devised hatching system enable him to represent any part of the body in transparent layers that afford an "insight" into the organ. Here Leonardo's mastery of drawing proved most useful. The genuine value of these *dimostrazione* and their superiority to descriptive words—as Leonardo proudly emphasized—lay in the fact that they were able to synthesize a multiplicity of individual experiences at the dissecting table and make the data immediately and accurately visible. The effect is unlike that of all dead anatomical preparations; in this way the "live quality" of the organism is retained.

Value of the *dimostrazione*

This great picture chart of the human body was what Leonardo envisaged as a *cosmografia del minor mondo* ("cosmography of the microcosm"). From the advanced portions that have survived, it is apparent how much and how long it occupied his mind. And it provided the basic principles for modern scientific illustration. Leonardo has not sufficiently received his due in this domain. Thanks to a method of seeing that was peculiarly his own, he elevated the art of drawing into a means of scientific investigation and teaching of the highest quality.

Mechanics and cosmology. With Leonardo, mechanics also proceeds from artistic practice, with which he became quite familiar as an architect and engineer. Throughout his life Leonardo was an inventive builder; he was thoroughly at home in the principles of mechanics of his epoch and contributed in many ways to advancing them.

His model book on the elementary theory of mechanics, which appeared in Milan at the end of the 1490s, was discovered in the Madrid Codex 8937. Its importance lay less in its description of specific machines or work tools than in its use of demonstration models to explain the basic mechanical principles and functions employed in building machinery. Leonardo was especially concerned with problems of friction and resistance. These elements—screw threads, gears, hydraulic jacks, swivelling devices, transmission gears, and the like—are described individually or in various combinations; and here, too, drawing takes precedence over the written word. As in his anatomical drawings, Leonardo develops definite principles of graphic representation—stylization, patterns, and diagrams—that guarantee a precise demonstration of the object in question.

Importance of primal mechanical forces to his thought

In the course of years his interest in pure mechanics merged increasingly with an interest in applied mechanics. Leonardo realized that the mechanical forces at work in the basic laws of mechanics operate everywhere in the organic and inorganic world. They determine animate and inanimate nature alike as well as man. Leonardo wrote on a page of his treatise on anatomy:

> See to it that the book of the principles of mechanics precedes the book of force and movement of man and the other living creatures, for only in that way will you be able to prove your statements.

So, finally, "force" became the key concept for Leonardo; as *virtù spirituale* ("spiritual property"), it shaped and ruled the cosmos.

Wherever Leonardo probed the phenomena of nature, he recognized the existence of primal mechanical forces that govern the shape and function of the universe: in his studies on the flight of birds, in which his youthful idea of the feasibility of a flying apparatus took shape and led to exhaustive research into the element of air; in his studies of water, the *vetturale della natura* ("conveyor of nature"), in which he was as much concerned with the physical properties of water as with its laws of motion and currents; in his researches on the laws of growth of plants and trees as well as the geological structure of earth and hill formations; and finally in his observation of air currents, which evoked the image of the flame of a candle or the picture of a wisp of cloud and smoke. In his drawings, especially in his studies of whirlpools, based on numerous experiments he undertook, Leonardo again found a stylized form of representation that was uniquely his own: this involved breaking down a phenomenon into its component parts—the traces of water or eddies of the whirlpool—yet at the same time preserving the total picture, analytic and synthetic vision.

Thus, for all the separate individual realms of his knowledge, Leonardo's science offered a unified picture of the world: a cosmogony based on *saper vedere.* Its final wisdom is that all the workings of nature are subject to a law of necessity and a law of order that the *Primo Motore,* the divine "Prime Mover," created. "Marvelous is Thy justice, O Prime Mover! Thou hast seen to it that no power lacks the order and value of your necessary governance."

Leonardo as artist-scientist. As the 15th century expired, Scholastic doctrines were in decline, and Humanistic scholarship was on the rise. Leonardo, however, was part of an intellectual circle that developed a third, specifically modern form of cognition. In his view the artist—as transmitter of the true and accurate data of experience acquired by visual observation—played a significant part. With this sense of the artist's high calling, Leonardo approached the vast realm of nature to probe its secrets. His utopian idea of transmitting in encyclopaedic form the knowledge thus won was still bound up with medieval Scholastic conceptions, but the results of his research were among the first great achievements of the thinking of the new age because they were based on the principle of experience in an absolutely new way and to an unprecedented degree.

Finally, Leonardo, although he made strenuous efforts to teach himself and become erudite in languages, natural science, mathematics, philosophy, and history, as a mere listing of the wide-ranging contents of his library demonstrates, remained an empiricist of visual observation. But precisely here—thanks to his genius—he developed his own "theory of knowledge," unique in its kind, in which art and science form a synthesis. In the face of the overall achievements of Leonardo's creative genius, the question of how much he finished or did not finish becomes pointless. The crux of the matter is his intellectual force—self-contained and inherent in every one of his creations. This force has remained constantly operative to the present day.

(L.H.H.)

MAJOR WORKS

PAINTINGS: "The Annunciation" (*c.* 1472–77; Uffizi, Florence); "The Annunciation" (*c.* 1472–77; Louvre, Paris); "Madonna with the Carnation" (*c.* 1474; Alte Pinakothek, Munich); "Portrait of Ginevra de' Benci" (*c.* 1475–78; National Gallery of Art, Washington, D.C.); "Madonna Benois" (1478–after 1500; Hermitage, Leningrad); "St. Jerome" (*c.* 1480; Vatican Museums, Rome); "The Adoration of the Magi" (1481; Uffizi); "The Virgin of the Rocks" (*c.* 1483–85; Louvre); "The Musician" (*c.* 1490; Pinacoteca Ambrosiana, Milan); "Lady with an Ermine" ("Cecilia Gallerani"; *c.* 1490; Muzeum Narodowe, Kraków, Poland); "The Virgin of the Rocks" (1494–1508; National Gallery, London); "Last Supper" (1495–97; Sta. Maria delle Grazie, Milan); decoration of the Sala delle Asse (1498; Castello Sforzesco, Milan); "The Virgin and Child with St. Anne" (cartoon, *c.* 1499; National Gallery, London); "Virgin and Child with St. Anne" (*c.* 1501–12; Louvre); "Mona Lisa" ("La Gioconda"; 1503–06; Louvre); "St. John the Baptist" (before 1517; Louvre). Lost: "Madonna with the Yarn-Winder" (1501; best copy in the Duke of Buccleuch Collection, Boughton, Kettering); "Leda" (1503–06; best copy at Galleria Borghese, Rome); "Battle of Anghiari" (1503–06; copy at Palazzo Vecchio, Florence).

DRAWINGS AND NOTEBOOKS: Main collections: Institut de France, Paris; British Museum; Uffizi, Florence; Biblioteca Ambrosiana, Milan; Accademia, Venice; Royal Library, Windsor Castle; Biblioteca Reale, Turin; Biblioteca Nacional, Madrid; Victoria and Albert Museum, London.

BIBLIOGRAPHY. ANGELA OTTINO DELLA CHIESA (ed.), *The Complete Paintings of Leonardo da Vinci* (1969; originally published in Italian, 1967), catalogs the paintings. The most informative account of Leonardo's workshop and pupils is W. SUIDA, *Leonardo und sein Kreis* (1929). ARTHUR E. POPHAM (ed.), *The Drawings of Leonardo da Vinci* (1945, reissued 1973), is important for the study of Leonardo as a draftsman; the standard publication on the drawings is KENNETH CLARK and CARLO PEDRETTI, *The Drawings of Leonardo da Vinci in the Collection of Her Majesty the Queen at Windsor Castle,* 2nd ed., 3 vol. (1968). A. MARIONI, "I manoscritti di Leonardo da Vinci," in *Leonardo: Saggi e richerche* (1954), is a concise summary of all manuscripts, their facsimile editions, and chronology. This collection contains other excellent essays by various authors on Leonardo as artist and scientist. The Madrid Codices are presented in LEONARDO DA VINCI, *The Madrid Codices,* 5 vol. (1974), of which vol. 1 and 2 contain the facsimiles, vol. 3 has commentary by LADISLAO RETI, and vol. 4 and 5 contain Reti's transcription and translation into English. See also two articles on the rediscovered codices by Reti in *Burlington Magazine,* vol. 110 (1968). Aspects of Leonardo's personality and creativity made evident in the Madrid Codices are discussed in LADISLAO RETI (ed.), *The Unknown Leonardo* (1974), 10 essays; RICHARD MCLANATHAN, *Images of the Universe: Leonardo da Vinci: The Artist as Scientist* (1966); and EMANUEL WINTERNITZ, *Leonardo da Vinci as a Musician* (1982). AMOS P. MCMAHON (ed.), *Treatise on Painting,* is a facsimile edition of *Codex Urbinas Latinus 1270,* accompanied by an English translation, 2 vol. (1956). The best anthologies of Leonardo's literary heritage are JEAN P. RICHTER, *The Literary Works of Leonardo da Vinci,* 3rd ed., 2 vol. (1970, reissued 1977); and EDWARD MCCURDY (ed.), *The Notebooks of Leonardo da Vinci,* 2 vol. (1955, reissued 1977). For additional sources of information, see ETTORE VERGA, *Bibliografia Vinciana, 1493–1930,* 2 vol. (1931, reprinted 1970); and *Raccolta Vinciana,* fasc. 1–20 (1905–64). Two institutions devoted exclusively to the study of Leonardo are the Raccolta Vinciana, Castello Sforzesco, Milan, and the Elmer Belt Library of Vinciana at the University of California at Los Angeles. *Leonardo da Vinci,* 2 vol. folio, ed. by the ISTITUTO GEOGRAFICO DE AGOSTINI, NOVARA (1964), contains numerous essays and is a richly illustrated compendium of Leonardo's artistic and scientific activity. The two standard publications on Leonardo sources are LUCA BELTRAMI, *Documenti e memorie riguardanti la vita e le opere di Leonardo da Vinci in ordine cronologico* (1919); and GEROLAMO CALVI, *I manoscritti di Leonardo da Vinci, dal punto di vista cronologico, storico e biografico* (1925). KENNETH D. KEELE and CARLO PEDRETTI (eds.), *Leonardo da Vinci: Corpus of the Anatomical Studies in the Collection of Her Majesty the Queen at Windsor Castle,* 3 vol. (1978–80), includes a volume of facsimile plates. A selection, with drawings, is found in EMERY KELEN (ed.), *Fantastic Tales, Strange Animals, Riddles, Jests, and Prophesies of Leonardo da Vinci* (1971). The following six monographs are among the most valuable of the countless studies: GABRIEL SEAILLES, *Léonardo de Vinci: l'artiste et le savant* (1892); WOLDEMAR VON SEIDLITZ, *Leonardo da Vinci,* rev. ed. (1935), accompanied by extensive documentation (in German); KENNETH CLARK, *Leonardo da Vinci: An Account of His Development as an Artist,* 2nd ed. (1952, reprinted 1980); LUDWIG H. HEYDENREICH, *Leonardo da Vinci,* 2 vol. (1954; originally published in German, 1953); VASILI P. ZUBOV, *Leonardo da Vinci* (1968; originally published in Russian, 1961); and PETER R. RITCHIE-CALDER, *Leonardo and the Age of the Eye* (1970). MORRIS PHILIPSON (ed.), *Leonardo da Vinci: Aspects of the Renaissance Genius* (1966), contains valuable contributions to the historical and psychological aspects of Leonardo. Other works include CHARLES D. O'MALLEY (ed.), *Leonardo's Legacy: An International Symposium* (1969), a collection of essays: CARLO PEDRETTI, *Leonardo da Vinci: The Royal Palace at Romorantin* (1972), and *Leonardo: A Study in Chronology and Style* (1973, reprinted 1982); CECIL GOULD, *Leonardo: The Artist and the Nonartist* (1975); ROBERT PAYNE, *Leonardo* (1978), an account of Leonardo's career, with several new interpretations; and MARTIN KEMP, *Leonardo da Vinci: The Marvelous Works of Nature and Man* (1981).

(L.H.H./Ed.)

Libraries

A library (from Latin *liber*, "book") is a collection of written, printed, or other graphic or visual material (including films, photographs, tapes, phonograph records, videodiscs, microforms, and computer programs) organized and maintained for reading, study, and consultation. In this article the general term books is used to denote collectively these various forms of the contents of libraries, except when a particular form, such as manuscript or film, needs to be specified.

The English word "library" has a long history, occurring in a prose translation of the Roman philosopher Boethius' *Consolation of Philosophy* that Geoffrey Chaucer made in about 1374. The word *librairie* in French (and its counterpart in other Romance languages) does not have the same meaning, being used to denote a bookshop or, by extension, a publisher; the word used in many other countries to signify a collection of books, public or private, is derived from a Latinized Greek word, *bibliotheca:* hence *bibliothèque* in French, *biblioteca* in Italian and Spanish, *Bibliothek* in German, *biblioteka* in Russian. In Japanese the word is *toshokan* ("building of books"). The use of the word library to denote a building, room, or set of rooms in which a collection of books is contained goes back to the 15th century.

Libraries may be roughly classified in two ways: by ownership or purpose (*e.g.*, national, county or municipal, university, research, school, industrial, club, private) or by subject content (*e.g.*, general or special, the latter including medical, legal, theological, scientific, engineering, music, etc.). General libraries frequently contain special collections or departments. Organization ranges from the complex system of a great library—with catalogs, indexes, and a large staff—to the simple arrangement or listing that may suffice for the owner of a small private library. Faced with an ever-increasing quantity of information in a variety of technical forms, modern libraries have developed highly sophisticated mechanical and electronic systems for processing and retrieval. These systems have both widened the librarian's horizon and complicated the organizational problems of the library. The result has been the increased emphasis on a variety of active information services among libraries of all types.

The history of these developments is discussed in this article as a part of the general history of libraries; further information on the application of the theory and technology of information science in libraries and related fields is covered in the article INFORMATION SCIENCE. (Ed.)

The article is divided into the following sections:

HISTORICAL PERSPECTIVES

The ancient world. In earliest times there was no distinction between a record room (or archive) and a library, and in this sense libraries can be said to have existed for almost as long as records have been kept. A temple in the Babylonian town of Nippur, dating from the first half of the 3rd millennium BC, was found to have a number of rooms filled with clay tablets, suggesting a well-stocked archive or library. Similar collections of Assyrian clay tablets of the 2nd millennium BC were found at Tell el-Amarna in Egypt. Ashurbanipal (668–627 BC), the last of the great kings of Assyria, maintained an archive of some 25,000 tablets, comprising transcripts and texts systematically collected from temples throughout his kingdom. The majority carry his name, and some state that the King had "edited" them and caused them to be collected in his palace at Nineveh.

Ashurbanipal's library

Many collections of records were destroyed in the course of wars or were purposely purged when rulers were replaced or when governments fell. In ancient China, for example, the emperor Shih huang-ti (Shi Huangdi), a member of the Ch'in (Qin) dynasty and ruler of the first unified Chinese empire, ordered that historical records other than those of the Ch'in be destroyed so that history might be seen to begin with his dynasty. Repression of history was lifted, however, under the Han dynasty, which succeeded the Ch'in in 206 BC; works of antiquity were recovered, and the writing of literature as well as record keeping were encouraged. Private libraries flourished in some later dynasties, and texts held in these libraries were more likely to survive periods of war than were those held in government collections. Eventually the proliferation of collections in government offices, schools, and monasteries helped to assure the survival—and to increase availability—of valuable records and texts.

Greece and Alexandria. In the West the idea of book collecting, and hence of libraries as they are now understood, had its origin in the classical world. Most of the larger Greek temples seem to have possessed libraries, even in quite early times; many certainly had archive repositories. The tragic playwright Euripides was known as a private collector of books, but the first important institutional libraries came in Athens during the 4th century BC with the great schools of philosophy. Their texts were written on perishable material such as papyrus and parchment, and much copying took place. The Stoics, having no property, owned no library; the schools of Plato and of the Epicureans did possess libraries, the influence of which lasted for many centuries. But the most famous collection was that of the Peripatetic school, founded by Aristotle and systematically organized by him with the intention of facilitating scientific research. A full edition of Aristotle's library was prepared from surviving texts by Andronicus of Rhodes and Tyrannion in Rome *c.* 60 BC. The texts had reached Rome as war booty carried off by Sulla when he sacked Athens in 86 BC.

Aristotle's library formed the basis, mainly by means of copies, of the library established at Alexandria, which became the greatest in antiquity. It was planned by Ptolemy I Soter (died 283 BC) and brought into being by his son Ptolemy II Philadelphus (308–246 BC) with the collaboration of Demetrius of Phaleron, their adviser. The founders of this library apparently aimed to collect the whole body of Greek literature in the best available copies, arranged in systematic order so as to form the basis of published commentaries. Its collections of papyrus and vellum scrolls are said to have numbered hundreds of thousands. Situated in a temple of the Muses called the Mouseion, it was staffed by many famous Greek writers and scholars, who included the grammarian and poet Callimachus (died 240 BC), Eratosthenes (died *c.* 194 BC), the philosopher Aristophanes of Byzantium (died *c.* 180 BC), and Aristarchus of Samothrace (died 145 BC), the foremost critical scholar of antiquity.

Pergamum. In Asia Minor, a library rivaling that of Alexandria was set up at Pergamum during the reigns of Attalus I (died 197 BC) and Eumenes II (died 159 BC). Parchment (*charta pergamena*) was said to have been developed there after the copying of books was impeded by Ptolemy Philadelphus' ban on the export of papyrus from Egypt. (Parchment proved to be more durable than papyrus and so marks a significant development in the impact of technical advances on the dissemination of knowledge.) The library was bequeathed with the whole of the kingdom of Pergamum to the Roman people in 133 BC, and Plutarch records an allegation that Antony gave its 200,000 volumes to Cleopatra, to become part of the Alexandrian library.

Rome. There were many private libraries in classical Rome, including that of Cicero. Indeed, it became highly fashionable to own a library, judging from the strictures of the moralizing statesman Seneca and the spiteful jibes by the poet Lucian on the uncultured "book clown." Excavations at both Rome and Herculaneum have revealed what were undoubtedly library rooms in private houses, one at Herculaneum being fitted with bookcases around the walls. A Roman statesman and general, Lucullus, who was reckoned one of the richest men in the Roman world at that time and was famous for his luxurious way of life, acquired as part of his war booty an enormous library, which he generously put at the disposal of those who were interested. His biographer, Plutarch, speaks appreciatively of the quality of his book collection, and Cicero tells of an episode when he visited the library to borrow a book to find his friend, Cato, already ensconced there surrounded by books of the Stoic philosophy.

The library planned by Julius Caesar

Julius Caesar planned the creation of a public library and entrusted the implementation of his plans to an outstanding scholar and writer, Marcus Terentius Varro, also the author of a treatise on libraries, *De bibliothecis* (which has not survived). Caesar died before his plans were carried out, but a public library was built within five years by the literary patron Asinius Pollio. Describing its foundation in his *Natural History,* Pliny coins a striking phrase which has application to libraries generally: *ingenia hominum rem publicam fecit* ("He made men's talents a public possession"). Libraries were also set up by Tiberius, Vespasian, Trajan, and many of the later emperors; the Bibliotheca Ulpia, which was established by Trajan in about AD 100 and continued until the 5th century, was also the Public Record Office of Rome.

Byzantium and Islām. In the East the library tradition was picked up at Constantinople. It was probably at Caesarea that Constantine the Great's order for 50 copies of the Christian Scriptures was carried out. Under Constantine himself, Julian, and Justinian, the imperial, patriarchal, and scholarly libraries at Constantinople amassed large collections; and their real significance is that for a thousand years they preserved, through generations of uncritical teachers, copyists, and editors, the treasures of the schools and libraries of Athens, Alexandria, and Asia Minor. Losses occurred, but these were mostly due to the habit, noticeable especially in the 9th century, of replacing original texts with epitomes, or summaries. By far the greater part of the Greek classics, however, was faithfully preserved and handed on to the schools and universities of western Europe, and for this a debt is owed to the great libraries and the rich private collections of Constantinople.

The links with classical Greece provided by Constantinople were supplemented by the libraries of Islām, which incorporated Arabic versions of Greek medical, mathematical, and scientific works, including those of Aristotle. From the 9th century richly equipped libraries existed throughout the Islāmic world, including Baghdad under Hārūn ar-Rashid, Cairo, Alexandria, and also Spain, where there was an elaborate system of public libraries centred on Córdoba, Toledo, and Granada. Arabic works from these libraries began to reach Western scholars in the 12th century, about the time that Greek works from Constantinople were filtering through to the West.

Middle Ages and Renaissance. *Role of the monasteries.* As monastic communities were set up (from as early as the 2nd century AD) books were found to be essential to the spiritual life. The rule laid down for observance by several monastic orders enjoined the use of books: that of the Benedictine Order, especially, recognized the importance of reading and study, making mention of a "library" and its use under the supervision of a precentor, one of whose duties was to issue the books and make an annual check of them. Scriptoria, the places where manuscripts were copied out, were a common feature of the monasteries—again, especially in those of the Benedictine Order, where there was a strict obligation to preserve manuscripts by copying them. Many—Monte Cassino (529) and Bobbio (614) in Italy; Luxeuil (*c.* 550) in France; Reichenau (724), Fulda (744), and Corvey (822) in Germany; Canterbury (597), Wearmouth (674), and Jarrow (681) in England—became famous for the production of copies. Rules were laid down for the use of books, and curses invoked against any person who made off with them. Books were, however, lent to other monasteries and even to the secular public against security. In this sense, the monasteries to some extent performed the function of public libraries.

Contents of monastic libraries

The contents of these monastic libraries consisted chiefly of the Scriptures, the writings of the early Church Fathers and commentaries on them, chronicles, histories such as Bede's *Ecclesiastical History of the English Peoples,* philo-

sophical writings such as those of Anselm, Abelard, St. Thomas Aquinas, and Roger Bacon, and possibly some secular literature represented by the Roman poets Virgil and Horace and the orator Cicero. After the universities were founded, beginning in the 11th century, monkish students, on returning to their monasteries, deposited in the libraries there the lecture notes they had made on Aristotle and Plato, on law and medicine, and so forth, and in this way expanded their contents.

The new learning. The libraries of the newly founded universities—along with those of the monasteries—were the main centres for the study of books until the late Middle Ages; books were expensive and beyond the means of all but a few wealthy people. The 13th, 14th, and 15th centuries, however, saw the development of private book collections. Philip the Good, duke of Burgundy, and the French kings Louis IX and Charles V (who may be looked upon as the founder of the Bibliothèque du Roi [King's Library], which later became the Bibliothèque Nationale [National Library] in Paris) were great collectors, as were also such princes of the church as Richard de Bury, bishop of Durham (died 1345), who wrote a famous book in praise of books, *Philobiblon* (first printed in Cologne, 1473). But new cultural factors—including the growth of commerce, the new learning of the Renaissance (that was based on newly discovered classical texts), Gutenberg's invention of movable type for printing, and a substantial expansion of lay literacy—widened the circle of book collectors to include wealthy merchants whose libraries contained books of law and medicine, herbals, books of hours, and other devotional works. Italian humanists, such as Petrarch, searched for and copied manuscripts of classical writings to establish their scholarly libraries. Niccolò Niccoli (librarian to Cosimo de' Medici, the 14th-century ruler of Florence and a considerable patron of the arts) and Gian Francesco Poggio Bracciolini were two scholars who shared Petrarch's enthusiasm and ransacked Europe and the Middle East for manuscripts of the writers of Greece and Rome. Notable collections of books were made outside Italy, too (though Florence remained the centre of the rising book trade): by Diane de Poitiers, mistress of Henry II of France; by Jean Grolier, a high French official and diplomat, who was a great patron of bookbinders; by John Tiptoft, earl of Worcester; by Henry VII and Henry VIII of England and by many others.

Petrarch had wished to bequeath his collection to the municipality of Venice as a public library, but his intention was not realized. Cosimo de' Medici, however, set up, on the basis of Niccolò Niccoli's library, the Biblioteca Marciana in Florence in the convent of San Marco. The rich library of Lorenzo the Magnificent, grandson of Cosimo and an even greater patron of learning and the arts, also became a public library. It was opened in 1571 in a fine building designed by Michelangelo and still exists as the Biblioteca Laurenziana (though in 1808 it was amalgamated with the Marciana to form the Biblioteca Medicea-Laurenziana). Many other princely libraries were formed at this time, including that of Matthias I Corvinus of Hungary. Like the Medici, Corvinus employed agents to purchase manuscripts in the Levant, and he was also a customer of a well-known Florentine dealer in manuscripts, Vespasiano da Bisticci. Corvinus' library was destroyed when the Turks overran his capital of Buda in 1526 (a few books that survived are in the Austrian National Library at Vienna). The library of the Escorial in Madrid, founded in 1557, was based on the collections of Philip II. The Vatican library also dates its foundation from this time, the real founder of the collections as they are today having been Pope Nicholas V (reigned 1447–55), who dispatched agents to Germany, England, and Greece in search of manuscripts; Sixtus IV (reigned 1471–84) reassembled the Vatican collection in its present location.

Renaissance public libraries

Effects of the Reformation and religious wars. In England the end of the monastic libraries came in 1536–40 when the religious houses were suppressed by Henry VIII and their treasures dispersed. No organized steps were taken to preserve their libraries: it seems likely that a few—though only a very small proportion of the whole—were taken for the Royal Library. Even more wholesale destruction came in 1550: Henry VIII and Edward VI aligned with the "new learning" of the humanists; and university, church, and school libraries were purged of books embodying the "old learning" of the Middle Ages. The losses were incalculable. A change of attitude came about with Elizabeth's reign when those in authority realized that the kind of books that had been dispersed would form useful propaganda for the government's policy; the archbishop of Canterbury, Matthew Parker, and the Queen's principal adviser, William Cecil, took the lead in seeking out and acquiring the scattered manuscripts. Many other collectors were also active, including Sir Robert Cotton and Sir Thomas Bodley. As a result, some considerable portion of the libraries that had been scattered at the suppression was, by 1660, reassembled in collections—Parker's eventually went to Corpus Christi College at Cambridge; Cotton's to the British Museum; and Bodley's to form the Bodleian Library at Oxford—where they remain to this day.

Elsewhere in Europe, the period of the Reformation also saw many of the contents of monastic libraries destroyed, especially in Germany and the northern countries. The Reformation leader Martin Luther, however, did himself passionately believe in the value of libraries, and in a letter of 1524 to all German towns he insisted that neither pains nor money should be spared in setting up libraries, or book houses, particularly in the larger towns. As a consequence, many town libraries in Germany, including those at Hamburg (1529) and Augsburg (1537), date from this time. These, and the libraries of the newly created universities (such as Königsberg, Jena, and Marburg), were partly, at any rate, built up on the basis of the old monastic collections. In Denmark, similarly, some books from the churches and monasteries were incorporated with the new university library, though many were destroyed.

Libraries in Germany suffered severely in the Thirty Years' War. The Bibliotheca Palatina at the University of Heidelberg, for example, which had been founded in 1386, was taken as the spoil of war by Maximilian I of Bavaria, who offered it to Pope Gregory XV in 1623; and Gustavus Adolphus sent whole libraries to Sweden, most of them to swell the library of the University of Uppsala, which he had founded in 1620. The collections of the Royal Library in Stockholm were similarly enriched by the war booty that fell to Sweden during the reigns of Queen Christina and Charles X.

In France, Italy, Southern Germany, and Austria, where the Catholic faith remained unshaken, the old libraries remained and were supplemented by new ones set up for educational purposes by the Society of Jesus (the Jesuits).

17th and 18th centuries and the great national libraries. In the 17th and 18th centuries book collecting became more widespread. The motive sometimes was sheer ostentation, but often it was genuine love of scholarship. Several fine private collections were assembled, many of which were eventually to become the core of today's great national and state libraries—for this was also the period that saw new national and university collections springing up all over Europe.

There were, of course, other developments. In England were established a number of parish libraries, attached to churches and chiefly intended for the use of the clergy (one of the earliest, at Grantham in Lincolnshire, was set up as early as 1598, and some of its original chained books are still to be seen there). They were sometimes the result of lay donation: a Manchester merchant, Humphrey Chetham, left money in 1653 for the foundation of parish libraries in Bolton and Manchester and also for the establishment of a town library in Manchester (which still exists, housed in its original bookcases, in its original building). Later, in the 18th century, especially in England (though also elsewhere in Europe) and America, there was a great vogue for the circulating and subscription libraries—societies that provided reference service and lending collections for their members and had much influence on the formation of popular literary taste, especially in fiction.

Parish, town, and subscription libraries

Library planning. The private libraries of powerful and influential collectors such as Cardinal Mazarin in France were so large that a new approach to library organization was needed. The Escorial library in Madrid, erected in

1584, had been the first to do away with book bays on the medieval pattern and to arrange its collection in cases lining the walls. The old practice of chaining books to their cases was gradually abandoned; and the change to the present arrangement of standing them, spines facing outward, began in France, probably with the personal library of the lawyer, councillor of state, historian, and bibliophile Jacques-Auguste de Thou (died 1617). Mazarin's library was in the charge of Gabriel Naudé, who produced the first modern treatise on library economy, *Advis pour dresser une bibliothèque* (1627; *Instructions Concerning Erecting of a Library*). This work marked the transition to the age of modern library practice. One of its first fruits was the library of the diarist Samuel Pepys; in the last 14 years of his life Pepys devoted much time to the organization of his collection, and he left it to Magdalene College, Cambridge.

Naudé's concept of a scholarly library, systematically arranged, displaying the whole of recorded knowledge and open to all scholars, took root. It was above all absorbed by the philosopher Gottfried Wilhelm Leibniz (died 1716), a prominent librarian of his age, who conceived the idea of a national bibliographical organization that would provide the scholar with easy access to all that had been written on his subject. He realized that scientific progress is encouraged by communication among scholars and that an important purpose of great libraries and museums is to provide and keep open the channels of communication.

Emergence of national collections. The scope of scholarship and inquiry expanded rapidly during the 17th and 18th centuries, especially in the field of historical studies and in philosophy, resulting in a vast outpouring of books that went to swell the libraries of private collectors. In France, Jacques-Auguste de Thou, highly qualified as a collector, was made director in 1593 of the Bibliothèque du Roi (founded by Charles V and largely reorganized during the 15th century by Louis XII). Mazarin's library was scattered when he was compelled to leave France during the period of unrest known as the Fronde, but it was reassembled when he returned to power in 1661. Rehoused in a new building, it was opened to the public in 1691 and remained one of France's great libraries until after the French Revolution when it was incorporated with other collections (including the Bibliothèque du Roi) to form the Bibliothèque Nationale, today one of the world's great libraries. August, duke of Brunswick, established a library in 1604 that later became the Herzog August Bibliothek at Wolfenbüttel, one of the finest libraries in Europe (Leibniz was its librarian from 1690 to 1716). A library assembled by the elector Friedrich Wilhelm of Brandenburg was founded in 1659 and later became the Prussian State Library. The collections of the English book collectors Sir Hans Sloane, Sir Robert Cotton, and Edward and Robert Harley, earls of Oxford, formed the basis of the British Museum collection, founded in 1753, which from the start was regarded as the national library; it was further enlarged by the addition in 1757 of the Royal Library, containing books collected by the kings of England from Edward IV to George II.

The great national collections

The effects of the French Revolution. On the continent of Europe the anticlerical movement that found expression in revolution sealed the fate of many monastic and church libraries: those in France, for example, were expropriated in 1789; in Germany in 1803; in Spain in 1835. The dispersal of books was, however, better organized than that resulting from the dissolution of the English monasteries under Henry VIII. In France books were collected in the main towns of the *départements* in what were called *dépots littéraires.* In 1792 the same fate befell the collections of aristocratic families, and these, too, were added to the *dépots.* The enormous accumulations caused problems, and many books were lost, but the plan of coordinating library resources throughout the country was carried out. The Bibliothèque Nationale received some 300,000 volumes; and new libraries were set up in many important provincial cities. Napoleon's successful campaigns throughout Europe also brought acquisitions, in the form of war booty, to the Bibliothèque Nationale, but most of the books were returned to their original owners after the Congress of Vienna in 1814–15. In Bavaria the state library was greatly enriched by the contents of over 150 confiscated libraries, and many of the provincial libraries were similarly enlarged. In Austria, as a result of confiscations, *Studienbibliotheken* (study libraries) were set up at Linz, Klagenfurt, and Salzburg, the university libraries at Graz and Innsbruck were substantially enlarged, and many valuable acquisitions accrued to the Hofbibliothek in Vienna.

Later developments. The difficulties of library management grew more noticeable in the 19th century. Libraries had grown in size, but their growth had been haphazard; administration had become weak, standards of service almost nonexistent; funds for acquisition tended to be inadequate; the post of librarian was often looked on as a part-time one; and cataloging was frequently in arrears and lacked proper method.

The university library at Göttingen was a notable exception. Johann Gesner, the first librarian, working in close association with the curator of the university, G.A. von Münchhausen, and proceeding on the principles laid down by Leibniz, made strenuous efforts to cover all departments of learning; the library provided good catalogs of carefully selected literature and was available to all as liberally as possible. The next director, C.G. Heyne, enthusiastically followed the same principles, with the result that Göttingen became the best organized library in the world.

By the middle of the century new conceptions of the purpose and scope of learned libraries were everywhere taking shape. Within a few years the picture of library service had been transformed, and a leading figure in this development was Antonio (later Sir Anthony) Panizzi, a political refugee from Italy who began working for the British Museum in 1831 and was its principal librarian from 1856 to 1866. From the start he revolutionized library administration, demonstrating that the books in a library should match its declared objectives and showing what these objectives should be in the case of a great national library. He perceived the importance of a good catalog and to this end elaborated a complete code of rules for catalogers. He also saw the potentiality of libraries in a modern community as instruments of study and research, available to all, and, by his planning of the British Museum reading room and its accompanying bookstacks, showed how this potential might be realized. His ideas have dominated library thought in the field of scholarly—or, as they are now called, research—libraries and have achieved major expression in the Library of Congress in Washington, D.C.

The revolution in library administration

By the middle of the 19th century the idea had been accepted that community libraries might be provided by local authorities at public expense. This proved a significant stage in the development of library provision. Panizzi had stated that he wanted the facilities of a great library to be available to poor students so that they could indulge their "learned curiosity"; in England in 1850 an act of Parliament was passed enabling local councils to levy a rate for the provision of free library facilities. From the first tentative beginnings there has been continuous growth in the providing of reading and other services and in the use that is made of them by the public.

KINDS OF LIBRARIES

Library services available throughout the world vary so much in detail from country to country that it is impossible to present anything but the most general picture of their activities. Nevertheless, they follow a broad but discernible pattern that has evolved over the years.

Aims of a national library

National libraries. In most countries there is a national or state library or group of libraries maintained by national resources, usually bearing responsibility for publishing a national bibliography and for maintaining a national bibliographical information centre. National libraries strive principally to collect and to preserve the nation's literature, though they try to be as international in the range of their collections as possible.

Most national libraries receive, by legal right, one free copy of each book and periodical printed in the country. Certain other libraries throughout the world share this privilege, though many of them receive their legal (or copyright) deposit only by requesting it.

The Bibliothèque Nationale in Paris, the British Library in London, the Library of Congress in Washington, D.C., and the Lenin Library in Moscow are the most famous and possibly the most important national libraries in the Western world. Their importance springs from the quality, size, and range of their collections, which are comprehensive in scope and attempt to maintain their comprehensiveness. This latter they achieve with diminishing success in view of the vastly increased number of publications that daily appear throughout the world, the failure of publishers to provide legal-deposit copies, and the difficulty of ensuring adequate representation of publications issued in the developing countries.

Bibliothèque Nationale. The Bibliothèque Nationale was before the Revolution known as the Bibliothèque du Roi and owes its origin (as is indicated above) to Charles V. It was the recipient during the 15th and 16th centuries of a number of important collections of manuscripts; in 1617, under the librarianship of the great collector de Thou, its right to legal deposit was reaffirmed and continued to be rigidly enforced. In the first quarter of the 18th century four of the library's departments (of prints, coins, printed books, and manuscripts) were created; it was opened to the public in 1735. Enormous additions accrued to the library as a result of the French Revolution and the confiscation of aristocratic and church private collections. The catalog of the library on cards was completed under the librarianship (1874–1905) of Léopold Delisle, and in 1897 he made a start to the task of compiling a printed catalog in volume form.

The present-day Bibliothèque Nationale plays a leading role in the French national library service. It houses the Direction des Bibliothèques, which oversees all public libraries, and participates in the training of library professionals. The library has undertaken the retrospective conversion of its catalog into machine-readable form.

The British Library. For more than two centuries the British Museum combined a great museum of antiquities with a great comprehensive library. The library was founded in 1753 by the acceptance of the bequest of the collections of Sir Hans Sloane, physician to King George II and president of the Royal Society. The library was built up on the basis of two other important collections, that of Sir Robert Cotton and that of Edward and Robert Harley, earls of Oxford; to these were added the Royal Library, given by George II in 1757. With this collection came also the right to legal deposit of one copy of every book published in the British Isles; this right is generally enforced, yet many titles arrive only slowly and some not at all. These four basic collections were notably enlarged during the first century of the library's history by the addition of many private collections, including the libraries of King George III (1823) and of Thomas Grenville (1846). Sir Anthony Panizzi reorganized the library; he was also responsible for its printed catalog, made between 1881 and 1905.

British Library Act of 1972

The British Museum Library was separated from the Museum under the British Library Act of 1972 and by July 1, 1973, was reorganized as the British Library Reference Division. The British Library Lending Division was formed from the amalgamation of two previously existing libraries: the National Central Library, which grew out of the Central Library for Students founded in 1916 and was the centre for interlibrary lending from 1927, and which had a collection of some 400,000 books and periodicals, mainly in the humanities and social sciences; and the National Lending Library for Science and Technology, which had been opened in 1962 by the Department of Scientific and Industrial Research. The Lending Division is located in Yorkshire and operates an extensive lending service through the mail.

The British Library Bibliographic Services Division was formed from the British National Bibliography Ltd., an independent organization set up in 1949 to publish a weekly catalog of books published in the United Kingdom and received at the British Museum by legal deposit. The *British National Bibliography,* as this weekly catalog was called, quickly established itself as a foremost reference work, both for book selection and cataloging and for reference retrieval. Since the reorganization of 1973 the division has continued and expanded the computerizing of current cataloging and the central provision of both printed cards and machine-readable entries. The BLAISE service (British Library Automated Information Service) offers a cataloging facility to any library wishing to participate, and the Bibliographic Services Division and its predecessor, the British National Bibliography, have cooperated closely with the U.S. Library of Congress in the Project for Machine-Readable Cataloging (MARC), which provides on-line access to the catalogs of the current acquisitions of the British Library Reference Division and the Library of Congress.

Library of Congress. The U.S. Library of Congress, located in Washington, D.C., probably is the largest of the national libraries, and its collection of modern books is particularly extensive. It was founded in 1800 but lost many of its books by fire during a bombardment of the Capitol by British troops in 1814. These losses were to some extent made good by the purchase of Thomas Jefferson's library shortly thereafter. The library remained a strictly congressional library for many years, but as the collections were notably enlarged by purchases and by additions under the copyright acts, the library became and remained—in effect, although not in law—the national library of the United States. The public has access to many of the collections.

The Library of Congress makes its catalog available to many thousands of subscribing American libraries and institutions. The service was begun by Herbert Putnam, librarian from 1889 to 1939. At the program's inception, in 1902, printed cards were used, and in the first year there were 212 subscribers.

The library's impact on librarianship has always been of the highest value. Through the Library of Congress Classification, the printed catalog cards, and the Project for Machine-Readable Cataloging (MARC; see below *Technical services*), the library's practices are widely followed. It publishes the *National Union Catalog,* its many editions totaling several hundred volumes and representing the stock of several thousand libraries. The library began producing most of the catalog on microfiche in 1983.

Lenin Library. Of a size and importance comparable to the Library of Congress, the Lenin Library of the U.S.S.R., in Moscow, is the national library of the Soviet Union. It receives several copies of all publications from the constituent republics of the Soviet Union and distributes copies to specialist libraries. It issues printed cards for the *Bibliography of Periodicals, 1917–1947* and for a cooperative catalog called *Books Published in the USSR, 1917–1945,* which lists the holdings of the Lenin Library, the

Saltykov-Shchedrin Public Library in Leningrad, the Library of the U.S.S.R. Academy of Sciences in Leningrad, and the Central Book Office. It has produced the Soviet Library–Bibliographical Classification scheme based on a Marxist–Leninist classification of knowledge. It organizes domestic and international lending and exchanges and offers courses of lectures for professional education and also for readers.

Other national collections. There are many other national libraries with important collections and very long histories. The Bibliothèque Royale Albert I, in Brussels, founded in 1837 and centred on the 15th-century collection of the dukes of Burgundy, is the national library of Belgium and the centre of the country's library network; it maintains a regular lending service with the university libraries and with the large town library of Antwerp. The Dutch Royal Library in The Hague was founded in 1798, and it, too, is the centre of a well-developed interlibrary loan system. Because the unification of Italy in the 19th century brought together many city-states that had major libraries, the country has a number of national libraries, the chief being the Biblioteca Nazionale Centrale Vittorio Emanuele II in Rome, founded in 1875, and the historically richer Biblioteca Nazionale Centrale at Florence, founded in 1747. Other Italian national libraries are at Milan, Naples, Palermo, Turin, and Venice. Germany was equally remarkable before World War II both for the importance of its state or provincial libraries and for the lack of a recognized national library. The former Preussische Staatsbibliothek was given national status in 1919; after World War II, under the name Deutsche Staatsbibliothek, it became the national library of East Germany. West Germany has no national library as such, the functions of such a library being performed by the Deutsche Bibliothek in Frankfurt and the Staatsbibliothek Preussischer Kulturbesitz in West Berlin. The Austrian National Library, founded by the emperor Maximilian I in 1493, has rich collections—notably of manuscripts from the Austrian monasteries and from the library of Matthias I Corvinus, dispersed after the capture of his capital, Buda, by the Turks in 1526. The National Library of Australia in Canberra, formally created by legislation in 1960, grew out of the Commonwealth Parliamentary Library, established in 1901.

National libraries in Asia

Many nations in Asia have national libraries, some of them—including the National Library of Peking and the National Diet Library in Tokyo—with holdings of more than 2,000,000 volumes. The National Library of India (formerly the Imperial Library) in Calcutta was founded in 1903. In some countries, such as Iceland, Norway, and Israel, the national library is combined with a university library. In Nigeria the library of the University of Ibadan served as the national library until the national library in Lagos was founded.

University and research libraries. Before the invention of printing, it was common for students to travel long distances to hear famous teachers. Printing made it possible for copies of a teacher's lectures to be widely disseminated, and from that point universities began to create great libraries. The Bodleian Library at Oxford University and Harvard University Library at Cambridge, Mass., are superior to many national libraries in size and quality. The collections of the libraries of the University of California together nearly equal those of the Library of Congress. In addition to a large central library, often spoken of as the heart of a university, there are often smaller, specialized collections in separate colleges and institutes. The academies of science in the Soviet Union and the countries of eastern Europe consist of groups of these specialized institutes, and while not all act as universities in awarding degrees, their research function has the same importance. Some, as in Hungary and Romania, serve as the national library.

In a university library many users may seek the same books at the same time. The difficulty of providing multiple copies has vexed most university librarians, who must balance slender resources against sometimes vociferous demand. To handle the problem, many libraries have set up a short-loan collection from which books may be borrowed for as little as a few hours. The use of a microcomputer for short-loan records has brought some relief through its great flexibility of operation and capacity for instant recall of information on the whereabouts of a particular work.

Cooperation among libraries

The range of research carried out at a traditional university may encompass every aspect of every discipline, and even the largest university libraries have long recognized the need for cooperation with others, first in cataloging and later in acquisitions. Automation has helped, too, by making it possible for readers in one library to consult the catalogs of others by means of computer networks. Previously, much effort was expended in printing volumes of union catalogs, especially for periodicals, and although these were costly to maintain, they proved the value to scholars of sharing information on catalogs and collections. Many universities have published catalogs of their special collections and have arranged for the production of microfilms both of rare individual works and of complete collections. An example is the Goldsmiths'–Kress collection of early works in economics, which combines the holdings of the Goldsmiths' Library at the University of London and the Kress Library at Harvard.

Role of public libraries

Public libraries. Public libraries are now acknowledged to be an indispensable part of community life as promoters of literacy, providers of a wide range of reading for all ages, and centres for community information services. Yet although the practice of opening libraries to the public has been known from ancient times, it was not without considerable opposition that the idea became accepted, in the 19th century, that a library's provision was a legitimate charge on public funds. It required legislation to enable local authorities to devote funds to this cause.

Public libraries now provide well-stocked reference libraries and wide-ranging loan services based on systems of branch libraries. They are further supplemented by traveling libraries, which serve outlying districts. Special facilities may be provided for the old and the disabled, and in many cases library services are organized for local schools, hospitals, and jails. The services provided vary in proportion to the size of the municipality or the area covered. In the case of very large municipalities, library provision may be on a considerable scale, including a reference library, which has many of the features associated with large research libraries. The New York Public Library, for example, has rich collections in many research fields; and Boston Public Library, the first of the great city public libraries in the United States (and the first to be supported by direct public taxation), has had from the first a twofold character as a library for scholarly research as well as for general reading. In the United Kingdom, the first tax-supported public libraries were set up in 1850; they provide a highly significant part of the country's total national library service. The importance of public library activities has been recognized in many countries by legislation designed to ensure that good library services are available to all without charge.

In many cases, public libraries build up collections that relate to local interests, often providing information for local industry and commerce. It is becoming more and more usual for public libraries to provide, for home loan, music scores, phonograph records, and, in some countries—notably in Sweden and the United Kingdom—original works of art for enjoyment, against a deposit, in the home.

Not all countries provide public library services of an equally high standard, but there has been a tendency everywhere to recognize their value and to improve services where they exist or to introduce them where they do not. Public librarians work strenuously, through such organizations as the International Federation of Library Associations, for such developments.

Some public libraries have begun to promote a program called public lending right, under which authors of books lent from public libraries receive a fee for each loan. The programs are popular in small countries with minority languages, where writers have little hope of earning their living from royalties on sales. The principle has been widely accepted, despite fierce opposition, even in countries with well-established book trade and the advantages of an international language.

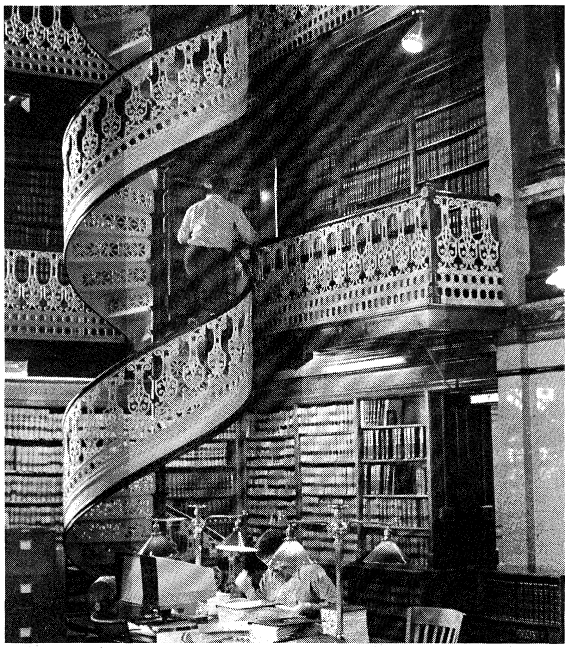
Special libraries. The national, university, and public libraries form the network of general libraries more or less accessible to the general public. The libraries take pride in special collections, which are built around a special subject interest. Outside of the network are a large number of libraries established by special groups of users to meet their own needs. Many of these originated with learned societies and especially with the great scientific and engineering societies founded during the 19th century to provide specialist material for their members. Thus some special libraries were founded independently of public libraries and before major scientific departments were developed in national libraries. For example, the National Reference Library of Science and Invention, now the Science Reference Library and part of the British Library, was originally established at the U.K. Patent Office.

With the coming of the Industrial Revolution arose the need for a working class educated in technology, and industrialists and philanthropists provided facilities and books of elementary technical instruction. In the United Kingdom the Mechanics' Institutes were founded in the rapidly growing industrial towns to provide books and lectures to workers and tradesmen at prices lower than those of the subscription libraries.

Functions and services of specialist libraries

Special libraries are often attached to official institutions such as government departments, hospitals, museums, and the like. For the most part, however, they come into being to meet specific needs in commercial and industrial organizations. They are planned on strictly practical lines, with activities and collections carefully controlled in size and scope, though they may be and often are large and wide-ranging in their activities; they cooperate widely with other libraries. They are largely concerned with communicating information to specialist users, in response to, or preferably in anticipation of, their needs. They have therefore been much concerned with the theoretical investigation of information techniques, including the use of computers for indexing and retrieval. It was in this area that the concept of a science of information flow and transfer emerged as a new field of fundamental theoretical study. The concept underpins the practices not only of special libraries but of all types of library and information services.

School libraries. Where public libraries and schools are provided by the same education authority, the public library service may include a school department, which takes care of all routine procedures, including purchase, processing with labels, and attaching book cards and protective covers; the books are sent to the schools ready for use. This is done in Denmark and in some parts of the United Kingdom. In other countries, the United States for example, processing may be contracted out to a specialist supplier. In the Soviet Union the All-Union Book Chamber prepares bibliographical data for distribution to all school libraries in the country. Everywhere, in fact, school and public libraries cooperate closely.



The law library serving the special needs of state legislators in Des Moines, the capital of Iowa.

Erich Hartmann—Magnum

Teachers who take an interest in the school library make a considerable contribution to its progress, and many have acquired qualifications in librarianship, recognizing that a modern library requires full-time attention and a variety of skills. Like the special librarian, the school librarian must have a close knowledge of and sympathy with the work of the teaching staff; and school libraries have been the scene of significant research and experiment with many different media, so much so that some school libraries have been promoted to become resource centres. Teachers accustomed to using visual aids, often indeed to making their own, have come to expect the library to provide collections of photographs, slides, films and filmstrips, and artifacts for work in subjects such as history and mathematics. Some school librarians use the term "realia" to describe these resources.

Private libraries. The libraries owned by private individuals are as varied in their range of interest as the individuals who collected them, and so they do not lend themselves to generalized treatment. The phrase private library is anyway unfortunate because it gives little idea of the public importance such libraries may have. Private collectors are often able to collect in depth on a subject to a degree usually impossible for a public institution; being known to booksellers and other collectors, they are likely to be given early information about books of interest to them; they can also give close attention to the condition of the books they buy. In these ways they add greatly to the sum of bibliographical knowledge (especially if they make their collections available to scholars).

Henry Clay Folger, for example, collected no fewer than 70 copies of one book—the first collected edition of Shakespeare's plays. (In 1932 he opened the Folger Shakespeare Library in Washington, D.C., which had been built to house his collection.) As a result of his collecting he added greatly to the sum of knowledge about the printing of Shakespeare's plays and about 17th-century printing in general. Collectors of private libraries have sometimes benefited posterity by leaving their collections to public institutions or founding a library. Examples in the United States include Henry E. Huntington, John Carter Brown, William L. Clements, and J.P. Morgan. The tradition has long been established in Europe, where many important libraries have been built up around the nucleus of a private collection.

Subscription libraries. Part public, part private, these libraries enjoyed much popularity from the late 17th to the 19th century. Many of them were set up by associations of scholarly professional groups for the benefit of academies, colleges, and institutions; but their membership was also open to the general public. Some of them are still in existence: perhaps the most famous are the Library Company of Philadelphia, founded by Benjamin Franklin in 1731; the Boston Athenaeum, founded in 1807; and the London Library, opened largely at the instance of Thomas Carlyle in 1841, which today has a wide-ranging collection for loan to its members in their homes.

Famous subscription libraries

During the 19th century, the great size of many subscription libraries enabled them to wield much influence over publishers and authors: Mudie's Circulating Library, for instance, established in London in 1842, would account for the sale of as much as 75 percent of a popular novel's edition. Nevertheless, these libraries were for the most part unable to survive, and the service they gave is now largely provided by the free public libraries.

Archives. Archives are created in the course of conducting business activities of a public or private body; they are accumulations of documentary material. Originally, such records were not distinguished from library materials and were preserved in the same places as other manuscripts, up until the mid-15th century and the invention of printing. The importance nowadays accorded to public records has been recognized as one outcome of the French Revolution, when for the first time an independent national system of archive administration was set up, for whose preservation and maintenance the state was responsible and to which there was public access.

The science of archive administration embraces the study of records management, records appraisal, accessioning and arrangement, archival buildings and storage facilities, preservation and rehabilitation, and reference services, including exhibition and publication. Academic courses offering instruction in archive work are available in many parts of the world.

While the administration of archives shares with libraries the basic obligation to collect, to preserve, and to make available, it has to employ different principles and management techniques. Libraries might be described as collecting agencies, whereas archival institutions are receiving agencies: they do not select—their function is to preserve documents as organic bodies of documentation. They must respect the integrity of these bodies of documents and maintain as far as possible the order in which they were created. And, of course, the documents need catalogs and finding aids, or guides.

A distinction has to be drawn between public and private archives. Every state, broadly speaking, now recognizes the need to preserve its own official records and is expected to maintain a system of archive administration, which has the function of collecting them, preserving them, and making them publicly available after the appropriate lapse of time. Among the best known are the Archives Nationales in France, the U.S. National Archives, and the British Public Record Office. Nonofficial archives—the records of the day-to-day activities of an institution or a business—are now recognized as having great value for socioeconomic history, and they are frequently sought by libraries for their historical value and preserved in manuscript and similar collections. It is the practice of many institutions such as universities, professional and commercial organizations, and ecclesiastical establishments to set up their own archive departments. (F.C.F./D.J.F.)

Distinction between public and private archives

LIBRARY ARCHITECTURE

Function and design. The basic function of a library building is to house the library's collections, to provide adequate space for staff administration and procedures, and to offer acceptable accommodation in which the collections can be used. The form given to the library is undoubtedly of great importance, but its success will in the long run be measured by its ability to meet the basic functional requirements. These requirements have to be interpreted differently according to the objectives and needs of different types of libraries, whether large research, university, public, or special.

In planning a research or university library, due regard to the following considerations is essential: (1) The space set aside for the collections must not only be adequate for immediate needs but also allow for planned growth over a reasonable period of time. (2) Adequate provision should be made to ensure the preservation and safety of the collections, such as proper temperature and humidity control, air conditioning, and a building plan calculated to provide security against misuse. (3) Provision should be made for the convenience and comfort of the readers and of the library staff, including the avoidance of unnecessary and time-wasting movement within the building.

The same strictures apply, on the whole, to the planning of other kinds of libraries. A good public library would pay more attention to providing an attractive exterior, a convenient layout, and pleasing conditions for users so that they can browse at leisure and discuss their reading and information requirements comfortably with the staff employed for that purpose. The functional emphasis in a special library would be on ease and speed of consultation.

The final form to be aimed at in all these cases is a library building both functionally and architecturally distinguished. Hence, the closest collaboration is essential between librarian and architect, the former supplying as complete a brief as possible (after careful discussion with library colleagues) and the latter endeavouring to understand the librarian's brief and interpret it in building terms. Difficulties and misconceptions are removed by close and constant discussion. Cooperation of this kind has become normal practice only in recent years; indeed, it is only in recent years that the concept of a fully documented brief prepared by the librarian has been accepted or even understood by architects and librarians alike. In the early days, libraries were often associated with temples; and it is still common to look upon a library as a central feature in a municipal or university complex, hence the temptation to erect a "prestigious" building, which may and often does subordinate function to appearance.

Essential collaboration between architect and librarian

Historical developments. The clay-tablet rooms in the temple at Nippur in Babylonia may be looked upon as functionally designed for their purpose, as was an "archive room" excavated at Herculaneum; and, in the cloister of the early monasteries, the *armarium,* or book cupboard, was appropriately placed for its purpose in the well-lighted cloister. Monastery and cathedral libraries of the later medieval period employed the chained library stall system and were designed to meet the readers' need for well-lit workspace. Each consisted of a long room that ran the length of the building, usually on the first upper floor, lighted on both sides with rows of windows. Between the windows and at right angles to the walls were rows of back-to-back presses, or cupboards, with two or three fixed shelves on each side and with desks attached to the presses at the level of the lowest shelf; the books were chained to a long bar running the width of the presses by chains just long enough to enable them to lie open on the desk. When not in use, the books, usually at the time bulky folios and quartos, stood on the shelves, with their front edges facing outward so that the chains, which were normally attached to the front edge of the upper or lower cover, should not damage the binding of the other books on the shelves. A centre gangway ran the length of the room between the presses; and in the alcoves formed by the presses there were fixed benches for readers, who were thus able to get at the books on the desks and have enough light from the windows to read by.

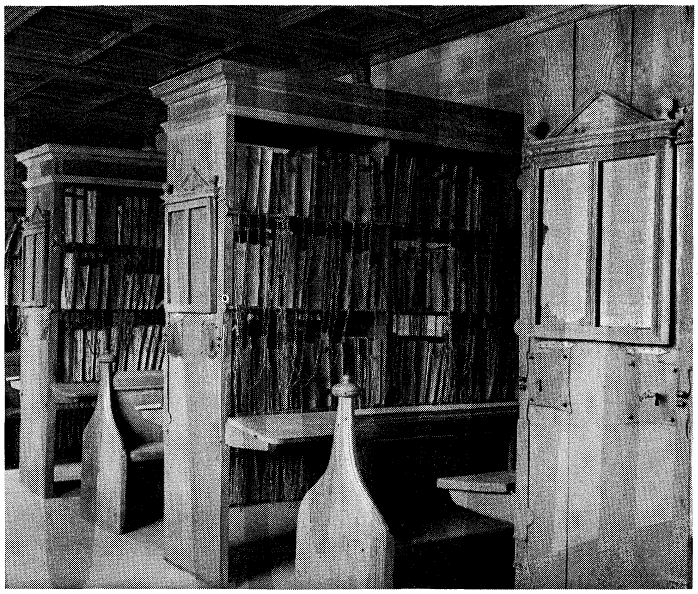
17th and 18th centuries. The "long room" was retained even in 17th- and 18th-century libraries, a reminder of the older system. The abandonment of chaining, however, coupled with a change in the pattern of publication—marked by decreasing cost and greater numbers of publications, particularly in smaller sizes—made possible the adoption of wall shelving. Wall shelving, in turn, made possible the greater use of the height of a building—the higher the walls, the greater the number of books that could be shelved. Besides this, the disappearance of chains made it possible for books to be taken away from the shelves for reading, and seats could be disposed as desired; the walls thus left unencumbered with desks and benches could be experimented with, and the main floor area could be left empty or provide an elegant setting for statuary or exhibits of other kinds, such as coin cabinets. Sometimes spaciousness and display were more highly prized than convenience for study. An example of this architectural emphasis is to be found in the Prunksaal in the Austrian National Library in Vienna, erected in 1723–26 after a plan by Johann Fischer von Erlach, which consists of a magnificent Baroque hall, decorated with marble Corinthian columns; a statue of Charles VI stands in the middle and other statues of princes of the empire are placed along the walls. A number of the libraries in the Oxford and Cambridge colleges—the Wren Library at Trinity College, Cambridge, and that at Christ Church, Oxford—also provide excellent examples. Perhaps the last great flourish of library design of this kind was the King's Library in the British Museum, built between 1823 and 1826 to house the library of King George III, acquired by the museum in 1823. It consists of a room 300 feet (about 100 metres) in length with a gallery; the walls are lined with bookshelves from floor to ceiling.

Wall shelving

British Museum reading room. A complete innovation in functional planning was made with the celebrated reading room in the British Museum. By the middle of the 19th century, readers were too numerous for the space provided for them in the existing reading rooms. In 1854 Sir Anthony Panizzi, by a brilliant application of the "engineering age" to library construction, planned a bookstack in cast iron with exterior enclosing walls and widely spaced brick piers, to hold some 1,500,000 volumes; it was designed to surround and support a huge, circular reading room whose radiating rows of reading desks with places for 450 readers naturally followed the circular plan, facilitating supervision, and whose walls provided space for an open access general reference library of 25,000 volumes. The "iron library," which provided an extensive library in close proximity to the reading area, reduced the risk of fire and demonstrated immense saving of space by eliminating brick supports and substituting metal. Modern stack construction has greatly improved on it, substituting steel for cast iron and generally economizing on space; but the basic plan of this stack was followed in subsequent stacks.

Bookstacks and reading rooms

The modern period. Panizzi's creation focused attention once more on functionalism in library planning. From that time up to World War II, the design of libraries was conditioned largely by architects' interpretation of the functions to be performed by the library, and their buildings rarely gave any indication of what was actually performed within them. General style tended toward the monumental, as befitted (so it seemed to them) a building devoted to noble and scholarly pursuits. The librarian had little say—indeed, as a rule probably had little to say—on the design of the building, except to indicate the proportion of space to be allotted to bookstacks, reading rooms, and administrative quarters.



The chained library of the Cathedral Church of the Blessed Virgin Mary and St. Aethelberht, Hereford, England.

A specific part of the building was set aside for bookstacks, and, not surprisingly in view of the constant growth in library collections, the stack frequently came to be designed as a tower. Reading rooms were treated as separate architectural units, in many cases, related neither in proportion nor access to the bookstacks. Finally, the

space provided for administrative purposes and the routine library procedures (such as control and recording of acquisitions, cataloging, binding, and so on) was frequently planned without properly appreciating the importance of a relationship between bookstacks, reading rooms, and public. Fixed function planning produced buildings with little possibility of the flexible use of space and as a rule with only limited, if any, possibility of expansion. Much frustration was caused to the librarian, who had to put up with (and provide) light and heat for unnecessarily high reading rooms, spacious corridors, and, sometimes, monumental halls and staircases. The reader was expected to climb unnecessary stairs and to walk long distances from entrance to reading room and often from the catalog and the reference shelves back to a reading place.

Access to the stacks by readers was rarely provided in the large research libraries (nor is it always desirable that it should be). Public libraries, however, though they too were often housed in monumental buildings, found it possible to introduce open access to their stock of books very early on (in England during the 1890s). Open access made bookstacks with high shelves impracticable for readers, and it encouraged the use of classified arrangement of books so that readers could easily locate the subjects and the volumes of special interest to them.

A remarkable change of attitude toward the design and construction of library buildings took place following World War II. It is of considerable interest for the history of libraries and their development to consider what the reasons for this change may have been. Scientists, technologists, and others had, during the war, needed precise information, speedily supplied; there was undoubtedly much dissatisfaction with the traditional library services and hence a more critical attitude toward libraries and their characteristic features. Afterward, the needs of users and their convenience were given greater consideration and more careful regard. There were also many more people using libraries—more students in a greater number of universities and colleges and more members of the general public looking to libraries for information, instruction, and recreation. Significant improvements in building techniques, moreover, made new building designs and methods possible, whereas very many new libraries were needed, partly because of the interruption of building during the war, partly because many libraries in Europe and other parts of the world had been destroyed or damaged. The old kinds of library, with their monumental and inflexible structure, were no longer acceptable.

The modular system of building

The new look at library design, thus prompted, has been further encouraged by development of the modular system of building. In the modular building, the basic floor area is divided into equal rectangles defined by structural columns at the corners, which are the only weight-bearing structures within the building. Subdivisions of these areas can be created by non-weight-bearing walls, bookstacks, and freestanding furniture; it follows, in theory, that nothing within the building is fixed and immovable except the columns (and of course stairways, elevators, heating facilities, ducts, and plumbing) so that the use made of an area can be extended or modified at will. (F.C.F./Ed.)

LIBRARY MATERIALS

Historically library services have depended on what materials were available to build collections. The evolution of libraries in antiquity involved the search for a material durable enough to survive as a permanent record and relatively easy to use. Clay and stone provided permanence, but inscribing the records required considerable labour. Palm leaves, bamboo strips, and papyrus offered a flat surface that more readily accepted handwriting, and it was said that parchment came into use in Asia Minor after the export of papyrus from Egypt was banned. In about AD 105 the invention of paper was announced by Ts'ai Lun to the Chinese emperor Ho Ti, and the British Museum has a paper fragment dated about 137. The use of paper spread slowly, however, and most of the oldest surviving manuscripts are of other materials, particularly vellum.

Samples of ancient writing are rare and therefore are highly valued, and national and other scholarly libraries collect and preserve them as part of their responsibility to the preservation of history and the advancement of learning. Most universities have collections of rare books. Eton College, for example, has a fine collection of incunabula, some purchased when they were first printed. A Gutenburg Bible is one of its finest examples. Some, such as the Duke Humphrey Library in the Bodleian at Oxford and the Beinecke Library at Yale, contain collections of manuscripts, and wealthy private collectors have established world-famous institutions such as the Henry E. Huntington Library in San Marino, Calif., the Folger Shakespeare Library in Washington, D.C., and the Cotton and Harley collections in the British Library Reference Division.

Uses of roll film and microfiche

The invention of photography in the 19th century made possible a new kind of record, and collections of photographs are popular, particularly in public libraries with an interest in local history. Specialized picture libraries, such as the BBC Hulton Picture Library, are regularly used to provide illustrative material for film and television programs. For the general use of libraries, however, microphotography has played a much more important role. Many leading newpapers and periodicals have reproduced their entire sets of back issues on roll film, which offers a considerable saving of space and makes it feasible for even a small library to house an entire set. The disadvantage of roll film is that the user must start searching the roll film from the beginning of the reel, no matter where the relevant pages may be on the reel. A considerable advance was achieved by the invention of the transparent Microcard, or microfiche. This is a piece of film cut to a specified size and shape usually approximating a library catalog card but available in more than one size (although the most favoured size is five by three inches). The microfiche offers the advantage of random access; that is, instead of starting at the beginning, the user can bring any section of the microfiche directly into view on the screen. Microfiche also are more convenient to store and handle, and they have become very popular for the production of catalogs and bibliographies as well as for reproduction of texts.

There are various forms of audiovisual media. The most common in libraries is the audio recording on disc or tape, and most libraries, especially public and school libraries, have built up extensive collections of nonbook materials, from the recordings of symphony orchestras on long-playing records to tape-recorded oral history interviews. Cooperation among school and public libraries in this field has made a considerable contribution to local history. The importance attached to these media, particularly in schools, is indicated by the use of the name resource centre for what was formerly called the school library. When teachers are eager to use audiovisual materials, they are often also eager to create materials, and this enthusiasm can enable school librarians to build up a strong and productive relationship between the library and the teaching program.

New articles requiring library storage are the machine-readable magnetic tape and disk. These need such specialized treatment, for the safeguarding of their contents from accidental erasure, that most computer centres employ their own specialist librarian. Like roll film, magnetic tapes and disks do not readily yield information about their contents and therefore require particular care in labeling and indexing.

These are some of the physical materials to be found in library stocks. There are other variations in the form of the contents of records, and these too usually require some form of specialist attention. The literature of science and technology, more than other subjects, contains a multitude of other forms. The printed specifications issued by patent offices and standards institutions form a class with problems peculiar to itself, in that they are written in a highly esoteric language that requires expertise to decipher and index. Patents also illustrate one of the most complex forms of subject classification known, but they are almost always sought by their serial number, and this is how they are usually filed and retrieved.

As in many other areas of information service, the world's major wars have resulted in a spate of documents that

Ann Hagen Griffiths—Omni-Photo Communications, Inc.

are not published but achieve circulation. They are usually duplicated reports from the laboratories and offices of research organizations and have a more or less restricted readership. Reports on atomic energy research are an outstanding example, the magnitude of the research effort being matched by the magnitude of the document output. The many variations in degree of secrecy have produced a situation of some confusion, and librarians who eagerly sought to attract gifts of these reports in the early days may have lived to regret their enthusiasm. This material, known as grey literature, has established itself and now has a secondary bibliographic literature of its own.

The term "secondary source" applies to documents that contain not original material but catalogs and bibliographies of such. Indexes may apply to the indexes at the ends of books and also may be bibliographies of currently published material, usually of articles in periodicals. The long series, covering many different fields, published by the H.W. Wilson Company of New York City are well known and widely used in other countries, though their coverage is mainly limited to American publications. This has resulted in other national efforts, such as the *Current Technology Index* (British) and the *British Education Index.*

Indexes and abstracts

Abstracts, which are summaries of documents that indicate contents as well as authors and titles, have a respectable history going back at least as far as the *Weekly Memorials for the Ingenious,* published in London in 1682. The *British Librarian* of 1737 published abstracts of well-known and useful books and claimed to cover all the sciences "in a manner never before attempted."

LIBRARY SERVICES

The processes and services found in modern libraries are usually divided into two major categories: technical services, comprising those processes directed at acquiring, arranging, indexing, and storing the stock; and reader services, comprising those processes directed at actively exploiting the stock in satisfying the information needs of the library users.

Technical services. *Acquisition and supply.* The output of published materials, in all forms, is so vast that no single library, not even the largest, can hope to acquire everything; even in relatively specialized fields, some selection has become necessary, and most libraries have an explicit selection policy. The basic principles of selection vary little among different types of libraries, inasmuch as they derive directly from the known interests of the users. Practice is another matter and varies according to the types of user. A national library aims to hold at least one copy of all the publications of its own country and to have a good representation of foreign works, many of which may be obtained through exchange agreements with other national libraries. University, college, and school libraries relate their choice of acquisitions to the programs of teaching and research in their institutions; the academic level of the material naturally varies according to the level of the student population. An elementary school will hold a good selection of books written for children, but a university will tend not to. Many university libraries try to maintain a relatively complete coverage of the reports issued by government and other research establishments. Some universities are designated as repositories for the reports issued by intergovernmental agencies, such as the United Nations, the International Atomic Energy Agency, and the European Economic Community.

Selection of library materials

An important aspect of selection is learning about new publications that would enhance the library. Various surveys have been made of the ways in which specialists gain new information about their fields of work, and the most popular usually turns out to be informal discussions with colleagues. But this is by nature a haphazard process, and most countries now have, or aim to have, a national bibliography based on the acquisitions of the national library. The *British National Bibliography,* begun in 1950 at the British Museum, is a leading example: it is published weekly, with regular cumulations for easy access over long periods. It is a tool for subject inquiry searches as well as for current selection.

The International Federation of Library Associations has established a program to increase the range and number of such bibliographic tools. The program, called Universal Bibliographic Control (UBC), aims to encourage national libraries, or groups of libraries, to institute methods of recording their national publications in a standard format and, wherever possible, of entering them into computer files.

The UBC program is accompanied by a second effort, the Universal Availability of Publications (UAP) program, which aims to provide the necessary follow-up service of document delivery. Both programs have been supported by the British Library Reference and Lending Divisions.

Other aids to the selection of material for acquisition are legion. Many libraries join professional societies and institutions to obtain their publications, which usually contain lists and reviews of new work relevant to their subjects. Leading journals such as *The Times Literary Supplement, The New York Review of Books, Nature,* and *Science* contain reviews by experts, advertisements for new and forthcoming publications, and review articles covering important new books in special fields.

Similarly, the development of electronic means of document delivery is unlikely to supplant the more traditional sources of supply, the publishing and bookselling trades. Some companies combine the two functions. Purchases by libraries have traditionally generated much of the revenue of local bookshops, but firms operating as specialist library suppliers are able to offer many auxiliary services, such as attaching plastic covers and inserting labels of ownership, because they deal in large-scale bulk supply and can afford to maintain machines for such processes. Also, some schools and colleges have set up bookshops of their own, to supply their libraries and also their students with textbooks.

Such is the situation in countries with long-established traditions of reading, research, libraries, and book trade. Far greater difficulties confront the library services in the developing countries, particularly in Africa and Asia. Even in India and China, with their long history of using books, a steady and satisfactory progress is hindered by shortages of finance, materials, and trained staff. Some universities in these nations have large libraries and receive grants that enable them to acquire foreign as well as national publications, but they often meet with delays caused by administrative procedures, shortage of foreign currencies, and problems of language in the postal services. In most African countries, growth of a national literature is hampered by the cost of importing even basic materials such as paper.

Many countries in eastern Europe as well as in the Third World look to exchanges as a means of obtaining materials. Some governments allow libraries to exchange duplicate copies of national publications, as a recognized method of compensation without payment in foreign currency. The practice does present certain administrative problems, but it is a useful means of encouraging the international flow of publications as well as of giving practical help in collection building to libraries in countries with limited resources.

Cataloging. However careful and scholarly the methods used in building a collection, without expert guidance to its access and use the collection remains difficult to approach. Cataloging and classification, well-tried disciplines often combined under the general heading of "indexing," provide the needed guidance. Both techniques have been in use as long as libraries have existed, and their potential value in the "information age" has been enhanced by the sensible use of computers.

Function of the catalog

The function of the catalog is to identify all the items in a collection. All of the great libraries of the ancient world seem to have had lists and inventories, whether kept on clay, stone, papyrus, parchment, palm leaves, or bamboo strips. Examples may be found in museums throughout the world. For many centuries the feature that gave a work its unique identity was the name of the writer, and users of the library were expected to know the names of the authors whose works they wished to consult. Some libraries, scholarly libraries in particular, continue to offer only author catalogs as guides to their collections.

Many factors have contributed to the rise in importance of the subject approach to information. From the earliest times, librarians recognized that readers would be greatly helped if the catalog entries were arranged in groups of related subjects. General classifications of knowledge such as those of Aristotle and Porphyry, scholarly curricula such as the trivium and quadrivium (expounded by Julius Caesar's librarian Marcus Terentius Varro and persisting as a major influence on education), and practical considerations such as the governmental needs of emperors and priests all have formed the basis for the arrangement of subject catalogs. Many Chinese works published under a single title were actually hundreds of volumes, libraries in themselves, with important bibliographical sections cataloging other books now lost. Early in the 7th century the scholar Wei Cheng wrote the bibliographical section of the official *Sui Dynasty History,* dividing the books into four categories: Confucian Classics, historical records, philosophical writings, and miscellaneous works.

Since the late 19th century far more attention has been paid to cataloging the subject contents of books as well as the names of their authors. Most of the impetus for this change came from science and technology, where the practice of working in teams in research institutions largely superseded the practice of single individuals, such as Charles Darwin, working for years to complete their research and then publishing the results as a book. The proliferation of specialist journals that publish short papers charting the progress of teamwork has meant that the names of single authors have become somewhat less important as tools for identifying works in libraries. Catalogs that list the subjects of research are more useful to specialists in related fields around the world, who may not know researchers by name but wish to have access to their work.

Major catalog systems

Despite a steady, if slow, trend toward standardization, various forms of catalog continue to exist. Sets of entries generally are arranged in one of three catalog systems. The first is the dictionary catalog, in which author, title, subject, and any other entries are filed in a single alphabetical sequence. This form is popular in the United States and in public libraries generally and probably presents the least amount of difficulty for the general or casual reader. The second is the divided catalog, still in alphabetical sequence but with subject entries in a separate file. This form has increased in popularity, and many libraries have divided their former dictionary catalogs, recognizing the growing value of the subject approach. The third is the classed, or classified, catalog, which is more popular in Britain and continental Europe and in some developing countries whose librarians trained there. In the classed catalog, as its name suggests, all the entries are filed in the sequence of a classification scheme, that is, in a systematic order of subjects, but separate alphabetical files link names of authors and of subjects to the notation symbols of the classification scheme used in the main file. The chief advantage of a classed catalog is that the entries are related subjects grouped together in the file; thus, a subject search can be made much more simply than in a catalog based on the alphabet. In addition, when different languages are used, the sequence of entries in a classed catalog does not alter, as is the case with the dictionary.

The types of catalog differ on the basis of the information provided in the entries, but the actual physical form may also vary. Originally, catalogs took the same form as the books they listed; being made of the same material, the catalog was an extra item of the collection itself. The earliest catalogs of the great national and scholarly libraries were in book form, with handwritten entries and spaces for new additions. Such manuscript books still exist, for example in older British university libraries such as the Bodleian at Oxford. In the 19th century many libraries began to print a book catalog, of which several copies could be made available. Librarians found the main problem of the book-type catalog to be that of inserting entries for new acquisitions. Most plans, like that of the Bibliothèque Nationale in Paris, made no attempt to add to the printed file and instead placed vain hopes in the prospect of new editions. The British Museum in addition to its published general catalog maintains several copies of a guard book catalog, in many hundreds of volumes, in which entries for new acquisitions are typed on slips and pasted in at the appropriate part of the alphabet. Spaces are left for such inserts, and as these are used up, new pages are added, and the entries are redistributed to make more empty space.

The solution to the problem of adding to a catalog in book form was the catalog on cards, each entry having its own card and each card containing only one entry. In principle, such catalogs can grow in size indefinitely; any new entry can be filed between any two existing entries. Thus the catalog offers the opportunity to have a completely up-to-date file: an entry can be made in the catalog immediately after a book has been purchased.

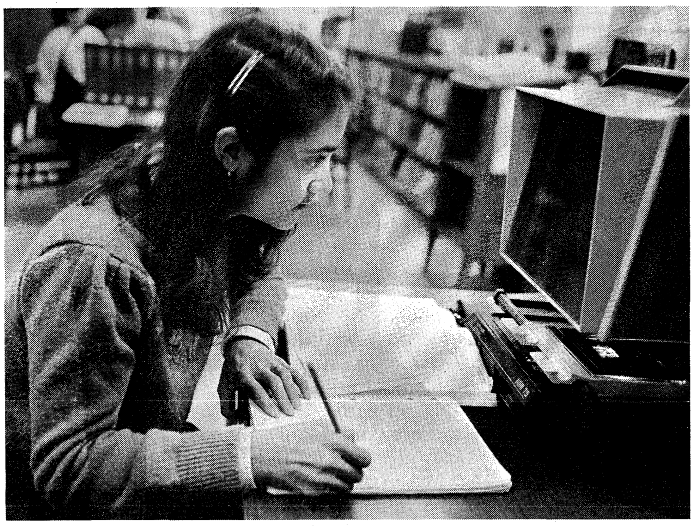
An outstanding innovation was introduced in 1901, when the Library of Congress began offering copies of its own catalog cards for sale to other libraries. For many years this proved of inestimable value, particularly to small libraries unable to afford skilled catalogers. The service was also intended to serve as a central cataloging agency. Many eminent librarians, in conferences and in published papers, had lamented what they argued was wasteful duplication of effort involved in the separate cataloging of the same books in many different libraries. They proposed that a central agency undertake the task and make the results generally available, so that any library could use the central catalog thus produced to complete its own highly professional catalog. In the 1950s the British National Bibliography also began to produce cards from the entries in its weekly lists.

These and similar schemes in other countries in Europe achieved a certain success but for various reasons could not be said to have provided the ultimate solution. The advent of the computerized catalog, however, offers a more practicable approach because the storage capacity and the operating speed of even small machines overcome the main drawbacks to card services: delays in production and the labour of filing the cards when they arrive. The computer makes it possible for the details of any document to be entered into a file at any point and then to be transmitted to a central data file from which other libraries can obtain details on a video display unit. These details can then be transferred to their own files, to be consulted either in printout form or directly on the video display unit if the library does not wish to maintain a printed form of catalog. The process is demonstrated by the revised Machine-Readable Cataloging Project, known since its revision in 1968 as MARC II. Library users find no difficulty in consulting such on-line catalogs and may well prefer them to the more cumbersome, if more familiar, form of cards in drawers.

Use of microform for catalogs

The ever-growing demand for more floor space has led to a widespread use of microform, either in roll film or, more satisfactorily, in the form of the transparent cards known as microfiche. Film and microfiche readers have become common features in libraries of all types, but they have met more resistance from readers than has the video display unit. The advantages they offer, in saving of space and in availability from a central source, have persuaded many librarians to close their card files completely and begin again. Improvements in photo technology make it possible to store hundreds, even thousands, of pages on one microfiche and to provide a perfectly legible enlargement on a reader machine. Because of the amount of time required to produce the microfiche and the mounting costs of cumulations, however, the microfiche is seen by some as only temporarily useful, a step in the evolution from the card file to the video display unit.

Patsy Davidson—The Image Works



High school student taking notes from source material displayed on a microfilm reader in her school library.

The ideal of centralized cataloging led to increased interest in standardized forms of entry. As libraries grew larger after the Renaissance and the invention of printing produced more authors, it became necessary to devise some form of standard to ensure consistency among several catalogs. Perhaps the most famous, the British Museum Rules, was inspired by Sir Anthony Panizzi and has influenced all succeeding codes, though most of them have departed considerably from the original. The Vatican Rules and the Prussian Instructions have both been subject to commissions for revision, but certainly the most influential code is the Anglo-American *Catalog Rules; Author and Title Entries,* first published in 1908 and revised in 1967. A further revision was published in 1978 as *Anglo-American Cataloguing Rules,* second edition; it is commonly referred to as *AACR2.*

Many other discussions, revisions, and simplifications took place after World War II. Short versions of the major codes were published for small libraries, in Czechoslovakia for example; the public instruction ministry in Italy issued new rules; a French commission on cataloging issued standards for anonymous works; and in the Soviet Union proposals were published for standardizing the transcription of Chinese names into Cyrillic script.

All of these codes dealt with the entering of names of authors, including Anonymous in the case of anonymous works, and sometimes, as in *AACR2,* with titles. A separate set of codes for subject cataloging emerged mainly in the United States, where they took the form of lists of subject headings, the three best known being the list compiled by Minnie E. Sears, the *Library of Congress Subject Headings,* and the Medical Subject Headings (MeSH) of the U.S. National Library of Medicine.

Thesaurus. A new use of the term thesaurus, now widespread, dates from the early 1950s in the work of H.P. Luhn, at International Business Machines Corporation, who was searching for a computer process that could create a list of authorized terms for the indexing of scientific literature. The list was to include a structure of cross-references between families of notions, in the manner of P.M. Roget's *Thesaurus of English Words and Phrases* (1852) and similar to the structure of faceted classification schemes. A major thesaurus, and one of the earliest, is the *Thesaurofacet,* a list of engineering terms in great detail designed by Jean Aitchison for the English Electric Company. The thesaurus has proved very useful both for indexing and for searching in machine systems.

Classification. While catalogs aim to identify and list items in a collection, schemes of classification have a more general application in arranging documents in a sequence that will make sense and be helpful to the user. Because they display subjects, and not documents, they can be used in several libraries, and some indeed have found applications in many different countries. Like schemes for grouping entries in catalogs, classifications—whether of knowledge based on philosophical principles, of the subject faculties of universities, or of the pragmatic grouping of books on shelves—have formed the basis of many individual systems.

Dewey Decimal Classification

The best known of all schemes for the classification of documents in libraries is the Dewey Decimal System of Classification, devised by Melvil Dewey in 1873 and published in 1876. Apart from being the first modern classification scheme for libraries, the Dewey system embodies two of Dewey's many contributions to the theory and practice of librarianship. First, he recognized that a systematic arrangement of books on shelves should make sense to the users; his scheme therefore reflected the dominant pattern of current thinking, exemplified by the "classificatory sciences." And second, he used decimals as notation symbols, which illustrated the way in which subjects were divided hierarchically, from main classes to specific topics. An example from the schedule for chemistry shows how numbers are subdivided:

540	chemistry and allied sciences
541	physical and theoretical chemistry
541.2	theoretical chemistry
541.3	physical chemistry
541.34	solutions
541.35	photochemistry
542	laboratories, apparatus, equipment.

Another feature of the Dewey system is the mnemonics used for certain types of subdivisions. Thus, many subjects can be subdivided geographically by the use of the historical-geographical number as decimals:

900	general geography and history
970	history of North America
973	history of the United States.

Combining with the art schedule, the number for history of art in the United States is obtained:

700	the arts
709	history of art
709.73	history of art in the United States.

Universal Decimal Classification

The Universal Decimal Classification, published in 1905, was an immediate offspring of the Dewey system. Paul Otlet and Henri-Marie Lafontaine adapted the Dewey system as the basis for a much more detailed scheme suitable for use in a vast card index of books and periodical articles in classified order—a universal bibliography of recorded knowledge. While retaining the basic generic hierarchies, the Universal Decimal Classification makes far greater use of the technique of synthesis, by providing a series of auxiliary tables for aspects of subjects likely to appear in several parts of the main schedules. These tables are indicated by the use of symbols such as punctuation marks. The colon sign (:) indicates a relationship between any parts and is the most commonly used sign. The numeral 669.1 being the notation for iron and steel and 546.22 for sulfur, the compound subject can be indicated by the notation 669.1:546.22, sulfur in iron and steel.

Like the Dewey Decimal Classification, the Universal Decimal Classification has been translated into many languages, and the International Federation for Documentation (Fédération Internationale de Documentation; FID) has undertaken responsibility for its continual revision. Scientific and technical libraries use the Universal system in preference to the Dewey system.

Library of Congress Classification

At the turn of the 20th century Herbert Putnam, the Librarian of Congress, decided to reclassify the library but rejected the Dewey system. His staff adopted a more pragmatic approach, based entirely on the way in which the books were arranged in their subjects on the shelves. They also rejected the decimal notation, preferring a purely ordinal system combining letters and numbers, leaving blank spaces where they expected new subjects to develop. (Not all of their expectations have proved correct.) American libraries and some scholarly libraries elsewhere have found the scheme attractive for its depth of detail, inasmuch as it is based on a very large library. An additional advantage is that Library of Congress notations appear on the library's catalog cards and on computer tapes produced by the MARC Project. Several American university libraries have undertaken the daunting task of reclassifying their stock from the Dewey system to the Library of Congress system in an effort to reap the maximum advantage of these features.

Other systems

Although not widely used, the bibliographic classification system invented by Henry E. Bliss of the College of the City of New York (published in 1935 as *A System of Bibliographic Classification*) has made important contributions to the theory of classification, particularly in Bliss's acute perception of the role of synthesis and his insistence that a library scheme should reflect the organization of knowledge and the system of the sciences. His systematic auxiliary schedules, designed to achieve what he called composite specification, carry the synthetic principle into every subject area and give a far higher degree of flexibility than does a purely enumerative scheme like the Library of Congress system. The Bliss Classification Association, founded in the United Kingdom in 1967, undertook the production of a new complete edition.

Perhaps the most important advance in classification theory has been made by the Indian librarian S.R. Ranganathan, whose extraordinary output of books and articles has left its mark on the entire range of studies from archival science to information science. He introduced the term facet analysis to denote the technique of dividing a complex subject into its several parts by relating them to a set of five fundamental categories of abstract notions, which he called personality, energy, matter, space, and time. He employed these in his Colon Classification system (1933), which is used in some Indian libraries and has found few followers elsewhere. Nevertheless, the ideas in the scheme, expounded in his *Colon Classification* (1933) and *Prolegomena to Library Classification* (1937), have influenced all later work in classification theory and practice, including subsequent editions of the Dewey, Universal, and Bliss systems.

In both the Soviet Union and the People's Republic of China schemes have been published that depart somewhat from the Anglo-American traditions and claim to reflect the structure of knowledge according to the principles of Marxist philosophy. Both have enumerative structures and may be distinguished by their detail of analysis of, and dependence on, the corpus of Marxist literature—a literature that, in Anglo-American schemes, usually occupies a relatively minor place.

Services to users. *Circulation.* Although many of the libraries in antiquity were open to the literate public, this was almost certainly for reference only. Some monastic libraries, however, are known to have allowed the monks to borrow books for study in their cells; the Rule of St. Benedict explicitly permitted this, and the librarian exacted penance from any monk unable to confirm that he had actually read his book. Some university libraries may have lent books to members of their faculties, but the notion of lending, or circulating, libraries did not become popular until the 18th century.

The rapid development of public libraries in the 19th century led to the extension of the practice and to the introduction of various systems for the recording of loans.

Introduction of circulation systems

All of the early systems depended on the use of one or more cards on which were recorded the name of the book, the name of the borrower, and the date on which the book should be returned. One system that remains popular in small libraries makes use of an author/title card, which is inserted in each book, and a pocketlike ticket, which is issued to the reader. When the reader borrows the book the book card is filed in the reader's ticket, and this "charge" is filed in the order of the return date. This chronologically organized system keeps a check on books that become overdue for return and enables librarians to limit the number of tickets issued to each reader, but the system cannot inform a reader of which books he has already on loan. Where such information may be useful, as in university libraries, a common practice is to require the reader to fill out a form, in duplicate or even triplicate, with the details of the book and the borrower's own name and address. Such a system gives more information but requires an inordinate amount of time and labour for maintenance of files. Variations of these two systems can be found throughout the world.

A computerized circulation system offers the opportunity of access to all of the information needed about loans and borrowers, and even small libraries can find circulation programs using relatively inexpensive hardware, as offered by several manufacturers. Information on each book is recorded on a bar-coded slip inserted into the book, usually adjacent to the date label on which the return date is stamped. Information about the borrower is likewise recorded on a bar code attached to a plastic identity card. Activating the two bar codes together, by a light pen, for example, enters all of the details of a loan into the library's computerized file; activating either bar code alone will then show on the video display unit the details of transactions involving the book or borrower. Computerized circulation methods make borrowing more convenient for the user and reduce staff time and labour required for the task.

Reference and retrieval services. Open access to the shelves and the facility to borrow books mean that much of the use of a modern library is at the free choice of the reader; scholars and scientists continue to emphasize the value of browsing among the shelves of a well-arranged library. "Chance favours only the prepared mind," said Louis Pasteur, and serendipitous discoveries of useful information when searching for some other subject have become a familiar and welcome aspect of using a library or other information service.

In reference service, librarians have traditionally given personal help to readers in making the best use of collections to satisfy their information needs. The publication of printed catalogs and bibliographies and the organizing of interlibrary cooperation have widened the range of the resources available to the individual reader. In scholarly libraries assistance to readers in the past may often have been limited to explaining the layout of the library and the use of the catalog; in universities, members of the faculty would have been expected to know the literature of their subject better than any librarian. But in public libraries, and still more so in special libraries in the fields of science and technology, readers have long been accustomed to seek guidance about information on their subject as well as about the library. This process has been greatly extended by the enormous increases in research worldwide and in the quantity of information and publications available in many languages and by the excellence of the indexes, abstracts, bibliographies, and data bases that help to control the documentation of this massive output.

Retrospective searching and current-awareness service

Reference services can be broadly divided into two main aspects, usually known as retrospective searching (or information retrieval) and current-awareness service (or selective dissemination of information). These terms indicate a specialization that has occurred in this core activity of libraries and that grew mainly out of the expansion of scientific and industrial research during and after World War I. Three factors strongly influenced this process. First, the increase in research and publication affected all types of libraries and brought with it a similar increase in subject specialization. Second, working scientists, accustomed to referring to reports in published papers, were content to leave the organizing of information searches to a colleague who knew and understood their work. And third, the widespread application of scientific research in industry provided an extra stimulus to the division of labour because of the necessity for speedy application of results to gain commercial success in production.

Some information specialists have tried to draw a distinction between their reference work and the more general reference services of librarians, but in most countries there is close cooperation among all engaged in these professional activities. Most acknowledge a mutual interest and influence, while the range of duties allows, indeed requires, different emphases in different institutions.

All agree, however, in acknowledging the duty to assist users to find answers to inquiries and to carry out retrospective searches in existing literature. Such a service requires many qualities, personal and professional: a detailed knowledge of books, periodicals, and all other forms of record; an ability to search efficiently in catalogs, indexes, abstracts, and data bases; and, above all, a sensitive understanding of each user's needs. Matching the terms used by a reader in posing a question to the terms used by authors, indexers, and catalogers may well constitute one of the subtlest of professional skills.

Computer search

The outcome of a search can take many forms, from a short factual statement that gives the needed information to a short list of relevant references or a full-scale bibliography. In a computer search the first request often reveals that the data base contains hundreds or even thousands of "hits," the references relating to the topic requested. The number can be reduced by narrowing the subject, adding more specific details, or persuading the reader to be more precise in defining the information needed. When a reasonable number of hits has been reached the computer can be instructed to display the details of a few references, to show the reader whether or not the search has covered the right subject area. If it has, the set of references or abstracts may then be obtained as printout; if it has not, the search begins again using new terms for the request.

In the specialized information centre a professional researcher can conduct the search and provide a state-of-the-art review of the literature in narrative form instead of as a collection of references. The service represents a peak of efficiency on behalf of the client, who has neither the time nor the resources to make the same review. The value to industry and commerce has encouraged private individuals to set up as information brokers to provide these services as a commercial enterprise.

Current-awareness services. The purpose of a current-awareness service is to inform the users about new acquisitions in their libraries. Public libraries in particular have used display boards and shelves to draw attention to recent additions, and many libraries produce complete or selective lists for circulation to patrons. Lists like these are a general response to the wishes of the users to know about new books and documents that may be of interest to them. Some libraries have adopted a practice of selective dissemination of information, whereby the notices go to specific readers or groups of readers, and their contents are selected with the special interests of those readers in mind. The items listed include books, periodical articles, patent and other specifications, the unpublished but circulated material known as grey literature, and any comment that the librarian or information specialist may identify as being relevant to particular users.

Each reader or group registers a profile of interests with the library staff, who then scan incoming items with the profiles in mind and select items of interest. Where computer equipment is available, profiles of the users can be run periodically against new additions to the public data bases, and the staff can prepare a customized printout showing new additions of interest to the user concerned.

Thus, while retrospective searches are a response to an expressed need on occasion, current-awareness service anticipates needs before they arise and enables the users of the service to rely on the information staff to keep them up-to-date with new work in their subjects. Both these services can be developed to a high degree of effectiveness by the use of computers: the former because of the immense range of data bases available for searching, the latter by means of electronic message transmission on local area networks.

Community information services. The growth of information services in special libraries, followed by college and university libraries, also has influenced public library practice in library extension programs and community information services. Extension programs are usually arranged in cooperation with local educational organizations, university extramural courses, parent–teacher associations, and so on. In developing countries with an infant publishing and book trade, public libraries can offer valuable assistance to local authors, particularly those writing in indigenous languages, by providing facilities for authors to give lectures, hold seminars, and develop their own skills in direct relation with their potential readers. In European, African, and American libraries, poets or writers in residence have appeared as a part of similar action to bring authors and readers together.

Community information service

The community information, or outreach, program has become a recognized feature of a public library service, in rural as well as urban or deprived areas. The Jamaica Library Service, for example, has long made a practice of setting up a stall at farmers' markets to supply up-to-date books and pamphlets on agriculture. Public libraries in China regularly set up special links with local factories for the supply of technical literature and specialist advisory staff.

INTERLIBRARY RELATIONS

Library cooperation. The publication of bibliographies and of library catalogs emphasized that no library could afford to be self-sufficient and stimulated interest in various forms of interlibrary cooperation. This probably originated informally, with readers referring to union catalogs to locate libraries that contained the books they wanted. One of the earliest formal organizations began with the Central Library for Students, founded in London by Albert Mansbridge in 1916. This was transformed in 1930 into the National Central Library, which continued to act as a lending library but also formed the centre of a network of regional library bureaus. The bureaus were located in a major regional library, and, with one exception, built up union catalogs of holdings in the local public libraries to facilitate interlibrary lending. The National Central Library encouraged other university and special libraries to participate. The National Central Library has become part of the British Library Lending Division, which undertakes a major part of interlibrary lending both in the United Kingdom and internationally.

Most countries have some form of organization for interlibrary cooperation. In Europe this has tended to be based on union catalogs compiled in a central national or university library, such as the National Széchényi Library in Hungary; in the Soviet Union the Lenin Library has played a prominent role, and, as in China, regional libraries cooperate extensively with local schools and industries in the provision of books, reading lists, and user education.

British National Book Centre

The progress of interlibrary lending, coupled with the great losses suffered by libraries in Europe and Asia during World War II, led to an interest in cooperative acquisition of new materials. In 1948 the British National Book Centre was set up at the National Central Library in London to gather unwanted duplicates and to distribute them to the libraries that had suffered losses. It proved to be of incalculable value and was soon followed by the United States Book Exchange; both distributed lists of wants and offers to their member libraries.

An ambitious program for cooperative acquisition of foreign materials by American libraries was conceived in the Library of Congress in 1942. This was the Farmington Plan: it involved the recruitment of purchasing agents in many countries, whose task was to buy their countries' current publications and distribute them to American libraries according to a scheme of subject specialization. Many criticisms were leveled at the scheme, and as a blanket operation it inevitably acquired a certain amount of trivia; but many research libraries have benefited by the acquisition of materials that otherwise would have been difficult to obtain.

Before the building boom of the 1960s, pressure on library space spurred librarians to discuss means of cooperative storage. Perhaps the foremost example is the Center for Research Libraries (formerly the Midwest Interlibrary Center) in Chicago, which began in 1952 as a centre for deposit of duplicate and little-used materials from research libraries. With the aid of a special grant, the University of London established a depository Library, at Royal Holloway College away from the centre of London, to which the colleges of the university can send materials for either cooperative or private storage. The British Library Lending Division also acts as a cooperative store; it receives unwanted items from any library and makes them generally available. Both libraries reserve the right to refuse items that they already have in cooperative storage.

International Federation for Documentation

International organizations. The oldest organization in the library and information field is the International Federation for Documentation. It was founded in 1895 in Brussels as the Institut International de Bibliographie by Paul Otlet and Henri-Marie Lafontaine, as part of their plan to create an index of world literature on cards. The institute has many international committees, and some, especially those concerned with classification research and the constant revision of the Universal Decimal Classification, are very active. The Soviet Union's All-Union Institute of Scientific and Technical Information (VINITI) issues *IFID,* the journal of the International Forum on Information and Documentation (IFID). It hosts the secretariat of an IFID committee charged to research the theoretical basis of information. The International Federation of Library Associations and Institutions, IFLA (Fédération Internationale des Associations de Bibliothécaires et des Bibliothèques, FIAB), was founded in 1927 and first met formally in Rome in 1928. The journal *IFLA Communications FIAB,* originally published as part of the international journal *Libri,* is now constituted as a separate *IFLA Journal,* and the organization's annual conference proceedings are published as a separate volume.

The International Council on Archives (ICA) was set up with the help of Unesco in 1948, and the first International Congress of Archivists was held in Paris in 1950. Early and continuing interest has centred on the microfilming, conservation, and preservation of historical records, particularly those of central and local governments. There has also been a considerable increase in interest in the records of business management, including those of what has come to be known as "industrial archaeology." The founding members were mostly from national archives, but universities in some countries have also assumed some responsibility for archive collection and preservation.

All of these associations have received considerable moral and financial support from Unesco, the first General Conference of which took place in 1947. From its inception Unesco has placed great importance on the encouragement of bibliography and libraries, and of public libraries in particular. (Part of its program was inherited from a League of Nations organization called the International Institute of Intellectual Cooperation, a main concern of which was libraries.) Unesco's support has led to seminars on public library development and to pilot public library projects in many nations. Not all have flourished, however, partly because of lack of local support. Other projects have covered education and provision of scholarships, library buildings, microfilming of archives and records, and establishment of scientific and technical documentation centres.

The technical committee of the International Organization for Standardization, another United Nations body, has helped to formulate and promulgate a number of standards on bibliographical formats, particularly those related to computer processing. Some of these have been modeled on national standards, such as those published by the British Standards Institution.

THE INFORMATION PROFESSIONS AND PROFESSIONAL EDUCATION

Throughout the centuries librarians have preserved books and records from the hazards of war, fire, and flood, and it is no idle boast to say that they have played a large part in maintaining the cultural heritage of their countries. Francis Bacon, in sending a copy of his book *The Advancement of Learning* to Sir Thomas Bodley, wrote, "you have built an Ark, to save Learning from Deluge." Although the traditional librarian acted primarily as a keeper of records, the concept of an active service of advice and information eventually appeared as a legitimate extension of the role of custodian.

The rise of scientific and industrial research and the establishment of public libraries in the 19th century led to the greatly increased emphasis on the subject approach and the role of systematic cataloging and classification in addition to the accepted function of building the collection and the consequent need for expert knowledge of bibliography, both systematic and analytical. In the industrial library in particular, the information officer was almost entirely concerned with the contents of documents and was indifferent to their form, so that a scrap of paper recording an important telephone call would have more significance than an incunabulum. The proliferation of different forms of record led to a much wider view of information storage and retrieval methods, used by subject specialists who knew and understood the work of their specialist colleagues.

Professional skills range from those of the archivist, concerned with provenance, preservation, and interpretation of administrative records, to those of the information scientist, concerned with research on the nature of information itself and the process of information flow and transfer between individuals and communities. These branches of the information profession share many objectives, practices, and skills. Each branch works to make the records of human progress readily available, and the contribution of each to society can only suffer if it is not allowed to become integrated with the others.

The personnel requirements of the profession include several categories, based on several kinds of specialist knowledge and skills: a knowledge of the nature of documents and their role in collection building; skills in the organization of knowledge through cataloging and classification; an ability to analyze and survey needs and to disseminate information in response to and in advance of inquiries. Efficient support staff is needed to maintain the machines, hardware and software; and clerical workers, technicians, and stewards are needed to ensure that the foundations on which the professions rely and the buildings in which they work operate in good order.

Programs for professional education have been the subject of debate throughout the world, and representatives of national associations, of Unesco, and of the international professional bodies have attempted to reach a consensus. For the higher levels of professional work, a degree from a university testifies to achievement in a subject field at the level likely to be found among the more demanding of the users of any library.

Library schools

Most of the initiatives for the setting up of courses for the education of professionals have come from librarians or their professional associations. In the United States the first university school for librarians was established in 1887 by Melvil Dewey at Columbia University. The American Library Association pursued a policy of "accreditation" to ensure that library schools offering a professional qualification should all reach a standard laid down by the profession itself. The first British library school was established in University College London in 1919, and until 1946 all other qualifications were gained through public examinations conducted by the Library Association. There are now many other schools, some in universities but most in polytechnic institutes, where the Library Association's own standards still influence the curriculum. The Library Association's successive syllabi have had considerable importance for some Commonwealth countries, such as Ghana, Nigeria, and the Caribbean countries.

In continental Europe most professional education takes place in universities and similar institutions of higher learning. In Hungary the University of Budapest began courses in the Faculty of Philosophy in 1949, and a senior-level course in documentation was later organized jointly by the Chair of Library Science in the university (now the Eötvös Loránd University) and the National Technical Library and Documentation Centre, in 1964. In Czechoslovakia, library and information science courses are given at the Chair of Library Science and Scientific Information, also in the Faculty of Philosophy and Letters of Charles University in Prague and Comenius University in Bratislava. In France the long-established École Nationale des Chartes, which mainly trains archivists, also prepares students for the public, national, and university libraries. The École Nationale Supérieure des Bibliothèques belongs to the Direction des Bibliothèques, and the École de Bibliothécaires-Documentalistes is a private institution of the Institut Catholique de Paris.

The universities of Peking and Wu-han in China have advanced courses and research programs in librarianship, and professional qualifications may also be gained by correspondence. In 1985, with the help of Unesco and the British Council, a master's degree course in information studies was begun at the Institute for Scientific and Technical Information in China.

The curriculum. In the older schools, and in those closely connected with national and scholarly libraries, the emphasis was on historical and bibliographical aspects. The history of libraries, the art of the book, classification and cataloging, literary studies, and the library in society occupied most of the teaching and examining. Subsequent generations of professionals have regarded such a syllabus as too biased toward the humanities to be appropriate for a scientific and technical organization's requirements and have devoted more time to the scientific literature, to indexing and abstracting techniques, and to information technology. Much more research effort is now directed also to the theory of information transfer and the development of mathematical models for this and to other aspects of management in library and information services.

Continuing education. Qualified library and information specialists have many opportunities to enroll in short or part-time refresher or reorientation courses to bring themselves up to date with changing methods or with developments in techniques and attitudes. Opportunities for systematic research, which have been available in the United States since the pioneering days of Louis R. Wilson at the University of Chicago in the 1930s, have now become almost universal. In the United Kingdom the University of Sheffield, the City University in London, and University College, London, have played an important role in offering such opportunities to teachers from the polytechnic library schools. Postgraduate scholarships and grants from Unesco, the Council on Library Resources, the British Council, universities, and academies of science have enabled students from Third World countries to advance their education in the United States, the United Kingdom, the Soviet Union, France, and Australia.

BIBLIOGRAPHY

Encyclopaedias: There are many encyclopaedias on the subject of libraries, especially in the German language. In English, the three most important are THOMAS LANDAU (ed.), *Encyclopaedia of Librarianship,* 3rd rev. ed. (1966); ROBERT WEDGEWORTH (ed.), *ALA World Encyclopedia of Library and Information Services* (1980); and ALLEN KENT *et al., Encyclopedia of Library and Information Science,* 35 vol. (1968–83), continued with supplemental volumes. For terminology see LEONARD MONTAGUE HARROD, *Harrod's Librarians' Glossary of Terms Used in Librarianship, Documentation and the Book Crafts, and Reference Book,* 5th ed., rev. and updated by RAY PRYTHERCH (1984). *The ALA Yearbook of Library and Information Services: A Review of Library Events;* and *The ALA Glossary of Library and Information Science,* ed. by HEARTSILL YOUNG (1983), are useful.

Origins and early history of libraries: A classic, well-written and well-illustrated account of the beginnings of printing and bookmaking is given in DOUGLAS C. MCMURTRIE, *The Book,* 3rd ed. (1943, reprinted 1972). The English library is dealt with in RAYMOND IRWIN, *The Origins of the English Library* (1958, reprinted 1981), and *The Heritage of the English Library* (1964). KARL CHRIST, *The Handbook of Medieval Library History,* rev. by ANTON KERN, trans. from the German and ed. by THEOPHIL M. OTTO (1984), is a part of the comprehensive work *Handbuch der Bibliothekswissenschaft,* 2nd rev. ed., ed. by FRITZ MILKAU and GEORG LEYH, 3 vol. in 4 (1952–61). A shorter survey, also international in scope, is D.N. MARSHALL, *History of Libraries, Ancient and Medieval* (1983).

Kinds of libraries: As a general guide to the field, see *The Bowker Annual of Library and Book Trade Information.* Several monographs aim to relate the library to society: a sociological approach to different types of libraries in different countries can be found in A. ROBERT ROGERS and KATHRYN MCCHESNEY, *The Library in Society* (1984). RONALD CHARLES BENGE, *Cultural Crisis and Libraries in the Third World* (1979), has a wide scope; and D.J. FOSKETT, *Pathways for Communication* (1984), examines the role of books and libraries in the information age.

National libraries are dealt with in MAURICE B. LINE and JOYCE LINE (eds.), *National Libraries* (1979); and in the beautifully illustrated ANTHONY HOBSON, *Great Libraries* (1970). JOHN Y. COLE, *For Congress and the Nation: A Chronological History of the Library of Congress Through 1975* (1979), is an informative survey. All aspects of university libraries are covered in RUTHERFORD D. ROGERS and DAVID C. WEBER, *University Library Administration* (1971); JAMES THOMPSON, *An Introduction to University Library Administration,* 3rd ed. (1979); and KEYES D. METCALF, *Planning Academic and Research Library Buildings* (1965). The general organization of public libraries has been the subject of many treatises: JOSEPH WHEELER and HERBERT GOLDHOR, *Wheeler and Goldhor's Practical Administration of Public Libraries,* rev. ed., ed. by CARLTON ROCHELL (1981); VERNON E. PALMOUR, MARCIA C. BELLASSAI, and NANCY V. DEWATH, *A Planning Process for Public Libraries* (1980); THOMAS KELLY, *A History of Public Libraries in Great Britain, 1845–1975,* 2nd rev. ed. (1977); MIRIAM BRAVERMAN, *Youth, Society, and the Public Library* (1979); DOROTHY M. BRODERICK, *Library Work with Children* (1977); and GENEVIÈVE PATTE and SIGRÚN KLARA HANNESDÓTTIR (eds.), *Library Work for Children and Young Adults in the Developing Countries* (1984). L.J. ANTHONY (ed.), *Handbook of Special Librarianship and Information Work,* 5th ed. (1982), has value for all types of libraries. Close relationship between modern educational methods and libraries is well explored in NORMAN BESWICK, *Resource-Based Learning* (1977); and S.R. RANGANATHAN, *New Education and School Library* (1973). FRANCES LAVERNE CARROLL (ed.), *Recent Advances in School Librarianship* (1981), has an international scope and authorship. Special topics are covered in S. JOHN TEAGUE, *Microform, Video and Electronic Media Librarianship* (1985); and GEORGE MARTIN CUNHA and DOROTHY GRANT CUNHA, *Library and Archives Conservation: 1980s and Beyond,* 2 vol. (1983), the second volume of which contains an extensive bibliography.

Automation in libraries and information services is introduced in C.J. VAN RIJSBERGEN, *Information Retrieval,* 2nd ed. (1979); and a more advanced account is found in F. WILFRID LANCASTER, *Information Retrieval Systems: Characteristics, Testing, and Evaluation,* 2nd ed. (1979). Two simple practical books are IAN LOVECY, *Automating Library Procedures* (1984); and J.E. ROWLEY, *Computers for Libraries,* 2nd ed. (1985).

Technical services: A detailed analysis of all aspects of technical services is offered in B.C. VICKERY, *Information Systems* (1973). ERIK J. HUNTER and K.G.B. BAKEWELL, *Cataloguing,* 2nd rev. ed. (1983), emphasizes automation and the role of networks; some perspectives are outlined in PETER GELLATLY (ed.), *Beyond "1984": The Future of Library Technical Services* (1983). A.C. FOSKETT, *The Subject Approach to Information,* 4th ed. (1982), covers the relation of cataloging and classification. S.R. RANGANATHAN, *Prolegomena to Library Classification,* 3rd ed. (1967), explores the theoretical basis in depth. DAGOBERT SOERGEL, *Indexing Languages and Thesauri* (1974), is an encyclopaedic work with an excellent bibliography.

Services to readers: A useful guide to all types of reference sources is GAVIN HIGGENS (ed.), *Printed Reference Material,* 2nd ed. (1984). Works of more theoretical and philosophical nature include K.J. MCGARRY, *Communication, Knowledge and the Librarian* (1983); and GIRJA KUMAR and KRISHAN KUMAR, *Philosophy of User Education* (1983). BILL KATZ (ed.), *Reference Services in the 1980s* (1982), is an overview of practical issues. J.E. ROWLEY, *Abstracting and Indexing* (1982), treats the subject as an aspect of reader services.

The information profession: The most detailed analysis of all aspects, in very readable form, is found in JESSE H. SHERA, *The Foundations of Education for Librarianship* (1972). See also PATRICIA LAYZELL WARD (ed.), *The Professional Development of the Librarian and Information Worker* (1980). The history of education for the profession is presented in L. HOUSER and ALVIN M. SCHRADER, *The Search for a Scientific Profession: Library Science Education in the U.S. and Canada* (1978); and CAROLYN LEOPOLD MICHAELS, *Library Literacy Means Lifelong Learning* (1985), surveys the role of libraries and librarianship.

(D.J.F.)

Life

The profusion of life on Earth has been studied in great detail, and a number of general principles have been revealed. Foremost among them is the principle of evolution by natural selection—the stepwise adaptation of organisms to their environment with increasing precision by small random mutations, or changes, in their hereditary material—which is the feature that distinguishes living from non-living matter. This article treats first the varieties of definitions of life and then covers, in some detail, the similarities and differences among organisms on Earth. It deals with the problem of the origin of life on Earth and concludes with a consideration of the possibility of life beyond the Earth.

This article is divided into the following sections:

DEFINITIONS OF LIFE

What is known about life

A great deal is known about life. Anatomists and taxonomists have studied the forms and relations of more than a million separate species of plants and animals. Physiologists have investigated the gross functioning of organisms. Biochemists have probed the biological interactions of the organic molecules that make up life on our planet. Molecular biologists have uncovered the very molecules responsible for reproduction and for the passage of hereditary information from generation to generation, a subject that geneticists had previously studied without going to the molecular level. Ecologists have inquired into the relations between organisms and their environments, ethologists the behaviour of animals and plants, embryologists the development of complex organisms from a single cell, evolutionary biologists the emergence of organisms from pre-existing forms over geological time. Yet despite the enormous fund of information that each of these biological specialties has provided, it is a remarkable fact that no general agreement exists on what it is that is being studied. There is no generally accepted definition of life. In fact, there is a certain clearly discernible tendency for each biological specialty to define life in its own terms. The average person also tends to think of life in his own terms. For example, the man in the street, if asked about life on other planets, will often picture life of a distinctly human sort. Many individuals believe that insects are not animals, because by "animals" they mean "mammals." Man tends to define in terms of the familiar. But the fundamental truths may not be familiar. Of the following definitions, the first two are in terms familiar in everyday life; the next three are based on more abstract concepts and theoretical frameworks.

Physiological. For many years a physiological definition of life was popular. Life was defined as any system capable of performing a number of such functions as eating, metabolizing, excreting, breathing, moving, growing, reproducing, and being responsive to external stimuli. But many such properties are either present in machines that nobody is willing to call alive, or absent from organisms that everybody is willing to call alive. An automobile, for example, can be said to eat, metabolize, excrete, breathe, move, and be responsive to external stimuli. And a visitor from another planet, judging from the enormous numbers of automobiles on the Earth and the way in which cities and landscapes have been designed for the special benefit of motorcars, might well believe that automobiles are not only alive but are the dominant life form on the planet. Man, however, professes to know better. On the other hand, some bacteria do not breathe at all but instead live out their days by altering the oxidation state of sulfur.

Metabolic. The metabolic definition is still popular with many biologists. It describes a living system as an object with a definite boundary, continually exchanging some of its materials with its surroundings, but without altering its general properties, at least over some period of time. But again there are exceptions. There are seeds and spores that remain, so far as is known, perfectly dormant and totally without metabolic activity at low temperatures for hundreds, perhaps thousands, of years but that can revive perfectly well upon being subjected to more clement conditions. A flame, such as that of a candle in a closed room, will have a perfectly defined shape with fixed boundary and will be maintained by the combination of its organic waxes with molecular oxygen, producing carbon dioxide and water. A similar chemical reaction, incidentally, is fundamental to most animal life on Earth. Flames also have a well-known capacity for growth.

Biochemical. A biochemical or molecular biological definition sees living organisms as systems that contain reproducible hereditary information coded in nucleic acid molecules and that metabolize by controlling the rate of chemical reactions using proteinaceous catalysts known as enzymes (see BIOCHEMICAL COMPONENTS OF ORGANISMS: *Enzymes*). In many respects, this is more satisfying than the physiological or metabolic definitions of life. There are, however, even here, the hints of counterexamples. There seems to be some evidence that a virus-like agent called scrapie contains no nucleic acids at all, although it has been hypothesized that the nucleic acids of the host animal may nevertheless be involved in the reproduction of scrapie. Furthermore, a definition strictly in chemical terms seems peculiarly vulnerable. It implies that, were a person able to construct a system that had all the functional properties of life, it would still not be alive if it lacked the molecules that earthly biologists are fond of—and made of.

Genetic. All organisms on Earth, from the simplest cell to man himself, are machines of extraordinary powers, effortlessly performing complex transformations of organic molecules, exhibiting elaborate behaviour patterns, and indefinitely constructing from raw materials in the envi-

Instructions for living systems

ronment more or less identical copies of themselves. How could machines of such staggering complexity and such stunning beauty ever arise? The answer, for which today there is excellent scientific evidence, was first discerned by the evolutionist Charles Darwin in the years before the publication in 1859 of his epoch-making work, the *Origin of Species.* A modern rephrasing of his theory of natural selection goes something like this: Hereditary information is carried by large molecules known as genes, composed of nucleic acids. Different genes are responsible for the expression of different characteristics of the organism. During the reproduction of the organism the genes also reproduce, or replicate, passing the instructions for various characteristics on to the next generation. Occasionally, there are imperfections, called mutations, in gene replication. A mutation alters the instructions for a particular characteristic or characteristics. It also breeds true, in the sense that its capability for determining a given characteristic of the organism remains unimpaired for generations until the mutated gene is itself mutated. Some mutations, when expressed, will produce characteristics favourable for the organism; organisms with such favourable genes will reproduce preferentially over those without such genes. Most mutations, however, turn out to be deleterious and often lead to some impairment or to death of the organism. To illustrate, it is unlikely that one can improve the functioning of a finely crafted watch by dropping it from a tall building. The watch may run better, but this is highly improbable. Organisms are so much more finely crafted than the finest watch that any random change is even more likely to be deleterious. The accidental beneficial and inheritable change, however, does on occasion occur; it results in an organism better adapted to its environment. In this way organisms slowly evolve toward better adaptation, and, in most cases, toward greater complexity. This evolution occurs, however, only at enormous cost: man exists today, complex and reasonably well adapted, only because of billions of deaths of organisms slightly less adapted and somewhat less complex. In short, Darwin's theory of natural selection states that complex organisms developed, or evolved, through time because of replication, mutation, and replication of mutations. A genetic definition of life therefore would be: a system capable of evolution by natural selection.

Genetic definition of life

This definition places great emphasis on the importance of replication. Indeed, in any organism enormous biological effort is directed toward replication, although it confers no obvious benefit on the replicating organism. Some organisms, many hybrids for example, do not replicate at all. But their individual cells do. It is also true that life defined in this way does not rule out synthetic duplication. It should be possible to construct a machine that is capable of producing identical copies of itself from preformed building blocks littering the landscape but that arranges its descendants in a slightly different manner if there is a random change in its instructions. Such a machine would, of course, replicate its instructions as well. But the fact that such a machine would satisfy the genetic definition of life is not an argument against such a definition; in fact, if the building blocks were simple enough, such a machine would have the capability of evolving into very complex systems that would probably have all the other properties attributed to living systems. The genetic definition has the additional advantage of being expressed purely in functional terms: it does not depend on any particular choice of constituent molecules. The improbability of contemporary organisms—dealt with more fully below—is so great that these organisms could not possibly have arisen by purely random processes and without historical continuity. Fundamental to the genetic definition of life then is the belief that a certain level of complexity cannot be achieved without natural selection.

Life as an ordered system

Thermodynamic. Thermodynamics distinguishes between open and closed systems. A closed system is isolated from the rest of the environment and exchanges neither light, heat, nor matter with its surroundings. An open system is one in which such exchanges do occur. The second law of thermodynamics states that, in a closed system, no processes can occur that increase the net order (or decrease the net entropy) of the system (see THERMODYNAMICS). Thus the universe taken as a whole is steadily moving toward a state of complete randomness, lacking any order, pattern, or beauty. This fate has been known since the 19th century as the heat death of the universe. Yet living organisms are manifestly ordered and at first sight seem to represent a contradiction to the second law of thermodynamics. Living systems might then be defined as localized regions where there is a continuous increase in order. Living systems, however, are not really in contradiction to the second law. They increase their order at the expense of a larger decrease in order of the universe outside. Living systems are not closed but rather open. Most life on Earth, for example, is dependent on the flow of sunlight, which is utilized by plants to construct complex molecules from simpler ones. But the order that results here on Earth is more than compensated by the decrease in order on the sun, through the thermonuclear processes responsible for the sun's radiation.

Some scientists argue on grounds of quite general open-system thermodynamics that the order of a system increases as energy flows through it, and moreover that this occurs through the development of cycles. A simple biological cycle on the Earth is the carbon cycle. Carbon from atmospheric carbon dioxide is incorporated by plants and converted into carbohydrates through the process of photosynthesis. These carbohydrates are ultimately oxidized by both plants and animals to extract useful energy locked in their chemical bonds. In the oxidation of carbohydrates, carbon dioxide is returned to the atmosphere, completing the cycle. It has been shown that similar cycles develop spontaneously and in the absence of life by the flow of energy through a chemical system. In this view, biological cycles are merely an exploitation by living systems of those thermodynamic cycles that pre-exist in the absence of life. It is not known whether open-system thermodynamic processes in the absence of replication are capable of leading to the sorts of complexity that characterize biological systems. It is clear, however, that the complexity of life on Earth has arisen through replication, although thermodynamically favoured pathways have certainly been used.

The existence of diverse definitions of life surely means that life is something complicated. A fundamental understanding of biological systems has existed since the second half of the 19th century. But the number and diversity of definitions suggest something else as well. As detailed below, all the organisms on the Earth are extremely closely related, despite superficial differences. The fundamental ground pattern, both in form and in matter, of all life on Earth is essentially identical. As will emerge below, this identity probably implies that all organisms on Earth are evolved from a single instance of the origin of life. It is difficult to generalize from a single example, and in this respect the biologist is fundamentally handicapped as compared, say, to the chemist or physicist or geologist or meteorologist, who now can study aspects of his discipline beyond the Earth. If there is truly only one sort of life on Earth, then perspective is lacking in the most fundamental way.

LIFE ON EARTH

Mechanism and vitalism. Human beings are ambulatory collections of some 10^{14} cells. Human cells are in many fundamental respects similar to those that make up all the other animals and plants on the Earth. Each cell typically consists of a central, usually spherical, nucleus and an outer more heterogeneous region, termed the cytoplasm. The substance of nucleus and cytoplasm together has for many decades been called protoplasm. Use of this term implied that there was some special substance underlying living organisms. In the use of the word protoplasm there is occasionally an implication that life cannot be explained solely by physics and chemistry, that some mysterious "vital force" must be invoked. A living cell is a marvel of detailed and complex architecture. Seen through a microscope there is an appearance of almost frenetic activity. On a deeper level it is known that molecules are being synthesized at an enormous rate. Almost any enzyme catalyzes the synthesis of more than

100 other molecules per second. In 10 minutes, a sizable fraction of the total mass of a metabolizing bacterial cell has been synthesized. The information content of a simple cell has been estimated as around 10^{12} bits, comparable to about a hundred million pages of the *Encyclopædia Britannica.* Faced with all this or its equivalent, it is not surprising that early biologists felt despair at ever being able to understand the detailed workings of life.

A Stone Age man, confronted for the first time with a watch, might also deduce that there was some special watch substance in nature, or perhaps even a god of the watch. In ancient times, the most common of biological activities, such as the hatching of an egg or the blooming of a flower, were attributed to the intercession of a deity. After the epochal work of Sir Isaac Newton, when the motion of the planets and comets of the solar system was predictable to some very great precision and understood on the basis of an underlying principle, the idea developed that organisms were also nothing more than a particularly intricate kind of clockwork. But when early investigations failed to unveil the clockwork, a kind of ghostly mainspring was invented—the "vital force." This force was a rebellion from mechanistic biology, an explanation of all that mechanism could not explain or for which mechanism could not be found. It also appealed to those who felt debased by the implication that they were "nothing more" than a collection of atoms, that their urges and apparent free wills arose merely from the interaction of an enormously large number of molecules in a way that, although too complex to use predictably, was in principle determined.

"Vital force"

Not only is there no evidence for a vital force but the idea itself is hardly thought out; it is a sort of catchall concept, covering anything otherwise inexplicable. The alternative approach, that all organisms are made of atoms and nothing else, has proven especially useful and has led to a fundamental new understanding of biological systems. This situation does not imply, of course, that atoms cannot be put together in so complex a way that their collective behaviour is too difficult to understand in terms of the individual atoms; in this sense there may be particular laws of biology not readily derivable from the elementary interaction of atoms. But this is a very different thing from a vital force. Indeed, there is nothing debasing in the thought that a person is made of atoms alone; it means that one is intimately connected with the matter that comprises the inanimate universe. What a wonder that atoms can be put together in so complex a pattern as to produce human beings. Man is a tribute to the subtlety of matter. As the American anthropologist Loren Eiseley has written, ". . . if 'dead' matter has reared up this curious landscape of fiddling crickets, song sparrows, and wondering men, it must be plain even to the most devoted materialist that the matter of which he speaks contains amazing, if not dreadful powers. . . ." (*The Immense Journey,* Random House, New York, 1957.)

Nucleic acids. It is now known that many if not all of the fundamental properties of cells are a function of their nucleic acids, their proteins, and the interactions among these molecules. Within the nuclear regions of cells is a mélange of twisted and interwoven fine threads, the chromosomes. During cell division, in all but the simplest organisms, the chromosomes display an elegantly choreographed movement, separating so that each daughter cell of the original cell receives an equal complement of chromosomal material. This pattern of segregation corresponds in all details to the theoretically predicted pattern of segregation of the genetic material implied by the fundamental genetic laws (see GENETICS AND HEREDITY). The chromosomes are composed of nucleic acids and proteins in a combination called nucleoprotein. The nucleic acid stripped of its protein is known to carry genetic information and to regulate cellular metabolism; the protein in nucleoprotein undoubtedly plays some secondary, probably regulatory, role.

The role of nucleic acids

The specific carrier of the genetic information in higher organisms is a nucleic acid known as DNA, short for deoxyribonucleic acid. DNA is a double helix, two molecular coils wrapped around each other and chemically bound one to another by bonds connecting adjacent bases. Each helix has a backbone that consists of a long sequence of alternating sugars and phosphates. Attached to each sugar is a base. Each sugar-phosphate-base combination is called a nucleotide; a nucleic acid strand can be thought of as a sequence of nucleotides. There is a very significant one-to-one base pairing in the connection of adjacent helices, in the sense that once the sequence of bases along one helix is specified, the sequence along the other is also specified. The specificity of base pairing plays a key role in the replication of the DNA molecule, where each helix makes an identical copy of the other from molecular building blocks in the cell. These nucleic acid replication events are mediated by enzymes, and with the aid of enzymes have been produced in the laboratory.

Ribonucleic acid (RNA) differs from DNA in having a slightly different five-carbon sugar, and in replacing one of the four bases that make up DNA by a slightly different base. RNA does not appear to exist in a double-stranded form. Now DNA, RNA, and the enzymes have a curiously interconnected relation, which appears ubiquitous in all organisms on Earth today.

Commonalities among organisms on Earth. The genetic code was broken in the 1960s. It was found that three consecutive nucleotides code for one amino acid of a protein molecule; *e.g.,* an enzyme. By controlling the synthesis of enzymes, the nucleic acids control the functioning of the cell. Of the four different bases taken three at a time, there are $4^3 = 64$ possible combinations. The meaning of each of these combinations, or codons, is known. Most of them represent a particular amino acid. A few of them represent punctuation marks; for example, instructions to start or stop a synthesis. Some of the code is degenerate in the sense that more than one nucleotide triplet may specify a given amino acid. These interactions among nucleic acids and proteins seem absolutely central to living processes on Earth today. Not only are these processes apparently the same in all organisms on Earth but even the particular dictionary that is used for the transcription of nucleic acid information into protein information seems to be essentially the same in all organisms. Moreover, this code has various chemical advantages over other conceivable codes. The complexity, ubiquity, and advantages of these processes clearly argue that the present interactions among proteins and nucleic acids are themselves the product of a long evolutionary history. At the time of the origin of life this very complex replication and transcription apparatus could of course not have been in operation. A fundamental problem in the origin of life is the question of the origin and early evolution of the genetic code.

There are many other commonalities among organisms on Earth. For example, there is only one class of molecules that store energy for biological processes until the cell has use for it, and these molecules are all nucleotide phosphates. The most common example is ATP (adenosine triphosphate). For this very different function, a molecule identical to the building blocks of the nucleic acids is employed. There are metabolically important molecules—*e.g.,* molecules known as FAD (flavin adenine dinucleotide) and coenzyme A—which include subunits similar to the nucleotide phosphates. Porphyrins represent another category of ubiquitous molecules. Porphyrins are the chemical basis of hemoglobin, which carries oxygen molecules through the bloodstreams of animals; of chlorophyll, which is the fundamental molecule mediating photosynthesis in plants; and of the colours that many animals display. The left- or right-handedness of many biological molecules—discussed more fully below—runs identically through all organisms on Earth. In fact, of the billions of possible organic compounds, less than 1,500 are employed by contemporary life on Earth, and these 1,500 are constructed from less than 50 simple molecular building blocks. Similarly, organisms as diverse as paramecia and human sperm cells have little whiplike appendages called cilia or flagella used to propel themselves through their liquid environments. The cross-sectional structure of the cilia and flagella is almost always nine pairs of peripheral and one pair of internal fibres. There is no immediately obvious selective advantage of the 9 : 1 ratio.

Energy-storing molecules

These commonalities indicate that a few basic chemical and functional patterns are being used over and over again, reflecting the extremely close relations all organisms on Earth have to one another. Many biologists believe that these commonalities—particularly where no obvious selective advantage exists—imply that all organisms on the Earth are descendants of a single common ancestor. But it is possible that there are more subtle selective advantages. The issue may have to await the first detailed study of an extraterrestrial organism.

Chromosome possibilities

The number of possible ways of putting nucleotides together in a chromosome is enormous. The renowned geneticist H.J. Muller estimated that in a human chromosome there are about 4×10^9 base pairs. Each base pair position could be filled by any one of four possible bases; accordingly, the number of possible varieties of human chromosomes is $4^{4 \times 10^9}$ ($10^{2.4 \times 10^9}$), an inconceivably large number. By contrast, the number of elementary particles (electrons and protons) in the entire physical universe is only about 10^{80}. Thus a human being is an extraordinarily improbable object. Most of the $10^{2.4 \times 10^9}$ possible sequences of nucleotides would lead to complete biological malfunction. Our nucleotides work because natural selection, over a 4,000,000,000-year history of life, has destroyed enormous numbers of combinations that did not work. But there still may be combinations that work far better than any now present, and the future holds the promise that man will be able to assemble nucleotides in any desired sequence to produce whatever characteristics of human beings are thought desirable, an awesome and disquieting prospect.

Metabolism. The chemical bonds that make up living organisms have a certain probability of spontaneous breakage. Accordingly, mechanisms must exist to repair this damage, or to replace the broken molecules. In addition, the meticulous control that cells exercise over their internal activities requires the continued synthesis of new molecules. These processes of synthesis and breakdown of the organic molecules of the cell are collectively termed metabolism, and for synthesis to keep ahead of the thermodynamic tendencies toward breakdown, energy must be supplied to the living system. Organisms acquire this energy by two general methods. Some organisms are heterotrophs, acquiring their energy by the controlled breakdown of pre-existing organic molecules (food)—generally those supplied by other organisms. Human beings and most other animals are heterotrophs. Alternatively, organisms may be autotrophs, acquiring their useful free energy from some other source, either from the energy of sunlight, in which case the organism is called a photoautotroph, or from the controlled chemical reaction of inorganic materials, in which case the organism is known as a chemoautotroph. Organisms that use both modes are called photochemoautotrophs.

Methods of acquiring energy

A green plant is a typical example of a photoautotroph. It uses sunlight to break water into oxygen and hydrogen. Hydrogen is then combined with carbon dioxide to produce such energy-rich organic molecules as ATP and carbohydrates, and the oxygen is released back into the atmosphere. Many animals, on the other hand, utilize the atmospheric oxygen to combine chemically with organic materials they have eaten and release carbon dioxide and water as waste products in extracting energy from the organic materials. This is an example of an ecological cycle in which a material (here carbon) is pumped through two different organisms.

More generally, such metabolic cycles—used by the organism to extract useful energy from the environment—can be described in terms of oxidation-reduction reactions. In the case of respiration, molecular oxygen accepts electrons from glucose or other sugars. The oxygen is said to be an electron acceptor (it has a great affinity for electrons), the glucose an electron donor. This is the prototype of oxidation-reduction reactions, but not all such reactions necessarily involve oxygen. Biological electron acceptors other than oxygen include nitrates, sulfates, carbonates, nitrogen, and methanol. Biological electron donors other than sugars include nitrogen, sulfides, methane, ammonia, and methanol. For acceptor-donor transformations to occur over any period of time, biological cycles are necessary. It is possible that, for geologically short periods of time, organisms have lived off a finite supply of material, but for any long-term continuance of life, a dynamic cycling of matter, involving at least two different varieties of organisms, is necessary. If there is life on other planets, a similar cycling must exist. A search for such molecular transformations is one method of detecting extraterrestrial life.

On the Earth, all such useful biological electron transfer reactions lead to the net production of one or more molecules of ATP. Two of the three phosphates of this molecule are held by "energy-rich" bonds sufficiently stable to survive for long periods of time in the cell, but not so strong that the cell cannot tap these bonds for energy when needed. ATP and very similar molecules, all of them having a base, a five-carbon sugar, and three phosphates, are, so far as is known, the general and unique energy currency of living systems on Earth.

Energy from metabolic processes

Metabolic processes do not occur in one step. The ordinary sugar, glucose, is not oxidized to carbon dioxide and water by living cells in the same way that occurs if a flame is applied to glucose in air. The resulting release of energy would be much too sudden, and concentrated in too small a volume, for such a process to be utilized safely by the cell. Instead, the glucose is broken down by a series of successive and coordinated steps, each mediated by a particular and specific enzyme. In almost all organisms that metabolize glucose, the sugar is first broken down in a set of anaerobic steps (that is, in the absence of oxygen). The total number of such steps is about 11. Some organisms are anaerobes; that is, they do not utilize molecular oxygen. In them the anaerobic steps are as far as the glucose metabolism is carried. Other organisms, including man, carry the oxidation of glucose further, gingerly combining glucose breakdown products with molecular oxygen. Such aerobic oxidation of glucose requires about 60 more enzymatically catalyzed steps. Another indication of the relative simplicity of the anaerobic breakdown of sugar is that all the enzymes used are free in solution in the cell; the aerobic steps use enzymes that are localized in specific regions of the cell. The complete aerobic breakdown of sugar to carbon dioxide and water is about 10 times more efficient than the breakdown accomplished by anaerobes; 10 times as many ATP molecules are produced. Similar themes and variations exist for the metabolism of other molecules (see METABOLISM).

Efficiency of aerobic oxidation

The energy made available in this way to ATP is used in a variety of ways by the cell; for example, for motility. When an amoeba extends pseudopods, or a person walks, ATP molecules are being tapped for their energy-rich phosphate bonds. In addition, ATP molecules are used for the synthesis of molecules that the organism needs and does not have available. Among such molecules may be amino acids, the particular five-carbon sugars involved in nucleic acids, the nucleic acid bases, and so on. Each of these synthetic processes is again controlled and enzymatically mediated and may start from a variety of building blocks available to the organism, some simple, some more complex. For example, the amino acid L-leucine is produced from pyruvic acid, itself the product of the anaerobic breakdown of glucose. Synthesis of L-leucine from pyruvic acid involves eight enzyme-mediated steps and the addition of acetic acid and water.

These exquisitely interlocked and controlled metabolic steps are not usually performed in a diffuse manner all over the cell. Instead there is, at least in all higher organisms, a marvellously architectured cellular interior with particular specialized regions where particular chemical reactions are performed. Those oxidation-reduction reactions that involve molecular oxygen occur in an inclusion within the cytoplasm called the mitochondrion. The mitochondrion itself has an intricate substructure, and particular enzymes are thought to reside in particular sites within it; the molecule being metabolized may be passed on from one enzyme to another as through a conveyor belt in a factory. Similarly, photosynthesis occurs in a cytoplasmic inclusion called a chloroplast, which contains the chlorophyll and other pigments that absorb visible light, as well

The work of the mitochondrion

as the detailed enzymatic apparatus for the photosynthetic process. Chloroplasts and mitochondria, as well as other cytoplasmic inclusions at the base of flagella and cilia, all contain DNA. Moreover, this DNA has a somewhat different distribution of bases from that of the nucleus. It has been suggested that the cytoplasmic inclusions are the remnants of once free-living forms that, because of the favourable conditions found there, have taken up residence in the insides of other organisms.

Nucleic acids are known to pass from cell to cell and to perform their replication and coding functions efficiently in the new cell. In fact, viruses are essentially strands of nucleic acid, with a protein coat, that operate in just this way. It is also known that pieces of the genetic material from one cell may migrate into another cell of the same species and produce genetic and permanently heritable changes there. Alternatively, part of the virus nucleic acid may be permanently bound to the nuclear DNA of a host cell. It is likely that a virus is a degenerate form, now highly specialized to live off a specific host, of an organism once free-living and much more generally capable of performing a wide range of metabolic tasks. A virus must use the genetic transcription apparatus of its host cell. Many viruses do this extremely efficiently, turning a bacterium from a factory for making other bacteria into a factory for making viruses. In some cases it takes no more than 10 minutes for a bacterium infected by a single virus to produce a hundred new virus particles, which then burst forth from the host bacterium, destroying it. The line between benign or useful cytoplasmic inclusions and infective agents is not a very sharp one (see VIRUSES).

Differences in nuclear structure

Eucaryotes and procaryotes. In the very simplest one-celled organisms one may distinguish between eucaryotic and procaryotic cells. Many familiar one-celled organisms, such as paramecia and amoebas, as well as the cells of all higher organisms including man, are eucaryotic. Such cells undergo mitosis, a fundamental sequence of events that occurs after DNA replication and that ensures that the DNA is precisely and equally distributed to the daughter cells. Eucaryotic cells have nucleoprotein in their nuclei. There is a membrane that separates the nucleus from the cytoplasm. Mitochondria are generally present in the cytoplasm, as is a very intricately convoluted structure, called the endoplasmic reticulum, that probably serves as the anchoring point for many cytoplasmic enzymes not contained in such inclusions as mitochondria or chloroplasts.

On the other hand there are procaryotic cells, which are most generally typified by the bacteria and the blue-green algae. In these cells nuclear division is nonmitotic, there is no nucleoprotein, and a nuclear membrane is absent. While eucaryotic cells may have more than one chromosome, procaryotic cells have one chromosome only, and that one is dispersed in the cytoplasm. Mitochondria, chloroplasts, and the endoplasmic reticulum are always absent. It is clear from this description that the procaryotes are in many respects more primitive than the eucaryotes. A basic unsolved evolutionary question concerns the evolution of procaryotes into eucaryotes.

The smallest organism

An interesting subject of biological speculation concerns what the smallest and simplest contemporary free-living organism might be. The smallest free-living cells now known are the pleuropneumonia-like organisms (PPLO). While an amoeba has a mass of 5×10^{-7} grams (1 gram = 0.035 ounce), a PPLO weighs 5×10^{-16} grams and is only about $^1/_{10}$ of a micrometre across. It can be seen only in the electron microscope. Such organisms grow very slowly. There may be smaller organisms that grow even more slowly, but they would be extremely difficult to detect. Even an organism of the size of PPLO has room for only about a hundred enzymes. A much smaller organism would have room for many fewer enzymes, and its ability to accomplish the functions that contemporary living systems must accomplish would be severely compromised. Were there, however, an environment in which all the necessary organic building blocks and such energy sources as ATP were provided "free," a functioning organism could be substantially smaller than PPLO. In fact the inside of a cell provides just such an environment; this is why infectious agents, such as viruses, can be substantially smaller than PPLO. But it must be emphasized that such agents are not free-living organisms.

Metazoa, embryology, and sex. The distinction between single-celled and many-celled organisms (in animals, between protozoa and metazoa) is far from a sharp one. An interesting illustration is the slime molds, which undergo an extraordinary sequence of events during their life cycle. The cycle begins with single cells, somewhat like amoebas, which swarm, or combine, into a slimy mass with many nuclei called a plasmodium. The plasmodium in turn forms a sluglike mass that is certainly a multicelled organism. The slug develops into a stalked, fruitlike sporangium, still multicellular. The sporangium produces spores with cellulose cell walls similar to those of plants. The spores in turn germinate into small cells bearing flagella. The flagella are lost and the life cycle is completed with the production of an amoeboid form (for details, see PROTOPHYTES: *Slime molds*).

Biology is replete with life cycles of comparable complexity. The swarming of individual cells to form a plasmodium may in fact be an example of the events that led to the production of metazoa in the early history of the Earth. Such life cycles, while apparently very exotic, are shared by many organisms, including man, where a one-celled, free-swimming sperm stage is part of the life cycle.

The problem of development

The life cycle of slime molds, or men, or any other multicellular organism, brings up a fundamental and still largely unsolved problem. These organisms develop from a single cell that has a single complement of the genetic material. These cells then divide, forming many identical cells. The very early embryology of man goes through stages with 2, 4, 8, 16, etc., cells. Since the genetic information is identical in each cell, how does it ever happen that cells become specialized, forming hair cells, teeth cells, liver cells, blood cells, or bone cells? How can any given cell "know" what sort of specialized cell it must become, since all cells contain identical nucleic acids? Possibly the answer to this question has to do with geometry. After the 16- or 32-cell stage, there is a distinct difference between a cell on the inside of the embryo, which is entirely surrounded by cells, and a cell on the outside of the embryo, which is not entirely surrounded by other cells. One of the earliest major steps in embryonic development is a distinction in function between interior cells (the endoderm) and exterior cells (the ectoderm). There are physical and chemical interactions among adjacent cells. Perhaps any cell then has the capability of becoming any specialized cell, but cells are, as a result of their external cellular environment, called upon to develop in different ways. Occasional embryonic anomalies or cysts occur in which, for example, hair or teeth develop in totally inappropriate portions of the body. Similarly, eyes have been caused to develop on the limbs of frogs. Such incidents demonstrate the capability of the "wrong" cells to produce particular cellular specializations (see GROWTH AND DEVELOPMENT).

Much of the beauty and diversity of contemporary life on Earth is due to sex. A totally asexual organism will be genetically identical to its (single) parent except for occasional mutations. The development of any major new adaptation would then require the acquisition of large numbers of appropriate mutations. Consider, for example, how the ability of an organism to metabolize a given molecule depends on the interaction of many enzymes, each produced by the transcription of the genetic information in hundreds of nucleotides, each nucleotide being the product of a single mutation. Thus, the chance development of any advantageous adaptation in an asexual organism requires the mutations to wait in line for a fortuitous juxtaposition.

Sex: an added dimension

Sex solves this problem in an elegant way. The genetic material of the parents is reassorted so that totally new combinations of genes are produced. In this way mutations acquired by any member of the population are rather quickly distributed to other members, and mutations arising in separate organisms can be combined. The likelihood of producing a useful sequence of mutations is thereby greatly enhanced. The advantages of sexual reproduction are so great that even many simple forms, such as bacteria or protozoa, which largely reproduce asexually, have occasional sexual encounters. While two sexes are clearly adequate for such a random assortment of genetic material, some organisms have developed more sexes: paramecia, for example, have somewhere between five and 10 sexes, defined in terms of the elaborate taboos about which organisms can combine their genetic material. In the process of genetic reassortment, some organisms make a very large number of attempts; for example, frogs lay millions of eggs at a time, and the number of sperm cells in a single human ejaculation is about 3×10^8 (see SEX AND SEXUALITY).

The varieties of organisms and environments. The environment of the Earth is heterogeneous. There are mountains, oceans, and deserts, extremes of temperature and humidity. In addition, there are diverse microenvironments: oxygen-depleted oceanic oozes, ammonia-rich soils, mineral deposits with a high radioactivity content, and so on. The environment of an organism also includes the other organisms in its surroundings. For each of these environmental situations there are corresponding ecological niches, and the variety of ecological niches populated on the Earth is quite remarkable. Furthermore, ecological niches can be filled independently several times. For example, quite analogous to the ordinary mammalian wolf is the marsupial wolf that lives in Australia; the two have striking similarities in physical appearance and in predation behaviour. As another example, the same streamlined shape for high-speed marine motion has evolved independently at least three times: in *Stenopterygius* and other Mesozoic reptiles; in the tuna, which are fish; and in the dolphins, which are mammals. This case of convergent evolution must arise from the fact that hydrodynamics admits a narrow range of solutions to the problem of high-speed marine motion by large animals. Similarly, the eye has independently evolved several times among animals on the Earth; apparently such a structure is the best solution to the problem of visual recording. In those cases where physics or chemistry establishes one most efficient solution to a given ecological problem, natural selection will often tend to reach the solution, but not always. Some adaptations of undoubted utility, such as tractor treads in swampy environments, have never been evolved by natural selection on the Earth.

Life in extreme environments

There is an extraordinarily wide range of ecological niches to which organisms have adapted through the operation of natural selection. The same basic fabric of life has been used to produce very diverse organisms. The alga *Cyanidium caldarium* can grow in concentrated solutions of hot sulfuric acid. Other bacteria, algae, and fungi can live in extremely acidic (pH of 0) or extremely alkaline (pH near 13) environments. Procaryotic bacteria live in pools at Yellowstone National Park at temperatures above 90° C (194° F), almost at the boiling point of water. Sulfate-reducing bacteria are reported to grow and reproduce at 104° C (219° F) under very high pressures. Many organisms employ organic or inorganic antifreezes to lower the freezing point of their internal liquids, so that they can live at several tens of degrees below 0° C (32° F). Some insects use dimethyl sulfoxide as an antifreeze. Other organisms live in briny pools in which dissolved salts lower the freezing point. For example, Don Juan Pond in Antarctica has about one molecule of calcium chloride for every two water molecules and does not freeze until −45° C (−49° F). It contains a possibly unique microflora that continues to metabolize at least down to −23° C (−9° F). Biological activity does not cease at the freezing point of water; in fact some enzymes are actually more active in ice than in water. Many single-celled organisms can be frozen indefinitely to extremely low temperatures—the temperature of liquid air for example—and then be thawed with no decrease in activity. The primary damage that freezing causes is apparently due to the unavailability of liquid water and to the expansion and contraction attendant to freezing and thawing. Some arthropods can be severely dehydrated and then revived simply by adding water. In the dehydrated state they can be brought to any temperature from close to absolute zero to above the boiling point of water without apparent damage. When encysted in response to dehydration, some such organisms seem indistinguishable from a weathered grain of sand.

The great majority of familiar organisms on the Earth, however, are much more sensitive to the temperature of their surroundings. Warm-blooded animals internally regulate their temperatures for this reason. A human being whose body temperature drops below 30° C (86° F) or rises above 40° C (104° F) soon dies. Organisms that inhabit cold climates have special insulating layers of fat and fur. Other organisms adapt to seasonal temperature changes by producing dormant forms, such as spores or eggs, to survive the low temperatures. In all cases dormancy appears to be accompanied by dehydration.

Importance of water

Since organisms are composed largely of water, the availability of water is clearly a limiting factor. Here also, however, remarkable adaptations exist. Certain microorganisms can live on the water adsorbed on a single crystal of salt. Other organisms, such as the kangaroo rat and the flour beetle, obtain no water at all in the liquid state, relying entirely on metabolic water; that is, on water released from chemical bonds through the metabolism of food. A variety of plants, including Spanish moss, live in environments where they have no contact with groundwater—for example, on telephone wires—apparently extracting water directly from the air, although such plants require a relatively high humidity. Plants that live in deserts and other very dry environments have evolved wide-spreading root systems that adsorb subsurface water from a great volume of adjacent soil.

Organisms have been found from the stratosphere to the ocean depths. Bacteria and fungal spores have been discovered near the base of the stratosphere by balloons, and searches for organisms at much greater altitudes (up to 100,000 feet) have been attempted with ambiguous results. Birds have been observed flying at altitudes as great as 27,000 feet, and jumping spiders have been found at 22,000 feet on Mt. Everest. At the opposite extreme, microorganisms, fish, and a variety of other metazoa have been recovered from the ocean depths down to thousands of feet, where the corresponding pressures are hundreds of times that at sea level. At these depths no light can penetrate and the organisms, some of which are quite large and include unique phosphorescent adaptations to the dark, ultimately live off particles of organic matter raining down from the upper reaches of the oceans.

There is a range of adaptations to the radiation environment of the Earth. Some microorganisms are readily killed by the small amount of solar ultraviolet light that filters through the Earth's atmosphere at wavelengths near 3,000 angstrom units (Å; 1 Å = one ten-billionth of a metre). On the other hand, the bacterium *Pseudomonas radiodurans* thrives in the large neutron flux at the cores of swimming-pool reactors, to the continuing annoyance of nuclear physicists. Organisms can avoid radiation by shielding. For example, some algae and some desert plants live under a superficial coating of soil or rocks that are more transparent to visible light than to ultraviolet light. In addition, organisms have active methods of undoing the damage produced by radiation. Some of these repair mechanisms work in the dark; others require visible light. The usual reason for the ultraviolet sensitivity of organisms is that their nucleic acids absorb ultraviolet light very effectively at a wavelength near 2,600 Å. Generally speaking, there is an upper limit to the amount of ionizing radiation (such as gamma rays, X-rays, electrons or protons) that an organism can receive without being killed: in the vicinity of 1,000,000 roentgens. Such a lethal dose applies only to extremely radiation-resistant microorganisms; mammals, for example, are killed by much lower doses because there is more that can go wrong with such complex organisms. A lethal dose of ionizing radiation for human beings is a few hundred roentgens applied to the whole body. A thermonuclear weapon dropped on a populated area may deliver, through direct radiation and fallout, doses of a few hundred roentgens or more to people within a radius of some tens of miles of the target. Much smaller doses can produce a variety of diseases and predominantly deleterious mutations in the hereditary material. Moreover, the effect of small doses is cumulative. But until very recently human beings have not lived in environments characterized by large doses of ionizing radiation (see RADIATION).

Size range of living things

The sizes of organisms on the Earth vary greatly. As discussed above, the smallest free-living organisms on the Earth, PPLO, are about 1,000 Å in diameter; a limitation on the size of the smallest free-living organism is its volume: it must contain all the molecules necessary for metabolism. A variety of influences place an upper limit to the size of organisms. One is the strength of biological materials. Galileo calculated in 1638 that a tree taller than roughly 300 feet (91.4 metres) would, when displaced slightly from the vertical (for example, by a breeze), buckle under its own weight. (Sequoias, some of which exceed 300 feet, are apparently near the upper limit of height for an organism.) Because of the buoyancy of water, large whales are not presented with such stability problems, but other difficulties arise. For a fixed shape, the volume of tissues to be nourished increases as the cube of the characteristic length of the organism, but the surface of the gut, which adsorbs the ingested food, increases only as the square of the length. As the length is increased, a point of diminishing returns is ultimately reached.

The range of organic molecules that organisms on Earth can metabolize is very wide and occasionally includes such foods as formaldehyde or petroleum, which seem unlikely from a human point of view. *Pseudomonas* bacteria are capable of using almost any organic molecule as a source of carbon and of energy, provided only that the molecule is at least slightly soluble in water. Microorganisms cannot metabolize plastics, not because of any fundamental chemical prohibitions but probably because plastics have not been part of the environment of microorganisms for very long. Man tends to think of oxygen as extremely important for life, but there are facultative anaerobes that can take their oxygen or leave it, and obligate anaerobes that are actually poisoned by oxygen. Such organisms use a variety of alternative electron acceptors, as previously discussed.

Chemical constituents

The water content of organisms usually represents between 50 and 90 percent of the live weight. Unless there is a massive mineral skeleton, the dry matter of organisms constitutes about one-half carbon by weight, reflecting the fact that organic molecules are based upon carbon. A wide variety of other chemical elements are used for diverse functions. Amino acids are made of nitrogen and sulfur in addition to carbon, hydrogen, and oxygen. Nucleic acids, as has been seen, employ phosphorus in addition to hydrogen, nitrogen, oxygen, and carbon. Sodium and potassium are used in maintaining the electrolyte balance, and calcium and silicon as structural materials. Iron plays a fundamental role in the transport of molecular oxygen as part of the hemoglobin molecule. In some ascidians (sea squirts), however, vanadium replaces iron. Ascidian blood also contains unusually large amounts of niobium, tantalum, titanium, chromium, manganese, molybdenum, and tungsten. The vanadium and niobium compounds in ascidian blood may be adaptations to low oxygen levels. Occasional organisms use selenium or tellurium as electron acceptors; others may produce the fully saturated gas hydrides of arsenic, phosphorus, or silicon, as metabolic wastes. Still others form compounds of carbon with such halogens as chlorine or iodine. Many of the foregoing elements, plus copper, zinc, cobalt, and possibly gallium, boron, and scandium, perform particular functions in the enzymatic apparatus of cells. Many of these elements, both the uncommon ones and those as common as phosphorus, are very highly concentrated in organisms over their general availability in the environment. This concentration must indicate that such chemicals play unique functional roles where other more abundant elements will not serve.

Behaviour and sensory capabilities. Analogous to the wide range of physiological adaptations and the great variety of elements used by organisms on Earth, there is an enormous range of behaviour patterns and sensory capabilities. Coded into its nucleic acids is the information that allows a bird raised from the egg in the absence of other birds to migrate when migration time arrives, to build a nest characteristic of its species, or to engage in elaborate courtship rituals. Those birds that do not perform acceptably do not leave descendants. Such behavioral information must itself have evolved. Rats that pass through mazes easily can be interbred, as can rats that pass through with difficulty; eventually two populations with inherited characteristics called "maze-smart" and "maze-dumb" will be produced. Fruit fly populations attracted to the light can be separated from those that avoid light. Classical genetic crossing experiments reveal that the two populations differ largely in a small number of genes for phototropism. Similar genetic determinants of behaviour exist in man. Possession of a supernumerary Y-chromosome in males is strikingly correlated with aggressive tendencies—which may, however, have been a selective advantage in more primitive societies. Myopia may have had strong survival value in earlier times: near-sighted males, useless in the hunt, stayed home and painted the walls of the cave. As technology develops, natural selection enters new behavioral arenas; for example, in an age of artificial contraception, the clumsy and forgetful preferentially reproduce.

Response to the electromagnetic spectrum

Human beings use only a small part of the total electromagnetic spectrum, the part called visible light, which extends from about 4,000 to about 7,000 Å in wavelength. While many plants and animals are sensitive to this same range of wavelengths, many of them are sensitive to other wavelengths as well. Most insects are sensitive to ultraviolet light at wavelengths below 4,000 Å, and many flowering plants take advantage of this fact and present patterns visible only in the ultraviolet range. Honeybees use polarized light, which the unaided human eye is quite unable to detect, for direction finding on partly cloudy days. The "pit" of such pit vipers as the rattlesnake is an infrared receptor and direction finder. These reptiles can sense the thermal radiation emitted by warm-blooded prey, radiation to which human beings are completely insensitive.

It is common knowledge that some animals (for example, dogs) are sensitive to sounds that the human ear cannot detect. Bats emit and detect sound waves at ultrahigh frequencies, in the vicinity of 100,000 cycles per second, about five times the highest frequency to which the human ear is sensitive. Bats use these sounds not so much to communicate, however, as to echolocate their prey and were doing this for millions of years before radar and sonar were invented. The audio receptors of many moths that are prey to bats are responsive only to the frequencies emitted by the bats. When the bat sounds are heard, the moths take evasive action. Dolphins have a very wide frequency range and several communication channels, as well as a "click" echolocator. Dolphins and whales use their blowholes rather than their mouths to utter these sounds. Sharks and other marine predators are said to locate their prey by the low-frequency sounds the prey makes when in distress. Some animals develop highly specialized and exotic organs for the detection or transmission of sound—for example, a European grasshopper has a relatively large parabolic antenna on its back that looks very much like a small radio telescope. This antenna is used for producing noises evidently thought attractive by the female of the species.

Many organisms are capable of smell and taste; that is, the detection of specific chemical molecules. According to one theory of smell, there are particular olfactory sensors, each receptive only to a specific chemical group on airborne molecules. The ultimate in olfactory specialization is probably the male silkworm moth: with its feathery antennae it is able to smell essentially nothing except the chemical sex attractant discharged by the female of the species. But it can detect this molecule very well, needing an impact of only 40 molecules per second on its antennae to produce a marked response. One female silkworm moth need release only 10^{-8} grams of sex attractant per second in order to attract every male silkworm moth in a volume hundreds of metres to kilometres on a side.

Extraordinary senses

Besides the senses of sight, hearing, smell, taste, and touch, various animals have a wide variety of other senses (see SENSORY RECEPTION). Man has an inertial orientation system and accelerometer in the cochlear canal of the ear. The water scorpion (*Nepa*) has a fathometer sensitive to hydrostatic pressure gradients. Most higher plants have chemically amplified gravity sensors. Fireflies and squids communicate with their own kind by producing time sequences or patterns of light on their bodies. The African freshwater fish *Gymnarchus niloticus* operates a dipole electrostatic field generator and a sensor to detect the amplitude and frequency of disturbances in the impressed field, an adaptation well suited for its nocturnal activities in turbulent waters. Other organisms have salinity sensors, or humidity sensors. There may be sensors involved in homing instincts of animals that have not yet been discovered. All of these senses confer upon their possessors an awareness of the environment that may be very different from that of such other organisms as man. Man, however, has the remarkable ability to extend his sensory and intellectual capabilities artificially, through the use of instrumentation.

THE ORIGIN OF LIFE

Hypotheses of origins. Perhaps the most fundamental and at the same time the least understood biological problem is the origin of life. It is central to many scientific and philosophical problems and to any consideration of extraterrestrial life. Most of the hypotheses of the origin of life will fall into one of four categories:

1. The origin of life is a result of a supernatural event; that is, one permanently beyond the descriptive powers of physics and chemistry.

2. Life—particularly simple forms—spontaneously and readily arises from nonliving matter in short periods of time, today as in the past.

3. Life is coeternal with matter and has no beginning; life arrived on the Earth at the time of the origin of the earth or shortly thereafter.

4. Life arose on the early Earth by a series of progressive chemical reactions. Such reactions may have been likely or may have required one or more highly improbable chemical events.

The early theological view

Hypothesis 1, the traditional contention of theology and some philosophy, is in its most general form not inconsistent with contemporary scientific knowledge, although this knowledge is inconsistent with a literal interpretation of the biblical accounts given in chapters 1 and 2 of Genesis and in other religious writings. Hypothesis 2 (not of course inconsistent with 1) was the prevailing opinion for centuries. A typical 17th-century view follows:

> [May one] doubt whether, in cheese and timber, worms are generated, or, if beetles and wasps, in cowdung, or if butterflies, locusts, shellfish, snails, eels, and such life be procreated of putrefied matter, which is to receive the form of that creature to which it is by formative power disposed[?] To question this is to question reason, sense, and experience. If he doubts this, let him go to Egypt, and there he will find the fields swarming with mice begot of the mud of the Nylus [Nile], to the great calamity of the inhabitants.

It was only in the Renaissance, with its burgeoning interest in anatomy, that such transformations were realized to be impossible. A British physiologist, William Harvey, during the mid-17th century, in the course of his studies on the reproduction and development of the king's deer, made the basic discovery that every animal comes from an egg. An Italian biologist, Francesco Redi, in the latter part of the 17th century, established that the maggots in meat came from flies' eggs, deposited on the meat. And an Italian priest, Lazzaro Spallanzani, in the 18th century, showed that spermatozoa were necessary for the reproduction of mammals. But the idea of spontaneous generation died hard. Even though it was proved that the larger animals always came from eggs, there was still hope for the smaller ones, the microorganisms. It seemed obvious that, because of their ubiquity, these microscopic creatures must be generated continually from inorganic matter.

Meat could be kept from going maggoty by covering it with a flyproof net, but grape juice could not be kept from fermenting by putting over it any netting whatever. This was the subject of a great controversy between the famous French bacteriologists Louis Pasteur and F.A. Pouchet in the 1850s, in which Pasteur triumphantly showed that even the minutest creatures came from germs floating in the air, but that they could be guarded against by suitable filtration. Actually, Pouchet was arguing that life must somehow arise from nonliving matter; if not, how had life come about in the first place?

boiling nutrient solution
solution sterile for months

Pasteur's swan-necked flask experiment (see text).

Life from outer space

Toward the end of the 19th century Hypothesis 3 gained currency, particularly with the suggestion by a Swedish chemist, S.A. Arrhenius, that life on Earth arose from panspermia, microorganisms or spores wafted through space by radiation pressure from planet to planet or solar system to solar system. Such an idea of course avoids rather than solves the problem of the origin of life. In addition, it is extremely unlikely that any microorganism could be transported by radiation pressure to the Earth over interstellar distances without being killed by the combined effects of cold, vacuum, and radiation.

Pasteur's work discouraged many scientists from discussing the origin of life at all. Moreover they were anxious not to offend religious feeling by probing too deeply into the subject. Although Darwin would not commit himself on the origin of life, others subscribed to Hypothesis 4 more resolutely, notably the famous British biologist T.H. Huxley in his *Protoplasm, the Physical Basis of Life* (1869), and the British physicist John Tyndall in his "Belfast Address" of 1874. Although Huxley and Tyndall asserted that life could be generated from inorganic chemicals, they had extremely vague ideas about how this might be accomplished. The very phrase "organic molecule" implies that there exists a special class of chemicals uniquely of biological origin, despite the fact that organic molecules have been routinely produced from inorganic chemicals since 1828. In the following discussion the word organic carries no imputation of biological origin. In fact the problem largely reduces to finding an abiological source of appropriate organic molecules.

The primitive atmosphere. Darwin's attitude was: "It is mere rubbish thinking at present of the origin of life; one might as well think of the origin of matter." The two problems are, in fact, curiously connected, and modern scientists are thinking about the origin of matter. There is convincing evidence that thermonuclear reactions and subsequent explosions in the interiors of stars generate all the chemical elements more massive than hydrogen and helium and then distribute them into the interstellar medium from which subsequent generations of stars and planets form. Because of the commonality of these thermonuclear processes, and because some thermonuclear reactions are more probable than others, there exists a cosmic distribution of the major elements, so far as is

Table 1: Relative Abundances of the Elements (percent)

atom	universe	life (terrestrial vegetation)	earth (crust)
Hydrogen	87	16	3
Helium	12	0*	0
Carbon	0.03	21	0.1
Nitrogen	0.008	3	0.0001
Oxygen	0.06	59	49
Neon	0.02	0	0
Sodium	0.0001	0.01	0.7
Magnesium	0.0003	0.04	8
Aluminum	0.0002	0.001	2
Silicon	0.003	0.1	14
Sulfur	0.002	0.02	0.7
Phosphorus	0.00003	0.03	0.07
Potassium	0.000007	0.1	0.1
Argon	0.0004	0	0
Calcium	0.0001	0.1	2
Iron	0.002	0.005	18

*0% here stands for any quantity less than 10^{-6}%.

known, throughout the universe. Table 1 compares, for some atoms of interest, the relative numerical abundances in the universe as a whole, on the Earth, and in living organisms. There is of course some variation in composition from star to star, from place to place on the Earth, and from organism to organism, but such comparisons are nevertheless very instructive. The composition of life is intermediate between the average composition of the universe and the average composition of the Earth. Ninety-nine percent both of the universe and of life is made of the six atoms, hydrogen (H), helium (He), carbon (C), nitrogen (N), oxygen (O), and neon (Ne). Can it be that life on Earth arose when the chemical composition of the Earth was much closer to the average cosmic composition, and that some subsequent events have changed the gross chemical composition of the Earth?

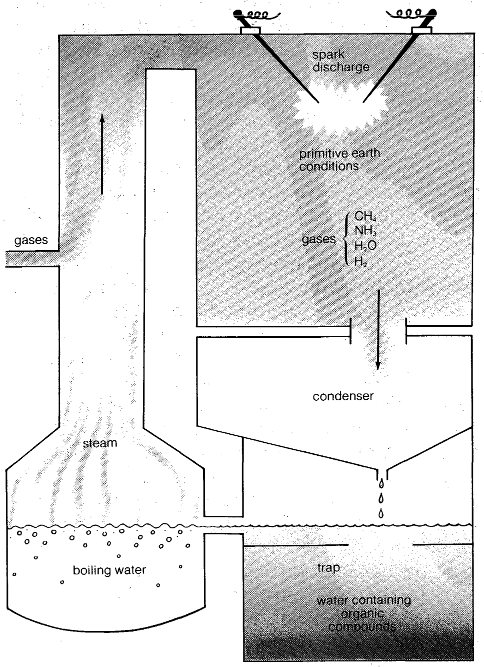
Composition of life

The Jovian planets (Jupiter, Saturn, Uranus, and Neptune) are much closer to cosmic composition than is the Earth. They are largely gaseous, with atmospheres composed principally of hydrogen and helium. Methane (CH_4) and ammonia (NH_3) have been detected in smaller quantities, and neon and water are suspected. This circumstance very strongly suggests that the Jovian planets were formed out of material of typical cosmic composition. They have very large masses, and because they are so far from the sun their upper atmospheres are very cold. Therefore it is impossible for atoms in the upper atmospheres of the Jovian planets to escape from their gravitational fields; escape was probably very difficult even during planetary formation. The Earth and the other planets of the inner solar system, however, are much less massive and most have hotter upper atmospheres. It is possible for hydrogen and helium to escape from the Earth today, and it may well have been possible for much heavier gases to have escaped during the formation of the Earth. It is reasonable to expect that in the very early history of the Earth a much larger abundance of hydrogen prevailed, which has subsequently been lost to space. Thus the atoms carbon, nitrogen, and oxygen were present on the primitive Earth, not as CO_2 (carbon dioxide), N_2, and O_2 as they are today but rather in the form of their fully saturated hydrides, CH_4 (methane), NH_3 (ammonia), and H_2O. In the geological record, the presence of such reduced minerals as uraninite (UO_2) and pyrite (FeS_2) in sediments formed several billions of years ago implies that conditions then were considerably less oxidizing than they are today.

In the 1920s J.B.S. Haldane in Britain and A.I. Oparin in the Soviet Union recognized that the abiological production of organic molecules in the present oxidizing atmosphere of the Earth is highly unlikely; but that, if the Earth once had more reducing (in this context, hydrogen-rich) conditions, the possible abiogenic production of organic molecules would have been much more likely. If large numbers of organic molecules were somehow synthesized on the primitive Earth, there would not necessarily be much trace of them today. In the present oxygen atmosphere, largely produced by green-plant photosynthesis, such molecules would tend, over geological time, to be oxidized to carbon dioxide, nitrogen, and water. In addition, as Darwin recognized, the first microorganisms would consume prebiological organic matter produced prior to the origin of life.

Production of simple organic molecules. The first deliberate experimental simulation of these primitive conditions was carried out in 1953 by a U.S. graduate student, S.L. Miller, under the guidance of the eminent chemist H.C. Urey. A mixture of methane, ammonia, water vapour, and hydrogen was circulated through a liquid water solution and continuously sparked by a corona discharge elsewhere in the apparatus. The discharge may be thought to represent lightning flashes on the early Earth. After several days of exposure to sparking, the solution changed colour. Subsequent analysis indicated that several amino and hydroxy acids, intimately involved in contemporary life, had been produced by this simple procedure. The experiment is in fact so elementary, and the amino acids can so readily be detected by paper chromatography, that the experiment has been repeated many times by high school students. Subsequent experiments have substituted ultraviolet light or heat as the energy source or have altered the initial abundances of gases. In all such experiments amino acids have been formed in large yield. On the early Earth there was much more energy available in ultraviolet light than in lightning discharges. At long ultraviolet wavelengths, in which methane, ammonia, water, and hydrogen are all transparent, but in which the bulk of the solar ultraviolet energy lies, the gas hydrogen sulfide (H_2S) is a likely ultraviolet absorber.

Synthesis of amino acids



Miller–Urey spark-discharge apparatus.

Following such reasoning, a U.S. astrophysicist, Carl Sagan, and his colleagues made amino acids by long wavelength ultraviolet irradiation of a mixture of methane, ammonia, water, and H_2S. The amino acid syntheses, at least in many cases, involve hydrogen cyanide and aldehydes (*e.g.,* formaldehyde) as gaseous intermediaries formed from the initial gases. It is quite remarkable that amino acids, particularly biologically abundant amino acids, can be made so readily under simulated primitive conditions. When laboratory conditions become oxidizing, however, no amino acids are formed, suggesting that reducing conditions were necessary for prebiological organic synthesis.

Under alkaline conditions, and in the presence of inorganic catalysts, formaldehyde spontaneously reacts to form a variety of sugars, including the five-carbon sugars fundamental to the formation of nucleic acids and such six-carbon sugars as glucose and fructose, which are extremely common metabolites and structural building blocks in contemporary organisms. Furthermore, the nucleotide bases as well as porphyrins have been produced in the laboratory under simulated primitive Earth conditions by several investigators. While there is still debate on the generality of the experimental synthetic pathways and on the stability of the molecules produced, most if not all of the essential building blocks of proteins, carbohydrates, and nucleic acids can be readily produced under quite general primitive reducing conditions, plus probably ATP as well.

Production of polymers. The construction of polymers, long-chain molecules made of repeating units of these essential building blocks, however, is a much more difficult experimental problem. Polymerization reactions are generally dehydrations, in which a molecule of water is lost in the formation of a two-unit polymer. Dehydrating agents must be used to initiate polymerization. The polymerization of amino acids to form long protein-like molecules was accomplished through dry heating by a U.S. investigator, S.W. Fox. The polyamino acids that are formed are not random polymers and have some distinct catalytic activities. The geophysical generality of dry heat-

Polymerization as dehydration reactions

ing and return to solution, however, has been questioned. Long polymers of amino acids can also be produced from hydrogen cyanide and anhydrous liquid ammonia. Some evidence exists that nucleotide bases and sugars can be combined in the presence of phosphates or cyanides under ultraviolet irradiation. Some condensing agents such as cyanamide are efficiently made under simulated primitive conditions. Despite the breakdown by water of molecular intermediates, condensing agents are often quite effective in inducing polymerization, and polymers of amino acids, sugars, and nucleotides have all been made this way.

A famous British scientist, J.D. Bernal, suggested that adsorption of molecular intermediates on clays or other minerals may have concentrated these intermediates. Such concentration could offset the tendency for water to break down polymers of biological significance. Of special interest is the possibility that such concentration matrices included phosphates, for this would help explain how phosphorus could have been incorporated preferentially into prebiological organic molecules at a time when biological concentration mechanisms did not yet exist. Mineral catalysis implies that organic synthesis could also occur in deep water where ultraviolet light had been filtered out.

Quite apart from concentration mechanisms, the primitive waters themselves may have been a not very dilute solution of organic molecules. If all the surface carbon on the Earth were present as organic molecules in the contemporary oceans, or if many known ultraviolet synthetic reactions producing organic molecules were permitted to continue for a billion years with products dissolved in the oceans, a 1 percent solution of organic molecules would result. For similar reasons, Haldane suggested that the origin of life occurred in a "hot dilute soup." In addition, concentration mechanisms do exist, such as evaporation or freezing of pools or adsorption on interfaces or the generation of colloidal enclosures called coacervates.

The origin of the code. It has been shown that all the essential building blocks for life and their polymers may have been produced in some fair concentration on the primitive Earth. This possibility is certainly relevant to the origin of life, but it is not the same thing as the origin of life. By the genetic definition of life discussed above in *Definitions of life,* a self-replicating, mutable molecular system, capable of interacting with the environment, is required. In contemporary cells the nucleic acids are the sites of self-replication and mutation. Laboratory experiments have already shown that polynucleotides can be produced from nucleotide phosphates in the presence of a specific enzyme of biological origin and a pre-existing "primer" nucleic acid molecule. If the primer molecule is absent, polynucleotides are still formed, but they of course contain no genetic information. Once such a polynucleotide spontaneously forms, it then acts as primer for subsequent syntheses.

Production of polynucleotides

Imagine a primitive ocean filled with nucleotides and their phosphates and appropriate mineral surfaces serving as catalysts. Even in the absence of the appropriate enzyme it seems likely, although not yet proved, that spontaneous assembly of nucleotide phosphates into polynucleotides occurred. Once the first such polynucleotide was produced, it may have served as a template for its own reproduction, still of course in the absence of enzymes. As time went on there were bound to be errors in replication. These would be inherited. A self-replicating and mutable molecular system of polynucleotides, eventually leading to a diverse population of such molecules, may have arisen in this way. Alternatively, the primitive hereditary material may have involved some other molecule altogether, but no concrete suggestion for such a molecule has ever been proposed.

In any case, a population of replicating polynucleotides cannot quite be considered alive because it does not significantly influence its environment. Eventually, all the nucleotides in the ocean would have been tied in polynucleotides and the entire synthetic process would then have ground to a halt. So far as is known, polynucleotides have no an catalytic properties, and proteins have no reproductive properties. It is only the partnership of the two molecules that makes contemporary life on Earth possible. Accordingly, a critical and unsolved problem in the origin of life is the first functional relation between these two molecules, or, equivalently, the origin of the genetic code. The molecular apparatus ancillary to the operation of the code—the activating enzymes, adapter RNAs, messenger RNAs, ribosomes, and so on—are themselves each the product of a long evolutionary history and are produced according to instructions contained within the code. At the time of the origin of the code such an elaborate molecular apparatus was of course absent.

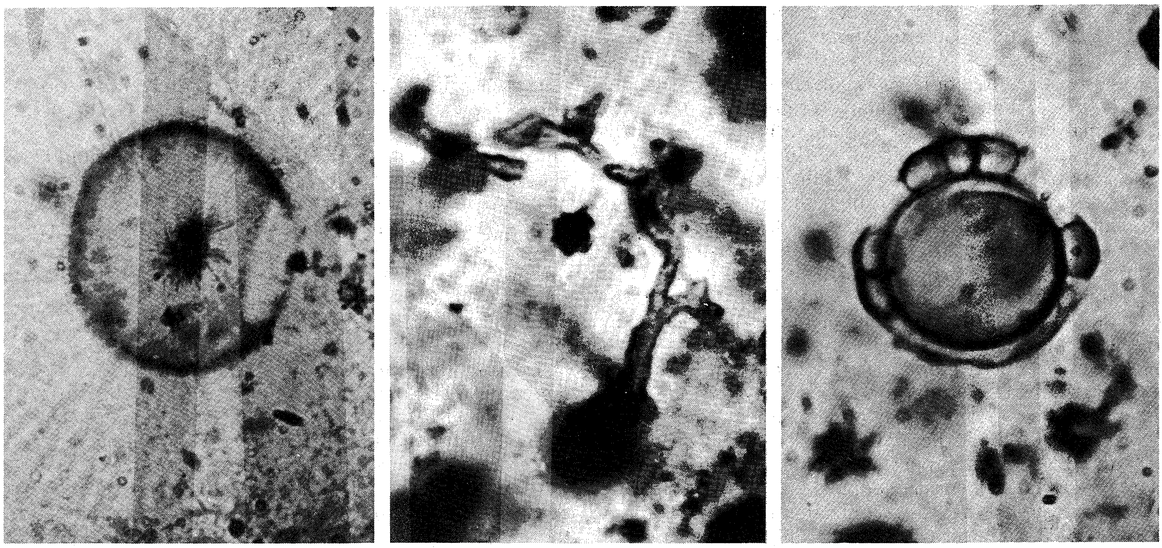
Catalysis and reproduction as necessary for life

It has been proposed that a weak but selective chemical bonding does exist, even in the absence of any of this apparatus, between amino acids and nucleotides. There need not be a very great selectivity; a given nucleotide sequence might in primitive times have coded for many different amino acids or, conversely, the same amino acid may have been coded for by several different nucleotide sequences. All that is required is that a particular linear sequence of nucleotides must code for some nonrandom sequence of amino acids. The active sites largely responsible for the catalytic activity of contemporary enzymes are generally only five or six amino acids long; the remainder of the enzyme is devoted to more sophisticated functions, such as arranging for the enzyme to be turned on and off by the machinery of the cell. With, say, 20 different varieties of amino acids available in the primitive environment, the chance of any given active site being produced by a random sequence of nucleotides is one in 20^5, or one in about 3,000,000. But 3,000,000 combinations to form units five amino acids long is not a very large number for the chemistry and time periods in question. To conclude this speculation, then, if polynucleotides were initially capable of crude, nonenzymatic replication, and if a crude primitive genetic code existed, then any one of a very large number of catalytic properties was available to some self-replicating polynucleotides on the primitive Earth. This situation is all that would be necessary for the origin of life; those polynucleotides that could code for a primitive protein having catalytic properties furthering the replication of the polynucleotide would preferentially replicate. Other polynucleotides coding for less effective proteins would have replicated more slowly. The foregoing is one of several possibilities for the origin of the first living systems. Many separate and rather diverse instances of the origin of life may have occurred on the primitive Earth, but competition eventually eliminated all but one line. Every organism on Earth today would be a descendant of that line.

Optical activity of biological molecules

The earliest living systems. One curious feature of biological organic molecules is their optical activity: they rotate the plane of a beam of plane-polarized light. Organic molecules produced abiologically do not show optical activity. Molecules made of the same units can be put together in complementary ways like a left- and right-handed glove. The same building blocks can be used to produce molecules that are three-dimensional mirror images of each other. This asymmetry is responsible for optical activity. At the time of the origin of life, organic molecules, corresponding both to left- and right-handed forms, were produced. The laboratory simulation experiments always produce both types. But the first living systems could have been made only of one type, for the same reason that carpenters do not use random mixtures of screws with left- and right-handed threads. Whether left- or right-handed activity was adopted was probably purely a matter of chance, but once a particular asymmetry was established in the first living systems, it maintained itself. This belief implies that optical activity should be a feature of life on any planet, and also that the chances should be equal of finding a given terrestrial organic molecule or its mirror image molecule in extraterrestrial life forms.

The first living systems probably resided in a molecular garden of Eden, where all the building blocks that contemporary organisms must work hard at synthesizing were available free. Under such conditions the numbers of organisms must have increased very rapidly. But such increases cannot go on indefinitely. In time the supply of some molecular building block must have become short. Those primitive organisms that had the ability to synthesize the scarce building block, say A, from a more



Photomicrographs of 2,000,000,000-year-old organisms from the geological stratum called the Gunflint Chert. These organisms are about 10 microns across. Organisms more than 1,000,000,000 years older are known.

By courtesy of Elso S. Barghoorn

abundant one, say B, clearly had a competitive advantage over those organisms that could not perform such a synthesis. In time, however, the secondary source of supply, B, would have also become depleted and those organisms that could produce it from a third building block, C, would have preferentially replicated. A U.S. biochemist, N.H. Horowitz, proposed that in this way the enzymatic reaction chains of contemporary organisms—each step catalyzed by a particular enzyme—originally evolved.

Even the evolution of enzymatic reaction chains may have occurred in free nucleic acids before the origin of the cell. The cell may have arisen in response to the need for maintaining a high concentration of scarce building blocks or enzymes, or as protection against the gradually increasing abundance of oxygen on the primitive Earth. Oxygen is a well-known poison to many biological processes, and in contemporary higher organisms the mitochondria that handle molecular oxygen are kept in the cytoplasm, far from contact with the nuclear material. Even today processes are known whereby polyamino acids form small spherical objects, microns to tens of microns across, with some of the properties of cells. These objects, called proteinoid microspheres by Fox, are certainly not cells, but they may indicate processes by which the ancestors of cells arose. Procaryotic cells almost certainly preceded eucaryotic cells, and the evolution of so extremely complex an apparatus as the mitotic spindle (which ensures equal segregation of replicated chromosomes) must have taken very long periods of time to evolve. The development of mitochondria and chloroplasts (each of which contains its own DNA) in the eucaryotic cell may have been the result of a symbiosis, a cooperative arrangement entered into at first tentatively by originally free-living cells.

Proteinoid microspheres

As the competition for building blocks increased among early life forms, and also perhaps as the abiological production of organic molecules dwindled because of the increasing oxygen abundance, the strictly heterotrophic way of life became more and more costly. The utilization of porphyrins, which are also made abiologically, by primitive photoautotrophs would have had great selective advantage. Many of the intermediates and enzymes in photosynthesis and in the anaerobic breakdown of carbon compounds are similar, but there is no generally accepted view of the origin of the photosynthetic process. Photosynthesis in procaryotes is more primitive than in such eucaryotes as green plants. In bacteria, water is not the ultimate source of hydrogen atoms for reducing carbon dioxide, and therefore oxygen is not produced. In addition, when a chlorophyll-containing cell is exposed both to light and to oxygen, it is killed unless it also contains an accessory carotenoid pigment. Thus green-plant photosynthesis had to wait until the appearance of carotenoids while bacterial photosynthesis, which does not produce oxygen, could function without carotenoids.

The antiquity of life. Among the oldest known fossils are those found in the Fig Tree chert from the Transvaal, dated at 3,100,000,000 years old. These organisms have been identified as bacteria and blue-green algae. It is very reasonable that the oldest fossils should be procaryotes rather than eucaryotes. Even procaryotes, however, are exceedingly complicated organisms and very highly evolved. Since the Earth is about 4,500,000,000 years old, this suggests that the origin of life must have occurred within a few hundred million years of that time.

By performing chemical analyses on the oldest sediments, it is possible to say something about the sorts of organic molecules produced, either biologically or abiologically, in primitive times. Thus, amino acids and porphyrins have been identified in the oldest sediments, as have pristane and phytane, typical breakdown products of chlorophyll. There are several indications that these organic molecules, dating from 2,000,000,000 to more than 3,000,000,000 years ago, are of biological origin. For one thing their long-chain hydrocarbons show a preference for a straight chain geometry, whereas known abiological processes tend to produce a much larger proportion of branched chain and cyclic hydrocarbon molecular geometries than have been found in these sediments. Abiological processes tend to produce equal amounts of long-chain carbon compounds with odd and with even numbers of carbon atoms. But the oldest sediments show a distinct preference for odd numbers of carbon atoms per molecule, as do products of undoubted biological origin. Finally, a C^{12} enrichment, for which no abiological process seems able to account, has been discovered in the oldest sediments, evidence that suggests that plantlike life, which concentrates the carbon isotope C^{12} preferentially to C^{13}, was present very early. These departures from thermodynamic equilibrium are often considered to be compelling signs of biological activity. Such evidence again points to the great antiquity of life on Earth.

The fossil record, in any complete sense, goes back only about 600,000,000 years. In the layers of sedimentary rock known by geological methods and by radioactive dating to be that old, most of the major groups of invertebrates appear for the first time. All these organisms appear adapted to life in the water, and there is no sign yet of organisms adapted to the land. For this reason, and because of a rough similarity between the salt contents of blood and of seawater, it is believed that early forms of life developed in oceans or pools. With no evidence for widespread oxygen-producing photosynthesis before this time, and for cosmic

Oceanic origin of life

abundance reasons described above, the oxygen content of the Earth's atmosphere in Precambrian times was very likely less than today. Accordingly, in Precambrian times, solar ultraviolet radiation, especially near the wavelength of 2,600 Å, which is particularly destructive to nucleic acids, may have penetrated to the surface of the Earth, rather than being totally absorbed in the upper atmosphere by ozone as it is today. In the absence of ozone, the ultraviolet solar flux is so high that a lethal dose for most organisms would be delivered in less than an hour. Unless extraordinary defense mechanisms existed in Precambrian times, life near the Earth's surface would have been impossible. Sagan suggested that life at this time was generally restricted to some tens of metres and deeper in the oceans, at which depths all the ultraviolet light would have been absorbed, although visible light would still filter through. As the amount of atmospheric oxygen and ozone increased, due both to plant photosynthesis and to the photodissociation of water vapour and the escape to space of hydrogen from the upper atmosphere, life increasingly close to the Earth's surface would have been possible. It has been suggested that the colonization of the land, about 425,000,000 years ago, was possible only because enough ozone was then produced to shield the surface from ultraviolet light for the first time.

Life then had insinuated itself between the sun and the Earth. It diverted solar energy to its own uses and contrived more and more ways of exploiting more and more environments. Some experiments were faulty and the lines became extinct; others were more successful and the lines filled the Earth. Evolution through natural selection directed the proliferation of a growing array of life forms throughout the biosphere (see EVOLUTION; THE THEORY OF).

EXTRATERRESTRIAL LIFE

It is not known what aspects of living systems are necessary in the sense that living systems everywhere must have them; it is not known what aspects of living systems are contingent in the sense that they are the result of evolutionary accident, so that somewhere else a different sequence of events might have led to different characteristics. In this respect the possession of even a single example of extraterrestrial life, no matter how seemingly elementary in form or substance, would represent a fundamental revolution in biology. It is not known whether there is a vast array of biological themes and counterpoints in the universe, whether there are places that have fugues, compared with which our one tune is a bit thin and reedy. Or it may be that our tune is the only tune around. Accordingly the prospects for life on other planets must be considered in any general discussion of life.

The chemistry of extraterrestrial life. What are the methods and prospects for a search for life beyond the Earth? Each of the definitions of life described in *Definitions of life* (see above) implies a method of searching for life. Particular physiological functions, particular metabolic activities, such specific molecules as proteins and nucleic acids, self-replication and mutation, processes not in closed-system thermodynamic equilibrium—all these might be sought. All the search methods significantly depend upon chemistry.

Life on Earth is structurally based on carbon and utilizes water as an interaction medium. Hydrogen and nitrogen have significant accessory structural roles; phosphorus is important for energy storage and transport, sulfur for three-dimensional configuration of protein molecules, and so on. But must these particular atoms be the atoms of life everywhere, or might there be a wide range of atomic possibilities in extraterrestrial organisms? What are the general physical constraints on extraterrestrial life?

Prerequisites for life

In approaching these questions several criteria can be used. The major atoms should tend to have a high cosmic abundance. A structural molecule for making an organism at the temperature of the planet in question should not be extremely stable, because then no chemical reactions would be possible; but it should not be extremely unstable, because then the organism would fall to pieces. There should be some medium for molecular interaction. Solids are not appropriate because the diffusion times are very long. Such a medium is most likely a liquid (but could possibly be a very dense gas) that is stable in a number of respects. It should have a large temperature range (for a liquid, the temperature difference between freezing point and boiling point should be large). The liquid should be difficult to vaporize and to freeze; in fact, it should be very difficult to change its temperature at all. In addition it should be an excellent solvent. There should also be some gas on the planet in question that could be used in various biologically mediated cycles, as CO_2 is in the carbon cycle on Earth.

The planet, therefore, should have an atmosphere and some near-surface liquid, although not necessarily an ocean. If the intensity of ultraviolet light or charged particles from the sun is intense at the planetary surface, there must be some place, perhaps below the surface, that is shielded from this radiation but that nevertheless permits useful chemical reactions to occur. Since after a certain period of evolution, lives of unabashed heterotrophy lead to malnutrition and death, autotrophs must exist. Chemoautotrophs are, of course, a possibility but the inorganic reactions that they drive usually require a great deal of energy; at some stage in the cycle, this energy must probably be provided by sunlight. Photoautotrophs, therefore, seem required. Organisms that live very far subsurface will be in the dark, making photoautotrophy impossible. Organisms that live slightly subsurface, however, may avoid ultraviolet and charged particle radiation and at the same time acquire sufficient amounts of visible light for photosynthesis.

Thermodynamically, photosynthesis is possible because the plant and the radiation it receives are not in thermodynamic equilibrium; for example, on the Earth a green plant may have a temperature of about 300 K while the sun has a temperature of about 6,000 K. (K = Kelvin temperature scale, in which 0 K is absolute zero; 273 K, the freezing point of water; and 373 K, the boiling point of water at one atmosphere pressure.) Photosynthetic processes are possible in this case because energy is transported from a hotter to a cooler object. Were the source of radiation at the same (or at a colder) temperature as the plant, however, photosynthesis would be impossible. For this reason the idea of a subterranean plant photosynthesizing with the thermal infrared radiation emitted by its surroundings is untenable, as is the idea that a cold star, with a surface temperature similar to that of the Earth, would harbour photosynthetic organisms.

Chemical requirements

It is possible to approach some of the foregoing chemical requirements and see just which atoms are implied. When atoms enter into chemical combination, the energy necessary to separate them is called the bond energy, a measure of how tightly the two atoms are bound to each other. Table 2 gives the bond energies of a number of chemical bonds, mostly involving abundant atoms. The energies are in electron volts (eV; $1 \text{ eV} = 1.6 \times 10^{-12}$ ergs). The symbols are as follows: H, hydrogen; C, carbon; N, nitrogen; O, oxygen; S, sulfur; F, fluorine; Si, silicon; Bi, bismuth (very underabundant, biologically uninteresting, and present only as an illustration of the relatively weak chemical bonds in some metals). Bond energies generally vary between 10 eV and about 0.03 eV; double and triple

Table 2: Energies of Representative Chemical Bonds

(Hydrogen bonds 0.08–0.45 eV; van der Waals bonds 0.04 eV)

bond	energy (eV)	bond	energy (eV)
N≡N	9.8	Si—O	3.8
C≡N	9.4	C—O	3.7
C≡C	8.4	C—C	3.6
C—O	7.4	S—H	3.5
C=C	6.4	Si—H	3.1
H—F	5.4	C—N	3.0
O—H	4.8	Si—Si	1.8
N=N	4.4	N—N	1.7
C—H	4.3	Bi—Bi	1.1
N—H	4.1	O_2N—NO_2	0.57

bonds where two or three electrons are shared between two atoms tend to be more energetic than single bonds, single bonds more energetic than hydrogen bonds where a hydrogen atom is shared between two other atoms, and hydrogen bonds more energetic than the very weak (van der Waals) forces that arise from the attraction of the electrons of one atom for the nucleus of another. At room temperature, atoms, free or bound, move with an average kinetic energy corresponding to about 0.02 eV. Some of the atoms have greater energies, some lesser. At any temperature a few will have energies greater than any given bond energy; hence bonds occasionally will break. The higher the temperature, the more atoms there are moving with sufficient energy to spontaneously break a given bond.

Suppose it is decided arbitrarily (although the decision will not critically affect the conclusions) that for life to exist at any time the fraction of bonds broken by random thermal motions must be no larger than 0.0001 percent. It then turns out that any hypothetical life where the structural bonds are based upon van der Waals forces can only exist where the temperature is below 40 K, for hydrogen bonds below about 400 K, for bonds of 2 eV below 2,000 K, and for bonds of 5 eV below 5,000 K. Now, 2,000 to 5,000 K are typical surface temperatures of stars; 400 K is somewhat above the highest surface temperature found on Earth; and 40 K is about the cloud-top temperature of distant Neptune. Thus, over the entire range of temperatures, from cold stars to cold planets, there seem to exist chemical bonds of appropriate structural stability for life, and it would appear premature to exclude the possibility of life on any planet on grounds of temperature.

Life on Earth lies within a rather narrow range of temperature. Above the normal boiling point of water, much loss of configurational structure or three-dimensional geometry occurs. At these temperatures proteins become denatured, in part because above the boiling point of water the hydrogen bonding and van der Waals forces between water and the protein disappear. Also, similar bonds within the protein molecule tend to break down. Proteins then change their shapes, their ability to participate in lock-and-key enzymatic reactions is gravely compromised, and the organism dies. Similar structural changes, some of them connected with the stacking forces between adjacent nucleotide bases, occur in the heating of nucleic acids. But it is significant that these changes are not fragmentations of the relevant molecules but rather changes in the ways they fold. There appears to be no reason that configurational bonds should not have been evolved that are stable at higher temperatures than terrestrial organisms experience. On planets hotter than the Earth there seems to be no reason that slightly more stable configurational forces should not be operative in the local biochemistry.

Molecular factors

While the bonds that characterize life on Earth are too weak at high temperatures, they are too strong at low temperatures, tending to slow down the rates of chemical reactions generally. There are less stable bonds (*e.g.,* hydrogen bonds, silicon-silicon bonds, and nitrogen-nitrogen bonds), however, that might play structural roles at significantly lower temperatures. At higher temperatures, multiple bonds (*e.g.,* in aromatic, or ring-shaped, hydrocarbons) might be utilized for life. There clearly is a rich variety of little-studied chemical reactions that proceed at reasonable rates either at much lower or at much higher temperatures than those on Earth.

Except for bismuth and fluorine, all the atoms in Table 2 have relatively high cosmic abundances. At terrestrial temperatures, carbon is the unique atom for biological structure. Not only does it have high abundance but it forms a staggering variety of compounds of great stability, it lends itself to compounds that are configured by weaker bonds, and it enters into multiple bonds. These double- and triple-bonded molecules, among other useful properties, absorb long-wavelength ultraviolet light, a process leading to the synthesis of a variety of more complex molecules. A photon of ultraviolet light at a wavelength of 2,000 Å has an energy of 6.2 eV, capable of breaking many bonds, and permitting more complex reactions among the resulting molecular fragments. Photons of blue light have energies of about 3 eV, and of red light about 2 eV.

Silicon compounds do not form double bonds. Silicon-oxygen bonds are slightly more stable than carbon-carbon bonds, but they tend to produce molecules like the silicates, which are crystals of the same unit repeated over and over again, rather than molecules with aperiodic side chains with potential information content. On low-temperature planets, silicon-silicon bonds are more promising than carbon bonds in terms of reaction times, but they do not form double bonds and the carbon abundance is likely to be greater. Nevertheless, silicon compounds may be of limited biological importance both on high-temperature and low-temperature worlds.

Hydrogen bonding confers on liquids the stability properties necessary for life. There seem to be very few reasonable candidates for liquid interaction media. By all odds water is the most suitable. The other candidates, all to some extent hydrogen bonded, are ammonia, hydrogen fluoride, hydrogen cyanide, and mixtures of liquid hydrocarbons. Hydrogen fluoride can be excluded because it is too scarce cosmically. The hydrocarbons are not good solvents of salts, but life elsewhere may not be based on the same acid-base chemistry as life on Earth. The liquid range of water is larger than commonly thought, ranging from about 210 K in saturated salt solutions to 647 K at enormous atmospheric pressures. Water is the biological liquid medium of choice above 200 K, particularly in view of its extremely high cosmic abundance. At lower temperatures ammonia or hydrogen cyanide could serve as a liquid medium.

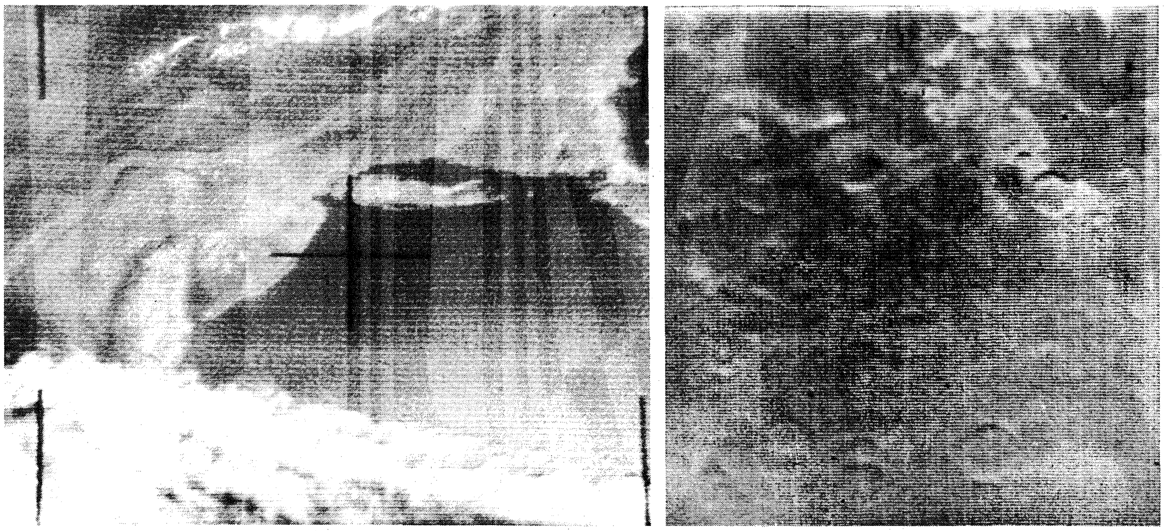
There are functional roles for specific atoms in biology, but except for considerations of structure and a liquid interaction medium they do not seem fundamental. For example, the energy-rich phosphate bonds in ATP are in fact of relatively low energy; they are about as energetic as the hydrogen bonds (see Table 2). The cell must store up large numbers of these bonds to drive a molecular degradation or synthesis. On high-temperature worlds the energy currency may be much more energetic per bond, and on low-temperature worlds much less energetic per bond.

It may be concluded that, in our present state of ignorance, it is premature to exclude life on grounds of temperature on any other planet, particularly when account is taken of the temperature heterogeneity of the other planets. But life does require an interaction medium, an atmosphere, and some protection from ultraviolet light and from charged particles of solar origin.

The conclusion that for the Earth, carbon-based aqueous life is the most appropriate may be slightly suspect, since terrestrial life is manifestly carbon-based and aqueous. In 1913 a U.S. biochemist, L.J. Henderson, published *The Fitness of the Environment* in which the biological advantages of carbon and water were stressed for the first time in terms of comparative chemistry. He was struck by the fact that those very atoms that are needed are just those atoms that are around; it remains a remarkable fact that atoms most useful for life do have very high cosmic abundances.

Exobiology

The search for extraterrestrial life. Exobiology, a term coined by a U.S. biologist, J. Lederberg, for the study of extraterrestrial life, has been called a science without a subject matter. It is certainly true that, as yet, no strong evidence for life beyond the Earth has been adduced. Exobiology, however, has deep significance even if extraterrestrial life is never found. The mere design of exobiological experiments forces man to examine critically the generality of his assumptions about life on Earth. In addition, a lifeless neighbouring planet presents a very interesting quandary: How is it that life has originated and evolved on Earth, but not on the planet in question? There is an entire spectrum of possibilities. A given planet may be lifeless and have no vestiges of primitive organic matter and no fossils of extinct life. It may be lifeless but may have either organic chemical or fossil relics. It may possess life of a simple sort or life of a quite complex biochemistry, physiology, and behaviour. It may possess intelligent life and a technical civilization. Establishment of any one of these five possibilities would be of fundamental biological importance.



(Left) Eastern seaboard of the United States photographed by a TIROS weather satellite; Cape Cod (right), Long Island (centre), and Delaware Bay (centre left) can be seen. (Right) Surface of Mars photographed by Mariner 4 spacecraft. Both photographs at one-kilometre resolution. No sign of life, intelligent or otherwise, can be discerned on either planet.

By courtesy of National Aeronautics and Space Administration

The difficulties and opportunities inherent in exobiological exploration, in determining which of these five possibilities applies to a given planet, is most clearly grasped by imagining the situation reversed, with man on some neighbouring planet, say Mars, examining the Earth for life with the full armoury of contemporary scientific instrumentation and knowledge. First a distinction must be made between remote and *in situ* testing. In remote testing light of any wavelength reflected from or emitted by the target planet can be examined, but with *in situ* studies samples of the planet must be acquired by visiting them or by sending instruments that land on the planet, perform experiments, and radio back their findings. Since biological exploration involves the detailed characterization of any life found, rather than its mere detection, *in situ* experiments are necessary.

Sensing methods

The bulk of the remote sensing methods are directed toward finding some thermodynamic disequilibrium on the planet. This may be a chemical disequilibrium, a mechanical disequilibrium, or a spectral disequilibrium. For example, it would be quite easy to determine spectroscopically from Mars that the Earth's atmosphere contains large amounts of molecular oxygen and about one part per million (10^6) of methane. It would also be possible to calculate that, at thermodynamic equilibrium, the abundance of methane should be less than one part in 10^{35}. This huge discrepancy implies the existence of some process continuously generating methane on the Earth so rapidly that methane increases to a very large steady-state abundance before it can be oxidized by oxygen. Now such a methane-production mechanism need not be biological. It is conceivable that relatively stable aromatic hydrocarbons were produced abiologically in the early history of the Earth and that their slow thermal degradation leads to a continuous loss of methane from the planetary subsurface. But this and similar nonbiological explanations of the observed disequilibrium are unlikely. From Mars this thermodynamic discrepancy would be considered not as proof of life on Earth but as a significant hint of life on Earth. In fact the methane abundance on the Earth is produced by bacteria that, in the course of the reduction of a more oxidized form of carbon, release methane. Some methane bacteria live in swamps (hence, the term marsh gas for methane), and others—a significant fraction—live in the intestinal tracts of cows and other ruminants. The methane abundance over India is probably larger than over most other areas of the world, and if an extraterrestrial observer knew how to interpret the methane disequilibrium accurately (which is unlikely) it would be possible for him to deduce cows on Earth by spectrochemical analysis. The existence of relatively large quantities of methane in the presence of an excess of oxygen would remain a tantalizing but enigmatic hint of life on Earth. Similarly, the large amount of oxygen might itself be a sign of life if one could reliably exclude the possibility that the photodissociation of water and the escape to space of hydrogen were the source of oxygen. Also such relatively complex reduced organic molecules as terpenes, a hydrocarbon given off by plants, might conceivably be detected spectroscopically, perhaps by a spectrometer in orbit about the Earth. Not only would the chemical disequilibrium of terpenes in an excess of oxygen be suggestive of life, but equally suggestive would be the fact that terpenes are much more abundant over forested areas than over deserts.

Photographic observation

Photographic observations of the daytime Earth from Mars would give equivocal results. Even with a resolution of 100 metres (that is, an ability to discriminate fine detail at high contrast only if its components are more than 100 metres apart), it would be extremely difficult to discern cities, canals, bridges, the Great Wall of China, highways, and other large-scale accoutrements of the Earth's technical civilization. In satellite photographs with 100-metres (one metre = 1.0936 yards) resolution only about one in a thousand random photographs of the Earth yields features even suggestive of life. As the ground resolution is progressively improved, it becomes increasingly easy to make out the regular geometrical patterns of cultivated fields, highways, airports, and so on. But these are only the products of a civilization recently developed on Earth, and even photographs of the Earth with a ground resolution of 10 metres, but taken 100,000 years ago, would still have shown no clear sign of life. The lights of the largest cities might be just marginally detectable from Mars at night. Seasonal changes in the colour or darkness of plants would be detectable from Mars, but such cycles might easily have nonbiological explanations.

To detect individual animals a ground resolution of a few metres is required, and even here a low sun and long shadows are generally necessary. This detection could be accomplished with a large telescope in Earth orbit. It would then be possible to determine, for example, that objects with the general shape of cows are frequent on the Earth. But suppose that members of the civilization examining the Earth thus remotely are not even approximately quadrupedal and do not immediately associate the shape of cows with life. They would nevertheless be able to deduce life. They would observe that certain locales on Earth have a quantity of raised lumps connected to the ground by four stilts. It would be possible to calculate that wind and water erosion would cause the lumps to topple to the ground in geologically short periods of time. Such stilted lumps are mechanically unstable; they are not in equilibrium; if pushed hard, they fall. Accordingly, there must be a process for generating stilted lumps on the Earth, and in short periods of time. It would be very difficult to avoid the implication that this generation process is biological.

Radio emission

A third detection technique arises upon scanning the radio spectrum of the Earth. Because of domestic television transmission, the high-frequency end of the AM broadcast band, and the radar defense networks of the United States and of the Soviet Union, the amount or energy put out by the Earth to space at certain radio frequencies is enormous. At some frequencies, if this radiation were interpreted as ordinary thermal emission, the temperature of the Earth would have to be hundreds of millions of degrees, according to an estimate made by a Soviet astrophysicist, I.S. Shklovskii. Moreover, it would be possible to determine that this radio "brightness temperature" of the Earth had been steadily increasing with time over the last several decades. Finally, it would be possible to analyze the frequency and time variation of these signals and deduce that they were not purely random noise.

Now imagine *in situ* studies by vehicles that enter the Earth's atmosphere and land at some predetermined locale. There are many places on the Earth (the ocean surface, the Gobi Desert, Antarctica) where large organisms are infrequent and a life-detection attempt based solely on television searches for large life forms would be a risky investment. On the other hand, if such an experiment were successful (the camera records a dolphin cavorting, a camel chewing its cud, a penguin waddling) it would provide quite convincing evidence of life.

Although the oceans, the Gobi Desert, and Antarctica are relatively devoid of large life forms, they are in many places replete with minute life forms. Therefore, microorganism detectors would be a good investment. A television camera coupled to a microscope (optical or electron) would be a promising life detector if the sample acquisition problem could be solved: the early Dutch microscopist Antonie van Leeuwenhoek had no difficulty at all in identifying as alive the little "animalcules" that he found in a drop of water, although nothing similar had previously been seen in human history.

In addition to morphological criteria for the detection of microorganisms, there are metabolic and chemical criteria. For example, a sample of terrestrial soil, or seawater, say, might be acquired and introduced into a chamber containing food the investigators guess the earthlings might find tasty. Such food might be an abundant product of prebiological organic synthetic experiments. It could then be determined whether any characteristic molecules, such as carbon dioxide or ethanol, are produced metabolically, or whether the medium containing food and terrestrial sample changes its acidity or becomes cloudy because of the growth of micro-organisms, or it might be investigated whether there is heat given off in the chamber containing sample and food. Alternatively, photosynthesis could be tested by measuring the fixation of some gas, say carbon dioxide, as a function of illumination provided artificially to the sample by the instrument. Along chemical lines a direct test of terrestrial soil or seawater for optical activity might be made. Organic molecules could certainly be searched for with a combined gas chromatograph and mass spectrometer, or by a remote analytic chemistry laboratory. The detection of any organic matter would of course be interesting and relevant, whether or not it was biological in origin. Such criteria as have been used in the analysis of Precambrian sediments (described in *The antiquity of life,* above) might be used to test for biological origin.

Ambiguities of tests for life

It is remarkable, however, that many of these tests are ambiguous. It would be possible, for example, for the Martian investigator to guess wrong about what terrestrial organisms eat and to make incorrect assumptions about their structural chemistry or their interaction medium. If forms of regular geometry that do not move were detected microscopically, there might be serious questions of biological versus mineralogical origin. Chemical criteria (such as the expectation that if odd-numbered carbon chains are more prominent than even-numbered carbon chains, then life is detected) might not be valid unless it was certain which processes actually occurred in the prebiological organic chemistry of the planet in question. In addition, there might be the galling problem of contamination. The Martians' spacecraft might carry living organisms from their own planet and report them as detected on the planet Earth. For this reason great care would have to be taken that spacecraft were rigorously sterilized.

In fact, many of these problems have already arisen in an analysis of a variety of meteorite called carbonaceous chondrites. These meteorites, which fall on Earth probably from the asteroid belt, contain about 1 percent organic matter by mass, far too much to be largely the result of terrestrial contamination. The most abundant organic molecules, however, are not clearly of biological origin, and some of the biologically more interesting molecules may be contaminants. Reports of optical activity have been contested and might alternatively be due to contamination. Geometrically interesting microscopic inclusions have been detected in these bodies. The most abundant inclusions, however, are probably mineralogical in origin, while the most highly structured and lifelike are very rare and, at least in some cases, are obviously due to contamination (in one case by ragweed pollen). Finally, claims have been made of the extraction of viable microorganisms from the interiors of carbonaceous chondrites. These meteorites are porous, however, and "breathe" air in and out during their entry into the atmosphere. There also have been significant opportunities for their contamination after arrival on the Earth. Moreover, one of the organisms extracted was a facultative aerobe. Since, as yet, no planet in the solar system besides the Earth is known to contain significant quantities of molecular oxygen, it seems quite curious that the complex electron transfer apparatus required for oxygen metabolism would be evolved out on the asteroid belt in expectation of ultimate arrival on the Earth. Here, again, contamination has proved a serious hazard. The large amounts of organic matter found in carbonaceous chondrites, however, suggest that the production of organic molecules occurred with very great efficiency in the early history of the solar system.

From such a hypothetical exercise as the instrumental detection of life on Earth by an extraterrestrial observer, and from the actual experience acquired in the analysis of carbonaceous chondrites, the following conclusions can be drawn: There is no single and unambiguous "life detector." There are instruments of great generality that make few ambiguous assumptions about the nature of extraterrestrial organisms, particularly their chemistry. These systems, however, require a fair degree of luck (an animal must walk by during the operating lifetime of the instrument), or they require the solution of difficult instrumental problems (such as the acquisition and preparation of samples for remote microscopic examination). Other instruments, such as metabolism detectors, have great sensitivity and are directed at the more abundant microorganisms. They are quite specific, however, and are critically dependent upon certain assumptions (for example, that extraterrestrial organisms eat sugars) that are no better than informed guesses. Therefore, an array of instruments, both very general and very specific, seems required. Stringent sterilization of such spacecraft appears necessary, both to avoid confusion of the life-detection experiments, and to prevent interaction of contaminants with the indigenous ecology. Many of the instruments and strategies discussed in the preceding paragraphs continue to be adapted by the United States and the Soviet Union in attempts to search for life on the Moon and the nearby planets (see EXPLORATION: *Space exploration*).

Biological prospects of the Moon

An exobiological survey of the solar system. A brief survey of the physical environments and biological prospects of the moons and planets of the solar system, so far as is known, follows. The Moon's surface seems inhospitable to life of any sort. The diurnal temperatures range from about 100 to about 400 K. In the absence of any significant atmosphere or magnetic field, ultraviolet light and charged particles from the Sun penetrate unimpeded to the lunar surface, delivering in less than an hour a dose lethal to the most radiation-resistant microorganism known. For other reasons already mentioned, the absence of an atmosphere and of any liquid medium on the surface also argues against life. The subsurface environment of the Moon is not nearly so inclement. About a metre or so subsurface there is no penetration of ultraviolet light or solar protons, and the temperature is maintained at a relatively constant value about 230 K. Even there, however, the absence of an atmosphere and the probable absence of abundant liquids make the biological prospects rather dim.

It is not out of the question, however, that prebiological organic matter, produced in the early history of the Moon, might be found sequestered beneath the lunar surface. Such organic matter may have been produced either in an original lunar atmosphere that has subsequently been lost to space, or in a secondary lunar atmosphere produced by release of gases after the formation of the Moon, and also subsequently lost to space. The depth at which such organic matter may be found depends upon the unknown history of the early lunar atmosphere, if any, and upon whether the Moon has, on the whole, gained or lost matter due to meteoritic impact. An apparent gaseous emission near the lunar crater Alphonsus was recorded in 1958 and a spectral identification was made of the molecule C_2, a likely organic fragment, but this identification subsequently has been disputed.

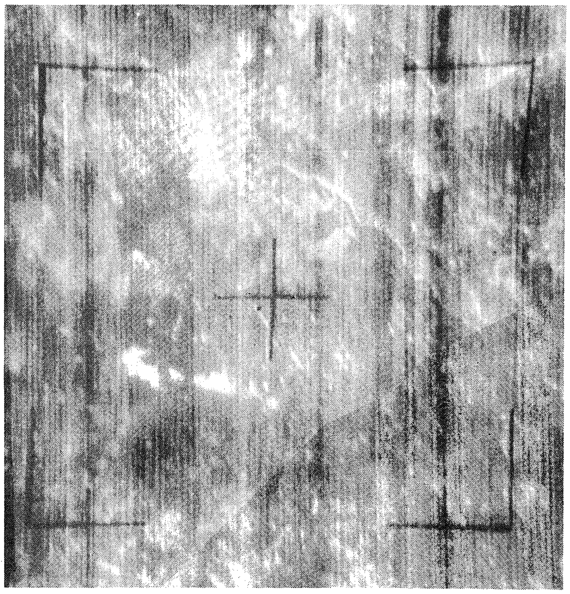
Because of contamination by unmanned spacecraft, the lunar surface had accumulated a microbial load estimated by the late 1960s at some 100,000,000 microorganisms. Since such organisms will be immediately killed unless shielded from radiation, and since the likelihood of their growth seems remote, such contamination may not be a serious problem in subsequent microbial analysis of returned lunar samples. A much more serious contamination problem occurs during the acquisition of such samples by astronauts. Samples obtained during the historic Apollo 11 Moon landing in July 1969 were tested for possible organic molecules, but results were inconclusive. Such a finding might shed significant light on the early history of organic molecules in the solar system.

The environment of Mercury is rather like that of the Moon. Its surface temperatures range from about 100 to about 620 K, but about a metre subsurface the temperature is constant, very roughly at comfortable room temperature on Earth. But the absence of any significant atmosphere, the unlikelihood of bodies of liquid, and the intense solar radiation make life unlikely.

Speculations about life on Mars

Direct evidence for life on Mars has been claimed for many decades. The first such argument was posed by a French astronomer, E.L. Trouvelot, in 1884: "Judging from the changes that I have seen to occur from year to year in these spots, one could believe that these changing grayish areas are due to Martian vegetation undergoing seasonal changes." The seasonal changes on Mars have been reliably observed, not only visually but also photometrically. There is a conspicuous springtime increase in the contrast between the bright and dark areas of Mars. Accompanying colour changes have been reported, but their reality has been disputed. While such changes have been attributed to the growth of vegetation, seasonally variable dust storms are an equally convincing possibility.

The most famous case, historically, for life on Mars is the discovery of the "canals," a set of apparent thin straight lines that cross the Martian bright areas and extend for hundreds and sometimes thousands of kilometres. They change seasonally as do the Martian dark areas. These lines, first systematically observed by an Italian astronomer, G.V. Schiaparelli, in 1877, were further cataloged and popularized by a U.S. astronomer, Percival Lowell, around the turn of the century. Lowell argued from the unerring straightness of the lines that they could not be of geological origin but must instead be the artificial constructs of a race of intelligent Martians. He suggested that they might be channels carrying water from the melting polar caps to the parched equatorial cities of Mars. While considerable skepticism has been expressed about these straight lines, there is no doubt that approximately rectilinear features do exist on the Martian surface. More probable explanations, however, include crater chains, terrain contour boundaries, faults, mountain chains, and ridges analogous to the suboceanic ridge systems that are features of the Earth.



Photograph, from a TIROS weather satellite, of a region near Cochrane, Ontario. The crisscross pattern in white (top left) shows logging swaths, a sign of intelligent life on Earth.

By courtesy of National Aeronautics and Space Administration

In July and August 1976, two U.S. probes bearing equipment designed to detect the presence or remains of organic material made successful landings on Mars. Analyses of atmospheric and soil samples met with procedural difficulties and yielded initially ambiguous and inconclusive results, although the data were later generally interpreted as negative, at least for the vicinity of the probe.

Features of Venus

According to both ground-based and space-borne observations, the average surface temperatures of Venus are around 750 K. It does not seem likely, either at the poles or on the tops of the highest Venus mountains, that the surface temperature will be below 400 K, and noontime temperatures are probably significantly hotter than 700 K. Thus, quite apart from the other surface conditions, the temperatures on Venus seem too hot for terrestrial life. It is still not possible to exclude a Venus surface life with a rather different chemistry, although hydrogen bonding would be much less suitable for the geometrical configuration of polymers on Venus than it is on Earth. The clouds of Venus, however, are another matter. There, carbon dioxide, sunlight, and (according to the results of the Venera space vehicles) water are to be found. These are the prerequisites for photosynthesis. Some molecular nitrogen also is expected at the cloud level, and some supply of minerals can be expected from dust convectively raised from the surface. The cloud pressures are about the same as on the surface of the Earth, and the temperatures in the lower clouds also are quite Earthlike. Despite the fact that there is little oxygen, the lower clouds of Venus are the most Earthlike extraterrestrial environment known. While there are no recorded cases of organisms on Earth that lead a completely airborne existence throughout their life cycle, it is not impossible that such organisms could exist in the vicinity of the Venus clouds, perhaps buoyed, as is a fish by its swim bladder, to avoid downdrafts carrying them to the hotter lower atmosphere.

A similar speculation can be entertained with regard to the lower clouds of Jupiter. On Jupiter the atmosphere is composed of hydrogen, helium, methane, ammonia, and probably neon and water vapour. But these are exactly those gases used in primitive-Earth simulation experiments directed toward the origin of life. Laboratory and computer experiments have been performed on the application of energy to simulated Jovian atmospheres. In addition to the immediate gas-phase products, such as hydrogen cyanide and acetylene, more complex organic molecules, including aromatic hydrocarbons, are formed in lower yield. The visible clouds of Jupiter are vividly coloured, and it is possible that their hue is attributable to such coloured organic compounds. There is also an apparent absorption feature near 2,600 Å, in the ultraviolet spectrum of Jupiter, which has been attributed both to aromatic hydrocarbons and to nucleotide bases. In any event it is likely that organic molecules are being produced in significant yield on Jupiter; it is possible that Jupiter is a vast planetary laboratory that has been operating for 5,000,000,000 years on prebiological organic chemistry.

Satellites and comets of the solar system

The other Jovian planets, Saturn, Uranus, and Neptune, are similar in many respects to Jupiter, although much less is known about them. Their cloud-top temperatures progressively decrease with distance from the Sun. In the case of Saturn, microwave studies have indicated that the atmospheric temperature increases with depth below the clouds; similar situations are expected on Jupiter, Uranus, and Neptune. Thus, it is by no means clear that the low temperatures of the upper clouds of the Jovian planets apply to the lower clouds, or to the underlying atmosphere. The environment of Pluto is almost completely unknown. In addition to these planets, the solar system contains 32 natural satellites, some of which, such as Titan, a satellite of Saturn, and Io, a satellite of Jupiter, appear to have atmospheres. There are also tens of thousands of comets, which, judging from their spectra, contain organic molecules, as well as some thousands of asteroids and asteroidal fragments revolving about the Sun between the orbits of Mars and Jupiter. These are the presumed sources of the carbonaceous chondrites, which contain organic matter.

In short, there is a wide range of environments of biological interest within the solar system. There is no direct evidence for extraterrestrial life on these planets, but, on the other hand, there is no strong evidence against life on many of these worlds. Beyond this is the near certainty that biologically interesting organic molecules will be found throughout the solar system.

Intelligent life beyond the solar system. For thousands of years man has wondered whether he is alone in the universe or whether there might be other worlds populated by creatures more or less like himself. The common view, both in early times and through the Middle Ages, was that the Earth was the only "world" in the universe. Nevertheless, many mythologies populated the sky with divine beings, certainly a kind of extraterrestrial life. Many early philosophers held that life was not unique to the Earth. Metrodorus, an Epicurean philosopher in the 3rd and 4th centuries BC, argued that "to consider the Earth the only populated world in infinite space is as absurd as to assert that in an entire field sown with millet, only one grain will grow." Since the Renaissance there have been several fluctuations in the fashion of belief. In the late 18th century, for example, practically all informed opinion held that each of the planets was populated by more or less intelligent beings; in the early 20th century, by contrast, the prevailing informed opinion (except for the Lowellians) held that the chances for extraterrestrial intelligent life were insignificant. In fact the subject of intelligent extraterrestrial life is for many people a touchstone of their beliefs and desires, some individuals very urgently wanting there to be extraterrestrial intelligence, and others wanting equally fervently for there to be no such life. For this reason it is important to approach the subject in as unbiased a frame of mind as possible. A respectable modern scientific examination of extraterrestrial intelligence is no older than the 1950s. The probability of advanced technical civilizations in our galaxy depends on many controversial issues.

The Green Bank formula

A simple way of approaching the problem, which illuminates the parameters and uncertainties involved, has been devised by a U.S. astrophysicist, F.D. Drake. The number N of extant technical civilizations in the galaxy can be expressed by the following equation (the so-called Green Bank formula):

$$N = R_* f_p n_e f_l f_i f_c L$$

where R_* is the average rate of star formation over the lifetime of the galaxy; f_p is the fraction of stars with planetary systems; n_e is the mean number of planets per star that are ecologically suitable for the origin and evolution of life; f_l is the fraction of such planets on which life in fact arises; f_i is the fraction of such planets on which intelligent life evolves; f_c is the fraction of such planets on which a technical civilization develops; and L is the mean lifetime of a technical civilization. What follows is a brief consideration of the factors involved in choosing numerical values for each of these parameters, and an indication of some currently popular choices. In several cases these estimates are no better than informed guesses and no very great reliability should be pretended for them.

There are about 2×10^{11} stars in the galaxy. The age of the galaxy is about 10^{10} years. A value of $R_* = 10$ stars per year is probably fairly reliable. While most contemporary theories of star formation imply that the origin of planets is a usual accompaniment of the origin of stars, such theories are not well enough developed to merit much confidence. Through the painstaking measurement of slight gravitational perturbations in the proper motions of stars, it has been found that about half of the very nearest stars have dark companions with masses ranging from about the mass of Jupiter to about 30 times the mass of Jupiter. The nearest of these dark companions orbit Barnard's star, which is only six light-years from the sun and is the second nearest star system. The most direct indication that planetary formation is a general process throughout the universe is the existence of satellite systems of the major planets of our own solar system. Jupiter, with 16 satellites, Saturn with 20 or more, and Uranus with five each closely resemble miniature solar systems. It is not known what the distribution of distances of planets from their central star are in other solar systems and whether they tend to vary systematically with the luminosity of the parent star. But considering the wide range of temperatures that seem to be compatible with life, it can be tentatively concluded that $f_p n_e$ is about one.

Likelihood of origin of life

Because of the apparent rapidity of the origin of life on Earth, as implied by the fossil record, and because of the ease with which relevant organic molecules are produced in primitive-Earth simulation experiments, the likelihood of the origin of life over a period of billions of years seems high, and some scientists believe that the appropriate value of f_l is also about one. For the quantities of f_i and f_c the parameters are even more uncertain. The vagaries of the evolutionary path leading to the mammals, and the unlikelihood of such a path ever being repeated has already been mentioned. On the other hand, intelligence need not necessarily be restricted to the same evolutionary path that occurred on the Earth; intelligence clearly has great selective advantage, both for predators and for prey.

Similar arguments can be made for the adaptive value of technical civilizations. Intelligence and technical civilization, however, are clearly not the same thing. For example, dolphins appear to be very intelligent, but the lack of manipulative organs on their bodies has apparently limited their technological advance. Both intelligence and technical civilization have evolved about halfway through the relevant lifetime of the Earth and Sun. Some, but by no means all, evolutionary biologists would conclude that the product $f_i f_c$ taken as 10^{-2} is a fairly conservative estimate.

Still more uncertain is the value of the final parameter, L, the lifetime of a technical civilization. Here, fortunately for man, but unfortunate for the discussion, there is not even one example. Contemporary world events do not provide a very convincing counterargument to the contention that technical civilizations tend, through the use of weapons of mass destruction, to destroy themselves shortly after they come into being. If we define a technical civilization as one capable of interstellar radio communication, our technical civilization is only a few decades old. If then L is about 10 years, multiplication of all of the factors assumed above leads to the conclusion that there is in the second half of the 20th century only about one technical civilization in the galaxy—our own. But if technical civilizations tend to control the use of such weapons and avoid self-annihilation, then the lifetimes of technical civilizations may be very long, comparable to geological or stellar evolutionary time scales; the number of technical civilizations in the galaxy would then be immense. If it is believed that about 1 percent of developing civilizations make peace with themselves in this way, then there are about 1,000,000 technical civilizations extant in the galaxy. If they are randomly distributed in space, the distance from the Earth to the nearest such civilization will be several hundred light-years. These conclusions are, of course, very uncertain.

Communications with extraterrestrial civilizations

How is it possible to enter into communication with another technical civilization? Independent of the value of *L*, the above formulation implies that there is about one technical civilization arising every decade in the galaxy. Accordingly, it will be extraordinarily unlikely for man soon to find a technical civilization as backward as his. From the rate of technical advance that has occurred on the Earth in the last few hundred years, it seems clear that man is in no position to project what future scientific and technical advances will be made even on Earth in the next few hundred years. Very advanced civilizations will have techniques and sciences totally unknown to 20th-century man. Nevertheless man already has a technique capable of communication over large interstellar distances. This technique, already encountered in the discussion of life on Earth, is radio transmission. Imagine that we employ the largest radio telescope available on Earth, the 1,000-foot-diameter dish of Cornell University, the Arecibo Observatory in Puerto Rico, and existing receivers, and that the identical equipment is employed on some transmitting planet. How distant could the transmitting and receiving planets be for intelligible signals to be transmitted and received? The answer is a rather astonishing 1,000 light-years. Within a volume centred on the Earth, with a radius of 1,000 light-years, there are over 10,000,000 stars.

There would of course be problems in establishing such radio communication. The choices of frequency, of target star, of time constant, and of the character of the message would all have to be selected by the transmitting planet so that the receiving planet would, without too much effort, be able to deduce the choices. But none of these problems seem insuperable. It has been suggested that there are certain natural radio frequencies (such as the 1,420-megacycle line of neutral hydrogen) that might be tuned to; the first choice might be to listen to stars of approximately solar spectral type; in the absence of a common language there nevertheless are messages whose intelligent origin and intellectual content could be made very clear without making many anthropocentric assumptions.

Because of the expectation that the Earth is relatively very backward, it does not make very much sense to transmit messages to hypothetical planets of other stars. But it may very well make sense to listen for radio transmissions from planets of other stars. Project Ozma, a very brief program of this sort, oriented to two nearby stars, Epsilon Eridani and Tau Ceti, was organized in 1960 by Drake. On the basis of the Green Bank formula, it would be very unlikely that success would greet an effort aimed at two stars only 12 light-years away, and Project Ozma was unsuccessful. It remains, however, the first pioneering attempt at interstellar communication. Related programs were organized on a larger scale and with great enthusiasm in the 1960s in the U.S.S.R., where a state scientific commission devoted to such an effort was organized. Other communication techniques including laser transmission and interstellar spaceflight have been discussed seriously and may not be infeasible, but if the measure of effectiveness is the amount of information communicated per unit cost, then radio is the method of choice.

The search for extraterrestrial intelligence is an extraordinary pursuit, in part because of the enormous significance of possible success, but in part because of the unity it brings to a wide range of disciplines: studies of the origins of stars, planets, and life; of the evolution of intelligence and of technical civilizations; and of the political problem of avoiding man's self-annihilation. But at least one point is clear. In the words of Loren Eiseley (also from *The Immense Journey*),

> Lights come and go in the night sky. Men, troubled at last by the things they build, may toss in their sleep and dream bad dreams, or lie awake while the meteors whisper greenly overhead. But nowhere in all space or on a thousand worlds will there be men to share our loneliness. There may be wisdom; there may be power; somewhere across space great instruments, handled by strange, manipulative organs, may stare vainly at our floating cloud wrack, their owners yearning as we yearn. Nevertheless, in the nature of life and in principles of evolution we have had our answer. Of men [as are known on earth] elsewhere, and beyond, there will be none forever.
