A brief treatment of photoreception follows. For full treatment, *see* MACROPAEDIA: Sensory Reception.

In plants the primary photoreceptive response is photosynthesis, the conversion of carbon dioxide and water to the essential nutritive elements of all life, using the energy of the Sun. A secondary consequence of photoreception in plants and in many animals is the indirect determination of growth and reproductive patterns by annual cyclic fluctuations in the availability of sunlight. Most frequently, however, the term photoreception is used in reference to the mechanism by which animals receive sensory data transmitted by light of different qualities and wavelengths, only some of which are perceptible by humans.

The apparatus for the reception of light may involve an entire organism, as in many single-celled animals, or may range in specialization and complexity from the simple eyespots, or light-receptors, distributed over the surface of some animals, to the intricate structure of the mammalian eye. The operation of most eyes relies on the chemical response of a light-sensitive pigment that begins a chain of nerve responses. The camera-like apparatus of vertebrate eyes uses a lens and an external layer of transparent membrane, the cornea, to focus and project an inverted image onto the retina, a lining within the eye structure. The size of the lens and its distance from the photosensitive retina are fixed in a ratio that provides the optimal balance between light-gathering and image-focussing capacities for each organism, according to its habits and its environment. In nocturnal animals such as the opossum, for instance, a wide lens relatively near the retina allows for a high light-gathering ability, but results in poor resolution. The amount of light entering the eye is also determined by the diameter of the pupil, the central channel through which light enters, which is controlled by the musculature of the surrounding iris, the coloured portion of the eye. In humans, because the pupil retains its circular shape, its range of expansion and contraction is limited, while in some nocturnal species such as cats the pupil contracts into a slit that can block nearly all light.

Image reception in the vertebrate retina is controlled by two types of photoreceptor cells: the longer rod cells are responsive to light under relatively dark conditions (scotopic reception), and cone cells are responsible for colour perception and for vision under brighter conditions (phototopic reception). The two types are found together on the retinas of animals that are active both day and night. Animals that function nocturnally have retinas composed mostly of rods. Diurnal vertebrates focus light on the fovea, a retinal depression containing only cones. The photoreception of both rods and cones is controlled by an outer sheath of disks known as lamellae. The optic structure of cephalopods, such as the octopus, is essentially the same as in vertebrates, though the retina is differently organized.

The most rudimentary optical apparatus is the eyespot, found in many unicellular animals and some primitive worms. Its basic structure in multicellular animals consists of an internal pocket coated with photosensitive pigment, known as a rhabdomere. A more sophisticated form of eye is the ocellus, found in mollusks and arthropods, which, like the eye of the vertebrates, inverts the image it focusses on a photosensitive membrane.

Certain worms and arthropods make use of compound eyes, which consist of a number of visual structures known as ommatidia that are densely set together. These take a rectangular or octagonal shape, and contain components analogous to those of the more complex, camera-like vertebrate eye. Each one is capable of receiving light independently, and they are sometimes separated by a thin film of pigment, as in the appositional eye of the honeybee, or by cilia that divide the rhabdomeres of different cells.

Photoreceptor cells absorb light through a layer of pigment and convert it into a stimulus directed toward the nervous system. In many photoreceptors small, hairlike projections, cilia, help in the internal and intercellular transport of essential substances. This is the case with mitochondria, minute structures that produce the adenosine triphosphate needed for photoreception. The function of the cilia is performed in vertebrate rod and cone cells by the surrounding lamellae. In rod cells old lamellae are replaced by new ones throughout the life of the cell, while in cone cells disks are renewed through the replacement of exhausted tissue materials. Photoreceptor cells in vertebrates are connected by means of a neural projection known as a foot piece, to the retina, which is itself an extension of the brain. The photoreceptors of invertebrates are linked to nerves or nerve ganglia within the eye through thin fibres called axons.

The pigment responsible for nerve excitation in both vertebrates and invertebrates consists of the chemical compound chromophore, which absorbs light, and a protein complex known as opsin. Though the chromophore contained in all visual pigments is virtually identical, variations in the range of wavelength reception by different pigments are the result of differences in the structures of animal proteins. In the conversion of light reception to nervous responses by photoreceptor cells, stimulation by light results in changes in the electrochemical equilibrium of cell membranes, which in turn produce nervous stimuli.

photorecovery, restoration to the normal state, by the action of visible light, of the deoxyribonucleic acid composing the hereditary material in animal skin cells and plant epidermal cells damaged by exposure to ultraviolet light. The phenomenon is also called photoreactivation, especially in microorganisms. The failure of cells to repair such damage, in individuals with certain biochemical disorders, leads to serious skin problems.

photosensitization, the process of initiating a reaction through the use of a substance capable of absorbing light and transferring the energy to the desired reactants. The technique is commonly employed in photochemical work, particularly for reactions requiring light sources of certain wavelengths that are not readily available. A commonly used sensitizer is mercury, which absorbs radiation at 1849 and 2537 angstroms; these are the wavelengths of light produced in high-intensity mercury lamps. Also used as sensitizers are cadmium; some of the noble gases, particularly xenon; zinc; benzophenone; and a large number of organic dyes.

In a typical photosensitized reaction, as in the photodecomposition of ethylene to acetylene and hydrogen, a mixture of mercury vapour and ethylene is irradiated with a mercury lamp. The mercury atoms absorb the light energy, there being a suitable electronic transition in the atom that corresponds to the energy of the incident light. In colliding with ethylene molecules, the mercury atoms transfer the energy and are in turn deactivated to their initial energy state. The excited ethylene molecules subsequently undergo decomposition. Another mode of photosensitization observed in many reactions involves direct participation of the sensitizer in the reaction itself.

photosphere, visible surface of the Sun, about 400 kilometres (250 miles) thick, from which is emitted most of the Sun's light that reaches the Earth directly. Light generated deeper in the Sun cannot get out without absorption and re-emission. Temperatures in the Sun's photosphere range from about 10,000 K (18,000° F) at the bottom to 4,400 K (8,000° F) at the top; density is about 1/1,000 that of air at the surface of the Earth. Sunspots are photospheric phenomena.

Large-scale photographic images of the photosphere show it to have a granular structure. Each grain or cell is a mass of hot gas several hundred kilometres in diameter; each rises from inside the Sun, radiates energy, and sinks back within a few minutes to be replaced by others in a constantly changing pattern, shown particularly well in time-lapse motion pictures of the Sun.

photosynthesis, the process by which green plants and certain other organisms transform light energy into chemical energy. Photosynthesis in green plants harnesses the energy of sunlight to convert carbon dioxide, water, and minerals into organic compounds and gaseous oxygen.

A brief treatment of photosynthesis follows. For full treatment, *see* MACROPAEDIA: Photosynthesis.

In addition to the green plants, photosynthetic organisms include certain protists (such as euglenoids and diatoms), cyanophytes (blue-green algae), and various bacteria. The process in photosynthetic protists and cyanophytes resembles that in green plants; it differs in the photosynthetic bacteria in that compounds other than water serve as a reactant and oxygen is not produced. All photosynthetic organisms—with the exception of a minor group of bacteria, the halobacteria—contain the light-absorbing pigment chlorophyll, which plays a key role in the transfer of energy from light to chemical compounds.

Photosynthesis is the fundamental process that maintains life on Earth. Living cells convert food into energy and structural components. Almost all organisms derive this food, directly or indirectly, from the organic compounds formed within plants during photosynthesis. The stored energy in these compounds is essential for growth, repair, reproduction, movement, and other vital functions. Without photosynthesis, not only would replenishment of the fundamental food supply halt but the Earth would eventually become devoid of oxygen.

Just as the organic molecules in the bodies of living organisms contain energy converted by photosynthesis from the energy of the Sun, so do the molecules of fossil fuels. The energy provided by coal, oil, and gas comes from photosynthesis carried on by plants of earlier times and preserved down through the ages, to be released by combustion in modern industrial processes. Most of the energy released both by the burning of fossil fuels and by the metabolism of living cells is given off as heat and must be replaced by the continued input of radiant energy from the Sun.

The principal organic products of plant photosynthesis are carbohydrates. Formation of the simple carbohydrate glucose is shown by the equation

$$\underset{\text{carbon dioxide}}{6CO_2} + \underset{\text{water}}{12H_2O} \xrightarrow[\text{green plants}]{\text{light}} \underset{\text{glucose}}{C_6H_{12}O_6} + \underset{\text{oxygen}}{6O_2} + \underset{\text{water}}{6H_2O}$$

The molecules of glucose produced are usually linked with other molecules to form more complex carbohydrates. Other products of photosynthesis are formed by incorporating mineral elements into the process. The energy required to break the chemical bonds in the reactants and to create new bonds in the products is provided by light. The excess energy not used up in the chemical reactions is stored as chemical energy in the organic products formed.

The rate of photosynthesis is dependent on the following environmental factors: light intensity, temperature, and the availability of carbon dioxide, water, and certain minerals. A shortage of any one of these factors can limit the rate of photosynthesis, and an increase in the particular rate-limiting factor will, up to a point, speed up the process. The rate also varies with the plant species and its physiological state.

Photosynthesis is not a single process but consists of a number of photochemical and enzymatic reactions. In green plants, the intricate apparatus required for such complex processes is located in the chloroplasts, the cell organelles that contain the chlorophyll. The chloroplasts are crowded with multiple layers of membranes, the lamellae, composed of proteins and lipids. The protein matter includes some of the enzymes and coenzymes used in the photosynthetic process; the lipid portion contains two types of chlorophyll, along with other pigments that assist in absorbing light energy.

The unique feature of photosynthesis consists in the coupling of enzymatic reactions to photochemical systems that can trap electrons set free by the impact of light. In essence, photosynthesis is an oxidation–reduction reaction between carbon dioxide and water, in which carbon dioxide is reduced and water oxidized when hydrogen atoms are transferred from the water to the carbon dioxide; light is the energy source that impels the reaction. Subreactions that form part of this complex process include photolysis (splitting by light) of water, photophosphorylation, and carbon dioxide fixation.

The reactions of photosynthesis include a photochemical, or light-dependent, stage and an enzymatic, or dark, stage that involves enzymatic reactions. During the light stage the chlorophyll absorbs light energy, which excites some electrons in the pigment molecules to higher energy levels. These high-energy electrons leave the chlorophyll and are transferred along through a series of molecules, called electron carriers, that can gain electrons (reduction) or lose them (oxidation). During the tandem operation of two different systems of light reactions, electrons are split off from water by photolysis, thus oxidizing it; oxygen gas is released; energy is stored in the compound ATP (adenosine triphosphate) by photophosphorylation and the coenzyme $NADP^+$ (nicotine adenine dinucleotide phosphate) is reduced to NADPH.

During the carbon-reduction cycle, occurring in the dark stage of photosynthesis, carbon dioxide is fixed, reduced, and used to synthesize carbohydrates and other organic compounds. The cycle involves formation of intermediate compounds called sugar phosphates. The compound RuBP (ribulose-l,5-bisphosphate) combines with the carbon dioxide to form PGA (phosphoglycerate). The carbon is then reduced by further enzymatic reactions involving the energy contained in the ATP and NADPH that were formed during the light reactions. The sugars produced by these reactions are used to synthesize higher carbohydrates, proteins, and fats—the plant foodstuffs that are the end products of photosynthesis. Regulatory enzymes control the rate at which the various steps in the photosynthetic process take place.

The manner in which plants convert light energy into chemical energy began to be understood somewhat in the 19th century. Investigation of the mechanism of photosynthesis is still going on, aided by the use of radioactive isotopes and fluorescence techniques and by the study of photosynthetic bacteria and algae.

phototransmutation: *see* photodisintegration.

phototube: *see* photoelectric cell.

phototypesetting: *see* photocomposition.

photovoltaic effect, process in which two dissimilar materials in close contact act as an electric cell when struck by light or other radiant energy.

Light striking such crystals as silicon or germanium, in which electrons are usually not free to move from atom to atom within the crystal, provides the energy needed to free some electrons from their bound condition. Free electrons cross the junction between two dissimilar crystals more easily in one direction than in the other, giving one side of the junction a negative charge and, therefore, a negative voltage with respect to the other side, just as one electrode of a battery has a negative voltage with respect to the other. The photovoltaic battery can continue to provide voltage and current as long as light continues to fall on the two materials. This current can be used to measure the brightness of the incident light or as a source of power in an electrical circuit, as in the modern solar battery.

A solar battery is a combination of many individual photovoltaic cells. One composed of two different types of silicon crystals, when exposed to sunlight outside the Earth's atmosphere, can capture 14 percent of the incident energy and supply 170 watts per square metre (16 watts per square foot) of the contact area between the two materials. *See also* photoelectric effect.

Phra (Egyptian god): *see* Re.

Phra Nakhon, also spelled PHRA NAKHORN or PHRA NAKORN, section of Bangkok Metropolis, Thailand's capital and largest city, on the east bank of the Mae Nam (river) Chao Phraya. It was a *changwat* (province) until 1972, when it was merged with Thon Buri, west of the river, to form the enlarged province of Krung Thep Mahanakhon (*q.v.;* Bangkok Metropolis).

Phra Naret (Siamese king): *see* Naresuan.

Phraates, Persian FARHĀD, name of Parthian kings, grouped below chronologically and indicated by the symbol •.

• **Phraates II** (d. 128 BC), king of Parthia (reigned *c.* 138–128 BC), the son and successor of Mithradates I.

Phraates was attacked in 130 by the Seleucid Antiochus VII Sidetes, who after initial successes was defeated and killed during 129 in Media. With his defeat, Seleucid dominion over the countries east of the Euphrates River was finally ended. During these wars two powerful nomadic tribes, the Śakas and the Tochari, had forced their way into eastern Persia. Phraates advanced against them, pressing into service Greek prisoners from the army of Antiochus; but when the Greeks deserted him in battle, Phraates was defeated and slain. He was succeeded by his uncle Artabanus II.

Consult the INDEX *first*

• **Phraates III** (d. *c.* 57 BC), king of Parthia (reigned 70–58/57 BC), the son and successor of Sanatruces (Sinatruces).

On Phraates' accession, the Roman general Lucullus was preparing to attack King Tigranes I of Armenia, who had wrested several vassal states from the Parthian kingdom. Phraates refused to help Tigranes fight the Romans; instead he made an alliance with the Roman general Pompey and invaded Armenia (66 BC). Pompey at first abandoned Mesopotamia to Phraates but later reversed his stand and occupied the Parthian vassal states of Gordyene and Osroëne. Before Phraates could take any action, he was murdered by his two sons, Orodes II and Mithradates III.

• **Phraates IV** (d. 2 BC), king of Parthia (reigned *c.* 37–2 BC) who murdered his father, Orodes II, and his brothers to secure the throne.

In 36 the Romans under Mark Antony attacked Parthia, penetrating through Armenia into Media Atropatene. Phraates, however,

Phraates IV, coin, 1st century

defeated Antony, who retreated with heavy losses. In 34 Phraates' vassal king in Media made an alliance with Antony; but when Antony later withdrew, the Parthians reoccupied Media. A revolt soon broke out in Parthia, and Tiridates II of Armenia drove Phraates from the throne, forcing him to take refuge with the Śaka nomads. In 30, however, Phraates was able to regain power, and Tiridates fled to the Romans with the son of Phraates as a hostage.

The emperor Augustus made peace with Phraates and returned his son. Armenia and Osroëne were recognized as Roman dependencies. Augustus also sent Phraates an Italian concubine named Musa. On her advice, Phraates sent four of his sons to Rome, where they remained as hostages of Augustus. Phraates was later poisoned by Musa, who then ruled jointly with her son Phraates V.

• **Phraates V** (d. *c.* AD 4), king of Parthia (reigned *c.* 2 BC–*c.* AD 4), the son and successor of Phraates IV.

Phraates' mother, Musa, secured the throne for him by murdering his father. The two were later married (AD 2) and ruled jointly. Under Phraates, war with Rome threatened to break out over the control of Armenia. When the Roman emperor Augustus sent his adopted son Gaius Caesar to invade Parthia, the Parthians preferred to conclude a treaty (AD 1), by which Armenia was recognized as being in the Roman sphere. Together with his mother, Phraates was later slain or driven into Syria.

Phrachomklao (Siamese king): *see* Mongkut.

Phrachunlachomklao (Siamese king): *see* Chulalongkorn.

Phrae, town in the mountainous northern region of Thailand. It is located on the Yom River and the Sukhothai-Nan road in a historic region with many temples and ruins. Teak lumbering is a major activity, and tobacco and rice are grown extensively around the town. Phrae has an airport with scheduled flights. Pop. (1986 est.) town, 20,180.

Phramongkutklao (Siamese king): *see* Vajiravudh.

Phranangklao (Siamese king): *see* Rama III.

Phraortes, Iranian FRAVARTISH, also called KHSHATHRITA, Assyrian KASHTARITI (d. 653 BC), king of Media from 675 to 653 BC. Phraortes, who was known by that name as a result of the writings of the 5th-century-BC Greek historian Herodotus, was originally a village chief of Kar Kashi, but he later subjugated the Persians and a number of other Asian peoples, eventually forming an anti-Assyrian coalition of Medes and Cimmerians. In his attack on Assyria, however, he was defeated and killed in battle.

Another Phraortes was a usurper who reigned for a short time in Media during a rebellion against the Achaemenian king Darius I in 522 BC. Darius' rock inscription at Bīsitūn relates that "a man of the name of Fravartish [*i.e.,* Phraortes], a Mede, rebelled in Media and spoke to the people thus 'I am Khshathrita, of the family of Uvakhshtra [Cyaxares].' " After a short reign this king was defeated and executed at Ecbatana, the Median capital. The deception of the usurper Phraortes may have led to Herodotus' mistake about the name of the earlier king.

Phraphutthaloetla Naphalai (Siamese king): *see* Rama II.

Phraphutthayotfa Chulalok (Siamese king): *see* Rama I.

Phrapokklao (Siamese king): *see* Prajadhipok.

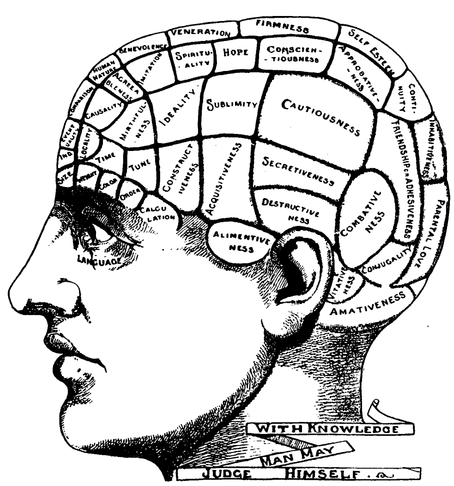
phratry, in anthropology, cluster of sibs, clans, or kinship groups that have grouped together, either because they share a belief in a common ancestor or because, even though the sibs or clans are not actually related by blood, they have adopted common ceremonial and kinship practices. The term phratry also must refer to three or more groups constituting a tribal society. (With only two such groupings, the society takes on features of dual organization, and the groups are termed moieties.)

A description of the phratry in relation to sib and moiety is useful. A sib is a group of unilineal descent groups, either matrilineal or patrilineal, whose members claim a common ancestor. (Some anthropologists, particularly in Europe, use the word clan instead of sib.) The next order of magnitude in social groupings above the lineage and the sib is the phratry, a group of sibs banded together for common practical or ceremonial purpose or because of kinship claims. Finally comes the moiety, one of two exhaustive divisions of a society, each moiety containing a number of sibs and possibly of phratries. If three or more phratries are not further distributed into moieties, however, relationships between members of different phratries will not take on the characteristics of dual organization, which appear only when a society is divided into two moieties. *See also* dual organization; clan.

Phraya Taksin (Siamese king): *see* Taksin.

phrenology, the study of the conformation of the skull as indicative of mental faculties and traits of character, especially according to the hypotheses of Franz-Joseph Gall (1758–1828), a Viennese doctor, and such 19th-century adherents as Johann Kaspar Spurzheim (1776–1832) and George Combe (1788–1858). Phrenology enjoyed great popular appeal well into the 20th century but was wholly discredited by scientific research.

The principles upon which phrenology was based were five: (1) the brain is the organ of the mind; (2) human mental powers can be



Phrenological diagram, 1893

BBC Hulton Picture Library

analyzed into a definite number of independent faculties; (3) these faculties are innate, and each has its seat in a definite region of the surface of the brain; (4) the size of each such region is the measure of the degree to which the faculty seated in it forms a constituent element in the character of the individual; (5) the correspondence between the outer surface of the skull and the contour of the brain-surface beneath is sufficiently close to enable the observer to recognize the relative sizes of these several organs by the examination of the outer surface of the head.

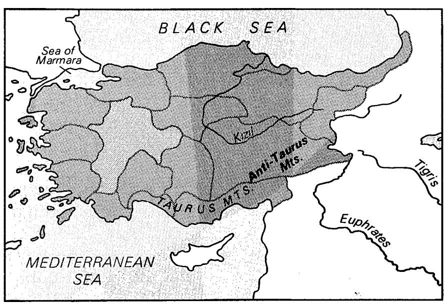
The system of Gall was constructed by a method of pure empiricism, and his so-called organs were identified on quite specious grounds. Having arbitrarily selected the place of a faculty, he examined the heads of his friends and casts of persons with that peculiarity in common, and in them he sought for the distinctive feature of their characteristic trait. Some of his earlier studies were made among inmates of jails and lunatic asylums, and some of the traits that he presumed to detect were "criminal." These he named after their excessive manifestations, mapping out organs of murder, theft, etc. However, the names were changed by Spurzheim to align with more moral and religious considerations. Gall marked out on his model of the head the places of 26 organs as round enclosures with vacant interspaces. Spurzheim and Combe divided the whole scalp into oblong and conterminous patches identified by such designations as amativeness, philoprogenitiveness, concentrativeness, adhesiveness, combativeness, destructiveness, secretiveness, acquisitiveness, constructiveness, self-esteem, love of approbation, cautiousness, benevolence, veneration, conscientiousness, firmness, hope, wonder, ideality, wit, imitativeness, individuality, form perception, size perception, weight perception, colour perception, locality perception, number perception, order perception, memory of things, time perception, tune perception, linguistic perception, comparative understanding, and metaphysical spirit.

Phrygia, ancient district in west-central Anatolia, named after a people the Greeks called Phryges, who dominated Asia Minor between the Hittite collapse (12th century BC) and the Lydian ascendancy (7th century BC). The Phrygians, perhaps of Thracian origin, settled in northwestern Anatolia late in the 2nd millennium. Upon the disintegration of the Hittite kingdom they moved into the central highlands, founding their capital at Gordium and an important religious centre at "Midas City" (modern Yazılıkaya).

Between the 12th and 9th century Phrygia formed the western part of a loose confederation of peoples (identified as "Mushki" in Assyrian records) that dominated the entire Anatolian peninsula. This early civilization borrowed heavily from the Hittites, whom they had replaced, and established a system of roads later utilized by the Persians. About 730 the Assyrians detached the eastern part of the confederation, and the locus of power shifted to Phrygia proper under the rule of the legendary king Midas.

Midas' kingdom came to an abrupt end (*c.* 700) with the invasions of the Cimmerians, a Transcaucasian people who burned Gordium and transferred the hegemony of western Anatolia to the Lydians. After the Cimmerian invasion Phrygia lingered as a geographical expression under the successive rulers of Anatolia; its people were valued as slaves by the Greeks. The Phrygians excelled in metalwork and wood carving and are said to have originated the art of embroidery. Phrygian carpets were famous. Some magnificently carved stone tombs and shrines were uncovered after World War II by American archaeologists. Among the various Phrygian religious practices, the cult of the Great Mother (Cybele) predominated and was passed on to the Greeks.

Little else is known of Phrygian society. Vast lands were owned by the great shrines such as Pessinus, as was the Oriental custom, the high priests being virtually autonomous rulers. Society was probably feudal. An intelligent and



The district of Phrygia under the Roman Empire

From W. Shepherd, *Historical Atlas*, Harper & Row, Publishers (Barnes & Noble Books), New York; revision copyright © 1964 by Barnes & Noble, Inc.

evidently cultivated elite (they were able to read and write) existed at Gordium and Midas City, together with an important nucleus of craftsmen and merchants, some doubtless being foreigners—Greeks, Phoenicians, Syrians, and Urartaeans.

A staple industry was sheep rearing, which provided a fine wool much in demand in Miletus, Pergamum, and other Greek centres of industry. The neighbourhood of Midas City harboured considerable forestland, and timber was clearly an important economic factor. Another specialty was horse rearing, the Phrygians probably being, like many of the Indo-Europeans, an equestrian aristocracy ruling over other native peoples.

Phrygian cap, soft felt or wool conical headdress fitting closely around the head and characterized by a pointed crown that curls forward. It originated in the ancient country

Youth wearing a Phrygian cap, marble, Roman copy of a Greek original, 4th century BC; in the Fitzwilliam Museum, Cambridge, Eng.

By permission of the Syndics of the Fitzwilliam Museum, Cambridge, Eng.

of Phrygia in Asia Minor and is represented in ancient Greek art as the type of headdress worn by Orientals. In Rome the Phrygian cap was worn by emancipated slaves as a symbol of their freedom. During the 11th and 12th centuries, it was again extensively used.

The Phrygian cap once more became the emblem of liberty in the 18th century during the French Revolution, when it was adopted by the Revolutionaries as "the red cap of liberty." It continues to be associated with the national allegorical figure of Liberté.

Phrygian language, ancient language spoken in north-central Asia Minor north and east of Lydia. Texts occur in two alphabets corresponding to two separate time periods: Old Phrygian texts in an early Greek alphabet, dating from about 730–450 BC, and New Phrygian texts (most of them sepulchral inscriptions) in the Greek alphabet from the 1st and 2nd centuries AD. Phrygian is believed by most scholars to be an Indo-European language somehow connected to Greek or Armenian. Some scholars believe it to be related to the Thracian language.

Phrygian mode, in music, third of the eight medieval church modes. *See* church mode.

Phryne (Greek: "Toad"), byname of MNESARETE (b. Thespiae, Boeotia; fl. 4th century BC), famous Greek courtesan; because of her sallow complexion she was called by the Greek name for "toad."

She was born in Boeotia but lived at Athens, where she earned so much by her beauty and wit that she offered to rebuild the walls of Thebes, on condition that the words "destroyed by Alexander, restored by Phryne the courtesan" were inscribed upon them. At a festival of Poseidon and also at the festival at Eleusis she walked into the sea naked with her hair loose, suggesting to the painter Apelles his great picture of "Aphrodite Anadyomene" ("Aphrodite Rising From the Sea"), for which Phryne sat as model. She was also (according to Athenaeus) the model for the statue of the Cnidian Aphrodite by Praxiteles, whose mistress she was; copies of the statue survive in the Vatican and elsewhere. When accused of blasphemy (a capital charge), she was defended by the orator Hyperides. When it seemed as if the verdict would be unfavourable, he tore her dress and displayed her bosom, which so moved the jury that they acquitted her; another version has Phryne tear her own dress and plead with each individual juror.

Phrynichus (fl. *c.* 500 BC, Athens), Athenian tragic poet, an older contemporary of Aeschylus; he was the earliest tragedian of whose work some conception can be formed.

Phrynichus' first victory probably occurred in about 510, and he was probably the first to introduce the female mask, *i.e.,* women characters, into his plays. After the fall of Miletus in 494 he produced the *Capture of Miletus,* which so harrowed Athenian feelings that he was fined; in 476 his *Phoenissae,* in which news of the battle of Salamis comes to the Persian court, proved a more acceptable subject and won the first prize.

Phrynichus (fl. *c.* 420 BC), Athenian poet of the Old Comedy.

A contemporary of Aristophanes, Phrynichus began producing in 430 and won two victories in the Great Dionysia. His most clearly recognizable subjects show an odd parallelism with Aristophanes: his *Monotropos* ("The Solitary"), which rejected contemporary civilization, was placed third when Aristophanes' *Birds* was second in 414, and Phrynichus' *Muses* second to Aristophanes' *Frogs* in 405.

Phrynichus ARABIUS (fl. 2nd century AD, Bithynia), grammarian and rhetorician who produced *Sophistike Paraskeue* ("A Grounding in Sophistic"), of which a few fragments and a summary by Photius survive, and an *Attikistes,* extant in an abridged form, called the *Ekloge* ("Selected Atticisms"). He is critical not only of contemporary deviations from the best Old Attic usage but also of what he considers the lapses of his Attic models themselves. In spite of some mistaken pedantry his judgments are often acute and learned and provide a useful commentary on the language of his own day.

Phthah (Egyptian religion): *see* Ptah.

phthalic acid, also called 1,2-BENZENEDICARBOXYLIC ACID, colourless, crystalline organic compound ordinarily produced and sold in the form of its anhydride. The annual production of phthalic anhydride exceeded 1,000,000 metric tons in the late 20th century; most of it was used as an ingredient of polyesters, including alkyd resins (vehicles for paints and enamels), and simple esters used as plasticizers for polyvinyl chloride and other polymers. Smaller quantities were consumed in the manufacture of anthraquinone (a dye intermediate), phenolphthalein (a laxative and acid-base indicator), and phthalocyanine pigments.

Phu Cuong (Vietnam): *see* Thu Dau Mot.

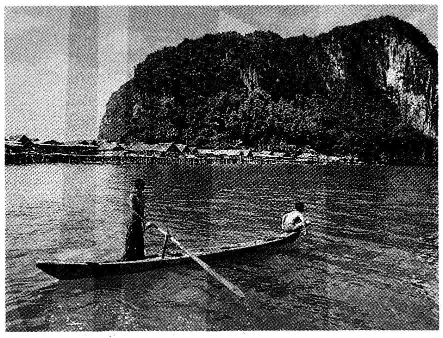
Phu Quoc Island, Vietnamese DAO PHU QUOC, island in the Gulf of Thailand, belonging to Vietnam. Lying 7 miles (11 km) off the Kampuchean (Cambodian) coast south of Bok Koŭ (formerly Bokor) and 43 miles (69 km) west of the west coast of southern Vietnam, the partially forested island is almost 30 miles (48 km) long from north to south and has a maximum width of 17 miles (27 km). It has an area of 230 square miles (596 square km). The climate is tropical monsoonal year-round with a short two- to three-month drier winter season. The eastern half has elevations ranging from about 2,000 feet (600 m) in the north to about 1,200 feet in the south. The western half and the southern tip are considerably lower.

The island's economic activities include the mining of jet (a dense, black mineral, a variety of coal) and anthracite, lumbering, and the production of pepper, cocoa, coffee, betel, and coconuts. Following World War I the

French imported 3,000 colonists from Tonkin (northern Vietnam) in an unsuccessful scheme to establish plantations. Fishing is important, and *nuoc mam* (a fish-sauce condiment), copra, and tortoise shells are exported. A garrison and a harbour have been built on the island. Duong Dong, in the west, is the chief town, and at An Thoi, on the southern tip, there is an airport. South of the island lie the associated Anthoi Islands, which have iron-ore deposits.

Phuket, city and island, southern Thailand. The island is located in the Andaman Sea, off the west coast of peninsular Thailand. Phuket city, located in the southeastern portion of the island, is a major port and commercial centre on the Andaman Sea. Its harbour exports tin, rubber, charcoal, lumber, and fish products south to Malaysia and Singapore and north to Myanmar (Burma). Rice and manufactures are imported. The city airport has regular flights to Bangkok, towns of southern Thailand, and Penang, Malaysia.

The island's area of 210 square miles (543 square km) is mostly level land but is dotted with isolated hills that reach a height of 1,700 feet (520 m). It was settled as early as the 1st century BC. The island was part of various Thai states from an early time and was incorporated into the Ayutthaya kingdom about the 16th century. After the 18th century, large



Children boating off the island of Phuket, Thailand

numbers of Chinese arrived; and more than half the population is now Chinese. Called Ujong Salang ("Cape Salang") by Malays, the island has also been known as Tongka, Junk Ceylon, and Jonsalam.

Phuket is noted for its rich tin mines, which account for approximately one-third of Thailand's production. The ore, found in lowland gravels and on the shallow sea floor, is mined by river and ocean boat dredges and pumps.

The island has also become a major seaside resort. It is reached by ferry from the mainland to the north across a narrow strait. A road links the major settlements of Thalang, Phuket, and Ban Rawai. Pop. (1986 est.) city, 47,430; island, 150,295.

Phūlbani, town, central Orissa state, eastern India. The city, located about 22 miles (35 km) southwest of the Mahānadi River, is relatively modern, although small in size. Its industries produce milled rice, glassware, and woven cloth. Phūlbani is the site of a government science college affiliated with Berhampur University. Roads connect the city with Berhampur and Bolāngir towns. Pop. (1981) city, 18,326.

Phumiphon Adunlayadet (Thai king): *see* Bhumibol Adulyadej.

phur-bu (Tibetan: "peg," or "nail"), a ritual dagger used in the Tantric (esoteric) rites of Tibetan Buddhism to exorcise evil. The dagger has a three-sided blade and a hilt that terminates in the head of Hayagrīva (Tibetan: Rta-mgrin), the fierce protective deity identified by a horse's head in the headdress. Other symbols characteristically used to ornament

the *phur-bu* are the knots of immortality, head of a *makara* (crocodile-like creature), and entwined serpents.

Phuthaditjhaba, formerly WITSIESHOEK, town, capital of the territory designated by South Africa as the nonindependent black state of Qwaqwa, northeastern Orange Free State, South Africa, near the merger point of the Orange Free State-Lesotho borders. The inhabitants of the town are mostly southern Sotho resettled from other areas of South Africa in the 1970s and early 1980s. The few industrial establishments in the town include a furniture factory, a bakery, and plants producing clothing and knitted articles. The inhabitants mostly commute to towns outside the state such as Marrismith and Bethlehem for employment. Pop. (latest est.) 7,043.

Phya Tak (Siamese king): *see* Taksin.

phycology: *see* algology.

Phycomycetes, in general, any of the six classes of lower fungi, or algal fungi: Chytridiomycetes, Hyphochytridiomycetes, Plasmodiophoromycetes, Oomycetes, Zygomycetes, and Trichomycetes (*qq.v.*). The term had class rank in earlier classification systems.

Phyfe, Duncan, original name DUNCAN FIFE (b. 1768, near Loch Fannich, Ross and Cromarty, Scot.—d. Aug. 16, 1854, New York, N.Y., U.S.), Scottish-born American furniture designer, a leading exponent of the Neoclassical style, sometimes considered the greatest of all American cabinetmakers.

The Fife family went to the United States in 1784, settling in Albany, N.Y., where Duncan worked as an apprentice cabinetmaker and eventually opened his own shop. In 1792 he moved to New York City (changing the spelling of his name to Phyfe about 1793). Two years later he was listed as a cabinetmaker in the *New York Directory and Register*. From his first shop on Broad Street, he later moved to Fulton Street. In later years he employed more than 100 carvers and cabinetmakers. One of the first U.S. cabinetmakers to successfully use the factory method of manufacturing furniture, in 1837 he took two of his sons, Michael and James, into partnership as Duncan Phyfe and Sons. After the death of Michael (1840), the firm name was changed to Duncan Phyfe and Son. In 1847 the business was sold and Duncan retired.

Although Phyfe did not originate a new furniture style, he interpreted fashionable European styles in a manner so distinguished by grace and excellent proportions that he became a major spokesman for Neoclassicism in the United States. He produced America's most highly individual Neoclassical furniture, using a unique combination of motifs. About 1800 his workshop was executing delicate furniture in the Sheraton, Regency, and French Directoire styles; by 1825, as taste changed, his pieces transpired into the Empire style. His Sheraton chairs, tables, and sofas often had delicate, reeded legs; and his Empire pieces, massive claw feet. His furniture, with its low relief carvings in the manner of the great English Neoclassicist Robert Adam, was decorated with typical period ornaments—harps, lyres, acanthus leaves, bow knots, and lion masks—and generally was made of high-quality mahogany; often he executed suites for fashionable New Yorkers.

The patronage of John Jacob Astor, Anglo-American tycoon and philanthropist, helped make Phyfe's furniture popular. Phyfe was particularly popular in the South. At his death

Mahogany side chair designed by Phyfe, 1807; in The Henry Francis du Pont Winterthur Museum, Delaware
By courtesy of The Henry Francis du Pont Winterthur Museum, Delaware

his fortune was estimated to have been almost $500,000. Interest in Phyfe's furniture was revived in 1922 when the Metropolitan Museum of Art, New York City, organized a comprehensive exhibition of his work.

phyi-mchod, in Tibetan Buddhist ceremonies, the eight offerings of external worship, presented before the tranquil deities. They are basically the eight ways of honouring a distinguished guest—by offering water for drinking, water for washing, flowers, incense, lamps, perfume, food (the sacrificial cake *gtor-ma*), and the music of cymbals. In the regular, daily attendance on the deities, the offerings are often represented by small bowls filled with water, though special ceremonies and festivals require the full offerings.

The *phyi-mchod* are distinguished from the *nang-mchod* (*q.v.*), or offerings of internal worship, also called offerings of the five senses.

For honouring the wrathful Tantric deities, the presentations are six in number—a cemetery flower, incense of singed flesh, lamp burning human fat (or a substitute), scent of bile, blood (usually symbolized by red water), and human flesh (symbolically made from parched barley flour and butter realistically coloured and modeled).

phylactery, Hebrew TEFILLIN, also spelled TEPHILLIN, or TFILLIN, in Jewish religious practice, one of two small, black leather, cube-shaped cases containing Torah texts written on parchment, which, in accordance with Deuteronomy 6:8 (and similar statements in Deut. 11:18 and Exodus 13:9, 16), are to be

Worshipper putting on phylacteries
Irving Herzberg, Brooklyn, N.Y.

worn by male Jews of 13 years and older as reminders of God and the obligation to keep the Law during daily life. The name phylactery is derived from the Greek *phylaktērion*, meaning amulet. Such outward signs are common to many religions, and the ancient Hebrews are known to have worn amulets and signs. Phylacteries, however, have a purely religious significance.

According to rabbinic regulations, one of the phylacteries is worn on the left arm facing the heart and the other on the forehead at the morning service (except on the Sabbath and festivals) and at the afternoon service on the Ninth of Av.

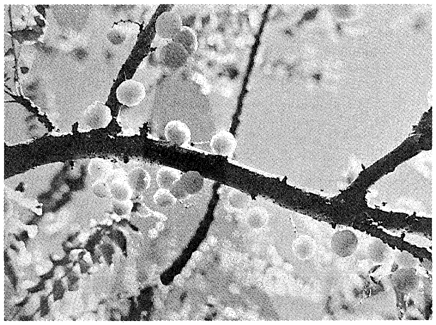
The *tefillin* are worn in a prescribed manner so as to represent the letters *shin*, *daleth*, and *yod*, which taken together form the divine name Shaddai. The hand phylactery (*tefillin shel yad*) has one compartment with the texts written on a single parchment; the head phylactery (*tefillin shel rosh*) has four compartments, each with one text. The extracts are Ex. 13:1–10, 11–16; Deut. 6:4–9, 11:13–21. Reform Jews interpret the biblical commandment in a figurative sense and, hence, do not wear phylacteries. Because of rabbinic indecision about the exact sequence of the four scriptural passages, very pious Jews may have two pairs of phylacteries.

phyle, plural PHYLAE, largest political subgroup of all Dorian and most Ionian Greek city-states in antiquity. Phylae were kinship groups embracing all citizens, corporations with their own officials and priests, and local units for administrative and military purposes. Sometimes the phylae of a state would be altered after a change in the form of government or makeup of the body of citizens. The original phylae of Athens were the Geleontes, Hopletes, Argadeis, and Aegicoreis (found sometimes in other Ionian states also).

At Athens the old phylae, which were dominated by the nobles and excluded a large number of new citizens, were supplanted by 10 new phylae in Cleisthenes' political reorganization (508/507 BC). They were, in their official order, Erechtheis, Aegeis, Pandionis, Leontis, Acamantis, Oeneis, Cecropis, Hippothontis, Aeantis, and Antiochis. Enrollment depended upon residence when the reform was instituted; thereafter membership was transmitted by descent. The governmental organs and personnel of the Athenian democracy were based on the phylae: the nine archons (magistrates) plus their secretary, the 10 *stratēgoi* ("generals"), and others were each chosen from a specific phyle; each of the 10 *prytaneis* (executive committees) of the Boule (council) of 500 represented a phyle; the 10 regiments of hoplites and 10 cavalry detachments were each drawn from a particular phyle. In dramatic competitions at festivals each phyle was represented by a *choros* and a *chorēgos* ("producer"). In the Hellenistic and Roman periods some new phylae were added to honour certain rulers; altogether their number usually did not exceed 12.

The original three Doric phylae at Sparta were supplanted by five local phylae (*c.* 8th century BC) from which the five ephors (magistrates) and the five *lochoi* (regiments) of the Spartan army were recruited.

Phyllanthus, genus of flowering plants, of the spurge family (Euphorbiaceae), that contains among its 650 species some of ornamental value and others with interesting botanical adaptations. Some have flattened, green stems, called phyllodes, that function as leaves. Whitish flowers cluster along the flattened stems of the West Indian seaside



Otaheite gooseberry (*Phyllanthus acidus*, or *Cicca disticha*)
W.H. Hodge

laurel (*P. arbuscula*). There are similar reddish blooms on *P. angustifolius*. Other species have deciduous twigs along which small leaves resembling leaflets alternate; the leaflets are shed along with the twig.

Species best showing this shedding adaptation are sometimes referred to two other genera, *Cicca* and *Emblica*, though many less known *Phyllanthus* species have the same adaptation. Otaheite gooseberry (*P. acidus, Cicca disticha*) is a small Indian tree bearing dangling clusters of light-yellow or green, vertically ribbed, acid-sour fruits, nearly 2 centimetres (0.8 inch) in diameter; the fruit is used for making preserves. The long, deciduous twigs are lined with rows of sharp-pointed, alternating leaves. Because of its even more feathery leaf-bearing twigs, each with about 100 tiny alternating leaves, the emblic, or myrobalan (*P. emblica*), gives the impression of a hemlock. Its acid-tasting yellow or reddish fruits are prescribed in traditional Indian medicine as a tonic. The leaves and bark contain tannin, utilized for tanning and as a colour concentrator in dyeing. The dried fruit has been used as ink, hair dye, and detergent. The delicately branched Polynesian shrub, snowbush (*Breynia nivosa*, formerly *P. nivosus*), is widely grown in the tropical gardens and as a greenhouse plant in the north for its gracefully slender branches and delicate green and white leaves (pink and red in *B. nivosa* variety *roseopicta*).

A list of the abbreviations used in the MICROPAEDIA *will be found at the end of this volume*

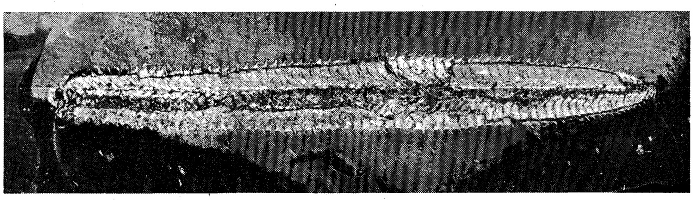
---

phyllite, fine-grained metamorphic rock formed by the reconstitution of fine-grained, parent sedimentary rocks, such as mudstones or shales. Phyllite has a marked fissility (a tendency to split into sheets or slabs) due to the parallel alignment of platy minerals; it may have a sheen on its surfaces due to tiny plates of micas. Its grain size is larger than that of slate but smaller than that of schist.

Phyllite is formed by relatively low-grade metamorphic conditions in the lower part of the greenschist facies. Parent rocks may be only partially reconstituted so that the original mineralogy and sedimentary bedding are partially preserved. Depending upon the direction of the stresses applied during metamorphism, phyllite sheets may parallel or crosscut the original bedding; in some rocks, two stages of deformation, called pre-crystalline and post-crystalline deformations, can be distinguished on the basis of two orientations of definable surfaces in the rock. Pre-crystalline surfaces have slaty cleavage, or flow cleavage, whereas post-crystalline surfaces have false, fracture, or strain-slip cleavage. Such terms can be used only when the type of deformation and its relation to time can be determined.

Phylloglossum, a plant genus of the order Lycopodiales (class Lycopsida), containing one species, *P. drummondii,* native to Australia and New Zealand. It is believed to be very old because of its high number of chromosomes. *Phylloglossum* has a bulblike underground base, a few spike-shaped, succulent leaves, and one stalk bearing a cluster of scale-like leaves bearing capsules. The plant is three to five centimetres (one to two inches) tall. It dies to the ground during the dry season and reappears with the return of the rains.

Phyllograptus, genus of graptolites, an extinct group of small colonial marine animals related to the primitive chordates, readily distinguished by its characteristic leaflike form and structure. Various species of *Phyllograptus* are excellent guide, or index, fossils for Ordovician rocks and time (the Ordovician Period began 500,000,000 years ago and lasted 70,000,000 years) and allow the correlation of sometimes widely separated rock units.



Phyllograptus

phyllosilicate, formerly called DISILICATE, compound with a structure in which silicate tetrahedrons (a central silicon atom surrounded by four oxygen atoms at the corners of a tetrahedron) are arranged in sheets. Examples are talc and mica. Three of the oxygen atoms of each tetrahedron are shared with other tetrahedrons, but no two tetrahedrons have more than one oxygen atom in common; each tetrahedron, therefore, is linked to three others. The silicon atoms are arranged at the corners of hexagons, and the unshared oxygen atoms are commonly oriented on the same side of the sheet. Because these are capable of forming chemical bonds with other metal atoms, the silicate sheets are interleaved with layers of other elements. The various layers are stacked to form a grouping with the unshared oxygen atoms toward the centre, and these groups are weakly held together; this gives the phyllosilicates their distinct cleavage parallel to the layers. Phyllosilicates have chemical formulas that contain silicon (Si) and oxygen (O) in some multiple of Si_2O_5.

Phyllostomatidae, family of about 130 species of tropical and subtropical bats known collectively as American leaf-nosed, or spear-nosed, bats. Phyllostomatid bats are native to the New World from the United States to Argentina and are found in habitats ranging from forests to deserts. Their features vary, but most species are broad-winged and have a simple, spear-shaped structure, the nose leaf, on the muzzle. Coloration of the fur ranges within and among the species from gray, pale brown, and dark brown to orange, red, yellow, or whitish; some forms, such as the tent-building, or yellow-eared, bat (*Uroderma bilobatum*), have striped faces. Phyllostomatid bats are 4.0–13.5 cm ($1\frac{1}{2}$–$5\frac{1}{3}$ inches) without the tail, which may be absent or to 5.5 cm ($2\frac{1}{6}$ inches) long. The largest member of the family is the tropical American false vampire bat (*Vampyrum spectrum*); it is 12.5–13.5 cm (5–$5\frac{1}{3}$ inches) long with a wingspan of 90 cm (35 inches) or more.

The diet of phyllostomatid bats varies. Many, such as the naked-backed bats (*Pteronotus*), are insect eaters; some larger forms are carnivorous. Many other species feed on fruit, nectar, or pollen; among these are the long-tongued and brown-flower bats, with specialized long snouts and tongues for feeding.

Phyllostomatid bats usually live in groups; some, such as the mustache bats (*Chilonycteris*), form colonies of tens of thousands. Roosting sites include caves, tree hollows, buildings, and the undersides of bridges. The tent-building bat and the small fruit-eating *Artibeus cinereus watsoni* are the only bats that create shelters; they roost on the undersides of palm leaves after biting across the leaves to make the ends hang downward.

phylogenetic tree, also called DENDROGRAM, a diagram showing the evolutionary interrelations of a group of organisms derived from a common ancestral form. The ancestor is in the tree "trunk"; organisms that have arisen from it are placed at the ends of tree "branches." The distance of one group from the other groups indicates the degree of relationship; *i.e.,* closely related groups are located on branches close to one another. Phylogenetic trees, although speculative, provide a convenient method for studying phylogenetic relationships.

phylogeny, the history of the evolution of a species or group, especially in reference to lines of descent and relationships among broad groups of organisms.

Fundamental to phylogeny is the proposition universally accepted in the scientific community that plants or animals of different species descended from common ancestors. The evidence for such relationships, however, is nearly always incomplete, for the diversification of life has been in progress for more than 3,000,000,000 years; and the vast majority of species that have ever lived have become extinct. Relatively few of their remains have been preserved. Most judgments of phylogenicity, then, are based on indirect evidence and cautious speculation. Even when biologists use the same evidence, they often hypothesize different phylogenies, though they do agree that life is the result of organic descent from earlier ancestors and that true phylogenies are discoverable, at least in principle.

Taxonomy, the science of classifying organisms, is based on phylogeny. Early taxonomic systems had no theoretical basis; organisms were grouped according to apparent similarity. Since the publication of Charles Darwin's *Origin of Species* in 1859, however, taxonomy has been based on the accepted propositions of evolutionary descent and relationship.

Biologists who postulate a phylogeny derive their most useful evidence from the fields of paleontology, comparative anatomy, comparative embryology, and biochemistry. Studies of the fine structure of cells and geographical distribution of flora and fauna are also useful. The fossil record is often used to determine the phylogeny of groups containing hard body parts; soft parts are generally not preserved.

Most of the data used in making phylogenetic judgments have come from comparative anatomy and from embryology. In comparing features common to different species, anatomists try to distinguish between homologies, or similarities inherited from a common ancestor, and analogies, or similarities that arise in response to similar habits and living conditions. Embryologists measure the affinity between species by tracing the similar development of their embryos.

Biochemical investigations carried out in the latter half of the 20th century have contributed valuable data to phylogenetic studies. By counting differences in the sequence of units that make up protein and deoxyribonucleic acid (DNA) molecules, researchers have devised a tool for measuring the degree to which different species have diverged since evolving from a common ancestor.

The earliest organisms were probably the result of a long chemical evolution, in which random reactions in the primeval seas and atmosphere produced amino acids and then proteins. It is supposed that droplets containing proteins then formed membranes by binding molecules to their surface, and these membrane-bound proteins are said to have become organisms when they developed the capacity to reproduce. It is not certain whether these earliest self-reproducing organisms were proteins, nucleic acid–protein associations, or free-living viruses. There is general agreement that they were heterotrophic organisms—*i.e.,* ones that absorbed nourishment in the form of organic matter from early seas. Later, autotrophic forms appeared, having the ability to make their own food from inorganic matter. These organisms were the earliest bacteria; they could store energy as food and release energy as needed through respiration.

Blue-green algae, or cyanophytes, are thought to have been the next evolutionary step, as shown in Figure 1. They had larger bodies of cytoplasm than did bacteria and formed large colonies. Using photosynthesis, these single-celled organisms were pigmented with chlorophyll.

After the blue-green algae there appeared an extensive array of algae, molds, protozoans, and higher plants and animals. Three groups of algae can be dismissed with passing mention, as they arose from uncertain ancestors and have given rise to no further groups. These groups are the chrysophytes (yellow-green and golden-brown algae, chiefly diatoms); the pyrrophytes (cryptomonads and dinoflagellates); and the rhodophytes, or red algae. Three more groups have greater phylogenetic importance: the chlorophytes (green algae), which almost certainly gave rise to the land plants, *i.e.,* the bryophytes (mosses and liverworts) and the tracheophytes, or vascular plants (including all of the higher plants); the euglenoids (unicellular, flagellate organisms), which suggest a broad connection between plants and animals at this primitive level; and the phaeophytes (brown algae), which some biologists have considered to be a probable source of the animal kingdom. Finally, the protozoans (unicellular or acellular animals) were derived from unknown, more primitive ancestors, and one or more groups of protozoans have given rise to metazoans—*i.e.,* the multicellular, higher animals.

Land plants contain two major groups, bryophytes and tracheophytes, which differ in many ways but which share distinctive characteristics for adaptation to dry land. These include the housing of the plant embryo in maternal tissue.

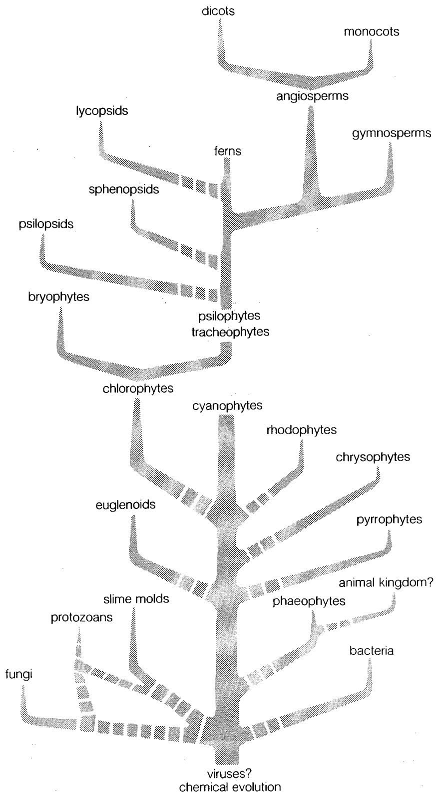

Figure 1: A summary of probable lines of plant evolution

Bryophytes are descended from green algae and include mosses, liverworts, and hornworts. Only small quantities of water are needed for their reproduction, so that the sperm may travel to the eggs. The fertilized egg matures within the maternal tissue. The plant is protected from dessication by a waxy cuticle. Bryophytes have apparently not advanced far beyond their algal predecessors and do not seem to be the evolutionary source of other groups.

All the dominant plants on Earth are included in the tracheophytes. The tracheophytes' development of large plant bodies has been made possible by having vascular parts that carry water and food inside these plants, and by a dominant sporophyte stage with a microscopic-sized gametophyte. Tracheophytes' tissues have differentiated into leaves, stems, and roots, and in the highest plants seeds and flowers are featured.

In explaining the evolution of tracheophytes from green algae, it has been suggested that a mutant form of green algae developed a primitive rootlike function with which to supply itself with water and minerals. The progeny of this organism eventually developed bundles of vascular tissues, a stem and leaves, and a cuticle for protection. The early vascular plants are called psilophytes. The development of seeds arose from the retention of the embryo inside maternal tissue. Early seed ferns gave rise to the gymnosperm group, including pines, spruces, and firs. Flowering plants, the angiosperms, probably came from the gymnosperm phase and have two subgroups: the dicotyledons, including most flowering plants; and the monocotyledons—grasses, palms, lilies, orchids, and related groups.

The problem of the origin of multicellular animals (metazoans) was long-dominated by the German embryologist Ernst Haeckel's theory that the original metazoan ancestor was a

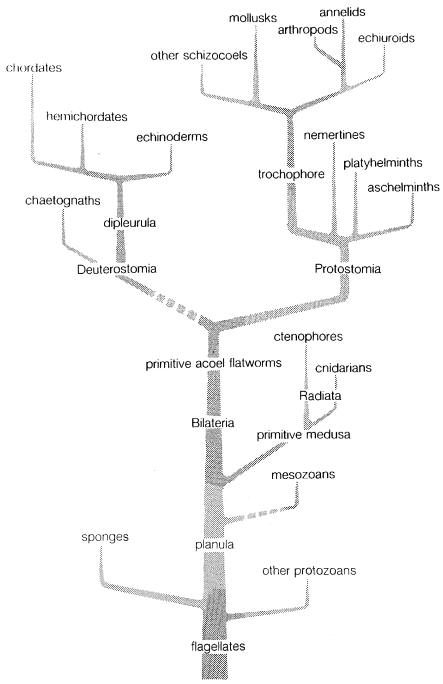

Figure 2: Hypothetical relationships in the animal kingdom

spherical protozoan that was structurally similar to the coelenterates (*e.g.,* jellyfishes, corals). Today there are two alternative explanations. The first traces metazoans back to flagellates, the presumed ancestors of flattened, ciliated animals (planulas) that eventually led to coelenterates and flatworms. Another theory hypothesizes that multinucleated protozoans, dividing into subcells, were the original metazoans, which developed into simple flatworms. No decisive information, however, yet exists to sustain either contention.

Lower metazoan forms developed the first symmetrical arrangement of body parts about a main axis, thus establishing the bilateral symmetry that characterizes most animals; major exceptions are the echinoderms (*e.g.,* starfishes, sea cucumbers). The development of tissues into an outer ectoderm, which provides protection and carries sense apparatus, and an inner endoderm, serving digestion and reproduction needs, was an important phase. Another important trend was cephalization (head formation). The anterior end of the body generally holds the central nervous system, sense organs, and mouth.

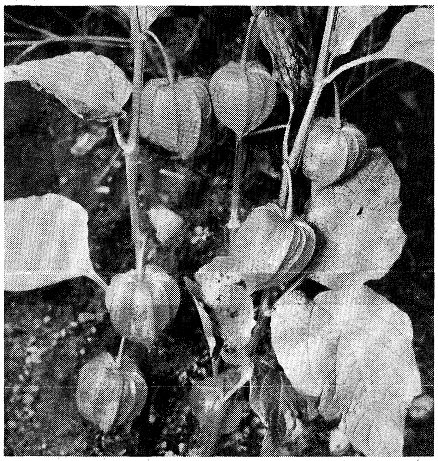
Two current theories postulate the lineage of the higher metazoans. The monophyletic sequence suggests that four groups evolved from lower forms to higher: Ameria (unsegmented animals), which includes flatworms, coelenterates, and mollusks; Polymeria (segmented animals), which includes annelids and arthropods; Oligomeria (reduced segmentation), which includes insects and echinoderms; and Chordonia (chordates). The (alternative) diphyletic theory has been proposed by many zoologists. It contends that the higher metazoans had two lines of descent, one of which led to annelids, arthropods, and mollusks and the other of which led to echinoderms and chordates, as in Figure 2. Both groups emanated from an ancient flatworm.

Humans are included in the chordates. Three basic structures are shared by all chordates: a dorsal nerve tube (brain and spinal cord in vertebrates); a notochord (supporting rod under the nerve tube); and a pharynx perforated by gill slits, at least during the embryonic stage.

The history of evolution is full of examples of primitive groups giving rise to more advanced groups, but it should be noted that it is the more primitive and less specialized members of a group—not the advanced members—that produce new groups. For example, birds and mammals arose not from advanced reptiles, but from primitive, unspecialized reptiles.

The data and conclusions of phylogeny show clearly that the world of life is the product of a historical process of evolution and that degrees of resemblance within and between groups correspond to degrees of relationship by descent from common ancestors. A fully developed phylogeny is essential for the devising of a taxonomy that reflects the natural relationships within the world of living things.

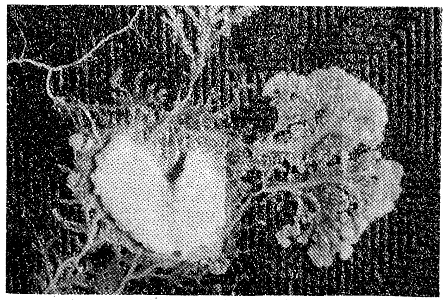
Physalis, genus of about 100 species (family Solanaceae) of small herbs noted for their inflated, baglike calyx (fused sepals), which encloses a fleshy berry and which occasionally becomes bright orange-red at maturity. The berries of some species of *Physalis* are edible, and the plants accordingly go by names such as Chinese lantern, or ground-cherry; winter



Chinese lantern (*Physalis alkekengi*)
G.E. Hyde from the Natural History Photographic Agency—EB Inc.

cherry; strawberry, or gooseberry, tomato; and husk tomato. Chinese lantern is a name alluding to the showy bladderlike calyx of the mature fruit of *P. alkekengi,* which has also been known as Japanese lantern. Tomatillos (*P. ixocarpa*) are raised commercially as vegetables in Mexico.

Physarum, large genus of true slime molds, accounting for about 20 percent of the species of the class Myxomycetes (*q.v.*). *Physarum polycephalum,* a fast-growing species, is the most notable; it has been used widely in physiological experiments in protoplasmic streaming and nuclear behaviour. *Physarum cinereum,* which forms an ashy-gray coating on lawn grasses under special conditions of



Streaming plasmodium (vegetative phase) of *Physarum*
Audrey Tomera

moisture and humidity, is unsightly but harmless and soon disappears.

Physcon (king of Egypt): *see* Ptolemy VIII Euergetes II.

physical anthropology, that branch of anthropology which is concerned with the comparative study of human evolution, classification, and physical variation, and which primarily uses techniques involving measurement and observation. *See* anthropology.

physical conditioning, the enhancement of physical fitness through the proper employment of exercise (*q.v.*).

physical constant, any of a set of fundamental, invariant quantities observed in nature and appearing in the basic theoretical equations of physics, mostly relating to the fundamental particles of which all matter is constituted. Accurate evaluation of these constants is essential in order to check the correctness of the theories and to allow useful predictions to be made on the basis of those theories.

The speed of light in a vacuum, c, appears in electromagnetic theory and in relativity theory; in the latter it relates energy to mass through the equation $E = mc^2$. Its value does not depend on any particular experimental conditions such as would be required for the determination of the speed of a sound wave in air (for which air temperature, density, and chemical composition would also have to be specified) but depends solely on an intrinsic property of the photon.

The charge on the electron, ε, is a fundamental property of a physical particle; it is the smallest unit of electric charge. Knowledge of its numerical value is required in many areas of physics and chemistry—*e.g.,* in calculating the mass of an element liberated by passage of current through an electrochemical cell.

Planck's constant, h, is not itself a property of a fundamental particle but is a constant appearing in the equations of quantum theory. It relates the energy of a photon (a quantum of electromagnetic radiation) to its frequency through the equation $E = h\nu$.

The universal gravitational constant, G, relates the magnitude of the gravitational attractive force between two bodies to their masses and the distance between them. Its value is extremely difficult to measure experimentally. It

Values of some selected fundamental constants

quantity	symbol	value
constant of gravitation	G	6.67259×10^{-11} cubic metre per second squared per kilogram
speed of light (in a vacuum)	c	$2.99792458 \times 10^{10}$ centimetres per second
Planck's constant	h	$6.6260755 \times 10^{-34}$ joule per second
Boltzmann constant	k	1.380662×10^{-23} joule per kelvin
Faraday constant	N_Ae	9.648456×10^{4} coulombs per mole
electron rest mass	m_e	9.109389×10^{-31} kilogram
proton rest mass	m_p	$1.6726231 \times 10^{-27}$ kilogram
neutron rest mass	m_n	$1.6749543 \times 10^{-27}$ kilogram
charge on electron	ε	4.803×10^{-10} electrostatic unit
Rydberg constant	R	1.09737×10^{5} per centimetre
Stefan–Boltzmann constant	σ	5.67032×10^{-8} watt per square metre kelvin
fine-structure constant	α	$7.29735308 \times 10^{-3}$

has been suggested that G has varied with time throughout the history of the universe and that it is scale-dependent. If such is the case, values determined in the laboratory would not be appropriate for terrestrial or astronomical problems.

Some physical constants can be expressed in terms of other constants; *e.g.*, the fine-structure constant (α)—which appears in the quantum-mechanical explanation of why certain atoms emit radiation of several closely spaced wavelengths rather than a single wavelength—can be expressed in terms of the permeability of free space (μ_0), the speed of light, the charge on the electron, and Planck's constant.

Numerical values of physical constants are determined at various laboratories throughout the world, such as the U.S. National Bureau of Standards, and are refined as experimental methods and techniques are improved. Definitive values are arrived at by international agreement.

physical education, training in physical fitness and in skills requiring or promoting such fitness. Many traditional societies included training in hunting, ritual dance, and military skills, while others—especially those emphasizing literacy—often excluded physical skills.

The spread of literacy in the West between 1500 and 1800 coincided with a new awareness that fitness helps the mind. Gymnasiums opened across Europe, the first in Copenhagen in 1799. The German *Turnverein* movement grew, expanding to the United States with immigration. Per Ling developed a teaching system for physical education in Stockholm in 1814, and Otto Spiess (1810–1858) popularized another system in Germany. As public schools in Germany, Denmark, and the United States tried these systems, physical education joined baccalaureate curricula, becoming a major at Columbia University in 1901 and elsewhere later.

Japan's schools have linked physical and mental training since the 17th century. Public schools with compulsory physical education were founded in 1872; the trend since 1945 has been toward individual physical and mental development. The Soviet Union, after 1917, placed great emphasis on physical education, both in schools and in special physical education institutes.

Today, physical education is a required course in most primary and secondary schools in countries with compulsory education. Most teaching takes place inside gymnasiums or other facilities built specifically for physical education activities, although outdoor sports are also emphasized.

physical medicine and rehabilitation, also called PHYSIATRY, PHYSICAL THERAPY, or REHABILITATION MEDICINE, medical specialty concerned with the treatment of chronic disabilities and with the restoration of normal functioning to the disabled through physical modes of treatment, such as exercise. This specialized medical service is generally aimed at rehabilitating persons disabled by pain or ailments affecting the motor functions of the body. Physical medicine is one means employed to assist these patients to return to a comfortable and productive life, often despite the persistence of a medical problem.

For centuries man used such natural physical agents as hot springs and sunlight to treat his ailments, but the development of physical medicine as a specialized medical service took place largely after World War I. Two factors influenced its growth in the 20th century—epidemic poliomyelitis and the two world wars—both of which created large numbers of young, seriously handicapped persons. Physical medicine was definitively established through the American physician Howard A. Rusk's efforts to rehabilitate wounded soldiers during and after World War II. Physical medicine then became available for the treatment of patients with such diverse problems as fractures, burns, tuberculosis, painful backs, strokes, nerve and spinal cord injuries, diabetes, birth defects, arthritis, and vision and speech impairments. Physical medicine is closely associated with orthopedic surgery, but it is also prescribed by physicians and surgeons in all branches of medicine. Physicians who specialize in physical medicine are called physiatrists.

The objectives of physical medicine are relief of pain, improvement or maintenance of functions such as strength and mobility, training in the most effective method of performing essential activities, and testing of function in various areas. Tests cover such fields as muscle strength, degree of joint mobility, breathing capacity, and muscular coordination.

The therapeutic means most commonly employed include heat, massage, exercise, electrical currents, and functional training. Since the 1970s these basic means have been supplemented and enhanced by psychological counseling, occupational therapy, and a variety of other treatments which may be used in concert to help the disabled person achieve the fullest possible life despite the persistence of his medical problem.

Heat is used generally to stimulate circulation and to relieve pain in the area treated. It may be applied by infrared lamps, shortwave radiation, or high-frequency electrical currents (diathermy); by hot, moist compresses or immersion in hot water (hydrotherapy); or by ultrasound. Massage primarily aids circulation and relieves local pain or muscle spasm.

Exercise, the most varied and widely used of all physical treatments, is usually designed to do one or more of three things: increase the amount of motion in a joint, increase the strength in a muscle, or train a muscle to contract and relax in useful coordination with other muscles. In addition to its obvious use following stiffness or paralysis, exercise may be used to improve the breathing of patients with lung disorders, assist circulation, relax tense muscles, and correct faulty posture.

In the late 20th century high technology was increasingly harnessed in efforts to rehabilitate paraplegics, quadriplegics, and others with severely impaired motor functions. Microcomputers were developed that could send precisely coordinated jolts of electricity directly into the muscles of such patients, mimicking the cerebral impulses that could no longer reach their muscle destinations because of a severed spinal cord. The microcomputers' sophisticated programs enable them to contract a patient's muscles in unison so that he can actually stand and sit, walk, and even use his hands to perform relatively fine movements. Such devices were still in the experimental stage and were costly to make and use, but they seemed to be the most promising development yet in efforts to restore the power of movement to nerve injury victims.

Other, less ambitious devices to help paralyzed patients include wheelchairs with specially equipped control systems that can be operated by the mouth and teeth movements of a quadriplegic. Mobile robotic arms have been developed that are equipped with a video camera so that they can move safely and intelligently about a patient's house. These personal robots can receive and execute oral commands from the patient to perform such simple household tasks as filling a glass with water or taking a book off a shelf.

Functional training teaches the impaired individual how to carry out most safely and effectively the activities of daily life. This training may mean learning to use crutches, a brace, or an artificial arm; or it may involve working out and practicing the movements required to do housework with the use of only one hand or the way to board public transportation with a stiff leg. Such training often requires long hours of practice; it may be facilitated by use of devices that make it easier to fasten buttons, hold a fork, or dial a telephone.

Physical medicine and rehabilitation underwent a rapid expansion during the late 20th century, largely because of the development of antibiotics and other fundamental advances in modern medicine, which not only save the lives of many who would not have survived illness or injury in earlier decades but also prolong life in general.

Physical medicine and rehabilitation are carried out by a "rehabilitation team," headed by a physiatrist who coordinates the team's efforts and assesses the areas of functioning in which the patient can improve. The physical therapist uses exercise to improve the patient's muscle strength and functioning, and a rehabilitation engineer may provide a special mechanical aid or device to assist that functioning. Meanwhile a rehabilitation nurse keeps track of the patient's physical condition and provides him with basic medical care, while a psychological counselor helps the patient cope with the discouragement or depression produced by the condition of physical disability. Respiratory or speech therapists may also be brought in to assist the patient with breathing or speaking difficulties. Eventually an occupational therapist and a social worker will help the patient adjust to life outside of the rehabilitation institute. *See also* occupational therapy.

physical science, the systematic study of the inorganic world, as distinct from the study of the organic world, which is the province of biological science. Physical science is ordinarily thought of as consisting of four broad areas: astronomy, physics, chemistry, and the Earth sciences. Each of these is in turn divided into fields and subfields.

A brief treatment of physical science follows. For full treatment, *see* MACROPAEDIA: Physical Sciences; Earth Sciences. For treatment of the scientific approach and methodology of the physical sciences, *see* MACROPAEDIA: Physical Science, Principles of.

Physics is the basic physical science. It deals with the structure and behaviour of individual atoms and their components, as well as with the different forces of nature and their relationships. It also is concerned with the physical properties of matter and with such phenomena as electricity and magnetism. Its goal is the formulation of comprehensive principles that summarize disparate phenomena in the most general way possible and that are expressed with economy and precision in the language of mathematics. The principal subject areas of physics are mechanics, gravitation, thermodynamics and heat, electricity and magnetism, optics, atomic and chemical physics, condensed-matter physics, nuclear physics, particle physics, quantum mechanics, relativistic mechanics, conservation laws and symmetry, and fundamental fields and forces.

Chemistry focuses on the properties and reactions of molecules. Broadly speaking, it tends to concentrate on the specific properties of different elements and compounds, as opposed to physics which is chiefly concerned with the general properties of matter as a whole. The principal divisions of chemistry are analytical chemistry, inorganic chemistry, organic chemistry, biochemistry, polymer chemistry, physical chemistry, and industrial chemistry.

Astronomy entails the study of the entire universe beyond the Earth. It includes investigations of the gross physical properties of the Earth (*e.g.*, mass and rotation period) primarily as they relate to interactions with other components of the solar system. Most other aspects are dealt with by the Earth sciences (*q.v.*). Modern astronomy includes astrophysics, the application of physical and chemical knowledge to the study of cosmic objects and the physical processes that control their formation, evolution, and emission of radiant energy. It also encompasses cosmology, the study of the structure and evolution of the universe.

physics, the science that deals with the structure of matter and the interactions between the fundamental constituents of the observable universe. In the broadest sense physics, which was long called natural philosophy (from the Greek *physikos*), is concerned with all aspects of nature on both the macroscopic and submicroscopic levels. Its scope of study encompasses not only the behaviour of objects under the action of given forces but also the nature and origin of gravitational, electromagnetic, and nuclear force fields. Its ultimate objective is the formulation of a few comprehensive principles that bring together and explain all such disparate phenomena.

Physics is treated in a number of articles in the MACROPAEDIA. For the history and principal treatment of the discipline, *see* Physical Sciences. For primary areas of study and divisions, *see* Subatomic Particles; Atoms; Matter; Electricity and Magnetism; Electromagnetic Radiation; Light; Radiation; Gravitation; Sound; Mechanics. For fundamental principles and theories, *see* Relativity; Thermodynamics, Principles of; Optics, Principles of. For methodology and instrumentation, *see* Analysis and Measurement; Particle Accelerators; Measurement and Observation. For general approach, *see* Physical Science, Principles of.

For a description of the place of physics in the circle of learning and for a list of both MACROPAEDIA and MICROPAEDIA articles on the subject, *see* PROPAEDIA: Part Ten, Division III.

physiocrat, any of a group of 18th-century writers and thinkers generally regarded as constituting the first scientific school of economics. The physiocrats are best understood as theorists reacting against the policies of the mercantilists, who had believed that national strength and security depended more on manufacturing and trade than on the products of the soil. The physiocrats instead regarded land, or agriculture, as the source of all wealth because they believed that only agriculture produced a clear surplus over the costs of production. Other forms of production merely changed the products of agriculture into consumable form; workers engaged in nonagricultural trades added only the value of their labour to the product and were regarded by the physiocrats as the sterile class. Agricultural products ought to be sold at high prices and manufactured products at low prices because a rise in agricultural income would mean a rise in net product (an increase in national prosperity). In addition to the productive (farming) and sterile (nonfarming and nonmining) classes, the physiocrats recognized the landowners as a legitimate class entitled to rent on their lands, because they or their ancestors were the first ones to clear it and prepare it for farming. In this sense, the physiocratic school accepted the prerevolutionary structure of society.

The founder of the physiocratic school was François Quesnay, court physician to Louis XV. His crowning work was the *Tableau économique* (1758), the first schematic portrayal of an entire economy. The term physiocracy denotes the rule of nature; their famous phrase *laissez faire, laissez passer* ("let it be, let it go") reflected their belief that natural economic laws should prevail. The physiocrats attacked mercantilism because of its mass of economic regulations.

Because they believed that only agriculture yielded a net surplus, the physiocrats favoured the imposition of an *impôt unique,* or single tax, directly on the net product that accrued to the landowners and the elimination of all the other taxes that had become so burdensome to the entire French economy.

Anne-Robert-Jacques Turgot became minister of finance in 1774 and began to effect some of the reforms suggested by physiocratic thought. As a result of some of these he was removed by the king in 1776 when the landed class strongly objected to his policies. With this, the influence of the physiocrats ended.

physiognomy, the study of the systematic correspondence of psychological characteristics to facial features or body structure. Because most efforts to specify such relationships have been discredited, physiognomy sometimes connotes pseudoscience or charlatanry on the level of fortune-telling or palmistry.

Physiognomy was regarded by those who cultivated it both as a mode of discriminating character by the outward appearance and as a method of divination from form and feature.

Physiognomy is of great antiquity, and in ancient and medieval times it had an extensive literature. Inasmuch as genetic flaws are sometimes revealed by physical characteristics (*e.g.,* the characteristic appearance of Down's syndrome—up-slanted eyes; broad, flat face), physiognomy has become a branch of physiology and biochemistry.

In its second aspect—*i.e.,* divination from form and feature—it was related to astrology and other forms of divination, and this aspect of the subject bulked large in the fanciful literature of the Middle Ages. There is evidence in the earliest classical literature, including Homer and Hippocrates, that physiognomy formed part of the most ancient practical philosophy.

The earliest-known systematic treatise on physiognomy is attributed to Aristotle. In it he devoted six chapters to the consideration of the method of study, the general signs of character, the particular appearances characteristic of the dispositions, of strength and weakness, of genius and stupidity, and so on. Then he examined the characters derived from the different features, and from colour, hair, body, limbs, gait, and voice. While discussing noses, for example, he says that those with thick, bulbous ends belong to persons who are insensitive, swinish; sharp-tipped belong to the irascible, those easily provoked, like dogs; rounded, large, obtuse noses to the magnanimous, the lionlike; slender, hooked noses to the eaglelike; and so on.

Among the Latin classical authors Juvenal, Suetonius, and Pliny refer to the practice of physiognomy, and numerous allusions occur in the works of the Christian scholars, especially Clement of Alexandria and Origen. While the earlier classical physiognomy was chiefly descriptive, the later medieval studies particularly developed the predictive and astrological side, their treatises often digressing into prophetic folklore and magic.

Along with the medical science of the period, Arabian writers such as the alchemist ar-Rāzī and Averroës also contributed to the literature of physiognomy. The medicine of systematic correspondence that evolved in China after the period of the Warring States is still associated with traditional Chinese science and has some bearing on the doctrine of yin–yang.

Physiognomy also is treated (in some cases extensively) by such scholars as Avicenna, Albertus Magnus, John Duns Scotus, and Thomas Aquinas. The development of a more accurate anatomy in the 17th century seems to have dampened the scientific interest in physiognomy. In the 18th and 19th centuries physiognomy was proposed as a means of detecting criminal tendencies, but each system was examined and discarded as fallacious, and by the 20th century physiognomy—as it was known in earlier times—was largely regarded as a historical subject.

physiological psychology, the study of the physiological basis of behaviour. Physiological psychology is primarily concerned with the relationship between psychological processes and the underlying physiological events, or, in other words, the mind-body phenomenon. Its focus is the function of the brain and the rest of the nervous system in activities (*e.g.,* thinking, learning, feeling, sensing, and perceiving) recognized as characteristic of human and other vertebrate animals. Physiological psychology has continually been involved in studying the physical basis for the reception of internal and external stimuli by the nervous system, particularly the visual and auditory systems. Other areas of study have included the physiological bases for motivated behaviour, emotion, learning, memory, cognition, and mental disorders. Also considered are other physical factors that directly affect the nervous system, including heredity, metabolism, hormones, disease, drug-ingestion, and diet.

Theories of the relationship between body and mind date back at least to Aristotle, who conjectured that the two exist as aspects of the same entity, the mind being merely one of the body's functions. In the dualism of French philosopher René Descartes, both the mind and the soul are spiritual entities existing separately from the mechanical operations of the human body. Related to this is the psychological parallelism theory of German philosopher Gottfried Wilhelm Leibniz. Leibniz believed that mind and body are separate but that their activities directly parallel each other. In recent times such behaviourists as American psychologist John B. Watson moved away from consideration of the spiritual or mental and focused on observable human and animal behaviour and its relationship to the nervous system.

physiology, study of the functioning of living organisms, animal or plant, or of the functioning of their constituent tissues or cells.

A brief treatment of physiology follows. For full treatment, *see* MACROPAEDIA: Biological Sciences.

Although historically physiology was usually considered separately from anatomy, with the development of high-powered microscopes, and in particular the electron microscope, structure and function at the cellular and even the molecular level came to be understood as inseparable. By the same token, while biochemistry is now a separate science, an understanding of biochemistry is fundamental to physiology.

A major feature of physiology is its dynamic state. Cells change their function in response to changes in the composition of their local environment, while the organism responds to alterations in both the internal and the external environment. Thus, many physiological reactions are aimed at preserving a constant physical and chemical internal environment, which Claude Bernard defined as the *milieu intérieur.* This property, known as homeostasis, a term introduced by American physiologist Walter Bradford Cannon, operates in animals through a range of sensory receptors for the detection of change in either the internal or external environment of the organism. These receptors initiate specific and appropriate responses from effector organs, such as the muscles, kidneys, liver, and endocrine glands.

Much of the current understanding of physiology has resulted from studying the responses of cells and tissues to imposed modifications in their environment. This has been done both in the living animal or plant (called *in vivo* studies) and in cells and tissues removed from the animal or plant and maintained alive in culture (called *in vitro* studies). For example, a lack of oxygen in arterial blood is sensed by receptors in small structures associated with the carotid arteries and the aorta called carotid and aortic bodies. By a variety of experimental procedures, both *in vivo* and *in vitro*, it has been shown that these receptors respond to reductions in the oxygen tension of blood perfusing through these structures and that they generate nerve impulses in afferent nerves that drive a reflex increase in the frequency and depth of breathing. This response tends to correct the reduction in oxygen tension. There are many similar examples of homeostasis—*e.g.*, the control of bodily metabolism by hormones. The release of insulin from the endocrine tissue of the pancreas is stimulated by glucose, among other factors, and this hormone then acts on muscle and fat cells to facilitate the transport of glucose and other substances into these cells. Thus, the level of glucose circulating in blood is continuously sensed and is also constantly being adjusted through the release of insulin and in other ways. There are physiological controls of almost all tissues and organs in the body. They form the basis for the understanding of clinical diseases and disorders in both human and veterinary medicine.

The advent of new techniques has significantly extended the boundaries of physiology; *e.g.*, radioactive isotopes have enabled the measurement of amounts and fluxes of substances present at low concentrations inside cells and in extracellular fluids. Also, by the application of techniques based on immunology, it has been possible to identify and trace the functions of minute quantities of hormones and other chemical agents that are important to understanding the responses of tissues to environmental stimuli. Parallel advances in the application of the physical and chemical sciences to physiology have promoted new understanding; such techniques as X-ray crystallography, nuclear magnetic resonance, and advanced forms of chromatography have enabled the molecular limits of cell physiology to be probed. Organic chemistry has assisted in the creation of new molecules similar in structure to natural molecules (called analogues), which have considerably advanced the understanding of tissue reactions to hormones and other substances and which form the basis of modern pharmacology.

Efforts are now being made to integrate all the information obtained from single cells, tissues, and organ systems into an understanding of the way in which the whole organism responds to its environment. Thus, the wide span of knowledge from subcellular molecular biology, including the biochemical basis of gene expression, to the behaviour of the whole animal is now appropriately encompassed by the term physiology.

phytoflagellate (class Phytomastigophorea in many traditional classifications), any of several flagellate protozoans that have many characteristics in common with typical algae, especially the pigment chlorophyll and various accessory pigments, which means that many phytoflagellates have a photosynthetic type of nutrition, although many organisms included in this group exhibit heterotrophy or myotrophy. Species without chlorophyll are similar in form to related chlorophyll-bearing species. Phytoflagellates may obtain nutrients by photosynthesis, by absorption through the body surface, or by ingestion of food particles. For some of the more important members of this group, *see* Euglena; Chlamydomonas; chloromonad; dinoflagellate; cryptomonad; and chrysomonad.

phytol, an organic compound used in the manufacture of synthetic vitamins E and K_1. Phytol was first obtained by hydrolysis (decomposition by water) of chlorophyll in 1909 by the German chemist Richard Wilstätter. Its structure was determined in 1928 by the German chemist F.G. Fischer. Phytol may be obtained in the process of separating chlorophyll from alfalfa.

Conversion of phytol to α-tocopherol, the most potent of the E vitamins essential for reproduction in rats, was reported from three laboratories in 1938 and has been applied in commercial manufacture. A synthesis of vitamin K_1 from phytol was developed in 1939.

phytoplankton, a flora of freely floating, often minute organisms that drift with water currents. Like land vegetation, phytoplankton uses carbon dioxide, releases oxygen, and converts minerals to a form animals can use. In fresh water, large numbers of green algae often colour lakes and ponds, and cyanobacteria may affect the taste of drinking water.

Oceanic phytoplankton is the primary food source, directly or indirectly, of all sea organisms. Composed of groups with siliceous skeletons, such as diatoms, dinoflagellates, and coccolithophores, phytoplankton varies seasonally in amount, increasing in spring and fall with favourable light, temperature, and minerals.

phytosaur, extinct, heavily armoured, semiaquatic reptile restricted to the Late Triassic (230 to 208 million years ago). Although they were not ancestral to the crocodiles, in many ways the phytosaurs resembled the modern crocodiles and probably had similar habits. The long and pointed jaws were armed with numerous sharp teeth; it is probable that the phytosaurs preyed largely upon fish. The nostrils in the phytosaurs were set in a mound high on the skull near the eyes, an adaptive feature related to an aquatic existence that allowed the animal to open its mouth underwater without drowning. The greater development of the hind limbs than of the forelimbs indicated that the phytosaurs descended from bipedal reptilian ancestors and reverted to a quadrupedal pose. Phytosaurs were well able to move about on land. Phytosaurian fossils occur in North America, Europe, and India, but their remains have not been found in the southern continents.

Familiar genera of phytosaurs include *Rutiodon* and *Phytosaurus*, the genus that gives its name to the group as a whole. *Rutiodon* was more than 3 m (10 feet) long; its skull alone was about 1 m (3.5 feet) long.

pi, Pinyin BI, in art, Chinese jade carved in the form of a flat disk with a hole in the centre. The earliest examples, which are unornamented, date from the Neolithic period (*c.* 3000–1500 BC).

Later examples, from the Shang dynasty (18th–12th century BC) and the Chou dynasty (1111–255 BC), have increasingly elaborate surface embellishment, especially in the late Chou (*c.* 600–255 BC), when the *pi* appears in combination with other forms. The *pi* may have been a symbol of heaven or of the Sun (in that it resembles the ancient graph for "sun."

pi, in mathematics, the symbol π denoting the ratio of the circumference of a circle to its diameter. The ratio is approximately 3.14159265, pi being an irrational number (one that cannot be expressed as a simple fraction or as a decimal with a finite number of decimal places) and a transcendental number (one without continuously recurrent digits). Electronic computers in the late 20th century have carried pi to more than 100,000,000 decimal places.

Pi occurs in various mathematical calculations. The circumference (c) of a circle can be determined by multiplying the diameter (d) by π: $c = \pi d$. The area (A) of a circle is determined by the square of the radius (r): $A = \pi r^2$. Pi is applied to mathematical problems involving the lengths of arcs or other curves, the areas of elipses, sectors, and other curved surfaces, and the volumes of solids. It is also used in various formulas of physics and engineering to describe such periodic phenomena as the motion of pendulums, the vibration of strings, and alternating electric currents.

In very ancient times, 3 was used as the approximate value of pi, and not until Archimedes (3rd century BC) does there seem to have been a scientific effort to compute it; he reached a figure equivalent to about 3.14. A figure equivalent to 3.1416 dates from before AD 200. By the early 6th century Chinese and Indian mathematicians had independently confirmed or improved the number of decimal places. By the end of the 17th century in Europe, new methods of mathematical analysis provided various ways of calculating pi. Early in the 20th century the Indian mathematical genius Srinivasa Ramanujan developed ways of calculating pi that were so efficient that they have been incorporated into computer algorithms, permitting expressions of pi in millions of digits.

pi bond, in chemistry, a cohesive interaction between two atoms and a pair of electrons that occupy an orbital located in two regions roughly parallel to the line determined by the two atoms. A pair of atoms may be connected by one or by two pi bonds only if a sigma bond also exists between them; in the molecule of nitrogen (N_2), for example, the triple bond between the two nitrogen atoms comprises a sigma bond and two pi bonds.

P'i-chia (Mongol khan): *see* Bilge.

pi meson, lightest member of the meson family of subatomic particles (*see* meson).

P'i-nan (Taiwan): *see* T'ai-tung.

p'i-p'a, Pinyin PIPA, short-necked Chinese lute prominent in Chinese opera orchestras and as a solo instrument. Ultimately of West Asian origin, it was known in China by the 2nd century AD. It has a shallow, pear-shaped body with a wooden belly and, sometimes, two crescent-shaped sound holes. There are 4 convex frets on the neck and 6 to 13 frets on the belly. The four silk strings run from a fastener on the belly to conical tuning pegs in the sides of the bent-back pegbox. Although formerly a plectrum was used, the strings are now plucked with bare fingers while the instrument is held vertically on the player's thigh. A common tuning (relative pitch) is c–f–g–c′ (top note around middle C).

There are several varieties of *p'i-p'a* in China, and closely related instruments are also found

Woman playing a *p'i-p'a*, detail from 18th-century silk painting; in the Náprstkovo Muzeum Asijských, Prague

By courtesy of the Naprstkovo Muzeum Asijskych, Prague in Vietnam and Korea. The *p'i-p'a* reached Japan by the 8th century AD. The Japanese form of the instrument, the *biwa,* exists in several varieties. The *biwa,* which has only four frets, is important in narrative and court music.

Pi Ramesse (ancient Egyptian city): *see* Per Ramessu.

Piacenza, Latin PLACENTIA, city, capital of Piacenza *provincia,* in the Emilia-Romagna *regione* of northern Italy, on the south bank of the Po River just below the mouth of the Trebbia, southeast of Milan. It was founded

Marconi Square, Piacenza, Italy
Photo Research International

as the Roman colony of Placentia in 218 BC. After being besieged unsuccessfully by the Carthaginian general Hasdrubal in 207 BC and sacked by the Gauls in 200, it was restored and reinforced. In 187 BC it became the terminus of the Via Aemilia, the great arterial road to Ariminum (Rimini), and was later the focus of other major Roman roads. After the barbarian invasions, Piacenza was governed by its bishops from 997 to 1035. It became a free commune in the 12th century and a leading member of the Lombard League of towns in opposition to the emperor Frederick I Barbarossa. Despite political vicissitudes, it prospered from its control of river and road traffic. A long period of struggle between the Visconti and Sforza families, alternating with papal and French rule, was ended in 1545 by the creation by Pope Paul III of the hereditary duchy of Parma and Piacenza for his son Pier Luigi Farnese. For the subsequent history of Piacenza, *see* Parma and Piacenza, duchy of.

No Roman monuments survive, but the rectangular street plan in the centre of the city is Roman. The brick cathedral (1122–1253) is a fine example of Lombard Romanesque style. Other noteworthy medieval churches are the former Cathedral of San Antonino, incorporating an 11th-century facade and elements of the 13th- and 14th-century construction; the restored San Savino (consecrated 1107), with unusual 12th-century floor mosaics; San Francesco (begun 1278); San Sisto (1499–1511), the original home of Raphael's painting "Sistine Madonna"; and Santa Maria di Campagna (1522–28), with frescoes by Pordenone. Notable palaces include the Palazzo Comunale (begun 1281) and the grandiose Palazzo Farnese, begun in 1558 for Margaret of Austria and never completed.

Piacenza is a rail and road centre on the main routes from Milan to Bologna. It is a long-established centre for cereal growing and viticulture and has a number of rapidly developing light industries, including the manufacture of chemicals, office furniture, and buttons. Pop. (1988 est.) mun., 104,976.

Piacenza, duchy of: *see* Parma and Piacenza, duchy of.

Piaf, Edith, byname of EDITH GIOVANNA GASSION (b. Dec. 19, 1915, Paris, Fr.—d. Oct. 11, 1963, Paris), French singer and actress whose interpretation of the *chanson,* or French ballad, made her internationally famous. Among her most famous songs was "Non, je ne regrette rien" ("No, I don't regret anything").

Piaf's singing reflected the tragedies of her own life. Her mother, a café singer, abandoned her at birth, and she was reared by her grandmother. She became blind at the age of three as a complication of meningitis but recovered her sight four years later. Her father, a circus acrobat, took her along on tours and first encouraged her to sing. She sang in the streets of Paris until discovered by a cabaret owner who gave her her first nightclub job and suggested that she change her name to *Piaf,* Parisian slang for "sparrow," in apparent reference to her diminutive size (under five feet tall and about 90 pounds in weight). Her debut was acclaimed by Maurice Chevalier, who happened to be in the audience.

In 1935 Piaf made her theatrical debut, and within a few years she was singing in the large music halls of Paris. During World War II

Edith Piaf, 1948
UPI/Bettmann Newsphotos

she would only entertain French prisoners of war and aided several in their escapes. The subsequent years were spent in tours of Europe, South America, and the United States. Her simple yet dramatic style and throaty, tender voice with its tragic overtones brought her wide acclaim and never ceased to move her audiences. Despite her success, however, her life continued to be marred by illness, accidents, and personal unhappiness.

Piaget, Jean (b. Aug. 9, 1896, Neuchâtel, Switz.—d. Sept. 17, 1980, Geneva), Swiss psychologist who was the first to make a systematic study of the acquisition of understanding in children. He is thought by many to have been the major figure in 20th-century developmental psychology.

Piaget's early interests were in zoology; at the age of 10 he published an article on his observations of an albino sparrow, and by 15 his several publications on mollusks had gained him a reputation among European zoologists. At the University of Neuchâtel, he studied zoology and philosophy, receiving his doctorate in the former in 1918. Soon afterward, however, he became interested in psychology, combining his biological training with his interest in epistemology. He first went to Zürich, where he studied under Carl Gustav Jung and Eugen Bleuler, and then began two years of study at the Sorbonne in Paris in 1919.

In Paris Piaget devised and administered reading tests to schoolchildren and became interested in the types of errors they made, leading him to explore the reasoning process in these young children. By 1921 he had begun to publish his findings; the same year brought him back to Switzerland, where he was appointed director of the Institut J.J. Rousseau in Geneva. In 1926–29 he was professor of philosophy at the University of Neuchâtel, and in 1929 he joined the faculty of the University of Geneva as professor of child psychology, remaining there until his death. In 1955 he established the International Centre of Genetic Epistemology at Geneva and became its director. In more than 50 books and monographs over his long career, Piaget continued to develop the theme he first discovered in Paris, that the mind of the child evolves through a series of set stages to adulthood.

Piaget saw the child as constantly creating and recreating his own model of reality, achieving mental growth by integrating simpler concepts into higher level concepts at each stage. He argued for a "genetic epistemology," a timetable established by nature for the development of the child's ability to think, and he traced four stages in that development. He described the child during the first two years of life as being in a sensorimotor stage, chiefly concerned with mastering his own innate physical reflexes and extending them into pleasurable or interesting actions. During the same period, the child first becomes aware of himself as a separate physical entity and then realizes that the objects around him also have a separate and permanent existence. In the second, or preoperational, stage, roughly from age two to age six or seven, the child learns to manipulate his environment symbolically through inner representations, or thoughts, about the external world. During this stage, he learns to represent objects by words and to manipulate the words mentally, just as he earlier manipulated the physical objects themselves. In the third, or concrete operational, stage, from age 7 to age 11 or 12, occurs the beginning of logic in the child's thought processes and the beginning of the classification of objects by their similarities and differences. During this period, the child also begins to grasp concepts of time and number. The fourth stage, the period of formal operations, begins at age 12 and extends into adulthood. It is characterized by an orderliness of thinking and a mastery of logical thought, allowing a more flexible kind of mental experimentation. The child learns in this final stage to manipulate abstract ideas, make hypotheses, and see the implications of his own thinking and that of others.

Piaget's concept of these developmental stages caused a reevaluation of older ideas of the child, of learning, and of education. If the development of certain thought processes was on a genetically determined timetable, simple reinforcement was not sufficient to teach concepts; the child's mental development would have to be at the proper stage to assimilate those concepts. Thus, the teacher became not a transmitter of knowledge but a guide to the child's own discovery of the world.

Piaget reached his conclusions about child development through his observations of and conversations with his own children, as well as others. He asked them ingenious and revealing questions about simple problems he had devised, and then he formed a picture of their way of viewing the world by analyzing their mistaken responses.

Among Piaget's major works available in English are *Le langage et la pensée chez l'enfant* (1923; *The Language and Thought of the Child*), *Le Jugement et la raisonnement chez l'enfant* (1924; *Judgement and Reasoning in the Child*), and *La Naissance de l'intelligence chez l'enfant* (1948; *The Origins of Intelligence in Children*). He also wrote a series of books dealing separately with children's conceptions of time, space, physical causality, movement and speed, and of the world in general.

Pian del Carpini, Giovanni da (Franciscan author): *see* Giovanni da Pian del Carpini.

piano, also called PIANOFORTE, French PIANO, or PIANOFORTE, German KLAVIER, a musical instrument having wire strings that sound when struck by felt-covered hammers operated from a keyboard. The modern standard piano contains 88 black and white keys.

A brief treatment of pianos follows. For full treatment, *see* MACROPAEDIA: Musical Instruments.

The piano is a keyboard musical instrument in which tone is produced by the striking of strings. The vibration of the strings is transmitted to a soundboard by means of a bridge over which the strings are stretched; the soundboard amplifies the sound and affects its tone quality. The hammers that strike the strings are affixed to a mechanism resting on the far ends of the keys; hammer and mechanism compose the "action." The function of the mechanism is to accelerate the motion of the hammer, catch it as it rebounds from the strings, and hold it in position for the next attack. Modern hammers are covered with felt; earlier, leather was used. The modern piano has a cast-iron frame capable of withstanding the tremendous tension of the strings; early pianos had wood frames and thus could only be lightly strung. Modern pianos are therefore much louder than were those of the 18th century, an increase in loudness necessitated in part by the size of 19th-century concert halls. Of the three pedals found on most pianos, the damper pedal on the right lifts all the felt dampers above the strings, allowing them all to vibrate freely; the left pedal shifts the keyboard and action sideways to enable the hammer to strike only one of the two or three unison strings of each tenor and treble key (the bass notes are only single-strung); and the middle pedal usually holds up the dampers only of those keys depressed when the pedal is depressed.

Credit for priority of invention has been much disputed, but there is little doubt that it belongs to Bartolomeo Cristofori, who devised his *gravecembalo col piano e forte* ("harpsichord with soft and loud") in Florence in about 1709. This was not the first instrument using keyboard striking action; examples of the piano principle existed as early as about 1440. Cristofori had arrived at all the essentials of the modern piano action by 1726, and it is from Cristofori's piano that the modern piano stems.

The piano, made in a variety of forms, was widely popular in the mid-18th century. Preferring a lighter, less-expensive instrument with a softer touch, German piano makers perfected the square piano. When Wolfgang Amadeus Mozart and Muzio Clementi began to write for the piano, a distinctively pianistic style of playing and composing developed. From that point on, it became the preferred medium for salon music, chamber music, concerti, and song accompaniments.

By about 1860 the upright piano had virtually replaced the square piano for home use. Early upright pianos were made according to the design of upright harpsichords with the strings rising from keyboard level. They were consequently very tall, and many were made in elegant shapes. But by taking the strings down to floor level, John Isaac Hawkins made the upright shorter and more suitable for small rooms.

A number of developments followed in the 19th and 20th centuries. String tension, determined at 16 tons in 1862, increased to as much as 30 tons in modern instruments. The result is a dynamic range, sostenuto (ability to sustain a tone), and tonal spectrum unknown to Frédéric Chopin, Ludwig van Beethoven, and even Franz Liszt. A significant development in the 20th century (beginning in the 1930s) was the appearance of the electronic, or electric, piano, which relied on electroacoustic or digital methods of tone production and was heard through an amplifier and loudspeaker.

Double-action pianoforte built by Bartolomeo Cristofori in 1720; in the Metropolitan Museum of Art, New York City

piano nobile (Italian: "noble floor"), in architecture, main floor of a Renaissance building. In the typical palazzo, or palace, erected by an Italian prince of the Renaissance, the main reception rooms were in an upper story, usually the story immediately above the basement or ground floor. These rooms had higher ceilings than the rooms on the other floors of the palace and were more elegantly decorated. Often a grand exterior staircase or pair of staircases led from ground level up to the piano nobile. The term is also used in reference to the main floors of similarly constructed buildings of the English Palladian style of the 18th century and of those built in Great Britain and the United States during the Renaissance revival of the mid- and late 19th century.

Pianosa Island, Italian ISOLA PIANOSA, ancient (Latin) PLANASIA, island of the Toscano Archipelago, in the Tyrrhenian Sea, part of Livorno (Leghorn) *provincia,* Italy, 8 miles (13 km) southwest of the island of Elba. It has an area of 4 square miles (10 square km) and is, as its name (Italian *piano,* "flat") indicates, flat, with its highest point only about 90 feet (27 m) above sea level. In Roman history it figures as the place of banishment of Agrippa Postumus, grandson of the emperor Augustus. It suffered from the depredations of the Turks in the 16th century. In 1856 an agricultural penal colony was established there. Pop. (1971) 784.

Piast DYNASTY, first ruling family of Poland. According to a 12th-century legend, when Prince Popiel of Gnesen (now Gniezno) died, in the second half of the 9th century, he was succeeded by Siemowit, the son of the prince's plowman, Piast, thus founding a dynasty that ruled the Polish lands until 1370. (The name Piast was not applied to the dynasty until the 17th century.) By 963 Mieszko I (reigned *c.* 963–992), probably the fourth prince of the Piast line, was ruling a highly developed, if somewhat isolated, political community in the territories later known as Great Poland and possibly also in Mazovia. Mieszko brought his state into closer association with western Europe, converted it to Christianity (966), and expanded it to include Pomerania (Polish Pomorze) on the Baltic Sea (967–990) as well as Silesia and Little Poland (989–992). His son Bolesław I the Brave (reigned 992–1025) continued the country's expansion, strengthened its internal administration and church organization, and was crowned its king shortly before his death.

A period of decline then set in during the reigns of Bolesław's successors—Mieszko II Lambert (1025–34), Bezprym (1031–32), Casimir I the Restorer (1034–37, 1038/39–58), Bolesław II the Bold (1058–79), and Władysław I Herman (1079–1102). The Piast princes lost their title of king (although Bolesław II held it briefly, from 1076 to 1079); they allowed the authority of the central government to diminish in favour of the power of the regional nobility, and they engaged the state in numerous struggles that resulted in a territorial loss. Only after Bolesław III the Wry-Mouthed (reigned 1102–38) succeeded to the throne and exiled his brother and coruler Zbigniew (1107) did Poland's boundaries reach those of Mieszko I's domain (by 1125). But Bolesław failed to regain the title of king as well as to reverse the decentralizing tendencies that were undermining the unity of his state. Therefore, in order to avoid future internal conflict based on regional rivalry and to retain unity among the Piast lands, Bolesław divided Poland among his sons. Each of the territorial subdivisions—defined by 1166 as Silesia, Great Poland, Mazovia, and Sandomir—was to be held as the hereditary domain of one of Bolesław's sons. The senior member of the entire dynasty was also to acquire temporary possession of Kraków and Pomerania and rule as grand prince over the entire loosely federated state of Poland.

The new arrangement, however, stimulated more divisiveness; the power of the grand prince of Kraków declined after the reign of Casimir II the Just (1177–94). For the next 150 years Poland suffered from increasing disunity and disintegration, aggravated by dynastic struggles and civil wars, foreign intervention and invasion, and the secession and conquest of its border regions.

Nevertheless, throughout this period of political division, the Piast lands retained their common church structure, language, and economy, all of which provided a basis for various

prince of Cujavia
1267–94
prince of Łeczycz
1288–94

princes to try to reunify the Polish kingdom. The first attempts failed; they were made by the Silesian princes Henry I and Henry II in the 1230s and by the prince of Great Poland Przemysł II (reigned at Kraków 1279–95 and as king of Poland 1295–96). But after Wenceslas II (Polish Wacław) of Bohemia gained control of two-thirds of the Polish lands and became king of Poland (1300–05), Władysław I the Short (Łokietek), a grandson of Conrad I of Mazovia, gained support from the gentry, the leading clergy, and some members of the upper nobility and won control of Sandomir and Kraków (by 1306); with the aid of Hungary and the pope, he became the ruler of Great Poland and also king of Poland (1320). Władysław I strengthened Poland substantially by forming close alliances, through the marriages of his children, with both Hungary and Lithuania.

His son Casimir III the Great assumed the throne of the restored Polish kingdom (1333) and further improved its position by coming to terms with his two major enemies, Bohemia and the Teutonic Knights. He accepted Poland's loss of Silesia and Pomerania, annexed Galicia, and regained Mazovia (1349). Casimir also consolidated his rule over the state by improving its economy and military and civil administrations, codifying the laws of Great and Little Poland, and founding a university at Kraków (1364).

Casimir's death, however, brought an end to his line of the Piast dynasty. Having developed the newly reunified Piast lands into a stable, prosperous, and powerful nation, he left his kingdom to his sister's son, Louis I of Hungary. After ruling from 1370 to 1382, Louis was succeeded by his daughter Jadwiga and her husband Jogaila (Władysław II Jagiełło), the grand duke of Lithuania. This succession marked the founding of the Jagiellon dynasty in Poland.

Piatigorsk (Russian S.F.S.R.): *see* Pyatigorsk.

Piatra-Neamţ, city, capital of Neamţ *judeţ* (county), northeastern Romania. It lies in the valley of the Bistriţa River and is surrounded by mountains. It is first documented in the 15th century as Piatra lui Crăciun, or Camena, a market town where fairs were held. Stephen the Great of Moldavia built the Church of St. John there in 1497–98, a classic example of ornate Moldavian architecture. The Bistriţa Monastery, founded at the beginning of the 15th century by Prince Alexander the Good and rebuilt in 1554 by Prince Alexander Lăpuşneanu, is 5 miles (8 km) west of Piatra-Neamţ. The city has a state theatre, a regional natural-science museum, and an archaeological museum of Neolithic pottery. The city's industries include a fertilizer plant, a pulp and paper mill, and several food-processing plants. Southeast of the city, in the Bistriţa River valley, are large factories producing synthetic fibre and nitrogenous fertilizer. Pop. (1986 est.) 109,393.

Piauí, *estado* ("state") of northeastern Brazil, bordered by the states of Ceará, Pernambuco, and Bahia, by a very small part of Tocantins on the east and south, and by Maranhão on the west and north. Covering less than 3 percent of Brazil's total area, it has an area of 96,886 square miles (250,934 square km). The state capital is Teresina, located at the confluence of the Parnaíba and Poti rivers. The state has a small Atlantic coastline of about 40 miles (64 km).

The settlement of Piauí in the 17th century came with the expansion of cattle ranching in the backlands of the interior, setting that area apart from the sugarcane agriculture of the coastal lowlands. The settlers arrived from the east, moving up the valley of the São Francisco River in Pernambuco and onward in a westward direction into Piauí. One of their leaders was Francisco Dias d'Avilla, who fought bloody battles with the Indians. Piauí was a part of the captaincy of Maranhão from 1718 until 1811, at which time Piauí became a separate administrative unit.

The Parnaíba River runs along the western boundary of the state, linking the Atlantic port of Parnaíba with the inland cities of Teresina and Floriano. As one moves away from the river and the coastal area toward the south and east, the land rises gradually in a series of plateaus edged by cliffs. On the border of the state of Ceará, the plateau is broken by a gap through which the Poti River runs.

Temperatures show little variation, averaging about 79° F (26° C) in the northern part of the state and a few degrees less in some of the higher elevations in the south. Annual rainfall is about 59 inches (1,500 mm) in the north, but, in the drier east and southeast, it averages about 20 inches (500 mm) a year. The dry months are in winter and spring.

The vegetation of the south and east is that of Brazil's semiarid northeastern backlands: a thorny, deciduous scrub woodland known as caatinga. This gives way in the north to deciduous forests interspersed with areas of palms and cocoa trees.

Piauí is sparsely populated. Most of its inhabitants are of mixed Indian and European ancestry, although blacks are found in the northeastern coastal zones, where the colonial sugar plantations once employed many African slaves. The largest city is Teresina, the capital. Other towns include Parnaíba, Floriano, Campo Maior, Picos, and Oeiras. The principal economic activities are the raising of livestock and the production of palm seeds, palm oil, and palm wax from the carnauba and babassu palm trees.

Standards of living in Piauí are among the lowest in Brazil. Infant mortality rates are very high, largely because of infectious and parasitic diseases. Hospital clinics reach about one-quarter of the population. The national government, however, is engaged in programs to control malaria and other endemic diseases.

Piauí had a few thousand primary schools in the late 20th century with a few hundred thousand students. In the lower-level secondary schools there were several thousand students. The state also had newspapers, radio stations, one theatre, and numerous cinemas.

Piauí is a somewhat isolated state, lacking good communications even with neighbouring states of the northeast. Teresina has rail connections across the state of Maranhão on the west to the port of São Luis; another railroad runs from Teresina northward through Campo Maior to the state's port of Luís Correia. One good all-weather federal highway runs from Teresina northeastward to Sobral in the state of Ceará. Several important new highways were under construction in the late 20th century by the federal government, including one from Teresina to Picos, another from Fortaleza in Ceará to Picos and southward toward Brasília, and an east-west trans-Amazonian road that will pass through Picos. Pop. (1989 est.) 2,616,900.

Piave River, Italian FIUME PIAVE, river in northeastern Italy. It rises on the slopes of Mount Peralba in the Carnic Alps near the Austrian frontier and flows southward to the Belluno basin and its gorge at Feltre, where it turns southeast to meander across the Venetian plain, reaching the Adriatic Sea at Cortellazzo, northeast of Venice. The river is 137 miles (220 km) long and has a drainage basin of 1,580 square miles (4,092 square km). The variations in its flow are extreme; during late summer most of the Piave's lower course is a bed of dry gravel. Until about 1500 the mouth of the Piave was farther south, near Treporti on the lagoon of Venice. After several changes, the river mouth settled near Caorle until a disastrous flood in 1683, when it shifted to its present outlet. In 1966, swollen by rains, the river burst its dikes in a major flood. The Piave's upper valley has major hydroelectric stations at Pieve di Cadore and Fadalto, while downstream its waters are used extensively for irrigation. In World War I the Piave River became the main line of Italian defense after the Austrian breakthrough at Caporetto in 1917. Despite concerted Austrian attacks in 1918, the line held, and the Austrians were decisively defeated at the Battle of Vittorio Veneto at the end of October 1918.

Piazza Armerina, town and episcopal see, Enna *provincia,* central Sicily, Italy, west-southwest of Catania. Among the many historic monuments in the town are the 17th-century cathedral, with a 14th-century campanile, the Baroque palace of Trigona della Floresta, the Church of San Rocco (1613), the Civic Museum, the 14th-century four-sided castle, and the well-preserved remains of the Roman villa of Casale. The Norman count Roger, associated with the foundation of the town in the 11th century, is said to have received from Pope Nicholas II the Byzantine statue "Madonna delle Vittorie" ("Our Lady of Victories") that is in the cathedral and that is borne through the streets on the Feast of the Assumption. There are sulfur mines in the neighbourhood, and nougat is produced in the town. Pop. (1988 est.) mun., 22,288.

Piazzetta, Giovanni Battista, also called GIAMBATTISTA PIAZETTA (b. Feb. 13, 1682, Venice [Italy]—d. April 28, 1754, Venice), painter, illustrator, and designer who was one of the outstanding Venetian artists of the 18th century. His art evolved from Italian Baroque traditions of the 17th century to a Rococo manner in his mature style.

Piazzetta began his career in the studio of his father, Giacomo, a woodcarver. Soon after assisting the latter to carve the still-surviving bookcases of the library of the Church of Santi Giovanni e Paolo at Venice, he abandoned the family profession and began to study painting under Antonio Molinari. In about 1703 he went to Bologna, where he worked in the studio of Giuseppi Maria Crespi. He was back in Venice by 1711 and continued to work there until his death.

Little is known of the dating of Piazzetta's paintings, especially those of his youth. His "St. James Led to Martyrdom" (Venice) dates to 1717; at this period he was a power-

"Fortune Teller," oil painting by Piazzetta, 1740; in the Accademia, Venice

Giraudon—Art Resource, New York City

ful influence on the young Giovanni Battista Tiepolo, who was to become the most famous Venetian painter of the 18th century. In about 1725–27 he undertook his only ceiling painting, the "Glorification of St. Dominic," for the Chapel of the Sacrament in Santi Giovanni e Paolo. The "Ecstasy of St. Francis," perhaps his finest religious work, dates from about 1732, and some three years later he was commissioned to execute an "Assumption" for the elector of Cologne. The celebrated "Fortune Teller" is dated 1740. "The Pastoral" and the "Idyll by the Seashore," both in the same Rococo-pastoral vein, must have been painted about the same time or a little before. In his last years he carried out a number of large-scale decorations with subjects taken from classical history.

In 1727 Piazzetta was elected a member of the Bolognese Clementina Academy, and, on the foundation of the Venetian Academy in 1750, he was made its first director and teacher of drawing from the nude. He was a very slow worker and in spite of his popularity was compelled to produce innumerable drawings for sale to support his large family.

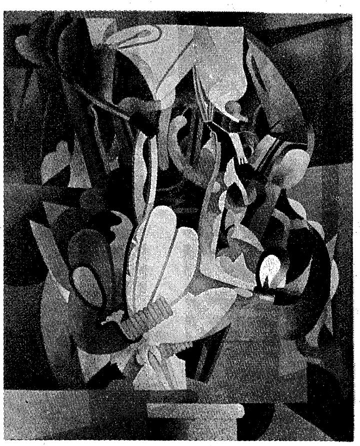
Piazzi, Giuseppe (b. July 16, 1746, Ponte di Valtellina, Lombardy, Habsburg crown land [Italy]—d. July 22, 1826, Naples), Italian astronomer who discovered (Jan. 1, 1801) and named the first asteroid, or "minor planet," Ceres.

Piazzi became a Theatine monk in about 1764 and a professor of theology in Rome in 1779, and in 1780 he was appointed professor of higher mathematics at the Academy of Palermo. Later, with the aid of the Viceroy of Sicily, he founded the Observatory of Palermo. There he produced his great catalog of the positions of 7,646 stars and demonstrated that most stars are in motion relative to the Sun. There also he discovered Ceres and the high proper motion of the important double star 61 Cygni.

Pibul Songgram (Thai premier): *see* Phibunsongkhram, Luang.

Picabia, Francis (b. Jan. 22, 1879, Paris, Fr.—d. Nov. 30, 1953, Paris), French painter, illustrator, designer, writer, and editor who was successively involved with the Cubist, Dadaist, and Surrealist movements.

After studying at the École des Beaux-Arts and the École des Arts Décoratifs, Picabia worked for nearly six years in an Impressionist mode akin to that of Alfred Sisley. In 1911 he became a member of the Section d'Or ("Golden Section"), a Cubist group. Also in 1911 he met the artist Marcel Duchamp, and Picabia's rejection of the unemotional themes of Cubism for intricate still lifes and symbolic figures is thought to have resulted from this association.



"I See Again in Memory My Dear Udnie," oil on canvas by Francis Picabia, 1914, perhaps begun 1913, 8 ft 2½ in. × 6 ft 6¼ in. (2.5 × 2m); in the Museum of Modern Art, New York City

By courtesy of the Museum of Modern Art, New York City, Hillman Periodicals Fund; © S.P.A.D.E.M., Paris, 1981

In 1913 he was in New York City, where he exhibited at the Armory Show and at Alfred Stieglitz' Photo-Secession Gallery. He contributed to the proto-Dadaist review *291* and also to Stieglitz' magazine *Camera Work*, where he promulgated Amorphism, a satire on current art trends. In 1917 Picabia and the wealthy poet-scholar-collector Walter Arensberg launched the periodical *391*, a continuation of *291*. With Marcel Duchamp, Marius de Zayas, and Man Ray, he was part of a Dada-like group of European artists living in New York City.

In 1917 Picabia returned to Europe and was active in Barcelona, Paris, and Zürich, where he collaborated in 1918 with Tristan Tzara on the fourth and fifth issues of the magazine *Dada*. In Paris in 1920 he started a review called *Cannibale*. After Dadaism broke up about 1921, he followed the poet André Breton into the Surrealist movement. Among his many literary works, *Poèmes et dessins de la fille née sans mère* (1918; "Poems and Drawings of a Daughter Born Without a Mother") is generally considered the most important.

Picard, (Charles-)Émile (b. July 24, 1856, Paris, Fr.—d. Dec. 11, 1941, Paris), French mathematician whose theories did much to advance research into analysis, algebraic geometry, and mechanics.

Émile Picard

H. Roger-Viollet

Picard became a lecturer at the University of Paris in 1878 and a professor at the University of Toulouse the following year. From 1881 to 1898 he held various posts with the University of Toulouse and the École Normale Supérieure, Paris, and in 1898 he was appointed professor at the University of Paris. In 1917 he was elected permanent secretary for the mathematical sciences in the Academy of Sciences, Paris.

Picard worked on quadratic forms, on Fuchsian and Abelian functions, and on the allied theories of discontinuous and continuous groups of transformation; he also discovered hyperfuchsian and hyperabelian functions. His work led to a study of the algebraic manifold now known as the Picard variety, which plays a fundamental role in algebraic geometry. In 1879 he proved the theorem known by his name, that an integral function of the complex variable takes every finite value, with one possible exception. His theorem became the starting point for many important studies in the theory of complex functions.

Picard introduced a new means of proving the existence of solutions to differential equations: the method of successive approximations. His method proved so useful that for ordinary differential equations it replaced the Cauchy–Lipschitz method. He also created a theory of linear differential equations, later extended by his pupil Ernest Vessiot, analogous to the Galois theory of algebraic equations.

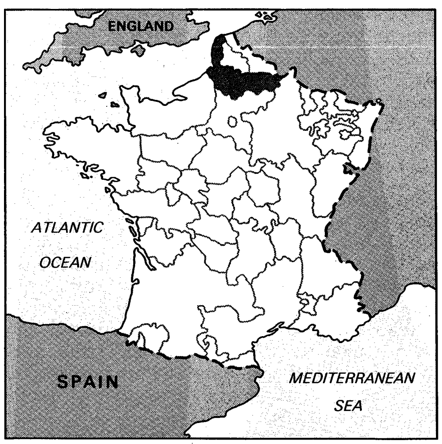
Inspired by Niels H. Abel of Norway and Bernhard Riemann of Germany, Picard's study of the integrals attached to algebraic surfaces and the related topological questions developed into an important part of algebraic geometry, with varied applications to topology and function theory. His research was expounded in the treatise that he published with Georges Simart, *Théorie des fonctions algébriques de deux variables indépendantes*, 2 vol. (1897, 1906; "Theory of Algebraic Functions of Two Independent Variables"). His studies of harmonic vibrations, coupled with the contributions of Hermann Schwarz of Germany and Henri Poincaré of France, marked the beginning of the theory of integral equations.

Picard, Jean (b. July 21, 1620, La Flèche, Fr.—d. July 12, 1682, Paris), French astronomer who first accurately measured the length of a degree of a meridian (longitude line) and from that computed the size of the Earth.

Picard became professor of astronomy at the Collège de France, Paris, in 1655. His measurement of the Earth was used by Sir Isaac Newton to verify his theory of gravitation. In 1671 Picard went to the observatory of the noted 16th-century Danish astronomer Tycho Brahe at Hven Island, Sweden, to determine its exact location so that Brahe's observations could be more precisely compared with those made elsewhere. He brought back copies of the originals of Brahe's principal work.

Picard is also given credit for the introduction of telescopic sights and the use of pendulum clocks as contributions to greater precision in astronomical observations. In 1675 he made the first recorded observation of barometric light, the light that appears in the vacuum above the mercury in a barometer when the barometer is moved about. In 1679 Picard founded and became editor of *La Connaissance des temps ou des mouvements célestes* ("Knowledge of Time or the Celestial Motions"), the first national astronomical ephemeris, or collection of tables giving the positions of celestial bodies at regular intervals.

Picardy, French PICARDIE, *région de programme* ("planning region") encompassing the northern French *départements* of Oise, Somme, and Aisne and roughly coextensive with the historical region of Picardy. The capital is Amiens. Picardy has an area of 7,490 square miles (19,399 square km) and is bounded by the *départements* of Pas-de-



The *gouvernement* of Picardy in 1789

Calais and Nord to the north, Ardennes and Marne to the east, Seine-et-Marne and Seine-Saint-Denis to the south, and Eure and Seine-Maritime to the west. Somme borders the English Channel to the west.

Since Picardy was never unified in the feudal period, its boundaries are disputable. Linguistically, Picardy extended beyond its geographic boundaries to Artois, Cambrésis, Tournésis, and parts of Flanders and Hainaut; ecclesiastically it embraced not only the medieval dioceses of Amiens, Noyon, and Laon but also the northern parts of those of Beauvais and of Soissons. The province of Picardy from the 16th century to the end of the ancien régime in 1789 comprised the Somme River basin from Saint-Quentin to the Channel, the basins of the Serre and of the upper Oise, and Montreuil on the Canche beyond the Authie.

Occupied by the Salian Franks in the 5th century, Picardy was divided in the feudal period and encompassed six countships: Boulogne, Montreuil, Ponthieu, Amiénois, Vermandois, and Laonnois. King Philip II Augustus gradually united Amiénois and Vermandois to his domain (from 1185), but Ponthieu was held by the English as a fief almost continuously from 1279 to 1360 and then as an outright possession until 1369. The dukes of Burgundy acquired Ponthieu, the Somme towns, and Montdidier under the Treaty of Arras in 1435. Reconquered for France by Louis XI in 1477, Picardy was thereafter a frontier area invaded frequently from the Habsburg Netherlands until the French acquisition of Artois and southern Hainaut in 1659. Some of the bloodiest fighting in World War I occurred in Picardy (reflected in the melancholy English popular song "Roses of Picardy" [1916]). It was also the scene of bitter fighting in World War II—in May 1940 and August–September 1944.

Picardy belongs to the Paris Basin and is essentially flat; elevations lie below 1,000 feet (300 m). The calcareous plateaus of Laon, Soissons, and Valois rise to the east. An oceanic climate prevails.

The population declined by 19 percent between 1861 and 1946, as did that of most of rural France during this period. It has subsequently grown at a rate above the national average. Demographic recovery has favoured Oise over Aisne and Somme. Oise has benefited from its proximity to Paris and has a large population of migrants. Much of the population lives in towns with fewer than 15,000 inhabitants. The countryside is densely populated.

Agriculture is highly mechanized. The average farm is large for France, exceeding 100 acres (40 hectares); crops include sugar beets, wheat, barley, and potatoes. Animal husbandry, which has been adversely affected by the policies of the European Economic Community, is of declining importance. Metalworking is the leading industry. Automotive parts are manufactured in Montataire, Beauvais, and Amiens. Bicycles, airplanes, agricultural machinery, and textiles are also produced. Picardy imports coal from the *département* of Nord and has benefited from the decentralization of Parisian industries since 1950. Pop. (1988 est.) 1,783,400.

picaresque novel, early form of novel, usually a first-person narrative, relating the adventures of a rogue or low-born adventurer (Spanish *pícaro*) as he drifts from place to place and from one social milieu to another in his effort to survive. In its episodic structure the picaresque novel resembles the long, rambling romances of medieval chivalry, to which it provided the first realistic counterpart. Unlike the idealistic knight-errant hero, however, the picaro is a cynical and amoral rascal who, if given half a chance, would rather live by his wits than by honourable work. The picaro wanders about and has adventures among people from all social classes and professions, often just barely escaping punishment for his own lying, cheating, and stealing. He is a casteless outsider who feels inwardly unrestrained by prevailing social codes and mores, and he conforms outwardly to them only when it serves his own ends. The picaro's narrative becomes in effect an ironic or satirical survey of the hypocrisies and corruptions of society, while also offering the reader a rich mine of observations concerning people in low or humble walks of life.

The picaresque novel originated in Spain with *Lazarillo de Tormes* (1554; doubtfully attributed to Diego Hurtado de Mendoza), in which the poor boy Lazaro describes his services under seven successive lay and clerical masters, each of whose dubious character is hidden under a mask of hypocrisy. The irreverent wit of *Lazarillo* helped make it one of the most widely read books of its time. The next picaresque novel to be published, Mateo Alemán's *Guzmán de Alfarache* (1599), became the true prototype of the genre and helped establish realism as the dominant trend in the Spanish novel. The supposed autobiography of the son of a ruined Genoese moneylender, this work is richer in invention, variety of episode, and presentation of character than *Lazarillo,* and it too enjoyed extraordinary popularity.

Among *Guzmán's* numerous successors were several short novels by Miguel de Cervantes in the picaresque manner, notably *Rinconete y Cortadillo* (1613) and *El Coloquio de los perros* (1613; "Colloquy of the Dogs"). Francisco López de Úbeda's *La picara Justina* (1605; "Naughty Justina") tells the story of a woman picaro who deceives her lovers just as the picaro does his masters. Francisco Gómez de Quevedo's *Vida del Buscón* (1626; "The Life of a Scoundrel") is a masterpiece of the genre, in which the profound psychological depiction of a petty thief and swindler is underlain by a deep concern for moral values. After *Buscón* the picaresque novel in Spain declined gradually into the novel of adventure.

In the meantime, however, the picaro had made his way into other European literatures after *Lazarillo de Tormes* was translated into French, Dutch, and English in the later 16th century. The first picaresque novel in England was Thomas Nashe's *Unfortunate Traveller, or, the Life of Jacke Wilton* (1594). In Germany the type was represented by H.J. von Grimmelshausen's *Simplicissimus* (1669). In England the female picaro was revived in Daniel Defoe's *Moll Flanders* (1722), and many picaresque elements can be found in Henry Fielding's *Jonathan Wild* (1725), *Joseph Andrews* (1742), and *Tom Jones* (1749), and Tobias Smollett's *Roderick Random* (1748), *Peregrine Pickle* (1751), and *Ferdinand, Count Fathom* (1753). The outstanding French example is Alain René Lesage's *Gil Blas* (1715–35), which preserves a Spanish setting and borrows incidents from forgotten Spanish novels but portrays a gentler, more humanized picaro.

In the mid-18th century the growth of the realistic novel with its tighter, more elaborated plot and its greater development of character led to the final decline of the picaresque novel, which came to be considered somewhat inferior in artistry. But the opportunities for satire provided by the picaresque novel's mingling of characters from all walks of life, its vivid descriptions of industries and professions, its realistic language and detail, and above all its ironic and detached survey of manners and morals helped to enrich the realistic novel and contributed to that form's development in the 18th and 19th centuries. Elements of the picaresque novel proper reappeared in such mature realistic novels as Nikolay Gogol's *Dead Souls* (1842–52), Mark Twain's *Huckleberry Finn* (1884), and Thomas Mann's *Confessions of Felix Krull* (1954).

Picasso, Pablo (Ruiz y) (b. Oct. 25, 1881, Málaga, Spain—d. April 8, 1973, Mougins, Fr.), Spanish expatriate painter, sculptor, printmaker, ceramicist, and stage designer, one of the greatest and most influential artists of the 20th century and the creator (with Georges Braque) of Cubism.

A brief treatment of Pablo Picasso follows. For full treatment, *see* MACROPAEDIA: Picasso.

Even Picasso's earliest drawings (*c.* 1890), executed when he was about 10 years old, showed an exceptional technical facility. When the family moved to Barcelona in October 1895, Picasso attended La Lonja, the school of fine arts there (1896), and the Royal Academy of Fine Arts of San Fernando in Madrid (1897). In October 1900 he made the first of three visits to Paris, where he established himself finally in April 1904. During the intensely creative years 1899–1905, Picasso's style varied considerably. At the start, he used strong colours in a Postimpressionist manner (1900–01). Then he painted predominantly in blue (the so-called Blue Period; late 1901–spring 1904). Until mid-1901 his principal subjects were lively scenes of popular and bourgeois life (cabarets, racecourses, dance halls, etc.); toward the end of 1901, however, Picasso's world became that of the suffering victims of society: prostitutes, beggars, drunkards, etc. In 1904 his gloom lifted, and he looked freshly at humanity with tenderness and admiration and adopted warmer colours and a more harmonious, classical style of draftsmanship; during this Rose Period, his favourite subjects were dancers and acrobats, particularly the Harlequin figure of the commedia dell'arte.

Between the end of 1906 and the spring of 1907, while influenced by the painting of Paul Cézanne, by Greco-Iberian art, and by African sculpture, Picasso produced a painting later called "Les Demoiselles d'Avignon" that constitutes a violent break with tradition. This painting pointed the way toward Cubism, a new pictorial style that Picasso and his friend Braque began to develop side by side and in close friendship. They disregarded the conventional means used for creating an illusion of reality, such as one-point perspective, chiaroscuro, and the definition of form and colour by light, aiming instead to represent objects more conceptually by breaking them into geometrical units, or small cubes, and by depicting a single object on the same canvas from a multiplicity of angles. Picasso was to continue elaborating and perfecting this style until about 1925. Simultaneously, from about 1915 onward, he began to work in the opposite direction, depicting figures of a subtly detached classicism—linear, sculptural, and monumental.

After 1925 Picasso began to depict emotionally charged bodies and heads whose dislocations give rise to double images and pictorial metaphors. A private Surrealist vocabulary of powerful symbols (*e.g.,* the Minotaur) emerged in the 1930s to express his personal dilemmas and distress. Picasso's interest in sculpture, dormant since 1905, revived at this time. The outbreak of the Spanish Civil War in 1936 inspired the great and harrowing mural painting "Guernica" (1937), the first reference in his work to political events. In 1944 Picasso joined the Communist Party, and in 1949 his "Dove" lithograph was adopted as the symbol of the World Peace Congress. In the postwar years much of Picasso's work centred on the themes of war and peace and man's right to leisure and peaceful relaxation. After 1955 the theme of the artist and his magic powers assumed great importance in his work.

Picasso's powerful inventive gifts led him to work in many fields. He produced (1917–24) some famous decors for Sergey Diaghilev's Russian ballet company (*e.g., Parade, Le Tricorne, Pulcinella*). He also made significant technical innovations in lithography and linocutting and produced a great quantity of painted pottery.

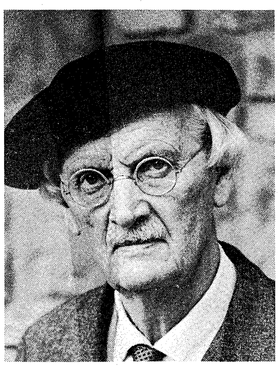
Piccard, Auguste (b. Jan. 28, 1884, Basel, Switz.—d. March 24, 1962, Lausanne), Swiss-born Belgian physicist notable for his exploration of both the upper stratosphere and the depths of the sea in ships of his own design. In 1930 he built a balloon to study cosmic rays. In 1932 he developed a new cabin design for balloons and in the same year ascended to 16,916 m (55,000 feet). He completed a bathyscaphe in 1948 and later made several dives with his son Jacques.

Piccard was born into a family of Swiss scholars. His father, Jules Piccard, was a professor of chemistry at the University of Basel. Auguste and his twin brother, Jean, enrolled together at the Swiss Federal Institute of Technology, in Zürich, where they studied physics and chemistry, respectively. When they became doctors of science, both decided to teach in universities; Jean, the chemist, went first to Munich, then to Lausanne, then to the United States; and Auguste, the physicist, stayed on at the Institute. In 1919 Auguste married the daughter of a French historian at the Sorbonne.

Piccard became interested in balloon ascents as a means of making experiments. He participated in many important research studies, and when the University of Brussels in 1922 created a chair for applied physics, Piccard, who was also a mechanic and an engineer, readily accepted the post. Having studied cosmic rays, he conceived of an experiment for observing them at 16,000 or more metres in the upper atmosphere. Previous ascents had shown that the stratosphere could be fatal and that to penetrate the isothermal layer, with its low pressure, a revolutionary balloon would be necessary. He built such a balloon in 1930, with Belgian financing. Its main innovative feature was an airtight cabin, equipped with pressurized air; today this technique has become commonplace on airplanes. Another innovation was the design of a very large balloon having sufficient ascent strength so that, on departure, it need not be completely filled. On May 27, 1931, Piccard and Paul Kipfer reached an altitude of 15,781 m (51,762 feet), where the atmospheric pressure is about $^1/_{10}$ that at sea level. Upon returning to the surface, the scientist-adventurers were received triumphantly in Zürich and then Brussels.

In 1932, in a new cabin, this time equipped with a radio, Piccard was able to reach an altitude of 16,940 m (55,563 feet). In 1933, using the same technique but with bigger balloons, other balloonists rose to 18,500 m (60,700 feet) in the Soviet Union and 18,665 m (61,221 feet) in the United States.

As a child, Piccard had been fascinated by accounts of marine fish and thought that man should also descend into the depths. Now, after his aeronautical successes, he wanted to build a device capable of resisting the pressures of the ocean depths, the bathyscaphe.



Auguste Piccard, 1961
Horst Tappe—EB Inc.

Depth-resistant cabins are, of necessity, heavier than water. Up to that time, around 1948, they had been suspended from a cable, but at great depths this procedure was not dependable. Piccard revolutionized the dive by the principle of the balloon. Just as a lighter-than-air balloon carried the nacelle, or balloon gondola, a lighter-than-water float would support the cabin. Just as the balloon required a release of ballast to rise, the bathyscaphe would release weight in order to ascend after having completed its dive. Air, because it is too easily compressed, was not used in the floats; Piccard chose gasoline.

World War II interrupted the construction of the bathyscaphe, which was not completed until 1948. In October 1948 an unpiloted trial dive with the bathyscaphe F.N.R.S. 2 was conducted successfully. The cabin withstood the 1,400-metre (4,600-foot) pressure perfectly, but the float was severely damaged by a heavy swell of water that it encountered after the dive. The bathyscaphe project was subsequently troubled by various difficulties until Jacques Piccard, Auguste's son, intervened.

Jacques, an assistant in economics at the University of Geneva, had already conducted the negotiations with the French government. Then, while in Trieste for the purpose of preparing a study of that port, he received an unexpected offer from that city's local industry to build a new bathyscaphe. Thus, in August 1953, two bathyscaphes competed in the Mediterranean, at Toulon, Fr., and at Naples: the French craft F.N.R.S. 3 descended to 2,100 m (6,900 feet), and the Piccards' *Trieste* went down to 3,150 m (10,330 feet). At the age of 69, Auguste Piccard had realized his dream. His son, abandoning economics, followed in his father's footsteps and collaborated in future work with bathyscaphes. In 1954 Piccard retired from teaching and left Brussels for Switzerland. (P.de L./Ed.)

BIBLIOGRAPHY. In French, see Pierre de Latil and Jean Rivoire, *Le Professeur Auguste Piccard* (1962). The same authors' *A la recherche du monde marin* (1954; *Man and the Underwater World,* 1956), deals with the explorations undertaken by Auguste and Jacques. English translations of Auguste Piccard's writings are: *Earth, Sky and Sea* and *In Balloon and Bathyscaph* (both 1956).

Piccard, Jacques (-Ernest-Jean) (b. July 28, 1922, Brussels), Swiss oceanic engineer, economist, and physicist, who helped his father, Auguste Piccard, build the bathyscaphe for deep-sea exploration and who also invented the mesoscaphe, an undersea vessel for exploring middle depths.

He was born in Brussels while his Swiss-born father was professor at the University of Brussels. After graduating from the École Nouvelle de Suisse Romande in Lausanne, Switz., in 1943, he studied at the University of Geneva, taking a year off in 1944–45 in order to serve with the French First Army. Upon receiving his licentiate in 1946, he taught at the university for two years before entering private teaching.

Meanwhile, he was helping his father to design bathyscaphes and in 1953 accompanied him in the *Trieste* on a dive of 10,168 feet (3,099 m) off the island of Ponza, Italy. In 1956 Jacques Piccard went to the United States seeking funding; two years later the U.S. Navy bought the *Trieste* and retained him as a consultant. On Jan. 23, 1960, he and Lieutenant Don Walsh of the U.S. Navy set a new submarine depth record by descending 35,800 feet (10,912 m) into the Mariana Trench in the Pacific Ocean using the *Trieste.* In the early 1960s, working with his father, he designed and built the mesoscaphe (capable of carrying 40 tourists) for underwater observation through portholes. In 1966 in the bathyscaphe he conducted research in the Gulf Stream for the U.S. Navy. In his later career he was consultant scientist for several private American organizations for deep-sea research, including the Grumman Aircraft Engineering Corporation, New York (1966–71).

Piccard, Jean-Felix (b. Jan. 28, 1884, Basel—d. Jan. 28, 1963, Minneapolis, Minn., U.S.), Swiss-born American chemical engineer and balloonist who conducted stratospheric flights for the purpose of cosmic-ray research.

The twin brother of Auguste Piccard, he graduated (1907) from the Swiss Federal Institute of Technology with a degree in chemical engineering and then earned a doctorate in natural science (1909). He taught at the universities of Munich (1914), Lausanne (1914–16, 1919–25), and Chicago (1916–18). He became a U.S. citizen (1931) and lectured in aeronautical engineering at the University of Minnesota (1936–52) until his retirement.

He made his first balloon ascent in 1913 with his twin brother. On Oct. 23, 1934, with his wife, he made the first successful stratosphere flight through clouds, ascending to a height of 11 miles (18 km). In 1937 he made an ascent of 11,000 feet (3,350 m) to test a metal gondola attached to a cluster of 98 balloons. Later he developed a frost-resistant window for balloon gondolas and an electronic system for emptying ballast bags.

Where the same name may denote a person, place, or thing, the articles will be found in that order

Piccinino, Niccolò (b. 1386, Perugia, Papal States—d. 1444, Milan), Italian soldier of fortune who played an important role in the 15th-century wars of the Visconti of Milan against Venice, Florence, and the pope.

A butcher's son, Piccinino became a soldier and eventually joined the forces of the condottiere Braccio da Montone, whose daughter he married. When Braccio was killed in battle (1424), Piccinino took over command of his company, and the following year, with the young soldier of fortune Francesco Sforza, he entered the employ of Duke Filippo Maria Visconti of Milan. After brief service against Venice and Florence, he was dispatched to fight Pope Eugene IV (1434) and helped to drive the latter out of Rome. In 1438 Piccinino, battling the Venetians at Lake Garda, faced Sforza, now the Venetian captain general. After destroying a Venetian fleet on the lake, Piccinino was surrounded by the enemy and barely escaped—according to one story, concealed in a sack.

Invading Tuscany in 1440, Piccinino suffered a crushing defeat by the Florentines at Anghiari near Florence, leading his Visconti employer to sue for peace. The following year Piccinino, so ill that he could hardly ride a horse, had a last confrontation with Sforza, who was now fighting for the pope and King Alfonso of Naples, in the Marches in east-central Italy. After a preliminary setback, Piccinino was summoned to Milan; as soon as he left, Sforza attacked, capturing Piccinino's son Francesco and inflicting a decisive defeat. Piccinino died a few days after receiving the news, a frustrated man.

Piccinni, Niccolò (b. Jan. 16, 1728, Bari, Kingdom of Naples—d. May 7, 1800, Passy, Fr.), one of the outstanding opera composers of the Neapolitan school, who wrote in both the comic and the serious styles but who, in the century following his death, was chiefly remembered as the rival of Gluck. He studied in Naples, where he produced several operas. The masterpiece of his early years was the opera buffa *La buona figliuola,* or *La cecchina* (1760), on a libretto by Goldoni based on Richardson's novel *Pamela.* It was written in the new style, later epitomized in the operas of Mozart, that incorporated serious or sentimental subject matter into the flexible musical style of the older, farcical, opera buffa.

In 1776 he was invited to Paris by supporters of the Italian operatic style, who opposed the opera reforms of Gluck. Piccinni was

Piccinni, engraving by J.F. Schröter

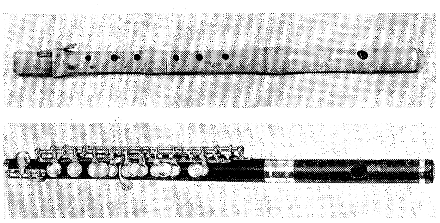
thus drawn into a continuation of the earlier controversy between supporters of Italian opera and supporters of French opera, the "Guerre des Buffons." Although Piccinni admired Gluck's operas and steadfastly refused to encourage his own partisans, the warring factions nevertheless created a rivalry. Each composer's work was compared unfavourably with that of the other, although their aims were quite dissimilar: Piccinni maintained the traditional sequence of arias and recitatives, whereas Gluck was laying the foundations of an operatic reform. At the height of the controversy, both composers were commissioned to write operas on the subject *Iphigénie en Tauride*. Gluck's famous opera was given in 1779, Piccinni's in 1781. After Gluck's departure from Paris in 1779, Piccinni continued to produce operas but was deprived of his post at the École Royale de Musique in 1789, during the Revolution. He then returned to Naples but went to Paris again in 1798 before retiring to Passy.

piccolo, in full FLAUTO PICCOLO (Italian: "small flute"), highest pitched woodwind instrument of orchestras and military bands. It is a small transverse (horizontally played) flute of conical or cylindrical bore, fitted with Böhm-system keywork and pitched an octave higher than the ordinary concert flute.

The piccolo's compass extends three octaves upward from the second D above middle C. Its orchestral use dates from the late 18th century, when it replaced the flageolet (also called flauto piccolo). A six-keyed piccolo in D♭ was



(Top) One-keyed English piccolo, in the Pitt-Rivers Museum, Oxford; (bottom) contemporary wood piccolo

Piccolomini FAMILY, noble family prominent in Sienese politics from the 12th century as leaders of the Guelf (papal) party and as operators of a banking firm with branches in France and England as well as in Italy.

Tracing their origins, according to family legend, to Lars Porsena, king of Clusium, the Piccolomini by the 12th century played an important role in the aristocratic consular commune of Siena. In the 13th century the family reached its commercial apogee, despite being twice banished from their native city, a Ghibelline (imperial) party stronghold. They managed to escape the economic crisis of the 14th century, thanks to large investments in land, and in 1458 were named counts palatine by the Holy Roman emperor Frederick III. The family included soldiers, prelates, literary men, and two popes—Enea Silvio, who became Pius II (1458–64), and his nephew Francesco, who was Pius III (1503).

Piccolomini, Enea Silvio (pope): *see* Pius II.

Piccolomini, Francesco Todeschini (pope): *see* Pius III.

Piccolomini-Pieri, Ottavio, DUCA (duke) D'AMALFI, REICHSFÜRST (imperial prince) (b. Nov. 11, 1599, Florence—d. Aug. 11, 1656, Vienna), general and diplomat in the service of the House of Habsburg during the Thirty Years' War (1618–48) and one of the

Ottavio Piccolomini, an anonymous engraving, *c.* 1640
Archiv fur Kunst und Geschichte, West Berlin

imperial generalissimo Albrecht von Wallenstein's most trusted lieutenants. His skills both on the battlefield (Thionville, 1639) and at the conference table (Congress of Nürnberg, 1649) made him an invaluable servant of the Austrian and Spanish crowns.

Born into a noble Tuscan family, Piccolomini entered the Habsburg service in 1616. After campaigning in Bohemia and Hungary (from 1618), he returned to Italy in 1623 as a volunteer in Spanish pay. In 1627, Piccolomini began his association with Wallenstein, whose bodyguard he soon commanded. From 1627 to 1629, he was used on a number of the generalissimo's diplomatic missions and, after the outbreak of the War of the Mantuan Succession, in which Austria opposed France, he went to Italy with both military and diplomatic powers (1629). Two years later, however, he was forced to sign an unfavourable peace in order to give Austria a free hand against the Swedes in the north.

After his return to Germany, Piccolomini, who was instrumental in Wallenstein's reinstatement as generalissimo and almost turned the Battle of Lützen (November 1632) into an imperial victory, became increasingly disillusioned when his superior bequeathed favours and promotions on other men. He played a leading role with the Austrian general Matthias von Gallas in the generals' conspiracy that toppled and assassinated Wallenstein on Feb. 25, 1634. Although Emperor Ferdinand II rewarded Piccolomini richly, he gave the supreme command to Gallas. After the victory at Nördlingen (Sept. 6, 1634), which freed Bavaria, Piccolomini returned to the Spanish service and campaigned against the French in the Netherlands (1635–39), winning the spectacular victory of Thionville (June 1639), for which he was created duke of Amalfi. He then reentered the Austrian Army, but, after his defeat at the second Battle of Breitenfeld (November 1642), he again returned to the Spanish service in the Netherlands. Finally, in May 1648, the emperor Ferdinand III named him commander in chief, and Piccolomini thus conducted the last campaign of the Thirty Years' War. The next year he served as head of the imperial delegation to the Congress of Nürnberg, which negotiated issues left unsettled by the Peace of Westphalia (1648). Named imperial prince (*Reichsfürst*) in 1650, he died in the Austrian capital six years later.

Piceni, English PICENES, Early Iron Age inhabitants of the Adriatic coast of Italy from Rimini to the Sangro River. Men and women dressed in wool; men wore armour, weapons, and ornaments of bronze or iron; women had numerous fibulae, torques, bracelets, girdles, and ornamental pendants. They had two main centres, one at Novilara in the north, and another around Belmonte and Fermo farther south. The Piceni traded with the Greeks as early as the 7th century BC, but there is little evidence of trade with Etruria, except at the inland site of Fabriano. The evidence suggests that Piceni were warlike, with little artistic ability of their own, but wealthy enough to sustain a flourishing trade. In 268 BC their territory was annexed by Rome.

Pichegru, (Jean-)Charles (b. Feb. 16, 1761, near Arbois, Fr.—d. April 5, 1804, Paris), general of the French Revolutionary Wars who played a leading role in the conquest of the Austrian Netherlands and Holland (1794–95); he subsequently ruined his reputation by conspiring with counterrevolutionaries (1795) and against Napoleon Bonaparte (1804).

Born into a peasant family, Pichegru taught mathematics at the military academy at Brienne before he joined an artillery regiment in 1780. He was sergeant major at the outbreak of the Revolution in 1789 and in 1792 became lieutenant colonel. Appointed commander of the Army of the Rhine in October 1793, he helped Gen. Lazare Hoche drive the Austro-Prussian armies from Alsace in December. Nevertheless, Pichegru was jealous of Hoche. By convincing the government that Hoche was a traitor, he managed to have his rival imprisoned (March 1794). Pichegru was given command of the 150,000-man Army of the North.

In April 1794, Pichegru and Gen. Jean-Baptiste Jourdan, commander of the Army of the Moselle, launched an invasion of the Austrian Netherlands, capturing Amsterdam by January 1795. Returning to Paris, he was hailed as a saviour of his country. Although he was appointed commander of the armies of the Rhine and Moselle in mid-1795, he had already begun to turn against France's republican regime. He initiated secret contacts with agents of French émigrés in August.

Pichegru, portrait by C.H. Hodges
H. Roger-Viollet

In March 1796, Pichegru resigned his commission. Elected president of the Council of Five Hundred (the lower chamber of the legislature) in May 1797, he sided with the royalist deputies. Nevertheless, word of his previous treasonable contacts reached Paris, and when the royalists were expelled from the government in the coup d'etat of 18 Fructidor (Sept. 4, 1797), Pichegru was arrested and deported to the Guianas. Escaping from the islands, he made his way to Germany, then to England. In January 1804, he secretly entered France and began plotting to overthrow Bonaparte's military regime. Arrested in Paris on February 28, he was found strangled with his cravat in Temple prison on April 5; it is not known whether he was murdered or committed suicide.

pichhwāi, cloth hanging used as a backdrop for images worshipped in temples of the Hindu Vallabhācārya sect, who are ardent devotees of the god Krishna. *Pichhwāi*s, which form a part of the temple decor, are frequently changed according to the day, the season, and the occasion. Some are fairly large and are made from such costly fabrics as velvet and brocade, while others are smaller and are made of cotton cloth decorated with embroidery or

Detail of a *pichhwāi* showing landscape and female figures, from Andhra Pradesh, 18th century; in the Prince of Wales Museum of Western India, Bombay
P. Chandra

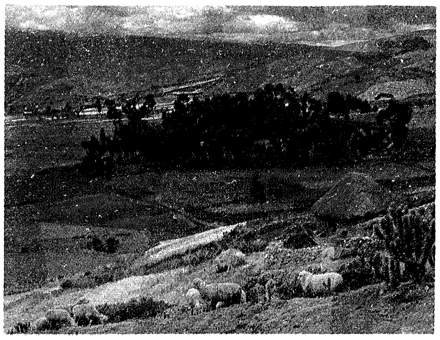
painting. In the 18th century the decoration consisted mainly of landscapes with small animal and human figures; later, large human figures began to predominate.

Among the main themes are episodes from the life of Krishna, such as the lifting of Mt. Govardhana, the stealing of the clothes of the bathing milkmaids, and the divine dance. Representations of rituals and festivals are also found. Although *pichhwāi*s were painted at several centres in Rājasthān, Gujarāt, and the Deccan, the main centre of manufacture has been Nathdwāra, near Udaipur in Rājasthān.

pichi, South American species of armadillo (*q.v.*).

pichiciago, species of armadillo (*q.v.*).

Pichincha, province of north central highland Ecuador, with a small lowland fringe to the west, covering a total area of 5,243 sq mi (13,579 sq km). The provincial capital, Quito



Sheep grazing in a valley of the Andean plateau, Pichincha province, Ecuador
Bjorn Bolstad—Photo Researchers

(*q.v.*), also the national capital, has made it a focal point of Ecuadorian history and politics.

In the early 15th century the Quitu Indians, original inhabitants of the area, were conquered by the Cara Indians. These last were soon supplanted by the Incas, who, from their Peruvian centre, swept through central Ecuador at about the same time as the landfall of Columbus. The Inca emperor Huayna Capac (died *c.* 1525) established Quito as an important governmental and military outpost, and his followers settled the territory now composing Pichincha province. Later, the province was the site of a decisive battle in the Latin-American wars of independence. *See* Pichincha, Battle of.

Most of the population is concentrated in the more temperate valleys of the high Andean plateau. Although agriculture and cattle raising are the main occupations, thriving industries (concentrated mainly in Quito), including textile mills and food-processing plants, contribute to the economy. The province produces cereals, potatoes, sugarcane, cacao, coffee, and rice. Its forests are sources of fine woods and there are copper deposits. Tourism is a growing economic factor. The Pan-American Highway and the Guayaquil–Quito railway run through the province from north to south. Pop. (1982 prelim.) 1,369,059.

Pichincha, Battle of (May 24, 1822), in the Latin-American wars of independence, a victory by South American rebels, commanded by Antonio José de Sucre, over the Spanish royalists on the lower slopes of Cerro Pichincha, an Andean volcano. It enabled the rebels to occupy nearby Quito, Ecuador, the following day. Simón Bolívar, leader of the revolutionary forces in northern South America, was acclaimed liberator, and Ecuador was joined to the newly formed but transitory Republic of Gran Colombia.

Picidae, bird family of the order Piciformes that includes woodpeckers, piculets, and wry-

Eurasian wryneck (*Jynx torquilla*)
Eric Hosking—The National Audubon Society Collection/EB Inc.

necks. The 210 species occur worldwide except in Madagascar and east of Borneo and Bali (*i.e.,* they do not cross Wallace's Line). Most are specialized for gleaning insects from tree bark, usually by boring with their bills; some also eat nuts, fruits, and sap; and a few gather ants and grubs from the ground.

piciform, order of birds (Piciformes) consisting of six families of arboreal birds: the familiar woodpeckers, their relatives the piculets and wrynecks (collectively, the family Picidae), and the exotic tropical jacamars (Galbulidae), puffbirds (Bucconidae), barbets (Capitonidae), honey guides (Indicatoridae), and toucans (Ramphastidae).

A brief treatment of piciforms follows. For full treatment, *see* MACROPAEDIA: Birds.

Piciforms vary in size from 3.5 inches (9 centimetres) to 24 inches. Characteristic of this order is the zygodactyl foot, where two toes point forward and two backward. The structure of the bill varies greatly throughout the Piciformes. That of some species of woodpeckers is chisel-like and broadly based, with slitlike nostrils to keep wood chips out. The huge, serrated bill of the toucans is supported by a crisscrossing of many bony fibres; it is strong but surprisingly lightweight for its size.

The medium-sized jacamars have long, slender bills and resemble hummingbirds in their body shape and their bright, iridescent plumage. The puffbirds are similar to the jacamars, although with shorter tails and bills. Their plumage is relatively subdued, usually brown, tan, or mottled. Large heads and stout bills on thick bodies typify the barbets, in addition to bristles at the base of the beak. The barbets include some of the most beautifully coloured of birds; many of these are bright green with red, orange, and yellow highlights. Honey guides have thick skins which protect them against bee stings. These birds are small and the plumage is generally drab. Coloration of the toucan is quite vivid—toucans are black or green with various patterns of bright hues on the underparts and the laterally flattened bill. The woodpeckers are well adapted to their life-style. Strong leg muscles and toes enable them to cling to vertical surfaces, and the central tail feathers are stiffened and help to support the birds while they are foraging on tree trunks. The woodpecker's tongue has tiny barbs and can be extruded at high speeds to take insects found in holes in the bark.

There is a great diversity of habits within the piciforms. Jacamars and puffbirds are the flycatchers of the order; both tend to go after their prey from a perch. Jacamars are more forest-oriented while puffbirds inhabit more open areas. When jacamars capture large insects, they take them back to the perch and beat them against it before eating them, pulling the wings off the prey if it is to be given to nestlings. Barbets are usually inhabitants of savannas and woodlands. They feed upon insects, fruits, berries, and buds.

The honey guides also dwell in forests or savannas, where they subsist mainly on insects, beeswax, and fruit. This wax-eating habit is unique among birds; honey guides have special intestinal bacteria which help break down this substance. A few species in the genus *Indicator* actually lead man or other mammals to bees' nests. The greater, or black-throated, honey guide (*I. indicator*) raises and spreads its tail and weaves about in flight. When this attracts attention, it flies to a perch and calls again; then it repeats the display, slowly moving toward the bees' nest where it feasts on wax and exposed larvae after the "guided" mammal has torn open the nest and taken the honey.

The toucans are well known as fruit eaters; they pick up small pieces of fruit in the bill and then throw them back into the mouth. Their diet, however, also includes insects, eggs, and even baby birds. Toucans usually reside in the forest but they may forage in clearings or around farms.

Among the woodpeckers, the soft-tailed wrynecks (*Jynx*) forage for ants in both terrestrial and arboreal situations, and the piculets tap and probe for insects in a woodpecker-like manner as they travel along vines and small branches. Most woodpeckers (Picinae) take insects from the surface of the tree or crevices within the bark. Only a few of the heaviest billed birds, such as the nearly extinct ivory-bills (genus *Campephilus*) and a few other species actually drill into the tree while foraging.

All the piciforms are hole nesters. Woodpeckers drill nesting cavities into living or dead trees. Their two to nine white eggs require an incubation period of 11 to 20 days. The adults share in the incubation of the eggs and in feeding the nestlings. Both jacamars and puffbirds usually nest at the end of tunnels dug into the ground, although some puffbirds nest in trees. Again, both male and female are involved in parenting. Barbets excavate their nests in dead trees with well-rotted heartwood. Two to five eggs are incubated from 13 to 15 days. The toucans usually take over an old woodpecker hole, which they may enlarge slightly. The parents take turns incubating the one to four eggs for about 16 days. The young of the larger toucan species may remain in the nest for seven weeks or longer and then may remain with the parents for an extended period.

Reproduction in the honey guides is unlike that of the other piciforms; they are brood parasites. The female honey guide lays one white egg within the nest of a hole-nesting host species; she breaks any other eggs in the nest at that time. When the young honey guide hatches it has a sharply hooked tip on its beak with which it kills off any other nestlings which have hatched. Black-throated honey guides frequently parasitize the red-throated bee-eater (*Merops bulocki*); the food call of the young honey guide sounds like the calls of two hatchling bee-eaters—this keeps the foster parents highly stimulated to provide food for their parasite.

pickaback plant, also called PIGGYBACK PLANT (*Tolmiea menziesii*), hairy-leaved herbaceous plant, in the family Saxifragaceae, native to western North America. The pickaback is a popular houseplant, particularly notable for its curious reproductive abilities: the leaves of the parent plant arise from an underground stem and, when mature, they produce new plantlets from buds at the base of their leaf blades.

Pickaback plant can be grown in shaded rock gardens in mild climates, as along the Pacific coastal United States but is primarily an indoor plant elsewhere.

Pickard, Greenleaf Whittier (b. Feb. 14, 1877, Portland, Maine, U.S.—d. Jan. 8, 1956, Newton, Mass.), U.S. electrical engineer who invented the crystal detector (one of the first devices widely used for receiving radio broadcasts) and who was also one of the first scientists to demonstrate the wireless electromagnetic transmission of speech.

Pickard, who was a grandnephew of the poet John Greenleaf Whittier, was educated at Harvard University and the Massachusetts Institute of Technology, Cambridge. In 1899, at the Blue Hills Observatory in Milton, Mass., he transmitted spoken messages by radio over a distance of 10 miles, using a carbon-steel detector to recover the audible signal that had been impressed on the radio-frequency carrier waves. As an engineer at the American Telephone and Telegraph Company (1902–06), he contributed to the development of the radiophone; from 1906 until 1931 he worked with the Wireless Specialty Apparatus Co., and after 1945 he headed the electronics engineering firm of Pickard and Burns.

Pickard is best known for discovering that the contact between a fine metallic wire ("cat's whisker") and the surface of certain crystalline materials (notably silicon) rectifies and demodulates high-frequency alternating currents, such as those produced in a receiving antenna by radio waves. This device, called a crystal detector and patented by Pickard in 1906, was an essential component of the crystal set, a form of radio receiver that was popular until the crystal detector was superseded by the triode vacuum tube. (The point-contact rectifier was the forerunner of the transistor, invented in 1948.)

pickerel, any of several North American pikes, family Esocidae, distinguished from the related muskellunge and northern pike by its smaller size, completely scaled cheeks and gill covers, and banded or chainlike markings. The chain pickerel (*Esox niger*) grows to about 0.6 metres (2 feet) and a weight of about 1.4 kilograms (3 pounds). The barred pickerel (*E. americanus*) and the grass pickerel (*E. vermiculatus*) are smaller species reaching a maximum weight of about 0.5 kilograms. *See also* pike.

pickerel frog (*Rana palustris*), dark-spotted frog (family Ranidae), found in eastern North America, usually in such areas as meadows, cool streams, and sphagnum bogs. The pickerel frog is about 5 to 7.5 centimetres (2 to 3 inches) long and has lengthwise rows of squarish spots on its golden or brownish skin.

When the pickerel frog leaps it reveals the orange or yellow on the inner surfaces of its hind legs. The skin secretions, which protect this frog from snakes, are reported also to be toxic to other frogs.

Pickerel frog (*Rana palustris*)

pickerelweed, any of several genera of aquatic plants comprising the family Pontederiaceae, especially those of the genus *Pontederia*. Most species are perennials, native primarily to tropical America. They have creeping rootstocks, fibrous roots, and leaves in clusters at the base of the plant or borne on branched stems. The fruit is a capsule containing many seeds, or a one-seeded winged structure. Plants of the genus *Pontederia*, about five species of perennials, have spikes of bluish-purple flowers at the top of a one-leaved stem, clusters of lance- or heart-shaped leaves at the base, and thick rootstocks.

Pickerelweed (*P. cordata*) is common in shallow lakes and muddy shores in eastern North America. It is sometimes cultivated as an ornamental garden pool or aquarium plant. Water hyacinth (*Eichhornia*) and mud plantain (*Heteranthera*) are other widely distributed genera of the family.

Pickering, Edward Charles (b. July 19, 1846, Boston—d. Feb. 3, 1919, Cambridge, Mass., U.S.), U.S. physicist and astronomer who introduced the use of the meridian photometer to measure the magnitude of stars and established the *Harvard Photometry* (1884), the first great photometric catalog.

In 1867 Pickering became professor of physics at the Massachusetts Institute of Technology, Cambridge, where he established the first U.S. laboratory in which students were required to use laboratory instruments to make measurements. In 1876 he was appointed professor of astronomy and director of the Harvard College Observatory.

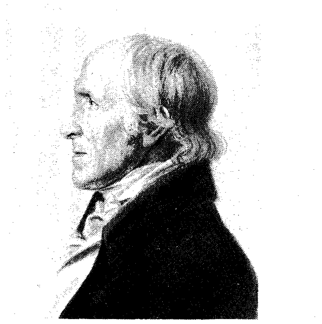
Edward Charles Pickering
By courtesy of Harvard College Observatory and the Niels Bohr Library, American Institute of Physics, New York

He invented the meridian photometer, which utilized a calcite prism to juxtapose the image of a star with one of a designated group of north polar stars to compare their brightnesses, and used it to compile his catalog. After the Arequipa Observatory was established in Peru in 1891, it became possible to include measurements of the southern stars within the scope of the work of the Harvard College Observatory. Under Pickering this work included photometry, a scale of photographic magnitudes, a system of classification of variable stars, and a system of stellar spectroscopy that was for many years universally adopted.

Pickering, Timothy (b. July 17, 1745, Salem, Mass.—d. Jan. 29, 1829, Salem, Mass., U.S.), American Revolutionary officer and Federalist politician who served (1795–1800) with distinction in the first two U.S. Cabinets.

During the Revolutionary War, Pickering served in several capacities under Gen. George Washington, among them quartermaster general (1780–85). In 1786, after taking up residence in Philadelphia, he helped resolve the dispute with Connecticut settlers over claims to Pennsylvania's Wyoming Valley and helped develop the town of Wilkes-Barre.

Pickering served as Indian commissioner (1790–95), postmaster general (1791–95), secretary of war (1795), and secretary of state (1795–1800). He was dismissed from office by Pres. John Adams after a policy dispute.



Timothy Pickering, pastel drawing by C.-B.-J. Fevret de Saint-Mesmin; in the Museum of Fine Arts, Boston
By courtesy of the Museum of Fine Arts, Boston, Frederick Brown Fund

During the administrations of Jefferson and Madison, Pickering led the Federalist opposition in Congress, serving as senator from Massachusetts (1803–11) and as a member of the House of Representatives (1813–17). Remaining friendly to England and fearing the power of Napoleon, he bitterly opposed the War of 1812. After his retirement from Congress, he devoted himself to agricultural experimentation and education.

Pickering, William Hayward (b. Dec. 24, 1910, Wellington, N.Z.), U.S. engineer, physicist, and head of the team that developed Explorer 1, the first U.S. satellite.

He studied at the California Institute of Technology, Pasadena (B.S. 1932, M.S. 1933, Ph.D. 1936), and joined the staff of the Institute in 1936. Working under the U.S. physicist Robert A. Millikan, Pickering developed cosmic-radiation-detection gear for high-altitude balloon flights. In 1944 he became a section chief of the Jet Propulsion Laboratory, where he developed the first telemetry system used in U.S. rockets. He was manager of the Corporal rocket project, which brought about important early advances in guidance and communication techniques.

In 1951 Pickering became chief of the division of guided-missile electronics and three years later was appointed director of the Jet Propulsion Laboratory. He was in charge of the development of the Explorer 1 satellite and the modification of the Jupiter C launch vehicle. Among other important projects of the laboratory were the Ranger and Surveyor spacecraft for unmanned flights to the Moon, the Mariner spacecraft for survey flights to Venus and Mars, and numerous other unmanned probes into the solar system.

Pickering retired from the Jet Propulsion Laboratory in 1976 and served for two years as director of the research institute of the University of Petroleum and Minerals in Saudi Arabia. He then returned to Pasadena to establish a private consulting practice.

Pickering, William Henry (b. Feb. 15, 1858, Boston—d. Jan. 17, 1938, Mandeville, Jam.), U.S. astronomer who discovered Phoebe, the ninth satellite of Saturn.

In 1891 Pickering joined his brother Edward in establishing the Boyden station of the Harvard Observatory at Arequipa, Peru. He returned to the United States in 1893 and the next year erected the observatory and telescope at Flagstaff, Ariz., for the noted U.S. astronomer Percival Lowell. In 1900 he established a station for the Harvard Observatory at Mandeville.

He discovered Phoebe in 1899 and noted that it revolves around Saturn in the opposite direction (retrograde) from that of Saturn's other satellites. His announcement in 1905 of a 10th satellite, which he named Themis, is generally discounted, for it was never observed again. The 10th satellite (Janus) that was discovered in 1967 is probably not the same one, for its orbit is the innermost of all Saturn's moons, whereas Pickering's Themis was supposed to lie between Titan and Hyperion. In 1919 Pickering also predicted the existence of, and gave a position for, the planet Pluto.

pickeringite, magnesium-rich variety of the mineral halotrichite (*q.v.*).

Pickett, Bill (b. Dec. 5, 1870?, Williamson County, Texas, U.S.—d. April 21, 1932, Tulsa, Okla.,), American rodeo cowboy who introduced bulldogging, a modern rodeo event that involves wrestling a running steer to the ground.

Pickett was descended from American Indian and black slave stock in the Southwest. He grew up in West Texas, learning to ride and rope as a boy, and became a ranch hand; he performed simple trick rides in town on weekends. In 1900 he became a showman, sponsored by Lee Moore, a Texas rodeo entrepreneur. In 1907 Pickett signed with the 101 Ranch Wild West Show, becoming one of its star performers and assuming the status of a legendary figure for his masterful handling of both wild and domestic animals. For bulldogging, or steer wrestling, he perfected a technique of jumping from his horse, grabbing the steer around the neck or horns, sinking his teeth into the animal's lip, and pulling it to the ground. Pickett's most gruelling performance came in 1908 in a bullring in Mexico City. He there wrestled and rode a Mexican fighting bull for seven minutes before a riotous audience enraged at this original interpretation of the Mexican national pastime of bullfighting.

Pickett performed until about 1916, working as a cowhand and rancher thereafter. He died after being kicked by a horse in April 1932.

Pickett, George Edward (b. Jan. 25, 1825, Richmond, Va., U.S.—d. July 30, 1875, Norfolk, Va.), Confederate Army officer during the American Civil War, known for Pickett's Charge at the Battle of Gettysburg.

After graduating last in his class from the U.S. Military Academy at West Point, N.Y.,

George Edward Pickett

By courtesy of the Library of Congress, Washington, D.C.

(1846), Pickett served with distinction in the Mexican War (1846–47). He resigned his commission in June 1861 and entered the Confederate Army, in which he was made brigadier general in February 1862. Pickett rose to major general in October and was given command of a Virginia division. At the Battle of Fredericksburg he commanded the centre of Gen. Robert E. Lee's line but saw little action.

At Gettysburg (July 3, 1863) three brigades of Pickett's division (4,300 men) constituted somewhat less than half the force in the climactic attack known as Pickett's Charge. The attack was actually under the command of Gen. James Longstreet. Its bloodily disastrous repulse is often considered the turning point of the war. Although Pickett was much criticized and charged by some with cowardice, Lee retained him in divisional command throughout the Virginia Campaign of 1864. Eight days before the surrender at Appomattox (April 9, 1865), Pickett's division was almost destroyed at Five Forks while he was attending a shad bake. After the war he worked in an insurance business in Norfolk, Va.

Pickett, Joseph (b. 1848, New Hope, Pa., U.S.—d. 1918, New Hope), U.S. primitivist or folk painter known for his naive depictions of town and landscape around his native New Hope, Pa.

After a life spent as a carpenter, shipbuilder, carny, and storekeeper, Joseph Pickett began painting when he was about 65. His works exemplify an untrained artist's detailed interest in local landscape and history, portrayed with straightforward disregard of perspective but with full sense of colour and flat pattern design; *e.g.*, "Manchester Valley" (*c.* 1914–18; Museum of Modern Art, New York City). Pickett's works were not discovered by the art critics and public until the 1930s.

Pickford, Mary, original name GLADYS MARY SMITH (b. April 9, 1893, Toronto—d. May 28, 1979, Santa Monica, Calif., U.S.), Canadian-born U.S. motion-picture actress,

Mary Pickford

By courtesy of United Artists Corp. and the Museum of Modern Art, Film Stills Archive, New York City

"America's sweetheart" of the silent screen, and one of the first film stars. At the height of her career, she was one of the richest and most famous women in the United States.

She made her first stage appearance in a Toronto stock company at the age of five. At eight she went on tour and within 10 years was playing on Broadway under her original name. Mary Pickford began working as a motion-picture extra at D.W. Griffith's Biograph Studio, starring in his 1909 film *The Lonely Villa.* By 1913 she had turned permanently to the screen, rising to first rank with Adolph Zukor's Famous Players Company. She is famous for such films as *Tess of the Storm Country* (1914), *Pollyanna* (1920), *Rebecca of Sunnybrook Farm* (1917), and *Poor Little Rich Girl* (1917).

Pickford was not only America's symbol of sweetness and innocence but also a shrewd businesswoman. In 1919 she was primarily instrumental in forming the United Artists Corporation with two actors, Charlie Chaplin and Douglas Fairbanks, and the director D.W. Griffith. She married Owen Moore, a fellow actor at Griffith's Biograph Studio, in 1911 (divorced, 1919); Douglas Fairbanks in 1920 (divorced, 1935); and actor Charles (Buddy) Rogers in 1937. Pickford retired from motion pictures in the early 1930s.

Pick's disease, form of premature senility caused by atrophy of the frontal and temporal lobes of the brain. It resembles Alzheimer's disease (pre-senile dementia) but is much less common. There is a progressive deterioration of intellect, judgment, and memory, resulting in increased irritability, inappropriate behaviour, depression, and paranoia. Some cerebral nerve cells are swollen and contain abnormal inclusions called Pick bodies. The cause of cerebral atrophy is not known but in some cases the disease appears to be inherited as an autosomal (*i.e.,* carried on other than a sex chromosome) dominant trait. Average survival from onset to death is about 10 years; there is no specific treatment.

pickwickian syndrome, a complex of respiratory and circulatory symptoms associated with some cases of extreme obesity. The name of this disease originates from the red-faced, fat man depicted in Charles Dickens' *Pickwick Papers,* who showed some of the same traits. (Extreme obesity is medically classified as body weight of 325 pounds [147 kilograms] or more.) The main symptoms are breathlessness on exertion and drowsiness. There may also be a bluish tint to the skin, increased heartbeats, high blood pressure with dilation of the vessels, enlargement of the liver, and an abnormally high number of red blood cells. The increased abdominal fat causes elevation of the diaphragm, diminished total lung volume, and more airway resistance during breathing. The oxygen saturation level of the blood may be much reduced, particularly during sleep, and there is retention of carbon dioxide in the bloodstream.

The factors causing this syndrome are not clear, but obesity seems to be a predominant factor. Obesity causes an increased work load, which always places stress on the heart. With a low oxygen level and high blood pressure in the pulmonary circulation, heart and lung failure eventually ensue. The abundance of fat in the chest muscles and diaphragm has been blamed for the reduced ability to expand and contract the lungs; some authorities think that merely the added body weight on the chest restricts the respiratory movements. The treatment is directed toward loss of weight.

Pico della Mirandola, Giovanni, CONTE (count) DI CONCORDIA (b. Feb. 24, 1463, Mirandola, Duchy of Ferrara—d. Nov. 17, 1494, Florence), Italian scholar and Platonist philosopher whose *De hominis dignitate oratio* ("Oration on the Dignity of Man"), a characteristic Renaissance work composed in 1486, reflected his syncretistic method of taking the best elements from other philosophies and combining them in his own work.

His father, Giovanni Francesco Pico, prince of the small territory of Mirandola, provided for his precocious child's thorough Humanistic education at home. Pico then studied canon law at Bologna and Aristotelian philosophy at Padua, and visited Paris and Florence, where he learned Hebrew, Aramaic, and Arabic. At Florence he met Marsilio Ficino, a leading Renaissance Platonist philosopher.

Introduced to the Hebrew Kabbala, Pico became the first Christian scholar to use Kabbalistic doctrine in support of Christian theology. In 1486, planning to defend 900 theses he had drawn from diverse Greek, Hebrew, Arabic,

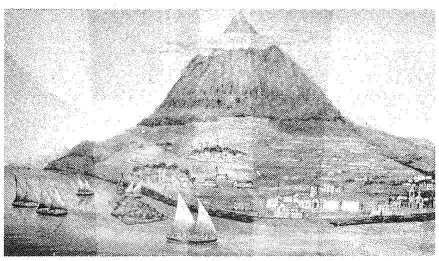
Pico della Mirandola, detail of a portrait by an unknown artist, late 15th century; in the Uffizi, Florence
Alinari—Art Resource/EB Inc.

and Latin writers, he invited scholars from all of Europe to Rome for a public disputation. For the occasion he composed his celebrated *Oratio.* A papal commission, however, denounced 13 of the theses as heretical, and the assembly was forbidden by Pope Innocent VIII.

Despite his ensuing *Apologia* for the theses, Pico found it prudent to flee to France, where he was arrested. After a brief imprisonment he settled in Florence, where he became associated with the Platonic Academy, under the protection of the Florentine prince Lorenzo de' Medici. Except for short trips to Ferrara, Pico spent the rest of his life there. He was absolved from the charge of heresy by Pope Alexander VI in 1492. Toward the end of his life he came under the influence of the strictly orthodox Girolamo Savonarola, martyr and enemy of Lorenzo.

Pico's unfinished treatise against enemies of the church includes a discussion of the deficiencies of astrology. Though this critique was religious rather than scientific in its foundation, it influenced the 17th-century scientist Johannes Kepler, whose studies of planetary movements underlie modern astronomy. Pico's other works include an exposition of Genesis under the title *Heptaplus* (Greek *hepta,* "seven"), indicating his seven points of argument, and a synoptic treatment of Plato and Aristotle, of which the completed work *De ente et uno* is a portion. Pico's works were first collected in *Commentationes Joannis Pici Mirandulae* (1495–96); E. Garin began a modern edition in 1942.

Pico Island, Portuguese ILHA DO PICO, island, part of the Portuguese Azores archipelago in the North Atlantic Ocean and administratively within Horta district. Separated from the Ilha do Faial by the Canal (channel) do Faial, it has an area of 163 sq mi (433 sq km) and



Ships off the coast of Pico Island, detail of "A Whaling Voyage Round the World," tempera panorama by Russell-Purrington, 1846; in the Whaling Museum, New Bedford, Mass.
By courtesy of the Whaling Museum, New Bedford, Mass.

is dominated by the Ponta do Pico volcano, highest in the Azores (7,713 ft [2,351 m]). Its economy is basically agricultural, dairying being the most important activity, followed by cattle raising and vine cultivation. Whaling is still practiced in small boats without mechanical aids. Lajes and São Roque do Pico are the island's two urban centres. Pop. (1981) 15,224.

Piconnerie, Thomas-Robert Bugeaud, marquis de la: *see* Bugeaud, Thomas-Robert.

picornavirus, any of a group of viruses constituting the family Picornaviridae, a large group of the smallest known animal viruses, "pico" referring to small size and "rna" referring to its core of ribonucleic acid (RNA). This group includes enteroviruses, which attack the vertebrate intestinal tract and often invade the central nervous system as well; rhinoviruses, which infect the tissues in the vertebrate nose; and the virus agent of foot-and-mouth disease. Among the enteroviruses are polioviruses, echoviruses (*e*nteric, *c*ytopathogenic, *h*uman, *o*rphan), and Coxsackie viruses. Echoviruses cause fever with rash and meningitis. Coxsackie viruses cause sore throat or fever with chest or abdominal pains. The virus particle lacks an envelope, is spheroidal, measures from 20 to 30 nanometres (nm; 1 nm=10^{-9} metre) across, and is covered with subunits called capsomeres.

picric acid, also called 2,4,6-TRINITROPHENOL, pale yellow, odourless crystalline solid that has been used as a military explosive, as a yellow dye, and as an antiseptic. Picric acid (Greek *pikros,* "bitter") was so named by J.-B.-A. Dumas, a 19th-century French chemist, because of the extremely bitter taste of its yellow aqueous solution. Percussion or rapid heating can cause it (or its salts with heavy metals, such as copper, silver, or lead) to explode.

Picric acid was first obtained in 1771 by Peter Woulfe, a British chemist, by treating indigo with nitric acid. It was used as a yellow dye, initially for silk, beginning in 1849.

As an explosive, picric acid was formerly of great importance. The French began using it from 1886 as a bursting charge for shells under the name of melinite. By the time of the Russo-Japanese War, picric acid was the most widely used military explosive. Its highly corrosive action on the metal surfaces of shells was a disadvantage, however, and after World War I its use declined.

Ammonium picrate, one of the salts of picric acid, is used in modern armour-piercing shells because it is insensitive enough to withstand the severe shock of penetration before detonating.

Picric acid has antiseptic and astringent properties and is used medically incorporated in a surface anesthetic ointment or solution, and in burn ointments.

Picric acid is a much stronger acid than phenol; it decomposes carbonates and may be titrated with bases. In a basic medium, lead acetate produces a bright yellow precipitate, lead picrate.

picrite, intrusive igneous rock of ultrabasic (very silica-poor) composition that is composed largely of olivine and augite and is somewhat similar to peridotite. Picrites are dark, heavy rocks and contain a small but variable amount of plagioclase feldspar; hornblende and biotite may also be present. Picrites usually occur in sills (tabular bodies inserted while molten between other rocks), but, unlike peridotites, seldom in large plutonic masses. Varieties include augite-, enstatite-, and hornblende-picrite. The term picrite-basalt is reserved for feldspar-poor basalts rich in olivine.

The minerals in picrite are, in many cases, decomposed. Serpentine partially or wholly replaces olivine, and hornblende, talc, and chlorite appear as secondary products after the mineral. Augite passes into hornblende or chlorite, and the essential feldspar is often represented by epidote, prehnite, and white mica. In some picrites, as in the peridotites, a lustre mottling is produced by the inclusion of unoriented grains of olivine within large crystals of augite or hornblende.

The augite picrites of Scotland and central Czechoslovakia contain interstitial analcime and are closely related to the teschenites with which they are associated. Other picrites are more clearly calc-alkaline and are associated with diorites or diabases; the hornblende picrites of Gwynedd and Anglesey, Wales, are of this type. Picrites accompany diabases in the Devonian rocks of the Fichtelgebirge (in Germany) and Nassau, as well as Cornwall and Devon.

Pict (from Latin Picti, "painted"), one of an ancient non-Celtic people who inhabited an area in what is now eastern and northeastern Scotland, from Caithness to Fife. Their name may refer to their custom of body painting or possibly tattooing.

Probably descendants of pre-Celtic aborigines, the Picts were first noticed in AD 297, when a Roman writer spoke of the "Picts and Irish [Scots] attacking" Hadrian's Wall; warfare with the Romans during the occupation was almost continual. Then or soon after, they seem to have developed two kingdoms north of the Forth, a southern and a northern; but, by the 7th century, there was a united "Pictland," which already had been penetrated by Christianity. In 843, Kenneth I MacAlpin, king of the Scots (centred in Argyll and Bute), became also king of the Picts, uniting their two lands in a new kingdom of Alba, which evolved into Scotland.

The Pictish kingdom is notable for the stylized but vigorous beauty of its carved memorial stones and crosses. The round stone towers known as brochs, or "Pictish towers," and the underground stone houses called weems, or "Picts' houses," however, both predate this kingdom.

Pictet de Rochemont, Charles (b. Sept. 21, 1755, Geneva—d. Dec. 28, 1824, Lancy, Switz.), statesman, writer, and diplomat who prepared the declaration of Switzerland's permanent neutrality ratified by the great powers in 1815.

After serving in the French Army, Pictet settled in Geneva in 1789 and reorganized the militia. He was arrested during the Reign of Terror (1794) in Geneva following the French Revolution and subsequently was imprisoned. With the reestablishment of the Republic of Geneva after the retreat of Napoleon's armies (1813), he resumed political activity, taking part in the provisional government created in December 1813.

In January 1814 Pictet argued on behalf of Geneva's independence and union with the Swiss Confederation before the allied sovereigns at Basel and later obtained recognition of his canton's independence in the Treaty of Paris (May 1814). In October 1814 he was delegated to the Congress of Vienna, where he helped secure Geneva's attachment to the reconstructed Swiss Confederation; and at the Paris peace conference (August–November 1815) that followed Napoleon's defeat at Waterloo, he served as representative of the whole confederation. He personally redrafted the act that was accepted as the basis of permanent Swiss neutrality by the powers on March 20, 1815. His last diplomatic mission—to Turin (January–March 1816)—secured a rectification of the Swiss–Sardinian frontier (Treaty of Turin, March 1816). A man of letters, he helped edit the *Bibliothèque britannique* (the *Bibliothèque universelle* after 1815) and wrote works on politics and agriculture.

Pictish language, language spoken by the Picts in northern Scotland and replaced by Gaelic after the union in the 9th century of the Pictish kingdom with the rest of Scotland. Knowledge concerning the Pictish language is derived from place-names, the names in medieval works such as the *Pictish Chronicle* and the writings of Bede, inscriptions from the Pictish areas of Britain, statements about the language by medieval writers who wrote while the language was still in use, and names from northern Scotland found in classical works.

Pictish was apparently a Celtic language (more closely related to Gaulish and Brythonic than to Goidelic), but some scholars think that it was not Celtic, nor even Indo-European.

pictography, expression and communication by means of pictures and drawings having a communicative aim. These pictures and drawings (called pictographs) are usually considered to be a forerunner of true writing and are characterized by stereotyped execution and by omission of all details not necessary for the expression of the communication. (Pictographs that are drawn or painted on rocks are known as petrograms; those that are incised or carved on rocks are called petroglyphs.) A pictograph that stands for an individual idea or meaning may be called an ideogram; if a pictograph stands for an individual word, it is called a logogram (*q.v.*). Pictographs are also used as memory aids. Various North American Indian tribes used pictographs both as ideograms and as memory aids.

Picton, town, seat of Prince Edward County, southeastern Ontario, Canada, on Lake Ontario's Bay of Quinte, 15 mi (25 km) southeast of Belleville. Founded in 1786 by United Empire Loyalists led by Andrew and Henry Johnson, the town was known as Hallowell before being renamed in honour of Sir Thomas Picton, a British major general in the Napoleonic Wars. Picton is the commercial centre of the county; its deepwater port on Picton Bay, an arm of the Bay of Quinte, handles iron-ore shipments from mines near Marmora, 40 mi northwest. Industries include fruit and vegetable canning, textile and lumber milling, and dairying. A large army base and several provincial parks are nearby. Inc. 1837. Pop. (1981 prelim.) 4,361.

Picton, borough and port, northeastern South Island, New Zealand, on Waitohi Bay (Picton Harbour), a southwest extension of Queen Charlotte Sound off Davis Strait. In 1848 a Maori *pa* (fortified settlement) on this site was occupied by Gov. Sir George Grey (1845–53) and Francis Dillon Bell, of the New Zealand Company. They proceeded to lay out the village of Newton, renamed in 1859 to honour Sir Thomas Picton, a commander under the Duke of Wellington in the Peninsular War. In 1864 its population increased for a time as the result of a gold strike to the west on the Wakamarina River. Sir Edward Stafford, prime minister of New Zealand, was then waging an unsuccessful campaign to have the town designated as the national capital. It was made a borough in 1876. Picton is the northern terminus of the South Island Main Trunk Railway from Christchurch (218 mi [351 km] southwest) and has regular ferry service (for cargo and vehicles) to Wellington, 40 mi west across Cook Strait. Its deepwater port exports wool, grain, and fruit. Other industries are meat freezing, fish packing and curing, general engineering, and small boatbuilding. Picton serves as the centre of a holiday resort area based on the many inlets along the coast. Pop. (1983 est.) 3,190.

Pictor, Quintus Fabius: *see* Fabius Pictor, Quintus.

Pictou, town, seat of Pictou county, northern Nova Scotia, Canada, just northwest of New Glasgow, on Pictou Harbour, facing Northumberland Strait. The site, a former Micmac Indian village, was settled in 1767 by a group of families from Maryland and Pennsylvania. They were joined in 1773 by Highlanders from Scotland. The community probably derived its name from an Indian word *piktook* ("bubbling water" or "explosion"). It has developed one of Canada's largest lobster fisheries and holds a lobster carnival each July. Lumbering and coal mining are also well established; other industries include foundries, canneries, tire factories, and the production of biscuits. During World War II, steel merchant ships were built in the shipyard. Pictou Academy was founded in 1816. There are ferry services from nearby Caribou to Pictou Island (5 mi [8 km] long by 2 mi wide) offshore, and to Wood Islands, P.E.I., 14 mi across the strait. Inc. 1874. Pop. (1981) 4,628.

picture frame, mounting assemblage designed to protect, display, and often enhance a painting, drawing, photograph, or other visual representation. *See* frame design.

picture-winged fly: *see* otitid fly.

Pictured Rocks, cliff formations of red Cambrian sandstone, extending east of Munising for about 15 mi (24 km) along the southern shore of Lake Superior in Alger County, in the Upper Peninsula of Michigan, U.S. Rising to 200 ft (60 m) above the shoreline, the cliffs are multicoloured and form intricate designs, caves, and columns carved by wind and wave action. Named as the dwelling place of the gods of thunder and lightning in Longfellow's poem *The Song of Hiawatha*, the area was created a national lakeshore by the U.S. Congress in 1966 and includes Grand Sable Dunes and Banks (west of Grand Marais) and surrounding forest.

Picturesque style, English-based architectural mode of the late 18th and early 19th centuries that was a precursor of the Gothic Revival. Picturesque evolved through a reaction against early 18th-century trends toward the formality of scientific and mathematical exactitude. The fundamental tenets of proportion and order in architecture were overthrown, emphasizing natural sensibilities and variety and irregularity.

Thomas Whately's *Observations on Modern Gardening* (1770) was the pioneering study espousing the Picturesque theory. It was through English gardens that the Picturesque style evolved. Gardens, or more generally the environment, were essential to the Picturesque style. One of the most striking effects of this era was that of architecture as part of an environment.

The prominent English architect and town planner John Nash (1752–1835) produced the first "garden city" and some of the most exemplary establishments during the ensuing era. The Picturesque love of irregularity was noteworthy in the asymmetrical silhouettes of his Cronkhill (1802) at Atcham in Salop. Nash's Blaise Hamlet (1811) is a model village of neo-thatched "Rustic Cottages," arranged in irregular clusters. James Renwick's Smithsonian Institute in Washington, D.C., surrounded by a charming parklike landscape, is another example of Picturesque style. *See also* folly.

piculet, any of about 29 species of small, stub-tailed birds related to the woodpeckers and constituting the subfamily Picumniae, family Picidae (*q.v.*). Nearly all are restricted to Central and South America; there are three species in eastern Asia and one in western Africa. Piculets, 9–14 centimetres (3½–5½ inches) long, are mottled gray-green to brown above, often with salt-and-pepper head, and are white below, with spots or bars. They climb like nuthatches, looking for insects,

White-scaled piculet (*Picumnus albosquamatus*)
Painting by Murrell Butler

and are able to perch crosswise on branches. Though small-billed, piculets dig nest holes in soft wood. The most widely distributed New World species is the white-barred piculet (*Picumnus cirratus*), found from the Guiana Highlands to Argentina. The speckled piculet (*P. innominatus*) of southeast Asia drums on dry bamboo.

Picus, in Roman mythology, ancient Roman woodpecker sacred to the god Mars. It was widely worshipped in ancient Italy and developed into a minor god. Picus was an agricultural deity associated particularly with the fertilization of the soil with manure. The woodpecker was also an important bird in augury.

Later rationalizations made Picus an early king of Italy. The Roman poet Virgil, for instance, made him son of Saturn, father of Faunus, and grandfather of Latinus. His bride, Circe, for reasons of unrequited love, changed him into a woodpecker. As son of Saturn he later came to be identified with Zeus. His earliest representations were as a wooden pillar mounted with the image of a woodpecker. In more sophisticated form, Picus is a youth carved of marble with a woodpecker on his head. In zoology, *Picus* is a genus of woodpecker (*q.v.*).

Pidal, Ramón Menéndez: *see* Menéndez Pidal, Ramón.

piddock, any of the marine bivalve mollusks of the family Pholadidae (Adesmoidea). Worldwide in distribution, they are especially adapted for boring into rock, shells, peat, hard clay, or mud. Most species occur in the intertidal zone, a few in deeper water.

One end of each of the two valves is armed with rows of serrated cutting edges for boring. Some species drill to a depth only slightly more than the length of the shell. Others, with extensible siphons, may bore to depths several times the length of the shell. The siphons of many deep borers are protected by tough plates. Like most bivalves, piddocks feed on minute organisms in the water.

The great piddock (*Zirfaea crispata*), which attains lengths of up to eight centimetres (about three inches) and has an oblong shell that is grayish white or rusty in colour, occurs on both sides of the Atlantic Ocean. Found from the intertidal zone to depths of 75 metres (250 feet), *Z. crispata* bores into limestone and wood.

The wood piddock (*Martesia striata*), up to 2.5 centimetres long and grayish white in colour, commonly occurs in waterlogged timbers cast up on the beach and ranges from North Carolina to Brazil. *M. pusilla* and *M. cuneiformis* have similar habits and distribution. Smith's martesia (*M. smithi*), which resembles a fat, gray pea, bores into rocks and mollusk shells in the Atlantic from New York to the Gulf of Mexico.

The flat-topped piddock (*Penitella penita*), from the Arctic Ocean to Lower California, bores into hard clay, sandstone, and cement, sometimes damaging man-made structures. Some *Penitella* and *Diplothyra* species bore into the shells of other mollusks, particularly oysters and abalone.

Pholas dactylus, which bores into gneiss—a very hard rock—is luminescent. At one time it was highly esteemed in Europe as food. *Pholas chiloensis,* found on the Pacific coast of South America, is eaten locally.

pidgin, a language with a greatly reduced vocabulary and a simplified grammar, often based on a western European language. Pidgins usually arise as methods of communication between groups that have no language in common; the pidgins in some instances later become established first or second languages of one of the groups involved. Some examples of pidgin are Chinese Pidgin English, Haitian French Creole, and Melanesian Pidgin English.

A brief treatment of pidgin follows. For full treatment, *see* MACROPAEDIA: Languages of the World.

A pidgin is a linguistic adaptation to nonintimate contact and remains in existence as long as it is required for communication. If closer relations develop between the groups, one of them may learn the language of the other fully, and the pidgin will no longer be needed. When a pidgin persists, however, relations between the two groups have often become socially institutionalized. They may be master and servant, as was the case in New Guinea and the South Seas, or they may be owner and slave, as in Africa and on early American plantations. Or they may be pairs of diplomats desiring to maintain a comfortable distance in their relations, with neither really wanting to learn the other's language. This was the case for certain speakers of Chinese Pidgin English, which survived for some 300 years. Pidgins may also be very useful for communication in multilingual societies, of which modern New Guinea is a good example. No one speaks a pidgin as his native language. If a pidgin does become established as the native language of a people, it is then known as a "creole."

The first recorded pidgin was the simplified Italian used by European crusaders and merchants who visited eastern Mediterranean ports in the Middle Ages. Because there were many French among these travellers, this pidgin was known as Lingua Franca. The expression lingua franca that is used today means something rather different: it refers to any language used for communication in multilingual settings, as, for example, English might be used in an international assembly. A pidgin is therefore a reduced lingua franca.

A Chinese Pidgin English arose as the English increased their commercial activity in the Far East. Other pidgins appeared with the slave trade in Africa and with the importation of West African slaves to the Caribbean plantations. A number of these New World pidgins of English, French, Spanish, and Portuguese have survived as creoles. English creoles are still spoken in the islands off the South Carolina coast, in the Antilles, and in Suriname. French creoles remain in Louisiana, Haiti, and the Lesser Antilles; the creole of Curaçao is based on Spanish and Portuguese.

The appearance and attestation of pidgin languages since the 17th century followed the increase in European commercial trading and colonization. The establishment of these languages reflected the ethnocentric European view of the indigenous peoples as intellectually and culturally inferior. In his first encounter with the newly arrived European, the native may have attempted a few words in the European's language. The European, believing the other to be incapable of further learning, would respond in a similarly incomplete fashion. The native would assume that this simplified speech was the proper form of the language and so would continue to use the forms that he had heard, naturally adding some vocabulary and a few grammatical elements from his own language. This is not to suggest that pidgins have no grammar or that they are merely a variety of the indigenous language with borrowed European words inserted. In fact, pidgins are considered languages; although their structures are simpler than those of the languages from which they derive, they are complete. English pidgins spoken in different areas have been found to share the same underlying structure, that of English, although they may differ with regard to inflectional suffixes and other details.

A very small vocabulary is another characteristic of pidgins and creoles, although the size of the lexicon may vary: Melanesian Pidgin has 2,000 words, while Chinese Pidgin English has only 700. Most of this vocabulary is from English. Melanesian Pidgin, with its great lexicon, for example, has an English word stock of more than 90 percent (greater than the percentage of Anglo-Saxon words in English). This figure is even higher for Chinese Pidgin English. Pidgins are therefore not mixed languages, as is often supposed. Within this small lexicon, each word can have a wide variety of meanings, with a range far greater than its European counterpart. Words are frequently combined in compounds and phrases for further flexibility.

Pidgins originally are spoken languages only. In some cases, often when pidgins have become creoles, the need has arisen for an orthography to record them, especially in connection with missionary and other educational programs. Attempts to impose European spelling conventions have been misguided; the most successful, efficient orthographies have been phonemic, with consistent spelling patterns reflecting the sound and structure of the creole without reference to the language from which it was derived.

pidyon ha-ben (Hebrew: "redemption of the son"), plural PIDYON HA-BONIN, or PIDYON HA-BENS, Jewish ceremony in which the father redeems his wife's firstborn son by offering to a cohen (a male Jew descended from the first priest, Aaron) the equivalent of five silver shekels (ancient coins). The ceremony, which normally takes place 30 days after the child's birth, dates from Old Testament times, when the firstborn sons of the Israelites were spared from death on the first Passover (Exodus 12). These children subsequently belonged to God in a special way and would have constituted the Jewish priesthood had not the Levites been substituted in their place. *Pidyon ha-ben* thus commemorates a historical event, for the father ritually gives money to a cohen in order to keep his son. If the father is a cohen or if either parent is related to the tribe of Levi, such children already belong to God by reason of heredity, and no redemption is required.

In rabbinic law, the firstborn son may not actually have been the first, since the law does not apply to stillbirths, cesarean deliveries, and malformed offspring. *Pidyon ha-ben* also acknowledges the general law that, in the broadest sense, all "first fruits" (including grain, animals, and fruit) rightfully belong to God.

pie, dish made by lining a shallow container with pastry (*q.v.*) and filling the container with a sweet or savoury mixture. A top crust may be added; the pie is baked until the crust is crisp and the filling is cooked through. Pies have been popular in the United States since colonial times, so much so that apple pie has become symbolic of traditional U.S. home cooking. The typical U.S. pie is round, 8–10 inches (20–25 centimetres) in diameter, 2–3 in. thick, and usually contains a sweet filling of fruit, custard, or a pastry cream. Some U.S. specialties are pecan pie, pumpkin custard pie (traditionally served on Thanksgiving Day), lemon cream pie with a soft meringue topping, and shoo-fly pie, a Pennsylvania Dutch pie with a rich filling containing molasses.

In the United Kingdom, meat, game, and fish pies have been staple dishes since the Middle Ages. Steak and kidney, pork, game, veal and ham, and poultry are all popular. Tourtière, a pork pie, is one of Canada's national dishes.

Tarts are similar to pies and the names are often used interchangeably. Tarts are made with short rather than flaky pastry and are frequently baked "blind," or empty, and filled after baking. A flan is a tart made in an open-bottom pan that is placed on a baking sheet. Tarts and flans, which are usually straight-sided, are often removed from their pans before serving. Because pies are baked in pie pans with flaring sides, they are usually served from the pans.

pièce bien faite (theatre): *see* well-made play.

pied goose: *see* magpie goose.

Piedmont, Italian PIEMONTE, region, northwestern Italy, comprising the provinces of Alessandria, Asti, Cuneo, Novara, Torino, and Vercelli, with an area of 9,807 square miles (25,399 square km).

A brief treatment of Piedmont follows. For full treatment, *see* MACROPAEDIA: Italy.

Surrounded to the south, west, and north by the vast arc of the Ligurian Apennines and the Maritime, Cottian, Graian, and Pennine Alps, the core of Piedmont is the Po River Valley, which lies open to the east and consists of some of the best farmlands in Italy. The name piedmont ("at the foot of a mountain") has become a term generally applied to such a region. South of the Po River are the low and intensively cultivated hills of Monferrato and of Langhe. In the foothills of the Alps are Lakes Maggiore and Orta. The Po and its tributaries, the Dora Baltea, Dora Riparia, Sesia, Tanaro, and Scrivia, provide the area with ample water for agriculture.

In Roman times Piedmont was important because its passes connected Italy with the transalpine provinces of the empire. After periods of Lombard and Frankish rule, the House of Savoy emerged as the most important feudatory of northwestern Italy. This dynasty first became powerful as successor to the marquesses of Ivrea and of Turin, but after 1400 Savoy's control of both slopes of the Alps, ruling over what is now French Savoie and over Piedmont, gave it undisputed sovereignty over much of the region. After 1700 practically all of Piedmont passed under Savoyard domination, and the addition of Sardinia and its territories provided still wider interests. During the Risorgimento (movement for Italian independence), Piedmont led the attempts of 1848, 1859, and 1866 to unite all Italy; and Victor Emmanuel II, originally king of Piedmont and Sardinia, became modern Italy's first king in 1861.

The Alpine arc of Piedmont plays a vital part in the power production of the region and of northern Italy as a whole; the region's hydroelectric plants supply energy for industry, transportation, and domestic use. The forests provide lumber, and the Alpine and sub-Alpine meadows afford excellent pasture for cattle as the base of a prosperous dairy industry. The lowlands produce wheat and rice, vegetables and fruit, and milk and cheese; the hills south of the Po are noted for the production of some of Italy's highest-quality wines, both of the sparkling (Asti) and still (Barbera) varieties. Piedmont forms part of the great industrial triangle of northern Italy (Turin–Genoa–Milan), and its manufactures are widely diversified. Turin (*q.v.*), the capital, largest city, and leading industrial centre, is the site of one of the largest automobile plants in Europe, as well as of printing, textile, and machine industries. Ivrea (*q.v.*), northeast of Turin, is the headquarters of one of Europe's leading makers of office machinery. Textiles, chemicals, and glass are among the other important Piedmontese industries. The principal rail connection between France and Italy, the Turin–Col du Mont Cenis (Mount Cenis Tunnel)–Paris line, passes through Piedmont, while to the north the Simplon Tunnel leads to Switzerland. An excellent network of roads and expressways ties all parts of the region closely together; Genoa, easily reached from Piedmont, is its port. Developments in the 1970s included an all-weather road between France and Italy, passing through a 7-mile (11-kilometre) tunnel under Mont Blanc and thence through the Valle d'Aosta to Turin and Milan. Pop. (1985 est.) 4,411,921.

Piedmont, geographical region in the eastern United States, running some 600 miles (950 km) between New Jersey (north) and Alabama (south) and lying between the Appalachian Mountains (west) and the Atlantic Coastal Plain (east). It comprises a relatively low rolling plateau (from 300 to 1,800 feet [90 to 550 m]) cut by many rivers and is a fertile agricultural region. Cotton is the most important crop in the southern areas, while tobacco and fruit predominate in the north.

piedmont, in geology, landform created at the foot of a mountain (Italian *pie monte*) or mountains by debris deposited by shifting streams. Such an alluvial region in a humid climate is known as a piedmont for the Piedmont district of Italy; in arid climates such a feature is called a bajada (*q.v.*).

Piedmont-Sardinia, Kingdom of: *see* Sardinia, Kingdom of.

piedmontite, a silicate mineral that belongs to the epidote (*q.v.*) series.

Piedras Negras, city, northeastern Coahuila state, northeastern Mexico. It lies at 722 feet (220 m) above sea level on the Rio Grande (Bravo del Norte River), just across from Eagle Pass, Texas, U.S., with which it is connected by two bridges. Founded in 1849, it was renamed Ciudad Porfirio Díaz in 1888; after that dictator's downfall, the original name was restored. Much of the city's prosperity is due to its function as a customs station and an international highway, railroad, and airline hub 840 miles (1,350 km) north by west of Mexico City. Piedras Negras is also the commercial and manufacturing centre for the agricultural hinterland, in which cotton and corn (maize) are cultivated and cattle are raised. Coal, silver, gold, and zinc are mined nearby. Industries in the city include zinc smelters, a cement plant, flour and textile mills, a lard factory, and sawmills. Its principal exports are cattle, sheep, hides, wheat, and bran. A superhighway to Mexico City was opened in 1958. Pop. (1980) 67,455.

Where the same name may denote a person, place, or thing, the articles will be found in that order

Pielinen, Lake, Finnish PIELISJÄRVI, lake located in Pohjois-Karjalan *lääni* (Pohjois-Karjala province), eastern Finland, near the U.S.S.R. border. The lake is approximately 60 miles (100 km) long between the town of Nurmes and the village of Uimaharju and ranges from 1 to 25 miles (1.5 to 40 km) in width. Its area is about 328 square miles (850 square km). Lake Pielinen has many islands and is drained southward into the large Saimaa lake system by the Pielis River. It is surrounded by dense forests, particularly on its scenic and rugged western shore, capped by Koli hill, which rises to a height of 1,141 feet (348 m); the hill is the centre of an important winter-sports area. There is no passenger ship service on the lake. Apart from Nurmes, the town of Lieksa on the eastern shore and the village of Juuka on the western shore are the only major settlements on the lake.

Pieman River, river, northwestern Tasmania, Australia, formed near Tullah by the confluence of the Rivers Macintosh and Murchison. The 61-mile- (98-kilometre-) long main stream is fed by the Huskisson and Stanley rivers and then flows generally west to its estuary, which also receives the Donaldson, Whyte, and Savage rivers at Belton Bay on the Indian Ocean. The river was named for an infamous convict, Alexander Pierce (Jimmy the Pieman), who was recaptured at its mouth after escaping from the Macquarie Harbour penal colony. It was the scene of some gold and tin mining during the 1870s and 1890s. After 1965 the development of iron-ore mining on the Savage and increased copper-mining activity at nearby Mount Lyell provided the impetus for the harnessing of the Pieman's hydropower potential. There is a small timber industry based at the port of Corinna on the estuary.

Pien Canal, Wade-Giles romanization PIEN HO, Pinyin BIAN HE, canal running through Honan, Anhwei, and Kiangsu provinces of China. In medieval times the name was given to several different canals that connected the Huang Ho (Yellow River), north of Cheng-chou in Honan, with the Huai River, and thus via the old-established Shan-yang Canal to the Yangtze River at Yang-chou, in Kiangsu. The terrain in the region is so flat and the drainage system so impermanent that no major engineering works were involved, apart from the manpower needed to excavate new channels. The canals made considerable use of existing waterways, which were widened, linked, and canalized.

The eastern section of the canal, from the Huang Ho to the region of modern K'ai-feng (Honan), was constructed as early as Han times (206 BC–AD 220), possibly before, and was known as the Lang-tang Canal. The Han Canal, known in later times as the Old Pien Canal, ran southeast from K'ai-feng as far as modern Shang-ch'iu (Honan) and then ran eastward to pass through the gap in the southward spur of the Shantung Hills at modern Suchow in Kiangsu Province. There it joined the Ssu River, which flows into the Huai above Ch'ing-chiang (Kiangsu).

The New Pien Canal was built in 605 by the emperor Sui Yang Ti of the Sui dynasty (581–618). It followed the old canal as far as Shang-ch'iu (Honan) but then flowed southeastward through Yung-ch'eng (Honan) and Su-hsien (Anhwei) to Ssu-hung (Kiangsu), where it joined the Huai above the Hung-tse Lake in Kiangsu, which was very much smaller in the 7th century. The New Pien Canal was constructed on a much larger scale than its predecessors. The whole length of the canal was followed by a post road and lined with willow trees; the canal itself had regular anchorages and guard stations. A million corvée labourers were mustered for its construction and worked under terrible conditions, leaving a legacy of disaffection with the Sui government. In 610, with the construction of the Yung-chi Canal, joining the Huang Ho to the region of modern Peking, there was a direct transport link from the Yangtze Basin to the north of the North China Plain.

Increasingly dependent upon revenue and grain supplies from the Huai and Yangtze region, the T'ang dynasty (618–907) developed this canal system still further during the 8th century. Under the Pei (Northern) Sung (960–1127), when the capital was moved to K'ai-feng, the canal became even more important, and by the 11th century the volume of traffic on it was probably about three times that in T'ang times.

In the early 12th century, however, with the division of China between the Juchen (Chin; 1115–1234) in the north and the Southern Sung (1127–1279) in the south, the canal was abandoned. When, under the Mongols (1206–1368) and the Ming dynasty (1368–1644), the unity of the empire was restored, the political centre was transferred to Peking (known to the Mongols as Ta-tu) and a totally new north–south canal—the Grand Canal—was built. The old east–west link between the Huang Ho and the Huai River lost its importance.

In the late 1960s, however, a New Pien Canal was constructed, as a part of the water-conservancy project for the Huai River Basin. The New Pien Canal scheme was initiated in 1966 and completed in 1970, with 450,000 labourers working on it for four successive years. Altogether some 155 mi (250 km) long, it takes the canalized upper waters of the Tuo and Kuo rivers, via the canalized course of the Sui-dynasty New Pien Canal, through a new channel 85 mi long, roughly following the course of the T'ang-period Pien Canal, through Ling-pi (Anhwei), Ssu-hsien, and Ssu-hung, and thus into the Hung-tse Hu. Although designed as a flood-control project, the canal also provides transport facilities for the area on the borders of Honan, Anhwei, and Kiangsu and is used for irrigation in several counties.

piepoudre court, piepoudre also spelled PIEPOWDER, lowest and most expeditious of the courts of justice known to the ancient common law of England. It was generally constituted by merchants and dealt with fair trading. The name is derived from the dusty feet of the participants (from French *pied poudré*, "dusty foot"), for the courts were often held outdoors.

The court decided summarily and on the spot disputes arising in fairs and markets. Its civil jurisdiction extended to all matters of contract arising within the district of the fair or market. These cases were mostly trade disputes; hence, the decisions were based upon the law as it was interpreted by the local merchants (*see* law merchant). Its criminal jurisdiction extended to all offenses committed at the particular fair where the court was held.

pier (marine architecture): *see* dock.

pier, in building construction, vertical load-bearing member such as an intermediate support for adjacent ends of two bridge spans. In foundations for large buildings, piers are usually cylindrical concrete shafts, cast in prepared holes, while in bridges they take the form of caissons, which are sunk into position. Piers serve the same purpose as piles but are not installed by hammers and, if based on a stable substrate, will support a greater load than a pile.

Especially adapted to large construction jobs, pier shafts having widths of more than 6 feet (1.8 metres) have been excavated to depths greater than 100 feet (30 metres). The lower portion of a pier may be widened to better distribute the downward pressure of a massive overlying structure. Formerly hand-dug shafts were widely used for piers where ground water presented no serious problem, but hand excavation has been largely superseded by the use of rotary or percussion drilling. The massive augers used to drill shafts for the piers of modern skyscrapers are mounted vertically on derricks, and the piers themselves are sufficiently long and wide to support the tremendous weight of even the tallest building. Piers for bridges are often installed by the caisson method. The caisson is a hollow boxlike structure that is sunk down through the water, and then through the ground to the bearing stratum by excavating from its interior, and it ultimately becomes a permanent part of the completed pier.

Pierce, Franklin (b. Nov. 23, 1804, Hillsboro, N.H., U.S.—d. Oct. 8, 1869, Concord, N.H.), 14th president of the United States (1853–57). He failed to deal effectively with the corroding sectional controversy over slavery in the decade preceding the American Civil War (1861–65).

An attorney and the son of a governor of New Hampshire, Pierce entered political life there as a Democrat, serving in the state legislature (1829–33), the U.S. House of Representatives (1833–37), and the Senate (1837–42). He became a devoted supporter of Pres. Andrew Jackson but was continually overshadowed by older and more prominent men on the national scene. Resigning from the Senate for personal reasons, he returned to Concord, where he resumed his law practice and also served as federal district attorney.

Except for a brief stint as an officer in the Mexican War (1846–48), Pierce remained out of the public eye until the Democratic nominating convention of 1852, at which a deadlock developed among the leading presidential contenders. Pierce's name was entered as a compromise candidate after the leading candidates, Lewis Cass, Stephen A. Douglas, and James Buchanan, failed in their bids for the nomination due to factional rivalries. The ensuing presidential campaign was dominated by controversy over the slavery issue. Both the Democrats and the Whigs were too badly split internally to stake out strong stands on the issue; the chief question in the public mind was the finality of the Compromise of 1850, and while both parties declared themselves in favour of it, the Democrats were more thoroughly united in its support. As a result, Pierce, who was almost unknown nationally, unexpectedly swept the country in the November election. Pierce then tried to promote sectional unity in the selection of his Cabinet, to which he named a coalition of Southern planters and Northern businessmen.

Franklin Pierce
By courtesy of the Library of Congress, Washington, D.C.

The youngest man to have been elected to the presidency as of that date, Pierce was handsome, genial, and possessed of a certain superficial brilliance. He represented the Eastern element of the Democratic Party, which was inclined for the sake of harmony and business prosperity to oppose antislavery agitation and generally to placate Southern opinion. Pierce accordingly sidestepped the fierce sectional antagonisms of the domestic scene by ambitiously and aggressively promoting the extension of U.S. territorial and commercial interests abroad. In an effort to buy Cuba, he ordered the U.S. minister to Spain, Pierre Soulé, to try to secure the influence of European financiers upon the Spanish government. The resulting diplomatic statement, the Ostend Manifesto (October 1854), was interpreted by the public as a call to wrest Cuba from Spain by force if necessary. The ensuing controversy forced the administration to disclaim responsibility for the document and to recall Soulé. The following year a U.S. adventurer, William Walker, conducted a notorious filibustering expedition into Central America with the hope of establishing a proslavery government that would be under the control of the United States. He established himself as military dictator, and then as president, of Nicaragua, and his dubious regime was recognized by the Pierce administration. A more lasting diplomatic achievement came from the expedition that had been sent out by Pres. Millard Fillmore in 1853 under Commo. Matthew C. Perry to Japan. In 1854 Pierce received Perry's report that his expedition had been successful and that U.S. ships would have limited access to Japanese ports. The Pierce administration also effected a reorganization of the diplomatic and consular service and the creation of the U.S. Court of Claims.

Among Pierce's domestic policies were preparations for a transcontinental railroad and the opening up of the Northwest for settlement. In order to open the way for a southerly route to California, almost 30,000 square miles (78,000 square kilometres) of territory were acquired from Mexico (1853; the Gadsden Purchase) for $10,000,000. Mainly to stimulate migration to the Northwest and to facilitate the construction of a central route to the Pacific, the Kansas–Nebraska Act was enacted in 1854 and received the President's sanction. This measure opened two new territories for settlement and provided resolution of the slavery question by popular sovereignty (local option). The indignation aroused by the act, which included repeal of the Missouri Compromise of 1820 (prohibiting slavery in the territories north of latitude 36° 30′), and the resultant violent conflict over slavery in the territories were the main causes of the rise of the Republican Party in the mid-1850s. Pierce's ineptness in handling the Kansas struggle made him unacceptable as a candidate for a second term, and he retired from public life in 1857.

Pierce, George Washington (b. Jan. 11, 1872, Webberville, Texas, U.S.—d. Aug. 25, 1956, Franklin, N.H.), U.S. inventor who was a pioneer in radiotelephony and a noted teacher of communication engineering.

The second of three sons of a farm family, Pierce grew up on a cattle ranch and fared well enough in the modest rural schools of central Texas to graduate (1893) after three years at the University of Texas, Austin. He taught in rural secondary schools in his native central Texas until 1898, when he won a fellowship to Harvard University. There he turned to physics, and after receiving his Ph.D. in 1900 he had an opportunity to study for a time in the laboratory of Ludwig Boltzmann in Leipzig.

Pierce returned to the United States and took up teaching at Harvard, where he served from 1903 to 1940. Upon the establishment of Harvard's Cruft High Tension Electrical Laboratory in 1914, Pierce became its director. There he did work that led to the practical application of a variety of experimental discoveries in piezoelectricity and magnetostriction. He developed the Pierce oscillator, which utilizes quartz crystal to keep radio transmissions precisely on the assigned frequency and to provide similar accuracy for frequency meters.

Pierce was an exceptional teacher, and he offered a number of the earliest courses in radio communications. This pioneering teaching, together with his numerous influential publications on radiotelegraphy and electroacoustics, led to his being credited with building the scientific foundations of electrical communication. His other accomplishments include the mathematical calculation of the radiation properties of radio antennas; invention of the mercury-vapour discharge tube, which was the forerunner of the thyratron; invention of a method of recording sound on film; and work on the magnetostriction of nickel and nichrome, which has important applications for underwater signalling and submarine detection. His later work concerned sound generation by bats and insects, a field in which he was still active and publishing in 1948.

Pierce wrote two classic textbooks, *Principles of Wireless Telegraphy* (1910) and *Electric Oscillations and Electric Waves* (1919).

Pierce, John Davis (b. Feb. 18, 1797, Chesterfield, N.H., U.S.—d. April 5, 1882, Medford, Mass.), Michigan's first superintendent of public instruction and leader in the establishment of the University of Michigan.

Though denied an extensive education as a youth because of his father's early death and consequent family financial limitations, Pierce decided at age 20 to educate himself. He succeeded so well that he was accepted at Brown

University, Providence, R.I., from which he was graduated in 1822. After a brief stint of teaching, he enrolled in the Princeton Theological Seminary and was ordained a minister of the Congregational Church by 1825.

He held pastorates in Sangerfield, N.Y., and Goshen, Conn., but Pierce was a Freemason, and when the Anti-Masonic Movement caught fire in America in the late 1820s, he lost his pulpits. He then moved to Michigan as a missionary and settled in 1831 in the pioneer town of Marshall.

After playing a prominent role in formulating the articles on education in Michigan's first constitution (1837), Pierce was appointed the state's first superintendent of public instruction. In that post he organized the primary schools; arranged for the sale of public lands to support public education; established qualifications for teachers; divided the state into school districts, providing for a library in each; and laid the groundwork for the creation of the University of Michigan.

He resumed his role of town preacher in Marshall in 1841 but in 1847 was elected to the state legislature. There he supported legislation establishing Michigan's first normal school. He left state government after serving as a member of Michigan's constitutional convention in 1850, and his only other participation in public life occurred in 1867–68, when he served as county superintendent of schools for Washtenaw County. He lived nearly all of the final three decades of his life in retirement at his farm near Ypsilanti.

Pierce was the founder and, from 1838 to 1840, the editor of *The Journal of Education,* the first professional education journal in the Great Lakes region.

Pierce, John Robinson (b. March 27, 1910, Des Moines, Iowa, U.S.), U.S. communications engineer, scientist, and father of the communications satellite.

Pierce began working for Bell Telephone Laboratories, Inc., New York City, in 1936. He improved the travelling-wave tube, which is used as a broad-band amplifier of microwaves, and designed a new electrostatically focussed electron-multiplier tube, used as a sensitive radiation detector. His Pierce electron gun produces high-density electron beams. During World War II, in collaboration with J.O. McNally and W.G. Shepherd, Pierce developed the low-voltage reflex klystron oscillator that was almost universally used in U.S. radar receivers.

In 1952 Pierce became director of electronics research at the New Jersey division of Bell Laboratories at Murray Hill. Two years later he began work on the theory of communications satellites. Although he wrote numerous papers detailing the advantages of using satellites to relay radio communications to all parts of the Earth, his ideas were largely ignored. Seeing the opportunity offered by the Echo balloon satellite for studying space phenomena, he persuaded the National Aeronautics and Space Administration (NASA) to convert the 100-foot (30-metre) aluminized sphere into a radio-wave reflector. Echo I was launched on Aug. 12, 1960. The success of the communications experiments carried out with Echo I provided the impetus to develop Telstar, a satellite designed to amplify signals from one Earth station and relay the signals back to another Earth station. These early satellites marked the beginning of efficient worldwide radio and television communication.

Pierce retired from Bell Laboratories in 1971 and became professor of engineering at California Institute of Technology, Pasadena; in 1979 he was named chief technologist at the Jet Propulsion Laboratory in Pasadena. He had begun writing science fiction in high school and later published stories under the pseudonym J.J. Coupling; in one of his stories he forecast the advent of communications satellites. His nonfiction works include *Traveling-wave Tubes* (1950) and *Symbols, Signals and Noise* (1961).

pierced work, in metalwork, perforations created for decorative or functional effect or both; the French term for such work is ajouré. Both hand-operated and mechanical tools such as saws, drills, chisels, and punches are used. The principal present-day exponents of this ancient technique are perhaps Asiatic Indian craftsmen. In European metalwork—apart from its functional and decorative use on handles, lids, covers, finials, and the like—pierced work is most often associated with such articles as locks and keys, iron and steel caskets, and guns, as well as with jewelry and other small objects. In the 18th century, however, it enjoyed a period of great popularity, when certain pieces of domestic silver—for example, cake baskets, sugar basins, and coasters—consisted almost entirely of intricate pierced-work patterns. A new tool was developed in order to pierce Sheffield plate in this manner. *See also* opus interassile.

Pieris, genus of about eight species of evergreen, white-flowered shrubs and small trees, of the heath family (Ericaceae), native to eastern Asia and eastern North America.

The leaves are usually alternate, broad, leathery, lance-shaped, and toothed. The flowers, which are cylindrical or urn-shaped, have a five-lobed calyx (the sepals, collectively) and grow in a terminal or axillary (*i.e.,* from the leaf axil) cluster.

Pieris (*Pieris*)

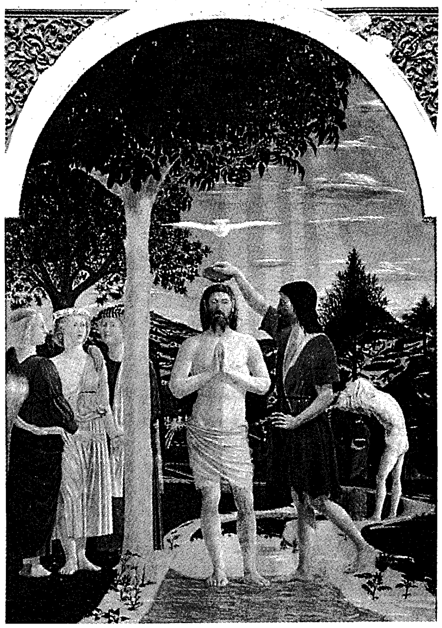
Valerie Finnis

Several species of *Pieris,* including *P. floribunda, P. japonica,* and *P. taiwanensis,* are cultivated as ornamentals. *P. japonica,* the lily-of-the-valley bush or Japanese andromeda, is very popular and is found in several varieties.

Pierleoni, Pietro (pope): *see* Anacletus (II).

Piero (Italian personal name): *see under* Peter, except as below.

Piero DELLA FRANCESCA (b. *c.* 1420, Sansepolcro?, Republic of Florence—d. Oct. 12, 1492, Sansepolcro), painter whose serene, disciplined exploration of perspective had little influence on his contemporaries but came to be recognized in the 20th century as a major contribution to the Italian Renaissance. The fresco cycle "The Legend of the True Cross" (1452–66) and the diptych portrait of Federico da Montefeltro, duke of Urbino, and his consort (1465) are among his best known works.



"The Baptism of Christ," panel painting by Piero della Francesca, *c.* 1440–45; in the National Gallery, London

Formative period. The documented facts of Piero della Francesca's life, which are few, permit a reasonably accurate reconstruction of his career and interests but not an exact chronology of his surviving paintings. His father, Benedetto de' Franceschi, was evidently a tanner and shoemaker, prosperous enough for his son to become well educated and literate in Latin. Nothing is known about Piero's early training as a painter, though it is assumed that he was instructed by local masters who had been influenced by Sienese art.

In 1439 Piero worked as an associate of Domenico Veneziano, who was then painting frescoes for the hospital of Sta. Maria Nuova in Florence, where the early Renaissance style was beginning to flourish. There he probably studied the statuary of Donatello and Luca Della Robbia, the buildings of Filippo Brunelleschi, and the paintings of Masaccio and Fra Angelico, and he might have read a theoretical treatise on painting by the Humanist and architect Leon Battista Alberti. Undoubtedly, he would have been directed to these luminaries by Domenico Veneziano, whose own works demonstrate a Renaissance emphasis on colour and light as elements of pictorial construction. It was Piero's contact with the early Renaissance art of Florence that provided the foundation of his own style.

Back in Sansepolcro by 1442, Piero was elected to the town council. Three years later the Confraternità della Misericordia commissioned an altarpiece from him. This polyptych shows Piero's indebtedness to the Florentines Donatello and Masaccio, his fondness for geometric form, and the slowness and deliberation with which he habitually worked—for the Misericordia altarpiece was not completed until 1462.

Periodic retreat to the provincial isolation of Sansepolcro seems to have been necessary for Piero's work. For the rest of his life he alternated between the calm of Sansepolcro and contact with the Humanistic life of the Renaissance in artistic and intellectual centres such as Ferrara and Rimini.

Around 1448 Piero probably worked in the service of Marchese Leonello d'Este in Ferrara, where he may have been influenced by northern Italian art. In 1451, at another northern Italian city, Rimini, he executed a splendidly heraldic fresco (*i.e.,* resembling a heraldic emblem in design) of "Sigismondo Malatesta Before St. Sigismund" in the Tempio Malatestiano, a memorial church built according to the architectural designs of Alberti. Also to this early formative period before 1451 belongs "The Baptism of Christ."

Mature period. Piero della Francesca's mature style is revealed in frescoes painted in the choir of the church of S. Francesco at Arezzo. The decorations had been begun in 1447 by the elderly Bicci di Lorenzo, who died in 1452; Piero presumably was retained to complete the work shortly thereafter. The narrative cycle, depicting "The Legend of the True Cross," was completed by 1466. Its simplicity and clarity of structure, controlled use of perspective, and aura of serenity are all typical of Piero's art at its best. Contemporary with the Arezzo cycle are a fresco of the "Magdalen" in Arezzo cathedral, the "Resurrection" in the Palazzo Comunale at Sansepolcro, and a "Madonna del Parto" in the chapel of the cemetery at Monterchi. In 1454 a burgher of Sansepolcro, Agnolo di Giovanni di Simone d'Angelo, commissioned an altarpiece for S. Agostino that Piero, characteristically, did not complete until 1469. The surviving panels of the altarpiece reveal Piero's interest in the creation of monumental human figures through the sculptural use of line and light.

In 1459 Piero was in Rome to paint frescoes (now destroyed) for Pope Pius II in the Vatican. "St. Luke" (Sta. Maria Maggiore), executed at the same time, was probably done by assistants in the studio he had established in Rome. More fruitful was Piero's long association with Count (later Duke) Federico da Montefeltro, whose highly cultured court was considered "the light of Italy." In the late 1450s Piero painted the "Flagellation of Christ," originally in the sacristy of the cathedral of Urbino; its lucid perspectival construction contrasts with treatment of the subject wherein Christ is relegated to the background while three unidentified figures dominate the foreground. The content of the picture has become the focus of modern academic controversy. A famous diptych portrait of Count Federico and his consort, Battista Sforza (Uffizi, Florence), probably commemorates their marriage in 1465. The paintings show Piero's respect for visual fact in the unidealized features of the Count and in the enchanting landscape backgrounds, which also indicate that he had discovered Netherlandish painting. The reverse depicts the couple in a triumphal procession accompanied by the Virtues. The Count reappears as a kneeling donor in an altarpiece from S. Bernardino, Urbino (now in the Brera, Milan). He, the Madonna and her child, and accompanying saints are placed before the apse (semicircular choir) of a magnificent Albertian church. The painting may have been a memorial to Countess Battista, who died in childbirth, and it has been dated between 1472 and 1474. The altarpiece is one of the most accomplished Renaissance presentations of forms in space and exerted a decided influence on the development of monumental devotional paintings in northern Italian and Venetian art.

Last years. The last two decades of Piero's life were spent in Sansepolcro, where paintings, now lost, were commissioned by local churches in 1474 and 1478. In 1480 Piero became prior of the Confraternità di San Bartolomeo. Among the few extant paintings from this period are the harmonious "Nativity," in London, the "Madonna" from the church at Sta. Maria delle Grazie near Senigallia, now in Urbino, and an awkwardly constructed altarpiece in Perugia, "Madonna with Child and Saints." The "Annunciation" from that altarpiece, however, indicates that Piero's interest in perspectival problems remained keen.

In his old age Piero seems to have abandoned painting in favour of more abstruse pursuits. Between 1474 and 1482 he wrote a treatise on painting, *De prospectiva pingendi* ("On Perspective in Painting"), dedicated to his patron, the Duke of Urbino. In its range of topics and method of organization, the book follows Alberti and the ancient Greek geometer Euclid. The principal manuscript, in Parma (Biblioteca Palatina), was handwritten by the artist himself and illuminated by him with diagrams on geometric, proportional, and perspectival problems. A second treatise, the *De quinque corporibus regularibus* ("On the Five Regular Bodies"), written some time after 1482, follows Plato and Pythagoras in dealing with the notion of perfect proportions. The manuscript, again illustrated by Piero, is in the Vatican Library. *Del abaco* ("On the Abacus," Laurentian Library, Florence) is a pamphlet on applied mathematics.

Piero's fascination with geometry and mathematics is a corollary of his own art; his manner of theoretical expression owes much to his mentor Alberti and is analogous to that of his younger contemporary Leonardo da Vinci; the rigour and logic of the arguments, however, are unique to Piero.

A reliable 16th-century tradition claimed that Piero was blind in his last years. If true, this must have occurred after 1490 because several autographs from that year survive. Moreover, his will of 1486 refers to the painter as aged but sound of mind and body.

Piero did not establish a lasting tradition in central Italy. Luca Signorelli and Perugino, who are presumed to be his most important pupils, followed the examples of other masters. Although Piero's reticent art had little influence on the experiments of his great Florentine contemporaries, he enjoyed great fame for his scientific contributions. In 1497 he was described as "the monarch of our times of painting and architecture," and the biographer Giorgio Vasari gave him high praise two generations later. In the 20th century, Piero's career has been reconstructed and his position reevaluated, giving proper credit to both the science and the poetry of his art. (P.F.W.)

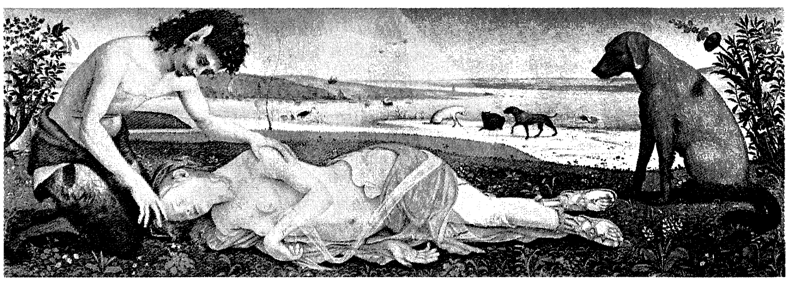
MAJOR WORKS. The following list includes nearly all of Piero's surviving works—panel paintings except where stated otherwise. "The Baptism of Christ" (*c.* 1440–45; National Gallery, London); "Polyptych of the Misericordia" ("Madonna della Misericordia"; 1445–62; Palazzo Comunale, Sansepolcro, Italy); "St. Jerome Penitent" (1450; Staatliche Museen Preussischer Kulturbesitz, Berlin); "Sigismondo Malatesta Before St. Sigismund" (fresco, 1451; Tempio Malatestiano, Rimini, Italy); "The Legend of the True Cross" (fresco cycle, 1452–66; S. Francesco, Arezzo, Italy); panels from the altarpiece of S. Agostino in Sansepolcro (commissioned 1454, finished 1469): "St. Augustine" (Museu Nacional de Arte Antiga, Lisbon); "St. Michael" (National Gallery, London); "St. Simon the Apostle(?)" (Frick Collection, New York City); "St. Nicholas of Tolentino" (Museo Poldi Pezzoli, Milan); and "Flagellation of Christ" (late 1450s; Galleria Nazionale delle Marche, Urbino, Italy); "Hercules" (*c.* 1460–66; Isabella Stewart Gardner Museum, Boston); "Resurrection" (fresco, *c.* 1463; Palazzo Comunale, Sansepolcro); "Portraits of Federico da Montefeltro, Duke of Urbino and of His Wife, Battista Sforza" (1465; Uffizi, Florence); "The Madonna with Child, Angels, Saints and Federico da Montefeltro, Duke of Urbino" (1470s; Brera, Milan); "Senigallia Madonna" (1470s; Galleria Nazionale delle Marche); "Madonna with Child and Saints" (*c.* 1472–74; Galleria Nazionale dell'Umbria, Perugia, Italy); "The Nativity" (*c.* 1480; National Gallery, London).

BIBLIOGRAPHY. The earliest biography of the artist is Vasari's "Life of Piero" (1550 and 1568), included in his *Lives of the Painters, Sculptors, and Architects,* trans. by A.B. Hind, vol. 2 (1963). Roberto Longhi, *Piero della Francesca* (1927; 2nd ed., 1946; Eng. trans. 1930), is the definitive critical and scholarly monograph. A useful catalog of paintings is Piero Bianconi, *Tutta la pittura di Piero della Francesca,* 2nd ed. (1959; *All the Paintings of Piero della Francesca,* 1962). Kenneth Clark, *Piero della Francesca,* 2nd ed. rev. (1969), remains the standard account of the artist in English. It is a rare union of eloquence and scholarship.

Piero DI COSIMO, original name PIERO DI LORENZO (b. 1462, Florence—d. 1521, Florence), Italian Renaissance painter noted for his eccentric character and his fanciful mythological paintings.

His name derives from that of his master, Cosimo Rosselli, whom he assisted (1481) in the frescoes "Crossing of the Red Sea" and "Sermon on the Mount" in the Sistine Chapel in the Vatican. There he saw the frescoes of Sandro Botticelli and Domenico Ghirlandajo, whose styles dominate his early "Story of Jason" (1486; National Gallery of South Africa, Cape Town). In "The Visitation with Two Saints" (*c.* 1487; National Gallery of Art, Washington, D.C.), the permanent influence of the enamel-like colours of Hugo van der Goes' "Portinari Altarpiece" is first visible.

Piero's mature style is exemplified by his mythological paintings, which exhibit a bizarre, romantic fantasy. Many are based on Vitruvius' account of the evolution of man. They are filled with fantastic hybrid forms of men and animals engaged in revels ("The Discovery of Wine," *c.* 1500; Fogg Art Museum, Cambridge, Mass.) or in fighting ("Battle of the Centaurs and the Lapiths," 1486; National Gallery, London). Others show early man learning to use fire ("A Forest Fire," *c.* 1487; Ashmolean Museum, Oxford) and tools ("Vulcan and Aeolus," *c.* 1486; National Gallery of Canada, Ottawa). The multitude of firm, glossy-skinned nudes in these paint-



"The Death of Procris," panel painting by Piero di Cosimo, *c.* 1500; in the National Gallery, London

ings show Piero's interest in Luca Signorelli's work. But, while "The Discovery of Honey" (*c.* 1500; Worcester Art Museum, Worcester, Mass.) retains Signorelli's figure types, its forms are more softly modelled, and its light is warmer, showing Piero's mastery of the new technique of oil painting. In the "Rescue of Andromeda" (*c.* 1515; Uffizi, Florence), Piero adopts Leonardo da Vinci's *sfumato* (smoky light and shade) to achieve a new lush, atmospheric effect.

Piero painted several portraits, of which the best known is the memorial bust of Simonetta Vespucci (*c.* 1498; Musée Condé, Chantilly), mistress of Giuliano de' Medici. Simonetta is partly nude, and her rhythmic profile is accentuated by the black cloud placed behind it. She wears a gold necklace, around which two snakes coil, possibly an allusion to her death from consumption. The transience of youth and beauty is the theme of the famous "Death of Procris" (*c.* 1490–1500; National Gallery, London). The softly undulating form of the accidentally slain Procris lies in a meadow bathed in a golden light while a curious satyr kneels beside her and her faithful dog—considered the first humanized dog in art—mourns at her feet.

Piero's art reflects his bizarre, misanthropic personality. He belonged to no school of painting. Instead, he borrowed from many artists, incorporating elements of their style into his own idiosyncratic manner. He painted many works to please only himself (an unusual practice for the time) and declared that he often found inspiration for his paintings in the stains on walls.

fur trader. Growth was spurred by its position as a railhead for the mining industry and as a trade centre for a large area, including three Indian reservations and prosperous farming and cattle country. In 1889, when South Dakota became a state, Pierre was named the temporary capital; in elections in 1890 and 1904 it was chosen the permanent capital. The capitol building (1905–10) is on a 30-ac (12-ha) tract overlooking the Missouri River, which includes a war memorial building housing the State Historical Society and Museum (1930), the governor's mansion (1936), state office building (1951), state highway building (1955), and a 7-ac artesian-fed lake. The Oahe Dam (1948–62), a power, irrigation, and flood-control project 5 mi (8 km) north of Pierre, has impounded a 200-mi lake along the Missouri River.

Fort Pierre, across the river, was the fur-trade capital of the Northwest from 1817 to *c.* 1867. A monument there marks the place where Louis and François Vérendrye buried a lead plate in 1743 (found in 1913) claiming the region for France. Pierre is the hub of a large diversified agricultural area. Lakes created by the Missouri Basin Development Plan form the basis of a large tourist industry. The Farm Island State Recreation Area is 4 mi east. Inc. city, 1883. Pop. (1980) 11,973.

Pierre (French personal name): *see under* Peter, except as below.

Pierre DE TARENTAISE (pope): *see* Innocent V, Blessed.

Pierre Shale, division of Upper Cretaceous rocks in the United States (the Cretaceous Period began about 136,000,000 years ago and lasted about 71,000,000 years). Named for exposures studied near old Ft. Pierre, S.D., the Pierre Shale occurs in South Dakota, Colorado, Minnesota, New Mexico, Wyoming, and Nebraska. The Pierre consists of about 600 metres (2,000 feet) of dark-gray shale, some sandstone, and many layers of bentonite (altered volcanic-ash falls that look and feel much like soapy clays). In some regions the Pierre Shale may be as little as 200 metres (650 feet) thick. The fossil Cretaceous sea turtle *Archelon,* the largest known turtle species that ever lived, has been found in South Dakota.

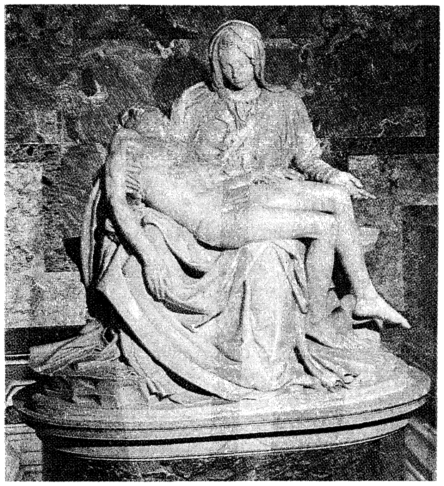
Pierrot (theatrical character): *see* Pedrolino.

Piešt'any, Hungarian PÖSTYÉN, town, Západoslovensky *kraj* (Western Slovakia region), Czechoslovakia, on the Váh River, about 48 mi (77 km) northeast of Bratislava. It is a Carpathian health resort, known since the Middle Ages for its warm sulfur springs and mud baths. It has specialized since the 16th century in treating rheumatic and arthritic diseases. The State Research Institute for Rheumatic Diseases is located there. Pop. (1983 est.) 31,257.

Pietà, as a theme in Christian art, depiction of the Virgin Mary supporting the body of the dead Christ. Some representations of the Pietà include John the Apostle, Mary Magdalene, and sometimes other figures on either side of the Virgin; but the great majority show only the two figures of Mary and her Son. The theme, which has no literary source but grew out of the theme of the lamentation over Christ's body, first appeared in the early 14th century in Germany. It soon spread to France and enjoyed great popularity in northern Europe in the 14th and 15th centuries. Although the Pietà remained primarily a Franco-German theme, its supreme representation is that completed by Michelangelo in 1499 and housed in St. Peter's Basilica. Influenced by the northern style, Michelangelo draped the figure of Christ across Mary's lap. Through this pyramidal design and the details of his figures, Michelangelo created a scene which displayed at once agony, solemnity, and heroic resignation.

The Pietà was widely represented in both painting and sculpture, being one of the most poignant visual expressions of current popular concern with the emotional aspects of the lives of Christ and the Virgin.

The format of the Virgin bearing the body



"Pietà," marble sculpture by Michelangelo, 1499; in St. Peter's, Rome (photo taken before the sculpture was damaged in 1972)
SCALA—Art Resource/EB Inc.

of Christ on her knees was standard until the 16th century, when, influenced by the Renaissance concern with logic and proportions, artists usually depicted Christ lying at the Virgin's feet, with only his head propped against her knees. This form was adopted by Italian Baroque art and was passed on to Spain, Flanders, and Holland. The theme of the Pietà found its most delicate and psychologically penetrating expression in France; in Spain it was treated with the greatest depth of emotion.

Most religious art suffered a decline after the 17th century, but, because of its special emotional appeal, the Pietà continued to be a vital theme through the 19th century.

Pietarsaari, Swedish JAKOBSTAD, city, Vaasan *lääni* (Vaasa province), western Finland, northeast of the city of Vaasa. Pietarsaari, which was formerly mainly Swedish speaking, was founded in 1652; it became an important commercial centre because of its location on the Gulf of Bothnia. The poet Johan Ludvig Runeberg (who wrote in Swedish but is Finland's national poet) was born there in 1804. Notable buildings include a 13th-century church, Malm House, which contains the municipal library and historical museum, and a wooden church built in 1731. Pietarsaari is a seaport and timber-export centre. Its industries include lumber and cellulose milling and the manufacture of lace, chicory, and machinery. Finland's oldest tobacco factory was founded there in 1762, and the city still maintains tobacco-processing facilities. Pietarsaari's outport, Leppäluoto (Swedish Alholm), is $2\frac{1}{2}$ mi (4 km) to the north. Pop. (1983 est.) mun., 20,658.

Pietas, in Roman religion, personification of a respectful and faithful attachment to gods, country, and relatives, especially parents. Pietas had a temple at Rome, dedicated in 181 BC, and was often represented on coins as a female figure carrying a palm branch and a sceptre or as a matron casting incense upon an altar, sometimes accompanied by a stork, the symbol of filial piety.

Pietermaritzburg, city, capital of Natal, South Africa, in the Umsindusi River Valley, at the base of a tree-covered escarpment, inland from Durban. Boers from the Cape Colony, who founded it in 1839 after a victory over the Zulus at Blood River, named it to honour their dead leaders Piet Retief and Gerrit Maritz. The British took control in 1843 and built Ft. Napier (now a historical monument). Pietermaritzburg was incorporated in 1854 and achieved capital status in 1856. Known as the "City of Flowers" for its azaleas, roses, and Botanical Gardens, the city shares with Durban the University of Natal (1909) and has many well-preserved late 19th-century government buildings, the Natal Museum, the Voortrekker Museum, and many recreational facilities. It has excellent highway and rail connections to Durban. Pietermaritzburg is the heart of an industrial complex; its industries include the manufacture of furniture and aluminum ware and the processing of wattle extract. At an elevation of 2,218 ft (676 m), the city is a gateway to Natal's game reserves and mountain resorts. Pop. (1983 est.) mun., 159,500.

Pietersburg, town, north central Transvaal, South Africa, located about midway between Pretoria and the Zimbabwe border, at an elevation of 4,199 ft (1,280 m). The town was founded by Voortrekkers (Afrikaans: "Pioneers") in 1886 on land purchased in 1884 from a local farmer and was named after Petrus (Piet) Joubert, a Boer general. It was the temporary capital in 1900 of both the Transvaal and the Orange Free State during the South African War. The British occupied the town in 1901.

Pietersburg is now a centre of trade for the surrounding agricultural area producing potatoes, alfalfa (lucerne), garlic, corn (maize), sorghum, peanuts (groundnuts), and fruits and is also a centre for some of the finest cattle ranches in South Africa. It is the largest urban area in the northern Transvaal and is an educational centre. The University of the North (founded 1959) serves the Tsonga, Sotho, Venda, and Tswana peoples and is located at Turfloop 14 mi (22.5 km) east of Pietersburg in the black homeland of Lebowa.

Industries in the town produce processed meat, asbestos and corundum products, dairy products, fruit juice, mineral waters, and candy. To the south of the town there is a nature reserve and recreation park. There is also a large military air installation (opened 1964). Pietersburg has major road and railway connections with the South Africa–Zimbabwe border (north) and with Johannesburg. Pop. (1983 est.) mun., 28,261.

Pieterszoon, Pieter: *see* Heyn, Piet.

Pietism, German PIETISMUS, an influential religious reform movement that began in German Lutheranism in the 17th century. Emphasizing personal faith in protest against secularization in the church, Pietism soon spread to other countries and during its history expanded its emphases to include social and educational concerns.

A brief treatment of Pietism follows. For full treatment, *see* MACROPAEDIA: Protestantism.

Throughout Christian history, pietistic movements have arisen in revolt whenever religion has become divorced from experience. By the beginning of the 17th century, Lutheranism had hardened into a scholastic system useful for contending with Roman Catholic and Reformed opponents but not for spiritual nourishment. Out of the devastation wrought upon Germany by the Thirty Years' War there appeared some notable signs of renewal. Interest was awakened in devotional literature and the pious mystical tradition. Influences of English Puritanism reached the Continent through the translation of works by Richard Baxter, John Bunyan, and others. Religious exiles in the Netherlands, among them William Ames, generated a distinctive brand of Dutch Pietism that soon spread into Germany as part of the reform movement that had already begun to take shape in German Lutheran circles as "Reform Orthodoxy." The "pectoral heart theology" of these orthodox Lutherans found its highest expression and widest audience in the writings of Johann Arndt (1555–1621). Lutheran hymnody of the period also contributed significantly to the atmosphere of spiritual renewal.

The various streams of the renewal movement converged in the life and work of Philipp Jakob Spener (1635–1705). Upon assuming an administrative pastorate in Frankfurt am Main, Spener became distressed by the degenerate life of the city and organized the first *collegia pietatis* ("assembly of piety"), in which lay Christians met regularly for devotional reading and spiritual exchange. The practice quickly became characteristic of the movement, and those who attended the conventicles acquired the name Pietists.

In his most famous work, *Pia Desideria* (1675; *Pious Desires*), Spener assessed contemporary orthodoxy's weaknesses and advanced proposals for reform. His proposals were: (1) greater private and public use of the scriptures; (2) greater assumption by the laity of their priestly responsibilities as believers; (3) the importance of bearing the practical fruits of a living faith; (4) ministerial training that emphasized piety and learning rather than disputation; and (5) preaching with the aim of edification. The *collegia pietatis* was the ideal instrument for such reforms.

From Spener, the leadership of German Pietism eventually passed to August Hermann Francke (1663–1727) of the University of Halle. Francke's capable leadership made Halle a thriving institutional centre of Pietism. A plethora of charitable institutions sprang up in association with the university. Among the illustrious figures sent out from Halle was Henry Melchior Mühlenberg (*see* Mühlenberg family), the organizer of colonial American Lutheranism.

Another Halle alumnus, Nikolaus Ludwig Count von Zinzendorf (1700–1760), founded the Moravian Church (*q.v.*) among Pietist-influenced Moravian refugees on his estate in Saxony. In contrast to the Halle Pietists' demand for penitential remorse, Zinzendorf's followers preached belief in Christ's atonement as the only requisite for salvation. It is perhaps through the efforts of Zinzendorf that Pietism exerted its greatest direct influence outside Germany.

John Wesley, the founder of Methodism, received his salutary inspiration among the Moravians and incorporated important pietistic elements, such as the emphasis on saving grace, into his fledgling evangelical movement. Other denominations felt the influence of Pietism on pastoral theology, mission activity, and modes of worship. The zenith of Pietism had been reached by the middle of the 18th century, but the movement continued to exist and still survives, both explicitly in parts of Germany and in the Moravian Church elsewhere and implicitly in evangelical Protestantism at large. The religious revival movements of the 19th and 20th centuries were connected directly or indirectly with Pietism, which in its turn received stimulation from them.

Consult the INDEX *first*

pietra dura (Italian: "hard stone"), in mosaic, any of several kinds of hard stone used in *commesso* mosaic work, an art that flourished in Florence particularly in the late 16th and 17th centuries and involved the fashioning of highly illusionistic pictures out of cut-to-shape pieces of coloured stone. The resulting decorative mosaics were used primarily for tabletops and small wall panels.

The term *pietra dura* signifies the requisite hardness and durability of the materials used in this work, officially describing those stones that fall between the 6th and 10th degrees of the Mohs scale of hardness—that is, between feldspar and diamond. The most commonly used of these hard stones were quartzes, chalcedonies, agates, jaspers, granites, porphyries, and petrified woods, all of which are variable in hue and together provide an almost limitless range of colour. Lapis lazuli, a semihard stone of brilliant blue, was the only stone regularly used in *commesso* work that does not fall into the *pietra dura* classification.

Pietrasanta, town, centre of a district known as Versilia, Lucca province, Toscana (Tuscany) region, central Italy, at the foot of the Alpi Apuane (mountains) just southeast of Carrara. Its piazza is surrounded by fine buildings including the cathedral of S. Martino and the church of S. Agostino (a baptistery with a medieval font), both dating from the 14th century, and the remains of the Rocca, a 12th-century citadel. Pietrasanta was strategically situated on the German Gothic Line in World War II and saw heavy fighting. Agricultural activities, tourism, and the quarrying and processing of marble are the principal industries of the town. Pop. (1981) mun., 25,384.

Pietro (Italian personal name): *see under* Peter, except as below.

Pietro DA CORTONA, French PIERRE DE CORTONE, original name PIETRO BERRETTINI (b. Nov. 1, 1596, Cortona, Tuscany—d. May

Church of Sta. Maria della Pace, Rome, by Pietro da Cortona

Anderson—Alinari from Art Resource/EB Inc.

16, 1669, Rome), Italian architect, painter, and decorator, an outstanding exponent of Baroque style.

Pietro studied in Rome from *c.* 1612 under the minor Florentine painters Andrea Commodi and Baccio Ciarpi and was influenced by antique sculpture and the work of Raphael. The most important of his earliest paintings were three frescoes (1624–26) in Sta. Bibiana, Rome. In the 1620s he designed the Villa del Pigneto near Rome and possibly another villa at Castel Fusano, both for his patrons, the Sacchetti family.

His fame reached its climax in the 1630s with the design of the church of SS. Luca e Martina, Rome (1635–50), and the ceiling fresco "Allegory of Divine Providence" (1633–39) in the Barberini Palace there. The design of SS. Luca e Martina derives more from Florentine than Roman sources, resulting in a different type of Baroque architecture from that of either Bernini or Borromini. The ceiling of the Gran Salone in the Barberini Palace, now the Galleria Nazionale, was conceived as a painted glorification of the Barberini pope, Urban VIII, and is treated illusionistically. Its strong colour and steep perspective recall Veronese, whose work Cortona may have seen in Venice in 1637.

Also in 1637 Pietro visited Florence, where he began painting the frescoes representing the "Four Ages of Man" for Grand Duke Ferdinand II of Tuscany in the Pitti Palace. In 1640 he returned to finish these and paint the ceilings of a suite of apartments in the palace named after the planets. He treated the entire surface as a single spatial unit, adding a wealth of real stucco decoration, partly gilt, in the carvings. He returned to Rome in 1647, where he painted the vault frescoes of Sta. Maria in Vallicella and the ceiling of the long gallery of the Pamphili Palace in Piazza Navona (1651–54) for Pope Innocent X. His chief architectural works of this period were the facades of Sta. Maria della Pace (1656–57)—perhaps his most ingenious conception—and Sta. Maria in Via Lata in Rome (1658–62). He also produced designs for the modernization of the Pitti Palace and the east front of the Louvre in Paris (1664). He painted religious and mythological easel pictures throughout his life. From 1634 to 1638 he was head of the Academy of St. Luke in Rome. Despite a correspondence in feeling between his architecture and his painting, there is little physical connection between them, and he never decorated one of his own churches.

Pietro DELLA VIGNA, also called PETRUS DE VINEA (b. *c.* 1190, Capua, Campania, Kingdom of Sicily—d. 1249, Pisa?), chief minister of the Holy Roman emperor Frederick II, distinguished as jurist, poet, and man of letters whose sudden fall from power and tragic death captured the imagination of poets and chroniclers, including Dante.

Born in the mainland part of the Kingdom of Sicily to a poor family (his parents were said to have been beggars), he studied law at Bologna, apparently at the expense of that city. In 1221 the Archbishop of Palermo presented him to Frederick, who made him a court notary. From 1225 to 1234, he served as a judge in the Magna Curia (high court) of Sicily, in which role he became the principal author of the constitution of Melfi (1231), a legal code that systematized Norman law, superimposing the new Hohenstaufen absolutism. The code was written in the elegant Latin style for which Pietro became famous. An exponent of the rhetorical *ars dictaminis* ("craft of composition"), Pietro influenced the literary form of Frederick's letters and public documents and, through them, the rhetoric of European courts. As a poet, writing in both Latin and Italian, he played a part in the development of the *dolce stil nuovo* ("sweet new style").

From 1230 on, Pietro was Frederick's closest adviser and most trusted ambassador. He undertook repeated missions to popes Gregory IX and Innocent IV and in 1234 travelled to England to arrange a marriage between Frederick and Isabella, sister of Henry III. The Emperor's collaborator and instrument in every important act of his reign, Pietro reached the apogee of his power in 1246, when he was appointed prothonotary (chief court official) and logothete (chancellor) of the Kingdom of Sicily.

In 1249, however, Pietro was accused of plotting to poison the Emperor. Arrested at Cremona, he was carried in chains from city to city until, finally, he was blinded at San Miniato, near Florence. It is not certain whether he died there from the injury or near Pisa by suicide. The question of the guilt of the man who, according to Dante, "held both keys of Frederick's heart" preoccupied contemporary writers, most of whom absolved him.

piezoelectricity, appearance of positive electric charge on one side of certain nonconducting crystals and negative charge on the opposite side when the crystals are subjected to mechanical pressure. This effect is exploited in a variety of practical devices such as microphones, phonograph pickups, and wave filters in telephone-communications systems.

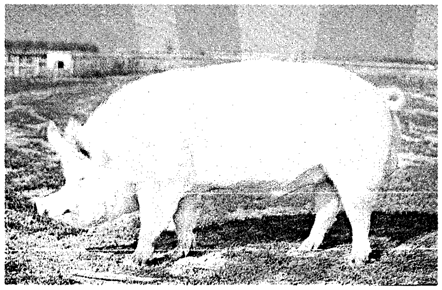
A brief treatment of piezoelectricity and piezoelectric devices follows. For a full treatment, *see* MACROPAEDIA: Electronics.

Pressure on certain electrically neutral crystals—those not having a centre of structural symmetry—polarizes them by slightly separating the centre of positive charge from that of the negative charge; equal and unlike charges on opposite faces of the crystal result. This charge separation may be described as a resultant electric field and may be detected by an appropriate voltmeter as a potential difference, or voltage, between the opposite crystal faces. This phenomenon, also called the piezoelectric effect, has a converse: the production of a mechanical deformation in a crystal across which an electric field or a potential difference is applied. A reversal of the field reverses the direction of the mechanical deformation. Alternating electric fields produce alternating mechanical vibrations of the same frequency. A piezoelectric material, such as a thin slab of quartz, can convert a high-frequency alternating electric signal to an ultrasonic wave of the same frequency. Or by the direct piezoelectric effect, such a crystal can convert a mechanical vibration, such as sound, into a corresponding electrical signal (alternating voltage). The converse piezoelectric effect is somewhat similar to electrostriction (*q.v.*).

Piezoelectricity was discovered in 1880 by Pierre and Paul-Jacques Curie, who found that when they compressed certain types of crystals including quartz, tourmaline, and Rochelle salt, along certain axes, a voltage was produced on the surface of the crystal. The next year, they observed the converse effect, the elongation of such crystals upon the application of an electric current.

For several decades piezoelectricity remained a laboratory curiosity. During World War I the converse piezoelectric effect was used to produce underwater acoustic waves in an early form of submarine-detecting sonar. Piezoelectric crystals later found wide use as frequency-control devices in radio communications. In World War II piezoelectric crystals were used in the detonators of air-dropped bombs; when the nose struck ground, the crystal sent a jolt of electricity to detonate the charge. The piezoelectric effect has subsequently been used in much electronic equipment, in clocks and watches, cigarette lighters, and many other items. Rochelle salt crystals exhibit strong piezoelectric effects, and they are used primarily in phonograph pickups. The mechanical vibration of the needle in the groove is converted by the crystal into a constantly varying electrical impulse. A problem with Rochelle salt crystals, however, is that the strength of their piezoelectric effect can change substantially with temperature, making them unsuitable for many applications, such as radio communications devices. For these, quartz crystals are used. While quartz crystals have a much weaker piezoelectric effect, they can be cut in ways to make them resist the effects of temperature change. About 1940 the ceramic material barium titanate was discovered to exhibit strong piezoelectric properties after being subjected to high temperature in a strong electric field. Similar ceramic materials are now widely used in high-power piezoelectric devices.

pig, wild or domestic swine, a mammal of the Suidae family. In Britain, the term pig refers to all domestic swine; in the United States, to younger swine not yet ready for market and weighing usually less than 180 pounds (82 kilograms), others being called hogs. Pigs are stout-bodied, short-legged, omnivorous mammals, with thick skins usually sparsely coated with short bristles. Their hooves have two functional and two nonfunctional digits. Domestic North American pigs originated from



Yorkshire Large White boar

J.C. Allen and Son

Breeds of domesticated pig

name and type	distribution	appearance	characteristics
Beltsville No. 1 and No. 2 (meat)	both developed in U.S.	No. 1 is black; No. 2 is red	both raised for meat
Berkshire (meat)	U.K., Japan, Australia, N.Z., South America	medium sized, colour mostly black	raised for pork and bacon in different areas
Chester White (lard)	developed Chester County, Pa.	large and white with pinkish skin	quiet disposition; sows prolific
Duroc, or Duroc-Jersey (lard)	North and South America	medium length body; drooping ears	½ Jersey Red, ½ Duroc
Hampshire (meat)	U.S. breed	medium weight, long body, black colour	active, alert, a good grazer
Hereford (lard)	developed U.S., about 1900	medium size; light to dark red colour	raised for lard
Landrace (meat)	north and central Europe and U.S.	medium size; white in colour	several breeds; raised for bacon
Maryland No. 1 (meat)	developed U.S., 1941	medium size; black and white spotted	about 60% Landrace, 40% Berkshire
Minnesota No. 1, No. 2, and No. 3	developed U.S.	various colours	all meat breeds
Montana No. 1 (meat)	developed U.S., 1930s	slightly curved back, trim jowls	combination of Landrace and Hampshire
Palouse (meat)	developed U.S., 1945	white, medium sized	⅔ Landrace, ⅓ Chester White
Poland China (meat)	developed U.S.	mostly black; white legs, nose, tail	developed from Russian, Byfield, Big China hogs
Spotted Poland China (meat)	developed U.S.	mostly white except for black legs	sometimes called Spots
Tamworth (meat)	U.S., U.K., N.Z., Australia, Canada	large, various colours	used for crossbreeding; raised for bacon
Yorkshire Large White (meat)	worldwide distribution	white colour	a bacon breed; sows are prolific

wild stocks still found in European, Asian and North African forests. Wild pigs are not truly native to North America but are believed to have been introduced on Columbus' second voyage in 1493 and brought to the mainland in the early 1500s. There is little difference between wild pigs, or boars, and domestic swine, though the tusklike teeth of domestic pigs are not as developed as the tusks of their wild kin, who use the sharp ends to forage for roots and as a defensive weapon. Wild pigs may live up to 25 years or more.

Domestic pigs are categorized according to three basic types: large-framed lard types with a comparatively thick layer of fat and carcasses usually weighing at least 220 pounds (100 kg); smaller bacon types, with carcasses of about 150 pounds (68 kg); and pork types with carcasses averaging around 100 pounds (45 kg). The U.S. Department of Agriculture's Regional Swine Breeding Laboratories oversee crossbreeding of domestic pigs, a process which has developed numerous breeds and strains.

In the late 20th century, China had the largest hog population of any country in the world, but scientific breeding was concentrated in Europe and the United States. Denmark produced the Landrace breed, raised for its excellent bacon. The Yorkshire Large White, the world's most popular breed, originated in Britain in the 18th century. Both Japan and the Soviet Union were endeavouring in the late 20th century to breed leaner hogs, partly with the help of imported breeds. *See also* livestock.

pig iron, crude iron obtained directly from the blast furnace and cast in molds. *See* cast iron.

Pigalle, Jean-Baptiste (b. Jan. 26, 1714, Paris—d. Aug. 21, 1785, Paris), French sculptor noted for his stylistically varied and original works.

Born into a family of master carpenters, Pigalle began training as a sculptor at age 18 with Robert Le Lorrain and then studied with Jean-Baptiste Lemoyne. After failing to win the Prix de Rome in 1735, he studied independently in Rome at his own expense from 1736 to 1739. While there Pigalle modeled the first version of his famous statue "Mercury Fastening his Sandals," a classicizing work conveying qualities of both graceful ease and youthful vitality. After returning to Paris he worked for local churches.

Pigalle was made a member of the Académie Royale in 1744, his reception piece being a marble version of the "Mercury." The statue became so popular that Louis XV commissioned a life-size marble version of it to present to Frederick II of Prussia in 1749. Pigalle was appointed a professor at the Académie Royale in 1752.

Pigalle enjoyed the patronage of Madame de Pompadour from 1750 to 1758. He created several allegorical figure groups for her, such as "Love and Friendship" (1758; Louvre), with some statues bearing her features in stylized form. He achieved considerable popularity with several smaller decorative, sentimental studies of children done in a Rococo style, such as the "Child With a Bird Cage" (1750; Louvre). He was also an original and intelligent portrait sculptor, as is evident in his forcefully observed bust of "Diderot" (1777; Louvre) and in the "Nude Voltaire" (1776; Louvre), an anatomically realistic rendering of the aged philosopher that caused a furor when first shown. Pigalle's two most important late commissions were the tomb of the Duc d'Harcourt (1769–76; Paris, Notre-Dame) and the grandiose and theatrically effective tomb of the Maréchal de Saxe in Strasbourg (1753–76). Stylistically, Pigalle was unable to harmoniously combine his naturalistic tendencies with the conventional classicizing formulas of the time, but his sculptures almost always show qualities of daring, inventiveness, and charm.

pigeon, any of several hundred species of birds constituting the family Columbidae (order Columbiformes). Smaller forms are usually called doves, larger forms pigeons. An exception is the white domestic pigeon, the symbol known as the "dove of peace" (*see* domestic pigeon).

Pigeons occur worldwide except in the coldest regions and the most remote islands. About 250 species are known; two-thirds of them occur in tropical Southeast Asia, Australia, and the islands of the western Pacific, but the family also has many members in Africa and South America and a few in temperate Eurasia and North America. All members of the family suck liquids, rather than sip and swallow as do other birds, and all pigeon parents feed their young "pigeon's milk," the sloughed-off lining of the crop, the production of which is stimulated by the hormone prolactin. The nestling obtains this "milk" by poking its bill down the parent's throat.

Pigeons are gentle, plump, small-billed birds with a skin saddle (cere) between the bill and forehead. All pigeons strut about with a characteristic bobbing of the head. Because of their long wings and powerful flight muscles, they are strong, swift fliers. Pigeons are monogamous; *i.e.,* they mate for life and the survivor accepts a new mate only slowly. The female lays two glossy white eggs in a flimsy nest that barely holds them. The female generally incubates the eggs by night, the male by day. The incubation period is 14 to 19 days, but the young are cared for in the nest for another 12 to 18 days.

The numerous genera of pigeons may be classified into subfamilies as follows:

The Columbinae, the typical, or true, pigeons, consists of about 175 species in about 30 genera. These often gregarious seed and fruit eaters are found worldwide in temperate and tropical regions. Some are ground feeders, others feed partly or wholly in trees. They are generally coloured soft gray and brown to black, sometimes with iridescent patches on the plumage. The cosmopolitan genus *Columba*—including the Old World wood pigeons and the New World band-tailed pigeons—is classified in this group, along with the *Streptopelia* species, the Old World turtledoves and ringdoves. To this genus also belong the street pigeons so common in urban areas. These are composed of a bewildering array of crossbreeds of domesticated strains, all of them ultimately traceable to the Old World rock dove (*Columba livia*). The rock dove is typically dull in colour—gray and white rump and two large black wing bars; this Eurasian species nests above 5,000 feet (1,525 m) in Asia. It has been domesticated and selectively bred since 3000 BC with the production of numerous colour variants and about 200 named strains—show pigeons, racing pigeons, and large edible types. Among such strains, pouter pigeons have a large, inflatable gullet; carrier pigeons have a long bill; runts, a massive bill and body; barbs, a short bill. Fantails may have 42 tail feathers; owl pigeons have diverging throat feathers; frillbacks, the feathers reversed; jacobins, hoodlike neck feathers. Tumblers tumble backward in flight.

The many other Old World genera in the subfamily Columbinae include the chicken-sized pheasant pigeon (*Otidiphaps nobilis*) of New Guinea. In the New World the white-winged doves and the mourning dove (*q.v.; Zenaida*) are popular game birds; Central and South America support the terrestrial ground doves (*Metriopelia*) and quail doves (*Geotrygon*). The New World passenger pigeon (*q.v.*) is extinct.

The Treroninae, or the fruit pigeons, consists of about 115 species in about 10 genera, found primarily in Africa, southern Asia, Australia, and the Pacific islands. These fruit-eating birds are soft-billed, short-legged, and arboreal in habit. Their plumage is usually greenish, often with yellow, red, or other brightly coloured markings. The group includes the heavyset imperial pigeons (*Ducula*); the small and extremely colourful fruit doves (*Ptilinopus*); the blue pigeons (*Alectroenas*), dark blue in colour with red wattles; and the usually crimson-legged green pigeons (*Treron*).

The Gourinae, or crowned pigeons, consists solely of three species (genus *Goura*), found in New Guinea. Blue-gray birds with fanlike head crests, they are the largest of all pigeons—nearly the size of a turkey.

The Didunculinae consists of a single species, the tooth-billed pigeon (*Didunculus strigirostris*), which is native to Samoa. This fruit-eating, terrestrial pigeon has adopted arboreal ways in response to near extermination by introduced predators. Unlike most pigeons, it uses its feet to hold down its food while pecking off pieces.

pigeon hawk: *see* merlin.

pigeon racing, also called PIGEON FLYING, racing for sport the homing pigeon, a specialized variety developed through selective crossbreeding and training for maximum distance and speed in directed flight.

The earliest record of the domestication of pigeons is from the fifth Egyptian dynasty (about 3000 BC). The sultan of Baghdad established a pigeon post system in AD 1150, and Genghis Khan used such a system as his conquests spread. Pigeons were widely used for messenger service in Europe during the Revolution of 1848, and in 1849 pigeons were used to carry messages during interruptions in telegraphic service between Berlin and Brussels. Pigeons were used as emergency message carriers in war well into the 20th century. The record flight for a U.S. Army Signal Corps pigeon was a flight of 2,300 miles (3,700 km). Flights of 1,000 miles (1,600 km) were routine.

Pigeon racing as a sport began in Belgium, where in 1818 the first long-distance race of more than 100 miles (160 km) was held. In 1820 a race took place between Paris and Liège and, in 1823, from London to Belgium. The sport gained prominence in the late 1800s in Great Britain, the United States, and France. Nowhere, however, did it match the popularity enjoyed in Belgium, where nearly every village had a Société Colombophile (Pigeon-fanciers Club). The annual Belgian Concours National, a race of about 470 miles (750 km) from Toulouse to Brussels, was inaugurated in 1881; during the same year, the first regular races in Great Britain—from Exeter, Plymouth, and Penzance to London—took place. The world governing body is the Fédération Colombophile Internationale, with headquarters in Brussels.

Racing pigeons are trained, by repeated practice, to return to their home loft when released at various distances and to enter the loft through the trapdoors. At the start of a race, competing birds are banded; they are then liberated together by a starter who records the time of release. The birds ascend rapidly, become oriented, and head directly toward their lofts. As the birds enter their home lofts, the band is removed from the leg and placed in a timing device that indicates the time of arrival. The distance of the pigeon's flight is divided by the time consumed to determine which pigeon has made the fastest speed. A bird is not considered to have arrived home until actually through the trap of its loft. Pigeons have been known to fly several thousand miles in returning home, and some have attained average speeds of more than 90 miles per hour (145 kilometres per hour) in races.

pigeon wheat: *see* hair-cap moss.

Piggott, Lester (Keith) (b. Nov. 5, 1935, Wantage, Berkshire, Eng.), one of the world's leading jockeys in Thoroughbred flat racing, British riding champion 11 times (1960, 1964–71, and 1981–82).

Born to parents whose families had long been associated with the turf, Piggott rode in his first race at the age of 12. He won the Derby nine times (1954, 1957, 1960, 1968, 1970, 1972, 1976, 1977, and 1983), the St. Leger eight times, the 2,000 Guineas four times, and the Oaks six times, along with other major British races. In 1974 he rode his 3,000th winner, in 1982 his 4,000th, and by the time he retired in 1985–86 to become a trainer he had won about 4,350 races in all. By 1985 he had won 29 victories in English classic races, more than any other rider. In 1970 he rode Nijinsky to victory as the winner of the English Triple Crown. He won numerous classic races in France and Ireland as well. He was created an officer in the Order of the British Empire in 1975. A biography by James Lawton was published in 1980.

piggyback plant: *see* pickaback plant.

pigment, any of a group of compounds that are intensely coloured and are used to colour other materials. Pigments are insoluble.

A brief treatment of pigments follows. For full treatment, *see* MACROPAEDIA: Chemical Compounds.

Pigments are applied not as solutions, but as finely ground solid particles. They are used in paints, printing inks, and plastics. Pigments may be organic (*i.e.,* contain carbon) or inorganic, but the organic pigments are generally brighter and last longer than the inorganic pigments. Pigments derived from natural sources have been used for centuries, but most pigments used today are synthetic. Organic synthetic pigments are derived from coal tars and other petrochemicals. Inorganic pigments are made by relatively simple chemical reactions—notably oxidation—or are found naturally as earths.

Inorganic pigments include white opaque pigments used to provide opacity and to lighten other colours. The most important member of the class is titanium dioxide. White extender pigments are added to paints to lower their cost or improve their properties. This class includes calcium carbonate, calcium sulfate, diatomaceous silica (the remains of marine organisms), and china clays. Black pigments are primarily created from particles of carbon. Iron oxide is used to give black colour to printing inks. Compounds of iron and oxygen are generally used to provide browns, maroons, reds, yellows, and oranges. The synthetic versions provide brighter, stronger colours. Certain compounds of chromium are used to provide yellows, oranges, reds, and greens. Various compounds of cadmium tend to be orange, red, yellow, or maroon. Iron blue, or Prussian blue, is the major inorganic blue pigment and is made of iron in combination with carbon, nitrogen, and hydrogen.

Organic pigments are primarily synthesized from aromatic hydrocarbons. These are compounds containing structures of carbon atoms with hydrogen atoms attached that are formed in closed rings. Organic pigments include azo pigments, which contain a nitrogen group. They account for most of the organic red, orange, and yellow pigments. Copper phthalocyanines are very important pigments because they provide brilliant, strong colours that are unusually colourfast for organic colours. Some pigments, such as fluorescent ones, are classified as precipitated dyestuff pigments. They are simply dyes that have been rendered insoluble by chemical reaction.

Pigneau de Béhaine, Pierre-Joseph-Georges (b. Nov. 2, 1741, Origny-Sainte-Benoîte, Fr.—d. Oct. 9, 1799, Qui Nhon, central Vietnam), Roman Catholic missionary whose efforts to advance French interests in Vietnam were regarded as important by later French colonizers.

Pigneau de Béhaine left France in 1765 and went to establish a seminary in southern Vietnam, then known as Cochinchina. He arrived at Ha Tien, near the Cambodian frontier, in 1767, and he remained there for two years, preparing Vietnamese pupils for the priesthood, until the seminary was destroyed in a Siamese invasion. He then escaped to Malacca with several of his students and reestablished the school in Pondicherry, India. He was made titular bishop of Adran in 1770, and about that time he left India and returned to Macau, where he compiled a dictionary and wrote a catechism in Vietnamese.

In 1774–75 Pigneau de Béhaine made his way back to Cochinchina via Cambodia. He remained at Ha Tien until 1777, when the rebel Tay Son brothers overthrew the seigneurial Nguyen family and orphaned the young heir, Nguyen Phuc Anh. In 1782, after Nguyen Anh's first attempt to regain control of the south had ended in disaster, the bishop met and befriended Nguyen Anh on the French-held island of Kah Kut, near Phu Quoc, for which he won the future king's enduring gratitude. The bishop returned to France in 1787 and persuaded King Louis XVI to sign a treaty with the Vietnamese prince, but he was unsuccessful in his attempts to obtain armaments and troops to reinstate his protégé. Undaunted, he returned to India, where he won support from French merchants for Nguyen Anh's cause. Unofficial French assistance played a significant, but not predominant, part in Nguyen Anh's successful battle to overcome the rebels. He became the emperor Gia Long over a united country in 1802.

Pigneau de Béhaine assisted Nguyen Anh in both foreign and domestic matters while the future emperor fought to extend his power over the whole country. The bishop was never able to convince Gia Long to do more than grudgingly tolerate Christian missionary work in Vietnam during his lifetime. After a long illness, Pigneau de Béhaine died on a journey to Nha Trang and was buried with military honours in Saigon.

pignut: *see* earthnut.

Pigot (of Patshul), George Pigot, Baron, 1ST BARONET (b. May 4, 1719, London—d. May 11, 1777, Madras), British East India merchant and governor of Madras who was arrested and deposed by his council in 1776.

At 17 Pigot entered the East India Company service, becoming governor and commander in chief of Madras in 1755. He stoutly defended Madras against the French in 1758–59, and after the capture of Pondicherry (a former French enclave on the southeast coast) by Lieutenant Colonel (afterward Sir) Eyre Coote in 1761, Pigot occupied the town on behalf of the Company. He returned to England in 1763 with a fortune of £400,000 and was given a baronetcy the following year. Member of Parliament for Wallingford (1765–68) and Bridgnorth (1768–77), he was created an Irish peer as Baron Pigot in 1766.

Pigot, oil painting by George Willison, 1777; in the National Portrait Gallery, London

By courtesy of the National Portrait Gallery, London

Returning to Madras in 1775 as governor, Pigot tried to suppress widespread corruption in the public service but in so doing created enemies. A majority of his council, backed by the East India trader Paul Benfield, opposed Pigot because of his proposed restoration of the raja (ruler) of Tanjore (Thanjāvūr). Pigot suspended two members of the council and ordered the arrest of the commandant, Sir Robert Fletcher. The government was then taken over by the majority of the council, and Pigot was imprisoned. From London, the court of directors ordered the restoration of Pigot to his post followed by his resignation; but he died before the order arrived. Parliament discussed the case in 1779, and four of those responsible for his arrest were tried and fined £1,000 each.

In the absence of male issue, the barony became extinct upon Pigot's death, but the baronetcy went to his brother Robert.

Pigou, Arthur Cecil (b. Nov. 18, 1877, Ryde, Isle of Wight—d. March 7, 1959, Cambridge, Cambridgeshire, Eng.), one of the most eminent British economists of the 20th century, noted for his studies in welfare economics.

Educated at King's College, Cambridge, Pigou succeeded Alfred Marshall in the Cambridge chair of political economy in 1908. It was primarily through his efforts that Marshall's ideas were disseminated and provided the leading theoretical basis for what subsequently became known as the Cambridge school of economics.

Pigou's most significant and influential work was *The Economics of Welfare* (1920), in which he sought to explore the effects of economic activity upon the total welfare of society and its various groups and classes. Pigou applied his powers of economic analysis to a number of other problems, including tariff policy, unemployment, and public finance. He also served on the Royal Commission on Income Tax (1919–20) and on two committees on the currency (1918–19; 1924–25).

pigpen: *see* hog house.

pigweed, any of several coarse annual plants of cosmopolitan distribution that are often troublesome weeds. Several of them belong to the genus *Amaranthus,* of the family Amaranthaceae. Prostrate pigweed, or mat amaranth (*A. graecizans*), grows along the ground surface with stems rising at the tips; spiny pigweed, or spiny amaranth (*A. spinosus*), has spines at the base of the leafstalks; and rough pigweed, or redroot (*A. retroflexus*), is a stout plant up to 3 m (about 10 feet) tall.

Other pigweeds are from the goosefoot family (Chenopodiaceae), such as the edible *Chenopodium album,* also called lamb's quarters (*q.v.*). Winged pigweed (*Cycloloma atriplicifolium*) is a much-branched upright plant with scalloped leaves; it grows to 60 cm (about 2 feet) tall and is often seen on sandy soils.

Pijao, extinct Indian people of the southern highlands of Colombia. The Pijao spoke a language of the Chibchan family, related to that of the Páez, their neighbours to the south. They were agriculturists, raising corn (maize), sweet manioc (yuca), beans, potatoes, and many fruits; they also hunted and fished. They lived in settlements of several families in houses built of wood and plastered with mud and clay. They made pottery, wove cotton, worked stone, and smelted and worked gold and copper. They generally wore no clothing except palm-leaf hats, though they painted the body and adorned it with feathers and sometimes gold ornaments. They deformed the skulls of their infants by tying boards against them. They were also cannibals who devoured their slain enemies. The Pijao worshipped idols and believed that the dead were reincarnated as animals. They refused to make peace with the Spaniards and were completely annihilated by the mid-17th century.

Pijia (Mongol khan): *see* Bilge.

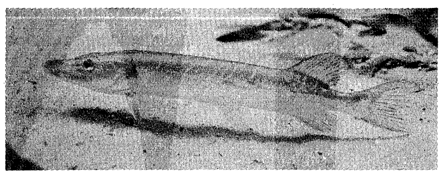
pika, also called LITTLE CHIEF HARE, MOUSE-HARE, WHISTLING HARE, or PIPING HARE, any of numerous small, essentially tailless, rabbitlike mammals found in parts of western North America as well as in Asia and eastern Eu-

Pika (*Ochotona princeps*)
Kenneth W. Fink—Root Resources

rope. Pikas belong to the genus *Ochotona,* the family Ochotonidae, and the order Lagomorpha. The names rock rabbit and cony (coney) are sometimes ambiguously applied to these animals as well as to the unrelated hyrax (*q.v.*).

Pikas have rounded ears; their brownish or reddish fur is soft, long, and thick. They are about 15 to 30 centimetres (6 to 12 inches) long and weigh about 125 to 440 grams (4 to 14 ounces). Most pikas live in rocky, mountainous areas, but, in Asia, some species inhabit burrows in forests and even in desert areas. Pikas do not seem to hibernate. During the summer and autumn months, pikas "harvest" vegetation, which they dry in the sun. This hay, stored under rocks or in other protected places, provides a source of food during the winter. Pikas bear several litters of two to six naked young in the spring and summer months. The gestation period is about one month.

pike, any of several voracious freshwater fishes, family Esocidae, caught both commercially and for sport. They are recognized by the elongate body, small scales, long head, shovellike snout, and large mouth armed with



Northern pike (*Esox lucius*)
Russ Kinne—Photo Researchers

strong teeth. The dorsal and anal fins are far back on the tail.

The northern pike (*Esox lucius*) of North America, Europe, and northern Asia has pale, bean-shaped spots on the body and lacks scales on the lower parts of the gill covers. It is a fairly common and prized game fish with a maximum size and weight of about 1.4 metres (4.5 feet) and 21 kilograms (46 pounds). The muskellunge and pickerel (*qq.v.*) are North American pikes similar in habit to the northern pike.

Solitary hunters, pikes, pickerel, and muskellunge lie motionless in the water or lurk in a clump of weeds. As the prey comes within reach, they make a sudden rapid lunge and seize it. They usually eat small fishes, insects, and aquatic invertebrates, but larger forms also take waterfowl and small mammals. They spawn in weedy shallows from late winter through spring.

Pikes are of the order Salmoniformes. Wall-eyed pikes are not true pikes; they are members of the perch order (Perciformes).

pike, ancient and medieval infantry weapon consisting of a long, metal-pointed spear with a heavy wooden shaft 10 to 20 feet (3 to 6 metres) long. Its use among the Swiss foot soldiers in the 14th century contributed to the decline of the feudal knights. The pike disappeared from land warfare with the introduction of the bayonet, though it was retained as a naval boarding weapon through the 19th century. A variety of pike is used by the picador in bullfighting.

Pike, Kenneth L(ee) (b. June 9, 1912, Woodstock, Conn., U.S.), U.S. linguist and anthropologist known for his studies of the aboriginal languages of Mexico, Peru, Ecuador, Bolivia, New Guinea, Java, Ghana, Nigeria, Australia, Nepal, and the Philippines. He was also the originator of tagmemics.

Tagmemics is an outgrowth of Bloomfieldian immediate constituent analysis and of Pike's own general theory of human behaviour, described in his *Language in Relation to a Unified Theory of the Structure of Human Behavior,* 3 vol. (1954–60; 2nd ed. 1967). The tagmeme is a unit comprising a function (for example, a subject) and a class of items fulfilling that function (*e.g.,* nouns). It is most suitable in describing languages (such as the Central and South American languages to which it has mostly been applied) in which a number of different classes can fulfill the same function or in which the same class can fulfill many functions. Tagmemics is also known as string constituent analysis and differs, in part, from Bloomfieldian linguistics in that semantic as well as syntactic function is used in identifying tagmemes. Pike later applied tagmemics to matrix of field theory and English rhetoric.

From 1955 to 1977 Pike held the post of professor of linguistics at the University of Michigan at Ann Arbor, where he received his Ph.D. in 1942. In addition to his work in tagmemics, Pike has done research in phonology and is the author of *Intonation of American English* (1945); co-editor of *Tone Systems of Tibeto-Burman Languages of Nepal, Parts I–IV* (1970); and co-author of *Grammatical Analysis* (1977) and *Songs of Fun and Faith* (1977). Selections from his work were published in *Selected Writings* in 1972.

Pike, Zebulon Montgomery (b. Jan. 5, 1779, Lamberton, N.J., U.S.—d. April 27, 1813, York, Ont.), U.S. army officer and explorer for whom Pikes Peak in Colorado was named.

In 1805 Pike, then an army lieutenant, led a 20-man exploring party to the headwaters of the Mississippi River with instructions to discover the river's source, negotiate peace treaties with Indian tribes, and assert the legal claim of the United States to the area. Pike travelled 2,000 miles (3,200 kilometres) by boat and on foot from St. Louis, Mo., to Leech and Sandy lakes, in northern Minnesota. He erroneously identified Leech Lake as the river's source.

In July 1806 Pike was dispatched to the Southwest to explore the Arkansas and Red rivers and to obtain information about the adjacent Spanish territory. Pike established an outpost near the site of present-day Pueblo, Colo., and then led his party northwest, where they encountered the Front Range of the Rocky Mountains. After trying unsuccessfully to scale the mountain peak later named for Pike, the party proceeded southward to northern New Mexico, where they were apprehended by Spanish officials on the charge of illegal entry into New Mexico. They were escorted across Texas to the Spanish–American border at Natchitoches, La., where on July 1, 1807, they were released.

Zebulon Pike, portrait by Charles Willson Peale, 1808; in Independence National Historical Park, Philadelphia
By courtesy of the Independence National Historical Park Collection, Philadelphia

Pike's report on Santa Fe, with information noting particularly the military weakness of the capital and the lucrativeness of the overland trade with Mexico, stimulated the expansionist movement into Texas. Pike served in the War of 1812, attaining the rank of brigadier general. He was killed in action during the attack on York.

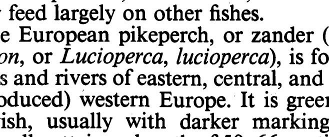
pikeperch, any of several freshwater food and game fishes of the family Percidae (order Perciformes), found in Europe and North



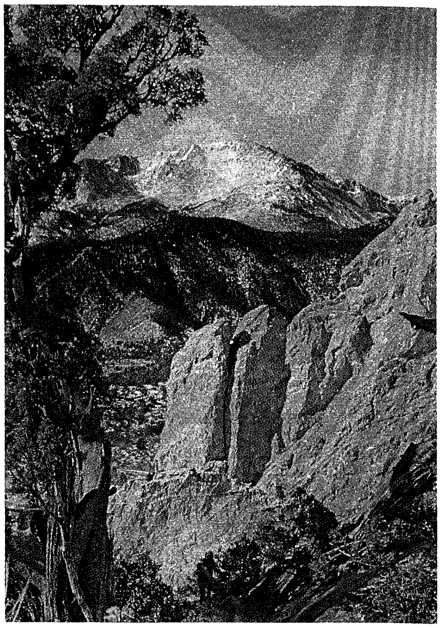
Pikeperch (*Stizostedion lucioperca*)
Painted especially for *Encyclopaedia Britannica* by Tom Dolan, under the supervision of Loren P. Woods, Chicago Natural History Museum

America. Although more elongated and slender than perches, pikeperches have the two dorsal fins characteristic of the family. They are, like perches, carnivorous, and as adults they feed largely on other fishes.

The European pikeperch, or zander (*Stizostedion,* or *Lucioperca, lucioperca*), is found in lakes and rivers of eastern, central, and (where introduced) western Europe. It is greenish or grayish, usually with darker markings, and generally attains a length of 50–66 centimetres (20–26 inches) and a weight of 3 kilograms (6.6 pounds).

The North American pikeperches include the walleye (*S. vitreum*), found in clear, cool lakes and rivers, and the sauger (*S. canadense*), found in lakes and rather silty rivers. Both are darkly mottled fishes native to eastern North America. The sauger, the smaller of the two, does not usually exceed a length and weight of about 30 cm and 1 kg. The walleye rarely weighs more than 4.5 kg and has a maximum length and weight of about 90 cm and 11 kg.

Pikes Peak, peak in the Front Range of the Rocky Mountains in El Paso County, Colorado, U.S., 10 mi (16 km) west of Colorado Springs. It ranks 32nd in altitude (14,110 ft [4,301 m]) among Colorado peaks and is widely known because of its commanding location and easy accessibility. Located on the edge of the Great Plains, it is in the southeastern corner of Pike National Forest; to the southwest is the famous Cripple Creek gold district. Ascent to the summit (a fairly level area of about 60 ac [24 ha]) may be easily accomplished by trail, cog railway (8.75 mi), or automobile toll road (18 mi). An average snowfall of about 9½ ft on the northern



Pikes Peak above Gateway Rocks, Colorado
David Muench—EB Inc.

slope and 14 ft on the southern assures skiing conditions. Colorado Springs draws its main water supply from Pikes Peak Watershed. The timberline is between 11,400 and 12,000 ft; above it rise nearly 2,500 ft of bare granite. The view from the summit is said to have inspired Katharine Lee Bates to write "America the Beautiful" in 1893.

The peak was discovered in November 1806 by Lieut. Zebulon Pike, who abandoned his attempt to climb it because of snow and a lack of warm clothing. It was climbed by Edwin James, J. Verplank, and Z. Wilson of Maj. Stephen Harriman Long's expedition on July 14–15, 1820; this was the first recorded ascent of a 14,000-ft peak in any area of what became the United States. Long named the mountain for James, but common usage had bestowed Pike's name upon it by 1859, when it became the focal point of a gold rush with the slogan "Pikes Peak or bust."

A list of the abbreviations used in the MICROPAEDIA *will be found at the end of this volume*

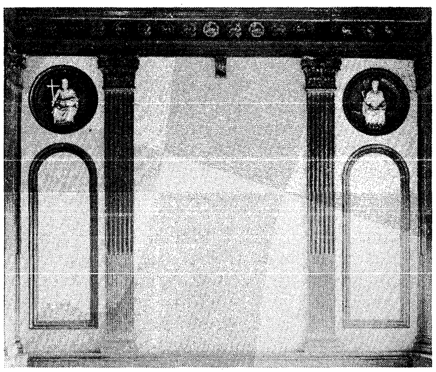
Piła, *województwo* (province), west central Poland, established 1975, comprising an area of 3,168 sq mi (8,205 sq km). It is bordered by the provinces of Koszalin and Słupsk on the north, Bydgoszcz on the east, Poznań on the south, and Gorzów Wielkopolski on the west. The Noteć River crosses the province from northeast to southwest on its way to the Oder, and the Gwda River flows from north to south to join the Noteć. Industries include lumber mills, railroad workshops, potato-processing facilities, and building-materials plants. Three inland ports are located on the Noteć River at Wieleń, Czarnków, and Ujście. Health spas and resorts are situated throughout the province's wooded areas. Piła city is the provincial capital. It suffered much damage in World War II and is largely rebuilt. Other major cities in the province are Wałcz, Wągrowiec, and Chodzież. The province's industry, almost completely destroyed in World War II, has been restored and expanded. Pop. (1984 est.) 455,000.

Piła, German SCHNEIDEMÜHL, city, capital of Piła *województwo* (province), west central Poland, on the Gwda River. Its economic growth has been steady since World War II. Industries include lumber mills, railroad workshops, and potato-processing facilities. The city lies on the Berlin–Gdańsk (Danzig) rail line.

First chronicled in the 15th century, Piła received town rights in 1512. It passed to Prussia in 1772 and was returned to Poland in 1945. About 80 percent of Piła was destroyed during World War II. Pop. (1984 est.) 64,600.

Pilar, capital, Ñeembucú department, southwestern Paraguay. It lies on the eastern bank of the Paraguay River across from the mouth of the Arrogo Bermejo (Bermejo Stream). Founded in 1779, the settlement was originally known as Ñeembucú. The city is now an important river port handling the agricultural products of the fertile area between the Paraguay and Paraná rivers; it is also a manufacturing centre, with textile mills, sawmills, and distilleries. The city has a teachers college, church, hospital, and a branch of the Bank of Paraguay. A road leads eastward from Pilar to the Asunción-Encarnación highway, and there is a small airport. Pop. (1982 prelim.) 13,135.

pilaster, in Greco-Roman Classical architecture, shallow rectangular column that projects slightly beyond the wall into which it is built and conforms precisely to the order or style of the adjacent columns. The anta of ancient



Renaissance pilasters in the Pazzi Chapel, Sta. Croce, Florence, designed by Filippo Brunelleschi
Foto Marburg—Art Resource/EB Inc.

Greece was the direct ancestor of the Roman pilaster. The anta, however, which served a structural purpose as the terminus of the side-wall of a temple, was not required to conform in style to the temple columns.

In ancient Roman architecture the pilaster gradually became more and more decorative rather than structural, as it served to break up an otherwise empty expanse of wall. The fourth-story wall of the Colosseum, the great amphitheatre built in Rome during the 1st century AD, contains examples of the Roman use of pilasters. In Renaissance architecture, beginning in Italy and spreading to France and England, pilasters were extremely popular on both interior and exterior walls. The decorative pilaster was also common in the designs of the later European Neoclassical periods.

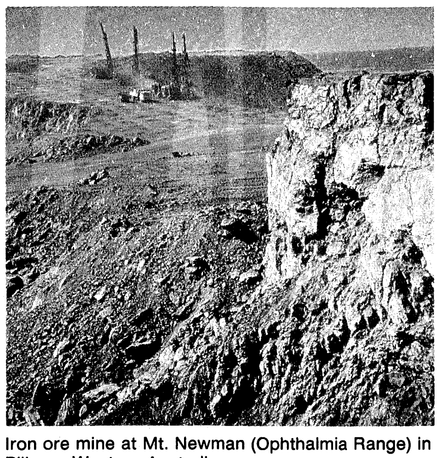
Pilate, Pontius (d. after AD 36), Roman prefect (governor or procurator) of Judaea (AD 26–36) under the emperor Tiberius; he presided at the trial of Jesus and gave the order for his crucifixion.

According to the traditional account of his life, Pilate was a Roman equestrian (knight) of the Samnite clan of the Pontii (hence his name Pontius). He was appointed prefect of Judaea through the intervention of Sejanus, a favourite of the Roman emperor Tiberius. Protected by Sejanus, he incurred the enmity of the Jews by insulting their religious sensibilities, as when he hung worship images of the Emperor throughout Jerusalem and had coins bearing pagan religious symbols minted. After Sejanus' fall (AD 31), Pilate was exposed to sharper criticism from the Jews, who may have capitalized on his vulnerability by obtaining a legal death sentence on Jesus (John 19:12). The Samaritans reported him to Vitellius, legate of Syria, after he had attacked them on Mt. Gerizim (AD 36). He was then ordered back to Rome to stand trial for cruelty and oppression, particularly on the charge that he executed men without proper trial. According to an uncertain 4th-century tradition, Pilate killed himself on orders from Emperor Caligula in AD 39.

Judgments of the man himself must be made inferentially, almost entirely on the basis of later Jewish and Christian writings, chiefly Josephus and the New Testament. Josephus' references appear to be consistent. They seem to picture a strong-willed, strict, authoritarian Roman leader who was, nevertheless, both rational and practical and who knew how far he should go in a given case. For example, Josephus tells us that "in order to abolish Jewish laws," and with the intent of diminishing privileges Jews had hitherto enjoyed, Pilate ordered his troops to encamp in Jerusalem and sent them into the city with images of the emperor attached to their ensigns. When the Jews demonstrated in Caesarea, Pilate's city of residence, he threatened them with death unless they desisted; but when the Jews showed their readiness to die, he ordered the images removed. Josephus states his inferential judgment that Pilate "was deeply affected with their firm resolution," suggesting his own strength of character.

The New Testament, however, suggests a weak, vacillating personality. Would the mob be just as happy if he released Jesus instead of Barabbas on the feast day (Mark 15:6 ff.)? Pilate weakly capitulates. His wife sends him word of her dream (Matt. 27:19), and Pilate abdicates his responsibility to the emperor. In the Fourth Gospel, Pilate is depicted as having accepted the Christian interpretation of the meaning of Jesus (John 19:7–11), and he rejects the Jews' reminder that Jesus has merely said that he is "the king of the Jews" (19:21). Clearly, as an index to the character and personality of Pilate, the New Testament is devastating. But it is preoccupied with concerns of the nascent Christian communities, increasingly making their way among the Gentiles and anxious to avoid giving offense to Roman authorities. Eventually, in Christian tradition, Pilate and his wife became converts, and the latter is a saint in the Eastern Church.

Pilbara, also spelled PILBARRA, region of northwestern Western Australia, extending south from the De Grey River to the Ashburton River and as far as 450 mi (720 km)



Iron ore mine at Mt. Newman (Ophthalmia Range) in Pilbara, Western Australia
By courtesy of the Australian Information Service

inland. It occupies an area of about 197,000 sq mi (510,000 sq km) and averages 1,000 ft (300 m) in elevation. It includes one of Australia's hottest spots at Marble Bar, where daytime temperatures from October to May often exceed 120° F (49° C); in a record heat wave in 1923–24, temperatures reached 100° F or more on 170 consecutive days.

Gold, discovered in the region in 1883, led to the declaration of the Pilbara (1888) and West Pilbara (1895) goldfields. Tin was found in 1899, and deposits of copper, talc, manganese, magnesium, silver, beryllium, and columbite have also been worked. There still remain valuable deposits of asbestos at Wittenoom Gorge in the Hamersley Range and tantalite at Wodgina.

Massive development of the iron industry, based on ore mined in the Hamersley Range (*q.v.*), brought an influx of population to the area in the 1970s. One of the principal mines is Mt. Newman, from which ore is shipped by rail northward to Port Hedland. Another railroad carries ore from Paraburdoo and Mt. Tom Pierce to Dampier, a newly built ore port west of old Roebourne. Salt is produced at Dampier and Port Hedland.

The Pilbara forms a statistical division comprising four shires: East and West Pilbara, Roebourne, and Port Hedland. Pop. (1981) 47,284.

pilchard, a species of sardine (*q.v.*) found in Europe. It is the local name in Great Britain and elsewhere.

Pilcher, Percy Sinclair (b. January 1866—d. Oct. 2, 1899, Leicestershire, England), British engineer, aviation pioneer, and glider experimenter. He began the study of heavier-than-air flight in 1895 under the influence of Otto Lilienthal, whom he twice visited in Germany.

In 1895 Pilcher built his first glider, the *Bat,* which he modified after Lilienthal's ideas and used in many successful glides. His second machine, the *Beetle,* was also built in 1895, and his third, the *Gull,* in 1896. With his fourth glider, the *Hawk* (1896), Pilcher achieved his most productive flying. It was a monoplane, with rear fin and tail plane and a wheeled undercarriage, controlled in the Lilienthal manner of swinging the torso and legs from a hanging position between the wings.

He then turned his attention to the problem of powered flying. He had almost completed his first powered machine—for which he had also built the engine—when on Sept. 30, 1899, the *Hawk* broke up in the air when Pilcher was gliding in it at Stanford Park, near Market Harborough. Two days later he died from his injuries.

Pilcomayo River, Spanish RÍO PILCOMAYO, chief western tributary of the Paraguay River, south central South America. It rises in the eastern Andes Mountains, in Bolivia, and flows in a southeasterly direction through the Gran Chaco plains of Paraguay to join the Paraguay River opposite Asunción, after a course of 1,550 mi (2,500 km). Its lower course (about 410 mi), used for navigation by small craft, flows through a number of small channels separated by bars and shifts direction with each flood season. The Pilcomayo (Guaraní: "River of the Birds") forms part of the international border (delimited in 1945) between Formosa Province (Argentina) and Paraguay.

pile, in textiles, the surface of a cloth composed of an infinite number of loops of warp threads, or else of an infinite number of free ends of either warp or of weft, or filling, threads that stand erect from the foundation or ground structure of the cloth. In looped pile the loops are uncut; in cut pile the same or similar loops are cut, either in the loom during weaving or by a special machine after the cloth leaves the loom.

Velvet is a short-pile fabric and plush a long-pile fabric, both of which have pile formed by warp threads. Velveteen is fabric with pile formed of filling threads that have been cut.

Among the loop-pile fabrics are Brussels tapestry, imitation Brussels carpeting, and Moquettes. In some cases the surfaces of carpets, such as Wilton and Axminster, are formed of cut pile; in others, both looped and cut pile appear on the surface of the same fabric. Imitation seal and other furs are pile fabrics. The surfaces of pile fabrics may have decorative designs appearing in both kinds of pile and in several colours.

pile, in building construction, a postlike foundation member used from prehistoric times. In modern civil engineering, piles of timber, steel, or concrete are driven into the ground to support a structure; bridge piers may be supported on groups of large-diameter piles. On unstable soils, piles are indispensable building supports and may also be used on stable ground when exceptionally large structural loads are involved. Piles are driven into the ground by pile drivers, machines consisting usually of a high frame with appliances for raising and dropping a pile hammer or for supporting and guiding a stream or air hammer.

pile (disease): *see* hemorrhoid.

Pilea, genus of herbaceous creeping plants in the nettle family (Urticaceae) but lacking the stinging hairs typical of that family. Of the more than 200 species widespread in temperate and tropical regions, a few are useful as border-edging plants in warm areas and many varieties are available as indoor pot plants and for hanging baskets.

Especially popular are the artillery plant (*P. microphylla*), with fine fernlike foliage and anthers that forcefully expel their pollen when mature; aluminum plant, or watermelon pilea (*P. cadierei*), with silvery markings on glossy dark green leaves; and friendship plant, or panamiga (*P. involucrata*), with quilted bronzy leaves.

One of several basket plants called Creeping Charlie, or Swedish Ivy, is *P. nummulariifolia,* with small, round, quilted leaves and a vigorous trailing habit. Giant baby tears (*P. depressa*), of similar habit, has small, smooth green leaves.

pileus, close-fitting, brimless hat worn by the ancient Romans and copied from the Greek sailor's hat called the *pilos.* In Roman times the head was generally left uncovered, but

Man wearing a pileus, detail of a Greco-Roman statue

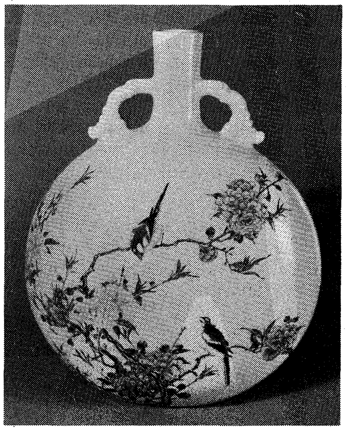
The Mansell Collection

commoners and freed slaves sometimes wore the felt pileus.

The hat was again popular during the Renaissance, especially in Italy, when it was square or rounded and made of black or red velvet or felt. The zucchetto and the biretta, worn by some orders of clergy, developed from the pileus.

pileworm (mollusk): *see* shipworm.

pilgrim bottle, vessel with a body varying from an almost full circle, flattened, to a pear shape, with a shortish neck, spreading foot and, generally, two loops on the shoulders.



Porcelain pilgrim bottle, Ch'ing dynasty, Yung-cheng period (1723–35); Percival David Collection

By courtesy of the Percival David Foundation of Chinese Art

Through the loops either a chain or cord was passed for carrying the bottle or for maintaining the stopper in place.

Pilgrim bottles date to ancient Roman times in the West and to 7th-century China in the East. They were made in a wide range of materials, including earthenware, porcelain, silver, and glass, and also in more perishable materials such as leather. Originally, these vessels may have been carried by travelers on their journeys; but the ones that have survived are so sumptuous that their function was probably purely ornamental, or, if they were used, it must have been—as in the case of some of the traveling tea or coffee sets in Meissen—exclusively by the very wealthy. Pottery pilgrim bottles are found in China from the T'ang dynasty (618–907), possibly imitations of even earlier metal prototypes dating as far back as the Chou dynasty (1111–255 BC). In 16th-century Europe, metal pilgrim bottles—generally of silver or silver gilt and probably of Chinese inspiration—were made mainly in Augsburg, Ger.; they were also made in coloured glass (generally green) with ormolu, or gilded brass, mounts. Along with the Chinese blue-and-white Ming (1368–1644) pilgrim bottles, the most famous are the pear-shaped stoneware bottles made at Meissen by Johann Friedrich Böttger.

Pilgrim Fathers, in American colonial history, settlers of Plymouth (*q.v.*), Mass., the first permanent colony in New England (1620). Of the 102 colonists, 35 were members of the English Separatist Church (radical faction of Puritanism) who had earlier fled to Leyden, the Netherlands, to escape persecution at home. Seeking a more abundant life along with religious freedom, the Separatists negotiated with a London stock company to finance a pilgrimage to America. Approximately two-thirds of those making the trip aboard the *Mayflower* (*q.v.*) were non-Separatists, hired to protect the company's interests; these included John Alden and Myles Standish.

These first settlers, initially referred to as the Old Comers and later as the Forefathers, did not become known as the Pilgrim Fathers until two centuries after their arrival. A responsive chord was struck with the discovery of a manuscript of Gov. William Bradford referring to the "saints" who had left Holland as "pilgrimes." At a commemorative bicentennial celebration in 1820, orator Daniel Webster used the phrase Pilgrim Fathers, and the term became common usage thereafter.

Pilgrim Festivals, Hebrew SHALOSH REGELIM, in Judaism, the three occasions on which male Israelites were required to go to Jerusalem to offer sacrifice at the Temple and bring offerings of their produce from the fields. In the synagogue liturgy, special Psalms (called collectively Hallel) are read and prayers are recited that vary with the nature of the festival. Thus, the Song of Solomon is read on Passover (*q.v.*), the Book of Ruth on Shavuot (*q.v.*), and Ecclesiastes on Sukkot (*q.v.*).

pilgrimage, in Christianity, journey to a saint's shrine or other sacred place, undertaken for a variety of motives: to gain supernatural help; as an act of thanksgiving or penance; for the sake of devotion. Records indicate that pilgrimages were made to Jerusalem as early as the 2nd century; and excavations in the 1940s at St. Peter's Basilica in Rome unearthed a 2nd-century memorial to the Apostle with numerous scratched inscriptions of the 2nd and 3rd centuries, evidencing acts of piety. The Roman liturgical calendar of the year AD 354 lists 29 local sanctuaries of the saints at which the faithful gathered annually. The travel memoir of Etheria (*c.* AD 400), a Spanish nun, testified to a system of guides and lodgings for those visiting the Palestinian holy sites. In Britain, Bede, the Venerable (died 735), a church historian, catalogued visits to graves of several saints from the 5th to the 8th century.

The medieval pilgrim began his journey with a blessing by a priest. His garb was recognizable, and on his return trip he would wear on his hat the badge of the shrine visited. Along the way he would find hospices set up specifically for pilgrims. The chief attractions for pilgrims in medieval times were the Holy Land, Santiago de Compostela in Spain, and Rome; but there were hundreds of pilgrim resorts of more local reputation, including the tombs of St. Francis (died 1226) in Assisi, Italy; of St. Martin (died 397) in Tours, Fr.; of St. Boniface (died 754) in Fulda, Ger.; of Thomas Becket (died 1170) at Canterbury, Eng.; and of St. Patrick at Downpatrick, Ire.

Not all churchmen approved entirely of pilgrimages. Some warned against excesses and questioned the value of the practice, while others questioned the authenticity of some of the relics.

Though many medieval centres still attract Roman Catholic pilgrims, the more recent shrines of St. Francis Xavier (died 1552) in Goa, India; of the Shroud of Turin (1578) at Turin, Italy; of St. Anne de Beaupré (1658) in Canada; of St. Jean-Baptiste-Marie Vianney (died 1859) at Ars and of St. Thérèse de Lisieux (died 1897) at Lisieux, both in France; and the Marian centres of Our Lady of Guadalupe (1531) in Mexico, of La Salette (1846) and Lourdes (1858) in France, and of Fâtima (1917) in Portugal have grown steadily in importance.

Members of the Eastern Orthodox faith commonly make pilgrimages to celebrated monasteries to ask for spiritual and practical help from the holy men (*startsy*).

The attitude of the 16th-century Protestant Reformers found expression in 1530 in the Augsburg Confession, which portrayed pilgrimages as "childish and useless works." Although modern Protestants may visit such places as Martin Luther's grave at Wittenberg or the Wesleyan Memorial at Epworth, Lincolnshire, such visits are regarded neither as a Christian duty nor as devotional acts to which spiritual benefits are attached; nor are the places viewed as shrines where miracles may occur.

Pilgrimage of Grace (1536), a rising in the northern counties of England, the only overt immediate discontent shown against the Reformation legislation of King Henry VIII. Part of the resentment was caused by attempts, especially under Henry's minister Thomas Cromwell, to increase government control in the north; there was an element of agrarian opposition to enclosures for pasture; and there was a religious element, aroused especially by the dissolution of the monasteries, then in progress. The arrival of commissioners sent by Cromwell to collect a financial subsidy and to dissolve the smaller monasteries triggered the rising. In Louth in Lincolnshire there were riots on October 1, and commissioners were attacked. The rebels occupied Lincoln, demanding an end to the dissolution, revenge on Cromwell, and the dismissal of heretical bishops. But Henry refused to treat with men in arms against him (although professing their loyalty), and the Lincolnshire movement collapsed on October 19. Meanwhile, a more serious rising had begun in Yorkshire, led by Robert Aske, a country gentleman and lawyer. Aske took York and by October 24 was supported by about 30,000 armed men and by magnates such as Edward Lee, archbishop of York, and Thomas Darcy, Baron Darcy of Templehurst. The government had insufficient troops in the area, but on October 27, at Doncaster Bridge, Thomas Howard, the 3rd duke of Norfolk, temporized with Aske, playing for time until adequate forces could be assembled. At a council at Pontefract on December 2, the rebels drew up their demands, similar to those of the Lincolnshire men but including a return of England to papal obedience and the summoning of a Parliament free from royal influence. To these Norfolk, on December 6, made vague promises and offered a full pardon, whereupon Aske naively assumed he had gained his objectives and persuaded his followers to disperse. Sporadic riots in January and February 1537 enabled the government to deal with the troubles piecemeal; about 220–250 men were executed, including Darcy and Aske. The pilgrimage achieved nothing and received no support from other parts of the country.

Pilgrim's Progress, religious allegory by the English writer John Bunyan, a symbolic vision of the good man's pilgrimage through life, at one time second only to the Bible in popularity. Part I (1678), in which Christian travels from the City of Destruction to the Celestial City, is presented as a dream. His anguished struggle toward salvation, though it dominates Part I, does not totally eclipse other, contrasting, qualities. Written in homely, yet dignified biblical prose, the work has some of the qualities of a folktale; and in its humour and realistic portrayals of Mr. Worldly Wiseman, Faithful, Hopeful, Pliant, and Obstinate, it anticipates the 18th-century novel. In Part II (1684), which deals with the effort of Christian's wife and sons to join him, the psychological intensity is relaxed and the capacity for humour and realistic observation becomes more evident. Christian's family has a somewhat easier time because Christian has smoothed the way, and even such companions as Mrs. Much-afraid and Mr. Ready-to-halt manage to complete the journey.

Pilgrims' Way, the North Downs trackway in southern England. It is a famous prehistoric route between the English Channel and the chalk heartland of Britain in Wessex and survives as minor roads or as bridle paths in many areas. Both a ridgeway and a lower terrace way beneath the chalk escarpment can be traced. Such tracks shifted seasonally with changing ground conditions. The name, not attested before the 18th century, was given further currency by the poet Hilaire Belloc. In *The Old Road* (1904), he posited a continuous prehistoric track between Winchester and Canterbury revived by pilgrims journeying to St. Thomas Becket's shrine. Pilgrims possibly did use it, although the London–Canterbury road celebrated earlier by Chaucer was the frequented route. Belloc's "Pilgrims' Way," however, does not coincide with the prehistoric trackway west of the Hog's Back in Surrey.

pili nut, the nut of any tree of the genus *Canarium* (family Burseraceae), particularly the edible nut of the Philippine tree *Canarium ovatum*. In the South Pacific the pili nut is a major source of fat and protein in the diet. The densely foliated tropical tree grows to 20 metres (65 feet) in height and produces up to 32 kilograms (70 pounds) of nuts annually. The fruit is 6–7 centimetres (2¼–3 inches) long, with a hard, thick-shelled, triangular nut surrounded by a small amount of pulp. The pulp is edible when cooked, but the main food source is the roasted nut, similar in shape and taste to the almond. The uncooked nuts are used as a laxative. The shell is removed by dipping the nut in hot water. Pili nuts are high in fat content and easily digestible. The sweet oil is used in confectionary. Roasted and powdered pili nuts are sometimes used to extend chocolate.

Pīlībhīt, town, administrative headquarters of Pīlībhīt district, Uttar Pradesh state, northern India, northeast of Bareilly, on a tributary of the Rāmganga River. It is a rail junction and is linked with Bareilly by road. Sugar processing is the largest industry, and there is an active trade in agricultural products, both locally and with Nepal. On the town's western outskirts is a large 18th-century mosque built by Ḥāfiz Raḥmāt Khān, the town's founder.

Pīlībhīt district, 1,352 sq mi (3,504 sq km) in area, lies on the Ganges Plain near the Himalayan foothills and adjoins Nepal on the northeast. It is watered by the Sārda Canal and by tributaries of the Ganges River. There are forests in the east. The most productive land and the greatest population density are in the district's extreme south. Crops include rice, wheat, gram, barley, and sugarcane. Pop. (1981) town, 88,548; district, 1,008,312.

Pílion, Óros (Greece): *see* Pelion, Mount.

Pilipinas: *see* Philippines.

Pilipino language, standardized form of Tagalog, and one of the two official languages of the Philippines (the other being English). It is a member of the Austronesian language phylum.

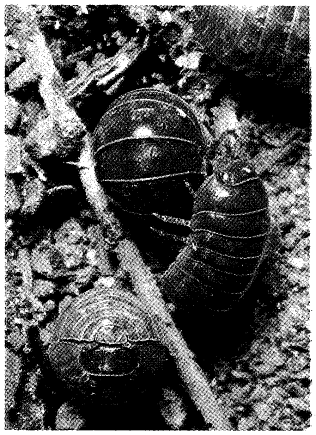
Tagalog is the mother tongue for nearly 25 percent of the population and is spoken as a first or second language by more than half of all Filipinos. The mandatory teaching of Pilipino in public schools since 1973 and the extensive literature in Tagalog has contributed to its increased use in the popular media.

Pilkington, Francis (d. 1638, Chester, Cheshire, Eng.), English composer of lute songs and madrigals.

Pilkington took a bachelor of music degree from Oxford in 1595, became a cantor at Chester cathedral in 1602, and a minor canon in 1612. His *First Book of Ayres* (1605) contains 21 songs for four voices or for solo voice and lute and a *Pavin for Lute and Bass Viol*. He published sets of madrigals in 1613 and 1624. Though not of the first rank, they are pleasing and well constructed. Particularly known is the madrigal "O softly singing lute," for six voices. He also composed a number of attractive lute solos.

pill bug, any of the terrestrial crustaceans of the families Armadillididae and Armadillidae (order Isopoda). When disturbed, the pill bug rolls itself up into a tiny ball. Like the related sow bug (*q.v.*), it is sometimes called the wood louse. For mollusks also known as pill bugs, *see* chiton.

The common pill bug *Armadillidium vulgare*



Pill bugs (*Armadillidium vulgare*)
E.S. Ross

(family Armadillididae) is about 17 millimetres (0.7 inch) long. The gray body, with its plate-like segments, somewhat resembles a miniature armadillo, an armoured mammal that also curls into a ball when disturbed. *A. vulgare* occurs in dry, sunny places, in leaf litter, and on the edges of wooded areas. Originally found in Europe, it now occurs worldwide. *A. nasatum,* native to northern Europe, has been introduced into North America. *Armadillo officinalis* (family Armadillidae), which attains lengths of 19 millimetres (0.75 inch), is native to southern Europe.

pillar, in architecture and building construction, any isolated, vertical structural member such as a pier, column, or post. It may be constructed of a single piece of stone or wood or built up of units, such as bricks. It may be any shape in cross section. A pillar commonly has a load-bearing or stabilizing function, but it may also stand alone, as do commemorative pillars. *See also* column.

pillar and scroll shelf clock, wooden shelf clock mass-produced in the United States

from the second decade of the 19th century onward. The rectangular case is topped by a scroll broken in the centre by an ornament such as an urn; on either side of the case is a vertical pillar topped by the same kind of ornament that breaks the scroll.

These clocks usually had a 30-hour wooden movement, using oak plates, laurelwood pillars, and black cherry wood gears, though these were later supplanted by brass around 1840, when that metal became cheaper. The clocks are usually associated with the name of Eli Terry (1772–1852), who gave them their definitive form.

Pillar of Fire, a white Holiness church of Methodist antecedence that was organized (1901) in Denver, Colo., U.S., as the Pentecostal Union by Alma Bridwell White, who married a Methodist minister. Her evangelistic fervour brought opposition from Methodist officials, which led to her withdrawal from the Methodist Church in 1917. At that time the church was renamed Pillar of Fire, and she was ordained bishop.

The church stresses holiness and sanctification by prayer and generally follows Methodist teachings. Women can occupy any ministerial office. The Pillar of Fire maintains several schools and conducts missions in Liberia. Headquarters, teacher-training facilities, and a publishing house are located in Zarephath, N.J., U.S.

Pillau (Russian S.F.S.R.): *see* Baltiysk.

Pillow Book, Japanese MAKURA NO SŌSHI (*c.* 1000), title of a book of reminiscences and impressions by the 11th-century Japanese court lady Sei Shōnagon (*q.v.*). Whether the title was generic and whether Sei Shōnagon herself used it is not known, but other diaries of the Heian period (794–1185) indicate that such journals may have been kept by both men and women in their sleeping quarters, hence the name. The entries in *Makura no sōshi,* although some are dated, are not in chronological order but rather are divided under such headings as "Amusing Things" and "Vexatious Things." A complete English translation of *Makura no sōshi* by Ivan Morris appeared in 1967 (*The Pillow Book of Sei Shōnagon*). The *Pillow Book* belongs to the genre of *zuihitsu* ("random jottings"). *Tsurezuregusa,* by Yoshida Kenkō (*q.v.*), is an outstanding 14th-century example of this genre.

Pillsbury, Charles Alfred (b. Dec. 3, 1842, Warner, N.H., U.S.—d. Sept. 17, 1899, Minneapolis, Minn.), U.S. flour miller who built his company into one of the world's largest milling concerns in the 1880s.

After selling his share in a Montreal dry-goods business, Pillsbury went to Minneapolis in 1869 to join his uncle, John S. Pillsbury, who would later become the state's governor.

Staked by his uncle and his father, Pillsbury paid $10,000 for a one-third share of a small flour mill. A floundering enterprise, the mill used water power from the Falls of St. Anthony to produce 200 barrels of flour a day. Pillsbury installed purifiers, machines recently invented by Edmund La Croix, that could produce fine white flour from the district's hard spring wheat. The mill showed a $6,000 profit a year later. His was also the first American mill to use steam rollers instead of burr stones to crush the wheat.

In 1872, he founded C.A. Pillsbury & Co. and began purchasing and building more mills. By 1889, the Pillsbury mills produced 10,000 barrels a day.

Pillsbury had a share in getting low freight rates for Minneapolis, as well as in building up the railroad system that helped make Minneapolis the centre of the grain trade. To protect his supplies, he founded a grain elevator company that owned storage elevators throughout the Northwest.

In 1889, he sold his company to an English syndicate. He remained managing director of the combined Pillsbury-Washburn Flour Mills until his death.

Pillsbury was elected to the Minnesota state senate for five terms.

Pilnyak, Boris, pseudonym of BORIS ANDREYEVICH VOGAU, Pilnyak also spelled PILNIAK (b. 1894, Mozhaisk, Russia—d. 1937), Soviet writer of Symbolist novels and stories, prominent in the 1920s.

Pilnyak spent his childhood in provincial towns near Moscow, in Saratov, and in a village on the Volga river. He attended high school in Nizhny Novgorod and a commercial institute in Moscow. In his autobiography he stated that he began writing at the age of nine, but it was the publication of his novel *Goly god* (1922; *The Naked Year,* 1928) that brought him popularity. This book was a panorama of the Revolution and Civil War, seen through a series of flashbacks and close-ups encompassing all levels of society. Its fragmentary, chaotic style matched the character of the times he portrayed.

In 1926 he caused a scandal with his *Povest nepogashennoy luny* (*The Tale of the Unextinguished Moon*), a scarcely-veiled account of the death of Frunze, the famous military commander, during an operation. The issue of the magazine in which the tale was published was withdrawn immediately, and a new issue omitting it was put out. Pilnyak was compelled to recant, and the editorial board of the magazine admitted that it had committed a "gross error." Pilnyak was again in trouble in 1929, when he permitted an émigré publishing house in Berlin to publish his novel, *Krasnoye derevo* ("Mahogany"). The book, which included an idealized portrait of a Trotskyite Communist, was immediately banned in the Soviet Union.

Pilnyak's doubts and distaste with respect to Communist goals and methods were increasingly visible in his novels and stories. By the late 1920s he was the object of harsh official censure. In an attempt to redeem himself he wrote *Volga vpadayet v Kaspiyskoye more* (1930; *The Volga Falls to the Caspian Sea,* 1931), a novel glorifying the five-year plan on the theme of the construction of a Soviet dam. Pilnyak's ambivalence did not escape the authorities, and he fell into deeper disfavour. During 1937—at the height of the Stalin terror—his name and his works completely disappeared from Soviet literature. Nothing definite was learned concerning his fate until after Stalin's death, when official Soviet sources acknowledged that he had been arrested in 1937, placing the date of his death in the same year. Although Pilnyak was "posthumously rehabilitated," only in 1976 did a volume offering a very limited selection of his works appear.

Pilon, Germain (b. 1535, Paris—d. Feb. 3, 1590, Paris), French sculptor whose work, principally monumental tombs, is a transi-

Gisants of Catherine de Médicis and Henry II by Pilon, 1563–70; in the church of Saint-Denis, Paris
J.E. Bulloz

tional link between the Gothic tradition and the sculpture of the Baroque period.

A sculptor's son, Pilon was employed at the age of 20 on the decoration of the tomb of King Francis I at Saint-Denis. His earlier work clearly shows an Italian influence, but eventually he developed a more distinctively French expression by fusing elements from classical art, Gothic sculpture, and Michelangelo with the Fontainebleau adaptation of Mannerism, a style characterized by subjective conceptions, studied elegance, and virtuoso artifice.

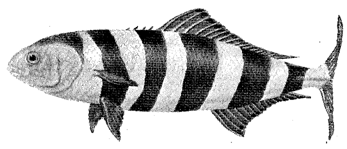
Pilon's best known works are funerary sculptures for Henry II. It was a custom of the period for men of high estate to assign their remains to more than one burial site—often one for the body, one for the heart, and one for the entrails. Pilon's monument for the heart of Henry II (*c.* 1561; Louvre) consists of three marble Graces of great elegance supporting an urn. It was perhaps based on a design by Primaticcio. For the principal tomb of Henry II and Catherine de Médicis at Saint-Denis (1563–70), also designed by Primaticcio, Pilon created four bronze corner figures and, above, the kneeling figures of the King and Queen in bronze. Most important, however, are the seminude, marble gisants, or figures of the royal pair recumbent in death. Considered by some to be his most sublime achievement, the gisants are a Renaissance idealization of a Gothic convention and possess a depth of emotion that Pilon perhaps never again attained.

Sculptor royal from 1568, Pilon enjoyed a successful career as a portraitist, his most celebrated work in the genre being the kneeling figure of René de Birague (1583–85; Louvre). Appointed controller of the mint in 1572, in 1575 he brought eminence to French medal casting with a distinguished series of bronze medallions.

Pílos (Greece): *see* Pylos.

pilot fish (*Naucrates ductor*), widely distributed marine fish of the family Carangidae (order Perciformes). Members of the species are found in the open sea throughout warm and tropical waters.

The pilot fish is elongated and has a forked tail, a lengthwise keel on each side of the tail base, and a few small spines in front of the dorsal and anal fins. It grows to a length of about 60 centimetres (2 feet) and is distinctively marked with 5 to 7 vertical, dark bands



Pilot fish (*Naucrates ductor*)
Painting by Gilbert Emerson

on a bluish body. It is carnivorous and follows sharks and ships apparently to feed on parasites and leftover scraps of food.

pilot whale, also called BLACKFISH, or CAA'ING WHALE (*Globicephala*), any of a genus of slender whales belonging to the family Delphinidae, found in all oceans of the world except the Arctic and Antarctic. One to three species, all more or less similar, are recognized, depending on the authority. They are *G. melaena, G. macrorhyncha,* and *G. scammoni.* The pilot whale is also known as caa'ing whale because of a roaring sound it makes when stranded. It is black, usually with a lighter splash on the throat and chest, and has a round, bulging forehead; a short, beaklike snout; and slender, pointed flippers. Its length is usually about 4 to 6 metres (13 to 20 feet); males are larger than females.

The pilot whale is highly gregarious and lives in schools, sometimes of hundreds or

Pilot whale (*Globicephala melaena*) performing at Marineland of Florida
Appel Color Photography with Marineland of Florida

thousands of individuals. It feeds mainly on squid. In some areas it is hunted for meat and oil and in the Faeroe Islands is captured in schools, the hunters frightening and driving them ashore. Pilot whales have been kept in oceanariums and have been trained to perform.

Piloty, Karl (Theodor) von (b. Oct. 1, 1826, Munich—d. July 21, 1886, Ambach, Ger.), the foremost representative of the realistic school of painting in Germany.

Piloty was the younger brother of Ferdinand Piloty, a noted lithographer. His picture of "Seni at the Dead Body of Wallenstein" (1855) gained for the young painter the membership of the Munich Academy, where he became a professor. He executed a number of mural paintings for the royal palace in Munich, and for Baron von Schach he painted the celebrated "Discovery of America." In 1874 he was appointed keeper of the Munich Academy and was later ennobled by the King of Bavaria. Many of Piloty's pupils became distinguished painters.

Pilsen (Czechoslovakia): *see* Plzeň.

Piłsudski, Józef (Klemens) (b. Dec. 5, 1867, Żułów, Pol., Russian Empire—d. May 12, 1935, Warsaw), Polish revolutionary and statesman, the first president (1918–22) of the newly independent Poland established in November 1918.

Early life and political activities. Piłsudski was the second son of an impoverished Polish nobleman. His mother, *née* Maria Billewicz, inspired him with hatred for the Russian imperial regime, which was treating the Poles with great harshness after their insurrection of 1863. On leaving the secondary school in Wilno (modern Vilnius), Piłsudski studied medicine at Kharkov in 1885 but was suspended as politically suspect in 1886. Returning to Wilno, he consorted with young Socialists and tried to read Karl Marx's *Kapital,* but its abstract argument proved uncongenial. Arrested in March 1887 on a false charge of plotting the assassination of the tsar Alexander III, he was banished to eastern Siberia for five years.

Piłsudski returned in 1892, determined to organize an insurrection and to work for the reestablishment of Poland's independence. He joined the newly founded Polish Socialist Party (PPS), of which he soon became a leader. He started a clandestine newspaper, *Robotnik* ("The Worker"), in Wilno. In July 1899 he married, in a Protestant church, the beautiful Maria Juszkiewicz, the divorced wife of a Polish civil engineer, and moved to Łódź, where he continued to edit and print his paper.

In February 1900 he was incarcerated by the Russians in the Warsaw citadel. He feigned insanity so successfully that he was transferred to a military hospital in St. Petersburg, from which he escaped in May 1901. He took refuge in Cracow in Austrian Poland, but in April 1902 he was back in Russian Poland looking after the party organization.

When the Russo-Japanese War broke out in February 1904, Piłsudski went to Tokyo to solicit Japanese assistance for an insurrection in Poland. He had been preceded by Roman Dmowski, his rival in the patriotic movement, who had told the Japanese that Piłsudski's plan was impracticable. The two Polish leaders agreed to disagree. Piłsudski returned clandestinely to Russian Poland to help direct the revolutionary movement that was spreading throughout the empire. After the Russian revolution was put down late in 1905, a split occurred within the PPS: the left wing, which proposed to delete from the party's program the stipulation that its main aim was an independent Poland, broke with Piłsudski's group, which insisted on that stipulation.

Attempts to organize a Polish army. Aware of the Russian Empire's structural weakness and foreseeing a European war, Piłsudski concluded that it was imperative to organize the nucleus of a future Polish army. In 1908 he formed a secret Union of Military Action—financed with a sum of money stolen from a Russian mail train by an armed band led by Piłsudski himself. In 1910, with the help of the Austrian military authorities, he was able to convert his secret union into a legal Union of Riflemen, actually a school for Polish officers. At a meeting of Polish sympathizers in Paris in 1914, he declared that war was imminent and that

> . . . the problem of the independence of Poland will be definitely solved only if Russia is beaten by Austria-Hungary and Germany, and Germany vanquished by France, Great Britain and the United States; it is our duty to bring that about.

World War I justified Piłsudski's prediction. Until 1916 the three brigades of the Polish Legion, technically under Austro-Hungarian command, distinguished themselves against the Russians. On Nov. 5, 1916, Germany and Austria-Hungary, short of manpower, proclaimed the independence of Poland, hoping that Polish divisions could be deployed on the Eastern Front so that German divisions could be moved to the west. Piłsudski, appointed head of the military department of the newly created Polish council of state, accepted the idea of a Polish army on condition that it be part of a sovereign Polish state. His position was unexpectedly reinforced by the Russian Revolution of March 1917. The German government, however, refused to bind itself as to Poland's future, demanding instead that the existing Polish units should swear "fidelity in arms with the German and Austrian forces." Piłsudski, refusing to comply, was arrested in July 1917 and imprisoned in Magdeburg.

An independent Poland. Released after the German collapse in the west, Piłsudski arrived in Warsaw on Nov. 10, 1918, as a national hero. Four days later he was unanimously accepted as head of state and commander in

Piłsudski
Culver Pictures

chief of the Polish Army. From that moment he ceased to be the man of a party, though his main support came from the left and from the centre; the right saw its leader in Dmowski, who had been heading the Polish National Committee in Paris and was now appointed by Piłsudski to be Poland's first delegate at the peace conference.

Piłsudski devoted himself to protecting Poland against the Russian Red Army, which was trying to fight its way into Germany in order to consolidate the revolution there. He led the Polish forces far to the east, occupying large areas that had belonged to Poland before the 18th-century partitions. He envisioned a federal state comprising Poles, Lithuanians, and Ukrainians, whereas Dmowski argued that these areas should simply be incorporated within a unitary Poland. In 1920 a counteroffensive by the Red Army forced the Poles to retreat westward almost to the suburbs of Warsaw, but Piłsudski, made marshal of Poland on March 19, conceived and directed a manoeuvre that in August brought victory to Poland.

After the adoption of a democratic constitution and a new general election, Piłsudski transmitted his powers on Dec. 14, 1922, to his friend Gabriel Narutowicz, the newly elected president of the republic, who two days later was assassinated. Stanisław Wojciechowski, another of Piłsudski's old colleagues, was next elected president, the marshal agreeing to serve as chief of the general staff. When a right-wing government assumed power, Piłsudski resigned his post on May 29, 1923, and went into retirement at Sulejówek, near Warsaw, with his second wife, *née* Aleksandra Szczerbińska, and his two daughters.

Piłsudski became disillusioned with the working of the parliamentary system, and on May 12, 1926, during a time of economic depression, he marched on Warsaw at the head of a few regiments. Wojciechowski and his government resigned two days later. The parliament elected Piłsudski president of the republic on May 31, but he refused the honour, and another of his old friends, Ignacy Mościcki, was elected instead. In the new government Piłsudski assumed the Ministry of Defense, which he held until his death. During the ensuing years he was the major influence behind the scenes, especially in the field of foreign policy.

Later years. With few exceptions, Piłsudski's former Socialist friends abandoned him and joined a centre-left coalition, which in the summer of 1930 started a mass campaign to overthrow his "dictatorship." Piłsudski's reaction was ruthless; to "cleanse" political life, he had 18 party leaders arrested and imprisoned in the fortress of Brześć. Though all of them were subsequently released, and their political parties were not dissolved, the country was ruled by Piłsudski's men. The most prominent among them was Col. Józef Beck, Piłsudski's former *chef de cabinet,* who became deputy foreign minister in December 1930 and foreign minister in November 1932.

When Hitler came to power in Germany on Jan. 30, 1933, Piłsudski sent to Paris a secret emissary, Count Jerzy Potocki, his former aide-de-camp, to find out whether France, Poland's ally from 1921, would operate in joint military action against Germany. The latter had been openly rearming in flagrant violation of the Treaty of Versailles. The French leadership answered in the negative, and consequently Piłsudski accepted Hitler's suggestion of a 10-year German-Polish nonaggression agreement (Jan. 24, 1934).

To show that Poland's intentions were above suspicion, Beck was sent to Moscow in February, and the existing Soviet-Polish nonaggression treaty was prolonged to Dec. 31, 1945. Later, Hitler repeatedly suggested a German-Polish alliance against the U.S.S.R., but Piłsudski took no notice of the proposal; he also declined to meet with Hitler. Piłsudski sought to gain time, believing that Poland should be ready to fight when the necessity arose. Such were the last instructions he gave to Beck. Shortly afterward, he died in Warsaw of cancer of the liver. He was buried in a crypt of the Wawel Cathedral in Kraków, among Polish kings.

A romantic revolutionary, a great soldier without formal military training, a man of rare audacity and willpower, as well as of great insight into European politics, Piłsudski was nevertheless poorly equipped to rule a modern state. He left Poland undeveloped economically and with an army that was ready to fight heroically but was doomed because of its composition and inadequate armament.

(K.M.S.)

BIBLIOGRAPHY. The best biography of Piłsudski in English is W.F. Reddaway, *Marshal Pilsudski* (1939). Two authoritative works in French are J. de Carency (K.M. Smogorzewski), *Joseph Pilsudski, soldat de la Pologne restaurée* (1929), and *Joseph Pilsudski et les activistes polonais pendant la guerre,* 2 vol. (1930–31). There is also a biography of him by his second wife, A. Piłsudska, *Pilsudski: A Biography by His Wife Alexandra* (1941, reprinted 1971). Of political interest is R. Machray, *The Poland of Pilsudski* (1936). For some of Piłsudski's writings, see D.R. Gillie (trans. and ed.), *Joseph Piłsudski: The Memories of a Polish Revolutionary and Soldier* (1931).

Piltdown man (*Eoanthropus dawsoni*), proposed species of prehistoric man whose fossil remains, later proved fraudulent, were discovered in England in 1912. The forgery was sufficiently convincing to generate scholarly controversy that lasted about 40 years. Apparently fossilized fragments of cranium and jawbone were found by Charles Dawson in a gravel formation at Barkham Manor, on Piltdown Common near Lewes, Eng. Together with these were fossil remains of extinct animals, which suggested an early Pleistocene age for the site, and worked implements of bone and flint, the latter attributable to a very early human culture (pre-Abbevillian). In 1926 the gravels were found to be much less ancient than supposed, and in 1953 and 1954, as an outcome of later discoveries of fossil man and intensive re-examination, the remains were shown to be skillfully disguised fragments of a quite modern human cranium and an ape (orangutan) jaw fraudulently introduced into the shallow gravels, as were the implements. The animal bones were found to be genuine remains of extinct species, but they were not of British provenance.

As long as the remains were accorded a high antiquity, Piltdown man seemed a feasible alternative to *Homo erectus* (then known from scanty remains as *Pithecanthropus*) as an ancestor for modern man. From 1930, more finds of *Pithecanthropus*, the discoveries of the more primitive *Australopithecus*, and further examples of Neanderthal man left Piltdown man completely isolated in the evolutionary sequence. The eventual exposure of the fraud clarified the sequence of human evolution by removing the greatest anomaly in the fossil record. At the same time, a series of valuable new tests were developed for paleontological study. Evidence sufficient to name those responsible for the fraud has not been found, however, and the issue remains unsolved.

For scientific papers dealing with all aspects of the exposure, see *Bulletin of the British Museum* (*Natural History*), vol. 2, no. 3 and 6. For accounts of the finds at Piltdown and for discussions of the authorship of the deception and the tests carried out, see J.S. Weiner, *The Piltdown Forgery* (1955), and Ronald Millar, *The Piltdown Men* (1972).

Pima, North American Indians who traditionally lived along the Gila and Salt rivers in Arizona in what was the core area of the prehistoric Hohokam culture (*q.v.*). The Pima, who speak a Uto-Aztecan language and call themselves the "River People," are usually considered to be the descendants of the Hohokam, although this has not been proved. Like their presumed ancestors, the Pima originally were sedentary farmers who lived in one-room houses and utilized the rivers for irrigation. Some hunting and gathering were done to supplement the diet; but in drought years, which occurred on the average of one year in five, the crops of corn (maize) and other vegetables would fail, and hunting and gathering became the sole mode of subsistence. During these dry years jackrabbits and mesquite beans were the dietary staples.

"Pima *Ki,*" photograph by Edward S. Curtis, 1907; from *The North American Indian*
Courtesy of the Edward E. Ayer Collection, The Newberry Library, Chicago

The intensive farming of the Pima made possible larger villages than were feasible for their neighbours and relatives, the Papago. With larger communities came a stronger and more complex political organization. In early Spanish times the Pima possessed a strong tribal organization, with a tribal chief elected by the chiefs of the various villages. The tribal chief attained his status through his personal qualities rather than through birth, and this was true of local chiefs also. The village chief, aided by a council of all adult males, had the responsibilities of directing the communal irrigation projects and of protecting the village against alien tribes, notably the Apache. Planting and harvesting of crops were handled as a cooperative venture.

From the time of their earliest recorded contacts with whites, the Pima have been regarded as a friendly people. At the time of the California Gold Rush (1849–50), the Pima often gave or sold food to white emigrants and gold seekers and provided them with an escort through Apache territory. During the Apache wars (1861–86), Pima served as scouts for the U.S. Army. Such close contacts with white culture contributed to disintegration of aboriginal Pima culture.

In the late 20th century the Pima numbered about 10,000. With their traditional neighbours, the Maricopa, a group of Yuman Indians, the Pima live chiefly on the Gila River and Salt River reservations in Arizona.

pimiento, any of various mild peppers of the genus *Capsicum. See* pepper.

Pimiko, also spelled PIMIKU: *see* Himiko.

pimpernel (genus *Anagallis*), any of several plants of the primrose family (Primulaceae), consisting of about 30 species of low herbs mostly native to western Europe.

Most species are prostrate in habit. The plant has leaves that are opposite or in whorls and small, solitary flowers that are short-stalked and bell-shaped. The five-lobed corolla (the structure formed by the petals) is red, pink, or blue.

The scarlet pimpernel (*A. arvensis*), also called poor-man's weatherglass, is an annual native to Europe, Asia, and North America. It grows 6 to 30 cm (2.4 to 12 inches) tall and has red, pink, or blue flowers.

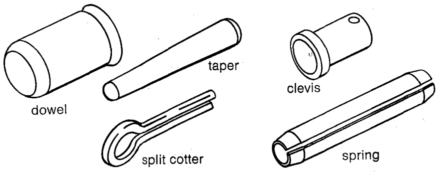
pin, the small, pointed and headed piece of stiff wire used to secure clothing or papers. In mechanical and civil engineering the term pin, or more properly pin fastener, designates a peg- or boltlike device designed to fasten machine and structural components together or to keep them properly aligned.

Bronze pins 2 to 8 inches (5 to 20 cm) long with gold heads or decorative gold bands have been found in ancient Egyptian tombs. The Greeks and Romans used pins or brooches similar to the safety pin for fastening their clothing. In medieval Europe, skewers of wood, bone, ivory, silver, gold, or brass were used, elaborately fashioned for persons of wealth and simply made of wood for common people. By the end of the 15th century the manufacture of pins from drawn iron wire was well established, particularly in France.

Pinmaking machines were introduced early in the 19th century. In New York John Ireland Howe founded a successful factory with his improved machines, while in Birmingham, Eng., Daniel Foote-Taylen profitably applied the pinmaking patents of Lemuel W. Wright. Subsequently many pinmaking machines were developed, including devices for thrusting finished pins through crimped papers. Modern machines are completely automatic.

pin fastener, a steel pin, usually cylindrical, that can keep machine parts in proper alignment or fasten them together. The illustration shows several types of pin fasteners in common use.

Hardened and precisely shaped dowel pins are used to keep machine components in accurate alignment; they are also used as location guides for adjacent machine parts and to



Several types of pin fasteners

keep the two sections of a punch and die in alignment.

The taper pin provides a cheap, convenient method of fixing the hub of a gear or a pulley to a shaft. The pin is driven into a tapered hole that extends radially through the hub and shaft.

The split cotter pin is used to prevent nuts from turning on bolts and to keep loosely fitting pins in place. The head of the nut has radial slots aligned with one of the radial holes in the bolt. The pin is a loose fit in the hole and is kept in place by spreading the ends. The clevis pin is a fastening device with a flange at one end and is kept in place by a cotter pin inserted through a hole in the other end.

The spring pin is a split tube with a slightly larger diameter than the hole into which it is placed. The pin is compressed when driven into the hole and exerts a spring pressure against the wall of the hole to create a frictional locking grip. These pins can be removed and reused without appreciable loss of effectiveness; they are widely used for attaching lightly loaded pulleys and gears to shafts.

Groove pins are solid pins with longitudinal grooves produced by upsetting the metal so that it interferes with the walls of the hole when the pin is driven in.

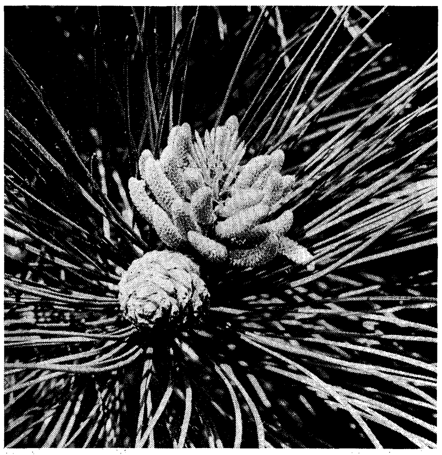
Pin-hsien, Pinyin BINXIAN, city in Heilungkiang *sheng* (province), China, situated on the eastern outskirts of Harbin (Ha-erh-pin). It is the communications centre of a prosperous and productive agricultural district that supplies a large part of the foodstuffs, particularly grain and vegetables, for Harbin. In addition to its importance as a collecting and commercial centre, Pin-hsien has also developed a number of light industries, consisting principally of food processing, light engineering, the production of bricks and tiles, and woodworking. Pop. (1984 est.) 40,499.

pin oak, either of two species of North American ornamental and timber trees belonging to the red oak group of the genus *Quercus* in the beech family (Fagaceae). The term is especially given to *Quercus palustris,* found on bottomlands and moist upland soils in the eastern and central United States. Usually about 25 m (80 feet) tall but occasionally reaching 35 m (115 feet), the tree has a broad, pyramidal crown and drooping lower branches. Spurlike, slender branchlets stand out like pins on the trunk and larger limbs. The elliptical, glossy green leaves, measuring about 13 cm (5 inches) long, have five to seven deeply cut lobes and turn scarlet in autumn. The dark brown acorns are enclosed at the base in a thin, shallow cup.

The northern pin oak, or jack oak (*Q. ellipsoidalis*), also has pinlike branchlets but usually occurs on upland sites that are dry. Its ellipse-shaped acorns are nearly half enclosed in a scaly cup. The leaves become yellow or pale brown in autumn, often with purple blotches.

Pin-yin romanization: *see* Pinyin romanization.

Pinaceae, the pine family of conifers, 10 genera of trees (rarely shrubs) native to north temperate regions. Fir (*Abies*), *Keteleeria, Cathaya,* Douglas fir (*Pseudotsuga*), hemlock (*Tsuga*), spruce (*Picea*), golden larch (*Pseudolarix*), larch, or tamarack (*Larix*), cedar (*Cedrus*), and pine (*Pinus*) contain many species that are sources of timber, paper pulp, oils, and resins. Some are cultivated as ornamentals. Both male and female reproductive structures are borne on the same plant. The needlelike leaves are solitary, in bundles, or on specialized short branches. The pollen-bearing male cones are solitary or clustered and have many spirally arranged scales, each bearing two pollen sacs. The compound, seed-bearing



(Centre) Pollen-bearing male cones and (left) immature seed-bearing female cone of red pine (*Pinus resinosa*)

Alvin E. Staffan from The National Audubon Society Collection/Photo Researchers—EB Inc.

female cones also have many spirally arranged scales. Each scale is free from the bract below it and bears two inverted ovules on its upper side. In members of the genus *Pinus,* the bract disappears as the cones mature.

pinacotheca, Greek PINAKOTHEKE, Latin PINACOTHECA, a picture gallery in either ancient Greece or ancient Rome. The original pinacotheca, which housed the tablets or pictures honouring the gods, formed the left wing of the Propylaea of the Acropolis in Athens. Evidence from ancient manuscripts indicates that the pictures were separate easel works rather than frescoes. Other Greek pinacothecas were at Ephesus and Samos.

In ancient Rome a pinacotheca was the gallery in a private home or villa in which were kept art objects, tablets, and statues. The Roman pinacotheca adjoined the atrium. In modern times the word may refer to an art gallery. The public galleries at Bologna and Siena, in Italy, are examples. In Munich, two famous galleries are called the Alte Pinakothek and the Neue Pinakothek, *i.e.,* the old and new pinacothecas.

Pinang (Malaysian island); *see* Penang.

pinang (nut): *see* betel.

Pinar del Río, *provincia,* western Cuba, bounded on the north by the Gulf of Mexico, on the west by the Yucatán Channel, on the south by the Caribbean Sea, on the southeast by the Gulf of Batabanó, and on the east by La Habana province. Low mountain ranges, including the Sierra de los Órganos and the Sierra del Rosario, form the backbone of the territory, which has an area of 4,218 square miles (10,925 square km). The sandy soils of the southern plain produce some of the world's best tobacco, in the Vuelta Abajo region, and the pine forests have been exploited heavily. Copper has been mined at Matahambre since 1913. The province also produces sugarcane, rice, pineapples, coffee, and live-

The Viñales Valley in Pinar del Río province, Cuba

stock. Railroads and highways traverse much of the province, passing through the capital city, Pinar del Río (*q.v.*). Pop. (1988 est.) 678,-197.

Pinar del Río, city, capital of Pinar del Río *provincia,* western Cuba. Founded in 1775, the city is situated in hilly pinelands at an elevation of about 200 feet (60 m) above sea level, near the base of the Sierra de los Órganos. In 1800 it was officially named Nueva Filipina and was made capital of the western jurisdiction of Cuba. Its economic importance dates from about 1830, when the tobacco industry of the Vuelta Abajo region was developed. With the completion of the railroad from Havana came the development of Pinar del Río as a commercial centre for the hinterland, which yields tobacco, sugarcane, rice, pineapples, coffee, and livestock. Industrial activity centres on the manufacture of cigars, cigarettes, and furniture. It has a small thermal-power plant. Pinar del Río is also the western terminus of the central highway. Pop. (1988 est.) 112,280.

Pinay, Antoine (b. Dec. 30, 1891, Saint-Symphorien-sur-Coise, Fr.), leader of the Republican Independents in France and premier in 1952. He later became his country's first ombudsman (1973–74).

Pinay got his start in politics with election in 1929 as mayor of Saint-Chamond, a position he held until he retired in 1977. He was a politically moderate deputy from 1936 to 1938 and a senator from 1938 to 1940. He supported Pétain and was a member of his government. After the war, he was again elected to the National Assembly, where he served as president of the Independents from 1956 to 1958. During those years he also held posts in several cabinets—secretary of state (1949), minister of public works (1950–52), and minister of foreign affairs (1955–56)—and for a brief period (March–December 1952) served as premier. Pinay helped bring Charles de Gaulle back to power in 1958. In the new government, Pinay served as minister of finance (1958–59, 1960) with a policy of limiting inflation even if it meant curtailing industrial expansion. He was president of regional economic development for Rhône-Alpes from 1964 to 1973 and was then appointed first ombudsman of France.

pinball machine, also called PINBALL GAME, earliest of the coin-activated popular electromechanical games, usually found in candy stores, pool halls, drinking establishments, and amusement arcades, some of which, at the height of the game's popularity, were exclusively devoted to pinball. Pinball originated in its modern form in about 1930. Earlier machines had been purely mechanical. The earliest machines with coin slots used marbles and cost a penny to play. Steel balls replaced the marbles, and the single-coin price to play rose with inflation.

The pinball player inserts a coin, which unlocks a spring plunger with which the player may propel a ball up an alley on the side of the glass-topped, inclined playing area. From the top, the ball descends through gates, between posts, and off bumpers, whose electrical contact points produce a cumulative score recorded on a lighted panel at the top of the machine. The scoring is accompanied by the ringing of bells and the flashing of lights. Finally, the ball drops into one of several holes, scoring variously. As the game grew in popularity, added features allowed the player control of choices by use of levers or buttons. A rollover slot acted to multiply scores, so that they rose from tens of thousands to hundreds of thousands and finally to millions. More than one ball could be put in play. The player could apply physical torque or impetus to the machine (called "body English"), the amount of such force allowable being controlled by cut-off switches, which could be set so that an excess of force would flash on a "Tilt" sign, ending the game automatically.

Games similar to pinball date back to ancient Greece, where an outdoor game using round stones and holes dug in a hillside was played. There were mechanical games in France in the 18th century and in the United States in the 19th century. The most obvious ancestor of the modern pinball-machine games, however, is the game of bagatelle.

Almost all pinball machines were manufactured in the United States, but the game came to be played worldwide. After World War II, the Japanese developed a similar vertical machine, onomatopoeically named pachinko, that hung on the wall and had an automatic payoff receptacle like that of a slot machine.

In the late 20th century, electronic games simulating sport contests, followed by video games that added the dimension of military and intergalactic struggles, displaced pinball games in popularity (*see* electronic game).

pinch effect, self-constriction of a cylinder of current-carrying plasma. When an electric current is passed through a gaseous plasma, a magnetic field is set up that tends to force the current-carrying particles together. This force can compress the plasma so that it is heated as well as confined, but such a self-pinched plasma cylinder is unstable and will quickly develop kinks or break up into a series of lumps resembling a string of sausages. The pinch effect, therefore, must be augmented with other magnetic-field configurations to produce a stable magnetic bottle.

Pinchback, Pinckney Benton Stewart (b. May 10, 1837, Macon, Ga., U.S.—d. Dec. 21, 1921, Washington, D.C.), black freedman who served as a Union officer in the American Civil War and played a leading role in Louisiana politics during Reconstruction (1865–77).

Pinchback was one of 10 children born to a white Mississippi planter and a slave mother—whom the father subsequently freed and who became his wife in everything but name (interracial marriages were prohibited by state law). When the father died in 1848, the family fled to Ohio, fearing that white relatives might attempt to disinherit and re-enslave them.

Destitute at 12 years of age, Pinchback found work as a cabin boy on a canal boat running out of Cincinnati and worked his way up to steward on the steamboats plying the Mississippi, Missouri, and Red rivers. When war broke out between the states, he ran the Confederate blockade on the Mississippi to reach Federal-held New Orleans; there he raised a company of black volunteers for the North, called the Corps d'Afrique. When he encountered racial discrimination in the service, however, he resigned his captain's commission.

Returning to the South after the war, Pinchback organized the Fourth Ward Republican Club in New Orleans and served as a delegate to the convention that established a new constitution for Louisiana. He was elected to the state senate in 1868 and then was named its president pro tempore; as such he became lieutenant governor upon the death of the incumbent in 1871. For 36 days he served as acting governor while impeachment proceedings were in progress against the holder of that office. In the meantime he went into business and acquired control of a Republican paper, the New Orleans *Louisianian.*

In 1872 Pinchback was elected to Congress, but his Democratic opponent contested the election and won the seat. A year later he was elected to the U.S. Senate, but he was again refused the seat amid charges and countercharges of fraud and election irregularities—although some observers said it was the colour

Pinchback

of his skin that counted against him. He was appointed to his last office in 1882 as surveyor of customs in New Orleans.

At the age of 50 he decided to take up a new profession and entered Straight College, New Orleans, to study law; he was subsequently admitted to the bar. Disillusioned with the outcome of Reconstruction and the return to power of the traditional white hierarchy, he moved to Washington, D.C., where he practiced law until his death.

Pincherle, Alberto: *see* Moravia, Alberto.

pinching bug: *see* stag beetle.

Pinchot, Gifford (b. Aug. 11, 1865, Simsbury, Conn., U.S.—d. Oct. 4, 1946, New York, N.Y.), pioneer of U.S. forestry and conservation and public official.

Pinchot was graduated from Yale in 1889 and studied at the National Forestry School in Nancy, Fr., and in Switzerland, Germany, and Austria. Upon his return home in 1892, he began the first systematic forestry work in the United States at Biltmore, the estate of George W. Vanderbilt, in North Carolina. In

Pinchot
By courtesy of Yale University Archives, Yale University Library

1896 he was made a member of the National Forest Commission of the National Academy of Sciences, which worked out the plan of U.S. forest reserves, and in 1897 he became confidential forest agent to the Secretary of the Interior. In 1898 he was appointed chief of the Division, later Bureau, of Forestry and then the Forest Service (created 1905) in the Department of Agriculture, which office he held under Presidents William McKinley, Theodore Roosevelt, and William Howard Taft, until 1910. During his administration the entire forest-service system and administrative machinery were built up, and Pinchot's enthusiasm and promotional work did much for the conservation movement in general. He also served as a member of the Public Lands Commission, which he initiated in 1903, and the Inland Waterways Commission (1908). In 1908 he became chairman of the National Conservation Commission. He founded the Yale School of Forestry at New Haven, Conn., as well as the Yale Summer School of Forestry at Milford, Pa., and in 1903 became professor of forestry at Yale. In 1920 he was appointed state forester of Pennsylvania and began a systematic administration of the forest areas of that state.

With Theodore Roosevelt, Pinchot helped to found the Bull Moose Party in 1912. From 1923 to 1927 and from 1931 to 1935 he was governor of Pennsylvania. In his first term he forced a reorganization of the state government and the establishment of a budget system. He settled a coal strike by arbitration in 1923.

Pinchot's autobiography, *Breaking New Ground,* was published posthumously in 1947.

Pinckney, Charles (b. Oct. 26, 1757, Charleston, S.C. [U.S.]—d. Oct. 29, 1824, Charleston), American Founding Father, political leader, and diplomat whose proposals for a new government—called the Pinckney plan—were largely incorporated into the Federal Constitution drawn up in 1787.

During the American Revolution, Pinckney was captured and held prisoner by the British. Serving in the Continental Congress for three years (1784–87), he played a leading role in calling a national convention to revise and strengthen the Articles of Confederation.

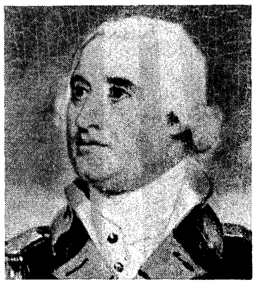
As a South Carolina delegate to the Constitutional Convention at Philadelphia, he submitted a detailed plan of government, which, although the original draft was not preserved, is known to have contained a number of provisions that were incorporated into the new Constitution. Pinckney possibly had as large a share in determining the style, form, and content of the document as any other individual. At home he supported ratification, presided over the convention that remodeled the South Carolina Constitution in 1790, and as governor (1789–92) guided the adjustment between the state and federal governments.

Pinckney began his political career as a Federalist but in 1791 transferred his allegiance to the Jeffersonian Republican Party. He served in the state legislature (1792–96, 1810–14) and as governor (1796–98, 1806–08), U.S. senator (1798–1801), and representative (1819–21). He supported amendments to the state constitution that gave greater representation to the back country and extended suffrage to all white men. By opposing Federalist policies, especially in 1798, he estranged his two politically active cousins, Charles Cotesworth Pinckney and Thomas Pinckney. Reflecting his Southern background, he bitterly assailed the proposed restrictions on slavery contained in the Missouri Compromise of 1820.

His fidelity to his party was rewarded by appointment as U.S. minister to Spain (1801–05), where he negotiated an agreement providing for a joint tribunal to settle spoliation claims (arising from the seizure of a ship's papers when confiscated for suspected smuggling, carrying contraband of war, or being an enemy ship) and the restoration to U.S. shippers of the right of deposit (temporary storage of goods) at the port of New Orleans. He also won Spain's reluctant consent to Napoleon's sale of Louisiana to the United States, but failed to achieve the U.S. acquisition of Florida.

Pinckney, Charles Cotesworth (b. Feb. 25, 1746, Charleston, S.C. [U.S.]—d. Aug. 16, 1825, Charleston), American soldier, statesman, and diplomat who participated in the XYZ Affair, an unsavory diplomatic incident with France in 1798.

Pinckney entered public service in 1769 as a member of the South Carolina Assembly. He served in the first South Carolina Provincial Congress (1775) and later in both houses of the South Carolina legislature. During the American Revolution he was an aide to General George Washington at Brandywine and Germantown, Pa. (both 1777), and later commanded a regiment at Savannah, Ga.; he was promoted to brigadier general in 1783. He took part in the Constitutional Convention of 1787, along with his cousin Charles Pinckney.



Charles Cotesworth Pinckney, detail of an oil painting on wood by John Trumbull, 1791; in the Yale University Art Gallery
By courtesy of the Yale University Art Gallery

Pinckney was appointed minister to France (1796) but was refused recognition by the French Directory and left Paris for Amsterdam. He returned to Paris the following year as a member of a commission that included John Marshall and Elbridge Gerry. When one of the group of French negotiators (later referred to in the correspondence as "X,Y, and Z") suggested that the U.S. representatives offer a gift, Pinckney is said to have replied, "No! No! Not a sixpence!" No treaty was negotiated, and an undeclared war with France ensued. Upon his return home Pinckney was made a major general. An unsuccessful Federalist candidate for vice president in 1800 and for president in 1804 and 1808, Pinckney spent his later years in law practice.

Pinckney, Elizabeth, *née* LUCAS, byname ELIZA PINCKNEY (b. *c.* Dec. 28, 1722, Antigua—d. May 26, 1793, Philadelphia, Pa., U.S.), British-American plantation manager known for the first successful cultivation of indigo in the United States, an accomplishment that subsequently helped to sustain the Carolina economy for 30 years.

When her father, George Lucas, was called to military duty in Antigua in the West Indies in 1739, Eliza Lucas remained to manage his three plantations in South Carolina. After three years of experimentation with ginger, cotton, indigo, and alfalfa, she succeeded in marketing the first crop of indigo. Parliament then subsidized the plant, and by 1754 South Carolina was exporting more than 1,000,000 pounds (454,000 kg) of the crop annually.

In 1744 she married Charles Pinckney, Carolina's first native lawyer, and on his Charleston plantation she revived the cultivation of silkworms and manufacture of silk. When her husband died in 1758, Eliza again became a plantation manager, guiding her family's extensive landholdings. Her sons Charles Cotesworth and Thomas became diplomats.

Pinckney, Thomas (b. Oct. 23, 1750, Charleston, S.C. [U.S.]—d. Nov. 2, 1828, Charleston), American soldier, politician, and diplomat who negotiated Pinckney's Treaty (Oct. 27, 1795) with Spain.

After military service in the American Revolutionary War, Pinckney, a younger brother of the diplomat Charles Cotesworth Pinckney, turned to law and politics. He served as governor of South Carolina (1787–89) and as president of the state convention that ratified the U.S. Constitution. As U.S. minister to Great Britain (1792–96) and envoy extraordinary to Spain in 1795, he negotiated the Treaty of San Lorenzo, or Pinckney's Treaty.

Pinckney was the unsuccessful Federalist candidate for vice president in 1796. He was a member of the U.S. House of Representatives (1797–1801) and a major general in the War of 1812. Upon retiring from public life, he practiced law and was a frequent contributor to the *Southern Agriculturist.*

Pinckney's Treaty, also called TREATY OF SAN LORENZO (Oct. 27, 1795), agreement between Spain and the United States, fixing the southern boundary of the United States at 31° N latitude and establishing commercial arrangements favourable to the United States. U.S. citizens were accorded free navigation of the Mississippi River through Spanish territory. The treaty granted Americans the privilege of tax-free deposit (temporary storage of goods) at New Orleans. Each side agreed to restrain Indians within its borders from attacks on the other, and there were provisions respecting freedom of the seas. The treaty was negotiated by Thomas Pinckney for the United States and Manuel de Godoy for Spain.

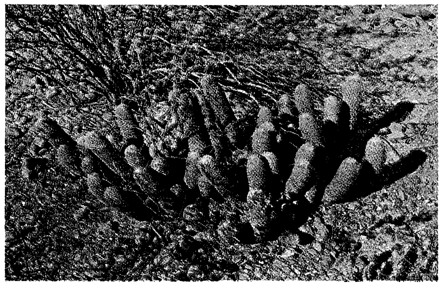
Pincus, Gregory (Goodwin) (b. April 9, 1903, Woodbine, N.J., U.S.—d. Aug. 22, 1967, Boston, Mass.), American endocrinologist whose work on the antifertility properties of steroids led to the development of the first effective birth-control pill.

Pincus was educated at Cornell University and Harvard University (M.S., Sc.D., 1927) and also studied in England and Germany. He was a faculty member at Harvard (1931–38), Clark University in Worcester, Mass. (1938–45), Tufts Medical School in Medford, Mass. (1946–50), and Boston University (1950–67).

In 1944 Pincus and Hudson Hoagland founded the Worcester Foundation for Experimental Biology, which became an important centre for the study of steroid hormones and mammalian reproduction. Margaret Sanger encouraged his work, and in 1951 Pincus and his collaborators began to work with synthesized hormones and the prevention of pregnancy. They found that inhibition of ovulation was an effective means of preventing pregnancy in laboratory animals and moved to perfect an oral contraceptive for women.

Pincus' publications include *The Eggs of Mammals* (1936) and *The Control of Fertility* (1965). He also edited a number of monographs on aspects of hormones.

pincushion cactus, any of about 60 species of the genus *Coryphantha,* family Cactaceae.



Pincushion cactus (*Coryphantha erecta*)
Edward F. Anderson

Pincushion also refers to the straight-spined species of the genus *Mammillaria.*

Coryphantha species are native to western North America and central Mexico, with one species in Cuba. Globose to cylindroid, with protuberances not connected into ribs, they range in size from *C. minima* of Texas, about 5 cm (2 inches) in height, to large Mexican species such as *C. calipensis,* which reach about 60 cm (24 inches) in length and 8 cm (3 inches) in diameter. A groove on the top of the tubercle, connecting the spine and flower-bearing parts, is characteristic of the genus and distinguishes it from *Mammillaria.*

C. vivipara (including its varieties) is almost as cold-resistant as the hardy prickly pears. It ranges from Alberta and Manitoba, in Canada, to Oklahoma and California, in the United States. *C. missouriensis* is also cold-resistant.

Coryphantha species have large flowers for the size of the plant. They are in shades of lavender, rose purple, pink, orange, yellow, and white. Fruits of the genus are green, red, or yellowish edible berries.

Neobesseya and *Escobaria* are usually considered subgenera of *Coryphantha.*

Pindar, Greek PINDAROS, Latin PINDARUS (b. 518/522 BC, Cynoscephalae, Boeotia, Greece—d. after 446, probably *c.* 438, Argos), the greatest lyric poet of ancient Greece, the master of epinicia, choral odes celebrating victories achieved in the Pythian, Olympic, Isthmian, and Nemean games.

Early training. Pindar was of noble birth, possibly belonging to a Spartan family, the Aegeids, though the evidence for this is inconclusive. His parents, Daiphantus and Cleodice, survive only as names; his uncle Scopelinus, a skilled flute player, doubtless helped with Pindar's early musical training. The family possessed a townhouse in Thebes (to be spared by express command of Alexander the Great in the general destruction of that city by the Macedonians in 335 BC). Such a background would give Pindar a ready entrée into aristocratic circles in other Greek cities, where his manifest gifts as a poet might be valued more highly than in his native Boeotia, which had little enough to offer in the way of precept and encouragement. (Two contemporary Boeotian female poets, Myrtis and Corinna, were of a very different tradition, more primitive and essentially feminine, though Corinna is reported to have criticized the lushness of Pindar's early style, advising him to "sow with the hand, not with the full sack.") It was natural, then, that Pindar should be sent to neighbouring Athens to complete his training and education. Athens and Thebes were seldom on neighbourly terms, but relationships between noble families transcended such difficulties. Pindar's horizons would have widened in the exciting atmosphere of a city beginning to realize its destiny, poised as it was on the verge of political and cultural greatness. He must have studied the choral lyric poets of the past, Alcman and Stesichorus in particular, and the work of his elder contemporaries, Simonides of Ceos and Lasus of Hermione. He would have steeped himself in the poetry of Homer and Hesiod, and he must have received detailed and systematic training in the techniques of choral composition in the city where dithyramb (a choral lyric) was cultivated and where tragedy was beginning to evolve from the dramatic ritual dance performed at religious festivals associated with the god Dionysus.

Professional career. Seventeen volumes of Pindar's poetry, comprising almost every genre of choral lyric, were known in antiquity. Only four books of epinicia have survived complete, doubtless because they were chosen by a teacher as a schoolbook in the 2nd century AD. They are supplemented by numerous fragments, and in recent years finds of papyri have helped toward a deeper understanding of Pindar's achievement, especially in paeans and dithyrambs. All the evidence, however, suggests that the epinicia were Pindar's masterpieces. These are divided as Olympian, Pythian, Isthmian, or Nemean—the games in which the victories he celebrated were held; the epinicia number 44 odes in all. The earliest surviving epinicion (Pythian ode 10) dates from 498, and Pindar already had an assured mastery of his medium when he wrote it. It would have been quite possible for him to evolve into a cosmopolitan artist like Simonides, welcome all over the Greek world and moving easily from city to city. No doubt Pindar visited the Panhellenic festivals, at Delphi (where the Pythian games were held) and Olympia in particular, to absorb the atmosphere of the games and the victories he celebrated. He would also have seen in person the homes of the aristocrats and the courts of the tyrants whose triumphs he sang. But in general he preferred to remain loyal to his native land and to reside in Thebes: it is Pindar's characteristic that his standards and values, like his poetry, changed little if at all over the years. Such patriotism meant sacrifices. Thebes, like Delphi, collaborated with the enemy in the Persian War—though admittedly Thebes had little alternative. But whereas Delphi's prestige was quickly restored after the retreat of the Persians, Thebes's defection was not lightly forgiven or forgotten. Athens was to dominate the history of the 5th century, and for the first two-thirds of it Athens had very much the better of its long, drawn-out quarrel with Thebes: from 457 to 447 BC Boeotia was virtually an Athenian dependency. And almost everywhere, the aristocratic way of life, integral alike to Pindar's personality and to his art, was threatened. Politically and economically the monopolies of power by the noble families were broken. The aristocratic code, with its ultimately selfish individualism (summed up in a famous line of Homer, "ever to excel and to surpass other men") was undermined by the radical rationalism of a new age. Choral lyric itself had little future as a separate art form: tragedy absorbed into itself what was most vital in the tradition, and Pindar had no worthy successors. It is a tribute to the quality of Pindar's poetry that although he must have regarded these contemporary cultural and political developments with disdain, or at best with indifference (apart perhaps from his reinterpretation of some of the traditional stories concerning the gods), he was universally respected and accepted as a major creative artist.

Pindar's early poems have almost all been lost; it is probable, however, that what gave him a growing reputation beyond the borders of Boeotia were hymns in honour of the gods. Pindar was born at the time of the Pythian festival, and from his youth he had a close connection with the Pythian priesthood, which served the oracular shrine of Apollo at Delphi. Pindar and his descendants, indeed, enjoyed special privileges at Delphi, where his memory was cherished in later times and where an iron chair, in which it was said he had sat to sing, was exhibited. The first commissions for epinicia came mostly from aristocratic connections: the Aleuads in Thessaly (Pythian ode 10; 498 BC); the Alcmaeonids in Athens (Pythian ode 7; 486 BC); Agesidamus of Epizephyrian Locri (Olympian ode 11; 484 BC); and above all the Aeacids of the island of Aegina (the series begins with paean 6, dating from 490 BC, and continues with Nemean ode 7). Progress in winning recognition seems to have been steady, if slow. A significant breakthrough came when Pindar established a link with the court of Theron of Acragas through the tyrant's brother Xenocrates, whose chariot won the Pythian contest (Pythian odes 6 and 12; both 490 BC). But the Persian invasion of Greece came before the promise of this new connection could be fulfilled. Pindar faced a crisis of divided loyalties, torn between a sense of solidarity with the aristocracy of Boeotia, who followed a pro-Persian policy, and a growing appreciation of Spartan and Athenian heroic resistance. Pindar was first and foremost a Theban and stood by his friends, many of whom paid for their policy with their lives. But it was Simonides, not Pindar, who wrote the poems of rejoicing at Greece's victories and of mourning for its glorious dead.

It took Pindar some years to reestablish himself: fortunately, his friends in Aegina were staunch (Isthmian ode 8; 478 BC). It is virtually certain that he visited Sicily in 476–474 BC and was made welcome at the courts of Theron of Acragas and Hieron I of Syracuse. They were to elicit much of his greatest poetry, and it was through these connections that Pindar's reputation spread all over the Greek world so that commissions flowed in from the mainland, the islands, and also from the remoter outposts of Hellenism. Promising new contacts were made with the royal houses of Macedon and Cyrene (Alexander of Macedon, Fragment 120; Arcesilas of Cyrene, Pythian odes 4 and 5; 462/461 BC). Theron and Hieron respected and admired Pindar, but his aristocratic temper made him dangerously outspoken. Diplomatic tact and finesse were not among his qualities, and his adroit rivals, Simonides and Bacchylides, were more pliant and adaptable (Bacchylides, not Pindar, celebrated Hieron's Olympic victory in the chariot race in 468 BC). Echoes of Pindar's bitter resentment sound in his poetry. So, too, Pindar's intervention on behalf of Damophilus, a noble exile from Cyrene (Pythian ode 4, 279 ff.), seems to have been taken amiss, and he was not invited to commemorate Arcesilas' triumph at Olympia in 460 BC. Nevertheless, these were the years of supreme achievement, and Pindar found a growing demand for his poetry and a growing appreciation of his skill. His debt to Athens was amply paid in a famous tribute (Fragment 76) that the Athenians never tired of citing, one that earned the poet special honours in that city (and, according to ancient tradition, a fine at Thebes). It was probably in this period that Pindar married.

The subsequent decade of Athenian domination in central Greece coincided with a period when Delphi was controlled by Phocis in northern Greece. These were dark years for Pindar, and his poetic output dwindled. But he continued to celebrate Theban victories (Isthmian odes 1 and 7); and he found inspiration in the achievements of his Aeacid friends of Aegina, though their days of nominal independence were clearly numbered (Isthmian odes 5, 6; Nemean odes 3–8; all celebrate Aeginetan successes). Pindar's last extant poem (Pythian ode 8) appropriately commemorates an Aeacid victory.

The tradition that Pindar lived to the age of 80 may be true, but there is no surviving poem from later than 446 BC.

Poetry. The epinicion form, which in Simonides' hands seems to have evolved into a relatively simple poem of rejoicing enhanced by touches of realism and humour, is assimilated by Pindar to the religious hymn. The praise and worship of the god whose festival is being celebrated set the tone, and thanksgiving is an integral part of the structure. A second constituent element is the myth, impressionistically treated in a series of short, sharply visualized scenes and meant to link the glorious present to the yet more glorious past, to give a new dimension to the transient moment of victory. A third ingredient is the aphoristic moralizing, often in Pindar of extreme beauty, even sublimity, in which the dangers of excessive pride in achievement are repeatedly stressed. The emotional impulse throughout stems from the aristocratic ideal of self-assertion, competition, and leadership—an ideal expressing itself most finely in battle but also finding fulfillment in athletic contests, in which the palm goes to superior physique and morale deriving from superior birth. His metrical range is exceptionally wide, with no two poems being identical in metre, and he controls difficult and involuted techniques with consummate professional mastery. His dialect is literary and eclectic, with few Boeotian elements; the vocabulary is enriched, poetic, and highly personal. Each poem is fused into a unity by the fire of Pindar's poetic inspiration, by a sweep and soar of imagination that give his poetry power and magnificence, by the shaping and controlling discipline of a fastidious art expressed in an intensely personal style. Delphic religious teaching found in Pindar a ready pupil, and he constantly spiritualized his material, turning away from the cruder traditional stories of the gods, avoiding the mundane details of the contest, striving to catch the fleeting radiance that plays about the moment of supreme endeavour when a man transcends his own limitations of physique and character and so proves worthy of his birth and ancestry. Delphi also profoundly influenced his style, which is frequently cryptic and oracular. He regarded himself as the Muse's prophet: she is the pythoness and he is the priest who puts her inspired message into intelligible shape.

The only other major poet produced by Boeotia was Hesiod, who had flourished in the 8th century BC. The two are poles apart in background and temperament, but they share a deep religiosity, a groping toward something more profound and satisfying than contemporary cults could offer, a fondness for abrupt and violent transitions in thought and mood, and a forthright pungency of speech. A somewhat muted epitaph preserved in the *Greek Anthology* (7, 35) describes Pindar as the servant of the Muses, welcomed by strangers, beloved by his fellow citizens. Perhaps the poet would have regarded it as adequate.

Pindar's odes make great demands on the modern reader, and it is only in recent times that his art has begun to be appreciated for what it is. (The so-called Pindaric ode has had a long and distinguished history in English literature, but it derives from an almost total misunderstanding and misapprehension of Pindar's own style and technique.) Even so, much essential evidence is missing. The musical settings that he composed to accompany his words are lost forever, though in view of the quality of the poetry it is probable that the words dominated the setting (as must have been the case in most Greek lyric). It is therefore impossible to re-create even in imagination the approximate sound of a Pindaric ode, or indeed to reconstruct visually the appearance and constitution of the choir: how many participated; what range of voices was employed; whether the singers were static, moved in procession, or danced—these are questions that cannot now be answered. Nor is it possible to picture at all clearly the festive occasion that was the background for the poetry. Yet efforts to understand the odes are rewarded by at least a glimpse of the poet behind them. The aristocratic society and standards, which meant everything to Pindar, were dead or dying. But in his art he re-created them, giving them new and permanent existence and value.

The tradition of Greek choral lyric culminated with the odes of Pindar. These are not easy to evaluate and appreciate, but it is still more difficult to comprehend and assess the poet who composed them. Even to his contemporaries, Pindar must have seemed an aloof and somewhat enigmatic figure. As an aristocrat he would more naturally have been a patron of poetry than himself a poet; he came from a part of central Greece that had made a relatively small contribution to literature and the arts. Because ancient biographies, dating from the 4th and 3rd centuries BC, are highly unreliable and of little help, any approach to the poet must be made through his poetry, and this involves a consideration of the historical setting, the religious usages, and the literary conventions that helped to shape his art. A modern reader needs a sympathetic insight into the nature and traditions of Greek aristocratic society before he can begin to understand how Pindar's subject matter—victory in an athletic contest or in a chariot race—could inspire poetry characterized by high seriousness and deep feeling. Pindar cannot, indeed, speak across the centuries with the directness of Homeric epic poetry or Sophoclean tragedy, but he does create, with disciplined mastery of a sophisticated and complex art form, a choral lyric of unsurpassed splendour and sustained nobility.

The best verse translations in English are by R.A. Lattimore, *The Odes of Pindar* (1947); and by C.M. Bowra, *The Odes of Pindar* (1969). (D.E.W.W.)

BIBLIOGRAPHY. A full account of editions, commentaries, translations, and criticism to 1966 may be found in Douglas E. Gerber, *A Bibliography of Pindar, 1513–1966* (1969). R.W.B. Burton, *Pindar's Pythian Odes* (1962), analyzes and explains these epinicia poem by poem. C.M. Bowra, *Pindar* (1964), gives a sensitive appreciation of the poet's personality and art.

Pindar, Peter, pseudonym of JOHN WOLCOT (baptized May 9, 1738, Dodbrooke, Devonshire, Eng.—d. Jan. 14, 1819, London), English writer of a running commentary in satirical verse on society, politics, and personalities, 1778–1817.

After studying medicine at Aberdeen, Scot., Wolcot went to Jamaica as physician to the governor in 1767. He was ordained in 1769 but then forsook the church. He returned to England in 1772 and practiced medicine in Cornwall until he settled in London in 1781. Despite blindness, he continued to write to the end of his life, producing more than 70 satirical works and some other poems. He was buried, at his own request, "close to the author of *Hudibras*," the 17th-century satirist Samuel Butler, in St. Paul's Covent Garden, London.

Although Pindar lacked the depth of the great satirists, he was a master of verse caricature, as shown especially in his scurrilous lampoons of George III in *The Lousiad, an Heroi-Comic Poem,* 1785–95; *Ode Upon Ode or a Peep at St. James's or New Year's Day,* 1787; and *The Royal Visit to Exeter,* 1795 (a tour de force of Devon dialect humour) and in the virtuosity of his doggerel rhymes. His other targets included James Boswell, author of *The Life of Samuel Johnson LL.D.,* and the painter Benjamin West. With some knowledge of art, he was at his best in attacks on painters; he became famous with his *Lyric Odes to the Royal Academicians* (1782–85).

Pindari, historically, an irregular horseman, plunderer, or forager attached to a Muslim army in India who was allowed to plunder in lieu of pay. The name is Marāṭhi and probably derives from two words, meaning "bundle of grass" and "who takes."

The Pindaris followed the Marāṭhā bands who raided Mughal territory from the late 17th century. With the collapse of the Mughal empire in the 18th century, these camp followers organized themselves into groups, each usually attached to one of the leading Marāṭhā chiefs. But as those chiefs themselves grew weak at the end of the century, the Pindaris became largely a law unto themselves and conducted raids from hideouts in central India. The majority of their leaders were Muslims, but they recruited from all classes.

After the regular forces of the Marāṭhās had been broken up by the British in the campaigns of 1803–04, the Pindaris made their headquarters in Mālwa, under the tacit protection of the rulers of Gwalior and Indore. They usually assembled in November to set forth over British-held territory in search of plunder. In one such raid on the Masulipatam coast, they plundered 339 villages, killing and wounding 682 persons, torturing 3,600 others, and carrying off much valuable property. In 1808–09 they plundered Gujarāt, and in 1812, Mirzāpur. In 1814 they numbered between 25,000 and 30,000 horsemen, half of them well armed.

At last their practices became intolerable, and in 1816 the British organized the campaign known as the Pindari War (1817–18). The Pindaris were surrounded by an army of about 120,000 men, which converged upon them from Bengal, the Deccan, and Gujarāt under the supreme command of the governor-general Warren Hastings. The Pindaris' protectors in Gwalior were overawed and signed a treaty (1817) against the Pindaris. Their other allies against the British took up arms but were separately defeated. The Pindaris themselves offered little resistance; most of the leaders surrendered, and their followers dispersed.

Pindaric ode, ceremonious poem by or in the manner of Pindar, a Greek professional lyrist of the 5th century BC. Pindar employed the triadic structure of Stesichorus (7th and 6th centuries BC), consisting of a strophe (two or more lines repeated as a unit) followed by a metrically harmonious antistrophe, concluding with a summary line (called an epode) in a different metre. These three parts corresponded to the movement of the chorus to one side of the stage, then to the other, and their pause midstage to deliver the epode.

Although fragments of Pindar's poems in all of the classical choral forms are extant, it is the collection of four books of epinicion odes that has influenced poets of the Western world since their publication by Aldus Manutius in 1513. Each of the books is devoted to one of the great series of Greek classical games: the Olympian, Pythian, Isthmian, and Nemean. Celebrating the victory of a winner with a performance of choral chant and dance, these epinicion odes are elaborately complex, rich in metaphor and intensely emotive language. They reveal Pindar's sense of vocation as a poet dedicated to preserving and interpreting great deeds and their divine values. The metaphors, myths, and gnomic sayings that ornament the odes are often difficult to grasp because of the rapid shifts of thought and the sacrifice of syntax to achieving uniform poetic colour.

With the publication of Pierre de Ronsard's four books of French *Odes* (1550), the Pindaric ode was adapted to the vernacular languages. Imitation Pindaric odes were written in England by Thomas Gray in 1757, "The Progress of Poesy" and "The Bard." Abraham Cowley's *Pindarique Odes* (1656) introduced a looser version known as Pindarics. These are irregular rhymed odes in which the length of line and stanza is capriciously varied to suggest, but not reproduce, the style and manner of Pindar. These spurious Pindarics are some of the greatest odes in the English language, including John Dryden's "Alexander's Feast" (1697), William Wordsworth's "Ode: Intimations of Immortality from Recollections of Early Childhood," Percy Bysshe Shelley's "Ode to the West Wind," Alfred Lord Tennyson's "Ode on the Death of the Duke of Wellington," and John Keats's "Ode on a Grecian Urn." *See also* ode.

Pindemonte, Ippolito (b. Nov. 13, 1753, Verona, Republic of Venice [Italy]—d. Nov. 18, 1828, Verona), Italian prose writer, translator, and poet, remembered for his pre-Romantic lyrics and particularly for his highly prized translation of the *Odyssey.*

Born into a noble and cultivated family, Ippolito Pindemonte was educated at a college in Modena and then traveled in Europe. He published a volume of Arcadian verse, *Le stanze* (1779), and one of lyrics, *Poesie campestri* (1788; "Rural Poetry"). Both showed a sensitivity to nature and the influence of the contemporary English poets Thomas Gray and Edward Young. A stay in Paris inspired the poem "La Francia" (1789) and a prose satire on political conditions in Europe, *Abaritte* (1790). Disillusioned by the French Revolution's Reign of Terror, Pindemonte left for London, Berlin, and Vienna. On his return to Italy his *Prose campestri,* a companion volume to the earlier poetry, was published (1794).

In 1805 Pindemonte began his translation of the *Odyssey;* it was published as *Odissea* (1822). Pindemonte also wrote two tragedies and some moralistic letters and sermons.

His older brother Giovanni wrote lyric poetry and popular tragedies.

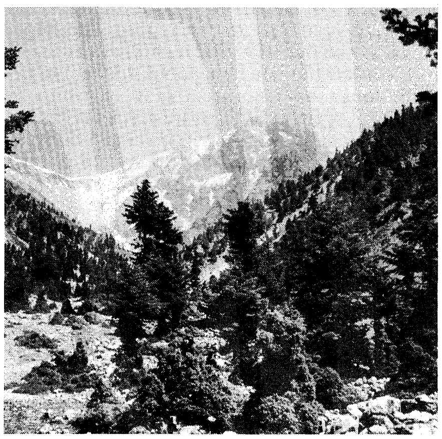
Pindus Mountains, Modern Greek OROSEIRÁ PÍNDHOU, principal range and backbone of mainland Greece, trending north-northwest–south-southeast from Albania to central Greece north of the Peloponnese.

In antiquity, the name Pindus applied to ranges south of the Aracynthus (Zygós) Pass west of Thessaly. Occasionally the Pindus is said to extend into Albania but also to include the Tymphrestos (Timfristós) massif and even the Gióna massif north of Amphissa in the *nomós* (department) of Phocis (Fokís). The highest point of the range is 8,651 feet (2,637 m) in the Smólikas massif, near the Albanian border.

An extension of the calcareous Dinaric range of the Balkans, the core of the Pindus appears to comprise metamorphic and volcanic rocks: schists, serpentines, granite, and jasper. The northern parts, less elevated, have folded Balkan characteristics. Lacking uniformity, the Pindus consists largely of a series of small ranges separated by transverse valleys eroded from limestones that on the eastern slopes often are overlain by geologically younger sandy and marl deposits. The result is often wild, precipitous slopes that afford few passes; the principal one is the Métsovo (Katára pass; 5,593 feet [1,705 m]), a historic defile that carries the highway from the Epirus to Thessaly.

The southern limits of the Pindus are generally considered to be the Tymphrestos Mountains northeast of Karpenísion. From the Albanian border, the local massifs are the Grámmos and Vóïon, Tímfi, Smolikas, Lingos, Lákmos (the latter rising at Peristéri to 7,529 feet [2,295 m]), and the Athamánon, between the Árakhthos and Achelous rivers, rising at Tzoumérka to 8,100 feet (2,469 m).

Forested with oak, fir, beech, and pine, the Pindus creates a barrier for the westerly weather fronts, which puts the Thessalian plain to the east in a rain shadow. The mountains, snowcapped in winter, receive heavy rainfall that feeds such rivers as the Achelous and Mégdhova on the western slopes and the Piniós and Aliakmon on the eastern.



Mount Tymphrestos in the southern Pindus range, Greece

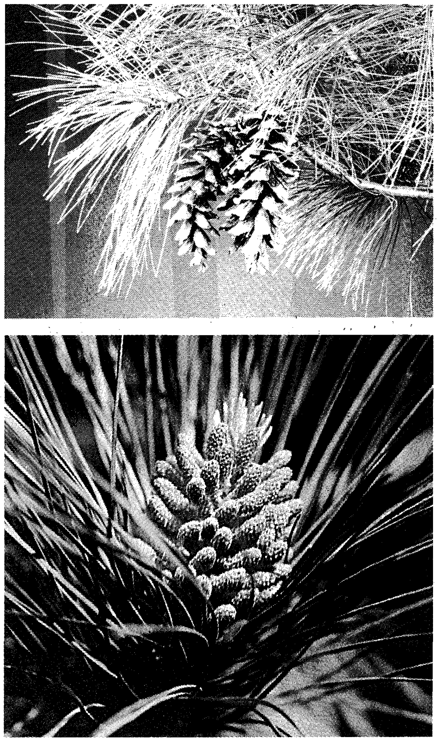
A list of the abbreviations used in the MICROPAEDIA *will be found at the end of this volume*

pine, any of about 90 species of ornamental and timber evergreen conifers of the genus *Pinus* (family Pinaceae), distributed throughout the world but native primarily to northern temperate regions.

Young trees are usually conical, with whorls of horizontal branches; older trees may have round, flat, or spreading crowns. Most species have thick, rough, furrowed bark. Pine trees can tolerate drought but require full sunlight and clean air for good growth and reproduction.

Pines have two types of branches, long shoots and short shoots, and three types of leaves, primordial, scale, and adult. Seedling plants bear the lance-shaped, spirally arranged primordial leaves; the triangular-scale leaves, also lance-shaped, are borne on the long shoots of older trees. Both long and short shoots develop in the axils of the deciduous scale leaves. The needlelike, photosynthetic adult leaves, with two or more resin canals, are borne in fascicles (bundles) of two to five (rarely, up to eight or solitary) at the tip of each short shoot; they remain on the tree 2 to 17 years.



(Top) Mature seed-bearing female cones of white pine (*Pinus strobus*) and (bottom) cluster of pollen-bearing male cones of Austrian (black) pine (*Pinus nigra*)
Grant Heilman—EB Inc.

Male cones are covered with many fertile scales, each of which bears two pollen sacs. Female cones, borne on the same tree, have several spirally arranged bracts (modified leaves), each of which is located below a scale with two ovules (potential seeds). In spring or early summer the pollen sacs release pollen through longitudinal slits; each grain has two air bladders for wind dispersal. The scales on the female cones open to receive the pollen and then close; actual fertilization takes place late the following spring. After fertilization, the woody female cone develops over a two- to three-year period. In some species, the cones open at maturity and the seeds are released; in others the cones remain closed for several years until opened by rotting, by food-seeking animals, or by fire. In some pines the scale bearing the nutlike seed may be expanded to form a wing for airborne dispersal.

Pines are softwoods, but commercially they may be designated as soft pines or hard pines. Soft pines, such as white, sugar, and piñon pines, have relatively soft timber, needles in bundles of five (rarely, one to four), stalked cones with scales lacking prickles, and little resin. Their wood is close-grained, with thin, nearly white sapwood; the sheaths of the leaf clusters are deciduous, and the leaves contain a single fibrovascular bundle. Hard pines, such as Scots, Corsican, and loblolly pines, have relatively hard timber, needles in bundles of two or three (rarely, five to eight), cone scales with prickles, and large amounts of resin. Their wood is coarse-grained and usually dark-coloured, with pale, often thick sapwood; the sheaths of the leaf clusters are persistent, and the leaves have two fibrovascular bundles.

The chief value of pines is in the construction and paper-products industries, but they are also sources of turpentine, rosin, oils, and wood tars (naval stores); longleaf, slash, cluster, and Chir pines are cut for these materials. Charcoal, lampblack, and fuel gases are distillation by-products. Pine-leaf oil, used medicinally, is a distillation product of the leaves. Edible pine seeds are sold commercially as pine nuts, piñons, or pignons, produced by stone, Armand, Siberian, piñon, Torrey, Coulter, and digger pines. Many species of pines are cultivated as ornamentals, including black, white, Himalayan, and stone pines; others, such as Scots, Corsican, cluster, and knobcone pines, are planted in reforestation projects or for windbreaks.

Pines are susceptible to several fungal diseases, among them white-pine blister rust, and are attacked by many insects, such as sawflies, weevils, bark beetles, and tip moths. Pine forests often suffer severe fire damage, being very combustible because of their high resin content.

Many botanists consider the genus *Pinus* to contain two subgenera. *Haploxylon,* or soft, pines have one fibrovascular bundle; *Diploxylon,* or hard, pines have two.

Many pines have both lumber trade names and several common names. Numerous trees commonly called pines are not true pines but belong to other genera in the family Pinaceae or to other families of conifers.

Major Eurasian pines. The Scots pine (*P. sylvestris*) of northern Europe, when grown under optimum conditions, attains a height of 20 to 40 m (70 to 130 feet). It is conical in youth, acquiring a mushroom crown in maturity, and has a straight trunk as much as a metre in diameter, fiery red-brown bark, and gnarled, twisted boughs densely clothed with blue-green foliage at the extremities. *P sylvestris* occurs in varying abundance from Finland and Sweden to the mountains of Spain and the higher slopes of Mount Etna and, longitudinally, from the shores of the North Sea to Siberia. Abundant in the Scandinavian peninsula, it is the fir (*fur, fura*) of the old Norsemen and still retains that name in Great Britain, although it is a true pine. Economically it is valued for timber but also for turpentine and tar.

Closely allied to the Scots pine—and perhaps to be regarded as a mere alpine form of that species—is the dwarf *P. pumilio,* a recumbent bush, generally only a metre or two high, but with long zig-zag stems that root occasionally at the kneelike bends where they rest upon the ground. It abounds in the Bavarian and Tirolese Alps.

P. laricio, the Corsican pine, grows to a height of 30 or even 45 m, with a straight trunk and branches in regular whorls, forming in a large tree a pyramidal head. This pine abounds in Corsica and is also found in Spain, southern France, and Greece.

The black, or Austrian, pine (*P. nigra)* derives its name from the sombre aspect of its dark green, sharp, rigid, rather long leaves. The tree, up to 30 m tall, displays a deeply fissured bark and light brown branches. This species, widely cultivated for ornament, is native to Europe and western Asia.

The cluster, or pinaster (*P. pinaster*), a vigorous grower in coastal sand, has been cultivated extensively for the purpose of stabilizing sand drifts, especially on the dunes of the Bay of Biscay and the Mediterranean. Growing to a height of from 12 to 24 m, the deeply furrowed trunk occasionally reaches a diameter of a metre or more at the base. Forests of pinaster, apart from the production of timber, have great economic value as a source of turpentine.

P. pinea is the stone pine of Italy. Its spreading, rounded canopy of light green foliage, supported on a tall and often branchless trunk, forms a striking feature of the landscape of Italy, as well as of some other Mediterranean lands. The cones have been prized from the ancient days of Rome for their edible seeds (pignons), which are still used for food.

Similar to *P. pinea* is *P. griffithi,* the Himalayan, or blue, pine, which differs chiefly in its longer cones and drooping, glaucous foliage. It grows in Kumaeon and Bhutan and on some of the Nepal ranges, where it attains large dimensions.

The Eurasian stone pine (*P. cembra*) abounds on the Alps, the Carpathians, and the Siberian ranges. The oily seeds, like those of *P. pinea,* are eaten by the inhabitants of the Alps and Siberia and yield a fine oil used for food. The wood is remarkably even-grained and is used by Swiss woodcarvers.

Major North American pines. The eastern white pine (*P. strobus*), known also as Weymouth pine, is one of the most valuable of North American timber trees because of its large size and the soft, even grain of its white wood. It once formed extensive forests from Newfoundland to Manitoba, from Minnesota to Maine and southward in the mountains to Georgia, but it has been cut intensively for so long that by the second half of the 20th century very few old trees remained. On deep rich soil *P. strobus* attains a height of 60 m and a trunk diameter of 1 to 1.5 m. The western white pine (*P. monticola*) grows in the mountains of the northwestern United States and British Columbia, has light brown wood, and is extensively cut for lumber.

The sugar pine (*P. lambertiana*) of California is the largest of known pines, often 60 to 70 m tall and with a trunk diameter of 2 or even 3.5 m. Its crown is pyramidal, with horizontal or slightly drooping branches.

North American stone pines are typically timberline species and are more important as protectors of valuable watersheds than for the timber they produce. The whitebark pine (*P. albicaulis*) extends along mountain slopes from British Columbia to California and eastward to Montana and Wyoming. The Mexican white pine (*P. ayacahuite*) attains its northern limits in the southwestern United States.

The single-leaf piñon (*P. monophylla*) occurs sporadically through northern Mexico and the southwestern United States. The Parry piñon (*P. quadrifolia*) is the four-needle piñon of southern California and northern Baja California. Nut pine (*P. edulis*) is the most widely distributed tree of this nut group. The seeds of the group are large and tasty and are sold in markets as pine nuts.

Longleaf pine (*P. palustris*) is the most notable yellow pine of the southern United States; it abounds on sandy soils from the Carolinas and Florida westward to Louisiana and Texas. The most marked features of the tree are its long, tufted foliage and its tall, columnar trunk, sometimes 35 m high, which furnishes one of the most valued pine timbers. Loblolly pine (*P. taeda*), shortleaf pine (*P. echinata*), and slash pine (*P. caribaea*) are other very important timber trees in the southern United States. The last-named extends over the Florida Keys to several islands in the Caribbean.

Ponderosa, western yellow, or bull pine (*P. ponderosa*), which grows from 45 to 60 m high, with a massive trunk 1.5 to 2.5 m in diameter, is noted for its soft, easily worked wood. It is the most widely distributed American pine, being found in the mountain forests of western North America from British Columbia to South Dakota and south to Texas and Mexico.

The beautiful Monterey pine (*P. radiata*), found sparingly along the California coast, is distinguished by the brilliant colour of its foliage. The Torrey pine (*P. torreyana*) is found only in a narrow strip along the coast near San Diego, Calif., and on Santa Rosa Island and is the least widely distributed of all known pines.

The pitch pine (*P. rigida*), found from the coast of Massachusetts southwestward throughout the Appalachian region, is a tree of from 12 to 15 m in height, with rugged trunk, occasionally a metre in diameter. The tree is one of the few pines that will flourish in salt marshes.

Pine Bluff, city, seat (1832) of Jefferson county, central Arkansas, U.S., on high bluffs overlooking the Arkansas River. Settled in 1819 as a trading post by Joseph Bonne and known as Mount Marie, it was renamed in 1832 for its forest of giant pines. It was the scene of an American Civil War engagement (Oct. 25, 1863) when a Confederate force under General John S. Marmaduke was repulsed by a Federal brigade under Colonel Powell Clayton, later a governor and U.S. senator. The city is an industrial, rail, and marketing centre and a river port. Cotton, paper, lumber, and archery supplies are basic to its economy. It is the seat of the University of Arkansas at Pine Bluff (formerly Arkansas Agricultural, Mechanical and Normal College [1873]) and a vocational technical school. Pine Bluff Arsenal (15,000 acres [6,100 hectares]) includes chemical- and biological-warfare laboratories. Inc. town, 1839; city, 1846. Pop. (1988 est.) 62,528.

Pine Falls, village, southeastern Manitoba, Canada, on the Winnipeg River, near its influx into Lake Winnipeg. It originated around a paper mill built in 1925 and was sustained by the arrival of a railroad branch line from Winnipeg (60 miles [100 km] southwest) in 1926. The site, within Fort Alexander Indian Reserve, was leased from the Department of Indian Affairs, and the Manitoba Pulp and Paper Company, which planned the village, is the administrator and chief employer of the community. Pine Falls is now a service centre for a lumbering and trapping region. Immediately to the east is Manitoba Hydro's Pine Falls power plant, which supplies electricity to metropolitan Winnipeg. Belair Provincial Forest and Grand Beach Provincial Park (9.5 square miles [25 square km]) are nearby. Pop (1981) 885.

Pine Mountain, ridge on the Cumberland Plateau, a section of the Appalachian Mountains in the United States, extending for 125 miles (200 km) across southeastern Kentucky, along the Virginia border, and into northern Tennessee. With average heights of 2,100 to 2,800 feet (640 to 850 m), the ridge rises to Big Black Mountain (4,145 feet [1,263 m]), the highest point in Kentucky. A scenic highway crosses a section of the wooded ridge, which is partly within a division of the Jefferson National Forest.

pine mouse, any of several burrowing rodents, species of voles. *See* vole.

pine oil, essential oil consisting of a colourless to light amber liquid of characteristic odour obtained from pine trees, or a synthetic oil similar in aroma and other properties. Pine oil is used as a solvent for gums, resins, and other substances. It has germicidal properties and is employed medically as a principal constituent of general disinfectants. It is also used in odorants, insecticides, detergents, wetting and emulsifying agents, wax preparations, and antifoaming agents and in textile scouring and the flotation process for refining lead and zinc ores.

Pitch-soaked wood of the pine tree, principally *Pinus palustris* but also certain other species of the family Pinaceae, is subjected to steam distillation, solvent extraction followed by steam distillation, or destructive distillation to obtain the pine oil, which boils at 200°–220° C (390°–430° F).

A variety of similar pine oils are obtained by distillation of cones and needles of various species of pines or by extraction from the stumps using solvents and steam. Synthetic pine oil is produced by conversion of terpene hydrocarbons into terpene alcohols.

Chemically, pine oils consist principally of cyclic terpene alcohols and are used in the manufacture of chemicals. Pine oil is insoluble in water but dissolves in alcohol and other organic solvents.

pine weevil, any wood-boring beetle of the insect family Curculionidae (order Coleoptera). Their most unusual physical characteristic is an elongated beak, or snout.

The white pine weevil (*Pissodes strobi*) of North America kills the central growth shoot of white pine trees, forcing one of the side shoots to take over the upward growth of the tree. This results in bends in the tree trunk and reduces its value as lumber.

pineal gland, also called PINEAL BODY, or EPIPHYSIS CEREBRI, an endocrine gland found in vertebrates that regulates the production of the hormone melatonin. Though it is not part of the brain, the pineal gland develops from the roof of the diencephalon, a section of the brain. In some lower vertebrates the gland has a well-developed eyelike structure; in others, though not organized as an eye, it functions as a light receptor. Studies that were carried out in the 1980s suggested that the pineal gland was the evolutionary forerunner of the modern eye.

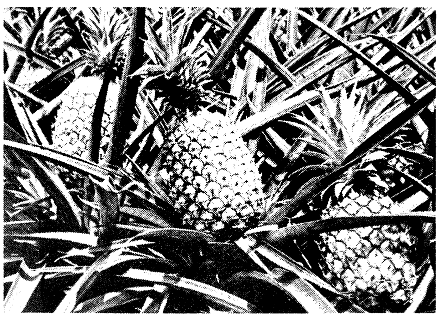
The pineal gland is located within the third cerebral ventricle along the midline of the brain. Its name is derived from its shape, which is like that of a pine cone (Latin: *pinea*). In the adult human, it is about 0.64 cm (0.25 inch) long and is pinkish gray or white in colour. It weighs little more than 0.1 gram. The gland is large in children and begins to shrink with the onset of puberty. In adults, small deposits of such minerals as calcium make the pineal body visible on X rays.

The apparent endocrine function of the gland is to elaborate the hormone melatonin. Studies of the pineal body in a number of vertebrates have conclusively proved that the pineal plays a major role not only in sexual development but also in hibernation and metabolism and seasonal breeding. In humans, however, its actual function is not understood very well; though humans have not responded as predictably to experimentation as have the lower vertebrates, evidence has suggested that the pineal gland plays a significant role in sexual maturation (the abundant production of melatonin in young children is believed to inhibit sexual development), circadian rhythm and sleep induction (secretion of melatonin is elevated at night), and so-called seasonal affective disease and depression (decreased daylight makes for longer periods of melatonin production).

pineapple (*Ananas comosus*), fruit-bearing plant of the family Bromeliaceae, native to tropical and subtropical America but introduced elsewhere. The pineapple plant resembles the agave or some yuccas in general appearance. It has from 30 to 40 stiff, succulent leaves closely spaced in a rosette on a thick, fleshy stem. With commercial varieties, a determinate inflorescence forms about 15 to 20 months after planting on a flower stalk 100–150 mm (4–6 inches) in length. The originally separate lavender flowers, together with their bracts, each attached to a central axis core, become fleshy and fuse to form the pineapple fruit, which ripens five to six months after flowering begins. Fruits of commercial varieties range from 1 to 2 kg (2 to 4 pounds) in weight. The earliest written references to pineapple are by Columbus, Gonzalo Fernández de Oviedo y Valdés, and Sir Walter Raleigh, who found pineapple growing in the West Indies, where it was used for food and wine making.

The Portuguese were apparently responsible for early dissemination of the pineapple. They introduced it to Saint Helena shortly after they discovered that island in 1502. Soon after, they carried it to Africa and, by about 1550, to India. Before the end of the 16th century, cultivation of the plant had spread over most of the tropical areas of the world, including some of the islands of the South Pacific.

When pineapple is cultivated on modern plantations, an asphalt-impregnated mulch paper is usually first laid on well-tilled soil in rows, with the edges covered to anchor the strips of paper. The pineapple propagating pieces are inserted through the paper into the soil, so spaced as to give a population of 15,000–20,000 plants per acre. The pineapple has become a characteristic ingredient in the meat, vegetable, fish, and rice dishes of what



Pineapple (*Ananas comosus*)

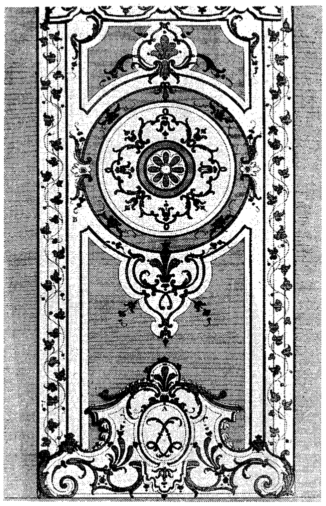
is loosely termed Polynesian cuisine, a blend of various Oriental styles of cooking. The fruit is eaten fresh where available and in canned form worldwide. In the United States and in Europe it is sometimes used as a pastry filling or in baked desserts.

Total world production of pineapples ordinarily averages about 8,300,000 metric tons annually, of which an estimated 20 percent is produced in Thailand, which during the 1970s replaced the former leading producer, the Hawaiian Islands. Other areas of substantial production include the Philippines, China, Brazil, Mexico, Côte d'Ivoire, India, and Taiwan.

Pineau, Nicolas (b. Oct. 8, 1684, Paris—d. April 24, 1754, Paris), French wood-carver and interior designer, a leader in the development of interior decorating in the light, asymmetric, lavishly decorated Rococo style.

After study with the architects François



Etching of a design for a counterpane by Pineau, *c.* 1740
By courtesy of the Victoria and Albert Museum, London

Mansart and Germain Boffrand, Pineau began his career as a carver of woodwork. His father, Jean-Baptiste Pineau, was a sculptor in wood, and his son, Dominique (1718–86), also became a wood sculptor.

One of a group of French artisans who were visiting the newly established city of St. Petersburg (now Leningrad) in 1716 at the invitation of Peter the Great, Pineau remained in Russia until about 1728, carving the tsar's cabinet in the Peterhof palace and also serving as an architect and interior designer. Returning to Paris, he became an important designer, launching the vogue for Rococo rooms in private dwellings.

Pineau's works are characterized by shallow recesses with rounded corners and ornamentation employing shell motifs, leafy scrolls, and classical busts in medallions. Later interior designers and architects were influenced by his engravings.

pinecone fish, any member of either of two genera of fishes (*Cleipodus* and *Monocentris*) belonging to the family Monocentridae (order Beryciformes), found in deepwater marine habitats of the Indo-Pacific region. The common name comes from the characteristically oval body covered with enlarged, platelike scales, which thus resembles a pinecone. Luminescent organs occur on the lower jaw.

The Japanese pinecone fish (*M. japonicus*) normally reaches a length of 13 cm (5 inches) and travels in schools near the ocean bottom. Although small, it is commercially important as a food fish and as a saltwater aquarium fish.

Pinel, Philippe (b. April 20, 1745, Saint-André, Tarn, Fr.—d. Oct. 25, 1826, Paris), French physician who pioneered in the humane treatment of the mentally ill.

Arriving in Paris (1778), he supported himself for a number of years by translating scientific and medical works and by teaching mathematics. During that period he also began visiting privately confined mental patients and writing articles on his observations. In 1792 he became the chief physician at the Paris asylum for men, Bicêtre, and made his first bold reform by unchaining patients, many of whom had been restrained for 30 to 40 years. He did the same for the female inmates of Salpêtrière when he became the director there in 1794.

Discarding the long-popular equation of mental illness with demoniacal possession, Pinel regarded mental illness as the result of excessive exposure to social and psychological stresses and, in some measure, of heredity and physiological damage. In *Nosographie philosophique* (1798; "Philosophical Classification of Diseases") he distinguished various psychoses and described, among other phenomena, hallucination, withdrawal, and a variety of other symptoms.

Pinel did away with such treatments as bleeding, purging, and blistering and favoured a therapy that included close and friendly contact with the patient, discussion of personal difficulties, and a program of purposeful activities. His *Traité médico-philosophique sur l'aliénation mentale ou la manie* (1801;

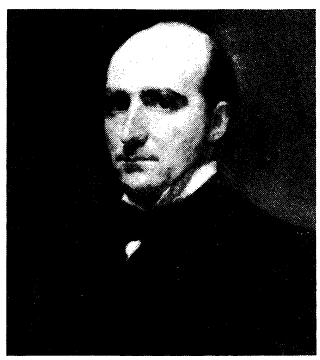
Pinel, engraving by Pierre-Roch Vigneron
Giraudon—Art Resource/EB Inc.

"Medico-Philosophical Treatise on Mental Alienation or Mania") discusses his psychologically oriented approach.

pinene, either of two colourless liquid hydrocarbons, α-pinene and β-pinene, occurring as major components of the essential oil of pine trees and used as a chemical raw material. Both compounds belong to the isoprenoid series and have the molecular formula $C_{10}H_{16}$. They often occur together and are separated by fractional distillation.

The principal source of α-pinene is turpentine obtained in the sulfate process for making paper. The commercial product is 90–95 percent pure. Large amounts of α-pinene are converted to synthetic pine oil or to camphene, which is chlorinated to toxaphene, an insecticide, or treated with acetic acid to form isobornyl acetate, a perfume with a pine-needle aroma and an intermediate in synthetic camphor manufacture.

Pinero, Sir Arthur Wing (b. May 24, 1855, London—d. Nov. 23, 1934, London), a leading playwright of the late Victorian and Edwardian eras in England who made an important contribution toward creating a self-respecting theatre by helping to found a "social" drama that drew a fashionable audience. It is



Pinero, detail of an oil painting by J. Mordecai, 1891; in the National Portrait Gallery, London

his farces—literate, superbly constructed, with a precise, clockwork inevitability of plot and a brilliant use of coincidence—that have proved to be of permanent theatrical value.

Born into an English family descended from Portuguese Jews, Pinero abandoned legal studies at age 19 to become an actor; and, though still a young man, he played older character parts for the leading theatre company headed by Henry Irving. His first play, *£200 a Year,* was produced in 1877. His best farces, such as *The Magistrate* (1885), *The Schoolmistress* (1886), and *Dandy Dick* (1887), were written for the Royal Court Theatre in London. They combine wildly improbable events with likable characters and a consistently amusing style. Pinero was at the same time studying serious drama by adapting plays from the French (including *The Iron Master,* 1884, and *Mayfair,* 1885) and also mining a profitable vein of sentiment of his own, as in *The Squire* (1881) and *Sweet Lavender* (1888). The two elements fused in *The Profligate* (1889) and—most sensationally—in *The Second Mrs. Tanqueray* (1893), which established Pinero as an important playwright. This was the first of several plays depicting women battling with their situation in society. These plays not only created good parts for actresses but also demanded sympathy for women, who were judged by stricter standards than men in Victorian society. In a less serious vein, *Trelawny of the "Wells"* (written for the Royal Court Theatre and produced in 1898) portrayed theatrical company life in the old style of the 1860s—already then a vanishing tradition—and *The Gay Lord Quex* (1899) was about a theatrical rake of no placeable period but having great panache. Pinero was knighted in 1909.

Pinerolo, town, Torino province, Piemonte (Piedmont) region, northwestern Italy, at the entrance to the Valle del Chisone, at the foot of the Alps, southwest of Turin. First mentioned in 996 as a possession of Torino, it belonged to the nearby Benedictine abbey of Sta. Maria in 1078. Under the House of Savoy from 1246, it was the capital (1295–1418) of the princes of Acaia, a subsidiary line. The town was occupied by the French in 1536–74, 1631–96, and 1801–14, and its fortress was used during the 17th century as a state prison for such political prisoners as the Duc de Lauzun, enemy of Louis XIV's mistress Mme de Montespan; Nicolas Fouquet, Louis's embezzling finance minister; and the mysterious "Man in the Iron Mask," whose story is best known from one of the novels of Alexandre Dumas *père.* Pinerolo became a bishop's see in 1748.

Notable buildings include the 15th–16th-century S. Donato's cathedral (founded 1044), the church of S. Maurizio (1334–1490; restored), the palace of the princes of Acaia (1318; later modernized), and remains of the old fortifications.

Pinerolo is a rail junction with textile, metal, chemical, printing, and food industries. Pop. (1981 prelim.) mun., 35,862.

Pines, Isle of (Cuba): *see* Juventud, Isla de la.

Pines, Isle of (New Caledonia): *see* Pins, Île des.

Pinetown, residential and industrial town, Natal, South Africa. Pinetown is situated at an elevation of 1,000 to 1,300 ft (305 to 395 m) in the hills adjoining Durban on the northwest. First laid out in 1847 and later named after Sir Benjamin Pine, governor of Natal (1873–75), Pinetown did not officially become a town until 1948. It is now an important industrial centre with factories producing leather goods, concrete products, corrugated containers, plywood products, aluminum products, and confectionery. Much of the population commutes to work in Durban, and a sizable minority of its population is Indian. Pinetown lies on the national road and railway from Durban to Pietermaritzburg. Pop. (1983 est.) mun., 86,000.

P'ing-ch'iao (China): *see* Hsin-yang.

Ping Di (Chinese emperor): *see* P'ing Ti.

P'ing-hsiang, Pinyin PINGXIANG, city in western Kiangsi *sheng* (province), China. It is a prefecture-level municipality (*shih*). P'ing-hsiang is situated on the borders of Hunan Province in the midst of the Wu-kung Shan (mountains) on the upper waters of the Lu Shui (river), on what has always been a major route between the city of Ch'ang-sha in Hunan Province and Nan-ch'ang in Kiangsi.

The county was established in AD 267 and has existed ever since, usually being dependent on Yüan-chou (now I-ch'un). For a brief period (1295–1367) it was an independent prefecture. Its modern importance began with the discovery of rich coal deposits there at the end of the 19th century by German experts employed by the Han-yang Iron Works in Hupeh Province, which was urgently seeking a source of coking coal. A railway was built during 1903–05 to transport the coal, and coke ovens were installed in the city. The depressed market for iron after World War I, however, led to the decline and eventual closing of the ironworks, so that demand for P'ing-hsiang coal and coke fell dramatically, the mines closing down for a time in 1925–26. In the 1930s production was only about 20 percent of what it had been during the peak period.

After much neglect and destruction during World War II, the mines around P'ing-hsiang were modernized in the 1950s, and by the 1970s the city had again become a major mining centre. In the late 1950s a large iron and steel industry, producing pig iron and ingot steel, was established there. P'ing-hsiang also has a ceramic industry. It is on the main railway line from Nan-ch'ang to Ch'ang-sha. Pop. (mid-1970s est.) 100,000–300,000.

P'ing-hsiang, Pinyin PINGXIANG, city in southwestern Kwangsi Chuang *tzu-chih-ch'ü* (autonomous region), China. The city is a county-level municipality (*shih*) on the border of Vietnam in Nan-ning *ti-ch'ü* (prefecture). Founded as a military outpost under the name P'ing-hsiang during the Sung dynasties (960–1279), under the Ming dynasty (1368–1644) it became a county (*hsien*) and later a prefecture (*fu*); it was, however, little more than an administrative outpost among non-Chinese tribesmen. The Ch'ing dynasty (1644–1911/12) made it a subprefecture. P'ing-hsiang's modern growth stemmed from the railway from Nan-ning, which provides a through route from central China to Vietnam, crossing the border a few miles to the south at Yu-i-kuan. Construction of this line was begun in 1938 by the French, who completed it as far as Ning-ming; but, following the Japanese occupation of Nan-ning, work was abandoned in 1943–44, and much of the track was dismantled. The line was completed in 1951 and linked with the Vietnamese rail system in 1955. After this, P'ing-hsiang rapidly grew into a commercial centre for international trade with Vietnam; it also developed some small-scale industries. A considerable part of Sino-Vietnamese trade passes through P'ing-hsiang because the rail link is superior to the older line that runs through Yunnan Province and also provides a direct route to Wu-han as well as connections to Kweichow and Szechwan provinces and to the Canton area. Pop. (mid-1970s est.) 10,000–50,000.

Ping Hsin (Chinese author): *see* Bing Xin.

P'ing-liang, Pinyin PINGLIANG, town in P'ing-liang *ti-ch'ü* (prefecture), eastern Kansu *sheng* (province), north central China, near the borders of Ningsia Hui Autonomous Region and Shensi Province. Located in the eastern Kansu loesslands, the town is situated in the upper valley of the Ching Ho (river), a tributary of the Wei Ho. Wheat is the chief crop in the area; other economic activities include wool and tobacco processing. P'ing-liang served as the transport centre by road for the eastern Kansu loesslands until the completion of the railroad between Hsien-yang (Shensi) and Lan-chou. It lost its city status in 1964. Pop. (mid-1970s est.) 50,000–100,000.

Ping-Pong: *see* table tennis.

P'ing Ti, Pinyin PING DI (fl. 8 BC–AD 8), last ruling emperor of China's Western, or Former Han, dynasty.

P'ing Ti was placed on the throne in 1 BC by the powerful minister Wang Mang, whose daughter he married five years later. Though proof is lacking, it has been claimed that P'ing Ti was poisoned by his father-in-law. In any case, P'ing Ti's death allowed Wang to assume the title of regent to a child emperor; in AD 9, Wang finally set aside the Han dynasty altogether and established himself as emperor of the Hsin dynasty.

P'ing-tung, southernmost *hsien* (county) of Taiwan, occupying an area of 1,072 sq mi (2,776 sq km). It is bordered by Kao-hsiung *hsien* (northwest), T'ai-tung *hsien* (northeast), and by the Luzon Strait (southwest). The Central Range (2,300 ft to 10,000 ft [700 m to 3,000 m] above sea level) is the source of the Hsia-tan, Kao-p'ing, and Wu-lo rivers and extends over the southeastern part of the region. Sugarcane, paddy rice, sweet potatoes, tobacco, bananas, and pineapples are grown in the irrigated, alluvial coastal plains of the county. P'ing-tung *hsien* is the centre of sugar refining in Taiwan. Its industries manufacture metal goods, machinery, and chemicals and produce alcoholic beverages and canned food. P'ing-tung city, the administrative seat, has a large military base. K'en-ting Kung-yüan (Tropical Botanical Forest Park) at Heng-ch'un covers an area of 100 ac (40 ha) and has one of the largest experimental forests in southeast Asia. A 19-sq-mi area in Heng-ch'un Pan-tao (peninsula) is being developed as Taiwan's first National Scenic Area and as the largest forest vacation area in southern Taiwan. The Haucha model aborigine village is at Wu-t'ai. The San-ti-men Ch'iao (bridge) on the Wu-lo Ch'i (river) is in the north, and the ancient Shih-men Battlefield and the O-luan-pi Lighthouse (built 1882), one of the largest in southeast Asia, are in the south. Pop. (1983 est.) 896,966.

P'ing-tung, also called (until 1920) AKOW, *shih* (municipality) and seat of P'ing-tung *hsien* (county), southwestern Taiwan. It is located 13 mi (21 km) northeast of Kao-hsiung city, in the southern part of the western plain. Founded in the early 18th century, the city is situated west of the Kao-p'ing Hsi (river). It is in an agricultural region that produces sugarcane, rice, bananas, tobacco, and fruits. P'ing-tung city is one of Taiwan's leading sugar-refining centres. Other industrial products include metal goods, machinery, chemicals, and alcoholic beverages. The South Link railway connects P'ing-tung city with the cities of T'ai-tung to the east and Kao-hsiung to the west; the city is connected by highway with O-luan-pi on the southern tip of the island. P'ing-tung city is the seat of the Taiwan Provincial Institute of Agriculture (founded 1954) and has junior colleges for teacher training, pharmacology, nursing, and technology. San-ti-men Ch'iao (bridge) is about 9 mi northeast of the city. Pop. (1982 est.) 189,347.

pingo, dome-shaped hill formed in a permafrost area when the hydrostatic pressure of freezing groundwater causes the upheaval of a

Ibyuk pingo near Tuktoyaktuk in the Mackenzie River Delta, N.W.Terr.; it is 140 feet high

J. Ross Mackay

layer of frozen ground. Pingos may be up to 90 metres (300 feet) high and over 800 metres ($^1/_2$ mile) across and are usually circular or oval. The core, which may be only slightly smaller than the pingo itself, consists of a lens of clear, injected ice. Modern pingos occur in the continental tundras and are generally restricted to latitudes of 65° to 75° N. Rupture of the overlying material at the top of the pingo exposes the ice to melting and may create a smaller crater and lake. Two types are recognized, the open-system pingo and the closed-system pingo.

The open-system pingo forms in regions of discontinuous or thin permafrost. Artesian pressure builds up under the permafrost layer, and as the water rises, pushing up the overlying material, it freezes in a lens shape. This variety of pingo is most frequently found in the alluvial material of a mountainous or hilly area.

The closed-system pingo forms in a shallow lake when advancing permafrost generates hydrostatic pressure under the lake basin. The confined mass of saturated soil freezes, pushing the overlying material upward as it expands.

Scars of former pingos have been found in areas near the edges of former Pleistocene ice sheets. Because pingos form under specific conditions, they serve as good indicators of climatic change.

pinguecula, yellowish nodule in the conjunctiva at the front of the eye, usually but not always on the nasal side. The conjunctiva is the mucous membrane that lines the eyelid and extends over part of the surface of the eyeball. Pinguecula occurs in elderly persons and is thought to represent degeneration in the conjunctiva as a result of exposure to wind and dust. The condition does not require medical or surgical treatment.

Pingxiang (China): *see* P'ing-hsiang.

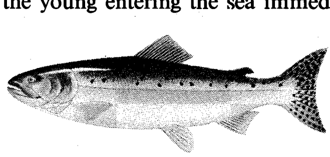
pinion: *see* rack and pinion.

Piniós River, Modern Greek PINIÓS POTAMÓS, also called PENEUS RIVER, principal stream of Thessaly, Greece, rising in the Óros (mountains) Lákmos of the Pindus Mountains just east of Métsovon in the *nomós* (department) of Tríkala; it is navigable in its lower course. In prehistoric times the Piniós formed a great lake before it broke through the Vale of Tempe. It now flows 127 mi (205 km) through the mountains and plains of Thessaly, thrusting itself through the Vale of Tempe between the Olympus and Ossa massifs and debouching at the entrance to the Thermaïkós Kólpos (gulf) of the western Aegean Sea. Entering the western Thessalian plain, it receives the Enipévs and immediately winds through the saddle of low hills between the Zarkou Mountains on the north and the Mavrovoúni outliers that divide the Thessalian plain into two distinct parts. Other tributaries include the Lithaíos and the Titarísios.

pink, any of several flowering plants of the genus *Dianthus* in the pink family (Caryophyllaceae), grown widely in garden borders. The approximately 300 species in the genus are natives of the Eastern Hemisphere and are found chiefly in the Mediterranean region. They are mostly short herbaceous perennials, many of which are tufted or mat-forming hardy evergreens, often with very showy flowers. Some annual forms also exist. Especially noteworthy are the fragrant-flowered grass, or cottage, pink (*D. plumarius*); maiden, or meadow, pink (*D. deltoides*); and rainbow, or China, pink (*D. chinensis*). Most pinks are suited to rock gardens. The small but showy and often fragrant flowers are mostly pink to deep rose, some being red, purple, white, or yellow. Pinks are widely grown in American and European gardens, being of relatively easy culture. Fine modern varieties of both the greenhouse and hardy types of carnation are largely grown commercially. Both annual and perennial *Dianthus* species may be grown from seed sown in the spring in ordinary moist garden soil in a sunny location. The perennials will bloom the following summer and may be increased by cuttings or division of clumps.

Related plants of the genus *Dianthus* are also sometimes referred to as pinks. The popular carnation (*q.v.*), for example, is often called clove pink in reference to its spicy scent, and sweet William (*q.v.*), a garden favourite, is often called bunch pink.

pink salmon, also called HUMPBACK SALMON (*Oncorhynchus gorbuscha*), North Pacific food fish, family Salmonidae, weighing about 2 kilograms ($4^1/_2$ pounds) and marked with large, irregular spots. It often spawns on tidal flats, the young entering the sea immediately



Pink salmon (*Oncorhynchus gorbuscha*)

Painted especially for *Encyclopaedia Britannica* by Tom Dolan, under the supervision of Loren P. Woods, Chicago Natural History Museum

after hatching. The alternative name humpback salmon refers to the hump that develops on the back of the breeding male. *See also* salmon.

Pinkerton, Allan (b. Aug. 25, 1819, Glasgow—d. July 1, 1884, Chicago), detective and founder of a famous American private detective agency.

Pinkerton was the son of a police sergeant. After completing his apprenticeship to a cooper, he emigrated to the United States in 1842 and settled in Chicago. Moving the next year to the nearby town of Dundee in Kane County, he set up a cooper's shop there. While cutting wood on a deserted island one day, he discovered and later captured a gang of counterfeiters. Following this and other similar achievements, he was appointed deputy sheriff of Kane County in 1846 and soon afterward deputy sheriff of Cook County, with headquarters in Chicago.

In 1850 Pinkerton resigned from Chicago's new police force in order to organize a private detective agency that specialized in railway theft cases. The Pinkerton National Detective Agency became one of the most famous organizations of its kind. Its successes included capture of the principals in a $700,000 Adams Express Company theft in 1866 and the thwarting of an assassination plot against President-elect Lincoln in February 1861 in Baltimore. In 1861, working for the Union during the Civil War, Pinkerton, under the name E.J. Allen, headed an organization whose purpose it was to obtain military information in the Southern states.

After the Civil War Pinkerton resumed the management of his detective agency. From 1873 to 1876 one of his detectives, James McParlan, lived among the Molly Maguires in Pennsylvania and secured evidence that led to the breaking up of this organization of coal miners supposedly engaged in terrorism. During the strikes of 1877 the Pinkerton Agency's harsh policy toward labour unions caused it to be severely criticized in labour circles, although Pinkerton asserted he was helping workingmen by opposing labour unions. Pinkerton wrote *The Molly Maguires and the Detectives* (1877); *The Spy of the Rebellion* (1883), his account of Lincoln's journey to Washington in 1861; and *Thirty Years a Detective* (1884).

pinkeye (veterinary medicine): *see* bovine infectious keratoconjunctivitis.

Pinkham, Lydia E(stes) (b. Feb. 9, 1819, Lynn, Mass., U.S.—d. May 17, 1883, Lynn), successful American patent-medicine proprietor who claimed that her Vegetable Compound could cure any "female complaint" from nervous prostration to a prolapsed uterus.

Pinkham first began making her medicine as a home remedy, which she freely shared with neighbours. The compound was a blend of ground herbs such as true unicorn root (*Aletris farinosa*) and pleurisy root (*Asclepias tuberosa*), with an alcoholic content of 18 percent. The label explained that the alcohol was "used solely as a solvent and preservative."

In 1875, after women from other towns began coming to buy the compound, for $1 a bottle, the Pinkham family decided to go into business. Mrs. Pinkham wrote handbills for her sons to distribute with slogans like, "Only a woman can understand a woman's ills." It was her son Daniel who, in 1879, had the idea of using his mother's picture in newspaper advertisements to emphasize the homemade quality of the compound. His strategy succeeded, and continued heavy advertising made the face of the "savior of her sex," as the ads described her, one of the best known in the country. Although medical proof was never found to substantiate the claimed therapeutic effects of the compound, it quickly gained acceptance with women, many of whom were hesitant to consult male physicians about "female problems." During her life, the business expanded from a cellar kitchen, in which she mixed the formula herself, to a laboratory that brewed, bottled, and shipped enough compound to gross just under $300,000 a year.

In pamphlets and ads, she invited women to write to her for advice, which they did in increasing numbers. Pinkham established a Department of Advice with an all-female staff to respond to the hundred letters a day that she reported receiving. Prompted by the ignorance of many who wrote to her, she also wrote and printed a facts-of-life manual for women. In it she described the female reproductive system from puberty through childbearing and menopause. The book was issued under various titles and distributed free.

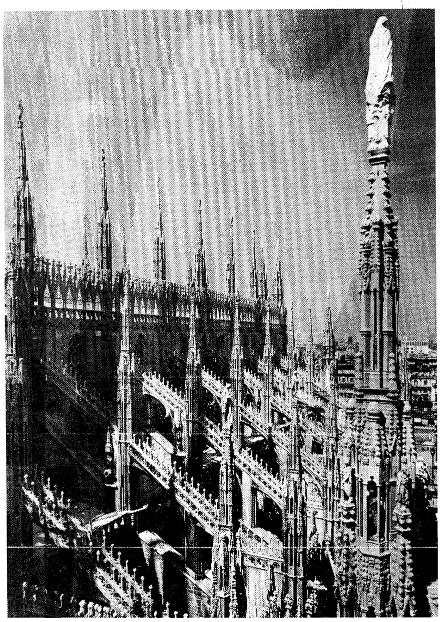
Not until the 1920s, when faced with increasing federal regulation of drugs and advertising, did the Lydia E. Pinkham Medicine Co. reduce both its claims for the compound and the alcoholic content of the product.

Pinkney, William (b. March 17, 1764, Annapolis, Md.—d. Feb. 25, 1822, Washington, D.C.), U.S. statesman and diplomat, considered one of the foremost lawyers of his day.

A member of the Maryland convention that ratified the federal Constitution in 1788, Pinkney himself voted against ratification. He served in the Maryland state legislature (1788–92; 1795) and on the state's Executive Council (1792–95). From 1796 to 1804 he represented the United States as a commissioner to negotiate an agreement with Great Britain concerning American maritime losses, and he served as U.S. minister to Great Britain from 1807 to 1811.

Pinkney was U.S. attorney general (1811–14) under President James Madison, served in the House of Representatives (1815–16), and was minister to Russia (1816–18). From 1819 to 1822 he was a member of the U.S. Senate, where he became a champion of the slave states. He successfully argued many important cases before the Supreme Court, including *McCulloch* v. *Maryland* (1819), in which the power of Congress to charter the Bank of the United States was upheld.

pinnacle, in architecture, vertical ornament of pyramidal or conical shape, crowning a buttress, spire, or other architectural member. A pinnacle is distinguished from a finial by its greater size and complexity and from a tower



Pinnacles on the flying buttresses and parapet of the Cathedral of Milan, about 1385–1485
A.F. Kersting

or spire by its smaller size and subordinate architectural role. A tower may be decorated with pinnacles, each one capped by a finial.

Simple pinnacles were used on Romanesque churches, especially to mask the abrupt transition from square tower to polygonal spire; but they were far more prominent in developed Gothic architecture and decoration, in which they were used to give vertical emphasis and to break up hard outlines. They appeared at every major corner of a building, flanked gables, and decorated parapets and buttresses. Some of the most striking pinnacles crown the piers of flying buttresses, on which, although primarily decorative, they enhance the stability of the buttresses, helping to counteract the lateral thrust of the vault. The buttress pinnacles around the choir of Notre-Dame at Paris and the magnificent 80-foot (24-metre) pinnacles at Reims Cathedral (13th century) are representative examples.

In the 18th, 19th, and 20th centuries, pinnacles were often used in eclectic architecture. Notable examples include London's Houses of Parliament (begun 1840) and the Woolworth Building in New York City (1913).

pinniped (suborder Pinnipedia), any of various families of aquatic, fin-footed mammals in the order Carnivora, often considered a separate order. There are three existing families of pinnipeds: Odobenidae (*see* walrus) and Phocidae and Otariidae (*see* seal).

Pinochet (Ugarte), Augusto (b. Nov. 25, 1915, Valparaiso, Chile), leader of the military junta that overthrew the Marxist government of President Salvador Allende of Chile on Sept. 11, 1973. He subsequently headed Chile's military government (1974–90).

Pinochet, a graduate of the military academy in Santiago (1936), was a career military officer who was appointed army commander in chief by President Allende 18 days before the coup. He planned and led the military coup in which Allende died. Pinochet was named president of the victorious junta's governing council, and he immediately moved to crush Chile's liberal opposition, arresting approximately 130,000 individuals in a three-year period. In June 1974 Pinochet assumed sole power, relegating the rest of the junta to an advisory role and dropping plans to rotate the presidency among its members.

Pinochet was determined to extirpate leftism in Chile and to reassert the primacy of free-market policies in the country's economy. His junta was widely condemned for its harsh suppression of dissent at the same time that its reversal of the Allende government's socialist policies resulted in a lower rate of inflation and an economic boom in the period from 1976 to 1979. A modest political liberalization began in 1978, after the regime announced that, in a plebiscite, 75 percent of the electorate had endorsed Pinochet's rule.

A new constitution went into effect in March 1981. Under its terms, the military junta's candidate for president, Pinochet, would serve as president for another eight-year term, and in 1989 the military's candidate would be submitted to a national referendum for either approval or rejection by a majority of the voters. During Pinochet's 1980–88 term, his free-market policies were generally credited with maintaining a low rate of inflation and an acceptable rate of economic growth despite a severe recession in 1980–83. Pinochet continued to maintain tight controls over the political opposition, but he fulfilled his constitutional obligation to hold the plebiscite scheduled for 1989. The actual plebiscite, held in October 1988, resulted in a "no" vote of 55 percent to a "yes" vote of 43 percent for Pinochet's continuation as president. Thus rejected by the electorate, Pinochet remained in office until after free elections installed a new president, the Christian Democrat Patricio Aylwin, on March 11, 1990.

pinochle, card game derived from bezique and most often played in North America. One popular version is auction pinochle, a three-handed game using two packs of 24 cards ranking ace, 10, king, queen, jack, and 9 of each suit. Each player is dealt 15 cards, 3 at a time; after the first 3 are dealt, 3 are dealt to the table to form the widow. Bidding goes clockwise from the dealer's left. The lowest bid is generally 300. Bids reflect the player's estimate of the number of points he may earn through melds and by taking high-card points in tricks. The high bidder names trump, takes the widow, discards three cards after melds are displayed, and tries to score the amount of his bid, while the others try to defeat him.

Before play begins, the bidder displays melds made up from his hand and the widow. The common melds and their point values are:

Pinochle (queen of spades and jack of diamonds)	40
Dix (9 of trump)	10
Four aces (one in each suit)	100
Four kings (one in each suit)	80
Four queens (one in each suit)	60
Four jacks (one in each suit)	40
Marriage (king and queen in a side suit)	20
Royal marriage (king and queen of trump)	40
Royal flush (ace through jack of trump)	150

Values of cards in auction pinochle are ace (11), 10 (10), king (4), queen (3), jack (2), and 9 (0). If two identical cards are played to a trick, the first beats the second. Points are scored for (a) capturing counting cards in tricks, plus 10 for winning the last trick, and (b) holding various melds at the outset of the game. The king or queen melded in a royal marriage may not also be melded in a royal flush, or vice versa. The 9 of trumps (called the dix) is worth 10 points: to the dealer if turned as trump, to a player by melding it or displaying it after winning a trick. The dix is then exchanged for the turned trump.

At any point up to the play of the first trick, the bidder may concede without further play, or his opponents may concede. To start play, the bidder leads to the first trick; others follow suit, or, if unable to follow, they must trump. If trump is led, the others must, if possible, play a higher trump.

A list of the abbreviations used in the MICROPAEDIA *will be found at the end of this volume*

pinocytosis, a process by which liquid droplets are ingested by living cells. Pinocytosis is also common among many microorganisms. Rather than passing as individual molecules through the cell membrane without disrupting it, the droplet first becomes bound, or adsorbed, on the cell membrane, which then invaginates (forms a pocket) and pinches off to form a vesicle, or vacuole, in the cytoplasm. It is believed that a vesicle may carry extracellular fluid to the opposite side of the cell, where it undergoes reverse pinocytosis. A droplet of fluid could thus be transported through the cell without disturbing its cytoplasm. Alternatively, intracellular digestion of the vacuole wall would permit the droplet to mix with the cytoplasm. *See also* phagocytosis.

Pinos, Isla de (Cuba): *see* Juventud, Isla de la.

Pins, Île des, English ISLE OF PINES, also called KUNIE ISLAND, island in the southwest-ern Pacific Ocean, within the French overseas territory of New Caledonia. With an area of 59 square miles (152 square km), it is forested with pinelike coniferous trees of the genus *Araucaria cooki* (hence its name) and is rugged, rising to Nga Peak (870 feet [265 m]). The island was once a penal colony but by the 1970s had a growing tourist trade. Exports include shrimp and oysters. The main town and administrative centre is Vao, on the south coast. Pop. (1983) 1,288.

Pinsk, city, Brest *oblast* (province), Belorussia, U.S.S.R., situated at the confluence of the Pina and Pripyat rivers. Pinsk was first mentioned in 1097 and was the seat of a Russian princedom. It passed under Lithuanian rule (13th–16th century), then Polish (1569–1793), Russian (1793–World War I), Polish again (1920–39), and then Soviet (with German occupation during 1941–44). Pinsk lies at the eastern end of the Dneprovsko-Bugsky Canal and is a significant river port. There are woodworking industries, metalworking, manufacture of artificial leather, and shipbuilding and repair yards. Pop. (1989 prelim.) 119,000.

Pinsker, Leo, original name JUDAH LEIB PINSKER (b. 1821, Tomaszów, Pol., Russian Empire [now in Poland]—d. Dec. 21, 1891, Odessa, Russian Empire [now in the Ukraine, U.S.S.R.]), Russian-Polish physician, polemicist, and pioneer Jewish nationalist, who was a forerunner of Theodor Herzl and other major political Zionists.

While conducting a medical practice in Odessa, Pinsker maintained a deep interest in Jewish community affairs. He joined the Society for the Promotion of Culture Among the

Jews of Russia, an assimilationist organization founded in 1863. He advocated secular education for Jews and the translation of the Bible and Hebrew prayer books into Russian. A pogrom in Odessa in 1871 shook but did not destroy his beliefs; in 1881, however, another severe pogrom broke out in Odessa, not only ignored but even abetted by the government and defended by the press. His assimilationist beliefs were shattered, and he turned to Jewish nationalism.

In 1882 Pinsker anonymously published in German an incisive, embittered, and impassioned pamphlet, "Auto-Emanzipation. Ein Mahnruf an seine Stammesgenossen. Von einem russischen Juden" ("Self-Emancipation. A Warning Addressed to His Brethren. By a Russian Jew"; *Auto-Emancipation*, 1884), which provoked strong reactions, both critical and commendatory, from Jewish leaders. In the pamphlet he contended that the only restorative for Jewish dignity and spiritual health lay in a Jewish homeland.

Pinsker's authorship was soon discovered, and a newly formed Zionist group, Ḥibbat Ẕiyyon (Love of Zion), made him one of its leaders. In 1884 he convened the Kattowitz (Katowice, Pol.) Conference, which established a permanent committee with headquarters in Odessa. Although Ḥibbat Ẕiyyon (later Ḥovevei Ẕiyyon [Lovers of Zion]) was crippled by lack of funds, it did establish a few colonies in Palestine and founded the Society for the Support of Jewish Agriculturists and Handicraftsmen in Syria and Palestine.

Pinski, David, Pinski also spelled PINSKY (b. April 5, 1872, Mogilyov on the Dnepr, Russia—d. Aug. 11, 1959, Haifa, Israel), Yiddish playwright, novelist, and editor.

Reared in Moscow, Vitebsk, and Vienna, Pinski moved as a young man to Warsaw, where he became a friend of the leading Yiddish writer, Isaac Peretz. It was also in Warsaw that Pinski began his lifelong associations with the Jewish workers' movement. His first short story, "Der Groyser Mentshenfraynd" ("The Great Philanthropist") was published in 1894. He edited a Yiddish anthology, *Literatur un Lebn* ("Literature and Life"), and travelled to Berlin to further his studies. In 1899 he emigrated to the United States, where he wrote for and edited several Jewish labour periodicals. After the Kishinev pogrom of 1903 in Russia, he also became involved in the Zionist labour movement. From 1920 to 1922 he was president of the Jewish National Workers' Alliance, and he was president of the Jewish Culture Society from 1930 to 1953. In 1949 he moved to Haifa, Israel, and his home became a gathering place for young Yiddish writers.

Pinski's most successful work was the comic play *Der Oitzer* ("The Treasure"), which was performed in New York City and Germany. His play *Der Eybiker Yid* (1926, "The Eternal Jew") was performed in Moscow by the Hebrew troupe Habima in 1919. His novels include *Dos Hoyz fun Noyakh Edon* (1913; *The Generations of Noah Edon,* 1931), which portrays the deterioration of Jewishness in America and argues against assimilation.

pint, unit of capacity in the British Imperial and U.S. Customary systems of measurement. In the British system the units for dry measure and liquid measure are identical; the single British pint is equal to 34.68 cubic inches (568.41 cubic centimetres). In the United States the unit for dry measure is slightly different from that for liquid measure; a U.S. dry pint is 33.6 cubic inches (550.6 cubic centimetres), while a U.S. liquid pint is 28.9 cubic inches (473.2 cubic centimetres). In each system, two cups make a pint, and two pints equal a quart.

A U.S. liquid pint holds 1.042 pounds of water at room temperature, a fact that gave rise to the saying "a pint's a pound the world around." The pint has been a common unit of measure in Great Britain since the 14th century. The actual volume of the pint, however, has varied considerably over the years; in medieval times it held about the equivalent of the modern quart.

pinta, chronic tropical skin disease characterized initially by the appearance of dry, scaly papular lesions followed after several years by abnormally coloured patches called pintides. The pintides may be white, where pigment cells have been destroyed by the disease, or blue, red, or pink. The disease is native to Central and South America and is caused by infection with *Treponema carateum,* an organism that is indistinguishable from that of syphilis. There is some evidence of a degree of cross-immunity between the two diseases, and the treatment of both is the same. Unlike syphilis, however, pinta has little effect on the general health of the patient and is transmitted by nonvenereal contact.

Pinta, Isla, English PINTA ISLAND, also called ABINGDON ISLAND, one of the northernmost of the Galápagos Islands, in the eastern Pacific Ocean, 600 mi (965 km) west of Ecuador, which administers the Galápagos. It is an uninhabited island with an area of 20 sq mi (52 sq km).

pintail, any of three species of sleek, long-tailed, long-necked dabbling ducks of the genus *Anas* (family Anatidae); they are swift fliers and popular game birds. The common, or northern, pintail (*A. acuta*), widespread in the Northern Hemisphere, is a long-distance flier; some Alaskan birds winter as far away as Hawaii. Pairs form at the wintering ground, and the males follow the females back to their summer range. The common pintail is 66 centimetres (26 inches) long and weighs about 900 grams (2 pounds). The male has a brown head and throat, white breast, and gray back. The black tail is distinctive for its long central feathers. The female is mottled brown. About eight olive-coloured eggs are laid in a nest in sparsely vegetated areas. The preferred diet is seeds. The brown pintail (*A. georgica*), also called the yellow-billed pintail, and the Bahama, or white-cheeked, pintail (*A. bahamensis*) are primarily South American species.

Pinter, Harold (b. Oct. 10, 1930, London), playwright who achieved international renown as one of the most complex and challenging post-World War II dramatists. His plays are noted for their use of understatement, small talk, reticence—and even silence—to convey the substance of a character's thought, which often lies several layers beneath, and contradicts, his speech.

The son of a Jewish tailor, Pinter grew up in London's East End in a working-class area and was exposed early to the violence that is a brooding presence in his plays. As a child during World War II, he was evacuated more than once but lived in London during some of the worst of the bombing. He was confirmed in his insecurity after the war by encounters with Fascist toughs.

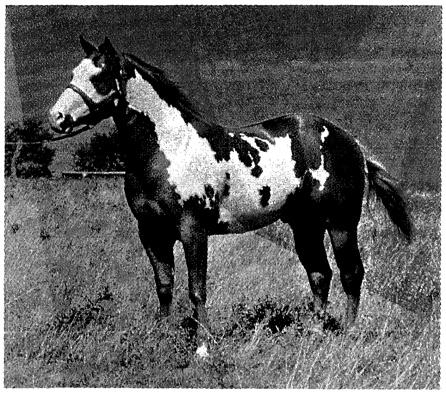
He studied acting at the Royal Academy of Dramatic Art but left after two terms. Called up for military service at 18, he declared himself a conscientious objector, underwent two court trials, and was eventually fined. In 1950 his poems began to appear in *Poetry London,* and the next year he resumed acting classes at the Central School of Speech Training and Dramatic Art, London.

Pinter toured Ireland with an acting company in 1951–52 (a period he writes of in his memoir, *Mac,* 1968) and from 1954 to 1957 acted under the name David Baron in provincial repertory theatres. In 1956 he married an actress, Vivien Merchant, who became an accomplished interpreter of his plays. *The Room* (performed 1957) was his first play, a one-act drama that established the mood of comic menace that was to figure largely in his early plays. His first full-length play, *The Birthday Party* (1958; filmed 1968), puzzled the London audiences and lasted only a week, but later it was televised and revived successfully on the stage.

Pinter's reputation was secured by his second full-length play, *The Caretaker* (1960; filmed 1963), in which a former mental patient brings a tramp to the house he shares with his brother. The play established Pinter as more than just another practitioner of the currently popular Theatre of the Absurd. *The Homecoming* (1965) focusses on the return to his East End London home of a man who has become a university professor in the United States and brings his wife to meet his family. Such later plays as *Landscape* (1969), *Silence* (1969), *Night* (1969), and *Old Times* (1971) virtually did away with physical activity on the stage. Later successes included *No Man's Land* (1975) and *Betrayal* (1978). From the 1970s on, Pinter did much directing, both of his own and others' works. His *Poems and Prose 1941–1977* was published in 1978.

Pinter also wrote radio and television dramas and screenplays, including *The Servant* (1962), *The Go-Between* (1971), *The Last Tycoon* (1974), *The Proust Screenplay: A la cherche du Temp Perdu* (1977), and *The French Lieutenant's Woman* (1981).

Pinto (Spanish: Painted), a spotted horse; the Pinto has also been called paint, particoloured, pied, piebald, calico, and skewbald, terms sometimes used to describe variations in colour and markings. The Indian ponies of the western United States were often Pintos, and the type was often considered of poor quality. The pure-breed associations usually refuse to register horses with pinto colouring. The colour does not determine the type of horse, however, and many fine Pintos have been developed. The Pinto Horse Association, organized in 1956, recognizes colour patterns called overo (white spreading irregularly up from the belly, mixed with a darker colour) and tobiano (white spreading down from the back in smooth, clean-cut patterns).



Sorrel and white Pinto
Margie Spence

Pinto, Fernão Mendes (b. *c.* 1510, Monte-mor-o-Velho, Port.—d. July 8, 1583, Almada, near Lisbon), Portuguese adventurer and author of the *Peregrinação* (1614, "Peregrination"; *The Voyages and Adventures of Fernand Mendez Pinto,* trans. H. Cogan, 1969), a literary masterpiece depicting the impression made on a European by Asian civilization, notably that of China, in the 16th century.

He went to India in 1537 and later claimed to have travelled, fought, and traded in almost every part of Asia during the next 21 years and also to have experienced drastic reversals of fortune, having been made "13 times a prisoner and 17 a slave." In China, for example, he was convicted of plundering royal tombs and, as punishment, had his thumbs severed and was sentenced to a year of hard labour on construction of the Great Wall. The *Peregrinação* was written after Pinto's return to Portugal in 1558. He settled in Almada, married, and received a pension from King Philip.

Pinturicchio, original name BERNARDINO DI BETTO DI BIAGO (b. *c.* 1454, Perugia, Romagna—d. Dec. 11, 1513, Siena, Republic of Siena), early Italian Renaissance painter known for his highly decorative frescoes.

By 1481 Pinturicchio was associated with the Umbrian artist Perugino, whose influence on him was to be permanent. It is generally agreed that he assisted Perugino on some of the fres-

Detail of "The Dispute of St. Catherine," fresco by Pinturicchio, 1492–94; in the Borgia Apartment of the Vatican
SCALA—Art Resource/EB Inc.

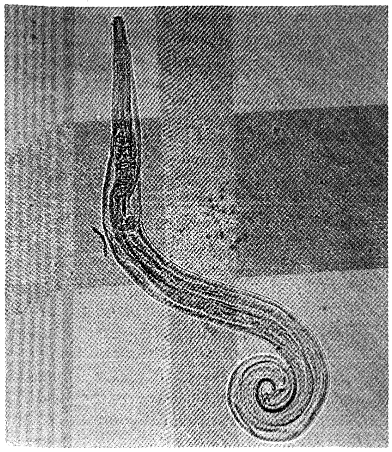
coes ("Journey of Moses" and the "Baptism of Christ") in the Sistine Chapel in the Vatican (1481/82). In the 1480s he worked in the Bufalini Chapel in Sta. Maria in Aracoeli and in Sta. Maria del Popolo (both in Rome).

Pinturicchio's most important work of this period was the decoration of the suite of six rooms in the Vatican known as the Appartamento Borgia for Pope Alexander VI between 1492 and 1494. In these frescoes he retains Perugino's figure types but lacks his clarity of conception. Instead, Pinturicchio relies on brilliant, often jarring colours, gilding, and ancient Roman ornamental motifs.

Pinturicchio's last major works were the 10 scenes from the life of Pope Pius II painted (1503–08) in fresco in the Piccolomini Library of Siena cathedral. In these, space, colour, and detail are handled with a crisp proficiency that may have influenced Raphael.

pinworm, also called SEAT WORM, or THREADWORM (*Enterobius,* or *Oxyuris, vermicularis*), worm of the class Oxyuroidea (phylum Aschelminthes). Pinworms are common human intestinal parasites, especially in children. They are also found in other vertebrates. Male pinworms are 2 to 5 millimetres (about 0.08 to 0.2 inch) long; females range in length from 8 to 13 millimetres. The long tails of the worms give them a pinlike appearance.

Pinworms usually occur in the large intestine but sometimes are found in the small intestine, the stomach, or farther up the gastrointestinal tract. After the eggs are fertilized by the male, the female travels to the anus, deposits the eggs on the skin near the anal opening, and usually dies. Movements of the



Pinworm (*Enterobius vermicularis*)
Walter Dawn

worm on the skin cause itching. Eggs, transferred beneath the fingernails by scratching, are passed to the mouth, from which the eggs or larvae make their way to the intestine. The life cycle requires 15 to 43 days.

Pinxton porcelain, English porcelain produced in Derbyshire from 1796 to 1813. The factory was established by John Coke (who had lived in Dresden, Ger.) with the help of William Billingsley, who had worked as a painter at Derby. Billingsley remained at Pinxton until 1801, concentrating on the production of the porcelain rather than its decoration. He made a ware that contained bone ash, was granular yet transparent, and had a brilliant glaze. He had probably obtained the formula from the Chelsea painter Zachariah Boreman. Pinxton produced only domestic and table ware. In 1804 the factory was taken

Pinxton porcelain goblet by William Billingsley, Derbyshire, England, *c.* 1800; in the Victoria and Albert Museum, London
By courtesy of the Victoria and Albert Museum, London; photograph, EB Inc.

over by John Cutts; the wares produced thereafter were inferior to those of Billingsley.

Pinyin romanization, also spelled PIN-YIN, also called CHINESE PHONETIC ALPHABET, Chinese (Pinyin) HANYU PINYIN WENZI (Chinese-language combining-sounds alphabet), system of romanization for the Chinese written language based on the pronunciation of the Peking dialect of Mandarin Chinese. The gradual acceptance of Pinyin as the official transcription used in the People's Republic of China signalled a commitment to promote the use of the Peking dialect as the national standard, to standardize pronunciation among national minorities, and to end the confusion in romanizing and alphabetizing Chinese characters.

National script reform began in 1913 with the creation of the National Phonetic Alphabet based on Chinese characters. Several attempts were made in the 1920s and '30s to devise and promote a Latin alphabet for the Chinese language, but with little concrete success. After the Communist takeover of China in 1949, work on a comprehensive script reform was begun. After considering and rejecting proposals for the use of either Chinese characters or the Cyrillic alphabet, the Latin alphabet was chosen for use. The resulting Chinese Phonetic Alphabet was adopted by the Committee on Language Reform in 1956 and modified in 1958.

Pinyin was not intended to replace the Chinese characters but to help teach pronunciation and popularize the Peking dialect. The adoption of Pinyin also made it possible to standardize the spelling of Chinese personal and place names abroad. Beginning on Jan. 1, 1979, the State Council of the People's Republic of China for Romanization prescribed that all translated diplomatic and foreign language publications employ Pinyin in English-speaking countries and Lessing in German-speaking countries. Chinese-language lessons for foreigners are conducted in Pinyin, and it is used for telegraphic codes, the Central Broadcasting System, braille for the blind, finger-spelling for the deaf, dictionaries, and indexes. Pinyin replaced the traditional writing systems of several ethnic minorities in China and is used to document the previously unwritten languages of many more. Some interesting features of Pinyin are the clear and consistent way that distinctions are drawn between aspirated and unaspirated consonants (*p, t, c, ch,* and *k* are aspirated and *b, d, z, zh,* and *g* are their unaspirated equivalents) and the use of digraphs (*zh, ch,* and *sh*) for retroflex consonants. Pinyin also dispenses with the use of hyphens and reduces use of the juncture symbol (') to a minimum. For tables of romanization equivalents in Pinyin and Wade–Giles, *see* pages 460–461.

Pinza, Ezio (Fortunato) (b. May 18, 1892, Rome—d. May 9, 1957, Stamford, Conn., U.S.), operatic bass and actor.

Pinza studied civil engineering before turning, at his father's urging, to singing. At 18 he sang Oroveso in Bellini's *Norma* at Cremona. His vocal studies at the Conservatory of Bologna were interrupted by army service during World War I. He made his Rome debut in 1920 as King Mark in Richard Wagner's *Tristan und Isolde.* He then sang for three years at La Scala in Milan, where in 1924 he sang Tigellino in the premiere of Arrigo Boito's *Nerone.* In 1926 he made his New York City debut at the Metropolitan as Pontifex Maximus in Gaspare Spontini's *La vestale,* and for the next 22 years he was that company's leading bass. He was admired for his commanding presence and sonorous voice and appeared in such varied roles as Boris Godunov, Figaro, and Don Giovanni.

In 1949, at the peak of his operatic fame, Pinza left the Metropolitan to star in Rodgers and Hammerstein's Broadway musical *South Pacific;* his success launched a new career for him in musical comedy, motion pictures, radio, and television. His recordings were also enormously popular.

Pinzón, Martín Alonso and Vicente Yáñez (respectively, b. *c.* 1441, Palos, Seville—d. 1493, Palos; b. *c.* 1460?, Palos—d. *c.* 1523?), brothers from a family of Spanish shipowners and navigators who took part in Christopher Columbus' first voyage to America.

Martín, part owner of the "Pinta" and "Niña," helped prepare them, procured crews for the expedition of 1492, and commanded the "Pinta," on which his brother Francisco was pilot. His suggestion to change course on October 7 brought the fleet to a landfall in the Bahamas on October 12. Near Cuba, however, he left the fleet, to search for the land of gold and spices. He rejoined Columbus a few months later but, returning with the fleet to Spain, he left once again, hoping to be the first to arrive with news of the discoveries. Columbus reached Spain first, however, and Martín is remembered only for his disloyalty.

Vicente commanded the "Niña" in 1492–93 and remained with Columbus throughout the expedition. A successful and capable explorer in his own right, he sailed early in 1500 and landed on the Brazilian coast at Cabo (cape) de Santo Agostinho. He probably rounded Cabo São Roque and then turned north; he discovered the Amazon Estuary and went as far as Costa Rica. He was made the governor of his newly discovered lands but did not take possession. In 1508, commissioned to discover a passage to the Spice Islands, he sailed with Juan Díaz de Solís along the coast of Central America. Historians are not sure whether he discovered Honduras and Yucatán on this voyage or went south to Venezuela and Brazil. Trouble developed with Díaz de Solís, and they returned to Spain in August 1509. No records exist of Vicente after 1523.

Pinzón Island, also called DUNCAN ISLAND, one of the Galápagos Islands, in the eastern Pacific Ocean, about 600 mi (965 km) west of Ecuador. It has an area of about 7 sq mi (18 sq km) and is flanked on the west by five small islets known as Guy Fawkes Island. The relief is made up of cactus-studded littoral and several volcanic craters, the highest rising to 1,300 ft (400 m). Originally named for Sir Anthony Dean (Deane), an English shipbuilder, the name was changed in the 18th century to honour the English admiral Viscount Duncan. The official Ecuadorian name is Isla Pinzón. It has a large marine tortoise reserve, as well as a seal rookery, but no human population.

Pio Nono (pope): *see* Pius IX.

Piombino, town, Livorno province, Toscana (Tuscany) region, central Italy, at the tip of the Piombino promontory below Monte Massoncello, opposite the island of Elba. Once a possession of the archbishops of Pisa, it was declared a princedom in 1594 and was variously owned or occupied before becoming part of the Kingdom of Italy in 1861. Nearby Populonia has Etruscan, Roman, and medieval remains. An old seaport with significant shipping traffic, Piombino has ironworks and steelworks and provides passenger and car ferry service to Elba; it is connected by branch railway with Campiglia Marittima on the main Rome–Genoa line. Pop. (1981 prelim.) mun., 39,389.

Piombo, Sebastiano del (Italian painter): *see* Sebastiano del Piombo.

pion, subatomic particle that constitutes the lightest form of meson (*q.v.*).

Pioneer, any of the first series of unmanned U.S. deep-space probes designed chiefly for interplanetary study. With the exception of Pioneer 1, which was launched into lunar orbit on Oct. 11, 1958, all other probes in the series were sent to explore planetary bodies or to measure various interplanetary particle and magnetic field effects. Pioneer 6 (1965), for example, was injected into solar orbit to determine space conditions between the Earth and Venus. It transmitted much data on the solar wind and solar cosmic rays in addition to measuring the Sun's corona and the tail of Comet Kohoutek. Pioneer 10 (1972) flew by Jupiter in December 1973, the first space probe to do so, and discovered its huge magnetic tail, an extension of the planet's magnetosphere. Pioneer 11 (1973), also called Pioneer-Saturn, passed by Jupiter in December 1974 and flew within about 13,000 miles (20,900 kilometres) of Saturn in September 1979. It transmitted data and photographs that enabled Earth-based scientists to identify two additional rings around the planet and the presence of radiation belts within its magnetosphere. Pioneer Venus 1 and Pioneer Venus 2 (1978) began orbiting Venus in December 1978. The first of these twin spacecraft sent back radio observations of the planet's lower atmosphere, and the second made radar photographs that revealed enormous mountains and deep basins on its surface.

Pioneers, Russian PIONERY, Soviet organization for youth aged 9 to 14, closely associated with the Komsomol (*q.v.*) for youth aged 14 to 28.

Piotrków Trybunalski, *województwo* (province), central Poland, established 1975, comprising an area of 2,419 sq mi (6,266 sq km). It is bordered by the provinces of Łódź and Skierniewice on the north, Radom and Kielce on the east, Częstochowa on the south, and Sieradz on the west. Piotrków Trybunalski (*q.v.*) city is the provincial capital. Other major industrial towns in the province include Tomaszów Mazowiecki and Radomsko. The province is drained by the Pilica and Widawka rivers and has a rich alluvial soil. Agriculture is the main economic activity; rye, wheat, and potatoes are the principal crops. Pop. (1982 est.) 613,000.

Piotrków Trybunalski, city, capital of Piotrków Trybunalski *województwo* (province), central Poland, in the Łódź highlands. It is a manufacturing centre containing textile (principally cotton) mills, woodworks, and glassworks and lies on the Warsaw–Katowice rail line. First chronicled in the 13th century, it obtained town rights in that century. In 1578 it became the seat of the Polish tribunal, after which it is named, and the meeting place of the diets (assemblies) and synods. Industry developed during the 19th century, with new mills constructed after World War II. The city contains the Piotrków Regional Museum. Pop. (1982 est.) 73,700.

Piozzi, Hester Lynch, *née* SALUSBURY, also called (1763–84) HARRIET LYNCH THRALE, byname MRS. THRALE (b. Jan. 27, 1740, Bodvel, Carnarvonshire, Wales—d. May 2, 1821, Clifton, Bristol, Eng.), English writer and friend of Samuel Johnson.

In 1763 she married a wealthy brewer named Henry Thrale. In January 1765 Samuel Johnson was brought to dinner, and the next year, following a severe illness, Johnson spent most of the summer in the country with the Thrales. Gradually, he became part of the family circle, living about half the time in their homes. A succession of distinguished visitors came there to see him, as well as to eat Thrale's excellent dinners and to listen to Mrs. Thrale's amusing chatter.

Hester Lynch Piozzi, drawing by George Dance, 1793; in the National Portrait Gallery, London

By courtesy of the National Portrait Gallery, London

In 1781 Thrale died, and his wife was left a wealthy widow. To everyone's dismay, she fell in love with her daughter's music master, Gabriel Piozzi, an Italian singer and composer, married him in 1784, and set off for Italy on a honeymoon. Dr. Johnson openly disapproved. The resulting estrangement saddened his last months of life.

When news reached her of Johnson's death, she hastily compiled and sent back to England copy for *Anecdotes of the late Samuel Johnson, LL.D., during the last Twenty Years of his Life* (1786), which thrust her into open rivalry with James Boswell. The breach was further widened when, after her return to England in 1787, she brought out a two-volume edition of *Letters to and from the late Samuel Johnson, LL.D.* (1788). Although less accurate in some details than Boswell's, her accounts show other aspects of Johnson's character, especially the more human and affectionate side of his nature.

When many old friends remained aloof, Mrs. Piozzi drew around her a new artistic circle, including the actress Sarah Siddons. Her pen remained active, and thousands of her entertaining, gossipy letters have survived. She retained to the end her unflagging vivacity and zest for life. The standard authorities remain J.L. Clifford's *Hester Lynch Piozzi* (*Mrs. Thrale*) (1941); and *Thraliana* (her journal kept sporadically between 1776 and 1809), ed. by K.C. Balderston, 2 vols. (1942). *The Thrales of Streatham Park*, ed. by Mary Hyde, including an unpublished journal of Hester's (1766–78) and a biography, was published in 1977.

pipa (musical instrument): *see* p'i-p'a.

pipal, also spelled PEEPUL (species of fig tree): *see* Bo tree.

pipe, in music, specifically, the three-holed flute played with a tabor drum (*see* pipe and tabor); generically, aerophonic (wind) instruments consisting of pipes, either flutes or reed pipes (as a clarinet), and also the reed and flue pipes of organs. A pipe's pitch depends on its length, a long pipe having a low pitch. Pipes stopped at one end sound an octave lower than open pipes of equal length. Additional notes are obtained by using fingerholes to alter the length of the air column enclosed by the pipe or by vigorously overblowing, forcing the air column to vibrate in segments and sound overtones (harmonics) of the fundamental pitch.

In reed pipes and organ reed pipes a vibrating reed causes the column of air in the pipe to vibrate. In flutes and organ flue pipes a stream of air passing a sharp edge sets up vibrations in the pipe's air column. *See also* flute; fipple flute; reed instrument.

pipe, also called TOBACCO PIPE, hollow bowl used for smoking tobacco; it is equipped with a hollow stem through which smoke is drawn into the mouth. The bowl can be made of such materials as clay, corncob, meerschaum (a mineral composed of magnesia, silica, and water), and most importantly, briar-wood, the root of a species of heather.

The smoking of tobacco through a pipe is indigenous to the Americas and derives from the religious ceremonies of ancient priests in Mexico. Farther north, American Indians developed ceremonial pipes, the chief of these being the calumet, or pipe of peace. Such pipes had marble or red steatite (or pipestone) bowls and ash stems about 30 to 40 inches long and were decorated with hair and feathers. The practice of pipe smoking reached Europe through sailors who had encountered it in the New World.

pipe and tabor, three-holed fipple, or whistle, flute played along with a small snare drum.

The player holds the pipe with his left hand, stopping the holes with the thumb and the first and second fingers; the other two fingers support the instrument. A scale is obtained by overblowing, using the second to the fourth harmonics; the gaps between the harmonics are filled by uncovering the finger holes. The tabor, suspended from the player's left wrist or elbow, is beaten with the right hand to provide rhythmic accompaniment.

Mention of the pipe and tabor first occurs in the Middle Ages, as an ensemble providing music for court dances. By the 17th century its popularity began to decline, and it survived primarily as a folk instrument. In Provence and Spain, where players of great virtuosity accompany regional dances, the tradition of playing remains unbroken. In England, where pipe and tabor playing was associated with the Morris dancers, the tradition was broken at the end of the 19th century; the 20th-century renewal of interest in English folk music stimulated a revival.

Pipe Rolls, also called GREAT ROLLS OF THE EXCHEQUER, the oldest and longest series of English public records and a valuable source for the financial and administrative history of medieval England. Apart from an isolated survival from 1130, they begin in 1156 and continue with few breaks until 1832. Their name probably derives from the fact that the sheepskin rolls, when stored in their presses, resemble a stack of pipes.

The rolls contain the yearly accounts of the sheriffs, who were the chief financial officers for individual counties. The rolls sometimes also contained the accounts of other royal officials. Royal income from feudal dues, judicial fees, and other sources is balanced against the expenses of the crown's officers, providing a basis for the calculation of the king's revenue. As new accounting offices were set up to handle revenue, the Exchequer accounts diminished in importance. In 1883 a Pipe Roll Society was founded and began publishing all the rolls.

pipe vine: *see* Dutchman's-pipe.

pipefish, any of more than 150 species of elongated fishes allied to the sea horses, in the family Syngnathidae (order Gasterosteiformes). Pipefishes are very slender, long-bodied fishes covered, like sea horses, with rings of bony armour. They have long, tubular snouts and small mouths, a single dorsal fin, and, usually, a small tail fin. Depending on the species, they may range in length from about 2.5 to 50 cm (1 to 20 inches).

Pipefishes are found in warm regions and are primarily marine, although some live in or enter fresh water. They are weak, slow swimmers and usually live in beds of seaweed, eelgrass, or other aquatic plants among which they can feed and hide. They feed by sucking their prey (small aquatic organisms) rapidly into their mouths. Their reproductive

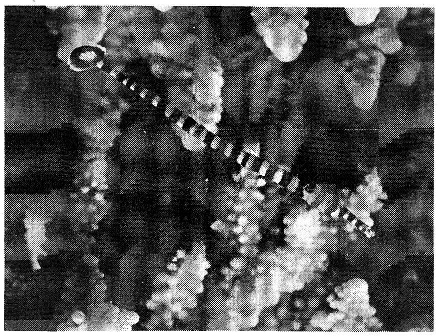
*Oral or dialectal syllable with no official Wade–Giles equivalent.



Banded pipefish (*Dunkerocampus caulleryi*)
Douglas Faulkner

behaviour, like that of sea horses, is distinctive in that the male, not the female, carries the fertilized eggs until they hatch. Among pipefishes, the eggs may be stuck to the surface of the body, embedded in a spongy area, or carried in a brood pouch. The brood pouch is derived from lengthwise folds of skin and, depending on the species, affords varying degrees of coverage for the incubating eggs.

Related to the pipefishes are the ghost pipefishes of the family Solenostomidae. These are small, rare, Indo-Pacific fishes with long snouts and enlarged fins. In this species the female's brood pouch is formed by the union of the ventral fins.

pipeline, line of pipe equipped with pumps and valves and other control devices for moving liquids, gases, and slurries (fine particles suspended in liquid). Pipeline sizes vary from the 2-inch- (5-centimetre-) diameter lines used in oil-well gathering systems to lines 30 feet (9 m) across in high-volume water and sewage networks. Pipelines usually consist of sections of pipe made of metal (*e.g.,* steel, cast iron, and aluminum), though some are constructed of concrete, clay products, and occasionally plastics. The sections are welded together and, in most cases, laid underground.

Various cleaning measures are undertaken to reduce the corrosion that often occurs in pipelines. These include maintaining a negative electrical charge throughout the pipe (cathodic protection); lining the interior with paints and coatings of plastic and rubber; fibreglass, asphalt, and felt wrappings; the injection of corrosion-inhibiting chemicals into the cargo; and periodic cleaning. Pipelines are also cleaned by passing devices called "pigs" through them. A pig may be simply a ball of the same size as the pipe's diameter, which scrapes the pipe's interior clean as it is propelled along by the flowing cargo. It may also be a complex scrubbing machine inserted through a special opening.

Piper, Carl, Greve (Count) (b. July 29, 1647, Stockholm—d. May 29, 1716, Nöteborg, Fin.), Swedish statesman who served as King Charles XII's leading minister during the Great Northern War (1700–21).

Piper was of lesser noble background. He became an official in the Swedish chancellery's department of home affairs under King Charles XI but reached the heights of Swedish government in 1697, when the newly crowned Charles XII raised him to a countship and appointed him to the council of state.

Piper was the only high councillor to accompany Charles in the field during the Great Northern War. While he approved, along with the other field advisers, a decision to invade Russia, Piper later strongly opposed Charles's determination to remain there following early setbacks.

Piper was captured during the Battle of Połtava (July 1709), and he remained a prisoner of the Russians until his death in 1716, despite Charles's repeated efforts to win his freedom through prisoner exchanges.

Piper, William T(homas) (b. Jan. 8, 1881, Knapps Creek, N.Y., U.S.—d. Jan. 15, 1970, Lock Haven, Pa.), manufacturer of small aircraft, best known for the Piper Cub, a practicable two-seater that became the most popular family aircraft. He earned the sobriquet "the Henry Ford of Aviation" for his efforts to popularize air travel.

Piper was graduated from Harvard University in 1903 and worked as a construction superintendent until 1914 and as an oil producer from that year. The Piper Aircraft Corporation was founded in 1929. Piper served as its president until his death. Piper learned to fly in 1931, and in 1945, at age 73, he received certification to pilot twin-engine aircraft.

In World War II, Piper delivered more than 5,600 Piper Cubs, long popular as a training plane, to the U.S. government for use as special personnel planes, for photo-reconaissance, and as artillery spotters. Because of their low landing speed (20 mph) and high manoeuvrability, the Pipers easily eluded enemy fighters.

In addition to the Piper Cub, the company manufactured light- to medium-size aircraft for use as business planes.

Piperaceae, the pepper family in the order Piperales, commercially important particularly because of *Piper nigrum*, the source of black pepper. The family comprises about 10 genera, of which 2, *Piper* (about 1,000 species) and *Peperomia* (*q.v.*; more than 500 species), are the most important. The plants grow as herbs, vines, shrubs, and trees and are widely distributed throughout the tropics and subtropics.

The leaves of Piperaceae, which have a pungent flavour, grow singly. The numerous flowers, lacking sepals and petals, are crowded in dense spikes. *Piper* species are mostly shrubs, woody vines, and small trees. Many are used in medicines and in food and beverages as spices and seasonings. *Piper nigrum* is a 30 foot (9 metre) woody climber native to southern India and to Sri Lanka; it is cultivated in most tropical regions where soil moisture is constant and temperatures are reliably warm. The pungency of *Piper* peppers is attributed to chavicine, a resin. Also present are the alkaloids piperine (which lends pungency to brandy) and piperidine. An essential oil distilled from peppercorns is used to make meat sauces. *P. cubeba*, of particular importance in Southeast Asia, is the source of cubeb, used in various medicines and for flavouring cigarettes and bitters. In the Orient, chewing the leaves of the betel (*q.v.*) pepper, *P. betle*, with slices of betel nut and lime, is widely practiced for its mildly stimulating effect. An intoxicating drink of Polynesia, variously known as kava, kawakawa, aiva, and yagona, is made from the root of *P. methysticum*. *Peperomia* species mostly grow as low herbs, although a few grow on trees as epiphytes. Several soil-growing species are cultivated for their attractive foliage. The young leaves and stems of *P. vividispica* are used as food in Central and South America.

Piperales, order of flowering plants comprising of about 15 genera and approximately 3,000 species in two families. It belongs to the class known as dicotyledon (*q.v.*; characterized by two seed leaves). The pepper family, Piperaceae (*q.v.*), is widely distributed in the tropics of both hemispheres and is the source of pepper.

A brief treatment of Piperales follows. For full treatment, *see* MACROPAEDIA: Angiosperms.

Inflorescences (flower clusters) of the Piperales are slender, spike-like, and covered with inconspicuous, closely-appressed flowers. In the Saururaceae, the elongate cluster bends at its tip to suggest the fanciful appellation "lizard's tail." Other features common to most species of this order include simple leaves, lack of sepals and petals, bisexual flowers (stamens and pistil in the same flower), and presence of one ovule per ovary chamber.

The lizard's-tail family, Saururaceae, with only five genera and seven species, is native to North America and Southeast Asia. Its members are aromatic herbs, with creeping rhizomes (horizontal stems), inhabiting wet areas.

Fragmentation of rhizomes in the lizard's-tail family assures vegetative propagation, but reproduction by seeds is the main method of species dispersal in both families of the Piperales order.

Even though individual flowers are small, floral spikes are showy in several species owing to the expanded, colourful bract that arises below each flower. Stamens usually number six, and the ovary chambers vary from one in the Piperaceae to several in the Saururaceae. This characteristic and the lack of wood in the Saururaceae distinguish the two families structurally. In a few species, stamens and pistils appear in different flowers.

Seeds and fruits form in the usual manner of dicots. The drupe is the prevailing fruit type in the pepper family, whereas a dry, closed fruit characterizes the lizard's-tail family.

piperazine, also called HEXAHYDROPYRAZINE, anthelmintic drug, or worming agent, effective against intestinal roundworm infection in man and domestic animals (including poultry) and against pinworm infection in man. It is administered orally, in repeated doses, usually as the citrate salt. Its action causes worms to be eliminated with normal stool.

piperine, an organic compound classed either with the lipid family (a group consisting of fats and fatlike substances) or with the alkaloids, a family of nitrogenous compounds with marked physiological properties. It is one of the sharp-tasting constituents of the fruit of the pepper vine (*Piper nigrum*).

Piperine constitutes approximately 5–9 percent of commercial black or white pepper. It was first isolated in 1820, and its chemical constitution was established by laboratory syntheses in 1882 and 1894.

The sharp flavour of freshly ground pepper is attributed to the compound chavicine, a geometrical isomer (having the same molecular formula but differing in structure) of piperine. The loss of pungency of ground pepper on storage is associated with slow transformation of chavicine into piperine.

Pipestone, city, seat of Pipestone County, southwestern Minnesota, U.S., on Coteau des Prairies, near the South Dakota line. Laid out in 1876, it developed with the coming of the railroads (1879–84), was incorporated (1901), and is the business centre for a mixed-farming area.

The Pipestone National Monument, immediately northwest, has quarries of a reddish-coloured stone that was used by Plains Indians to make ceremonial peace pipes (*see* sacred pipe). The site, considered sacrosanct, was long fought over before being declared neutral ground. The stone (named catlinite for George Catlin, an artist) is reserved for the Indians who quarry it under special permits issued by the National Park Service. Longfellow popularized the quarries in *The Song of Hiawatha*, and the city has a Hiawatha Club and stages an annual pageant. Pop. (1980) 4,887.

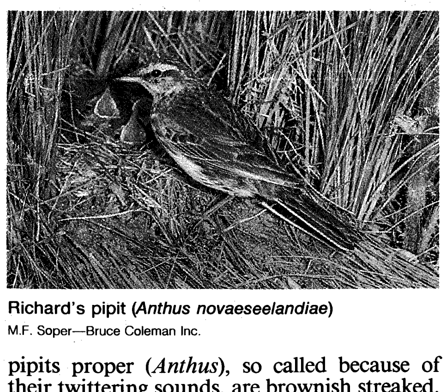
Pipino (Italian personal name): *see under* Pepin.

Pipiolo and Pelucón (Spanish: "novice" or "greenhorn," and "bigwig," respectively), members of the two political partisan groups active in Chilean politics for about a century after national independence was achieved in the 1820s. The Pipiolos were liberals and the Pelucones conservatives. Between 1830 and 1861 the Pelucones were ascendant. Between 1861 and 1891 both groups realigned and splintered; the liberal coalitions acquired the upper hand and used their strength to gradually reduce executive power in favour of congressional power. By the 1890s both liberals and conservatives represented mostly wealthy, vested interests, and after 1900 they were challenged by new middle and working class parties.

pipistrelle (*Pipistrellus*), any of about 40 to 50 species of bats of the common bat family, Vespertilionidae, found in almost all parts of the world. Pipistrelles are grayish, brown, reddish, or black bats about 3.5–10 centimetres (1.4–4 inches) long, not including the 2.5–6-cm tail. Erratic fliers, they appear before most other bats in the evening and sometimes fly about even during the day. Representatives include *P. pipistrellus* of Eurasia and the eastern (*P. subflavus*) and western (*P. hesperus*) pipistrelles of North America.

pipit, also called FIELDLARK, or TITLARK, any of about 50 species of small, slender-bodied ground birds of the family Motacillidae (order Passeriformes), found worldwide except in polar regions and on some islands.

Members range in size from 12.5 to 23 centimetres (5 to 9 inches) long. They have thin, pointed bills, pointed wings, and elongated hindtoes and claws. These trim birds walk and run rapidly (but never hop), seeking out insects along the ground. Their flight is strongly undulating, like that of many finches. The pipits proper (*Anthus*), so called because of their twittering sounds, are brownish streaked. Wagtails (*Motacilla*), which continually pump their long tails up and down, are more boldly marked. Both groups have white outer tail feathers, which show best in flight. An unusual group, called longclaws (*Macronyx*), are found on African prairies.



Richard's pipit (*Anthus novaeseelandiae*)
M.F. Soper—Bruce Coleman Inc.

The Motacillidae belongs to the songbird suborder (Passeres).

Pippi, Giulio: *see* Giulio Romano.

Pippin (German personal name): *see under* Pepin.

Pippin, Horace (b. Feb. 22, 1888, West Chester, Pa., U.S.—d. July 6, 1946, West Chester), U.S. folk painter known for his primitivist depictions of black American life and on the horrors of war.

Pippin's childhood was spent in Goshen, N.Y., a town that sometimes appears in his paintings. There he drew horses at the local racetrack and, to the despair of his school teachers, preferred drawing to writing. He was variously employed as an ironworker, junk dealer, and porter, until World War I, when he served in the infantry. He was wounded in 1918 and discharged with a partially paralyzed right arm and classified as unfit to work. He settled in West Chester and eventually began to paint by burning designs into wood panels with a red hot poker and then filling in the outlined areas with paint.

"John Brown Going to His Hanging," oil painting by Pippin, *c.* 1942; in the Pennsylvania Academy of the Fine Arts, Philadelphia

By courtesy of the Pennsylvania Academy of the Fine Arts, Philadelphia

His first large canvas was an eloquent protest against war, "End of the War: Starting Home" (1931–34), which was followed by other antiwar pictures, such as "Shell Holes and Observation Balloon" and the many versions of "Holy Mountain." His most popular themes centred on the black American, such as his series entitled "Cabin in the Cotton" and his paintings of episodes in the life of the anti-slavery leader John Brown. After the art world discovered Pippin in 1937, these pictures particularly brought him wide acclaim as the greatest black painter of his time. Pippin also executed portraits and biblical subjects. His early works are characterized by their heavy impasto and restricted use of colour. His later works are more precisely painted in a bolder palette.

Pipridae (bird family): *see* manakin.

pipsissewa, any of certain evergreen, herbaceous plants of the genus *Chimaphila*, of the wintergreen family (Pyrolaceae), especially *C. umbellata* and *C. maculata.* The former, sometimes also called prince's pine, love-in-winter, and wintergreen (*q.v.*), occurs in North America from Canada to Mexico and in Europe and Japan. *C. maculata,* sometimes called striped pipsissewa, rheumatism root, dragon's tongue, and spotted wintergreen, occurs in North America from Canada to the southern United States. The name pipsissewa derives from a Cree Indian word referring to the diuretic properties of the leaves when eaten.

Pipsissewa (*Chimaphila umbellata*)

Mary W. Ferguson

Pipsissewas are woodland plants with leathery leaves and five-petalled, fragrant, pink or white flowers that grow in a sparse, terminal cluster. They arise from rhizomes (underground stems). Though difficult to cultivate, they are sometimes grown in gardens.

Chimaphila maculata grows 10–25 centimetres (4–10 inches) tall; the stem is more or less prostrate. The lance-shaped leaves are 2.5–7.5 cm long and have white spots along the veins. The nodding flowers are about 2.5 cm across. *C. umbellata* grows 12–30 cm tall. The leaves are somewhat broader than those of *C. maculata* and are not spotted. The flowers are about 2 cm across and appear throughout the summer.

Piqua, city, Miami County, western Ohio, U.S., on the Great Miami River, 28 mi (45 km) north of Dayton. The original Indian village of Piqua (the name of a Shawnee tribal group), near present-day Springfield, was destroyed by George Rogers Clark and his Kentucky volunteers in 1780. The Indians then moved to the present site, where they established two settlements, Upper and Lower Piqua. In 1794 Gen. "Mad" Anthony Wayne built Ft. Piqua near Upper Piqua, and from there the Indian chief Tecumseh departed in 1796 for the headwaters of the Whitewater in Indiana. A town called Washington was subsequently laid out on the site in 1807. Renamed Piqua in 1816, it developed as a flatboat river port trading in corn (maize), flour, bacon, and flax and was incorporated in 1823. The completion of the Miami and Erie Canal (1836) and the arrival of the railroads (1850s) gave impetus to its growth as an industrial community (manufactures include vehicle bodies, felt, oil-milling machinery, sportswear, and air vents). The Piqua Historical Area (174 ac [70 ha]) includes the John Johnston Farmhouse (1810–15), a restored section of the canal, and the Historic Indian Museum. Piqua is the seat of Edison State General and Technical College (1973). Inc. city, 1850. Pop. (1980) 20,480.

piqué work, decorative technique, usually employed on tortoiseshell, in which inlaid designs are created by means of small gold or silver pins. The art reached its highest point in 17th- and 18th-century France, particularly for the decoration of small tortoiseshell articles such as combs, patch boxes, and snuffboxes. By an adroit arrangement of the gold and silver pins, by placing them in small or large clusters, effects of light and shade could be created in the design. In the finest French work, the pins are placed so close to each other and with such accuracy that they appear to form a continuous line. Decorative motifs include chinoiserie scenes, geometric designs, and arabesques. In England, where the craft had been brought by the Huguenots at the end of the 17th century, Matthew Boulton in 1770 developed mechanical methods of producing piqué panels. Many of his designs show the influence of the Neoclassical designer Robert Adam. During the 19th century, piqué was widely employed for small tortoiseshell jewelry, much of it after 1872 being made by machine in Birmingham, Eng.

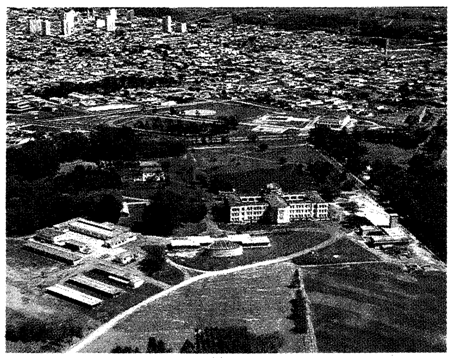
Piquet, card game known, under various names, since the 15th century, when it was played in France. Charles I of England gave the game its French nomenclature in honour of his French-born queen. Piquet is a game for two players, although there are variants for three and four. A pack of 32 cards is used, ranking ace (high), king, queen, jack, 10, 9, 8, and 7. Twelve cards are dealt to each player, two or three at a time. The remaining eight cards, the stock, are spread face down. A player who holds carte blanche (a hand with no court [face] card), announces it and scores 10 points. Players then discard and draw from the stock to improve their hands.

After the draw, players compare their holdings in each of three classes of scoring combinations. The classes are point, sequence, and set and are scored in that order. Only one player may score in each class. Point is the greatest number of cards in any one suit; sequence is the longest run of consecutive cards in one suit; and a set is three or four cards 10 or higher of the same rank.

Upon completion of the declarations, play begins: the nondealer leads first. Each lead requires the other to follow suit if able. The trick is won by the higher card of the suit led. There is no trump suit. A game is usually six deals.

Pīr Panjāl Range, part of the western Punjab Himalayas, lying in northwestern India and northern Pakistan and extending southeastward for more than 200 mi (320 km) from the Kishanganga to the upper Beās river. Rising sharply to an average elevation of more than 13,000 ft (4,000 m), it separates the Jammu Hills to the south from the Vale of Kashmir, beyond which lie the Great Himalayas. The major passes through the range include the Pīr Panjāl (11,462 ft) and Banihāl (8,985 ft); a highway tunnel near Banihāl Pass makes the Vale of Kashmir accessible to traffic from the south, even in winter. The mountains extending to the north of the Kishanganga River in Pakistan are sometimes considered part of the range.

Piracicaba, city, in the highlands of east central São Paulo state, Brazil, at 1,772 ft (540 m) above sea level on the Rio Tietê. Formerly called Santo Antônio de Piracicaba and Vila Nova da Constituição, the settlement was given town status in 1821 and made the seat of a municipality in 1856. The city is in the centre of the state's main sugarcane-producing area; cotton, rice, coffee, and other crops are also cultivated. In addition to sugar refineries, the city has distilleries, food-processing factories, and machinery plants. One of the state's chief agricultural colleges is nearby. Piracicaba is linked by road, rail, and air to São Paulo, the state capital, 85 mi (137 km) southeast. Pop. (1980 prelim.) 179,395.



Piracicaba, Braz., showing the Agricultural College (centre)

Plessner International

piracy, any robbery or other violent action, for private ends and without authorization by public authority, committed on the seas or in the air outside the normal jurisdiction of any state. Because piracy has been regarded as an offense against the law of nations, the public vessels of any state have been permitted to seize a pirate ship, to bring it into port, to try the crew (regardless of their nationality or domicile), and, if found guilty, to punish them and to confiscate the ship.

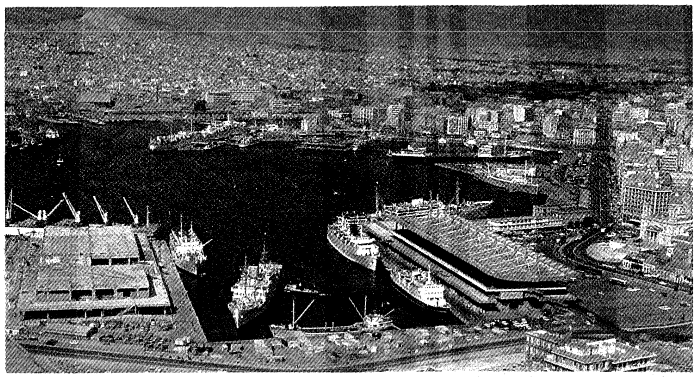
A key point in a definition of piracy according to international law is that the act takes place outside the normal jurisdiction of a state, without state authority, and that the intent is private, not political. Thus, although acts of unlawful warfare, acts of insurgents and revolutionists, mutiny, and slave trading have been defined as piracy by national laws of various countries or by special treaties, they are not, in most cases, piracy by the law of nations.

Piracy has occurred in all stages of history. In the ancient Mediterranean, piracy was often closely related to maritime commerce, and the Phoenicians appear to have engaged in both, as did the Greeks, Romans, and Carthaginians. In the Middle Ages, Vikings from the north and Moors from the south also engaged in piracy. At the conclusion of European wars during the Renaissance and after, naval vessels would be laid up and their crews disbanded. From among these men, pirates recruited their crews. A common source of piracy, for instance, was the privateer, a privately owned and armed ship commissioned by a government to make reprisals, to gain reparation for specified offenses in time of peace, or to prey upon the enemy in time of war, with the right of the officers and crew to share in prize money from captured vessels. The temptation was great to continue this profitable business after the war without authorization. During the Elizabethan wars with Spain in the late 16th century, treasure-laden Spanish galleons proceeding from Mexico into the Caribbean were a natural target for privateers, and the line between privateering and piracy became difficult to draw.

From the 16th to the 18th century, after the weakening of Turkish rule had resulted in the virtual independence of the Barbary States of North Africa, piracy became common in the Mediterranean. Morocco, Algiers, Tunis, and Tripoli so tolerated or even organized piracy that they came to be called pirate states. In the early 19th century they were suppressed by successive actions of American, British, and French forces.

The increased size of merchant vessels, the improved naval patrolling of most ocean highways, the regular administration of most islands and land areas of the world, and the general recognition by governments of piracy as an international offense resulted in a great decline in piracy in the 19th and 20th centuries. Piracy has, however, occurred in the 20th century in the South China Sea, and the practice of hijacking ships or airplanes has developed into a new form of piracy. *See also* hijacking.

Piraeus, Modern Greek PIRAIÉVS, city, the port of Athens and largest port in Greece, on Órmos Fálirou (Phaleron Bay), southwest of the metropolis by highway. The main harbour, Kántharos (ancient Cantharus), is embraced on the west by the small Ietionía peninsula, on the south by the main Akti peninsula (the Peraïki sector of the port), and on the east by Munychia (modern Kastélla), its highest point. The port has been rebuilt since the bombings of World War II. Its many new factories are mainly engineering and chemical support industries and shipyards. It is the terminal station for all the main Greek railways and is linked to Athens by electric railway and superhighway. It is the centre of all sea communication with the Greek islands.



The harbour at Piraeus, the port of Athens, on the Saronic Gulf, Greece
K. Honkanen—Ostman Agency

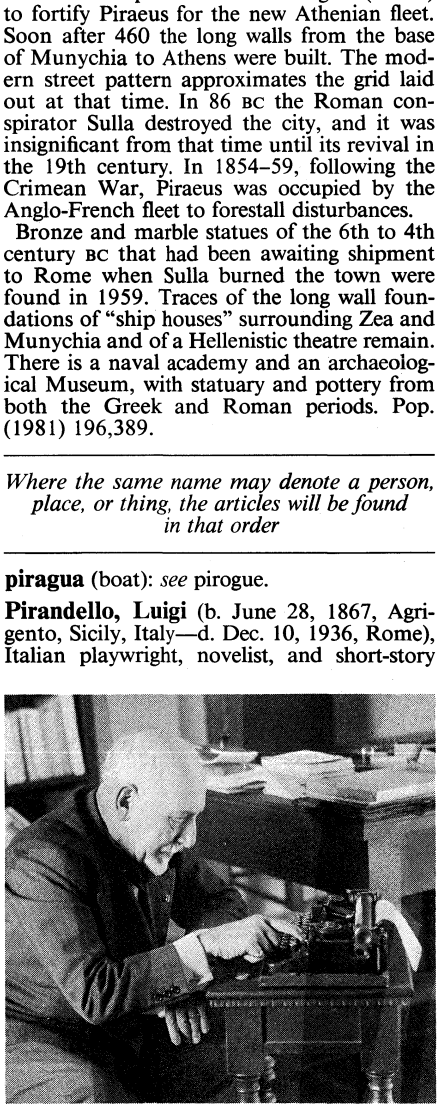
In the 7th and 6th centuries BC the Athenians used Phaleron Bay for mooring, since the present port was separated from the mainland by marshes. The Athenian statesman Themistocles persuaded his colleagues (*c.* 493) to fortify Piraeus for the new Athenian fleet. Soon after 460 the long walls from the base of Munychia to Athens were built. The modern street pattern approximates the grid laid out at that time. In 86 BC the Roman conspirator Sulla destroyed the city, and it was insignificant from that time until its revival in the 19th century. In 1854–59, following the Crimean War, Piraeus was occupied by the Anglo-French fleet to forestall disturbances.

Bronze and marble statues of the 6th to 4th century BC that had been awaiting shipment to Rome when Sulla burned the town were found in 1959. Traces of the long wall foundations of "ship houses" surrounding Zea and Munychia and of a Hellenistic theatre remain. There is a naval academy and an archaeological Museum, with statuary and pottery from both the Greek and Roman periods. Pop. (1981) 196,389.

Where the same name may denote a person, place, or thing, the articles will be found in that order

piragua (boat): *see* pirogue.

Pirandello, Luigi (b. June 28, 1867, Agrigento, Sicily, Italy—d. Dec. 10, 1936, Rome), Italian playwright, novelist, and short-story writer, winner of the 1934 Nobel Prize for Literature. With his invention of the "theatre within the theatre" (in *Sei personaggi in cerca d'autore* [*Six Characters in Search of an Author*]), he became an important innovator in modern drama.



Pirandello
By courtesy of the Italian Institute, London

Pirandello was the son of a sulfur merchant who wanted him to enter commerce. Pirandello, however, was not interested in business; he wanted to study. He first went to Palermo, the island's capital, and, in 1887, to the University of Rome. After a quarrel with the professor of classics, he went in the following year to the University of Bonn, Germany, where in 1891 he gained his doctorate in philology for a thesis on the dialect of Agrigento.

In 1894 his father arranged his marriage to Antonietta Portulano, the daughter of a business associate, a wealthy sulfur merchant. This marriage gave him financial independence, allowing him to live in Rome and to write. He had already published an early volume of verse, *Mal giocondo* (1889), which paid tribute to the poetic fashions set by Giosuè Carducci; and this was followed by other volumes of verse, including *Pasqua di Gea* (dedicated to Jenny Schulz-Lander, the love he had left behind in Bonn) and the translation of Goethe's *Römische Elegien* (*Elegie romane*). But his first significant works were short stories, at first contributed to periodicals without payment.

In 1903 a landslide shut down the sulfur mine in which his wife's and his father's capital was invested. Suddenly poor, Pirandello was forced to earn his living not only by writing but also by teaching Italian at a teacher's college in Rome. As a further result of the financial disaster, his wife developed a persecution mania, which manifested itself in a frenzied jealousy of her husband. His torment ended only with her removal to a sanatorium in 1919 (she died in 1959). It was this bitter experience that finally determined the theme of his most characteristic work, already perceptible in his early short stories—the exploration of the tightly closed world of the forever changeable human personality.

Pirandello's early narrative style stems from the *verismo* ("realism") of two distinguished Italian novelists of the late 19th century—Luigi Capuana and Giovanni Verga. The titles of Pirandello's early collections of short stories—*Amori senza amore* (1894; "Loves Without Love"), *Beffe della morte e della vita* (1902–03; "The Jests of Life and Death")—suggest the wry nature of his realism that is seen also in his first novels: *L'esclusa* (1901) and *Il turno* (1902). Success came with his third novel, often acclaimed as his best, *Il fu Mattia Pascal* (1904). Although the theme is not typically "Pirandellian," since the obstacles confronting its hero result from external circumstances, it already shows the acute psychological observation that was later to be directed toward the exploration of his characters' subconscious.

Pirandello's understanding of psychology was sharpened by reading such works as *Les altérations de la personnalité* (1892), by the French experimental psychologist Alfred Binet; and traces of its influence can be seen in the long essay *L'umorismo* (1908), in which he examines the principles of his art. Common to both books is the theory of the subconscious personality, which postulates that what a person knows, or thinks he knows, is the least part of what he is. Pirandello had begun to focus his writing on the themes of psychology even before he knew of the work of Sigmund Freud, the founder of psychoanalysis. The psychological themes used by Pirandello found their most complete expression in the volumes of short stories, *La trappola* (1915) and *E domani, lunedì . . .* (1917), and in such individual stories as "Una voce," "Pena di vivere così," and "Con altri occhi."

Meanwhile, he had been writing other novels, notably *I vecchi e i giovani* (1913) and *Uno, nessuno e centomila* (1925–26). Both are more typical than *Il fu Mattia Pascal.* The first, a historical novel reflecting the Sicily of the end of the 19th century and the general bitterness at the loss of the ideals of the Risorgimento (the movement that led to the unification of Italy), suffers from Pirandello's tendency to "discompose" rather than to "compose" (to use his own terms, in *L'umorismo*), so that individual episodes stand out at the expense of the work as a whole. *Uno, nessuno e centomila,* however, is at once the most original and the most typical of his novels. It is a surrealistic description of the consequences of the hero's discovery that his wife (and others) see him with quite different eyes than he does himself. Its exploration of the reality of personality is of a type better known from his plays.

He had first turned to the theatre in 1898 with *L'epilogo,* but the accidents that prevented its production until 1910 (when it was retitled *La morsa*) kept him from other than sporadic attempts at drama until the success of *Cosí è* (*se vi pare*) in 1917. This delay may have been fortunate for the development of his dramatic powers. *L'epilogo* does not greatly differ from other drama of its period, but *Cosí è* (*se vi pare*) began the series of plays that were to make him world famous in the 1920s. A demonstration, in dramatic terms, of the relativity of truth, and a rejection of the idea of any objective reality not at the mercy of individual vision, it anticipates Pirandello's two great plays, *Sei personaggi in cerca d'autore* (1921) and *Enrico IV* (1922). *Sei personaggi* is the most arresting presentation of the typical Pirandellian contrast between art, which is unchanging, and life, which is an inconstant flux. Characters that have been rejected by their author materialize on stage, throbbing with a more intense vitality than the real actors, who, inevitably, distort their drama as they attempt its presentation. And in *Enrico IV* the theme is madness, which lies just under the skin of ordinary life and is, perhaps, superior to ordinary life in its construction of a satisfying reality. The play finds dramatic strength in its hero's choice of retirement into unreality in preference to life in the uncertain world.

The production of the first of these two plays in Paris in 1923 made Pirandello widely known, and his work became one of the central influences on the French theatre; French drama from the existentialistic pessimism of Jean Anouilh and Jean-Paul Sartre to the absurdist comedy of Eugène Ionesco and Samuel Beckett is tinged with "Pirandellianism." His influence can also be detected in the drama of other countries, even in the religious verse dramas of T.S. Eliot.

In 1920 Pirandello said of his own art:

> I think that life is a very sad piece of buffoonery; because we have in ourselves, without being able to know why, wherefore or whence, the need to deceive ourselves constantly by creating a reality (one for each and never the same for all), which from time to time is discovered to be vain and illusory . . . My art is full of bitter compassion for all those who deceive themselves; but this compassion cannot fail to be followed by the ferocious derision of destiny which condemns man to deception.

This despairing outlook attained its most vigorous expression in Pirandello's plays, which were criticized at first for being too "cerebral" but later recognized for their underlying sensitivity and compassion. The plays reflect the *verismo* of Capuana and Verga in dealing mostly with people in modest circumstances, such as clerks, teachers, and lodginghouse keepers, but from whose vicissitudes he draws conclusions of general human significance.

The universal acclaim that followed *Sei personaggi* and *Enrico IV* sent Pirandello touring the world (1925–27) with his own company, the Teatro d'Arte in Rome. It also emboldened him to disfigure some of his later plays (*e.g., Ciascuno a suo modo* [1924]) by calling attention to himself, just as in some of the later short stories it is the surrealistic and fantastic elements that are accentuated.

After the dissolution, because of financial losses, of the Teatro d'Arte in 1928, Pirandello spent his remaining years in frequent and extensive travel. In his will he requested that there should be no public ceremony marking his death—only "a hearse of the poor, the horse and the coachman." (J.H.W.)

MAJOR WORKS. *Verse. Mal giocondo* (1889); *Pasqua di Gea* (1891); *Pier Gudrò* (1894); *Elegie renane* (1895); *Elegie romane* (1896), translations from Goethe's *Römische Elegien; Zampogna* (1901); *Scamandro* (1909), verse play; *Fuori di chiave* (1912).

Criticism. Arte e scienza (1908); *L'umorismo* (1908).

Short stories. The first book editions of collections of *novelle* include: *Amori senza amore* (1894); *Beffe della morte e della vita* (1902–03); *Quand'ero matto . . .* (1902); *Bianche e nere* (1904); *Erma Bifronte* (1906); *La vita nuda* (1910); *Terzetti* (1912); *Le due maschere* (1914); *La trappola* (1915); *Erba del nostro orto* (1915); *E domani, lunedì . . .* (1917); *Un cavallo nella luna* (1918); *Berecche e la guerra* (1919); and *Il carnevale dei morti* (1919). English translations have appeared in the following selections: *Horse in the Moon* (1932), contains *Un cavallo nella luna* and 11 other stories; *Better Think Twice About It!* [*Pensaci, Giacomino!*] *and Twelve Other Stories* (1933); *The Naked Truth* [*La vita nuda*], *and Eleven Other Stories* (1934, new ed. 1947); *A Character in Distress* (1938; U.S. title, *His Medals,* 1939), "La tragedia d'un personaggio" and 18 other stories; *Short Stories* (1959), translations of 22 stories, including "Pena di vivere cosí," "Such Is Life"; *Short Stories,* selected, translated, and introduced by Frederick May (1965), includes "Capannetta," "The Little Hut," Pirandello's earliest known prose work, and "La giara," "The Jar," probably his best known story.

Novels. L'esclusa (written 1893, published 1901; *The Outcast,* 1925); *Il turno* (written 1895, published 1902); *Il fu Mattia Pascal* (1904; *The Late Mattia Pascal,* 1923); *Suo marito,* later title *Giustino Roncella nato Boggiòlo* (1911); *I vecchi e i giovani* (1913; trans. by C.K. Scott-Moncrieff, *The Old and Young,* 1928); *Si gira . . .*, later title, *Quaderni di Serafino Gubbio operatore* (1916; trans. by Scott-Moncrieff, *Shoot! Si gira . . . the Notebooks of Serafino Gubbio, Cinematograph Operator,* 1927); *Uno, nessuno e centomila* (1925–26; *One, None and a Hundred Thousand,* 1933).

Plays. Pirandello wrote more than 50 plays. The following is a selection from the basic 31-volume Bemporad-Mondadori edition of the plays collected under the title *Maschere nude,* "Naked Masks" (1920–35): *Tutto per bene* (1920; *All for the Best,* 1960); *Sei personaggi in cerca d'autore* (1921; trans. by F. May, *Six Characters in Search of an Author,* 1954); *Enrico IV* (1922; *Henry IV,* trans. by F. May, 1960); *Vestire gli ignudi* (1923; *To Clothe the Naked,* 1962); *La vita che ti diedi* (1924; *The Life I Gave You,* 1959); *Ciascuno a suo modo* (1924; *Each in His Own Way,* 1924); *Cosí è (se vi pare)* (1925, first pub. 1918; *Right You Are [If You Think So],* trans. by F. May, 1960; by Eric Bentley as *Right You Are,* 1954); *Sagra del sigre della nave; L'altro figlio;* and *La giara* (1925; *Our Lord of the Ship; The House with the Column;* and *The Jar,* in *The One-Act Plays of Luigi Pirandello,* 1928); *Il piacere dell'onestà* (1925, first pub. 1918; *The Pleasure of Honesty,* in *To Clothe the Naked, and Two Other Plays,* 1962); *Il giuoco delle parti* (1925, first pub. 1919; *The Rules of the Game,* in *To Clothe the Naked, and Two Other Plays,* 1962); *All'uscita* (first pub. 1916); *Il dovere del medico* (first pub. 1912); *La morsa* (first pub. 1898 with the title *L'epilogo*); and *L'uomo dal fiore in bocca* (1926; *At the Gate; The Doctor's Duty; The Vise;* and *The Man with the Flower in His Mouth,* in *The One-Act Plays of Luigi Pirandello,* 1928); *Diana e la Tuda* (1927; *Diana and Tuda,* 1950); *La nuova colonia* (1928; *The New Colony,* in *The Mountain Giants and Other Plays,* 1958); *Lazzaro* (1929; *Lazarus,* 1952); *Questa sera si recita a soggetto* (1930; *Tonight We Improvise,* 1932); *Come tu mi vuoi* (1930; *As You Desire Me,* 1931); *Quando si è qualcuno* (1933; *When Someone Is Somebody,* in *The Mountain Giants and Other Plays,* 1958).

BIBLIOGRAPHY. *Editions.* The most complete edition of Pirandello's works is the so-called *edizione definitiva* in the series *I classici contemporanei italiani* (1956–60). It consists of the following volumes: *Novelle per un anno,* 2 vol. (1956–57); *Tutti i romanzi* (1957); *Maschere nude,* 2 vol. (1958); *Saggi, poesie, scritti varii* (1960).

Pirandello had planned to write 365 short stories, one for each day of the year, and himself began to edit the stories in a series entitled *Novelle per un anno;* the first volume appeared in 1922 and the 15th and last in 1937.

Bibliography. Manlio Lo Vecchio Musti, *Bibliografia di Pirandello,* 2nd ed. (1952).

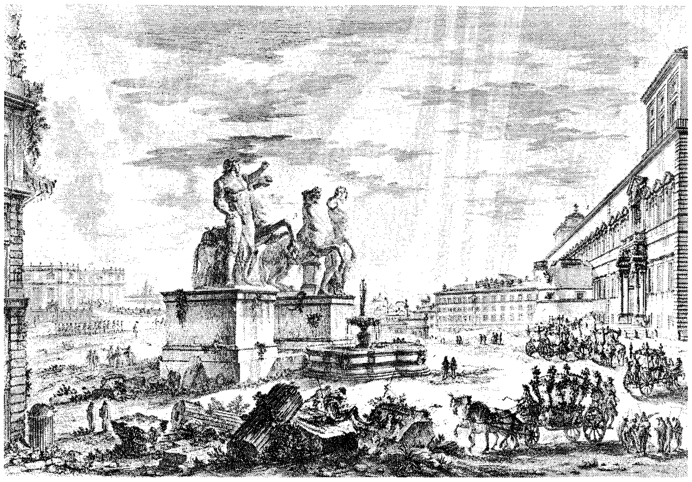
Biography. F.V. Nardelli, *L'uomo segreto: Vita e croci di Luigi Pirandello,* 3rd rev. ed. (1962), first written in 1932, with the collaboration of Pirandello himself, revealed the tortured background of Pirandello's life with Antonietta Portulano. It is fundamental for an understanding of the author, although from the circumstances of its writing, it appears now somewhat hero-worshipping in tone. Gaspare Giudice, *Luigi Pirandello* (1963; Eng. trans. 1975), presents the life and work of Pirandello in the setting of his time; it is probably the best general account of the author.

Criticism. W. Starkie, *Luigi Pirandello, 1867–1936,* 4th ed. (1967), a very personal, critical account, with extracts and synopses, of Pirandello's work in the context of European literature; Thomas Bishop, *Pirandello and the French Theater* (1960), a useful discussion of Pirandello's ideas, and an account of his lasting influence on the French theatre; J.H. Whitfield, "Pirandello and T.S. Eliot: An Essay in Counterpoint," in *English Miscellany* (1958), a study not of influences but of affinities and contrasts, not always expected; and "Pirandello and the Question-Mark of the Twentieth Century," in *A Short History of Italian Literature,* 2nd ed. (1969), a thumbnail account of Pirandello's work and importance; Glauco Cambon (ed.), *Pirandello: A Collection of Critical Essays* (1967), a helpful set of discussions of various aspects of Pirandello criticism; Oscar Budel, *Pirandello,* 2nd ed. (1969), a little book that will be more useful to those who already have some idea of the European background of Pirandello.

Piranesi, Giovanni Battista, also called GIAMBATTISTA PIRANESI (b. Oct. 4, 1720, Mestre, near Venice—d. Nov. 9, 1778, Rome), Italian draftsman, printmaker, architect, and art theorist, whose large prints depicting the buildings of classical and postclassical Rome and its vicinity contributed considerably to Rome's fame and to the growth of classical archaeology and to the Neoclassical movement in art.

At the age of 20 Piranesi went to Rome as a draftsman for the Venetian ambassador. He studied with leading printmakers of the day and settled permanently in Rome in 1745. It was during this period that he developed his highly original etching technique, producing rich textures and bold contrasts of light and shadow by means of intricate, repeated bitings of the copperplate.

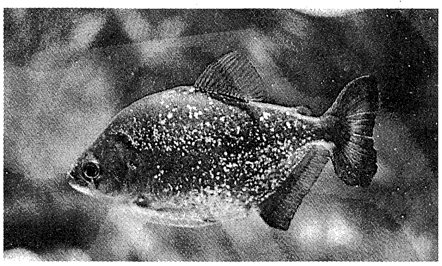
Piranesi created about 2,000 plates in his lifetime. The "Prisons" (*Carceri d'Invenzioni*) of *c.* 1745 are his finest early prints; they depict ancient Roman or Baroque ruins converted into fantastic, visionary dungeons filled with mysterious scaffolding and instruments of torture. Among his best mature prints are the series *Antichità Romane* (1756), the *Vedute di Roma* (appearing as single prints be-



"Veduta di Piazza Cavello," drawing from the series *Vedute di Roma* by Piranesi, *c.* 1748–60; in the British Museum
By courtesy of the trustees of the British Museum; photograph, J.R. Freeman & Co. Ltd.

tween 1748 and 1778), and the views of the Greek temples at Paestum (1777–78). His unparalleled accuracy of depiction, his personal expression of the structures' dramatic and romantic grandeur, and his technical mastery made these prints some of the most original and impressive representations of architecture to be found in Western art.

piranha, also called CARIBE, or PIRAYA, any of several species of carnivorous fishes of the genus *Serrasalmus*, in the characin family, Characidae, renowned for their voracity and reputed ferocity. Piranhas are abundant in rivers of eastern and central South America. Potentially one of the most dangerous species, *S. nattereri* attains a maximum length of about 60 centimetres (2 feet), but most species are smaller. Piranhas vary in colour: some are silvery with orange belly and throat, others are almost completely black. All have deep bodies, saw-edged bellies, and large, blunt heads with strong jaws bearing triangular, razor-sharp teeth that close in a scissor-like bite. Piranhas travel in groups and usually prey on other fishes. They are attracted to the scent of



Piranha (*Serrasalmus*)
Jim Annan—Annan Photo Features

blood and can reduce even a large animal to a skeleton in a short time.

pirarucu, also called ARAPAIMA, or PAICHE (*Arapaima gigas*), species of South American fish in the family Osteoglossidae (order Osteoglossiformes), one of the largest freshwater fishes in the world, attaining a length of 4.5 metres (14 feet). They belong to a group of fishes having primitive characteristics and an ancient fossil record. The pirarucu possesses a tail that appears unusually full and rounded because of the proximity of both dorsal and anal fins to the tail fin. The air bladder functions to permit limited air breathing.

pirate: *see* piracy.

pirate perch (*Aphredoderus sayanus*), freshwater fish, sole member of the family Aphredoderidae, found in weedy or muddy creeks, rivers, and lakes of eastern North America. Noteworthy is the peculiar position of its anus, which is located near the anal fin when the fish is young but gradually moves forward, to the throat, as the fish matures. The fish is small, greenish, and about 10 to 12.5 centimetres (4 to 5 inches) long. It is of no economic significance.

pirate spider, also called SPIDER-HUNTING SPIDER, any member of the family Mimetidae (order Araneida), noted for its habit of eating

Pirate spider (*Pirata piraticus*)
D.W. Greenslade—Ardea Photographics

other spiders. The approximately 100 species are distributed worldwide. They are characterized by a row of sharp bristles on the first pair of legs. Pirate spiders do not build nests or webs. They move slowly on low plants or among leaf litter.

Piratininga, city, São Paulo state, southeastern Brazil. Formerly called Patrimônio dos Inocentes, it was founded by the Portuguese explorer Martim Afonso de Sousa in 1532 and was colonized by Jesuits in 1554. In 1681 it succeeded São Vicente, on the coast near present-day Santos, as capital of the captaincy. Piratininga achieved city status in 1907 and became the seat of a municipality in 1913. Coffee growing and livestock raising are the main economic activities in the area. Rice, cotton, *feijão* (beans), and corn (maize) are also cultivated. Factories process coffee, cotton, rice, garlic, silk, and wine. Pop. (1980 prelim.) 5,833.

Pire, Dominique (Georges) (b. Feb. 10, 1910, Dinant, Belg.—d. Jan. 30, 1969, Louvain), Belgian cleric and educator who was awarded the Nobel Prize for Peace in 1958 for his aid to displaced persons in Europe after World War II.

Pire entered the Dominican Monastery of La Sarte, Huy, Belg., in 1928 and was ordained in 1934. From 1932 to 1936 he studied at the Dominican university in Rome and obtained his doctorate there in 1936. He returned to the Monastery of La Sarte to teach moral philosophy (1937–47). He was active in the World War II resistance movement and later became deeply involved in the enormous refugee problem. In 1949 he founded the Aide aux Personnes Déplacées, which sought to guarantee moral and material aid to displaced persons, regardless of their nationality or religion, and soon had branches throughout Europe. Between 1950 and 1954, Pire founded four "homes of welcome" in Belgium for aged refugees. Seven European "villages" were subsequently founded in Germany, Belgium, and Austria (1956–62). Pire also initiated the system of sponsors that allowed a refugee to be helped by a person in another country.

After accepting the Nobel Prize for Peace, Pire established (1960) in Huy the Mahatma Gandhi International Peace Centre, later known as the University of Peace, for instructing youths in the principles and practice of peace. He was also the founder of the World Friendships (to promote better understanding between races) and the World Sponsorships (to aid African and Asian refugees). Pire's *Bâtir la paix* (*Building Peace*) appeared in 1966.

Pirelli FAMILY, an Italian family of industrialists who contributed to the development of production and commerce in rubber goods, electric wire, and electric cable.

Giovanni Battista Pirelli (b. Dec. 27, 1848, Varenna, Como, Austrian Empire—d. Oct. 20, 1932, Milan) was educated in Milan, and it was there in 1872 that he started a small rubber factory, which was the first in Italy and one of the first in all of Europe. It pioneered the manufacture of electric cable (1884) and in 1899 began producing automobile tires. In 1902 the company began its foreign expansion by starting a subsidiary factory in Spain.

His two sons, Piero (b. Jan. 27, 1881, Milan—d. Aug. 7, 1956, Milan) and Alberto (b. April 28, 1882, Milan—d. Oct. 19, 1971, Casciano, Italy), joined the business in 1904. Factories were started—under the Société Internationale Pirelli of Basel, Switz.—in Great Britain, other European countries, Turkey, and the Americas; and eventually the Pirelli groups together employed more than 55,000 people. Piero Pirelli, chairman from 1932, greatly assisted the development of the Italian telephone service. His brother, Alberto, who was chairman from 1956 until his retirement in 1965, also was active in international affairs. He was a member of the Supreme Economic Committee of Versailles (1919), Italian dele-

gate to the first International Labour Office of Geneva (1920–22), a member of the League of Nations economic committee (1923–27), and a leading negotiator on war reparations and debts for the Dawes and Young committees (1924, 1929). He became a minister plenipotentiary in 1924 and a minister of state in 1938.

Pirelli SpA, international holding company and major Italian manufacturer of tires and other rubber products. It is headquartered in Milan. Three generations of the Pirelli family have managed the company since it was founded in 1872, at the outset of the rubber-tire industry. Nearly a century later, in 1971, the company merged with Dunlop Holdings, Ltd. (since 1981 a public limited company), a British tire maker also claiming a corporate history dating to the late 19th century. Under the terms of the merger, which brought together the resources of Europe's two largest tire and rubber companies, Dunlop–Pirelli Union operations were directed by a central coordinating committee that made policy recommendations pending the approval of both companies. At the same time, each company continued as a separate holding company and retained its existing trademarks. The union was not a success, however, and was dissolved in 1981. Some analysts attributed the breakup to nationalistic feelings on the part of both companies, stimulated by increasing competition in the industry from rising production costs that were linked to high oil prices.

A diversified company with operations in Europe, North and South America, the Middle East, and New Zealand, Pirelli sells more goods abroad than does any other Italian company. In addition to manufacturing tires, the company is also a major producer of metal cable and electrical equipment. One subsidiary specializes in making optical fibres for telecommunications cable. A major investor in the Fiat auto company of Italy, Pirelli contracted to make tires and rubber parts for cars made under Fiat license in the Soviet Union.

Pirenne, Henri (b. Dec. 23, 1862, Verviers, Belg.—d. Oct. 24, 1935, Eccle, near Brussels), Belgian educator and scholar, one of the most eminent scholars of the Middle Ages and of Belgian national development.

The son of a well-to-do industrialist, Pirenne studied for his doctorate (1883) at the University of Liège under the medievalist Godefroid Kurth and the historian of the Low Countries Paul Frédéricq. After attending the universities of Leipzig and Berlin and the École des Hautes Études in Paris, he began teaching paleography and diplomatics at the University of Liège in 1885. The following year he moved to the University of Ghent, where he remained until his retirement in 1930, as professor of medieval and Belgian history. He was imprisoned by the Germans (1916–18) for refusing to teach while they occupied Belgium. While in prison he composed from memory a history of Europe that was published after his death.

Pirenne's first important book was *Histoire de la constitution de la ville de Dinant au moyen âge* (1889; "History of the Constitution of the City of Dinant in the Middle Ages"), a study of medieval town life that became one of the major themes of his later works. His greatest work, *Histoire de Belgique,* 7 vol. (1900–32; "History of Belgium"), gained him international respect for his innovative approach to socioeconomic developments in town life and his contention that Belgian unity was not the result of ethnic identification or political centralization but instead emerged from the position of Belgium as a centre of industrial and intellectual commerce between Latin and Germanic cultures.

A series of lectures delivered at Princeton University in 1922 was published as *Medieval Cities* (1925), the classic exposition of Pirenne's analysis of the revival of urban centres and commercial activity during the late Middle Ages. In a work published posthumously, *Mahomet et Charlemagne* (1937), he set forth his now celebrated thesis that the Roman Empire and civilization declined not as a result of Germanic invaders, but rather because of Arab primacy in the Mediterranean by the 8th century. The decline of international trade and the disintegration of a money economy, he contended, brought about a regression to a less sophisticated, closed agricultural system based on a local subsistence economy and a stratified class system. His radical reinterpretation of the transition between Roman and medieval civilizations stimulated a great deal of criticism and controversy, particularly his almost exclusively economic interpretation of causation in history.

Pirenne's other works include *Origine des constitutions urbaines au moyen âge* (1895; "The Origins of the Constitutions of Medieval Cities"), *Les anciennes démocraties des Pays-Bas* (1910; "The Old Democracies of the Low Countries"), and *La Fin du moyen âge* (1931; "The End of the Middle Ages"). He also served as director of the Belgian Royal Commission on History and as the first president of the International Historical Congress, beginning at Brussels in 1923.

Pires, Diogo: *see* Molcho, Solomon.

Pírgos (Greece): *see* Pyrgos.

Piriatin (Ukrainian S.S.R.): *see* Piryatin.

Pirithous, also spelled PEIRITHOUS, in Greek mythology, the companion and helper of the hero Theseus in his many adventures, including the descent into Hades to carry off Persephone, the daughter of the goddess Demeter. They were detained in Hades until the Greek hero Heracles rescued Theseus but not Pirithous.

Pirithous originally belonged to the Lapiths, a northern mountain tribe, and probably his earliest legend was that of his marriage to Hippodamia (daughter of Butes the beemaster). The Centaurs, who had come to the wedding as guests, in drunken fury tried to violate the bride and her attendants; this led to the battle of the Lapiths and the Centaurs, a favourite subject of Greek art.

Pirkkalaiset (Scandinavian frontiersmen): *see* Birkarlar.

Pirmasens, city, Rhineland-Palatinate *Land* (state), southwestern Germany, near the French border. Named for St. Pirmin, who was supposed to have preached Christianity there in the 8th century, it originally belonged to the counts of Hanau-Lichtenberg but passed to Hesse-Darmstadt in 1736. Chartered in 1763, it was taken by the French in 1794 and passed to Bavaria in 1816. It was largely rebuilt after severe damage in World War II. An important shoe industry developed there in the 19th century; the city holds international shoe trade fairs and is the site of an internationally known technical school of shoemaking. It is the terminus of a branch of the railway linking Landau with Zweibrücken. Pop. (1989 est.) 47,102.

Pirmez, Octave (b. April 19, 1832, Châtelet, Belg.—d. May 1, 1883, Acoz), one of the outstanding Belgian men of letters of the period immediately before the literary revival of the 1880s. His works consist primarily of collections of essays, letters, and literary discussions; *e.g., Pensées et maximes* (1862; "Thoughts and Maxims") and *Heures de philosophie* (1873; "Hours of Thought").

A gentleman of private means, Pirmez led an uneventful life, interrupting the placid stays in his castle only for leisurely tours in France, Germany, and Italy. His temperament was retiring and reflective, and he was deeply influenced by such French writers as Rousseau and Chateaubriand, whose melancholy appealed to him, as did their love of nature.

Pirmez was deeply interested in Montaigne and Pascal, whose influence on the style and content of his maxims and philosophical notes is unmistakable. His view of man was pessimistic, for he considered that human reason was incapable of controlling sentiments and passions. The hallmark of Pirmez's work is its stylistic elegance and purity. There is little that is essentially Belgian about his writing, and the tradition within which he worked was already passing in France. But, over a period when there were very few distinguished Belgian authors, Pirmez was outstanding.

pirogue, Spanish PIRAGUA, in its simplest form, a dugout made from one log, but also a number of more elaborately fashioned boats, including various native canoes, the structure and appearance of which generally resemble those of a dugout. Widely distributed, the pirogue may be found as a fishing vessel in the Gulf of Mexico; as a shallow-draft boat that is used to manoeuvre through the Louisiana swamplands; and as a boat used by the Indians of Guyana. Pirogues may be broadened by constructing them from two curved pieces or deepened by affixing planks to their sides. *Compare* canoe.

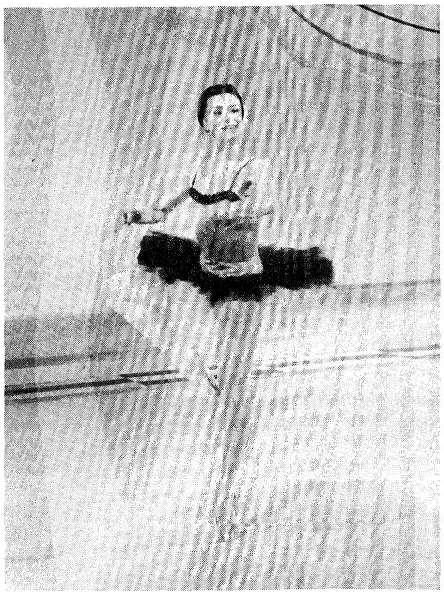
Piron, Alexis (b. July 19, 1689, Dijon, Fr.—d. Jan. 21, 1773, Paris), French dramatist and wit, famous for his epigrams and remembered for his comedy *La Métromanie* (1738). Piron was secretary to a banker and then studied law. He moved to Paris in 1719, where he worked as a copyist, struggling meanwhile to enter the world of letters. After *Arlequin Deucalion* (1722) and other successful pieces written for the popular Théâtres de la Foire, Piron produced *Les Fils ingrats* at the Comédie-Française in 1728. *La Métromanie,* a witty, urbane comedy portraying himself as a young poet intoxicated with literary aspirations, remains his most distinguished play; it was revived at the Comédie-Française until well into the 19th century. His tragedies included the moderately successful *Gustave Wasa* (1733). Having achieved a modest fame, Piron acquired noble patrons and the entree to several literary salons but continued to live an independent, carefree life and became known for his ready wit and his epigrams.

King Louis XV vetoed Piron's election to the Académie Française in 1753 because of the licentious *Ode à Priape*, which he had written as a young man. However, he was given a royal pension, and he took his revenge on the Académie in one of his most celebrated epigrams: Here lies Piron, who was nothing, Not even a member of the Academy.

piroplasmid, any protozoan of the class Piroplasmea, now generally classified with other sporozoan groups, although atypical in many ways. *See* sporozoan.

piroplasmosis (animal disease): *see* babesiasis.

pirouette (French: "to whirl about"), ballet turn in place on one leg. The pirouette is often done in spectacular series, which women usually perform on toe (pointe) and men on the ball of the foot (demi-pointe). In a *pirouette sur le cou-de-pied,* the raised foot rests on the supporting ankle; in a *pirouette à la seconde* or *grande pirouette,* it is extended in the second position at a 90° angle to the supporting leg. The leg may be held at the front (attitude), side (*à la seconde* or *grande pirouette*), or back (arabesque and attitude). The body may turn toward the raised leg (*en dehors:* "outside" or "backward") or the supporting leg (*en dedans:* "inside" or "forward").



Pirouette en dehors executed by Melissa Hayden; solo variation from "Don Quixote" pas de deux
Fred Fehl

Four and five pirouettes are now commonly performed, and up to 14 have been executed by 20th-century dancers.

Pirquet, Clemens, Freiherr von (baron of) (b. May 12, 1874, Vienna—d. Feb. 28, 1929, Vienna), Austrian physician who originated a skin test for tuberculosis that bears his name.

Von Pirquet attended the universities of Vienna, Königsberg, and Graz and graduated from Graz in 1900. He became a professor of pediatrics at Johns Hopkins University in Baltimore in 1908, a position he held for two years before returning to Austria.

In 1906 von Pirquet noticed that patients who had received injections of horse serum or smallpox vaccine usually had quicker, more severe reactions to second injections. He used the word allergy to describe the reactions. While studying the symptoms of cowpox vaccination, he also developed a new theory about the incubation time of infectious diseases and the formation of antibodies.

In Von Pirquet's skin test for tuberculosis, a drop of tuberculin is scratched into the surface of a small area of skin. The development of a red, raised area at the site of application, called Pirquet's reaction, indicates the presence of tuberculosis. In 1909 he published the results of a series of tuberculin tests of inhabitants of Vienna that showed that 70 percent of the children tested had been infected by tuberculosis by the age of 10 and more than 90 percent by the age of 14.

Pirrie (of Belfast), William James Pirrie, Viscount, also called (1909–21) BARON PIRRIE OF BELFAST (b. May 31, 1847, Quebec—d. June 7, 1924, at sea), Irish shipbuilder who controlled the largest ship-construction firm in the world and built the liner "Titanic."

In 1862 Pirrie became apprentice to the Belfast shipbuilding firm of Harland and Wolff. By the time he was 27 he had been made a partner and was soon left in almost exclusive control. He travelled widely to gain experience in ship design and to study practical shipping requirements. He contributed much to the burgeoning steel shipbuilding industry, and for many years the largest passenger liners in the world came from his yards, notably the "Olympic," the "Britannic," and the "Titanic." Pirrie was also prominent in the development of the diesel engine for marine propulsion.

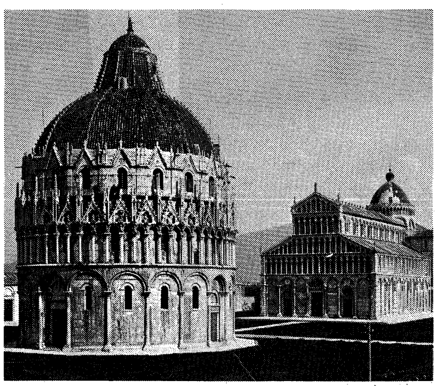
Pirrie
BBC Hulton Picture Library

Created a baron in 1906, Pirrie became a viscount in 1921. As comptroller general of merchant shipbuilding in 1918, he helped replace British shipping lost to submarine warfare. He was also mainly responsible for introducing the idea of standardizing ships, a principle that was adopted in Britain and the U.S. during World War II.

Pirrie's marriage was childless, and the peerage became extinct at his death.

Piryatin, also spelled PIRIATIN, city and centre of a *rayon* (district), Poltava *oblast* (administrative region), Ukrainian Soviet Socialist Republic, on the Uday River. Piryatin dates at least from 1155, when it is first documented, and was incorporated in 1781. Before the Revolution of 1917 it was an administrative centre and later became a railway junction. Today it has varied industries, including furniture, building materials, and foodstuffs. Pop. (1970) 16,000.

Pisa, capital of the province of Pisa, central Italy, in the region of Tuscany (Toscana). It is situated on the Arno River, about 6 mi (10 km) from the Ligurian Sea. Ancient Pisa, or Pisae, was possibly inhabited by the Ligurians before passing under Roman control as a naval base. It became a Roman colony shortly after 180 BC and by AD 313 had become a Christian bishopric.



Baptistery and cathedral, Pisa, Italy
Alinari—Art Resource/EB Inc.

During the Middle Ages it was a powerful Tuscan city-state and a flourishing commercial centre. In the 11th century Pisa not only exploited the products and markets of its large Tuscan hinterland but it also took the initiative against Muslim raiders; in 1016 the Pisans and Genoese drove the Saracens from Sardinia, and in 1063 the Pisan fleet sacked Muslim Palermo. Participation in the Crusades secured valuable commercial positions for Pisan traders in Syria. Pisa usually enjoyed the support of the German emperors in its long conflicts with Genoa at sea and with its Tuscan rivals, Lucca and Florence, on land. These struggles culminated in Pisa's defeat by the Genoese fleet at the decisive Battle of Meloria in 1284. Large quantities of merchandise continued to pass through the city until the 15th century, when silting, accompanied by changes in land levels and in the course of the river, made the movement of laden galleys up the Arno almost impossible.

Pisan prosperity was reflected in the characteristic *casatorre,* a tall inhabited tower usually built of brick and stone, and in the city's churches, particularly the grandiose and spectacular group of cathedral, baptistery, and campanile (the leaning tower). The cathedral and the baptistery were decorated by a succession of distinguished sculptors, including Guglielmo Pisano, who made the cathedral's first pulpit (1162); Bonanno Pisano, sculptor of its bronze doors (1180); Nicola Pisano, who carved the baptistery pulpit (1260); and Nicola's son Giovanni Pisano, sculptor of the existing cathedral pulpit (1310).

Internal struggles helped to bring about the occupation of Pisa by the Florentines in 1406. When French armies invaded Italy in 1494, Pisa temporarily reasserted its independence; the city sustained a series of wars and sieges until Florence reconquered it in 1509. Thereafter it declined as a provincial Tuscan town.

The birthplace of Galileo Galilei (1564–1642), Pisa remains the seat of an archbishopric and of a great university. It is also an important railway junction, and its light industries have brought prosperity. Widespread destruction in World War II diminished Pisa's charm, but tourists continued to flock there to see the world-famous leaning tower, now in some danger of collapse. Pop. (1983 est.) city, 104,554; province, 389,391.

Pisa, Council of, in Roman Catholic Church history, a council convened in 1409 with the intention of ending the Great Schism, when rival popes, each with his own Curia (bureaucracy), were set up in Rome and Avignon. This meeting, the result of concerted action by cardinals of both obediences, was well attended. It deposed the two existing pontiffs, who refused to cooperate, and elected a third, Alexander V. Western Christendom was therefore divided into three parties until the Council of Constance (1414–18) forced the three contending popes to resign and elected Oddone Colonna, a Pisan cardinal, as Pope Martin V. The Council of Pisa has never been regarded as valid by canonists or theologians.

Pisaca languages, also spelled PISACHA: *see* Dardic languages.

Pisanello, Il, original name ANTONIO PISANO (b. *c.* 1395, Pisa—d. 1455), Italian medalist and painter, an outstanding exponent of the International Gothic style. His early work suggests that he was the pupil of Stefano da Zevio, a Veronese artist. (He was wrongly called Vittore by Vasari and not until 1907 was his personal name verified as Antonio.)

Pisanello collaborated with Gentile da Fabriano on frescoes in the Doges' Palace in Venice (*c.* 1415–22) and in St. John Lateran in Rome (after 1427). After Gentile's death, Pisanello probably completed the Roman frescoes, known only through drawings, which show Gentile's great influence over the young Pisanello. His only surviving frescoes are an Annunciation at the tomb of Niccolò di Brenzoni in S. Fermo in Verona (*c.* 1423–24) and the legend of St. George in the Pellegrini Chapel in S. Anastasia, Verona (*c.* 1433–38). These works are characterized by the curvilinear design, calligraphic draperies, and decorative detail typical of the International Gothic style from which Pisanello never completely freed himself. Even a mature work such as his "St. Eustace" (National Gallery, London) is encrusted with rich detail that tends to work against spatial clarity. The "Madonna with SS. Anthony and George" (National Gallery) displays a simpler conception. It is dominated

"Madonna with SS. Anthony and George," painting by Antonio Pisanello, after 1422; in the National Gallery, London

By courtesy of the trustees of the National Gallery, London; photograph, J.R. Freeman & Co. Ltd.

by the monumental figures of the two saints and the bust of the Virgin in a mandorla, or almond-shaped aureole.

Pisanello's fame and his importance in court circles rested more upon his medals than upon his painting. They are thought to have resulted from his study of ancient Greek and Roman numismatic portraits. He had virtually no recent predecessors, and, with him, the art reached its highest point. His work includes the medal of the Greek emperor John VIII Palaeologus (1438), the wedding medal of Lionello d'Este (1444), Sigismondo Pandolfo Malatesta (1445), and the medal of Alfonso of Aragon (1448), generally cited as his most successful work in the genre. Most of Pisanello's painted portraits, such as the "Margherita Gonzaga" (*c.* 1438; Louvre, Paris), and "Lionello d'Este" (*c.* 1440; Accademia Carrara, Bergamo), show the sitter in profile (a convention of Pisanello's portrait medals) against a background of delicate, colourful flowers and butterflies.

Pisanello's drawings have been preserved in the Codex Vallardi (Louvre, Paris). This is the only instance in which the drawings of a 15th-century workshop have been preserved virtually intact. They are of unique value, therefore, for the study of the style and techniques of draftsmanship of the period. Pisanello uses a large variety of techniques and materials to produce masterful drawings (some coloured) of animals, plants, costume design, and perspective studies. His drawings of various views of horses are particularly well known. He was one of the first 15th-century artists to draw from life instead of adhering to the medieval tradition of copying the drawings of others. The drawings reveal Pisanello's breadth of interest and his sensitive eye. They combine delicately rendered Early Renaissance naturalism with the beauty of Late Gothic line and are one of his most important contributions to the history of art.

Pisani, Niccolò (fl. 14th century), Venetian admiral, renowned for his victories in the third war between the feuding republics of Venice and Genoa (1350–55).

In 1350 Pisani led a squadron to Constantinople (now Istanbul) to conclude an alliance with the Byzantines. At the mouth of the Bosporus he engaged in a fierce battle with the Genoese, defeating the distinguished admiral Paganino Doria (1352). A year later, surprising the Genoese fleet, he sank 33 enemy galleys and took 4,500 prisoners, who were later executed. In November 1354, however, Doria surprised him at Portolungo, near Greece. The Genoese admiral's audacity and tactical skill enabled him to capture Pisani and his entire fleet. Pisani was released when the two cities made peace (May 1355), and he spent the rest of his life in obscurity.

Pisani, Vettore (b. 1324, Venice—d. Aug. 15, 1380, Manfredonia, Apulia, Kingdom of Naples), Venetian admiral, victor in a decisive battle in the fourth war between the maritime republics of Venice and Genoa.

Pisani joined his father Niccolò during the third war with Genoa (1350–55) and later distinguished himself in a war against Hungary. Named captain and senator, he led a squadron against the Aragonese fleet and the pirates in the waters near Sicily.

In 1378 he was given command of the Venetian fleet, which he directed to victory over the Genoan fleet at the Capo d'Anzio (May 1378). He later held the Genoan fleet on the Adriatic in check, after sacking Cattaro (modern Kotor, Yugos.) and destroying the port of Sebenico (modern Šibenik, Yugos.). Eventually, however, he and his fleet were captured by the enemy at Pola (modern Pula, Yugos.; May 1379). On his return to Venice, he was imprisoned, but popular protest secured his release. Given command once again of the Venetian fleet, he blockaded the port of Chioggia, occupied by the Genoans, who were finally compelled to surrender, turning over to Pisani some 19 galleys and more than 4,000 prisoners. Dispatched to confront another Genoan squadron in the Adriatic, Pisani fell ill and died.

Consult the INDEX *first*

Pisano, Andrea, also called ANDREA DA PONTEDERA, (b. *c.* 1270–90, Pontedera, near Pisa—d. *c.* 1348–49, Orvieto, Papal States), one of the most important Italian sculptors of the 14th century whose chief works were executed in Florence, where he came under the influence of Giotto. Andrea is recorded as the author of the earliest of three bronze doors for the baptistery of the cathedral of Florence, which, completed in 1336, has 20 quatrefoil panels with scenes from the life of St. John the Baptist and 8 with figures of the virtues. The figures are gilded and set against a smooth bronze surface.

"The Baptism of Christ," bronze panel from the south door of the Baptistery, Florence, by Andrea Pisano, completed 1336

Brogi—Alinari from Art Resource/EB Inc.

On the death of Giotto, in 1337, Andrea succeeded him as the chief architect in charge of the construction of the campanile (bell tower) of the cathedral of Florence, to which he added two stories adorned with panel reliefs. Most of the reliefs on the lower part, depicting the arts, sciences, and occupations of man and three scenes from Genesis, are generally attributed to Andrea and his studio. Statues in niches of the campanile (originally placed above the reliefs now in the cathedral museum), representing David and Solomon and two sibyls, have been attributed to Andrea, but this has been disputed. Two statuettes of Christ and Saint Reparata also in the cathedral's museum are generally considered his.

The iconography of the baptistery door was indebted to the mosaics on the interior of the building and to Giotto's frescoes in Sta. Croce. The composition of the door was influenced by that of the bronze doors of the cathedral of Pisa. Andrea's style is marked by a simplicity, restraint, and skillful arrangement of figures that places him in the front rank of the sculptors of the period.

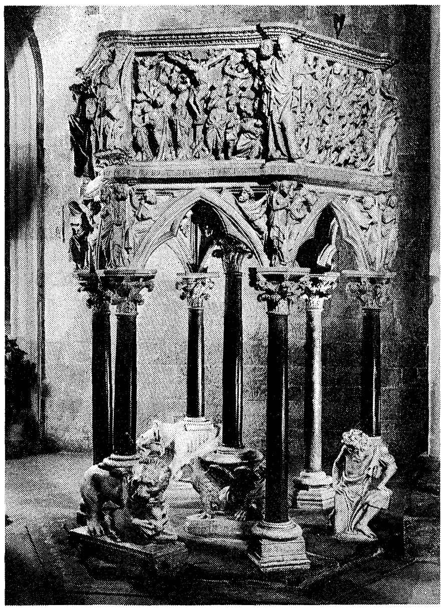
He is last recorded as superintending architect of the cathedral of Orvieto, in which office his son Nino succeeded him.

Pisano, Antonio: *see* Pisanello, Il.

Pisano, Giovanni (b. *c.* 1250, Pisa—d. after 1314, Siena?), sculptor, sometimes called the only true Gothic sculptor in Italy. He began his career under the classicist influence of his father, Nicola, and carried on this tradition after his father's death, continuously reintegrating the antique style into more northerly and contemporary Gothic forms.

Pisano began his career in his father Nicola Pisano's workshop and so thoroughly assimilated the ideas he found there that his early work is difficult to distinguish from that of his father. It was in the contract (1265) for the pulpit in the Siena cathedral that Pisano is first specifically mentioned as an assistant to his father. Since he was at that time not referred to as "magister," or independent master craftsman, Pisano must still have been in his teens. At any rate, by September 1285 he had rejected his Pisan citizenship and had become a resident of Siena. Around this time he began his work on the design and sculptural ornamentation of the facade for the cathedral of Siena which became, in its lavishness and ordering, the model for virtually all future Gothic facade decoration in central Italy. Unlike French examples, in which figural ornament pulsates over the entire facade, Pisano's designs for the Siena facade offer a much more architectural approach to the problem. The lower story is simply decorated with colonnettes (small columns) and a restrained foliate pattern, which follows the vertical movement of the colonnettes. Aside from the carved lintels over the doors, figural sculpture begins at the level of the arches over the entrances with slightly larger than life-size figures of prophets and sibyls and continues throughout the rest of the facade. Although each figure inhabits a discrete niche, agitated, forward-bending poses cause them to converse across the vast space of the facade and soften the otherwise clearly stated architectonic lines that order the structure. Recent research has emphasized particularly close relationships in design between the sculpture of the Siena facade and French foliate patterns and figural reliefs, especially from the cathedral at Auxerre. Since there are no known documentary references to Giovanni Pisano between 1268 and 1278, the possibility of a trip through France during these years seems extremely likely.

Next to the Siena cathedral facade, Pisano's pulpit in Pistoia, completed in 1301, is his greatest achievement. The five narrative reliefs of this pulpit roughly parallel the subject matter of his father Nicola's Pisa pulpit 40 years earlier, as does the overall architectural format, but the style pushes the expressive qualities innate in Nicola's Pisa pulpit to a new level of intensity. In the "Annunciation," the "Nativity," and the "Annunciation to the



Marble pulpit in the church of S. Andrea, Pistoia, Italy, by Giovanni Pisano, 1297–1301
SCALA—Art Resource/EB Inc.

Shepherds," the extreme agitation that characterizes all the reliefs for the Pistoia pulpit pulsates throughout the panel. Figures, animals, drapery, and landscape features are wrenched into physically impossible configurations; light shatters over the broken surfaces and deeply cut relief; and each figure responds convulsively to the individual situations in which he acts as a participant. What is critical to the change in style from the first Pisa pulpit reliefs to the Pistoia reliefs is a preference for an overall agitated and deeply cut surface as opposed to the earlier more massive and monumental organization of forms.

Pisano never repeated the frenzy of forms that covers the Pistoia pulpit. Instead he returned to the more stately, classical spirit that had been at the heart of his father's earliest work. The reasons for this cannot be documented, but they most likely stem in part from Giovanni's experience with Giotto's monumental and heroic style which was already in the ascendancy by the time that the Pistoia pulpit was completed. Pisano, in fact, carved a marble Madonna and Child for the Arena Chapel in Padua at approximately the same time that Giotto painted his profoundly moving fresco cycle there (*c.* 1305). In addition, the quasi-imperial political movements established by Pope Boniface VIII at the turn of the 14th century may also have prompted him to return to more overtly classical quotations.

From 1302 to 1310 Pisano again worked in Pisa, this time for a pulpit for the cathedral. In this pulpit, now badly reconstructed after having been disassembled, the relief style is considerably more docile than that of the Pistoia reliefs. His last recorded work was a tomb sculpture for Margaret of Luxembourg in Genoa in 1311 (fragments now in the Palazzo Bianco). He was last recorded in Siena in 1314, and it is presumed that he died shortly thereafter. If, as is clear from his work in Siena, Pisano was Italy's only Gothic sculptor, it is also true that he never lost sight of the heritage of classical Rome that underlies all of the artistic thinking of central Italy.

MAJOR WORKS. Fontana Maggiore (with Nicola Pisano) (1278; Perugia, Italy); external decoration of the Baptistery, Pisa (1278–85; Pisa); sculptural decoration of the facade, Siena cathedral (1284; Siena, Italy); pulpit (1297–1301; S. Andrea, Pistoia, Italy); pulpit (1302–11; Cathedral, Pisa); tomb of Margaret of Luxembourg (originally in S. Francesco di Casteletto, Genoa, but now destroyed, 1311; fragments in Palazzo Bianco, Genoa; Palazzo Rosso, Genoa).

Pisano, Nicola (b. *c.* 1220, Apulia?—d. 1278/84, Pisa?), sculptor whose work, along with that of his son Giovanni and other artists employed in their workshops, created a new sculptural style for the late 13th and the 14th centuries in Italy.

Pisano's origins are unclear. He is first recorded in 1260 in Pisa (or perhaps 1259, if corrections are made for the medieval Pisan calendar), but documents of 1266 twice call him "Master Nicola from Apulia," Apulia being the province located in the southeastern section of the Italian peninsula. While most scholars now accept an Apulian birth for Pisano, there is still little known about his artistic training. His sculptural training, in line with medieval practices, was probably obtained through an apprenticeship in an already established workshop. If he began his training in Apulia he would most likely have been taught by one of the army of craftsmen whom the Hohenstaufen emperor Frederick II had employed to decorate his vast new building projects. Frederick's artists consciously imitated an ancient Roman style of sculpture in order to give visual support to his role as the Holy Roman emperor. If on the other hand, Pisano had actually left Apulia before receiving his sculptural training, he might have apprenticed himself to either local Tuscan or Lombard workshops; strong echoes of both regional styles appear in his work.

Although no work can definitely be attributed to Pisano before his pulpit in the cathedral of Pisa (1259/60), the strong classical spirit that motivates its forms suggests more than simple first-hand experience and fascination with then visible ancient Roman sculpture. Quite specific formal motifs in the figures of the Pisa pulpit compare closely with sculptural fragments representing Jupiter and imperial advisers from Frederick's triumphal gateway over the Via Appia at Capua (now in the Museo Provinciale Campano in Capua) and argue persuasively for Pisano's training in the artistic workshops of the Emperor. Pisa's close alliance with the empire of Frederick II, even after Frederick's death in 1250, would

"Adoration of the Magi," detail of the marble pulpit in the Baptistery at Pisa, by Nicola Pisano, *c.* 1255–60
Alinari—Art Resource/EB Inc.

have provided good reasons both for his emigration to that city and for the rather sudden emergence of the overtly classicizing style of the pulpit which he carved.

The Pisa pulpit marks one of the extraordinary moments in the history of Western art when a new style, distinct from all its predecessors, though indebted to them, clearly asserted itself and opened new avenues for artistic expression drawing on the widest possible range of artistic motifs—Roman reliefs, early Christian fresco and mosaic decorations, and localized Tuscan and Lombard forms, as well as isolated motifs deriving from French Gothic sculpture and architecture, about which Pisano may have learned either by visiting French-influenced centres in Apulia or by an actual trip to France. He assimilated this encyclopaedic array of artistic expressions and transformed them into a brilliantly unified whole that gave new grandeur and new energy to his narratives and a new sense of direction to art in Tuscany from 1260 onward.

Pisano's style changed dramatically during the carving of the Pisa pulpit—from the amplitude of form and rhythmic fluency of movement evident in the relief panel of "The Presentation of Christ in the Temple," to a greatly more agitated treatment of the space and forms in which figures become smaller in relationship to the entire surface area of the relief and pile up on one another in a surface rather than a spatial organization. The figures themselves become more animated and are twisted to emphasize their dramatic potential more fully. Rather than being a rejection of Pisano's earliest known style, however, this later style in fact grew directly out of his concern for presenting the human emotional content of his subject matter. Some of this stylistic change, especially the last two reliefs from the Pisa pulpit, may also be attributable to apprentices or members of his workshop, including Giovanni Pisano, his son. Nicola Pisano's workshop, including Giovanni Pisano, Fra Guglielmo, and Arnolfo di Cambio, also shared in his next commissions, the pulpit for the cathedral of Siena, 1265–68, and the Fontana Maggiore in the main square of Perugia of 1278. In the Siena pulpit, the form of which is much like that of the Pisa pulpit, Pisano continued the investigations of expressive human figures which permeate the Pisan reliefs. Yet, although his authorship of the design is evident throughout the pulpit, the individual dispositions of the various assisting sculptors toward ancient Roman or Gothic forms is equally obvious; the separate strains of the two traditions that Pisano had so successfully united in the Pisa pulpit again reassert their independence at Siena. This uneasy relationship between the antique and the Gothic becomes increasingly clear at Perugia, where the 25-sided fountain mixes tales from Romulus and Remus with fables from Aesop, classical personifications of nearby places with representations of the liberal arts and the labours of the months, and contemporary historical figures with Old Testament characters and heraldic animals. The shifts in the style of the sculpture at Perugia were also influenced by the fact that single figures were employed rather than complex narratives as in Pisano's earlier work.

BIBLIOGRAPHY. E. Bertaux in *L'Art dans l'Italie mèridionale* (1904), is still important for his early discussion of Nicola's Apulian connections. G.H. and E.R. Crichton carried this discussion into English in *Nicolo Pisano and the Revival of Sculpture in Italy* (1938), but their arguments lack focus and oftentimes substance as well. C. Gnudi, *Nicola, Arnolfo, Lapo* (1948), is important for his discussion of Nicola's studio (in Italian). C. Seymour, Jr., "Invention and Revival in Nicola Pisano's 'Herioc Style'," *Studies in Western Art: Acts of the Twentieth International Congress of the History of Art,* vol. 1, pp. 207–226 (1963), reviews recent literature for Nicola and gives cogent political reasons for Nicola's classicizing style; he also carries the heroic mode of Nicola's sculpture into the 15th century. W.R. Valentiner's article on Nicola's Apulian connections, "Studies on Nicola Pisano," *Art Quarterly,* 15:9–36 (1952), is still useful.

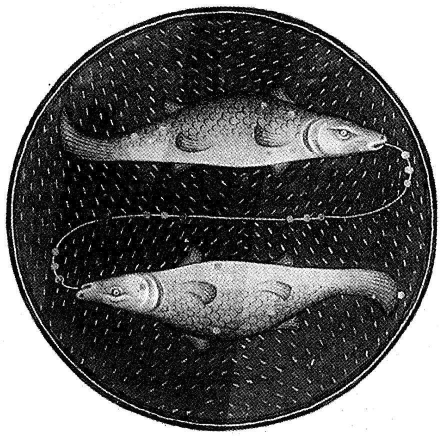
Piscator, Erwin (b. Dec. 17, 1893, Ulm, Ger.—d. March 30, 1966, Starnberg, W.Ger.), theatrical producer and director famed for his ingenious Expressionistic staging techniques; the originator of the epic theatre style later developed by the German playwright Bertolt Brecht.

Having studied at the König school of dramatic art and the university, Piscator began as a volunteer at the Hoft Theater; he became in turn an actor and director. Working in Berlin during the Weimar Republic (1919–33), Piscator frankly used the theatre to convey radical political instruction. Though not a communist, he sympathized at the time with the German working-class parties. A bold innovator, he used films and newsreels to enlarge landscapes and convey mass events, and he employed many optical, acoustical, and mechanical devices to create an experience of total theatre. His passion for machinery could be self-defeating, for sometimes the blaring loudspeakers, flashing lights, air-raid sirens, and revolving sets prevented the viewers from getting the message. In exile during World War II, he headed the Dramatic Workshop of the New School for Social Research in New York City, from 1939 to 1951, when he returned to West Germany as director of West Berlin's Volksbühne. He continued to produce sensational works, such as Rolf Hochhuth's *Deputy,* a study of the role of Pope Pius XII during the Nazi era, and *The Investigation* by Peter Weiss, dealing with the mass murders at Auschwitz concentration camp.

John Willett's *The Theatre of Erwin Piscator: Half a Century of Politics in the Theatre* was published in 1979.

Pisces (Latin: Fishes), in astronomy, zodiacal constellation lying between Aries and Aquarius, at about 1 hour right ascension (the coordinate on the celestial sphere analogous to longitude on the Earth) and 15° north declination (angular distance north of the celestial equator). The vernal equinox, the point where the Sun's annual apparent path takes it north



Pisces, illumination from a Book of Hours, Italian, *c.* 1475; in the Pierpont Morgan Library, New York City (MS. G.14)

By courtesy of the Pierpont Morgan Library, New York, the Glazier Collection

of the celestial equator and from which celestial longitude and right ascension are measured, lies now in Pisces. The constellation contains only faint stars without any striking grouping.

In astrology, Pisces is the 12th sign of the zodiac, considered as governing the period *c.* February 19–*c.* March 20. Its representation as two fish tied together is usually related to the Greek myth of Aphrodite and Eros, who jumped into the river to escape the monster Typhon and changed into fish, or, alternatively, the two fish that carried them to safety.

piscina, in Roman times, an artificial reservoir used for swimming or as a fish pond. During the Middle Ages a piscina was a pool or tank in which fish were stored by monastic communities, for whose members fish was a staple item of diet.

Although never a calculated feature of gardens, existing ponds or fish stews (tanks) were sometimes later incorporated in decorative schemes. At Monticello, Thomas Jefferson's home near Charlottesville, Va., an original piscina has been restored.

A stone vessel having a drain that leads directly to the ground, located near an altar of a church, and used for disposing of water from ablutions is also known as a piscina.

Pisco, city, Ica department, southwestern Peru, Pacific port at the mouth of the Río Pisco. Founded in 1640 by Pedro Toledo y Leiva, it was devastated by an earthquake in 1682 and by a tidal wave in 1686. It was incorporated as a city in 1898. Pisco (Quechua Indian for "bird") is noted for its brandy made from muscat grapes. Other economic activities include subsistence farming, milling of cottonseed oil, textile manufacturing, and fishing. The Bahía (bay) de Paracas, to the south, sheltered by the Península Paracas, is a resort area. On the peninsula is the Paracas Necrópolis (pre-Inca ruins). Pop. (1981 prelim.) 55,604.

Pisemsky, Aleksey Feofilaktovich (b. March 23 [March 11, old style], 1821, Ramenye, Kostroma province, Russia—d. Feb. 2 [Jan. 21, O.S.], 1881, Moscow), novelist and playwright whom many critics rank with the great masters of Russian Realism, though his Realism borders on Naturalism and he lacks the philanthropic conscience that informs the work of his great contemporaries.

Pisemsky came from an impoverished noble family, attended Moscow University, and was a civil servant in his native province when his first stories attracted attention in reviews. In 1854 he moved to St. Petersburg, where his lack of refinement, reactionary opinions, and general failure to conform to the image of a cultured liberal gentleman estranged him from literary society. His best achievements are the novel *Tysyacha dush* (1858; "A Thousand Souls"), a memorable portrait of a "new man," Kalinovich, who marries, in spite of his love for another girl, the crippled heiress of "a thousand souls" (serfs) and climbs to the rank of provincial governor, a post he fills with impeccable integrity. Pisemsky's tragedy *Gorkaya sudbina* (1859; "A Bitter Lot"), is one of the masterpieces of the Russian theatre. Pisemsky was further estranged from his colleagues and public by a novel satirizing the radical younger generation, *Vzbalamuchennoye more* (1863; "The Stormy Sea"). The critical attacks directed against him by the radicals obscured his reputation.

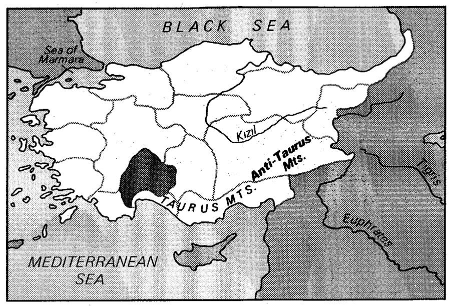
Pishīn, town and administrative headquarters of Pishīn district (once part of the former Quetta-Pishīn district), Quetta division, Baluchistan province, Pakistan. The present town, founded by the British as a military and civil station in 1883, is a market centre and has a noteworthy rest house with a fine garden. It is connected by road with nearby Quetta city.

Pishīn district is located north of Quetta district and fronts Afghanistan on the east and northeast. It comprises a series of long valleys 4,500–5,500 ft (1,370–1,680 m) above sea level enclosed by the Toba Kākar Range to the north; vegetation is sparse. The district is drained by the Pishīn Lora River and its tributaries. Crops grown in the valleys include wheat, barley, corn (maize), and potatoes; grapes, apples, apricots, and peaches are also economically important. Sheep and goats are herded. The main ethnic groups are Pashtun Kākaṛ and Tarīn. Wool, carpets, and sheepskin coats are locally produced; coal is mined. A major road and railway (completed 1888) connect Quetta city with Chaman, a commercial town, near the Afghanistan border. The railway runs through the Khojak tunnel (6,398 ft above sea level) in the Toba Kākar Range; it is one of the largest tunnels, with a length of 2.4 mi (3.9 km), in southern Asia. Pop. (1981 prelim.) town, 14,000; district, 374,000.

Pishpek (Kirgiz S.S.R.): *see* Frunze.

Pisides, Georgios: *see* George the Pisidian.

Pisidia, ancient region of southern Asia Minor, located north of Pamphylia and west of Isauria and Cilicia. Most of the district was composed of the abrupt, north–south-trending limestone ranges of the Taurus Mountains, providing refuge for a lawless population that stubbornly resisted successive conquerors. In



Pisidia

From W. Shepherd, *Historical Atlas,* Harper & Row, Publishers (Barnes & Noble Books), New York; revision copyright © 1964 by Barnes & Noble, Inc.

the 1st century BC the population was organized in small tribes or in groups of villages. The theocratic rule characteristic of ancient Phrygia seems also to have been practiced in Pisidia, where there is evidence of temples with large estates and slave labour.

On the death of King Amyntas (25 BC), most of Pisidia was incorporated in the Roman province of Galatia, though it was partly regrouped with Lycia and Pamphylia by Vespasian in AD 74. The advance of Roman civilization was at first slow, but in the 2nd century AD urbanization proceeded rapidly. After Diocletian's reorganization (*c.* AD 297) Pisidia was included in the Dioecesis Asiana, and in later Byzantine times it fell partly in the Thracesian and partly in the Anatolic theme (province).

Pisistratus (Athenian tyrant): *see* Peisistratus.

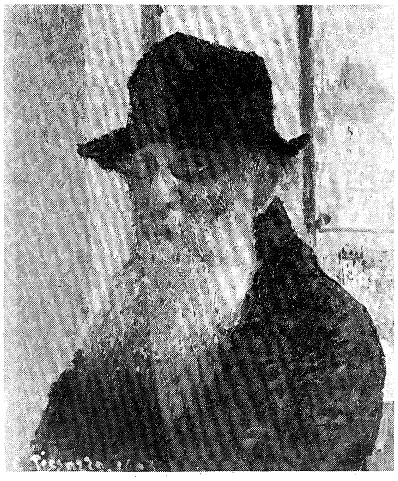
pisolite, spheroidal crystalline particle larger than 2 millimetres in diameter (*see* oölite).

Pissarro, Camille (b. July 10, 1830, St. Thomas, Danish West Indies—d. Nov. 13, 1903, Paris), French Impressionist painter, who endured prolonged financial hardship in keeping faith with the aims of Impressionism. Despite acute eye trouble, his later years were his most prolific. The Parisian and provincial scenes of this period include "Place du Théâtre Française" (1898) and "Bridge at Bruges" (1903).

Pissarro was the son of a prosperous Jewish merchant, Abraham Gabriel Pissarro, and Rachel Manzano-Pomié. At the age of 12 he left home for studies in Paris, where he showed an early interest in art. Returning to the West Indies after five years to work in his father's store, he began making sketches of the exotic island and its people. Because he was unable to obtain his father's permission to study art, he ran away to Caracas in 1853 and remained there for two years with the Danish painter Fritz Melbye. Finally, Pissarro's father relented, and in 1855 he returned to

France. His earliest canvases, dating from this period, are figure paintings and landscapes of the tropics and of the French countryside; although broadly painted, they show the careful observation of nature that was to remain a characteristic of his art throughout his life.

The uninspired academic teaching at the École des Beaux-Arts, where he was enrolled,



Pissarro, "Self-Portrait," oil painting, 1903; in the Tate Gallery, London

By courtesy of the trustees of the Tate Gallery, London

led Pissarro to seek out the painter Camille Corot, who permitted Pissarro to call himself Corot's "pupil" at a Salon exhibition in 1864. At this time Pissarro was also attracted to the rural, sentimental paintings of the Barbizon artist Jean-François Millet and to the works of Gustave Courbet, the leading proponent of everyday Realism. During the 1860s Pissarro participated in the famous Parisian Café Guerbois discussions, in which artists and writers exchanged ideas, and worked with the younger painters Auguste Renoir and Claude Monet. To escape the Franco-German War, in 1870 Pissarro fled to England; there he and Monet, who had also fled France, visited the museums, where they viewed British landscape paintings. It was in London that Pissarro married Julie Vellay, formerly his mother's maid, who had already borne him two of their seven children.

When Pissarro returned to France in 1871, he found his house in Louveciennes looted and a great number of his paintings destroyed. Soon he was to look for another house in Pontoise. (Because it was costly to live in Paris, Pissarro, like several of his painter friends, lived in villages not far from the city.) His surroundings formed the theme of his art for some 30 years and were always carefully chosen: "I require a spot that has beauty!" At Pontoise he was joined by Paul Cézanne in 1872, and the two of them painted out-of-doors, even in the middle of winter.

Pissarro's paintings are never dramatic; on the contrary, his leading motifs during the 1870s and 1880s are simply houses, factories, trees, haystacks, fields, labouring peasants, and river scenes. Forms do not dissolve but remain firm, and colours are strong; during the latter part of the 1870s his comma-like brushstrokes frequently recorded the sparkling scintillation of light, as in "Orchard with Flowering Fruit Trees, Springtime, Pontoise" (1877). Although his paintings were sold by the dealer Paul Durand-Ruel, who represented several of the Impressionists, Pissarro continued to experience financial hardships, which he described in letters to his eldest son, Lucien; this remarkable correspondence began in 1883 and lasted for 20 years.

In some of the letters to his son, Pissarro expressed dissatisfaction with his own work. Preoccupied by problems of style and technique, he eagerly embraced the Neo-Impressionist theories of Georges Seurat, whom he met in 1885 through the painter Paul Signac. Seurat's technique, consisting of meticulously painted small dots of juxtaposed colours, was adopted by Pissarro; for about five years he painted in this "divisionist" manner, a style which made his works unpopular with dealers, collectors, and even his old fellow artists. Overwhelmingly discouraged by their continuing state of poverty, Madame Pissarro considered drowning herself and their two youngest children. Finally, Pissarro abandoned the style, not, however, because of the opposition he met but because "it was impossible to be true to my sensations and consequently to render life and movement, impossible to be faithful to the effects, so random and so admirable, of nature. . . ." At about this time, also, there was an estrangement from Paul Gauguin, who had formerly worked at his side but now was involved with the new Symbolist movement.

A large and successful retrospective exhibition of Pissarro's paintings was held by Durand-Ruel in 1892, giving the artist greater financial stability, although by this time he was troubled by a chronic eye infection that frequently made it impossible for him to work out-of-doors. Both in 1893 and 1897 he took hotel rooms in Paris from which he painted 24 canvases of the city's streets by day and by night, in sun, rain, and fog. During the 1890s he also did a series of river scenes in Rouen, likewise depicting the various effects of nature. From 1900 until his death three years later, Pissarro continued working, mainly in Paris, Éragny, Dieppe, and Le Havre, with freshness of vision and increasing freedom in his technique. More than 1,600 works, consisting of oils, gouaches, temperas, pastels—and even paintings on fans and on porcelain—as well as nearly 200 fine prints, give testimony to the high quality of Pissarro's half century of work.

Pissarro was the only Impressionist painter who participated in all eight of the group's exhibitions. His kindness, warmth, wisdom, and encouraging words cast him in a fatherly role to struggling younger artists—Monet, Renoir, Cézanne, and Gauguin—who were exploring new means of personal expression. Despite financial burdens that continued until he reached his 60s, Pissarro never lost faith in the new art, believing that "one must be sure of success to the very end, for without that there is no hope!" (Mi.V.)

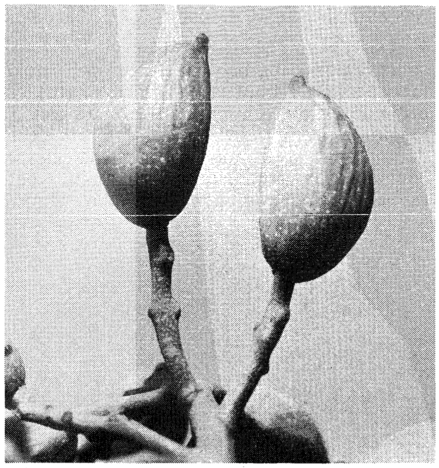
MAJOR WORKS. "The Hermitage at Pontoise" (*c.* 1867; Justin K. Thannhauser Collection, New York); "Still Life" (1867; Toledo Museum of Art, Ohio); "Jallais Hill, Pontoise (La Côte du Jallais, Pontoise)" (1867; Metropolitan Museum of Art, New York City); "Louveciennes, the Road to Versailles" (1870; Emil G. Bührle Collection, Zürich); "Lower Norwood, London, Snow" (1870; National Gallery, London); "Crystal Palace, London" (1871; Henry J. Fisher Collection, Greenwich, Conn.); "Quarry near Pontoise" (1874; Kunstmuseum, Basel, Switz.); "The Little Bridge" (1875; Städtische Kunsthalle Mannheim, Mannheim, Ger.); "Orchard with Flowering Fruit Trees, Springtime, Pontoise" (1877; Louvre, Paris); "The Red Roofs, View of a Village in Winter" (1877; Louvre); "Peasant Girl with a Stick" (1881; Louvre); "The Café au Lait" (1881; Art Institute of Chicago); "Towpath at Pontoise" (1882; Durand-Ruel Collection, Paris); "Île Lacroix, Rouen—Effect of Fog" (1888; Philadelphia Museum of Art); "Paris, the Boulevard Montmartre at Night" (1897; National Gallery, London); "Boulevard des Italiens, Morning, Sunlight" (1897; National Gallery of Art, Washington, D.C.); "Place du Théâtre Français" (1898; Minneapolis Institute of Arts, Minnesota); "Rue de l'Épicerie, Rouen—Morning, Gray Weather" (1898; Durand-Ruel Collection); "The Church of Saint-Jacques, Dieppe—Morning, Rainy Day" (1901; Nate B. and Frances Spingold Collection, New York); "Louvre from Pont Neuf" (1902; Sterling and Francine Clark Institute of Art, Williamstown, Mass.); "Bridge at Bruges" (1903; City Art Gallery, Manchester).

BIBLIOGRAPHY. A most useful annotated bibliography of the artist appears in *The History of Impressionism,* rev. ed., pp. 637–639 (1961), by John Rewald, who also wrote the monograph *Camille Pissarro (1830–1903)* (1954). Biographies include John Rewald, *Camille Pissarro* (1963); and Kathleen Adler, *Camille Pissarro* (1977). Indispensable for the study of the artist's work is the critical study and catalog by Ludovic Rodolphe Pissarro and Lionello Venturi, *Camille Pissarro: son art—son oeuvre,* 2 vol. (1939). Its extensive bibliography lists more than 500 publications. Pissarro's graphic works were cataloged by Loys Delteil, *Le Peintre-Graveur illustré,* vol. 17, *Camille Pissarro, Alfred Sisley, Auguste Renoir* (1923). For the artist's own writings see Camille Pissarro, *Letters to His Son Lucien,* ed. with the assistance of Lucien Pissarro by John Rewald, 3rd ed. rev. and enlarged (1972).

Pisseleu, Anne de: *see* Étampes, Anne de Pisseleu, duchesse d' (duchess of).

Pissevache Fall, waterfall on the Salanfe River, a tributary of the Rhône, in Valais canton, Switzerland, a short distance north of the village of Vernayaz. It attains its maximum flow in spring and summer and is best seen during the morning. The fall provides power for a hydroelectric power plant. It has a drop of 215 ft (65 m).

Pistacia, genus of flowering plants, of the cashew family (Anacardiaceae), comprising nine species of aromatic trees and shrubs native to Eurasia, with one species in southwest-



Pistachio fruits (*Pistacia vera*)

ern North America and another in the Canary Islands. The Chinese pistachio (*P. chinensis*) is a tall ornamental tree with scarlet fruits and colourful autumn foliage. The mastic tree (*P. lentiscus*) and turpentine tree, or terebinth (*P. terebinthus*), produce sweet-smelling gums used in medicine. Mastic also is used in liqueurs and varnishes. Commercial pistachio nuts are seeds from the fruit of *P. vera.* The nuts are extensively used as food and for yellowish-green colouring in confections.

Grown in dry lands in warm or temperate climates, the tree is believed indigenous to Iran; it is widely cultivated from Afghanistan to the Mediterranean region and to a limited extent in California. The tree has wide-spreading branches but rarely exceeds 9 metres (30 feet) in height. Each leaf has one to five pairs of thick, wide, leathery, pinnate leaflets; its small fruits are borne in clusters. The trees are usually dioecious (bearing either male or female flowers) and are pollinated largely by wind.

The white fruits are 1.5 to 2 centimetres (0.6 to 0.8 inch) long and tend to split at one side without discharging the nut, a greenish kernel enclosed in a thin, tightly adhering, reddish skin. The single, solid kernels have a pleasing mild resinous flavour. To ensure pollination and good yield, male trees are interplanted with female in a ratio of 1:5 or 1:6.

pistil, the female reproductive part of a flower. The pistil, centrally located, typically consists of a swollen base, the ovary, which contains the potential seeds, or ovules; a stalk, or style, arising from the ovary; and a pollen-receptive tip, the stigma, variously shaped and often sticky.

Differences in the composition and form of the pistil are useful in determining taxonomic relationships. There may be a single pistil, as in the lily, or several to many pistils, as in the buttercup. Each pistil is constructed of from one to many enrolled leaflike structures, or carpels. The carpel is a single megasporophyll, or modified seed-bearing leaf. A pistil then may be composed of one carpel (simple pistil), as in the sweet pea, or of two or more carpels (compound pistil) partially or completely joined, as in the mustard (two carpels) or lily (three carpels).

A flower that contains separate pistils (and therefore separate carpels) is termed apocarpous; if it contains a single pistil with two or more united carpels, it is syncarpous.

Pistils in the collective sense form the gynoecium, in distinction to the male reproductive parts, or androecium.

Pistoia, Latin PISTORIA, city, capital of Pistoia province, in the Toscana (Tuscany) region, north central Italy, located on the Ombrone River south of the Apennines and northwest of Florence. The town (recorded as Pistoria) was previously a site of Gallic, Ligurian, Etruscan, and Roman occupation and in 63 BC was the scene of the death in battle of the Roman demagogue Catiline. A bishopric from the 5th century and an early and vigorous free Italian commune from the late 11th century, it came under Florentine domination in 1329. In 1786 a famous Jansenist episcopal synod opposing devotion to the Sacred Heart of Jesus was convened there.

The medieval city centre is dominated by the 12th-century cathedral, with its freestanding bell tower (once a Lombard watchtower); the baptistery (begun 1337); the Palazzo Comunale (1294–1385); and the Palazzo Pretorio (1367). The cathedral contains the famous silver Altar of St. James, mentioned by the poet Dante. Churches include Giovanni Fuorcivitas (12th century; containing a Visitation in glazed terra-cotta by Andrea della Robbia), S. Andrea (12th century), S. Francesco al Prato (1294–1394), and the Madonna dell'Umiltà (1494–1519). The Ospedale del Ceppo (founded 1277) is noted for a frieze by Giovanni della Robbia.

Pistoia has several training schools and institutes. It is a road and rail junction and has tanning, shoemaking, ironworking, and glassmaking industries. Lace is also made; flowers are grown for sale and export.

The word pistol has been traditionally ascribed to Pistoia, where the weapon was possibly first manufactured in the early 15th century. Pop. (1983 est.) mun., 91,993; province 265,617.

Pistoia, Synod of, a diocesan meeting held in 1786 that was important in the history of Jansenism, a nonorthodox, pessimistic, and rigoristic movement in the Roman Catholic Church. The synod, presided over by Scipione de' Ricci, bishop of Pistoia-Prato, and under the patronage of Peter Leopold, grand duke of Tuscany (later the Holy Roman emperor Leopold II), was aimed at a reform of the Tuscan Church along the lines advocated by the Jansenists and the Gallicans, who sought to restrict the authority of the pope. The synod was attended by many priests who almost unanimously approved a series of decrees that were warmly approved by the Grand Duke and aroused the enthusiasm of Jansenists in many parts of Europe. At the insistence of Leopold, a national synod of Tuscan bishops then met at Florence (April 23, 1787); they, however, rejected the decrees of Pistoia. In 1794 Pope Pius VI condemned 85 propositions of Pistoia, and Ricci, who had resigned his see in 1790, subsequently recanted.

pistol, small firearm designed for one-hand use. According to most theories, pistols were first developed in Italy in the 14th century. The military advantages of a firearm that could be operated by one hand, leaving the other free for another weapon or for defense, were clear

Automatic .45-calibre pistol
By courtesy of Colt Industries

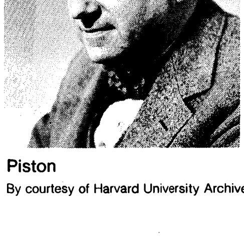
from the earliest days of gunpowder, and the pistol evolved simultaneously with its heavier counterpart, the shoulder weapon.

There are two important classes of pistol: revolvers and automatics. Revolvers embody an element that revolves; in early revolvers, sheaves or bundles of tubes serving as barrels were revolved by hand to allow more than one shot without reloading. The modern revolver employs a short, many-chambered cylinder positioned behind a single barrel so that the cartridge in each chamber is brought successively in alignment with the barrel. Pulling the trigger revolves the cylinder, brings a fresh cartridge in line with the hammer, locks the cylinder in place, and releases the hammer to discharge the cartridge.

Automatic pistols have their mechanism actuated by the energy of recoil when a bullet is fired; cartridges are fed into the mechanism through a magazine in the butt of the pistol. Though devotees of the automatic pistol have predicted the decline and disappearance of the revolver, there is little evidence that this is happening. Both weapons are used by the military in many countries. Police use varies, with the revolver favoured in the U.S., the automatic elsewhere. Both types are used extensively for sport and target shooting.

Piston, Walter (Hamor) (b. Jan. 20, 1894, Rockland, Maine, U.S.—d. Nov. 12, 1976, Belmont, Mass.), composer noted for his symphonic and chamber music and his influence in the development of the 20th-century Neoclassical style in the United States.

After graduating from the Massachusetts School of Art, Piston studied music at Harvard



Piston
By courtesy of Harvard University Archives

University and in Paris with Nadia Boulanger and Paul Dukas (1924–26). On his return to the U.S. he taught at Harvard, becoming professor of music in 1944 and retiring in 1960. Highly regarded as a teacher, he wielded considerable influence on contemporary American music through his students, who included Leonard Bernstein. He published four important textbooks, *Principles of Harmonic Analysis* (1933), *Harmony* (1941), *Counterpoint* (1947), and *Orchestration* (1955). His style of composition is Neoclassical, with occasional Romantic overtones, and is noted for its structural strength and rhythmic vivacity. His program music includes the orchestral suite *Three New England Sketches* (1959); his only composition for the theatre is the ballet *The Incredible Flutist* (1938). He composed eight symphonies, the third (1947) and seventh (1960) of which were awarded Pulitzer Prizes. He also wrote two violin concerti, a viola concerto, a concerto for two pianos, a *Capriccio* for harp and string orchestra (1963), a concerto for clarinet, the *Lincoln Center Festival Overture* (1962), and a concerto for string quartet and orchestra (1974). His chamber music includes five string quartets, a quintet for piano and string quartet, and a wind quintet.

piston and cylinder, in mechanical engineering, sliding cylinder with a closed head (the piston) that is moved reciprocally in a slightly larger cylindrical chamber (the cylinder) by or against pressure of a fluid, as in an engine or pump. The cylinder of a steam engine (*q.v.*) is closed by plates at both ends, with provision for the piston rod, which is rigidly attached to the piston, to pass through one of the end cover plates by means of a gland and stuffing box (steam-tight joint).

The cylinder of an internal-combustion engine is closed at one end by a plate called the head and open at the other end to permit free oscillation of the connecting rod, which joins the piston to the crankshaft. The cylinder head contains the spark plugs on spark-ignition (gasoline) engines and usually the fuel nozzle on compression-ignition (diesel) engines; on some engines the valves that control the admission of fresh fuel and the escape of burned fuel are also located in the head.

On most engines the cylinders are smoothly finished holes in the main structural component of the engine known as the block, which is usually made of cast iron or aluminum. On some engines the cylinders are lined with sleeves (liners) that can be replaced when worn. Aluminum blocks use centrifugally cast iron liners that are placed in the mold when the aluminum is being cast; these liners are not replaceable but can be rebored.

Pistons are usually equipped with piston rings. These are circular metal rings that fit into grooves in the piston walls and assure a snug fit of the piston inside the cylinder. They help provide a seal to prevent leakage of compressed gases around the piston and to prevent lubricating oil from entering the combustion chamber.

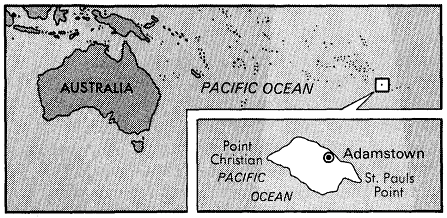
An important characteristic of an internal-combustion engine is its compression ratio, defined as the total volume of the combustion chamber with the piston fully extended (maximum volume) divided by the total volume with the piston fully compressed (minimum volume). The actual compression ratio in practice is somewhat less. Higher compression ratios usually provide better engine performance, but they require a fuel with better antiknock characteristics.

Closely associated with the compression ratio is a characteristic known as the displacement—*i.e.,* the change in volume (measured in cubic inches or cubic centimetres) of the combustion chamber that takes place as the piston moves from one extreme to the other. The displacement is related to the horsepower rating of an engine.

pit bull terrier, fighting dog developed in 19th-century England out of the bulldog and a terrier. *See* Staffordshire terrier.

pit organ, a temperature-sensitive organ in the head of venomous snakes of the subfamily Crotalinae, family Viperidae. Crotalines, known collectively as pit vipers, include rattlesnakes, moccasins, fer-de-lance, and a number of other New World vipers, as well as a few Old World species. The pit organs are located on each side of the face, somewhat below a line from the eye to the nostril. They function in the detection of the small, warm-blooded animals on which the snakes feed, and they aid in orienting the snake's strike.

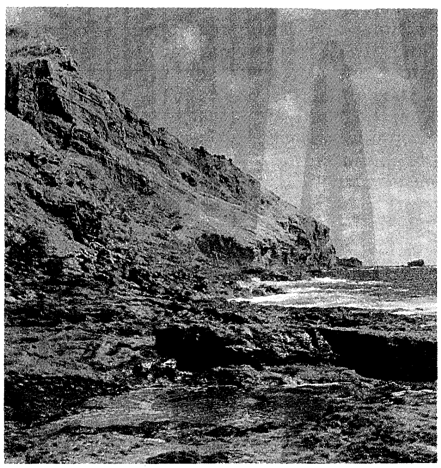
Pitcairn Island, isolated, volcanic formation in the south-central Pacific Ocean, 1,350 miles (2,170 km) southeast of Tahiti. With the uninhabited dependent islands of Oeno, Henderson, and Ducie, it constitutes the British colony of Pitcairn Island. The main island,



Pitcairn Island

with an area of about 2 square miles (5 square km), is a rugged half crater rising to 1,100 feet (about 300 m), girded by precipitous coastal cliffs. The climate is subtropical with an adequate rainfall, and the soil is fertile.

Discovered in 1767 by a British naval officer, Philip Carteret, Pitcairn is named for the sailor who first sighted it. Its population is descended from the mutineers of the British ship HMS *Bounty* and their Tahitian Polynesian consorts. On a voyage from Tahiti to the West Indies with a cargo of breadfruit saplings, the crew, led by the first mate, Fletcher Christian, mutinied and set their captain, William Bligh, and a number of loyal sailors adrift and set course for the Austral Islands. The mutineers and their Tahitian companions eventually reached uninhabited Pitcairn (1790), went ashore, and then burned the ship. The island community survived in obscurity until discovered by American whalers in 1808. Resettled



The rugged coast at Bounty Bay, Pitcairn Island
Peter J. Anerine—Shostal/EB Inc.

on Tahiti (1831), many islanders grew dissatisfied and returned to Pitcairn. Thereafter, the island became a port of call for whalers and passenger ships steaming between the United States and Australia. In 1856, because of overpopulation, some of the islanders were removed to Norfolk Island, and to this day the mutineers' descendants remain divided between the two places.

Adamstown, the chief settlement, is on the north coast near Bounty Bay, one of the few places where the island-made longboats can land. The islanders subsist on fishing, garden produce, and crops (including sweet potatoes, sugarcane, taro, oranges, bananas, and coffee). The sale of postage stamps and carved curios to passing ships brings cash income. Absentee land ownership and overpopulation have been persistent problems. The islanders have been Seventh-day Adventists since 1887.

In 1898 the settlement was placed under the jurisdiction of the British High Commissioner for the Western Pacific. In 1952 administrative responsibility was transferred to the governor of the British crown colony of Fiji. When Fiji became independent in 1970, the British High Commissioner in New Zealand assumed administrative control as governor of Pitcairn, carrying out his duties through a locally elected island council. Pop. (1983) 61.

pitch, in music, position of a single sound in the complete range of sound. Sounds are higher or lower in pitch according to the frequency of vibration of the sound waves producing them. A high frequency (*e.g.,* 880 hertz [cycles per second]) is perceived as a high pitch; a low frequency (*e.g.,* 55 Hz) as a low pitch.

In Western music, standard pitches have long been used to facilitate tuning. Usually a' above middle C (c') is taken as a referent pitch. The current standard pitch of $a' = 440$ Hz was adopted in 1939. For some eighty years previous, a' had been set at 435 Hz. A confusing variety of pitches prevailed until the 19th century, when the continual rise in pitch made some international agreement a matter of practical necessity.

In the mid-17th century, the Hotteterres, Parisian instrument makers, remodeled the entire woodwind family. They used the Paris organ pitch of about $a' = 415$, or a semitone below $a' = 440$. This new, or Baroque, pitch, called *Kammerton* ("chamber pitch") in Germany, was thus one tone below the old Renaissance woodwind pitch, or *Chorton* ("choir pitch").

After about 1760 the conventional pitch rose, reaching $a' = 440$ by about 1820. By the latter half of the 19th century, it reached the "Old Philharmonic Pitch" of about $a' = 453$. The inconvenience of this high pitch became apparent, for it strained singers' voices and made wind instruments quickly out of date. An international commission met in Paris in 1858–59 and adopted a compromise pitch called diapason normal (known in the United States as "French pitch," or "international pitch") at $a' = 435$. England, in 1896, adopted the "New Philharmonic Pitch" at $a' = 439$ and, in 1939, adopted the U.S. standard pitch of $a' = 440$. In the mid-20th century, pitch again tended to creep upward as some European woodwind builders used the pitch $a' = 444$.

When frequency numbers are not used for a particular pitch, say D or B, a system of lowercase and capital letters indicates the octave in which it occurs. The notes in the octave below middle C are indicated by lowercase letters from c to b; the notes of the second octave below middle C are shown as C, D, . . . B; the notes of the next lower octave as C_1, D_1, . . . B_1. Middle C is shown as c', and the notes in the octave above middle C as d', e', . . . b'. The C above middle C is shown as c'', and the next higher C as c'''.

Absolute, or perfect, pitch is the ability to identify by ear any note at some standard pitch or to sing a specified note, say $G\sharp$, at will. Fully developed absolute pitch is uncommon. It appears early in childhood and is apparently an acute form of memory of sounds of a particular instrument, such as the home piano. Some musicians slowly acquire a degree of absolute pitch, if only for the familiar $a' = 440$.

pitch, in speech, the relative highness or lowness of a tone as perceived by the ear, which depends on the number of vibrations per second produced by the vocal cords. Pitch is the main acoustic correlate of tone and intonation (*qq.v.*).

pitch, in the chemical-process industries, the black or dark-brown residue obtained by distilling coal tar, wood tar, fats, fatty acids, or fatty oils.

Coal tar pitch is a soft to hard and brittle substance containing chiefly aromatic resinous compounds along with aromatic and other hydrocarbons and their derivatives; it is used chiefly as road tar, in waterproofing roofs and other structures, and to make electrodes.

Wood tar pitch is a bright, lustrous substance containing resin acids; it is used chiefly in the manufacture of plastics and insulating materials and in caulking seams.

The pitches derived from fats, fatty acids, or fatty oils by distillation are usually soft substances containing polymers and decomposition products; they are used chiefly in varnishes and paints and in floor coverings.

pitch lake, large surface deposit of natural asphalt, a mixture of heavy oils that is left after the lighter, more volatile components of a crude-oil seepage have evaporated. An example is Guanoco Lake in Venezuela, which covers over 445 hectares (1,100 acres) and contains an estimated 6,000,000 tons of asphalt. It was used as a commercial source of asphalt from 1891 to 1935. Smaller deposits occur commonly where Tertiary marine sediments outcrop on the surface; an example is the tar pits at Rancho La Brea in Los Angeles (*brea* and "tar" are synonymous with "semisolid asphalt"). Although most pitch lakes are fossils of formerly active seeps, some, such as Pitch Lake on the island of Trinidad, continue to be supplied with fresh crude oil seeping from a subterranean source. Pitch Lake covers 47 hectares (115 acres) and contains an estimated 6,700,000 tons of asphalt. The asphalt is a major export of Trinidad and Tobago and is used mostly for road building.

pitchblende, amorphous, black, pitchy form of the crystalline uranium oxide mineral uraninite (*q.v.*); it is one of the primary mineral ores of uranium, containing 50–80 percent of that element. Three chemical elements were first discovered in pitchblende: uranium by the German chemist Martin Klaproth in 1789, and polonium and radium by the French scientists Pierre and Marie Curie in 1898. Deposits, frequently in association with uraninite or with secondary uranium minerals, are known in Zaire; Czechoslovakia; England; the Northwest Territories and Saskatchewan in Canada; and Arizona, Colorado, Montana, New Mexico, and Utah in the United States.

Pitcher, Molly, byname of MARY MCCAULY (b. *c.* 1753—d. Jan. 22, 1832, Carlisle, Pa., U.S.), heroine of the Battle of Monmouth during the U.S. War of Independence.

Molly's original surname is unknown, though she is thought to have been Irish. Military records indicate that her first husband, William Hays, enlisted as a gunner in a Pennsylvania artillery regiment in 1777. Molly was with him at the Battle of Monmouth (N.J.) on June 28, 1778, carrying a pitcher back and forth from a well so that the exhausted and wounded American soldiers could have water—hence her nickname, "Molly Pitcher."

Popular legend has it that, when Hays eventually collapsed from the scorching heat that day, Molly took her husband's place at the cannon, serving heroically for the remainder of the battle.

Hays was discharged shortly after the war, and in 1783 they went to Carlisle, where Hays became a barber. Hays died about five years later, and in 1793 Mary wedded John McCauly. Her second husband died in about 1813, and thereafter Mary was employed largely as a nurse. On Feb. 21, 1822, Pennsylvania awarded her an annual pension of $40 in recognition of her heroism at Monmouth. Monuments near the battle site and at her grave also recognize her contribution to American independence.

It had been previously believed that her original name was Mary Ludwig, that she was of German immigrant stock, and that her first husband was John Casper Hays.

BIBLIOGRAPHY. Samuel Stelle Smith's documented biographical study, *A Molly Pitcher Chronology,* was published in 1972.

pitcher plant, any carnivorous plant with pitcher-shaped leaves. Old World pitcher plants are members of the family Nepenthaceae (order Nepenthales; *q.v.*). New World pitcher plants belong to the family Sarraceniaceae (order Sarraceniales; *q.v.*). The flycatcher plant (*Cephalotus follicularis*) of southwestern Australia is the only species of the family Cephalotaceae (order Saxifragales). Another pitcher plant is *Dischidia rafflesiana,* of the family Asclepiadaceae (*q.v.*). Pitcher plants are found in a wide range of habitats, from pine barrens to sandy coastal swamps.

Common pitcher plant (*Sarracenia purpurea*)
Walter Chandoha

The name pitcher plant most commonly refers to members of the family Sarraceniaceae, especially the eight or nine species comprising the genus *Sarracenia,* native to eastern North America. The other two genera in the family are the cobra plant (*q.v.; Darlingtonia*), native to northwestern North America, and *Heliamphora,* native to South America.

Pitcher plants of the genus *Sarracenia* have unusual tubular leaves that are shaped like urns, trumpets, or small pitchers. Insects are attracted to the mouth of the pitcher by a trail of nectar-secreting glands that extend downward along the lip to the interior of the pitcher. The lip is covered with stiff, downward-pointing hairs that are not easy for an insect to climb upward on once it has partly descended to gather nectar. Just below the lip, in the steepest part of the pitcher's throat, is a very smooth area without hairs. Like a greased slide, this zone sends the insect (who by then is trying to escape by unsuccessfully climbing upward) tumbling down into the liquid pool at the bottom of the pitcher, where it quickly becomes submersed and drowns. The insect is then digested by an enzyme secreted within the leaf.

The purple, or common, pitcher plant (*S. purpurea*) has heavily veined, green to reddish, flaring, juglike leaves that bear downward-pointing bristles. Its flowers are purple-red. The parrot's head pitcher plant (*S. psittacina*) has small, fat, red-veined leaves that are topped by beaklike lids. It bears dark red flowers. The sweet pitcher plant (*S. rubra*) produces dull red, violet-scented flowers. The crimson pitcher plant (*S. leucophylla; S. drummondii* of some authorities) has white, trumpet-shaped pitchers with ruffled, upright hoods and scarlet flowers. The yellow pitcher plant (*S. flava*), also known as trumpets, has bright yellow flowers and a long, green, trumpet-shaped leaf the lid of which is held upright.

Different species of pitcher plants cross-fertilize easily, so that the number of species varies according to the authority consulted.

pitchstone, a natural glass with a conchoidal fracture (like glass), a resinous lustre, and a mottled, streaked, or uniform brown, red, green, gray, or black colour. It is formed by the rapid cooling of viscous lava or magma.

Most pitchstone occurs as dikes or marginal phases of dikes and therefore may grade into porphyry. Pitchstone porphyry (vitrophyre) consists of a glassy base (groundmass) enclosing abundant large crystals (phenocrysts) of such minerals as quartz, alkali feldspar, and plagioclase, as well as fewer crystals of pyroxene or hornblende. Pitchstone may reveal evidence of fluid flow by the presence of wavy streaks and trains of crystals; in pitchstone dikes, the lines and layers of flowage are oriented parallel to the dike walls.

Pitchstone is a rhyolite. Pitchstone has a chemical composition, index of refraction, and specific gravity similar to those of obsidian but is distinguished by a dull, rather than vitreous, lustre. Like obsidian it is translucent on thin edges, but it is much richer in microscopic embryonic crystal growths (crystallites), the abundance of which is generally believed to account for the duller lustre. Of all the glassy rocks, pitchstone is the richest in water, generally containing 4 to 10 percent by weight; most of this water may have been absorbed from the sea or wet sediments into which the pitchstone was intruded. Some lavas and magmas appear to have congealed partly as glass and partly as crystalline material; water driven out from those portions undergoing crystallization may have been trapped or taken up by the glassy portions to form pitchstone. Pitchstone is unstable, and its conversion to a very fine-grained crystalline aggregate resembles the devitrification of obsidian.

Piteå, town and port, *län* (county) of Norrbotten, northern Sweden. It lies along the Pite River near its outlet on the Gulf of Bothnia. The town was originally chartered at Öjebyn in 1621, but after a fire in 1666 it was moved to its present location. Lying in a forest-rich area, it is a centre for shipping timber and wallboard, and among its industries are sawmilling and others connected with forestry; there is also metalworking. Although it was burned by the Russians in 1716 and again in 1721, there are still many buildings predating that time, notably a church (1684–86). Pop. (1987 est.) mun., 38,688.

piteira (fibre): *see* Mauritius hemp.

Piteşti, city, capital of Argeş *judeţ* (county), south-central Romania. It lies 70 miles (110 km) northwest of Bucharest and is situated in the Argeş River valley, there sheltered by surrounding hills. Piteşti developed in the Middle Ages as a trading centre between the mountainous Transylvania region and the Danube Plain. It is first documented in 1388, though Roman coins and relics have been found in the area. Before 1939 the only industry was a textile mill at Găvana, a suburb; but from 1960 to 1970 an industrial district was built northwest of the city proper. Automobile production has become the most important industry; other manufactures include footwear

Local People's Council headquarters, Piteşti, Rom.
Art Resource—EB Inc.

and wood and metal products. Pop. (1985 est.) 146,915.

Pithecanthropus, former genus name assigned to fossil hominids including Java man (*q.v.*) and Peking man (*q.v.*), both now classified as *Homo erectus.*

Pithom, Egyptian PER-ATUM, or PER TUM ("Estate of Atum"), probably modern TALL AL-MASKHŪṬAH, ancient Egyptian city located near Ismailia in al-Ismāʿīlīyah *muḥāfaẓah* (governorate). Mentioned in the Bible (Exodus 1:11) as one of the treasure cities built for the pharaoh by the Hebrews, it was known to have been enlarged by the Ramesside pharaohs, especially by Ramses II (reigned 1279–13 BC), in whose reign the Exodus of the Hebrews may have taken place. The site has yielded sphinxes and statues of Ramses II and the best-preserved of the trilingual stelae that commemorated Darius I the Great's completion of the Nile-Red Sea Canal.

Pithoragarh, town, northern Uttar Pradesh state, northern India. It lies east of Almora, on a ridge of the Himalayan foothills. The surrounding area lies entirely within the Himalayan Range and is bordered by Nepal to the east and China to the north. Rice, barley, and wheat are grown. Pop. (1981) town, 17,657.

Pithou, Pierre (b. Nov. 1, 1539, Troyes, Fr.—d. Nov. 1, 1596, Nogent-sur-Seine), lawyer and historian who was one of the first French scholars to collect and analyze source material of France's history.

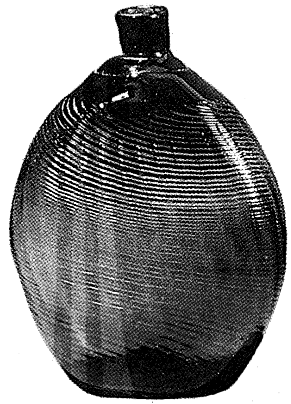
Reared as a Calvinist, Pithou received his lawyer's robes at Paris (1560) after he had earned recognition by his essays on Roman laws. On the outbreak of the Second War of Religion against the Protestants in 1567, he fled to Sedan and later to Basel, returning to France after the Edict of Pacification (1570). After the massacre of the Huguenots (1572), he converted to Catholicism in 1573 and was named procurer general (1579) for a temporary court set up by King Henry III to render justice in the province of Guyenne.

When the Holy League for the extermination of Protestantism prevented Pithou from practicing law, he devoted himself to his researches on the history and discipline of the church. Sympathetic to the royal cause, he helped in producing *Satire Ménippée* (1594), a polemical tract that did much to damage the cause of the League. In the same year, he was appointed procurer general for the parliament at Paris. On the order of King Henry IV, he wrote *Les Libertés de l'église gallicane* (1594; "Liberties of the Gallican Church"), a work echoing the position of the French legal scholars in the conflict between the government and the Holy See; it became the basis for the declaration of the French clergy (1682) concerning the authority of the pope.

Pithou's other historical works are *Leges Wisigothorum* (1579; "Laws of the Visigoths"), the first publication of the laws of the Visigoths, and *Annales Francorum* (1588; "Annals of the Franks").

Pitkin glass, a glassware originating from a glasshouse established by the Pitkin family in East Hartford (now Manchester), Conn., in 1783 and active until *c.* 1830.

The product's fame rests almost entirely on so-called Pitkin flasks, which were much



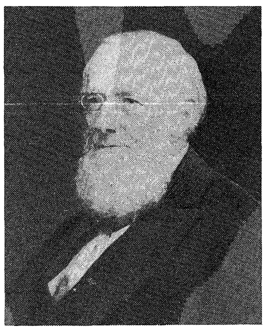
Pitkin flask made in the eastern United States, *c.* 1820; in the Brooklyn Museum, New York

By courtesy of the Brooklyn Museum, gift of Mr. & Mrs. A. L. Chapins in memory of Louis Chardon

sought by collectors in the 1920s. These flasks, which vary in colour from green to aquamarine and amber, were a kind of pocket bottle molded with a swirl or ribbed pattern. Pitkin flasks made in the Eastern glasshouses are generally olive green or amber, whereas those made in Ohio or Pennsylvania either vary from green to aquamarine or are amber and are somewhat rounder.

Pitman, Sir Isaac (b. Jan. 4, 1813, Trowbridge, Wiltshire, Eng.—d. Jan. 12, 1897, Somerset), English educator and inventor of the shorthand system named for him.

After clerking in a textile mill, Pitman entered a training college for teachers (1831) and



Pitman, detail of an oil painting by A.S. Cope; in the National Portrait Gallery, London

By courtesy of the National Portrait Gallery, London

taught in elementary schools for 11 years before opening his own private school in Bath. Earlier he had taken up Samuel Taylor's system of shorthand and become interested in developing shorthand based on sound. In 1837, at the suggestion of publisher Samuel Bagster, Pitman wrote *Stenographic Sound Hand,* which Bagster published at a low price for widest possible distribution. To encourage the adoption of his system, Pitman established a Phonetic Institute and a *Phonetic Journal* at Bath. He also printed standard works in shorthand, and his book *Phonography* (1840) went through many editions. He was an enthusiastic spelling reformer and adopted a phonetic system that he tried to bring into general use. In 1894 he was knighted.

Pitman shorthand, system of rapid writing based on the sounds of words (*i.e.,* the phonetic principle) rather than on conventional spellings. Invented by Sir Isaac Pitman, an English educator, the Pitman shorthand method was first published in 1837 as *Stenographic Sound Hand.* Pitman's system classifies the sounds of a language into basic groups and makes use of simple abbreviations for rapidity. Consonants are drawn from simple geometrical forms, straight lines, and shallow curves. As far as possible they are paired; thus, a light slanted line stands for *p* and a heavier slanted line for *b,* a light vertical line stands for *t* and a heavier one for *d,* and so on. Vowels are indicated by disjoined dots and dashes that are placed in specific positions relative to the consonants and the line of writing. The system makes use of circles, loops, and hooks for sounds frequently used in consonant combinations and syllables (*e.g.,* for *s, st, str, spr,* and *-ter, -der, -tion*). Syllables are also added by halving or doubling the length of a consonant stroke.

Pitman shorthand was introduced into the United States in 1852; among the many languages to which it has been adapted are Hindi, Hebrew, Arabic, Persian, German, French, Spanish, and Dutch.

Pitney, Mahlon (b. Feb. 5, 1858, Morristown, N.J., U.S.—d. Dec. 9, 1924, Washington, D.C.), associate justice of the United States Supreme Court (1912–22).

After graduating from the College of New Jersey (now Princeton University), Pitney studied law with his father and took over his father's practice when the latter was appointed vice chancellor of New Jersey in 1889. In 1894 Pitney was elected to the U.S. Congress, in which he served until 1899, followed by a term in the New Jersey state Senate and, in 1901, an appointment to the state Supreme Court. In 1908 he became the state's chancellor. In 1912 Pres. William Howard Taft named Pitney to the U.S. Supreme Court to succeed John Marshall Harlan, Sr.

Pitney's opinions were characterized by his conservative interpretations and meticulous care. He made his most important contributions in the area of labour law. His opinions in *Hitckman Coal and Coke Co.* v. *Mitchell* (1917) and *Duplex Printing Co.* v. *Deering* (1921), which limited the rights of workers to collective bargaining, were elaborations of his earlier opinion in *Coppage* v. *Kansas,* in which the court struck down a Kansas statute prohibiting an employer from preventing union membership among his employees by force or coercion. Another memorable opinion, in *Frank* v. *Mangum,* drew vigorous dissent from Justice Oliver Wendell Holmes on the grounds that it validated mob law. Pitney resigned from the court on Dec. 31, 1922.

Pitoëff, Georges (b. Sept. 4, 1884, Tiflis, Russia—d. Sept. 17, 1939, Geneva), Russian-born director and producer, noted for his popularization in France of the works of contemporary foreign playwrights, especially Pirandello, Shaw, Chekhov, Schnitzler, and O'Neill. He was a member of the Cartel des Quatre (Group of Four), a group including Louis Jouvet, Charles Dullin, and Gaston Baty, dedicated to rejuvenating the French theatre.

Pitoëff formed his first professional theatrical company in 1915 in Geneva and took it on tour to Paris. After World War I he returned to Paris. There, Pitoëff and his company performed in various theatres, including that of actor-producer Jacques Copeau, from 1922 to 1934, when they were finally established at the Théâtre des Mathurins. Pitoëff's work, which included the first successful French production of Pirandello's *Six Characters in Search of an Author* and a notable revival of Shaw's *Saint Joan* among his nearly 200 productions, demonstrated his skills at adapting, translating, designing, directing, and acting, although in the latter activity he was limited by his strong accent. He was eclectic in his choice of scripts but consistent in his direction, which sought to reveal with simplicity the essential ideas of each play. After his death, his wife, the actress Ludmilla Pitoëff, led the company.

Pitot, Henri (b. May 3, 1695, Aramon, Fr.—d. Dec. 27, 1771, Aramon), French hydraulic engineer and inventor of the pitot tube, which measures flow velocity.

Beginning his career as a mathematician and astronomer, Pitot won election to the Academy of Sciences in 1724. He became interested in the problem of flow of water in rivers and canals and discovered that much contemporary theory was erroneous—for example, the idea that the velocity of flowing water increased with depth. He devised a tube, with an opening facing the flow, that provided a convenient and reasonably accurate measurement of flow velocity and that has found wide application ever since (*e.g.,* in anemometers for measuring wind speed). Appointed chief engineer for Languedoc, he performed a variety of maintenance and construction works on canals, bridges, and drainage projects. His major work was construction of an aqueduct for the city of Montpellier (1753–86), including a stone-arch Roman-type section a kilometre (more than 1/2 mile) in length.

pitṛ, also spelled PITṚI (Sanskrit: "father"), plural PITAṚAS, PITṚS, or PITṚIS, in Hinduism, any of the spirits of the dead ancestors or of all the dead who have been cremated or buried in accordance with the proper rites. In the Vedas, the sacred scriptures of ancient India, the "fathers" were considered to be immortal like the gods and to share in the sacrifice, though they received different offerings. The "way of the fathers," characterized by observance of the traditional duties of sacrifice, almsgiving, and the practice of austerities that lead to rebirth, came to be distinguished from the "way of the gods," which was a way of faith directed toward the goal of liberation from rebirth.

Pitt, Thomas, byname DIAMOND PITT (b. July 5, 1653, Blandford St. Mary, Dorset, Eng.—d. April 28, 1726, Swallowfield, Berkshire), British merchant whose involvement in the East India trade brought him into conflict with the English East India Company; later, the company made him governor of Madras, India. Pitt was the grandfather of William Pitt, the Elder, the great 18th-century British statesman.

Without receiving permission from the East India Company, Pitt began to trade out of

Thomas Pitt, detail of a print after an oil painting by Sir Godfrey Kneller

Balasore, India, in 1674. The company retaliated by having him arrested (1683) and fined (1687). Nevertheless, he was elected to Parliament in 1689 and 1690, when he bought the manor of Old Sarum, thereby securing control of this parliamentary seat for his family.

In 1693 Pitt embarked on another trading venture in the East. Failing to put an end to his activities, the East India Company took him into its service in 1694 and appointed him president of Fort St. George, Madras, three years later. Dismissed from his post in 1709, he returned to England and resumed his seat for Old Sarum. In 1717 he sold an extremely valuable diamond to Philippe II, duc d'Orléans, regent of France; now known as the "Regent," the jewel is in the Louvre, Paris. Sir Cornelius Neale Dalton's *Life of Thomas Pitt* was published in 1915.

Pitt, William, THE ELDER, also called (from 1766) 1ST EARL OF CHATHAM, VISCOUNT PITT OF BURTON-PYNSENT, byname THE GREAT COMMONER (b. Nov. 15, 1708, London—d. May 11, 1778, Hayes, Kent, Eng.), British statesman, twice virtual prime minister (1756–61, 1766–68), who secured the transformation of his country into an imperial power.

William Pitt, the Elder, detail of a painting from the studio of W. Hoare, 1754; in the National Portrait Gallery, London

Background and education. Pitt was born in London of a distinguished family. His mother, Lady Harriet Villiers, daughter of Viscount Grandison, belonged to the Anglo-Irish nobility; his father, Robert Pitt, member of Parliament, was the son of Thomas ("Diamond") Pitt, governor of the East India Company's "factory" at Madras, India, where he made a vast fortune and secured one of the world's largest diamonds (sold in 1717 to the regent of France). "Diamond" Pitt had returned from India with a despotic temper made devilish with spleen and gout; he quarrelled violently with his wife and declared war on "that hellish confusion that is my family," but he treated his grandson William with affection. Father Robert was mean and cantankerous, and the Villiers blood was notoriously unstable. William inherited the gout, as well as a haughty temper and a strain of manic depression.

Such was the background and the smoky, explosive inheritance that was suddenly to blaze into genius. But William's passionate temper and Pitt truculence had to be disciplined, so he was sent to Eton College, where he acquired social polish and learned to be aloof and yet agreeable, to be politely insolent. Delicate health and the early onset of gout deprived him of field sports and hunting, but he learned to ride with a good seat and take his port wine, and he enjoyed the select company of clever and well-connected friends—the two Grenvilles (one to be Earl Temple; the other, George, to be first minister to George III), George Lyttelton, Charles Pratt (to become a follower of Pitt and, as the 1st Earl Camden, a member of his 1766 ministry), and other men who would later become influential in politics, as well as Henry Fielding, author of *Tom Jones*. But Pitt hated the brutal harshness of Eton and determined to have his own sons educated at home. He continued his education at Trinity College, Oxford, but left after a year without taking a degree. He then spent several months at the University of Utrecht in the Netherlands, probably studying law.

His classical education made him think, act, and speak in the grand Roman manner. His favourite poet was Virgil, and he never forgot the patriotic lessons of Roman history; he constantly read Cicero, the golden-tongued orator who could yet lash offenders with his indignation. Later, in Parliament, his organ-like voice could be distinctly heard outside the House. This voice, perfect timing, and splendid gestures were worthy of David Garrick, the greatest actor of the day and a personal friend; Pitt's lean, tall, commanding figure, combined with a Roman beaky nose and hawklike eyes—large and gray but turning black when he was roused—overwhelmed all onlookers. To his countrymen he was to become almost a divine portent, a voice from the Delphic oracle.

For the present, possessed of a mere £100 a year, he nevertheless rejected the church, a younger son's last resort as a career. While he was vegetating on a small family property in Cornwall, which he called a "cursed hiding-place" in one of his many letters to his adored sister and confidante, clever Nan (Ann) Pitt, help came from a politically powerful millionaire nobleman, Lord Cobham, who lived in splendour in a palatial mansion and vast park at Stowe, in Buckinghamshire, to which William and his friends paid visits. Cobham sent William abroad on "The Grand Tour" of Europe (only France and Switzerland were visited, however) and later bought him a cornetcy—a commission—in his own regiment of horse (1731).

Early political career. In 1735 Pitt was offered one of the "pocket" boroughs his brother controlled, Old Sarum in Wiltshire, and entered Parliament. He belonged to the small group known as "Cobham's cubs" and the "boy patriots," the connection of family friends and place hunters whom Cobham was mobilizing to oppose the ministry of Sir Robert Walpole (later the 1st earl of Orford). Walpole had governed England since 1720, monopolizing patronage, and had—they thought—become too ready to compromise in foreign affairs for the sake of peace. The "patriots" joined other discontented Whigs such as John Carteret (later Earl Granville) and William Pulteney (later the 1st earl of Bath) to rally opposition forces behind Frederick Louis, prince of Wales, who was vehemently estranged from his father, King George II.

There were no formal political parties in the 18th century, and political power, together with the financial opportunities it brought, was a gift of patronage from a handful of landowning family oligarchies and from the monarch himself; nor was there a formal opposition in Parliament, and opposition to the king's ministry was regarded as factious and even traitorous. Pitt's maiden speech in Parliament was so critical of the ministry that it provoked Walpole to deprive him of his military commission, to "muzzle this terrible young cornet of horse."

In 1737 the Prince of Wales made Pitt one of his court officials with a salary of £400 a year. He was still a relatively poor dependent of a powerful Whig clan but already showed an independence of mind and a readiness to appeal to public opinion outside Parliament that were new in English political life: when Walpole dismissed him from his cornetcy, he ostentatiously drove about London in a one-horse chaise to underline his poverty. His talents as an orator had already become clear. He repeatedly referred to the "voice of England," which had to be sought outside Parliament because Parliament was so packed with placemen and sinecurists. He claimed to speak for the commercial interests and even for the colonies overseas, the latter scarcely represented in the Commons. He was using arguments that carried far beyond the close interests of the Whig families; but he made lasting and valuable friendship with the rich sugar planter-aldermen of the City of London in his opposition to Walpole's cautious handling of the disputes with Spain over West Indian trade.

Walpole at last fell from power in 1742 and was replaced by a ministry that included his old colleagues Thomas Pelham-Holles, the 1st duke of Newcastle, and Philip Yorke, the 1st earl of Hardwicke, with Carteret as secretary of state. Pulteney was silenced by the grant of a peerage. The "boy patriots," of whom Pitt was the acknowledged leader, were still excluded. They opposed Carteret even more vigorously than they had Walpole. In the War of the Austrian Succession (1740–48), Pitt, a former warmonger, now vigorously opposed the sending of men and subsidies to check the French by protecting Hanover (the King's territory in Germany) and condemned Carteret as a "Hanover troop minister": for this he was never forgiven by his sovereign.

Pitt insisted that French power should be opposed at sea and in its colonial possessions, not on the Continent. When Carteret was forced to resign in 1744, Newcastle and his brother Henry Pelham took office and wanted to include Pitt in their ministry, but George II refused to accept him, though he did accept Cobham, Lyttelton, and Grenville. It was at this time that Pitt first appeared in Parliament swathed in bandages, on crutches, and with a huge gout boot on his foot, parading his illness. But, in the Jacobite rising of 1745 (the Forty-five Rebellion), Pitt gained new stature as the one effective statesman.

In February 1746 the King agreed to appoint Pitt joint vice treasurer of Ireland at £3,000 a year, and two months later he became paymaster general of the forces; he bowed very low as he kissed the King's hands, but George wept with rage. The post of paymaster was one of the most sought after in government, with ample opportunity for corruption. There was an outcry from Pitt's friends, who suspected he had been bought, but he proceeded to show both his contempt for moneymaking and his integrity as an honest but comparatively poor man by ostentatiously refusing to take for himself any more than the official salary of more than £4,000 a year: he put the interest that paymasters before had appropriated to themselves, together with the accounts of the paymaster's funds, into the Bank of England and won the people's hearts again. He introduced many reforms into the administration, and, though he supported the Pelhams' alliance with Hanover (which was a change of tack), he tried also to strengthen British naval power.

A legacy of £10,000 from the old duchess of Marlborough at this time, left to Pitt "for the noble defence he has made for the support of the laws of England, and to prevent the ruin of his country," enabled him to indulge in more lavish expenditure and generosity. He spent a good deal on landscape gardening and bought a new property near London. After a furious quarrel, he became estranged from his sister Nan, who had been his hostess for years.

When Henry Pelham died in office in 1754, Pitt hoped for advancement, but, after much reshuffling and intrigue, Newcastle and Henry Fox (later 1st Baron Holland) abandoned him for the sake of expediency. He then became ill and retired to a new house at Bath, groaning "I wish for nothing but a decent and innocent retreat, not to afford the world the ridiculous spectacle of being passed by every boat that navigates the river." An invalid and an aging bachelor, he suddenly fell in love with Lady Hester Grenville, became engaged at once, and was married by November 1754. She was 33 and he 46, and she adored him, possibly from the times in her childhood when he had visited Stowe with her brothers. She was attractive, clever, patient, and eminently practical—particularly about money, arranging mortgages, satisfying creditors, and pouring away her own fortune, in his last years of grandiose extravagance, to protect him.

It proved to be an ideally happy marriage with a well-ordered, loving home and family ("the infantry" Pitt called them); later he was to be found making hay with them at Hayes Place, his house in Kent, going for picnics, and chasing butterflies. He magically became healthy and happy, ready for his last big parliamentary fight for high office. But first, because of his attacks on Newcastle's ministry, he was dismissed, penniless, from the pay office in 1755. His brother-in-law Earl Temple helped with an annuity of £1,000.

Leadership during Seven Years' War. The outbreak of the Seven Years' War gave Pitt his supreme opportunity for statesmanship. The war began with heavy losses and considerable confusion of policy. The popular demand for Pitt became irresistible, and he declared, "I am sure I can save this country, and nobody else can." In November 1756 he formed a ministry that excluded Newcastle, with the Duke of Devonshire as its nominal head. In June 1757 Newcastle returned to office on the understanding that he should control all the patronage and leave Pitt to conduct the war.

Pitt determined that it should be in every sense a national war and a war at sea. He revived the militia, reequipped and reorganized the navy, and sought to unite all parties and public opinion behind a coherent and intelligible war policy. He seized upon America and India as the main objects of British strategy: he sent his main expeditions to America, to ensure the conquest of Canada, and supported the East India Company and its "heaven-born general," Robert Clive, in their struggle against the French East India Company.

He subsidized and reinforced the armies of Frederick the Great of Prussia to engage the French on the Continent, while the British Navy harassed the French on their own coasts, in the West Indies, and in Africa. Choosing good generals and admirals, he inspired them with a new spirit of dash and enterprise. His hand, eye, and voice were everywhere. By 1759, the "year of victories," Horace Walpole, man of letters and son of Sir Robert Walpole, wrote with reluctant admiration, "Our bells are worn out threadbare with ringing for Victories." Pitt, the "Great Commoner," was known and feared throughout the world. This resolute and concerted policy was too much for Bourbon France, and, by the terms of the Treaty of Paris in 1763, Great Britain remained supreme in North America and India, held Minorca as a Mediterranean base, and won territory in Africa and the West Indies.

Pitt had given Britain a new empire besides preserving and consolidating the old. But, before the war ended, he had been forced to resign. In 1760 George III came to the throne resolved, as was his chief adviser, the Earl of Bute, to end the war. When Pitt failed to persuade his colleagues to declare war on Spain to forestall its entry into hostilities, he resigned in October 1761. He alone was not tired of war. He never considered its carnage or the ruin facing a bankrupt country. He had tended to concentrate the whole conduct of government into his own hands and worked with furious energy. His haughty manner, which alienated many, and his high-handed treatment of affairs had earned him respect and admiration but little friendship.

When his resignation was accompanied by a peerage for Hester and an annuity to her of £3,000, there was again an outburst of abuse and scurrility. Just as when he had accepted the pay office, this acceptance of a peerage and a pension for his wife seemed to be the result of a political bargain. As rewards for his immense services they were meagre enough, but it was some measure of his unique reputation for highminded disinterestedness that his accepting them should provoke so much bitter disillusionment. His effigy was burned, and Hester was reviled as Lady Cheat'em. Pitt attacked the terms of the Treaty of Paris as an inadequate recognition of Great Britain's worldwide success. But, though his popular appeal was soon restored, his career as war minister was over.

Last years. Pitt fell back on his gout and his gardening. In 1765 an admirer left him a splendid estate at Burton Pynsent in Somerset, where he planted avenues of noble trees. He was frequently at Bath, where they stood up in the Pump Room when he drank the water. He now had the attacks of "gout in the head" that led to bouts of insanity.

When Bute resigned in 1763, he was succeeded by George Grenville, and Pitt's attacks on the administration completed a breach between the two brothers-in-law. Pitt was becoming a champion of liberty, condemning the high-handed action taken by the ministry against a member of Parliament, John Wilkes, whose paper, the *North Briton,* had attacked the King's speech at the opening of Parliament and who eventually had to flee abroad. Inactive in 1764 and 1765, Pitt reentered the stage in January 1766 to deliver a passionate plea for imperial liberty on behalf of the American colonists who had resisted the Stamp Act and to demand that act's repeal.

In July the King asked him to form a ministry drawn from all sections of the houses of Parliament. Pitt's judgment and wisdom were impaired at this time, and, never having paid attention to manoeuvring among political connections, he found it difficult to form a coherent ministry. It was a fiasco rightly called a "tessellated pavement" by his political opponent Edmund Burke. Pitt himself chose the secondary post of lord privy seal, for which he was created earl of Chatham, but this meant abandoning the House of Commons and the possibility of influencing it directly by his oratory there. The "Great Commoner" retired to the Lords and fell ill for another two years, leaving a rudderless government, under the luckless duke of Grafton and Charles Townshend, to abandon his policies. Engulfed in a black fit of insanity, Pitt withdrew completely and in 1768 resigned office. He acquired a group of followers in the House of Commons and, in an alliance with Lord Rockingham's group of opposition Whigs, offered a threat to Lord North's ministry, but this opposition was, in the end, without results.

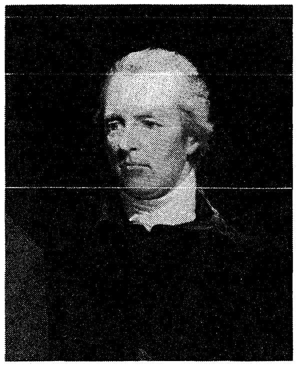
Pitt's last years were clouded by illness, yet he was to reappear in the House of Lords—with ever greater difficulty—as an elder statesman. He continued to plead for generous treatment of the American colonists though he did not wish to grant them independence, partly for fear of their falling into the hands of France; in 1775 he hurriedly introduced a bill designed to suspend repressive measures at Boston and to maintain the legislative authority of Parliament over the Colonies while using the Continental Congress established at Philadelphia as a body for assessing the monetary contributions of each colony. Although the bill was summarily rejected, it indicates how Pitt would have handled the American problem. His last speech, against any diminution of an empire based on freedom, closed a political career that had become devoted to a reconciliation of imperial power with constitutional liberty. Pitt died on May 11, 1778, falling back into the arms of his son William who was reading to him the passage in Homer's *Iliad* on Hector's farewell. He was buried in Westminster Abbey with all the funeral pomp he could have desired and with public grief.

(V.M.W.)

BIBLIOGRAPHY. Stanley Ayling, *The Elder Pitt, Earl of Chatham* (1976), is an excellent modern biography. Lord Macaulay's review (1834) of Rev. Francis Thackeray's *History of the Right Honourable William Pitt, Earl of Chatham* in his *Essays and Lays of Ancient Rome* (1884, reprinted 1954), brilliant but dated; J.H. Plumb, *Chatham* (1965), a short, interesting, and readable account; Lord Rosebery, *Chatham: His Early Life and Connections* (1910), a valuable, if lengthy, examination; O.A. Sherrard, *Lord Chatham: A War Minister in the Making,* 3 vol. (1952–58); and W.C.B. Turnstall, *William Pitt, Earl of Chatham* (1938), both scholarly and detailed.

Pitt, William, THE YOUNGER (b. May 28, 1759, Hayes, Kent, Eng.—d. Jan. 23, 1806, London), British prime minister (1783–1801, 1804–06) during the French Revolutionary and Napoleonic wars. He had considerable influence in strengthening the office of the prime minister.

Early life. William Pitt was the second son of William Pitt, 1st earl of Chatham, a famous statesman of the mid-18th century, whose energy contributed much to Britain's successful prosecution of the Seven Years' War (1756–63) with France. His mother was Lady Hester Grenville, sister of George Grenville (who headed the government from 1763 to 1765). Both because he was extremely delicate and because his father disliked public schools, he was educated at home. He was a precocious boy and went to Pembroke Hall, Cambridge, at the age of 14. Because of persistent ill health, he made use in 1776 of the antiquated privilege that allowed noblemen's sons to graduate without examination. Left, after his father's death in 1778, with an income of less than £300 a year, he was called to the bar in 1780 and joined the western assize circuit. In September 1780, because of his youth, he failed to secure election to Parliament for Cambridge University but four months later was provided with a seat for Appleby in Westmorland, on condition that he should resign it should his views and those of his patron diverge. Pitt made a successful maiden speech and, in March 1782, when it was clear that a new ministry would soon be formed, announced with astonishing self-confidence that he had no intention of accepting a subordinate position.



William Pitt, the Younger, detail of an oil painting by John Hoppner; in the National Portrait Gallery, London

Under Lord Shelburne, who succeeded as prime minister in July 1782, Pitt became chancellor of the Exchequer. With Shelburne's consent, Pitt, in February 1783, sought a compact with Charles James Fox, who had gone into opposition, but Fox absolutely refused to serve under Shelburne. According to his contemporary biographer, his form tutor and friend George Tomline, Pitt then replied that he had not come there to betray Lord Shelburne. This interview marked the beginning of the long political duel between Pitt and Fox and also rapidly brought to an end Shelburne's ministry, since Fox now surprisingly allied himself with Lord North, a politician who had always been willing to work in accordance with the King's wishes, and defeated Shelburne. King George III, unwilling to accept the coalition that would give office to Fox, whom he hated, invited Pitt to form a government; but Pitt declined, knowing he would not have a majority in the House of Commons, and the King had to commission Fox and North. To embarrass the new government, which, under the nominal premiership of the Duke of Portland, consisted of an admixture of reformers and anti-reformers, Pitt brought forward the question of parliamentary reform, with which he had already once, a year earlier, concerned himself. He suggested no extension of the franchise but recommended measures to prevent bribery and to make the representation more realistic. Although his resolutions were defeated, reformers now looked to him, rather than to Fox, as their parliamentary leader.

Pitt's first ministry, 1783–1801. In December 1783, after the defeat in the House of Lords of Fox's East India Bill, George III at once took the opportunity to dismiss the coalition and asked Pitt to form a government. Pitt clearly did not take the premiership as the King's tool, for his first step was to try, on his own terms, to include Fox and his friends in the new ministry. But Fox would not consent to join a government from which his ally Lord North would have been excluded.

When Parliament reassembled in January 1784, the government was at once defeated by 39 votes on a virtual motion of censure, but Pitt refused to resign, and George III was prepared to abdicate rather than again surrender to the Fox–North coalition. Pitt admitted that his situation was without precedent but denied that he was prime minister through backstairs influence. He hung on, and gradually the coalition's majority in Parliament began to crumble; many members, fearing the loss of their seats at a general election, went over to Pitt's side during February and March, doubtless in the hope that he would gain a majority in the existing house sufficient to make a dissolution unnecessary. By March 8 the majority against him was one vote, and on March 25 Parliament was dissolved.

No 18th-century government lost a general election, and Pitt's success in 1784 was never in doubt. The "influence of the Crown" ensured that the new House of Commons was chosen by the Treasury. Patronage and corruption gave Pitt a majority, and secret service money paid election bills. Although public opinion aided Pitt in the open constituencies, it is nevertheless misleading to say that he was "the choice of the people"; he was the dispenser of royal patronage. Pitt himself was returned for the University of Cambridge; only once again (1790), at subsequent elections, did he have to stand a contest.

When Pitt became prime minister, the national credit was impaired by the heavy cost of the American Revolution. The debt was about £250,000,000, a staggering amount for those days. Pitt imposed new taxes to wipe out the deficit, checked smuggling by reducing the high duties that encouraged it, and reduced frauds in the revenue by establishing an improved system of auditing. He also simplified customs and excise duties, bringing them into a single consolidated fund, out of which all public creditors were to be paid. In 1786 he introduced a sinking fund on a new principle: an annual surplus of £1,000,000 was to be appropriated to the purchase of stock and allowed to accumulate at compound interest for 28 years, by which time the income from it would amount to £4,000,000 a year. In 1792 another act provided that a sinking fund of 1 percent should be attached to every new loan, which would thereby be redeemed within 45 years. The system worked reasonably well in peacetime because there was an annual surplus of revenue, but, after the outbreak of war in 1793, the government redeemed debt bearing a low interest by fresh borrowing at a higher rate of interest.

Fox's East India Bill had been defeated, but the problems it was designed to solve remained. Britain's increased possessions in India made it necessary for the administration there to be supervised by the government rather than be left in the hands of the commercial East India Company. Pitt, therefore, introduced his own East India bill (1784). He set up a new government department, the Board of Control, to supervise the directors of the company. He also ended an inappropriate division of authority in India by making the governor general supreme over the subordinate governments of Bombay and Madras. In 1786 a supplementary act increased the authority of the governor general over his own council. Warren Hastings, governor general of Bengal since 1773, returned home in 1785, having greatly strengthened British power in India, only to undergo the ordeal of an impeachment for his conduct. Pitt honestly believed that there was a case against Hastings and, determined that the British name should be freed from the suspicion of injustice or oppression in the government of Asian peoples, supported the demand for an inquiry. But those who conducted the impeachment acted with unwarrantable rancour; the trial dragged on for seven years and, although Hastings was finally acquitted, the expenses almost ruined him.

Another imperial problem with which Pitt had to deal was that of the future of Canada. By the Constitutional Act of 1791 the then province of Quebec was divided into a predominantly French province of Lower Canada and a predominantly English province of Upper Canada. Pitt, who was in office when men were first transported to Australia, never regarded that country as anything more than a convict settlement.

Pitt's foreign policy was only moderately successful. In 1788 he made alliances with Prussia and with Holland, aimed at restricting French influence. But, in effect, the alliance served only one useful purpose: Prussia's diplomatic support enabled Pitt in 1790 to triumph over the Spanish without having to go to war in the Nootka Sound dispute. Thus, the Spanish claim to a monopoly of trade and settlement on the western seaboard of North America was finally destroyed. Pitt's intervention in eastern Europe, however, bore no such marks of triumph. Catherine II of Russia was bent on establishing her supremacy in the Black Sea. In March 1791 Pitt sent her an ultimatum demanding the restoration to the Sultan of all conquests except the Crimea. But his policy of bolstering up the Turkish Empire was supported neither by the entire Cabinet nor by public opinion, and the government, badly shaken, had to reverse its policy.

Although the British government clung to neutrality as long as possible, in face of the European wars started by the leaders of the French Revolution, war proved unavoidable. It was not the execution of the French king Louis XVI in January 1793 that made a continuation of peace impossible but it was the provocative French decrees of late 1792, which authorized their armies to violate neutral territory and which promised military assistance to any European people wishing to depose its rulers. The French, confident of victory after their successes against the Austro-Prussian forces and believing that England was ripe for revolution, declared war on England and Holland on Feb. 1, 1793. Pitt refused to intervene to restore the French monarchy. He fought to protect Britain's vital commercial and colonial interests.

The French Revolution had revived the agitation for parliamentary reform, dormant since a bill introduced by Pitt in 1785 had been defeated, but the cause of reform was soon discredited because its advocates were thought to approve of the violence in France. The unwise demonstrations of the radicals caused the government to have recourse to repressive legislation. In May 1792 a proclamation against seditious publications was issued; and the Habeas Corpus Act, which normally prevented the detention of persons without trial, was suspended in 1794 and remained so until 1801.

The French Revolution had disastrous repercussions in Ireland, too, creating new hatreds to exacerbate the old religious feuds and a rebellion in 1798. As early as 1792 Pitt had held that an ultimate union of the two countries was the only solution of the Irish religious problem; the events of 1798 convinced him that union was most urgently necessary. Large-scale corruption carried the measure through the Irish Parliament, but opposition from Pitt's Cabinet and particularly from the King prevented him from carrying his supplementary proposals—Catholic emancipation and state provision for Catholic and Dissenting clergy. As a result, Pitt resigned on Feb. 3, 1801, and his friend Henry Addington formed a government. The crisis again drove the King insane, and after his recovery in March he accused Pitt of having caused his illness. Pitt replied that he would never again press the Catholic question during the King's reign.

Patriotic motives induced Pitt to support the new ministry, but for several months during the session of 1802–03 he never attended Parliament, living in Walmer Castle, where, holding the ancient office of warden of the Cinque Ports, he organized a local volunteer force. In March 1803 Addington invited Pitt to join the government, but Pitt made it clear that he would return only as prime minister. War broke out again in May 1803, and by 1804 Pitt was increasingly critical of the government's financial polity and its measures to meet the growing danger of invasion. Addington's majority fell steadily, and he decided to resign. On April 30 Pitt was informed that the King wished him to plan a new ministry. Pitt replied that a nonparty government was desirable but fell in with the King's determination that Fox be excluded.

Pitt's second ministry, 1804–06. Pitt's second ministry was weaker than the first, for the Addington group, as well as others, went into opposition. The Third Coalition against Napoleon's France—an alliance with Russia, Sweden, and Austria engineered by Pitt—collapsed after the battles of Ulm and Austerlitz in 1805, and the year closed in disaster, in spite of Nelson's victory at Trafalgar in October, which ended the invasion threat and ensured Britain's naval supremacy for the rest of the war. Pitt's health, never robust, was now failing. He made his last public speech at the Guildhall in London on Nov. 9, 1805. By Jan. 15, 1806, some of his colleagues were determined to force him to resign as the only means of saving his life, and the King was thinking about his successor. He died a few weeks later and was buried in Westminster Abbey on February 22. A motion for a grant of £40,000 to pay his debts was unanimously carried in the Commons. Earlier (1801), his friends had raised £12,000 in order to relieve him from embarrassment. Careless to a fault about money and engrossed with public affairs, he had allowed his large official income to be squandered by irresponsible servants and tradesmen.

Private life and character. Though eloquent and forceful in Parliament and Cabinet, Pitt made no impact in society and altogether lacked the common touch. He was always notably withdrawn. He never married. He had few friends. Even members of the government complained of his inaccessibility. In 1801 his resignation from office caused extraordinarily little sensation; a contemporary wrote that "nobody speaks of him; no addresses, no subscriptions, no stir of any kind any where." Long before his death, bodily infirmities, increased by his addiction to port, curtailed his working day.

Pitt's experience was remarkably limited. He never set foot in Scotland or Ireland; the greater part even of England was unknown to him. He was once in France—for a few weeks. He never came into touch with men of letters or original thinkers; in his official patronage he neglected literature, science, and the arts. He was long overconfident of success in every cause he espoused; in the end only the weight of ill health and Napoleon's great victories of 1805 began to shatter his optimism. Although at first connected with the movement for parliamentary reform, he made no attempts to reintroduce the issue after the failure of his bill in 1785. He made no effort to deal with the social problems caused by the Industrial Revolution; and in all his long years of office, nothing was done to reform the barbarous criminal law, the harsh game laws, prison administration, and local government. Nevertheless, by reason of his superb debating powers he dominated the House of Commons, even in that age of notable oratory. His conduct in Parliament had a mixture of prudence, firmness, and transcendent ability never before seen and hardly ever again surpassed.

Historical importance. The constitutional significance of Pitt's career has often been misunderstood. He was not a prime minister of the modern type. At no time was he the leader of a well-organized, coherent party commanding a majority of the House of Commons, which itself owed its existence to the will of the electorate. He was not at all the choice of the country; he was the nominee of the King, and he retained office only as long as he retained the King's confidence. He had to resign in 1801 because his Irish policy was not acceptable to George III. Even though the inadequacy as a wartime prime minister of his successor made Pitt's return to office almost inevitable three years later, Pitt did not return on his own terms but on the King's. He was more dependent on the King's favour than he was on the support of the House of Commons. His most serious crisis came in the winter of 1788–89, when, during George III's madness, Pitt lost the support of the crown. Had the dissolute Prince of Wales, who favoured the opposition, become regent, Pitt would certainly have been dismissed. Without the support of the crown, neither he nor anyone else could remain long in office. Moreover, there were obvious limitations to his absolute authority in the Cabinet, where various colleagues opposed him on all the great questions of the day. And, finally, Pitt had to deal with a sovereign of narrow intellect and with intense and irrational prejudices—though, indeed, these were shared by a great many of George III's subjects.

Although Pitt's supremacy in the Cabinet has often been exaggerated, the necessity for a prime minster who would supervise and coordinate the work of the various departments and possess the chief confidence of the king was never again questioned after his ministries. Pitt's achievement of this status, while depending upon his forcefulness of character, was only made possible by his long tenure of office. His total of 19 years in power exceeded by almost 7 years the tenure of office, earlier in the 18th century, of Sir Robert Walpole, often regarded as "the first" British prime minister, and that of Lord North, nearer Pitt's own time.

It is sometimes claimed that Pitt emerged as the leader of a new Tory Party. Certainly, as a minister who accepted the royal prerogative, he represented the traditions of the Tory, or Court, Party, as distinct from those of the Whigs, who sought to dictate to the crown the choice of its servants; but he was far from being a great party leader commanding the votes of a majority in the House of Commons. He had a personal following of little more than 50. In spite of persistent efforts, great speeches, and the support of powerful and eloquent members, he failed to pass a slave trade abolition bill, a parliamentary reform bill, and Catholic relief bills.

Pitt-Rivers, Augustus Henry Lane-Fox (b. April 14, 1827, Hope Hall, Yorkshire, Eng.—d. May 4, 1900, Rushmore, Wiltshire), archaeologist often called the "father of British archaeology," who stressed the need for total excavation of sites, thorough stratigraphic observation and recording, and prompt and complete publication. Like Sir Flinders Petrie, Pitt-Rivers adopted a sociological approach to the study of excavated objects and emphasized the instructional value of common artifacts.

Pitt-Rivers, detail from a drawing by C.W. Walton, *c.* 1850; in the Pitt-Rivers Museum, Oxford
By courtesy of the Pitt-Rivers Museum, Oxford

An army officer for most of his life, Pitt-Rivers retired from the military in 1882 and in the following year embarked on a series of excavations of prehistoric, Roman, and Saxon sites on his 29,000-acre estate in Wiltshire. His large-scale excavations, models of organization and painstaking care, unearthed villages, camps, cemeteries, and barrows (burial mounds) at sites such as Woodcutts, Rotherley, South Lodge, Bokerly Dyke, and Wansdyke.

His efforts resulted in one of the classics of archaeology, the richly illustrated *Excavations in Cranborne Chase,* 5 vol. (1887–1903), which Pitt-Rivers printed privately. He also observed a similarity between the stone implements used in Europe when certain rhinoceroses and mammoths roamed there and the implements characteristic of the dawning stages of Egyptian culture.

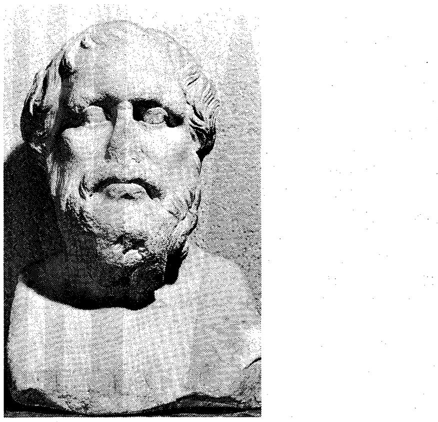
Where the same name may denote a person, place, or thing, the articles will be found in that order

pitta, any of about 23 species of Old World birds of the genus *Pitta* constituting the family Pittidae. All are stub tailed, long legged, and short necked. They have a rather stout bill and are 15–27 centimetres (6–10½ inches) in length. Pittas faintly resemble thrushes and are sometimes known as jewelthrushes. The sexes may be alike or unlike in appearance. Most species are found in the Indo-Malayan region, some ranging to the Solomon Islands; four occur in Australia, two in Africa. The Indian pitta (*P. brachyura*) is typically colourful, wearing shimmering blue, yellow, green, red, black, and white. The blue-winged pitta (*P. moluccensis*) is common in tropical Africa and from Burma to Sumatra. *P. nympha,* also called blue-winged pitta, is found in Japan, Korea, and eastern China.

Indian pitta (*Pitta brachyura*)
Tierbilder Okapia, Frankfurt am Main

Pittas are shy birds of forest or scrubland, where they move rapidly in long hops, foraging for insects and snails in ground litter. Their call is usually a trill or a short whistle. Their nests, on or near the ground, tend to be large and roughly made.

Pittacus OF MYTILENE (b. *c.* 650 BC—d. *c.* 570), statesman and sage who is known as one of the Seven Wise Men of ancient Greece. He collaborated with the brothers of the poet Alcaeus in the overthrow of the tyrant Melanchrus (612/611?) and distinguished himself as a commander in the war against Athens for Sigium, killing the Athenian commander, Phrynon, single-handedly. He was elected *aisymnetes* (dictator appointed during times of internal strife) by the Mytileneans (*c.* 590 BC) and served in that post for 10 years. Diogenes Laërtius quotes a number



Pittacus, herm; in the Louvre, Paris

of sayings ascribed to him (mostly moral or political maxims) and five lines of lyric verse, as well as a spurious letter to Croesus.

pitted shell turtle, also called FLY RIVER TURTLE, or NEW GUINEA PLATELESS TURTLE (species *Carettochelys insculpta*), any member of a single species in the turtle family Carettochelyidae. The species lives in rivers in southern New Guinea and in a limited region in northern Australia. A combination of characteristics separates *C. insculpta* from other turtles, including a leathery shell with no scutes and sea turtlelike flippers. Little is known of the ecology of this species.

Pittosporaceae, family of nine genera of trees, shrubs, or vinelike plants, in the order Saxifragales, distributed from tropical Africa to the Pacific islands. Members of the family have long, leathery, evergreen leaves; resin in stem ducts; and white, blue, yellow, or reddish flowers. Species of the genus *Pittosporum* are commonly known as Australian laurel. Tobira, or house-blooming mock orange (*P. tobira*), is a popular aromatic hedge plant in warm climates but a handsome indoor plant elsewhere. Karo (*P. crassifolium*) often is planted as a windbreak on seacoasts. The genera *Hymenosporum, Bursaria,* and *Sollya* also contain ornamental species.

Tobira (*Pittosporum tobira*)
Javier Palaus Soler—Ostman Agency

Pittsburg, city, Crawford county, southeastern Kansas, U.S., near the Missouri border. Laid out in 1876, it developed as a coal-mining town and railroad centre and was named after Pittsburgh, Pa. Besides strip coal-mining operations, it has large plants producing coal preparation equipment and ammonium nitrate. Pittsburg State University was founded in 1903. The city is also the site of the Personal Census Service Branch of the U.S. Bureau of the Census. Inc. 1880. Pop. (1988 est.) 18,288.

Pittsburg Landing, Battle of: *see* Shiloh, Battle of.

Pittsburgh, city, seat (1788) of Allegheny county, southwestern Pennsylvania, U.S., at the confluence of the Allegheny and Monongahela rivers, which unite at the point of the "Golden Triangle" (the business district) to form the Ohio River. A city of hills, parks, and valleys, it is the centre of an urban industrial complex that includes the cities of Aliquippa, McKeesport, New Kensington, Washington, and Wilkinsburg.

The conflict between the British and French over territorial claims in the area was settled in 1758, when General John Forbes and his British and colonial army expelled the French from Fort Duquesne (built 1754). Forbes named the site for the British statesman William Pitt the Elder. To assure their dominance at the source of the Ohio, the British built Fort Pitt (1761). After the defeat of Pontiac's Indian forces (1763), a later settlement with Indian tribes by the Penn family, and the end of a boundary dispute between Pennsylvania and Virginia, settlers began arriving. Pittsburgh was laid out (1764) by John Campbell in the area around the fort (now the Golden Triangle). Following the Revolutionary War, the town became an outfitting point for settlers traveling down the Ohio River.

Its strategic location and wealth of natural resources spurred its commercial and industrial growth in the 19th century. A blast furnace, erected by George Anschutz about 1792, was the forerunner of the iron and steel industry. The Pennsylvania Canal and the Portage Railroad, both completed in 1834, opened vital markets for trade and shipping. Industrial magnates such as Andrew Carnegie, Henry Clay Frick, and Thomas Mellon built their steel empires in Pittsburgh, which became the focus of historic friction between labour and management. There, the American Federation of Labor was born (1881). Pittsburgh is now one of the nation's largest inland river ports and a leading transportation centre. By the late 1970s and early '80s, the steel industry, Pittsburgh's economic foundation for over a century, virtually disappeared, as a result of foreign competition and decreased demand. Many of the surrounding mill towns were laid waste by unemployment. Pittsburgh, however, managed to thrive, through more emphasis on light industries and on such other industries as petroleum, glass, electrical equipment, machinery, and coal, coke, and chemical products. More than 150 industrial research laboratories are in the area.

Since World War II, the city has undergone an extensive redevelopment program with emphasis on smoke-pollution control, flood prevention, and sewage disposal. In 1957 it became the first American city to generate electricity by atomic energy. Much of the Golden Triangle has been rebuilt and includes the Civic Arena, Point State Park (site of Fort Pitt Blockhouse), and the Gateway Center (site of several skyscrapers and a garden). The University of Pittsburgh was chartered in 1787. Other educational institutions include Carnegie-Mellon University (1900), Duquesne University (1878), and Chatham (1869), Carlow (1929), Point Park (1933), and Allegheny County Community (1966) colleges. Carnegie Institute has a 2,000,000-volume library, museums of fine arts and natural history, and the Carnegie Music Hall. The Phipps Conservatory and Buhl Planetarium are also there. Three Rivers Stadium is the home of the Pittsburgh Pirates (baseball) and Steelers (football). Inc. borough, 1794; city, 1816. Pop. (1988 est.) city, 387,190; Pittsburgh-Beaver Valley metropolitan area (CMSA), 2,284,100.

Pittsburgh glass, American glassware produced from the end of the 18th century at numerous factories in that Pennsylvania city. Pittsburgh had the twin advantages of proximity to a source of cheap fuel (coal) and access to a good waterways system, which afforded an inexpensive means of distribution; thus, of the 50 glasshouses that sprang up in Pennsylvania between 1763 and 1850, 40 or more were situated in Pittsburgh (although of these only 14 produced flint glass, a type of clear crystal, the other 26 making strictly utilitarian items such as windowpanes and cider, beer, and whiskey bottles).

Pittsfield, city, seat (1761) of Berkshire county, western Massachusetts, U.S., on the headstreams of the Housatonic River, in the Berkshire Hills, 58 miles (93 km) northwest of Springfield. Settled in the 1740s as the Pontoosuc Plantation, it was incorporated as a town in 1761 and named for the English prime minister William Pitt. It developed from a farming to an industrial community during the early 19th century because of abundant waterpower. Manufactures now include electrical machinery, ordnance supplies, paper, textiles, plastics, and foundry products. The insurance business is also prominent.

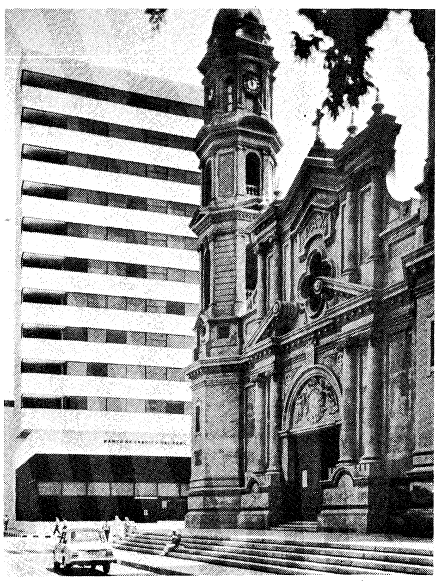
The city is a tourist base for the Berkshire Hills (including Pittsfield State Forest, lakes, ski resorts, and state parks). Herman Melville lived there and completed *Moby Dick* at his "Arrowhead" house; the Berkshire Athenaeum stores Melville memorabilia. Tanglewood, at Lenox, 6 miles (10 km) south, is the summer home of the Boston Symphony Orchestra. The city is the site of Berkshire Community College (established 1960). The restored Hancock Shaker Village is 5 miles (8 km) west. Inc. city, 1890. Pop. (1986 est.) city, 49,580; (1988 est.) metropolitan area (MSA), 79,300.

pituitary gland, also called HYPOPHYSIS, one of the endocrine (ductless) glands that secrete their hormones directly into the bloodstream. The term hypophysis (from the Greek, "lying under") refers to the gland's position on the underside of the vertebrate brain. Until the late 19th century the human pituitary was thought to be a vestigial organ, but it is now known to play a major part in the regulation of endocrine functions.

The pituitary is divided into two lobes: the anterior, or adenohypophysis, which is derived from an upward outpouching of the roof of the mouth (Rathke's pouch), and the posterior, or neurohypophysis, which is derived from embryonic nerve tissues. Most of the pituitary hormones are secreted by the anterior lobe and cause the production or release of hormone from other endocrine glands. The thyroid-stimulating hormone (TSH) stimulates the growth of the thyroid gland and release of its hormone; the adrenocorticotropic hormone (ACTH) regulates the endocrine activities of the cortex of the adrenal glands, which produces cortisol; follicle-stimulating hormone (FSH) promotes secretion of the female hormone estrogen and the development of egg and sperm cells; luteinizing hormone releases estrogen, progestin, and the male hormone testosterone; and growth hormone, or somatotropin, stimulates a variety of systems involved in the growth of the individual. The two other anterior pituitary hormones do not act on endocrine glands but directly affect specific tissues. They are prolactin, which causes breast development and milk production, and melanocyte-stimulating hormone (MSH), which stimulates pigment cells. The parent hormone of MSH, lipoprotein, also gives rise to chemical compounds, called enkephalins and endorphins, that have an effect on brain cells similar to that of opiates such as morphine.

The posterior lobe, or neurohypophysis, is connected to the anterior lobe by a portal vein, through which the hormones that control pituitary function are transmitted. These hormones originate in the hypothalamus of the brain and are stored in the neurohypophysis until needed. The neurohypophysis also releases two hormones that act elsewhere in the body: oxytocin, which causes contraction of the uterus and milk secretion in female mammals and lowers blood pressure in birds; and vasopressin, also called antidiuretic hormone (ADH), which raises blood pressure by causing the contraction of blood vessels and increases reabsorption of water from the kidneys.

Piura, department (formed 1861) of northern Peru, consisting of coastal desert, particularly in the west and south, and low, forested Andes in the east. Its area of 14,055 sq mi (36,403 sq km) is drained by the Río Chira, in the north, and the Río Piura, in the south. The irrigated valleys of these two rivers are used chiefly for the production of cotton. Upstream on the Río Piura, sugarcane, rice, tobacco, and corn (maize) are grown. Cattle are grazed in the mountains and fattened on lowland irrigated pastures. Piura is also important for the production of petroleum. The Brea–Parinas fields, Peru's major oil-producing region, form a belt about 80 mi (130 km) long on either side of the community of Talara, site of an oil refinery in northwest Piura. The Pan-American Highway traverses the desert, passing through the departmental capital, Piura (*q.v.*). Other roads connect Piura city and the oil fields with seaports and penetrate the mountains. Piura city and Talara are also accessible by air. Pop. (1981) 1,125,865.



A modern office building and the cathedral, Piura city, Peru

Walter Aguiar—EB Inc.

Piura, capital of Piura province and department, northwestern Peru, on the Río Piura in the warm coastal desert. San Miguel de Piura was the first city founded (1532) in Peru by the conquistador Francisco Pizarro. The site chosen proved unhealthful, and several locations were occupied before settlement of the present site in 1588. Piura retains a colonial flavour, especially in the church of San Francisco. It is the commercial centre of northwestern Peru, which produces cotton, rice, and sugarcane. In and around Piura are cotton gins and cottonseed-oil mills, in addition to various small manufacturing plants. The city is accessible by the Pan-American Highway, by air, and by sea through the coastal town of Paita, 40 mi (65 km) west. Pop. (1981) city, 186,354; province, 413,688.

Pius, name of Roman Catholic popes grouped below chronologically and indicated by the symbol •.

• Pius I, SAINT (b. Aquileia, Venetia—d. 155, Rome; feast day July 11), Latin pope from *c.* 140 to 155.

Pius was a slave, according to his supposed brother, the apostolic father Hermas. As pope, Pius combatted Gnosticism—a religious movement teaching that matter is evil and that emancipation comes through spiritual truth attained only by revelatory esoteric knowledge—and the Marcionites, followers of a heretical Christianity proposing especially a doctrine of two gods as taught by the semi-Gnostic Marcion, whom Pius is believed to have excommunicated in 144/150. The claim that Pius was martyred is unsubstantiated.

• Pius II, original name ENEA SILVIO PICCOLOMINI (b. Oct. 18, 1405, Corsignano, Republic of Siena—d. Aug. 14/15, 1464, Ancona, Papal States), outstanding Italian humanist and astute politician who as pope (reigned 1458–64) tried to unite Europe in a crusade against the Turks at a time when they threatened to overrun all of Europe. He wrote voluminously about the events of his day.

Pius II, bronze medal by Andrea Guacialoti; in the Samuel H. Kress Collection, National Gallery of Art, Washington, D.C.

Early life and career. Enea Silvio Piccolomini was born near Siena, Italy, into a noble family in very reduced circumstances. He acquired his humanistic education by assiduous work under unfavourable conditions. To earn a living he became secretary to Cardinal Domenico Capranica and went with him to the Council of Basel, a meeting of bishops concerned with church reform (1431–37), which was already at loggerheads with Pope Eugenius IV. With Cardinal Niccolò Albergati he visited many European countries on a diplomatic mission. On returning to Basel in 1436, he became an official of the council, which gave him opportunities to show his great skill as an orator. He became secretary to the antipope Felix V, elected on Nov. 5, 1439, by the remnant of bishops at Basel, who refused to obey Pope Eugenius' order to transfer the council to Ferrara and Florence.

As representative of the Basel remnant at the Diet (imperial assembly) of Frankfurt, he attracted the attention of Frederick III of Austria, who invited him to Vienna (1442) and made him imperial poet laureate and his private secretary. Thereupon, he broke his connection with the antipope in 1445 and was absolved of the ban of excommunication that he had been under. A serious illness is said to have led him to amend his dissolute life (he was the father of several illegitimate children). In Frederick's name he proposed to end the rivalry between the papal council at Florence and the rebellious council at Basel by summoning a third council but could persuade neither Eugenius nor the bishops at Basel. Hitherto a layman, Enea received sacred orders in 1446. He next managed to calm the storm raised by Eugenius' deposition of two of the German archbishop electors and was chiefly responsible for reconciling the German princes with the Pope and for Frederick's withdrawal of support for the council at Basel.

Made bishop of Trieste by the new pope, Nicholas V, in 1447, he continued his successful mediation between the German states and the Holy See, explaining in a "letter of retractation" his change of role from supporting Basel to being advocate of the papacy. He was transferred in 1449 to the see of Siena, where he was still able to be of service to King Frederick by negotiating his marriage with a Portuguese princess and arranging his coronation as Holy Roman emperor in Rome by Nicholas V (1452). Nicholas' successor, Calixtus III (1455–58), made Enea cardinal-priest of Sta. Sabina as a reward for negotiating peace with Alfonso V, king of Aragon and Naples, and persuading him to cooperate in the crusade against the Turks that Calixtus was energetically promoting.

Pontificate. On Calixtus' death Enea Silvio was elected pope as Pius II (Aug. 19, 1458). As pope he had one main purpose: to organize a grand crusade to drive back the Turks, who, having captured Constantinople in 1453, were threatening to overrun the rest of Europe. He summoned the Christian princes to a congress in Mantua to study and meet the danger. When he arrived on the appointed day, June 1, 1459, he was alone. Very gradually some came but only to squabble for advantages to themselves.

The patient diplomacy of the Pope achieved little. A condition for success was to restore peace to the West. In Italy, Pius slowly regained control of the Papal States. His negotiations with France for the repeal of the Pragmatic Sanction of Bourges (of 1438, which made France largely independent of the papacy in ecclesiastical jurisdiction) failed with King Charles VII but succeeded with his son Louis XI (1461). The Greek cardinal Bessarion was sent to Germany (1460) to promote the crusade, but local feuds and wars blocked his efforts. He was equally unsuccessful in Vienna and returned to Rome in the following year but had some success later in Venice. Wars in the Tyrol and discord in Bohemia increased the general unrest. A lull in some hostilities and promises of support from the emperor Frederick and Philip the Good, duke of Burgundy, encouraged the intrepid but sick pope to proclaim in October 1463 a crusade, which he himself would lead. Pius left Rome on June 18, 1464, for the rendezvous of the armies in Ancona, an Adriatic seaport on the east coast of Italy, where he arrived to find nearly no one. Two Venetian ships arrived on

August 11. Pius died during the night of August 14–15. His heart was interred at Ancona, still facing, as it were, the infidel East. His body was taken to Rome and there buried in St. Peter's; it was transferred to the church of S. Andrea della Valle when the new St. Peter's was being built.

Achievements. Pope Pius II's great knowledge of conditions in Germany and elsewhere inspired a scheme of wide church reform, but the political conditions of the time and the resistance of the various vested interests rendered its application impossible. He did what he could, particularly by encouraging the movements toward strict observance of the rules of life within religious orders. On the whole, he created worthy cardinals, and on Jan. 17, 1460, he issued a bull condemning appeals from a pope to a general (ecumenical) council of the church. A voluminous writer about the events he had participated in, he wrote also general history and geography, poetry, and at least one scurrilous novel (*The Tale of Two Lovers*). As pope he was a patron of humanists but not to excess either in the use of money or in being complacent about their morals. (J.Gi.)

BIBLIOGRAPHY. *Writings.* Pius II's complete works, *Opera omnia,* ed. by M. Hopperus, were printed in 1551. Other collections are *Orationes politicae,* ed. by J.D. Mansi (1755–59); and *Opera inedita,* ed. by J. Cugnoni (1883).

English translations. His novel *De duobus amantibus* was much translated (first Eng. trans., *The Goodly History of the . . . Ladye Lucres of Scene in Tuskan,* 1560; later Eng. trans., *The Tale of Two Lovers,* by F. Grierson, 1929). "The Commentaries of Pius II," ed. by F.A. Gragg and L.C. Gabel, were published in *Smith College Studies in History,* vol. 22, 25, 30, 35, and 43, abbreviated into the autobiographical account *Memoirs of a Renaissance Pope* (1959, reprinted 1961). The *De gestis Concilii Basiliensis commentariorum libri II,* ed. by D. Hay and W.K. Smith (1967), was written in 1440 supporting conciliarism.

portant legations, as by Paul II at the Diet of Regensburg (1471) and by Innocent VIII to restore ecclesiastical authority in the Italian compartimento of Umbria.

He opposed the flagrant nepotism of Pope Alexander VI, after whose death Cesare Borgia, Alexander's son, seized the Vatican with his troops in an attempt to control the conclave. Protected by the Romans, the cardinals gathered in the Church of the Minerva, and on Sept. 22, 1503, elected Francesco, who took the name of Pius. He was consecrated on the following October 1 but died soon after. In honour of Pius II he founded the Piccolomini Library adjoining the Siena Cathedral.

• **Pius IV,** original name GIOVANNI ANGELO DE' MEDICI (b. March 31, 1499, Milan—d. Dec. 9, 1565, Rome), Italian pope (1559–65) who concluded the Council of Trent.

Pius IV, contemporary medallion; in the coin collection of the Vatican Library

A canon lawyer, in 1545 he was ordained and consecrated archbishop of Ragusa and in 1547 was appointed papal vice legate for Bologna. He was made cardinal priest in 1549.

After a long conclave Giovanni was elected pope on Dec. 25, 1559, as Pius IV. Though he had long agreed with those who saw a need for definite reforms, particularly of nepotism, in the Curia, he called his own nephew Charles Borromeo, to Rome, where he created him cardinal deacon in 1560. Pius nevertheless took prompt action to bring Cardinal Carlo Carafa, his brother, Giovanni, and Pope Paul IV's nephews to trial, which resulted in their controversial execution on March 6, 1561. He concurrently collaborated with Borromeo in composing crucial letters appealing to Europe's Roman Catholic princes to resume the Council of Trent, which had been suspended since 1552.

Despite the peace between France and Spain, many obstacles stood in the way of the council. The Holy Roman emperor Ferdinand I, still hoping for the return of the Lutherans to the Roman Church, sympathized with doctrinal concessions in their favour; King Philip II of Spain, on the contrary, opposed any change and was cool toward reopening the council, and the Roman Curia was totally opposed to any doctrinal change, though willing to discuss the reform of abuses. Pius was prepared to concede communion in both kinds and perhaps also clerical marriage. He especially hoped to prevent France from following Germany into apostasy.

Pius' bull of convocation was issued on Nov. 29, 1560; the opening session took place on Jan. 18, 1562. A year was spent in overcoming major differences, and the outcome was an almost unmitigated triumph for the papacy. With Borromeo as his chief adviser, Pius' conciliatory attitude calmed imperial opposition. The effective reforms of the council gradually restored the pastoral efficiency of the Roman Catholic Church and represented the middle-of-the-road conservative Catholics. The council was dissolved on Dec. 4, 1563, and Pius confirmed its decrees and definitions in his bull *Benedictus Deus* (Jan. 26, 1564); on the following November 3, he published a summary of doctrine generally known as the *Professio Fidei Tridentina* ("Tridentine Profession of the Faith"), imposing it on the bishops as obligatory.

Several important works that the council recommended or initiated but could not effectually carry out were given to Pius for completion; among these were drafting the *Index of Forbidden Books* and reforming the catechism, missal, and breviary. In 1564 he made Borromeo cardinal priest, designating him chief reformer of the Curia and head of the Consulta, thus making him secretary of state. Under the direction of Borromeo, the catechism was completed some months after the Pope's death. Pius also encouraged St. Teresa of Ávila's celebrated Carmelite reform and reduced the powers of the Inquisition. Having revived the Roman university, he launched an energetic building program, patronizing Michelangelo.

Pius did not long outlive the conclusion of the legal enactment of the Counter-Reformation, and his desire for a continued endeavour to reconvert the German Protestants died with him. During his last days the stiff taxation needed for his reform caused a conspiracy against him.

• **Pius V,** SAINT, original name ANTONIO GHISLIERI (b. Jan. 17, 1504, Bosco, Duchy of Milan—d. May 1, 1572, Rome; canonized May 22, 1712; feast day May 5), Italian ascetic, reformer, and relentless persecutor

Pius V, contemporary medallion; in the coin collection of the Vatican Library
Leonard von Matt—EB Inc.

of heretics, whose papacy (1566–72) marked one of the most austere periods in Roman Catholic Church history. During his reign, the Inquisition was successful in eliminating Protestantism in Italy, and the decrees of the Council of Trent (1545–63) were put into effect.

Early life and career. Pius V, born Antonio Ghislieri, came from a poor family in northern Italy. He was a shepherd until the age of 14, when he became a Dominican friar. His first important appointment was as inquisitor, a high office of the Inquisition, then the Roman Catholic Church's judicial system for discovering, examining, and punishing heretics. Ghislieri's methods, prompted by excessive zeal, provoked such opposition from his bishop's officials as well as his chapter that he was recalled in 1550. The chief inquisitor in Rome, Giovanni Pietro Carafa, convinced of his value, sent him on a mission to Lombardy and, in 1551, appointed him commissary general of the Roman Inquisition. When Carafa became pope (as Paul IV), Ghislieri was made bishop of Nepi and Sutri (1556), cardinal (1557), and finally grand inquisitor of the Roman Church (1558). He was continued in this office by Pius IV, whom, however, he antagonized by his censoriousness and obstinacy.

Papal reforms. After the death of Pius IV, the adherents of strict religious rules, led by Cardinal (later St.) Charles Borromeo, the nephew of Pius IV, had no difficulty making him pope (Jan. 7, 1566). Retaining his ascetic mode of life, Pius immediately began the work of reform. Decrees and ordinances were issued rapidly; the papal court became a model of sobriety; prostitutes were driven from the city or confined to a certain quarter; penalties were fixed for Sunday desecration, profanity, and animal baiting; clerics holding benefices were required to spend definite periods in their administrative districts; members of convents were compelled to live in strict seclusion according to their vows; instruction in the catechism, the short manual outlining the principles of Catholicism, was ordered. A new catechism appeared in 1566, followed by an improved breviary (the daily prayers for clergy and nuns [1568]) and an improved missal (a book containing the prayers and responses for celebrating the mass [1507]). The use of indulgences—*i.e.,* the remission of temporal punishment due for sin—and dispensations from vows was restricted, and the whole system of penance was reformed.

Pius was an avowed enemy of nepotism. Though it is true that he made one nephew cardinal, he was allowed to have no influence, and the rest of the family was kept at a distance. By the constitution *Admonet Nos* (March 29, 1567), he forbade the reinvestiture of fiefs—those landed estates held under feudal tenure that were intended to revert to the Holy See—and bound the cardinals by oath to observe it. In March 1569 Pius ordered the expulsion of the Jews from the States of the Church, though for commercial reasons they were allowed to remain under humiliating conditions in Rome and Ancona. In February 1571 the Humiliati, a corrupt monastic order of Milan, was suppressed on account of an attempt upon the life of the archbishop, Cardinal Borromeo.

The rules governing the Inquisition were sharpened; old charges, long suspended, were revived; rank offered no protection but rather exposed its possessor to fiercer attack. None was pursued more relentlessly than the intellectuals, among whom many of the Protestant doctrines had found acceptance. Princes and states withdrew their protection of heretics and courted the favour of the Holy See by surrendering distinguished offenders. Philip II of Spain in 1566 surrendered Bartolomé de Carranza, the Spanish theologian and former confessor to Queen Mary of England, and Cosimo de Medici in 1567 gave up Pietro Carnesecchi, the Florentine heretic who had been suspected even during Paul IV's papacy (receiving two years later as a reward the title of grand duke of Tuscany). In March 1571 the special Congregation of the Index, a list of books condemned as dangers to faith and morals, was established distinct from the Inquisition, and hundreds of printers took flight to Switzerland and Germany. The regret of Pius was that he had sometimes been too lenient. He encouraged Philip II of Spain to use the most ruthless tyranny to preserve his Dutch subjects in the Catholic faith and sent troops to France to help Catherine de Médicis repress the Huguenots; he protested against the tolerance shown by the Holy Roman emperor Rudolf II.

Influence. In all this work, Pius confirmed Borromeo's belief that a spiritually minded pope was above all else necessary if the decrees of the Council of Trent (1545–63) that were intended to rebut Protestant doctrines and to reform Catholicism were to be put into practical effect. The moral standing of the papacy was greatly raised, its effectiveness was immensely increased by the obliteration of heresy in Italy, and the morale of the church was much improved by the insistence on interpreting church doctrine according to precepts established at the council. Yet it is uncertain how much of this improvement was due to Pius' continuous use of the Inquisition. Some credit belongs to the new generation of higher and lower clergy in the several provinces whose attitude was so different from that of their predecessors. The council left him to finish the reform of the missal and breviary, but he left the medieval canon virtually unchanged, as it remained until 1970.

Moreover, Pius' policy had practical disadvantages. It took too little account of the wishes of secular rulers at a time when their support was essential for the defense of the church against heresy. He excommunicated Elizabeth I of England and declared her a usurper (Feb. 25, 1570) without possessing the means to enforce his judgment, and he antagonized not only England but Spain, France, and the Holy Roman Empire as well. Much more successful was his organization of a crusade against the Turks, which resulted in a decisive naval victory of Lepanto (Oct. 7, 1571). He made October the month of the rosary because of his victory. (I.F.B./D.Wo.)

BIBLIOGRAPHY. The fullest biography is F.A.P. de Falloux, *Histoire de St. Pie V,* 2 vol. (1844). Slighter biographical works (*Vita di Pio V*) are two that appeared soon after his death: Girolamo Catena (1586) and Giovanni Antonio Gabuzio (1605). There is a study of the Pope's policy toward France by C. Hirschauer, *La Politique de St. Pie V en France 1566–1572* (1922). H. Daniel-Rops, *Une Ère de renouveau: La Réforme catholique* (1955; *The Catholic Reformation,* 1962), has a good section on Pius V.

• **Pius VI,** original name GIANNANGELO BRASCHI (b. Dec. 25, 1717, Cesena, Papal States—d. Aug. 29, 1799, Valence, Fr.), Italian pope from 1775 to 1799, whose tragic pontificate was the longest of the 18th century.

He held various papal administrative positions before being ordained priest in 1758.

Pius VI, detail from a portrait by Pompeo Girolamo Battoni
By courtesy of the National Gallery of Ireland, Dublin

Progressing rapidly, he became treasurer of the apostolic chamber under Pope Clement XIII in 1766, and in 1773 was made cardinal by Pope Clement XIV, after whose death a four-month conclave elected Braschi on Feb. 15, 1775.

The church needed spiritual and institutional reform, and the papacy was nearly stripped of power and influence. The religious orders, the essential medium of papal influence in the church, were under attack by the protagonists of the Enlightenment; and the royal leaders of Catholic Europe, the pope's traditional allies, were now indifferent to papal interests, being concerned only with the possibilities of using the national churches in their schemes for administrative reform.

In October 1781 the Holy Roman emperor Joseph II inaugurated his reforming Edict of Toleration, whereby non-Catholic minorities received considerable religious toleration, "unnecessary" monasteries were dissolved, diocesan boundaries were redrawn, and seminaries were placed under state control. Further detailed reforms were intended to abolish such practices as festivals and superstitious reverences that were not considered in keeping with the Enlightenment. Pius intervened in 1782 by personally visiting Vienna but failed to secure any concessions. Joseph's application of Febronianism, an ecclesiastical doctrine that advocated restriction of papal power, subsequently became known as Josephinism. Meanwhile, the church in the Habsburg dominions remained wealthy and influential but subordinate to the state.

The French issue was equally overwhelming. Preliminaries to the Revolution were occurring, and the new government turned to the church's wealth, which it confiscated as a direct backing for its currency. Under the Civil Constitution of the Clergy (1790), France intended to force a reform of the French Church, thus causing a major conflict between Rome and the Revolution, whose scheme resembled Joseph's designs. Pius took no immediate action, but when an oath of fidelity to the new regime was demanded from the clergy, he formally denounced the Civil Constitution and the Revolution on March 10, 1791. The French Church was completely split.

Pius was on good terms with the allies against France in 1793 and felt that he could rely on them, but in 1796 his territory was invaded after the last Austrian defeat by Napoleon, who forced the Pope to sign a peace treaty at Tolentino on Feb. 19, 1797. In the following December, a riot in Rome led to French occupation of that city on Feb. 15, 1798, and the proclamation of a republic by a group of Italian patriots. Pius and the Curia were expelled from Rome, and in March 1799 he was seized by the French. Aged and physically crippled, he died a prisoner.

• **Pius VII,** original name BARNABA GREGORIO CHIARAMONTI (b. Aug. 14, 1742, Cesena, Papal States—d. Aug. 20, 1823, Rome), Italian pope from 1800 to 1823, whose dramatic conflicts with Napoleon led to a restoration of the church after the armies of the French Revolution had devastated the papacy under Pius VI.

He became a Benedictine at Cesena in 1758 and was made cardinal and bishop of Imola, Papal States, in 1785 by Pius VI, whose death in French captivity marked a collapse of the church's central administration. Under Austrian protection at Venice, a 14-week conclave elected Chiaramonti on March 14, 1800.

Pius wanted to make peace with Napoleon and to reach a prompt compromise with the Revolution insofar as it was compatible with the principles of the church. Overriding some shocked opposition within his entourage, he made a bold decision and negotiated the celebrated Concordat of 1801 with Napoleon, which established complete reorganization of the dioceses and declared Roman Catholicism France's chief religion. Pius renounced the ecclesiastical property that had been secularized and asked surviving bishops to resign their French sees. In 1802, however, certain Organic Articles were appended to the Concordat by a French unilateral action, forbidding the exercise of any papal jurisdiction in France without the permission of the government. Pius protested and in 1804 tried to use the occasion of his formal consecration of Napoleon (Paris, December 2) to have the articles modified. He was unsuccessful, and thenceforth relations between Pius and Napoleon rapidly deteriorated. Rome was occupied by French troops in 1808, and Napoleon declared the Papal States annexed to France (1809). Pius bravely excommunicated the invaders on June 10, 1809, and was taken prisoner the following July, remaining in exile until the invasion of France by the allies in 1814.

The Emperor's bullying of Pius aroused a far-reaching sympathy and respect for the Pope, especially among northern Catholics, who helped align Pius with the allies who eventually defeated Napoleon. In June 1812 Napoleon transferred Pius to Fontainebleau, where he forced the Pope to sign a humiliating concordat on Jan. 25, 1813, which Pius renounced two months later.

Released in 1814, Pius was greatly acclaimed en route to Rome. The Congress of Vienna (1814–15) restituted nearly all the Papal States, and in 1815 Rome was formally restored to Pius, who then sought to reestablish the church on traditional foundations. Politically, Pius followed a flexible line. In France and Spain he cooperated with the counterrevolution. But after some hesitation, he recognized the new Latin-American republics that had revolted against Spain, and he did not appeal to new ideas of liberty in Germany and in Austria, where Francis I maintained Josephinism, an extreme application of restricting papal power.

Ecclesiastically, Pius revived the Society of Jesus (1814) and encouraged the religious orders to reorganize themselves. Unlike many of his 18th-century predecessors, he showed great concern for doctrine and issued stern condemnations of church enemies, especially against Freemasons. In the tradition of the Humanist popes, he sponsored educational reform and the establishment of Rome as a cultural centre. Despite his efforts to adapt the papacy to the political, intellectual, and social conditions of the modern world, the reinstatement of authoritarianism in the Papal States was inevitable, and a "government by priests" followed his death. Ernesto Vercesi's *Pio VII, Napoleone e le Restaurazione* was published in 1933.

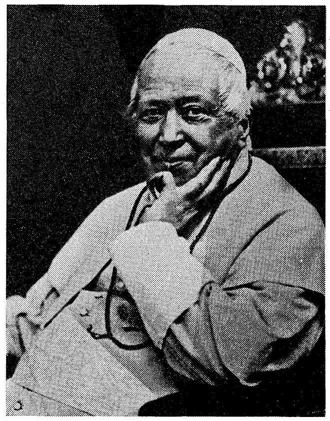
• **Pius VIII,** original name FRANCESCO SAVERIO CASTIGLIONI (b. Nov. 20, 1761, Cingoli, Papal States—d. Nov. 30, 1830, Rome), Italian pope from March 1829 to November 1830.

Versed in canon law, he became vicar general at Anagni, and later at Fano, until 1800, when he was made bishop of Montalto by Pope Pius VII. He was imprisoned in 1808 during the French domination of Italy for refusing to take the oath of allegiance to Napoleon. In 1816 he was elevated to cardinal and appointed bishop of Cesena. He subsequently became bishop of Frascati and grand penitentiary (1821), a leading role in the Curia. Despite his ill health, Francesco, the candidate of France, was elected Pope Leo XII's successor on March 31, 1829, and was crowned on the following April 5.

Pius VIII, detail from a monument by Pietro Tenerani; in St. Peter's, Rome
Alinari—Art Resource/EB Inc.

In strictly ecclesiastical matters, Pius, a disciple of Pius VII, was generally broad-minded and conciliatory; he delegated foreign policy to his secretary of state, Cardinal Giuseppe Albani. Considered to be somewhat liberal, Pius accepted the July Revolution (1830) in France that deposed Charles X in favour of Louis-Philippe. Pius encouraged French ecclesiastics to endorse the new regime, hoping it would secure amiable ties with the papacy. He approved the decrees of the Council of Baltimore (October 1829), the first formal meeting of U.S. bishops.

• **Pius IX,** original name GIOVANNI MARIA MASTAI-FERRETTI (b. May 13, 1792, Senigallia, Papal States—d. Feb. 7, 1878, Rome), Italian head of the Roman Catholic Church whose pontificate (1846–78) was the longest in history and was marked by a transition from liberalism to conservatism. Notable events of his reign included the declaration of the dogma of the Immaculate Conception (1854) and the sessions of the first Vatican Council (1869–70), during which the doctrine of papal infallibility was authoritatively defined.



Pius IX
Felici

Prepontifical life and early reign. Pius IX was the fourth son of Girolamo Mastai-Ferretti, gonfalonier of Senigallia, and the countess Caterina Solazzi. He first came into prominence as archbishop of Spoleto from 1827 to 1832, a time of revolutionary disturbance. He was made bishop of the important diocese of Imola in 1832, but it was not until 1840 that he received the hat, as cardinal priest of SS. Piero e Marcellino. He was not, in 1846, the most prominent liberal candidate likely to succeed Gregory XVI; but it took the conclave only two days to determine his election and so prevent that of the conservative Luigi Lambruschini. He took the name of Pius in deference to the memory of Pius VII, who had been his friend and who had, like him, been bishop of Imola. The choice was in some sense prophetic, for "Pio Nono," as his predecessor had done, began his career as a supporter of liberal ideas only to learn from bitter experience that liberals often tended to be anticlerical. In 1846, however, all this lay in the future and Europe was agog at the unusual spectacle of a liberal pope.

The new pope was confronted by a difficult situation. All Europe, save perhaps Metternich of Austria, considered that the Papal States stood in urgent need of reform. A memorandum of 1831 by the French, Austrian, Russian, and Prussian ambassadors in Rome had suggested that councils should be elected to assist in local government, that a central body, composed partly of elected representatives, control finance, and that the dominant position held by the clergy in the administration and in the judicial system be terminated. Liberal opinion clung to these measures as absolutely essential throughout the pontificate of Gregory XVI. In addition, the papacy was constantly under attack by Italian nationalists as one of the instruments through which Austria maintained its domination over the peninsula.

The Revolutions of 1848. The year of revolutions began in Sicily; soon all Europe was ablaze and Pius was faced with demands, both liberal and nationalist, much beyond what he had been prepared to grant. On March 14 he was compelled to grant a constitution establishing a two-chamber parliament with full legislative and fiscal powers subject only to the pope's personal veto. On March 23 Charles Albert of Sardinia declared war on Austria. For a time Pius continued to endeavour to steer a middle course, claiming in his address to the cardinals of April 29 that he was a disinterested spectator of the revolutionary activities sweeping Italy and that his program of reform was merely the fulfillment of the program long pressed upon the papacy by the powers. In the atmosphere of the time such sentiments were judged as displaying absolute hostility to the national cause, and the papacy was never again able to appear in Italy as anything other than a bulwark of reaction.

To prevent revolution from breaking out in Rome itself, Pius consented to the appointment of popular ministries, but none of the appointees was able to control the situation. A steadily deteriorating situation culminated in the assassination of one of them on November 15. A radical ministry was appointed; when the Swiss guards were disbanded the Pope was a virtual prisoner. On November 24–25, with the aid of the French and Bavarian ambassadors, he fled to Gaeta in the kingdom of Naples. In his absence, elections were held for a constituent assembly; this, on Feb. 9, 1849, declared the temporal power at an end and a democratic republic to be established. The papacy thereupon issued a formal appeal to the rulers of France, Austria, Spain, and Naples for assistance. Although it was generally considered that the Pope's restoration could take place only with some sort of undertaking to maintain constitutional government in the Papal States, and although Louis-Napoleon, the newly elected president of France, was in favour of such a policy, Pius held out against any concessions and asserted his determination to exercise his temporal power without any restrictions whatsoever. The upshot of a period of military and diplomatic manoeuvres on the part of France and Austria was the unconditional restoration of papal rule, and Pius returned to his capital on April 12, 1850.

The Roman question. It has often been asserted that Pius returned to Rome a changed man, that the former liberal had become a narrow reactionary. That his policy had changed there is no doubt, but his fundamental attitude remained the same. The interests of the church had always been his first concern. He had been prepared to countenance both nationalism and liberalism while they left the church intact, but experience had taught him that both led to revolution, which he had never been prepared to countenance. Furthermore, political concessions on his part had led to attacks on his spiritual power, and he considered that it could be protected only by his continued exercise of a temporal authority. Once these two aspects of his dominion had become indissolubly linked, it is easy to see why Pius considered himself obliged to oppose any alteration of his position as a temporal ruler.

In 1846 Pius had considered that a new departure was necessary to meet the legitimate demands for reform within the Papal States and perhaps also those for a change in the Italian system of states. Most of the administrative reforms carried out immediately after Pius' accession remained, and the papal territories benefitted from the general increase in European prosperity after 1850. But constitutional government was never restored; the amnesty granted on the Pope's return was so riddled with exceptions as to be worthless; and to all expressions of national sentiment the papacy was utterly hostile. It was not that papal government was tyrannical but that it formed an absolute barrier in the way of Italian unification upon which politically minded Italians were set.

On Sept. 20, 1870, Italian troops occupied Rome, and in October a plebiscite was held in which an overwhelming majority of the votes cast were for the incorporation of Rome in the kingdom of Italy. Pius remained for the rest of his days a prisoner, as he regarded himself, in the Vatican. He refused any intercourse with the Italian government, so that their relations rested upon a law passed by the Italian parliament in November. The sovereignty of the pope was declared to be untouched by the loss of his dominion in compensation for which he was to receive an annual sum of money. He was to be entitled to conduct his own diplomatic relations with other powers and to have exclusive authority within the Vatican itself and a small district around it. In the rest of Italy, church and state were to be separated. So, though the papacy did not formally recognize the fact until the concordat of 1929, the Roman question had been settled.

Ultramontanism. Important as the events just described were for the papacy, the doctrinal developments of Pius' pontificate, which spring directly out of these political disasters, constitute its most significant contribution. Ultramontanism began with Joseph de Maistre, as a reaction against Gallicanism and against Josephinism, seeking to free the church from the chains of secular control by binding it more closely with the papacy. H.-F.-R. de Lamennais developed it by suggesting that the church would benefit from a general increase in political freedom. Gregory XVI condemned Lamennais's teaching because he saw that freedom might mean freedom to deny religion altogether. Pius IX decided in 1846 to experiment with liberalism but later became convinced that Gregory XVI had rightly suspected it. Nevertheless, if Italy taught Pius one lesson, developments in France, where the church prospered more under the liberal regime of Louis-Philippe than it had under the clerical Charles X, suggested quite the opposite conclusions to the liberal Catholics there, whose spokesman was Charles de Montalembert. On the other hand, the coming of the Second Empire stimulated the party led by Louis Veuillot, whose Ultramontanism was of the older sort, completely divorced from liberalism and seeking freedom for the church in an authoritarian state that would guard it against revolution.

For a period after 1850, Pius' policy took little heed of either brand of Ultramontanism. Cardinal Giacomo Antonelli, the papal secretary of state, followed the paths of Consalvi, Pius VII's secretary of state, in seeking to procure more favourable concordats with Catholic rulers. Such agreements might be politically valuable but were no defense against intellectual anticlericalism, and Pius became increasingly convinced that the real danger to the church lay in the modern secular ideas that the liberal Catholics were endeavouring to incorporate into its doctrines. The events of 1860 finally convinced him that the notion of a "free church in a free state" was a snare. The encyclical *Jamdudum Cernimus* (1861) denounced not only Piedmontese aggression but all modern political doctrines. The Risorgimento not only convinced Pius that liberalism in the church must be destroyed but also placed the liberal Catholics in the difficult position of appearing to support those who had caused him so much distress. The alternative to Montalembert's doctrine was no longer an unconditional attachment to the principles of the ancien régime but a new kind of Ultramontanism, asserting the need for concentrating church authority in the pope's hands. The ground was being prepared for the first Vatican Council and the doctrine of papal infallibility.

But first the strong liberal party in the Catholic Church had to be defeated. In 1863 Montalembert was invited to address a large Catholic congress at Malines, and he took the opportunity to defend the concept of a free church in a free state and to condemn intolerance in principle. Pius was content in reply to point out that on these two points he was running counter to authoritative pronouncements of Pius VI and Gregory XVI. This was sufficient to deter Montalembert from accepting a second invitation to Malines in 1864, but his supporter F.-A.-P. Dupanloup proved an able substitute. Meanwhile, at a congress at Munich in 1863, J.J.I. von Döllinger had pleaded for the right of a scholar to pursue independent inquiry. It was clear to everyone that the church stood in need of authoritative pronouncements about its relations with the state and with modern society, and discussion began about the possibility of calling an ecumenical council for this purpose. But once again the Roman question intervened decisively in the struggle.

On Sept. 15, 1864, the French and Italian governments came to an agreement whereby the French garrison was to be withdrawn from Rome within two years. In fact, it was not finally withdrawn until the outbreak of the Franco-German War, but the conclusion of the September convention was sufficient to make Pius decide to take immediate action against liberalism. On Dec. 8, 1864, he issued the encyclical *Quanta Cura* with, attached to it, the famous *Syllabus* listing 80 of the "principal errors of our times." As the errors listed had already been condemned in allocutions, encyclicals, and other apostolic letters, the *Syllabus* said nothing new and so could not be contested. Its importance lay in the fact that it published to the world what had previously been preached in the main only to the bishops, and that it made general what had been previously specific denunciations concerned with particular events. Thus perhaps the most famous article, the 80th, stigmatizing as an error the view that "the Roman Pontiff can and should reconcile himself to and agree with progress, liberalism, and modern civilization," sought its authority in the pope's refusal, in *Jamdudum Cernimus,* to have any dealings with the new Italian kingdom. On both scores, the *Syllabus* undermined the liberal Catholics' position, for it destroyed their following among intellectuals and placed their program out of court.

Though Dupanloup tried to explain away the *Syllabus* by insisting upon its context and by stressing its purely negative aspect, the *Syllabus* nevertheless dealt a mortal blow at liberal Catholicism, which ceased after 1864 to be the main issue taxing Catholic controversialists. While some of Louis Veuillot's followers hoped that at the forthcoming council a positive statement of the orthodox doctrine of the position of the church in society would replace the negative denunciations of the *Syllabus,* the majority looked upon that battle as won and so turned to the question of defining the pope's infallibility, the keystone of the neo-Ultramontane program of centralizing the authority of the church in Rome so as to escape from the control of the secular state.

The Vatican Council. In the doctrine of papal infallibility itself there was nothing new. It had been employed to define, on Dec. 8, 1854, the dogma of the Immaculate Conception, which asserted that the freeing of the Virgin Mary from all taint of original sin had occurred at the moment of her conception. The Pope had previously made extensive inquiries among the bishops and other divines and there was little opposition to such an exercise of his undoubted prerogative. When, however, at a gathering of bishops and other dignitaries of the church in Rome in 1862 and again at another in 1867 it had been suggested that the doctrine of infallibility should be authoritatively defined, Dupanloup had led a successful opposition to the project. It was objected that such a definition was inopportune, tending to widen the breach between the church and modern society, and that it would present a one-sided view of the source of authority in the church; for while the pope possessed powers issuing directly from God, so too did the bishops, for instance, whose ordinary jurisdiction arose, not out of their nomination or institution but equally from divine origin; so that the pope's powers ought not to be defined without reference to other aspects of the nature of the church. The criticism that must attach to Pius is that he allowed the council to put aside discussion on the wider issue, which was its original program, in favour of the narrower definition. This was, of course, precisely what the Ultramontane party desired. The Ultramontanes, indeed, undoubtedly possessed the backing of by far the greater part of the church, partly because of the reaction engendered by the political misfortunes of the last decade, partly because of the immense prestige enjoyed by Pius as a result of his long and tragic pontificate, but to a larger extent because of the contemporary movement away from intellectualism and in favour of devotional religion.

The first Vatican Council opened on Dec. 8, 1869. The opposition, consisting of the German, French, and U.S. bishops, was strong enough to prevent a definition of the doctrines and nature of the church on the lines suggested by the *Syllabus;* but the Ultramontane party brought forward the question of infallibility, upon which their position was much stronger. Pius intervened decisively to alter the procedure of the council on Feb. 20, 1870, and again on April 29. The outcome was to postpone all deliberation except that upon infallibility. The decisive vote came on July 13 when 451 voted for it, 88 against it, and 62 in favour of some amendment. Thereupon the minority left Rome and the final definition was carried on July 18 by 533 votes to 2. Infallibility was confined to those occasions upon which the pope made pronouncements *ex cathedra.*

Pius reigned for another eight years, during which he became further estranged from the Italian government and witnessed a general outbreak of anticlericalism in western Europe. In Germany this culminated in Bismarck's *Kulturkampf,* which Pius condemned in the encyclical *Quod Nunquam* of Feb. 5, 1875, leaving the solution of the problem to his successor. Pius died three years later, having seen in his long pontificate the creation of the modern papacy.

Evaluation of his pontificate. The exact responsibility of Pius for the events of his pontificate is still a matter for controversy. The result is clearer. Church and state were finally separated, authority in the church was centralized in Rome, and the church was ranged in opposition to the dominant political forces.

Perhaps the most damaging criticism of Pius is that he assumed almost the sole direction of events while never appreciating their significance. The great events of his pontificate occurred despite him rather than because of him. Thus he condemned in the *Syllabus* that very separation of church and state which it was the work of the first Vatican Council—to which for the first time the secular Catholic rulers were not invited—to secure. At one time or another Pius was served by the leaders of all the important movements of his century, by liberal cardinals, by ecclesiastical statesmen, and by the ascetic H.E. Manning, a convert from Protestantism. Yet it is unfair to say that he changed his political principles; rather he never possessed any, save in his personal religious life, that were not rather naive, and so he was always open to be guided by experience. In view, however, of the benefit that has accrued to the church from the loss of the temporal power, it should at least be asked whether it was not Pius' determination to maintain it at all costs that contributed most to the temporal power's being lost.

BIBLIOGRAPHY. E.E.Y. Hales, *Pio Nono: A Study in European Politics and Religion in the Nineteenth Century* (1954), was written avowedly to explain events from the viewpoint of Pius IX. Fernand Hayward, *Pie IX et son temps* (1948), is the work of a French scholar, favourable to the Pope but showing much research. Frank J. Coppa, *Pope Pius IX* (1979), is a sympathetic biography. For a less favourable view, see *The Roman Question: Extracts from the Despatches of Odo Russell from Rome,* 1858–70, ed. by Noel Blakiston (1962). A.C. Jemolo, *Chiesa e Stato in Italia negli ultimi cento anni* (1948), is a massive study, particularly strong in the study of ideas. Roger Aubert, *Le Pontificat de Pie IX* (1952), and *Vatican I* (1964), are thoroughly reliable. Abbot Cuthbert Butler, *The Vatican Council,* 2 vol. (1930; new ed. by Christopher Butler, 1 vol., 1962), based on correspondence with the English bishop Ullathorne, gives a good account of Pius' activity at the council.

Articles are alphabetized word by word, not letter by letter

• **Pius X,** SAINT, original name GIUSEPPE MELCHIORRE SARTO (b. June 2, 1835, Riese, Venetia, Austrian Empire—d. Aug. 20, 1914, Rome; canonized May 29, 1954; feast day September 3), Italian pope from 1903 to 1914, whose staunch political and religious conservatism dominated the early 20th-century church.

Ordained in 1858, he became a parish priest in the Italian region of Venetia. Pope Leo XIII made him bishop of Mantua (1884) and in 1893 cardinal and patriarch of Venice. He was elected pope on Aug. 4, 1903.

Tepid toward Leo's social reforms, Pius decided to concentrate on apostolic problems and to make the defense of Roman Catholicism his cause. Three aspects of his policy particularly aroused bitter controversy: the repression of Modernism, a contemporary intellectual movement seeking to reinterpret traditional Catholic teaching in the light of 19th-century philosophical, historical, and psychological theories; his reaction against Christian Democrats; and his attitude toward separation of church and state in France.

Because Modernism tended to ignore certain traditional values in order to achieve its ends, Pius placed several Modernist books on the *Index of Forbidden Books* and issued (1907) the decree *Lamentabili Sane Exitu* (*On a Deplorable Outcome*) and the encyclical *Pascendi Dominici Gregis* (*Feeding the Lord's Flocks*), rejecting Modernist teachings and suggesting remedies to extirpate it. He also urged immediate compliance with his strict censorship program. On Sept. 1, 1910, he ordered that all teachers in seminaries and clerics before ordination take an oath denouncing Modernism and supporting *Lamentabili* and *Pascendi.*

Pius led the reaction against Christian Democracy because he could not tolerate the idea of some Catholics making their social work a matter independent of the hierarchy and conducting it in an increasingly political direction. He opposed the contemporary trend in European countries where Christians reacted against doctrines of materialism by forming their own social movements or popular action groups. Accordingly, he formally condemned the Italian priest Romolo Murri's popular action movement in 1903 and the pioneering Christian Democrat Marc Sangnier's Sillon movement in France. The Sillon broke from the church, whose authority it challenged.

On Pius' accession, the separation of church and state in France was already visible, and the break was inevitable, occurring amid a growing anticlericalism in France. In 1905 the French formally separated church from state, an act condemned by Pius on Feb. 11, 1906. Most of the French bishops were willing to try the new French legislation, which safeguarded all that could still be preserved of the church's material interests, but Pius rejected the compromise.

Some of his directives, though outmoded by later social developments, mark him as one of the forerunners of Catholic Action—*i.e.,* the organization of the laity for special and direct collaboration in the church's apostolic work. His eucharistic decrees eased the regulations governing daily communion, and his revival of the Gregorian plainsong and his recasting of the breviary and of the missal were important liturgical reforms. His decision to adapt and systematize canon law led to the publication of the new code in 1917, effective in 1918. His reorganization of the Curia modernized the church's central administration, including a codification of the conclave.

F.A.M. Forbes's *Life of Pius X* was published in 1918.

• **Pius XI,** original name AMBROGIO DAMIANO ACHILLE RATTI (b. May 31, 1857, Desio, Lombardy, Austrian Empire—d. Feb. 10, 1939, Rome), Italian pope from 1922 to 1939, one of the most important modern pontiffs whose motto "the peace of Christ in the

Pius XI
Felici

Kingdom of Christ" illustrated his work to construct a new Christendom based on world peace.

Ordained in 1879, he became a scholar, a paleographer, and prefect of the Vatican library. Nuncio to Poland in 1919, he was made cardinal and archbishop of Milan in 1921 by Pope Benedict XV, whom he was elected to succeed on Feb. 6, 1922.

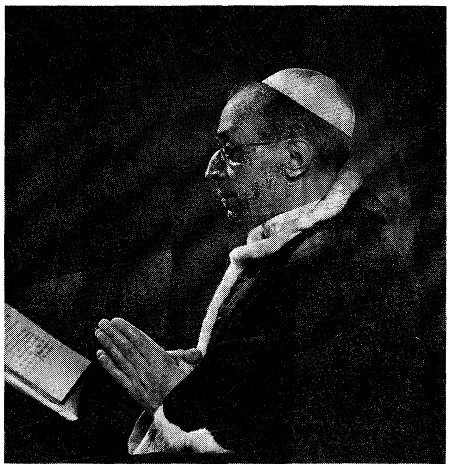
Pius' pontificate soon witnessed the rise to power of Benito Mussolini, who signed (Feb. 11, 1929) with him the Lateran Treaty that allowed the existence of the independent Vatican City state, over which the pope ruled. The papacy, in turn, recognized the establishment of the kingdom of Italy and announced permanent neutrality in military and diplomatic conflicts of the world. Pius further agreed that a pope would intervene in foreign affairs not as head of a sovereign state but as head of the church. Concurrently, a concordat established the validity of church marriage in Italy, provided compulsory religious instruction for Catholic schoolchildren, and declared Roman Catholicism to be Italy's exclusive religion.

Pius' role in these negotiations was considerable, their success owing much to his appreciation of the interests of the church and of contemporary political realities. With the aid of his secretaries of state, cardinals Gasparri (1922–30) and Pacelli (1930–39), he concluded concordats that strengthened and united Catholicism in countries suffering the aftereffects of World War I, including Latvia (1922), Poland (1925), Romania and Lithuania (1927), Prussia (1929), Austria and Germany (1933). Unfortunately, World War II ruined several of these treaties. He reached an agreement allowing the church to resume religious services in Mexico, where severe persecutions prompted the encyclical of 1926, and he made another agreement (1933), though short-lived, with Adolf Hitler's newly formed Nazi government in Germany, hoping to alleviate the difficulties confronting German Catholics. From 1933 to 1936 he wrote several protests against the Third Reich, and his attitude toward Fascist Italy changed dramatically after Nazi racial attitudes were introduced into Italy in 1938.

A learned humanist, Pius founded research establishments and institutes of higher education, including the Pontifical Institute of Christian Archaeology (1925) and the Pontifical Academy of Science (1936). He made great efforts to organize the laity, first in Italy and then throughout the whole church, calling for "specialized movements" and particularly encouraging Catholic Action (the "Jocists"), a Christian youth organization for the working classes. In 1922 he had defined Catholic Action as "the participation of the laity in the apostolate of the Church's hierarchy."

Surpassing his predecessors in support of overseas missions, he required every religious order to engage actively in this work, with the result that missionaries doubled their number during his pontificate. Most significant was his consecration of the first Chinese bishops, in 1926. He equally encouraged historians and liturgiologists to study Eastern Christianity, inaugurating the work of codifying Eastern canon law. In 1930 he witnessed the reunion of the Syro-Melankarese Christians (of southern India) with Rome. His response to the ecumenical movement was negative toward Protestantism, however, as revealed in an encyclical of 1928. Philip Hughes's *Pope Pius the Eleventh* was published in 1937, followed by Zsolt Aradi's *Pius XI: The Pope and the Man* in 1958.

• **Pius XII,** original name EUGENIO MARIA GIUSEPPE GIOVANNI PACELLI (b. March 2, 1876, Rome—d. Oct. 9, 1958, Castel Gandolfo, Italy), Italian head of the Roman Catholic Church during World War II and the years of postwar reconstruction (reigned 1939–58), who dealt with contemporary moral and theological issues in innumerable addresses and in several encyclicals. His ideas on in-



Pius XII, photograph by Yousuf Karsh

ternational structures and reforms in liturgy and biblical studies were important, but his conduct during World War II has been the subject of controversy.

Early life and career. Eugenio Pacelli was born in Rome. His family came from Tuscany and had supplied Vatican lawyers since 1819. Eugenio was educated at Roman day schools and studied for the priesthood at the Gregorian University there, though for reasons of health he soon lived at home, not at his college of Capranica. He was ordained in 1899. He was a successful student with a quick mind and an exceptional memory, although the theological formation then available at the Gregorian University was limited. It was in the subject of law that he made his mark and so passed into the Vatican Secretariat of State. There he rose rapidly and in 1917 was made archbishop and sent as nuncio—a diplomat—to the Bavarian Court to negotiate a concordat (a Vatican–state agreement). This done, he passed (1925) to Berlin with the same aim and remained there until he was named cardinal, by Pius XI, and recalled to Rome at the end of 1929 to become secretary of state. After 10 years in this office, during which he travelled on papal missions to North and South America and to France, he was elected pope in the shortest conclave since 1623.

Pontificate. These experiences are crucial in assessing Pacelli's pontificate. He grew up in a home of deep piety and of devotion to the papacy but also in a Rome smarting from the loss of the papal states, a Rome still clerical, resentful, and suspicious of the secular world. He inherited a diplomatic tradition and technique centred on the principle of the concordat, which aims to preserve the church's privileges and freedom of action, even under regimes irreconcilable with Christian principles.

Fascism came to power in Italy (1922) during Pacelli's absence in Germany, and his brother, a lawyer, helped to fashion the concordat with the dictator Benito Mussolini—to achieve which the Catholic Popular Party and any chance of ousting Mussolini were sacrificed. This settlement of the Roman Question, which created the Vatican city-state (1929), satisfied Pius XI's ambition and that of many Italians but created many problems for the next 30 years in Pacelli's life, in relations both with the increasingly hostile dictatorship and with the uneasy democracy that succeeded it after the war.

Twelve years in Germany had made Pacelli fluent in German and had given him great love for the Germans. A tireless and methodical worker, he admired such virtues in the Germans and had many German helpers in the Vatican. But his deep knowledge of German affairs precluded illusions about Nazism, and the concordat with Hitler's Germany (1933), largely his work, was (he often said) a calculated risk, aimed at preserving a platform for Catholic life and ministry in a hostile German society.

His part in the anti-Nazi encyclical *Mit brennender Sorge* (1937; *With Burning Sorrow*), his dozens of other notes and memoranda to the German government as secretary of state, his frigid and outspoken reception of the Nazi foreign minister Joachim von Ribbentrop in Rome, his bitter reproach of the Austrian cardinal Theodor Innitzer's weakness in face of the Austro-German *Anschluss*—the union of Austria and Germany—in 1938, and finally the unfavourable German reception of his election as pope, all showed his true estimate of the German tyranny.

During the few months between his election and the outbreak of war, Pius XII turned his diplomatic gifts to preventing the catastrophe, but not in the spirit of appeasement—the Vatican had disliked the Munich Agreement (1938), by which Czechoslovakia was sacrificed to expanding German power by Britain and France. Pius especially strove to keep Italy neutral and was deeply saddened when he failed.

War years. The demands of war harmonized with Pius' austerity and immense capacity for work; they enhanced his exalted, almost dramatic, conception of his office. His untiring efforts to humanize war and to relieve suffering, anxiety, and grief, though they did not always receive Axis cooperation, have been generally applauded. In a notable series of Christmas broadcasts (1939–48), he looked firmly toward the postwar future and to the opportunities it would offer for a new order in which the international community would be given real expression, replacing the egoistic nationalism that had bred war.

There has been less agreement about Pius' conduct and utterance in relation to the war itself. Deeply conscious of paternal responsibilities that transcended nationalism, pledged to neutrality, obliged to condemn unchristian conduct and yet fearful of provoking reprisals on the defenseless, the Pope clearly suffered many agonies of indecision, aggravated by his dislike of strife. He has been charged with neglecting, in the interests of a calculated neutrality, to raise an authoritative voice in defense of the persecuted, Christian or Jewish. Others have claimed that protests would have aggravated Nazi policy without achieving any good result. Both approval and censure of his choices during these difficult years have often been facile and superficial: the deeper question may be asked whether the nuances, the hints, the oblique allusions of traditional diplomacy, which came naturally to him and which often seemed to him much clearer than they seemed to others, were any longer appropriate to the savagery and cynicism of a death struggle for world domination and of deliberate genocide. The problems of a neutrality that is not completely silent are never wholly surmountable, since causes are not morally neutral.

Later papal concerns. Though Pius refused to be drawn into any crusade against international Communism, he enacted severe measures against Catholics collaborating with Communists (1946), and the precarious balance between Christian Democrats and the extreme left in postwar Italy led him to encourage the Catholic Action leader Luigi Gedda, whose meddling in politics embarrassed the parliamentary Christian Democratic Party. Premier Alcide De Gasperi's successful protest against this (1949) earned him disfavour at the Vatican. When Pius' failing health left power in the hands of a "bureaucracy" of cardinals, including the autocratic head of the Holy Office, Alfredo Ottaviani, clerical interference in Italian public life reached a high pitch.

Many of Pius' innumerable addresses to specialist audiences dealt with urgent moral problems; by the end of his life he was moving toward outright rejection of modern war and doubted the justification of a war deterrent policy. In the field of marital relations, he made a number of pronouncements about the "safe period" without carrying discussion of birth regulation substantially beyond the position of his predecessor. Nor did he advance Catholic thinking or policy in the ecumenical field, though slight concessions were made in 1949.

Perhaps Pius' greatest utterance was the encyclical *Divino Afflante Spiritu* (1943; "With the Help of the Divine Spirit"), which gave fresh impetus and direction to Catholic biblical studies. These studies had been hampered by the inquisitorial atmosphere persisting since the days of crisis under Pius X over Modernism—a movement that sought, among other things, to apply modern methods of historical criticism to both the Bible and the life of Christ, but was vitiated by arbitrary philosophical assumptions. The encyclical welcomed most of the techniques of modern biblical scholarship.

Mediator Dei (1947; "Mediator of God") was a similar charter for the liturgical movement; he aimed at restoring a community character to public worship but mistrusted extravagant experiment. More conservative and suspicious views prevailed in *Humani Generis* (1950; "Of the Human Race"), touching on theological tendencies.

Pius' later ill health accentuated his solitary bent, increased the power of his conservative curia—the papal administrative bureaucracy—and aroused misgivings in some countries, not least in France, where Roman handling of the worker-priest problem—by sending worker-priests, who had been sharing the work and living conditions of labourers in order to extend their ministry, back to traditional religious tasks—caused deep resentment. When he died, at Castel Gandolfo in 1958, respectful mourning was worldwide, but Rome showed few signs of the revolution in church life around the corner. Though he was gifted and deeply spiritual, history is unlikely to place him among the great creative popes. (W.A.P.)

Purdy, *The Church on the Move: The Characters and Policies of Pius XII and John XXIII* (1966). For the relationship between Pius XII and U.S. Pres. Franklin D. Roosevelt see *Wartime Correspondence Between President Roosevelt and Pope Pius XII,* with introduction and notes by Myron C. Taylor (1947, reprinted 1975).

Piute (people): *see* Paiute.

pivot area: *see* heartland.

pivot joint, also called ROTARY JOINT, or TROCHOID JOINT, in vertebrate anatomy, a joint that allows only rotary movement. It is exemplified by the joint between the atlas and the axis (first and second cervical vertebrae), directly under the skull, which allows for turning of the head. Pivot joints also provide for the movement of the bones of the forearm (radius and ulna) against the upper arm (humerus) at the elbow.

Pixérécourt, (René-Charles-) Guilbert de (b. Jan. 22, 1773, Nancy, Fr.—d. July 27, 1844, Nancy), astonishingly prolific dramatist who delighted popular audiences in Paris with a succession of more than a hundred plays during the first third of the 19th century. These were performed in the *théâtres des boulevards,* which were patronized by a far less exclusive audience than those of the official theatres and were less bound by convention. His greatest successes were melodramas—*e.g., Victor* (1798) and *Coelina* (1800). These are plays full of exciting incidents and local colour, with comedy and pathos juxtaposed, which invariably end with virtue saved and vice punished. Pixérécourt, who directed the production of his own plays, laid great stress on realistic scenery. With his melodramas Pixérécourt started a theatrical tradition that survived throughout the 19th century.

pixie, also spelled PIXY, in the folklore of southwestern England, tiny elflike spirit or mischievous fairy dressed in green who dances in the moonlight to the music of frogs and crickets. Its favourite pastimes are leading travelers astray and frightening young maidens. Pixies also delight in rapping on walls, blowing out candles, and playing in water. Pixies were first discussed at some length by Mrs. Anna Eliza Bray in *The Borders of the Tamar and the Tavy,* 3 vol. (1837).

Pixie, illustration by W. Measom from the 1853 edition of *A Peep at the Pixies,* by Mrs. Bray

Their prank of leading people astray gave rise to the terms pixie-led and pixilated to describe a person who becomes lost on a familiar road. It was later extended to mean any state of bewilderment or confusion.

Piye, formerly called PIANKHI (fl. 8th century BC), king of Cush (Kush, in the Sudan; *c.* 750–*c.* 719) who invaded Egypt from the south and ended the petty kingdoms of the 23rd dynasty (*c.* 823–*c.* 732 BC) in Lower Egypt. According to Egyptian tradition, his brother Shabaka founded the 25th dynasty, but Piye laid the foundations.

The kingdom of Cush, of which Piye was ruler, emerged out of the Egyptianized population of the Sudan near Mount Barkal, between the third and fourth Nile cataracts. The cult of the Egyptian god Amon Re was strongly entrenched among the Cushites, and a threat by Tefnakhte, a Libyan chieftain of the Delta, to Amon's homeland in Upper Egypt provoked Piye to move northward. Following a ritual visit to Thebes, Piye's forces met the Libyans' river fleet and defeated it. They then vanquished a land army near Heracleopolis, in Middle Egypt, and advanced to take Hermopolis, another Middle Egyptian stronghold of the Libyans, and Memphis, Egypt's ancient capital. Piye received the submission of several Delta potentates and, later, of the last representative of the 23rd dynasty. He then invaded the Delta, where more local rulers surrendered. Finally, Tefnakhte sent a message of submission, and Piye sent an emissary to obtain his oath of fealty. After some final submissions by holdouts, Piye sailed home to Mount Barkal with the spoils of his venture. He remained in his capital and was buried there; the great stela recounting his deeds also was found there and is dated in the 21st year of his reign.

piyyut, also spelled PIYUT, plural PIYYUTIM, or PIYUTIM, Hebrew PIYŪṬ ("liturgical poem"), one of several types of liturgical compositions or religious poems, some of which have been incorporated into Jewish liturgy and have become virtually indistinguishable from the mandatory service, especially on the Sabbath and on Jewish religious festivals.

Piyyutim were first composed in Palestine about the 4th or 5th century AD. It is not quite clear whether they arose merely as natural expressions of religious sentiments or as a deliberately disguised response to persecutions. In any case, piyyutim served a special purpose when, for example, a decree of Emperor Justinian (AD 553) forbade Talmudic studies and the teaching of the Bible. Since the liturgy itself was not proscribed, piyyutim were used to inculcate such fundamental precepts as observance of the Sabbath and religious festivals and to exhort the congregation to love the Torah, to believe in God, and to place its hope and trust in God's abiding providence. These religious poems also served as a reminder of times past when God showed he had not abandoned his chosen people.

The renowned Jewish philosopher Sa'adia ben Joseph (882–942) was an ardent advocate of piyyutim in Babylonia, but religious poetry met strong opposition there as an unnecessary innovation in the liturgy. Still, the piyyutim survived in Babylonia also because the common people responded to poetic songs that placed their suffering in a religious context.

During the Middle Ages, piyyutim were the most cultivated form of Hebrew literature, especially in Germany, France, Italy, and Spain. Rhyme was introduced in Spain, where piyyutim reached the height of their development. Among early masters of this poetry were Yose ben Yose, Yannai, and his pupil Eleazar Kalir, none of whose dates can be fixed with certainty.

As late as the 18th century, piyyutim continued to be written, but only rarely were these later poems made part of standard liturgies. In the 20th century new interest in the history of the piyyutim was generated by the discovery of some 800 of Yannai's compositions in the famous Cairo genizah (synagogue repository). The songs still have a unique appeal, and their continued use accounts for much of the diversity of different liturgies.

Pizarro, Francisco (b. *c.* 1475, Trujillo, Extremadura, Castile [Spain]—d. June 26, 1541, Lima), Spanish conqueror of the Inca Empire of Peru and founder of the city of Lima.

Early life. Pizarro was the illegitimate son of Captain Gonzalo Pizarro and Francisca González, a young girl of humble birth. He spent much of his early life in the home of his grandparents. According to legend he was for a time a swineherd, a not unlikely possibility since this was a common occupation of boys in that region. He doubtless participated in local manorial wars and, when these were ended, very probably went to fight in Italy. Certainly in 1502 he went to Hispaniola (modern Haiti and Dominican Republic) with the new governor of the Spanish colony.

Pizarro had little inclination toward the settled life of the colonizer, and in 1510 he enrolled in an expedition of the explorer Alonso de Ojeda to Urabá in Colombia. He appears to have been marked out as a hard, silent, and apparently unambitious man who could be trusted in difficult situations. Three years later, acting as captain, he participated in an expedition led by the explorer Vasco Núñez de Balboa that was credited with the European discovery of the Pacific. From 1519 to 1523 he was mayor and magistrate of the newly founded town of Panamá, accumulating a small fortune.

Discovery and conquest of Peru. It was not until 1523, when he was some 48 years old, that Pizarro embarked upon the adventure that was to lead to his lasting fame. In partnership with a soldier, Diego de Almagro, and a priest, Hernando de Luque, he made preparations for a voyage of discovery and conquest down the west coast of South America. The initial period of exploration took place from 1524 to 1527, during which time Pizarro and his men endured many hardships. After eventually sighting a raft occupied by what appeared to be civilized Indians dressed in manufactured cloth, they decided to send Almagro back to Panama for reinforcements. The new governor of Panama, however, sent back orders that the expedition be abandoned in order that no more lives be lost. At this point Pizarro is reputed to have drawn a line on the ground with his sword, inviting those who desired wealth and glory to cross it. The "famous thirteen" who did cross the line continued their exploration of the coast as far as 9° S, obtaining distinct accounts of a great Indian empire as well as many Inca artifacts. They christened the new land Peru, probably a corruption of Virú, the name of a river.

Finding the governor of Panama still opposed to their now promising enterprise, the explorers decided that Pizarro should go to Spain to ask Charles in person for permission to undertake conquest. Sailing in the spring of 1528, Pizarro was in Seville at the same time as Hernán Cortés, conqueror of Mexico, and was able to win Charles over to his scheme. He was decorated, granted a coat of arms, and, in July 1529, made governor and captain general of the province of New Castile for a distance 600 miles south of Panama along the newly discovered coast. Pizarro was invested with all the authority and prerogatives of a viceroy, and Almagro and Luque were left in subordinate positions. All the "famous thirteen" received substantial rights and privileges in the new territories.

Joined by four of his brothers, Pizarro sailed for Panama in January 1530 and by January of the following year was ready to set off for Peru. He set sail with one ship, 180 men, and 37 horses, being joined later by two more ships. By April they had made contact with emissaries of Atahuallpa, emperor of the Incas, who was residing near the city of Cajamarca with an army of about 30,000 men. Somewhat scornful of Pizarro's small force, the Inca accepted a proposal that the two leaders meet in that city.

Arriving on November 15, Pizarro immediately set up his artillery and sent his brother Hernando and another Spaniard to request an interview. After a day of tense waiting, Atahuallpa, borne on a litter, entered the great square of Cajamarca with an escort of between 3,000 and 4,000 men, who were either unarmed or carrying short clubs and slings beneath their tunics. Pizarro sent out a priest, Vicente de Valverde, to exhort the Inca to accept Christianity and Charles V as his master. Atahuallpa disputed both the religion and the sovereignty of the Spaniards and, after examining a Bible offered by the priest, flung the book to the ground. Valverde reported these events to Pizarro, who immediately ordered an attack. The astonished Incas were cut down from all sides, Pizarro himself seizing Atahuallpa.

Atahuallpa was held as hostage and failed to win his release, though he fulfilled a promise to fill the chamber in which he was held with gold and silver. Accused of ordering the execution of his brother Huascar, a rival for the title of Inca, and of plotting to overthrow the Spaniards, Atahuallpa was put to death by strangulation on Aug. 29, 1533. With news of Atahuallpa's death, the Inca armies surrounding Cajamarca retreated, and Pizarro progressed toward Cuzco, the royal capital, which was occupied without a struggle in November 1533. The Spaniards declared Manco Capac, Huascar's brother, as Inca.

For the remainder of his life, Pizarro was engaged in consolidating the Spanish hold on Peru and in defending his and his brothers' share of the spoils. A certain enmity and rivalry developed between him and Almagro as a result of Pizarro's overriding powers from the king of Spain. This contravened a solemn agreement between the original three partners that the spoils of the expedition should be shared equally. Almagro at one stage seized Cuzco but was persuaded by Pizarro to depart for Chile, over which he had been granted extensive powers by the king. Disappointed by the poverty of that country, however, he returned to Peru, where he was made prisoner and later executed by Hernando Pizarro.

Francisco Pizarro, meanwhile, was in Lima, a city that he had founded in 1535 and to which he devoted the last two years of his life. Almagro's former adherents had grouped around Almagro's son in Lima, where they were confined and watched. Suspecting that they were to be eliminated, they decided to move first, attacking Pizarro's palace on June 26, 1541. Pizarro died that day a protracted death, drawing a cross of his own blood on the ground, kissing it, and crying "Jesus" as he fell. (M.B.G./Ed.)

BIBLIOGRAPHY. Although not strictly concerned with Pizarro's actual life story, William H. Prescott, *History of the Conquest of Peru,* 2 vol. (1847, reissued in 3 vol., 1968); and Clements R. Markham, *A History of Peru* (1892, reissued 1968), are two classic accounts of the Pizarro brothers' exploits. Modern appraisals of the Pizarros' feat include Hammond Innes, *The Conquistadors* (1969, reissued 1986), lavishly illustrated; Manuel Ballesteros Gaibrois, *Francisco Pizarro* (1940), and *Descubrimiento y conquista del Perú* (1963); and John Hemming, *The Conquest of the Incas,* rev. ed. (1983).

Pizarro, Gonzalo (b. 1502?, Trujillo, Spain—d. April 10, 1548, Cuzco, Peru), Spanish conqueror and explorer and leader of antiroyal forces in Peru. Pizarro is considered by some historians to be the leader of the first genuine struggle by colonists for independence from Spanish domination in America.

A half brother of Francisco Pizarro, with whom he fought during the conquest of Peru (1531–33), Gonzalo received for his services extensive land grants and was made governor of Quito in 1539. In 1541, with 200 Spaniards, some 4,000 Indians, and numerous horses and other animals, he led an expedition into the unexplored region east of Quito. After his lieutenant, Francisco de Orellana, left him in search of provisions, Pizarro and his men waited in vain for his return. Forced to eat their dogs and horses, they finally staggered back to Quito in August 1542. Only a few Spaniards and no Indians survived the disastrous expedition.

On his return, Pizarro learned that his half brother Francisco had been assassinated in 1541 and that he had been ordered to dismiss his men. The king of Spain had promulgated new laws restricting the privileges of the conquistadores and protecting the rights of the Indians. Objecting to these edicts, the Spaniards intended to fight for their prerogatives and acclaimed Pizarro as the governor of Peru. As the leader of the antiroyal forces, he took the field against the viceroy Blasco Núñez Vela, winning the Battle of Anaquito in 1546, and against the viceroy Pedro de la Gasca in 1548. Defeated and captured by de la Gasca on April 9 of that year, Pizarro was executed the following day.

pizza, dish of Neapolitan origin consisting of a flattened disk of bread dough topped with olive oil, tomatoes, and mozzarella cheese, baked quickly and served hot. Pizza is now eaten throughout Italy—Roman pizza omits tomatoes from the topping and adds onions and olives; the Ligurian pizza resembles the *pissaladière* of Provence in France, with olives, onions, and anchovies.

The popularity of pizza in the United States began with the Italian community in New York City; the first pizzeria appearing there in 1905. After World War II the pizza industry boomed; soon there was scarcely a hamlet without a pizzeria. In the United States sausage, bacon, or ground beef, mushrooms, peppers, shrimps, and even oysters are sometimes added.

PKU (metabolic disorder): *see* phenylketonuria.

PL Kyōdan, in full PERFECT LIBERTY KYŌDAN, religious group or church (Japanese: *kyōdan*) founded in Japan in 1946 by Miki Tokuchika. The movement, unique for the use of English words in its name, is based on the earlier Hito-no-michi sect. It is not affiliated, however, with any of the major religious traditions of Japan. In the late 20th century the group claimed more than 2.5 million adherents worldwide.

Headquarters of the sect are at Habikino, near Ōsaka. PL Kyōdan operates a hospital, a golf course, and other sports facilities. Considerable missionary activity is carried on in Japan and among Japanese living abroad.

PL Kyōdan teaches that the goal of man is joyful self-expression. Forgetting God brings misfortune and suffering, but the believer may pray that his troubles be transferred by divine mediation to his patriarch, who is strengthened for his vicarious suffering by the group's collective prayers.

Plaatje, Solomon Tshekiso (b. 1877, Boshof, Orange Free State, S.Af.—d. June 19, 1932, Kimberley?), linguist, journalist, politician, statesman, and writer whose mind and activities ranged widely both in literary and in African affairs. His native tongue was Tswana, the chief language of Botswana, but he also learned English, Afrikaans, High Dutch, German, French, Sotho, Zulu, and Xhosa.

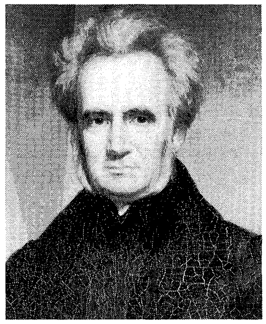
Plaatje used his knowledge of languages in his various roles as war correspondent during the South African War (1899–1902), editor of *Koranta ea Becoana* ("The Tswana Gazette") from 1901 to 1908, editor of *Tsala ea Batho* ("The Friend of the People") beginning in 1912, secretary-general of the South African Native National Congress and member of subsequent delegations to Europe, and contributor to various South African English-language newspapers and British journals. He traveled in Europe, Canada, and the United States with the intent of enlightening the public on the black African's situation in South Africa.

To preserve the traditional Bantu languages, stories, and poetry, Plaatje published his famous *Sechuana Proverbs and Their European Equivalents* (1916), the *Sechuana Phonetic Reader* (with the linguist Daniel Jones) in the same year, and the collection *Bantu Folk-Tales and Poems* at a later date. He also translated a number of Shakespeare's plays into Tswana. His novel *Mhudi* (1930), a story of love and war, is set in the 19th century. The characters are vivid and the style that of a traditional Bantu storyteller (a mixture of song and prose).

Near the end of Plaatje's life the people of Kimberley gave him a gift of land in recognition of his outstanding public service.

Place, Francis (b. Nov. 3, 1771, London—d. Jan. 1, 1854, London), British radical reformer, best-known for his successful campaign for the repeal in 1824 of the antiunion Combination Acts.

The son of a bailiff, Place was drawn into trade club and radical activity after suffering great hardships as a leather-breeches maker. In 1793 he organized an unsuccessful strike of the members of that trade. From 1794 to 1797 he was a member of the London Corresponding Society, one of the first working-class movements. He opened a tailoring shop in 1799 and rapidly became successful.



Place, detail of a portrait by Samuel Drummond, 1833; in the National Portrait Gallery, London

Place was already known as a radical politician when in 1814 he took up the campaign against the Combination Acts, passed in 1799 and 1800, prohibiting the organization of working-class trade associations. In 1824, through Joseph Hume, a member of Parliament, Place brought about the appointment of a parliamentary committee that reported in favour of repealing the acts. Place and Hume argued that repeal would leave the trade and employers' associations equal in status and that, with their legal equity established, it would no longer be necessary for the trade associations to exercise the right to bargain with employers. Manufacturers in turn favoured repeal, feeling that the acts contributed to their difficulty with labour. The repeal legislation passed. The immediate result, however, was an increase in trade unions and their activity. The government, alarmed, failed in its attempt to reverse the repeal, thanks to Place and his allies. In 1831 and 1832 Place rallied the supporters of the Reform Bill in London.

Place's only published book was *Illustrations and Proofs of the Principle of Population* (1822), but his manuscripts and press clippings, an excellent source of political information from 1790 to 1850, are in the British Museum.

placenta, in zoology, the vascular (supplied with blood vessels) organ in most mammals that unites the fetus to the uterus of the mother. It mediates the metabolic exchanges of the developing individual through an intimate association of embryonic tissues and of certain uterine tissues, serving the functions of nutrition, respiration, and excretion.

All of the fetal membranes function by adapting the developing fetus to the uterine environment. Lying in the chorionic cavity (a thin liquid-filled space) between two membranous envelopes (chorion and amnion) is a small balloon-like sac, yolk sac, or vitelline sac, attached by a delicate strand of tissue to the region where the umbilical cord (the structure connecting the fetus with the placenta) leaves the amnion. Two large arteries in the umbilical cord radiate from the attachment of the cord on the inner surface of the placenta and divide into small arteries that penetrate outward into the depths of the placenta through hundreds of branching and interlacing strands of tissue known as villi. The chorionic villi cause the mother's blood vessels in their vicinity to rupture, and the villi become bathed directly in maternal blood. The constant circulation of fetal and maternal blood and the very thin tissue separation of fetal blood in the capillaries from maternal blood bathing the villi provide a mechanism for efficient interchange of blood constituents between the maternal and fetal bloodstreams without (normally) allowing any opportunity for the blood of one to pour across into the blood vessels of the other.

Nutrients, oxygen, and antibodies (proteins formed in response to a foreign substance, or antigen), as well as other materials in the mother's blood, diffuse into the fetal blood in the capillaries of the villi, and nitrogenous wastes and carbon dioxide diffuse out of these capillaries into the maternal blood circulation. The purified and enriched blood in the capillaries of the villi is collected into fetal veins, which carry it back to the inner surface of the placenta and collect at the attachment of the cord to form the umbilical vein. This vein enters the cord alongside the two arteries and carries the blood back to the fetus, thus completing the circuit to and from the placenta.

placenta, plural PLACENTAS, or PLACENTAE, in botany, the surface of the carpel (highly modified leaf) to which the ovules (potential seeds) are attached. The placenta is usually located in a region corresponding somewhat to the margins of a leaf but is actually submarginal in position. The placentation, or arrangement of ovules within the ovary, is frequently of taxonomic value. Placentation is usually submarginal in a simple pistil (female sex organ). In a compound pistil, two or more carpels are used in various ways, placentation being parietal, carpels united by their adjacent margins and the ovules disposed along the inner ovary walls; axile, carpels folded inward and the ovules along the central axis of the ovary; free central, derived from the axile, with a central column bearing the ovules; basal, ovules positioned on a low column at the base of the ovary; or laminar, ovules scattered over the inner surfaces of carpels.

placenta accreta, abnormal adherence of the placenta to the wall of the uterus, so that it remains in the uterus after the baby has been delivered. Although uncommon, placenta accreta poses serious dangers to the mother. If complicated by coexisting placenta praevia (development of the placenta in an abnormally low position near the cervix), severe bleeding before labour is common. If placenta accreta arises on the site of a scar from a former cesarean section, the uterus may rupture during labour. Otherwise, depending on the firmness with which the placenta is anchored, it may be removed manually after the baby is delivered. If such removal is unsuccessful, an immediate total hysterectomy is usually indicated.

placenta praevia, implantation of the placenta at a point so low in the uterus that the placenta is close to the opening into the cervix or covers the opening, either partially or completely. The placenta is the temporary organ that develops during pregnancy to nourish the fetus and to carry away its wastes, and the cervix is the narrow lower portion of the uterus that projects into the vagina. Placenta praevia is suspected if there is painless bleeding during the last three months of pregnancy. The likelihood of the abnormality increases with the number of pregnancies of the individual woman and with the rapidity with which one pregnancy follows another. Untreated, the condition may result in early labour, delivery of a premature or stillborn child, and danger of death to the mother from bleeding. Treatment includes hospitalization, control of the bleeding and replacement of lost blood by transfusion, and delivery of the infant by cesarean section if the mother or the child would be endangered by delivery through the vagina.

placentae abruptio, premature separation of the placenta from its normal implantation site in the uterus. The placenta is the temporary organ that develops during pregnancy to nourish the fetus and carry away its wastes. Placentae abruptio occurs in the latter half of pregnancy and may be partial or complete. The separation causes bleeding, so extensive in cases of complete separation that replacement of the lost blood by transfusion is necessary. In instances of complete placentae abruptio, the infant dies unless delivered immediately. In partial separation the mother is given oxygen, and the infant is delivered as soon as it is safe to do so. The cause of placentae abruptio is not known. It is more common in women who have borne several children and in women suffering from high blood pressure.

placental infarction, formation of yellowish-white or bloodstained deposits of fibrin (a fibrous protein) on the surface or in the substance of the placenta, the temporary organ that develops during pregnancy to nourish the fetus and to carry away its wastes. Formation of placental infarcts is normal during the later stages of the organ's development. The term infarct, which usually signifies an area of dead tissue, is loosely used in this instance. Although extensive placental infarcts are sometimes present in stillbirths and in instances of premature separation of the placenta from its implantation site in the wall of the uterus, the infarcts are thought by most gynecologists and obstetricians not to be the causes of the other abnormalities.

placental mammal, any member of the mammalian infraclass Eutheria, characterized by the presence of a placenta, which facilitates exchange of nutrients and wastes between the blood of the mother and that of the fetus. Some consider the marsupials (infraclass Metatheria) to be placental mammals, but these animals have a less developed, less efficient type of placenta that limits the gestation period. The true placenta of the eutherian allows for a longer developmental period within the protection of the womb, a factor considered to have contributed to the evolutionary success of the eutherians.

Placentia, town, southeastern Newfoundland, Canada, on the Avalon Peninsula and the east shore of Placentia Bay. Basque fishermen arrived in the 16th century and probably named the site for Plasencia, Spain. In 1662 the French permanently settled the place as Plaisance, which they strongly fortified for use as a base for attacks against the British-held St. John's, 67 mi (108 km) to the northeast. The old fortifications overlooking the town have been preserved as Castle Hill National Historic Site. Plaisance served as capital of the various French settlements in Terre-Neuve (Newfoundland) until the beginning of the British period (1713). Renamed Placentia, it was administered from Nova Scotia (1713–29) and after the fall of Quebec (1759) became the site of a British naval station. In 1941 the Atlantic Charter was signed by Roosevelt and Churchill aboard warships anchored in Placentia Bay. The town's economy is based on fishing and employment at a U.S. naval station in nearby Argentia. Inc. 1945. Pop. (1981) 2,204.

placer deposit, natural concentration of heavy minerals caused by the effect of gravity on moving particles. When heavy, stable minerals are freed from their matrix by weathering processes, they are slowly washed downslope into streams that quickly winnow the lighter matrix. Thus the heavy minerals become concentrated in stream, beach, and lag (residual) gravels and constitute workable ore deposits. Minerals that form placer deposits have high specific gravity, are chemically resistant to weathering, and are durable; such minerals include gold, platinum, cassiterite, magnetite, chromite, ilmenite, rutile, native copper, zircon, monazite, and various gemstones.

There are several varieties of placer deposits: stream, or alluvial, placers; eluvial placers; beach placers; and eolian placers. Stream placers, by far the most important, have yielded the most placer gold, cassiterite, platinum, and gemstones. Primitive mining probably began with such deposits, and their ease of mining and sometime great richness have made them the cause of some of the world's greatest gold and diamond "rushes." Stream placers depend on swiftly flowing water for their concentration. Because the ability to transport solid material varies approximately as the square of the velocity, the flow rate plays an important part; thus, where the velocity decreases, heavy minerals are deposited much more quickly than the light ones. Examples of stream placers include the rich gold deposits of Alaska and the Klondike, the platinum placers of the Urals, the tin (cassiterite) deposits of Malaya, Thailand, and Indonesia, and the diamond placers of the Republic of Zaire.

Eluvial placers form on hillslopes from weathered deposits. They are not acted on by streams but by rainfall and wind, which carry away the light materials; thus they may be considered intermediate in the formation of stream placers. Examples include the earlier worked gold deposits of Australia and the cassiterite placers of Malaysia.

Beach placers form on seashores where wave action and shore currents shift materials, the lighter more rapidly than the heavier, thus concentrating them. Among the examples of beach placers are the gold deposits of Nome, Alaska; the zircon sands of Brazil and Australia; the black sands (magnetite) of Oregon and California; and the diamond-bearing marine gravels of Namaqualand, South Africa.

Eolian placers may form in arid areas where wind, not water, acts as the concentrating agent, removing fine particles of the lighter dross. The gold deposits of some parts of the Australian desert are examples.

placer mining, oldest method of recovering gold from alluvial deposits—*i.e.,* gold-bearing sands and gravel that settle out from rapidly moving streams and rivers at points where they slow down. Placer mining takes advantage of gold's high density, which causes it to sink more rapidly from moving water than the lighter siliceous materials with which it is found. Though the basic principles of placer mining have not altered since early times, methods have improved considerably.

Panning, used by miners during the great gold strikes of the 19th century, employed a pan or a batea (a pan or basin with radial corrugations) in which a few handfuls of the gold-bearing soil or gravel and a large amount of water were placed. By swirling the contents of the pan, the miner washed the siliceous material over the side, leaving the gold and heavy materials behind.

An improvement over the pan and batea was the cradle, named for its resemblance to a child's cradle. As it was rocked, it sifted large quantities of ore. Gravel was shovelled onto a perforated iron plate, and water was poured over it, causing the finer material to drop onto the apron that distributed it across the riffles, pieces of wood or iron perpendicular to the bottom and sides of the cradle. As the material moved through the cradle, the gold was caught on the riffles, to be removed later.

Dredging became the most important placer mining method in the early 20th century and remains so today. Used worldwide is the bucket-ladder dredge, characterized by a continuous chain of buckets rotating around a rigid adjustable frame called the ladder. Paddock dredging, a later development, allows mining of placer deposits even if they are not in or near a riverbed. The dredge floats in its own pond that is continuously extended by digging at one end and simultaneously filled at the other end with waste, or tailings.

In sluicing or hydraulicking methods, a slightly sloping wooden trough called a box sluice, or a ditch cut in hard gravel or rock called a ground sluice, is used as a channel along which gold-bearing gravel is carried by a stream of water. Riffles placed transversely along the bottom of the sluice cause the water to eddy into small basins, retarding the current so that gold may settle and be trapped.

Placetas, city, east central Villa Clara province, central Cuba. Placetas is a commercial and manufacturing centre for the rich agricultural and pastoral hinterland. Tobacco, sugarcane, fruits, and cattle are processed in the city, while gold and asphalt are found in the vicinity. Goods are exported through the port of Caibarién or sent to Santa Clara via the central highway and major railroad. Pop. (1983 est.) 73,456.

Placide, Alexander (b. 1750, France—d. July 26, 1812, New York City), French-born U.S. dancer, mime, acrobat, and impresario who produced in the U.S. such diverse and novel entertainment as ballets, pantomime dramas, patriotic pageants, fencing matches, and bird imitations.

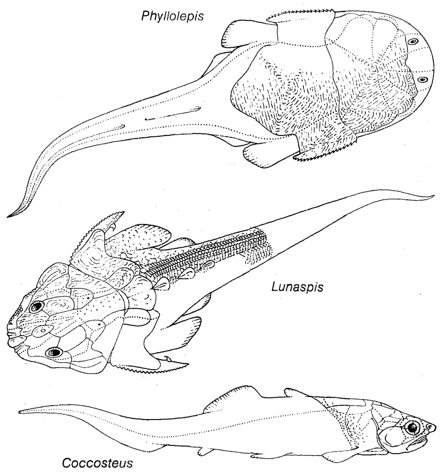
The son of travelling acrobats, Placide studied dance in Paris, had his first theatrical success as a tightrope walker at the court of Louis XVI, and toured Europe with his acrobat troupe. In Santo Domingo he met the dancer and choreographer Suzanne Theodore Vaillande (later Douvillier), who, though not his wife, appeared with him as "Madame Placide" when he performed a "dancing ballot" [*sic*] called *The Bird Catcher* in New York (1792). In 1794 Placide established a dance and pantomime company at the French (later City) Theatre in Charleston, S.C. There, with the choreographer Jean-Baptiste Francisqui and the dancers Jean-Baptiste Val, "Madame Placide," and the young Louis Duport, Placide produced such ballets as Jean-Georges Noverre's *Caprices de Galathée* and Maximilien Gardel's *Chercheuse d'esprit* (*Searchers for Spirit*). He also presented French actors in pantomime dramas and once used the local militia for a spectacle commemorating the Battle of Fort Moultrie. In 1798 he began producing in Savannah and Augusta, Ga. He married the actress and dancer Charlotte Sophia Wrighten in 1796; their son Henry (1799–1870) became one of the most popular U.S. actors of his generation.

Placidia, Aelia Galla (b. *c.* 390—d. Nov. 27, 450), Roman empress, the daughter of the emperor Theodosius I (ruled 379–395), sister of the Western emperor Flavius Honorius (ruled 393–423), wife of the Western emperor Constantius III (ruled 421), and mother of the Western emperor Valentinian III (ruled 425–455).

Captured in Rome when the city fell to the Goths in 410, she was carried off to Gaul and married (414) to the Visigothic chieftain Ataulphus, who was assassinated in 415. In 416 Galla Placidia was restored to the Romans, and the following year she was married to Constantius. She adorned Ravenna with a number of churches; the small chapel usually—though wrongly—known as the Mausoleum of Galla Placidia contains some of the finest examples of early Byzantine mosaics.

placoderm, any member of an extinct class (Placodermi) of primitive fishes known only from fossil remains. Placoderms existed throughout the Devonian period (408,000,000–360,000,000 years ago), but only two species persisted into the succeeding Carboniferous period. During the Devonian they were a dominant group, occurring in all continents except South America in a variety of marine and freshwater sediments.

Most placoderms were small or moderate in size, but a few may have reached a length of



Representative placoderms

13 feet (4 metres). The name is derived from their characteristic armour of dermal, or skin, bones. This armour formed a head shield and a trunk shield, the two commonly connected by a paired joint in the neck region. The arrangement of bones is so different from that of modern fishes with bony skeletons that it is unlikely that the bones of the two groups are homologous (similar in origin).

The earliest placoderms were heavily armoured, bottom-dwelling (benthic) fishes; they were poor swimmers. Many later forms became highly specialized for this way of life. Others became adapted for fast swimming between the surface and the bottom (*i.e.,* were nektonic). The sluggish benthic placoderms had small, ventrally placed mouths and presumably fed on bottom detritus and small invertebrates. Fossil remains indicate that some species had heavy, blunt jaw plates adapted for crushing hard-shelled invertebrates, while others were able to open their jaws wide enough to swallow smaller fish.

The origin of the placoderms is unknown, although it is possible that they may have shared a common ancestor with the sharks, skates, and rays. Some authorities speculate that one order (Ptyctodontida) may have given rise to the modern class Holocephali, of which the chimaeras are the only living representatives.

Plafond (French: Ceiling), French card game popular in Europe in the 1920s, a predecessor of Contract Bridge. Trick values and scoring were as in Auction Bridge except that, as in Contract Bridge, only tricks bid and made counted toward game; overtricks scored 50 points each in the honour score, which did not count toward game score, and slams, bid or unbid, scored 100 points for small and 200 points for grand. In 1925–26 Harold S. Vanderbilt, expert Auction Bridge player, revised the scoring table and added the factor of vulnerability. His changes were incorporated into the game of Contract Bridge, which replaced Plafond in popularity in the 1930s.

plagiarism, the act of taking the writings of another person and passing them off as one's own. The fraudulence is closely related to forgery and piracy—practices generally in violation of copyright laws.

If only thoughts are duplicated, expressed in different words, there is no breach of contract. Also, there is no breach if it can be proved that the duplicated wordage was arrived at independently.

plagioclase, any member of the series of abundant feldspar minerals usually occurring as light-coloured, glassy, transparent to translucent, brittle crystals. Plagioclase is a mixture of albite (*Ab*), or sodium aluminosilicate ($NaAlSi_3O_8$), and anorthite (*An*), or calcium aluminosilicate ($CaAl_2Si_2O_8$); the two intermingle and form a continuous chemical range (called a solid-solution series) between albite and anorthite (the end-members of the series). Intermediate members are homogeneous mixtures of the pure end-members. Divided according to their composition, the members of the plagioclase series are named in the Table.

Most of the crystals of the members of this series exhibit microscopic, repeated lamellar albite twinning; this produces the fine parallel striations observed on some surfaces. The twinning sometimes causes an iridescence, usually blue or green, that may arise either from reflection or diffraction at the edges of the lamellae, or from diffusion by adjoining areas with different optical properties.

Plagioclase is used in the manufacture of glass and ceramics; the iridescent varieties peristerite and labradorite are valued as gemstones or ornamental material. The primary importance of plagioclase, however, derives from its role in rock formation. Oligoclase, the most common plagioclase, occurs in granite, diorite, and other acidic igneous rocks and in some metamorphic rocks; notable occurrences are at Aust-Agder, Norway, and Fine, N.Y., United States. Andesine, less common, occurs in many granular and volcanic rocks with medium silica content, as in Marmato, Colom., and Bodenmais, Bavaria, Ger. The rarest plagioclase is bytownite, which occurs in basic igneous rocks and in stony meteorites. For detailed physical properties of the plagioclase series, *see* feldspar (table).

Composition of the plagioclase minerals

mineral	composition (in percent)
albite	100–90 *Ab*; 0–10 *An*
oligoclase	90–70 *Ab*; 10–30 *An*
andesine	70–50 *Ab*; 30–50 *An*
labradorite	50–30 *Ab*; 50–70 *An*
bytownite	30–10 *Ab*; 70–90 *An*
anorthite	10–0 *Ab*; 90–100 *An*

plague, an infectious fever caused by the bacillus *Yersinia pestis,* transmitted by the rat flea. It is primarily a disease of rodents, and epidemics in human beings originate in contact with the fleas of infected rodents. The disease in man has three clinical forms: bubonic, characterized by swelling of the lymph nodes (buboes); pneumonic, in which the lungs are extensively involved; and septicemic, in which the bloodstream is so invaded by *Yersinia* that death ensues before the bubonic or pneumonic forms have had time to appear. Plague as spread from rats to man in crowded urban areas is sometimes called murine (rat) or urban plague; plague in desert or rural areas where the human population is sparse but the wild rodent population large and infected may be called sylvatic (woodland) or campestral (field).

In the 14th century, when this disease was known as the Black Death (*q.v.*), some plague infections were bubonic and some were pneumonic. The number of deaths was enormous, reaching in various parts of Europe two-thirds or three-fourths of the population in the first pestilence. It has been calculated that one-fourth of the population of Europe, or 25,000,000 persons, died from plague during the great epidemic.

The Great Plague of London in 1664–65 resulted in more than 70,000 deaths in a population estimated at 460,000. An outbreak in Canton and Hong Kong in 1894 left 80,000 to 100,000 dead, and within 20 years the disease spread from the southern Chinese ports throughout the whole world, resulting in more than 10,000,000 deaths.

Plague is primarily a disease of rodents, and man enters only accidentally into the usual cycle. This cycle—rodent–flea–rodent—as a rule is enzootic (present in an animal community at all times but occurring in only small numbers of cases), but under certain environmental conditions it reaches epizootic proportions (affecting many animals in any region at the same time). In some areas plague-infected rats from ships spread the infection in ports, where it became epizootic.

Spread of the infection among domestic rodents in the vicinity of human habitations creates conditions favourable for outbreaks of human plague, for when an epizootic outbreak reduces the rodent population, fleas from the dead animals fail to find another rodent host and thus begin to infest man. At first the cases are sporadic, but under suitable conditions large numbers of persons may be included.

The illness in man varies within the widest limits, exhibiting all gradations of severity from mere indisposition to violent death. The mild infections are almost always bubonic; pneumonic and septicemic plague are invariably severe and almost always fatal unless treated. The incubation period is usually three to six days but may be as short as 36 hours or as long as 10 days. As a rule the onset is sudden and well marked.

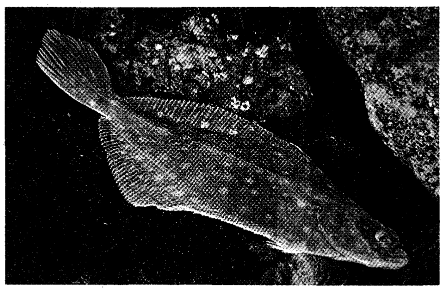
Bubonic plague constitutes about three-fourths of plague cases. Typically, bubonic plague starts with shivering, then vomiting, headache, giddiness, intolerance to light; pain in the back and limbs; sleeplessness, apathy, or delirium. The temperature rises rapidly to 104° F (40° C) or higher and frequently falls two or three degrees on the second or third day, with marked prostration. Constipation is usual; diarrhea is a grave sign. Most characteristic is the early appearance of buboes, which are usually distributed in the groin and armpits. Bubonic plague is not directly infectious from man to man; the bacillus is carried from one person to another by the flea.

In pneumonic plague the physical signs are those of bronchopneumonia; edema (filling with fluid) of the lungs soon follows; and death occurs in three or four days. Septicemic plague is marked by prostration and brain damage; death may occur within 24 hours. Septicemic plague may prove fatal before there is time for pneumonia to develop. If, however, pneumonia does occur, the patient becomes highly infectious. His contacts will contract pneumonic, not bubonic, plague. Pneumonic plague is nearly always fatal.

Treatment is primarily with streptomycin, tetracycline, and sulfonamides. Penicillin is without effect against plague.

The suppression of epidemic plague is attempted by appropriate sanitary measures directed simultaneously against fleas and rodents and isolation of the sick and the handling with greatest caution of all infectious material. A vaccine is available and may be used in endemic areas for people likely to be exposed to rodents and their fleas.

plaice (*Pleuronectes platessa*), commercially valuable European flatfish of the family Pleuronectidae. The plaice, like others of its family, normally has both eyes on the right side of



Plaice (*Pleuronectes platessa*)
Jacques Six

the head. It also has about four to seven bony bumps near its eyes. It reaches a maximum length of about 90 centimetres (36 inches) and is strikingly coloured, with red or orange spots on a brown background.

Another North Atlantic member of the family Pleuronectidae is the American plaice (*Hippoglossoides platessoides*). It is found both in Europe, where it is called the rough dab, and in America. It is a reddish or brownish fish and grows to about 60 centimetres long.

Plaid Cymru (Welsh: Party of Wales), English byname WELSH NATIONALIST PARTY, a political party founded in August 1925 and seeking self-government for Wales and preservation of the Welsh language and culture. Plaid Cymru seeks dominion status for Wales, which would give Wales a seat in the United Nations and a place in international life. The party majority favours devolution, which would include a Welsh parliament and maintenance of links with the United Kingdom. A minority calls for independence. A referendum in 1979 showed that 20 percent of Welsh voters favoured devolution, the same percentage as the proportion of native Welsh speakers. The party's social policies, with their emphasis on decentralization and cooperation, reflect Welsh political tradition.

When J.E. Jones was appointed general secretary in 1930, its membership was about 500, but by 1980 it was 30,000 which included working-class elements brought in by the economic crisis in Wales. L.E. Valentine was the party's first president, but during the 1930s its policy was developed mainly under the leadership of Saunders Lewis. In 1966, in a by-election, the party won its first seat in the House of Commons. Though the seat was lost in 1970, the party took three seats in 1974 and two in 1979 and again in 1983. The party is also represented in local governments and councils.

plain, any relatively level area of the Earth's surface exhibiting gentle slopes and small local relief. Plains vary widely in size. The smallest occupy only a few hectares, whereas the largest cover hundreds of thousands of square kilometres—as, for example, the Great Plains of North America and the expanse of gently undulating land that sweeps from the Pyrenees Range on the French–Spanish border across northern Europe and Asia almost halfway around the world nearly to the Bering Sea.

Occupying slightly more than one-third of the terrestrial surface, plains are found on all continents except Antarctica. They occur north of the Arctic circle, in the tropics, and in the middle latitudes. Corresponding to their broad geographical distribution, the plains of the world show considerable variation in vegetation. Some are tree covered and others are grassy. Still others support scrub brush and bunch grass, while a few, which are nearly waterless deserts, have only the most sparse and scanty plant life. *See* Pampa; prairie.

The major plains of North America, South America, Europe, and Asia occur in the continental interiors, but broad extensions of some of these flat lands reach the Atlantic coast. The largest plains of Africa occupy a vast portion of the Sahara and extend southward into the Congo and Kalahari basins. Most of the interior of Australia, from the mountains along the eastern margin to the plateaus in the far west, is one vast desert plain.

The majority of the world's most extensive plains were formed as a result of the dominance of erosional and depositional processes over tectonic activity—*e.g.,* uplift or subsidence of the Earth's crust. By contrast, a large number of smaller plains developed in areas where crustal deformation was quite intense. Most of these consist of depressed crustal segments that have been partly filled by sand, clay, and rock debris deposited by streams from adjoining highlands.

With certain exceptions, plains have become the sites of major centres of population, industry, commerce, and transportation. Their flat surfaces are easily cultivated and usually contain the most productive soil. Moreover, such areas of low relief present few obstacles to land transportation, and the rivers running across them are generally much easier to navigate than are those of rougher terrain.

plain, abyssal (deep-sea formation): *see* abyssal plain.

Plain, The, French LA PLAINE, in the French Revolution, the deputies of the centre in the National Convention who were the numerical majority. At first, such Plain leaders as Abbé Sieyès and Bertrand Barère backed the moderate Girondins but later gradually turned to the more radical Montagnards, joining the regicides in casting many votes for the execution of Louis XVI in January 1793. Both sides thus courted the favour of The Plain, whose majority support was essential. In July 1794 their numbers succeeded in helping to overthrow Robespierre and other extreme Jacobins. In November 1799, Sieyès was a leader in the coup that overthrew the Directory and brought Napoleon Bonaparte to power.

plain stitch, also called JERSEY STITCH, FLAT STITCH, or STOCKINETTE STITCH, basic knitting stitch in which each loop is drawn through other loops to the right side of the fabric. The loops form vertical rows, or wales, on the fabric face, giving it a sheen, and crosswise rows, or courses, on the back.

Plain-stitch knitting is a filling knit construction and can be made by hand and on both flat and circular knitting machines. The fabric produced is flatter and lighter in weight than other knit types, with more stretch in the width than in the length. The plain stitch is used for underwear, hosiery, T-shirts, gloves, and sweaters.

plain weave, also called TABBY WEAVE, simplest and most common of the three basic textile weaves. It is made by passing each filling yarn over and under each warp yarn, with each row alternating, producing a high number of intersections. Plain-weave fabrics that are not printed or given a surface finish have no right or wrong side. They do not ravel easily but tend to wrinkle and have less absorbency than other weaves.

The visual effect of plain weave may be varied by combining yarns of different origins, thickness, texture, twist, or colour. Fabrics range in weight from sheer to heavy and include such types as organdy, muslin, taffeta, shantung, canvas, and tweed. Variations of the plain weave include the rib weave, with either warp or filling yarns heavier, as in dimity and bengaline, and the basket weave, in which two or more filling yards, or a single heavier yard, pass alternately over and under two or more warp yarns, as in oxford shirting and monk's cloth.

plainchant, also called PLAINSONG, the Gregorian chant (*q.v.*) and, by extension, other similar religious chants. The word derives from the 13th-century Latin term *cantus planus* ("plain song"), which referred to the unmeasured rhythm and monophony (single line of melody) of Gregorian chant, as distinguished from the measured rhythm of polyphonic (multipart) music, which was called *cantus mensuratus* or *figuratus* ("measured" or "figured" song).

Its principal other application is to ancient Christian music with the same unmeasured rhythm and monophony—in the West, Ambrosian, Gallican, and Mozarabic chants (*qq.v.*); in the East, Byzantine, Syrian, Coptic, Ethiopian, and Armenian chants (*qq.v.*). It may also refer to similar non-Christian religious music, such as Jewish and Hindu chants.

Plainfield, city, Union County, New Jersey, U.S., at the base of the Watchung Mountains. The site was settled as Milltown, named for its large gristmill, in the 18th century and was incorporated as a township in 1847. Although now primarily a residential southwestern suburb of New York City, it is a focal point for a number of surrounding towns including North and South Plainfield, Scotch Plains, and Watchung. It has developed some major industries, including the manufacture of printing machinery, aircraft parts, electronic equipment, and glue. Drake House Museum (1746) served as Gen. George Washington's headquarters in 1777 and now houses the Historical Society of Plainfield and North Plainfield. Inc. city, 1869. Pop. (1980) 45,555.

Plains, town, Sumter County, southwest central Georgia, U.S., 10 mi (16 km) west-southwest of Americus. A post office was established there in 1839, and when the railroad was built in 1885 several local settlements, including Magnolia Springs (or Village) and the Plains of Dura (named for the biblical plain near Babylon), regrouped to form Plains, which was incorporated in 1896. The town became a tourist attraction in the late 1970s as the hometown of Jimmy Carter, 39th president of the United States. Pop. (1980) 651.

Plains Indian, also called BUFFALO INDIAN, member of an aboriginal people formerly inhabiting the Great Plains of what is now the central United States and south-central Canada, between the Mississippi River and the Rocky Mountains. The Plains Indians included groups speaking Algonkian, Siouan, Caddoan, Uto-Aztecan, Athabascan, and Kiowa-Tanoan languages.

A brief treatment of the Plains Indians follows. For full treatment, *see* MACROPAEDIA: American Indians.

Most of the Plains Indians were nomadic big-game hunters, and their primary game was the American bison, or buffalo, which supplied them with food, shelter, clothing, and bone tools. Other game included antelope, deer, and elk. Hunting, usually a tribal activity, involved driving the game down a cliff or into a corral or encircling it by fire. These nomadic tribes were made up of smaller local units called bands, which came together only for the summer communal hunt or for major religious ceremonies. The Teton Dakota and Cheyenne were typical nomadic tribes.

A few tribes, though mainly nomadic, practiced horticulture, produced pottery, and resided in fixed villages for part of the year. These semisedentary tribes spent part of the time planting and harvesting crops, which consisted of corn (maize), beans, squash, and sunflowers. The Pawnee, Mandan, Hidatsa, and Arikara were typical semisedentary tribes.

There were no hereditary social classes among the Plains Indians, although wealth and standing could be won through prowess at war, generosity to the poor, sharing goods with relatives, and lavish hospitality. Because individualism and violent experience were highly valued by almost every tribe, military organizations and clubs were often established in order to channel intratribal aggressiveness. Women participated in many of these associations, although they had their own societies among the Mandan and Hidatsa.

Local bands and villages were composed of families and kinship groups, which could be patrilineal (as among the Iowa, Kansa, Omaha, Osage, and Ponca), matrilineal (as among the Hidatsa, Mandan, and Crow), or both. Marriages were generally monogamous and were ordinarily arranged between the families of the bride and groom. Children were trained for adulthood as part of their play, and relatives often played important roles in their upbringing. Boys were given bows and arrows at a very early age, while girls were taught domestic skills by their mothers.

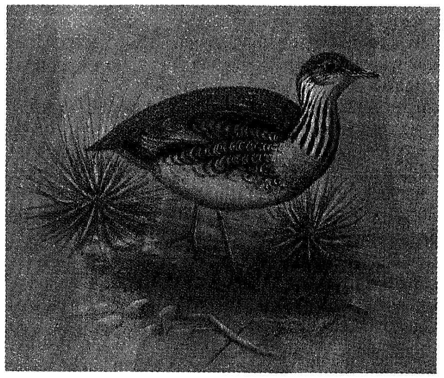
Before the appearance of European explorers, Indian tools were made of bone, horn, antler, and stone. Animal skins were used for clothing, receptacles of various kinds, and tepees, which were portable, cone-shaped tents. Basketry and pottery were known among the semisedentary tribes. Until horses were introduced by the Spaniards, dogs were probably the only domesticated animals. The introduction of the horse had a profound impact on Plains life, revolutionizing the hunt and warfare and providing a valuable commodity for both trade and theft, which latter in turn stimulated warfare.

Although some tribes, such as the Atsina, believed in a supreme deity, other tribes, such as the Crow, did not. However, rituals ranging from simple rites to ceremonies lasting weeks were common to almost all of the Plains Indians. Each tribe had a medicine man, or shaman, who was responsible for such activities as curing illness and locating enemies, game, or lost objects. Much importance was attached to visions, and success in life was attributed to the intervention of friendly spirits.

The culture of the Plains Indians changed radically as white settlers moved into the region. Systems of status and rank collapsed when the buffalo was virtually exterminated in the late 19th century, and native crafts declined as manufactured articles, such as metal utensils and cloth, were introduced. Even greater disturbances resulted when the Indians were placed on reservations. Nomadic groups found cattle a poor replacement for buffalo, and semisedentary groups, who considered cultivation to be women's work, resisted the change in the division of labour brought on by the introduction of the plow. Misunderstandings arose when matrilineal groups had to adopt father-son inheritance lines, and confusion resulted when government officials tried to list Indian families by surnames, which they did not possess. Although the Indians resisted such changes, they were ultimately overwhelmed, and those Indians who did manage to adapt to the white man's culture often found themselves in a difficult position among their own people.

Plains of ———: *see under* substantive word (*e.g.*, Abraham, Plains of).

plains wanderer, also called COLLARED HEMIPODE (*Pedionomus torquatus*), Australian bird resembling a tiny quail. It has a mottled reddish brown body and a collar of black spots against a white throat. The plains wanderer



Plains wanderer (*Pedionomus torquatus*)
Painting by Murrell Butler

constitutes the family Pedionomidae (order Gruiformes) but is placed by some authorities in the button quail family (Turnicidae). They inhabit dry grasslands. Unlike other hemipodes, the plains wanderer does not have a crouching posture.

plainsong (music): *see* plainchant.

Plainview, city, seat (1888) of Hale County, northwestern Texas, U.S., on the High Plains between Amarillo and Lubbock (40 mi [64 km] south). The site was surveyed in 1887 by Z.T. Maxwell and E.L. Lowe, who named it Plainview because of the unbroken view to the horizon. The settlement remained a trading post for cattlemen until the railroad arrived in 1907, when it was incorporated as a city. On Running Water Draw, it is now a service centre for extensive farmlands, irrigated by thousands of wells and growing chiefly wheat, cotton, castor beans, grain sorghums, and vegetables. Industries are farm based and include meat-packing and the manufacture of irrigation equipment. It is the seat of Wayland Baptist College (1909). Pop. (1980) 22,187.

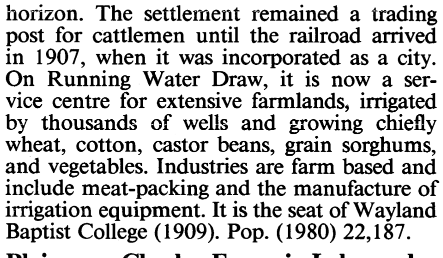
Plaisance, Charles-François Lebrun, duc de (duke of): *see* Lebrun, Charles-François.

Plaisancian Stage: *see* Piacenzan Stage.

Planalto Central (Brazil): *see* Brazilian Highlands.

planarian, any of a group of widely distributed, mostly free-living flatworms of the invertebrate class Turbellaria (phylum Platyhelminthes). *Planaria* is the name of one genus, but the name planarian is used to designate any member of the family Planariidae and related families.

Most planarians occur in fresh water and are sometimes seen in large masses; some species are marine, others are terrestrial. Some forms are parasitic; *i.e.,* they obtain nourishment from the body of another living animal.



Planarian (*Dugesia*)
William H. Amos—Helen Wholberg, Inc.

The body, when elongated, is soft, leaf-shaped, and ciliated. The spade-shaped head has two eyes and sometimes tentacles. The tail is pointed. The mouth is on the ventral, or lower, side, often more than half-way toward the tail. A body cavity, or coelom, is absent. The pharynx, which may be protruded from the mouth, ends in an intestine that is usually blind. The length is usually about 3 to 15 mm (0.1 to 0.6 inch); some grow to more than 30 cm (about 1 foot) long. Tropical species are often brightly coloured. Members of the North American genus *Dugesia* are black, gray, or brown.

Planarians swim with an undulating motion or creep like slugs. Most are carnivorous night feeders. They eat protozoans, tiny snails, and worms. All are hermaphroditic; *i.e.,* functional reproductive organs of both sexes occur in the same individual. The reproductive organs begin to develop in early autumn. Cocoons containing fertilized eggs are laid in spring. Fully developed young emerge and develop without metamorphosis (*i.e.,* radical change). In *Planocera* a larval stage is passed in the egg case. In some species, the organism in the cocoon divides into two parts, each of which develops into a complete individual. New individuals, called buds, form at the tail end of others in the genus *Microstomum* and may remain attached to the parent for some time; chains formed of three or four buds sometimes occur. Because of their remarkable ability to regenerate lost parts, planarians are often used experimentally in the laboratory.

Planasia (Italy): *see* Pianosa Island.

Planck, Max (Karl Ernst Ludwig) (b. April 23, 1858, Kiel, Schleswig [Germany]—d. Oct. 4, 1947, Göttingen, W.Ger.), theoretical physicist who originated quantum theory. For that achievement he was awarded the Nobel Prize for Physics in 1918.

A brief account of the life and works of Max Planck follows; for a full biography, *see* MACROPAEDIA: Planck.

Planck—whose forebears were scholars, lawyers, and public servants—was sent to the Maximilian Gymnasium in Munich, where he chose science as a career over his other great love, music. He went to Berlin to study with H.L.F. von Helmholtz and G.R. Kirchhoff but returned to Munich to take his doctorate in 1879 on the second law of thermodynamics. He became *Privat-Dozent* at the University of Munich in 1880 and extraordinary professor of theoretical physics at Kiel in 1885. Two years later he was made professor of theoretical physics at Berlin, where he lived for the rest of his life. In 1930 he had become president of the Kaiser Wilhelm Society in Berlin (after World War II, the Max Planck Society).

In 1900 Planck formulated the correct mathematical description of thermal radiation from a perfect absorber (blackbody) and showed that the formulation required a discontinuous process of emission or absorption involving discrete quantities of energy. Those discoveries initiated the field of quantum physics and earned for Planck the Nobel Prize.

Planck's constant (symbol h), fundamental physical constant characteristic of the mathematical formulations of quantum mechanics, which describes the behaviour of particles and waves on the atomic scale, including the particle aspect of light. The German physicist Max Planck introduced the constant in 1900 in his accurate formulation of the distribution of the radiation emitted by a blackbody, or perfect absorber of radiant energy (*see* Planck's radiation law). The significance of Planck's constant in this context is that radiation, such as light, is emitted, transmitted, and absorbed in discrete energy packets, or quanta, determined by the frequency of the radiation and the value of Planck's constant. The energy E of each quantum, or each photon, equals Planck's constant h times the radiation frequency symbolized by the Greek letter nu, ν, or simply $E = h\nu$. A modified form of Planck's constant called h-bar ($\hbar$), or Dirac h, frequently appears in the formulations of quantum mechanics, in which $\hbar$ equals h divided by 2π.

The dimension of Planck's constant is the product of energy multiplied by time, a quantity called action. Planck's constant is often defined, therefore, as the elementary quantum of action. Its value in metre-kilogram-second units is $6.6260755 \times 10^{-34}$ joule-second.

Planck's radiation law, a mathematical relationship formulated in 1900 by Max Planck, a German physicist, to explain the spectral-energy distribution of radiation emitted by a blackbody (a hypothetical body that completely absorbs all radiant energy falling upon it, reaches some equilibrium temperature, and then reemits that energy as quickly as it absorbs it). Planck assumed that the sources of radiation are atoms in a state of oscillation and that the vibrational energy of each oscillator may have any of a series of discrete values but never any value between. Planck further assumed that when an oscillator changes from a state of energy E_1 to a state of lower energy E_2, the discrete amount of energy $E_1 - E_2$ is emitted as a photon, or quantum of radiation. The energy of this quantum is equal to the product of the frequency of the radiation, symbolized by the Greek letter nu, ν, and a constant, h, now called Planck's constant; *i.e.,* $E_1 - E_2 = h\nu$.

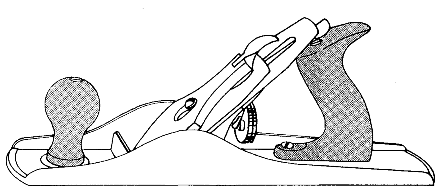
Planck's law for the energy E_λ radiated per unit volume by a cavity of a blackbody in the wavelength interval λ to $\lambda + \Delta\lambda$ ($\Delta\lambda$ denotes an increment of wavelength) can be written in terms of Planck's constant (h), the speed of light (c), the Boltzmann constant (k), and the absolute temperature (T):

$$E_\lambda = \frac{8\pi hc}{\lambda^5} \times \frac{1}{\exp(hc/kT\lambda) - 1}.$$

The wavelength of the emitted radiation is inversely proportional to its frequency, or $\lambda = c/\nu$. The value of Planck's constant is found to be $6.6260755 \times 10^{-34}$ joule-second.

For a blackbody at temperatures up to several hundred degrees, the majority of the radiation is in the infrared region of the electromagnetic spectrum. At increasingly higher temperatures, the total radiated energy increases, and the intensity peak of the emitted spectrum shifts to shorter wavelengths so that a significant portion is radiated as visible light.

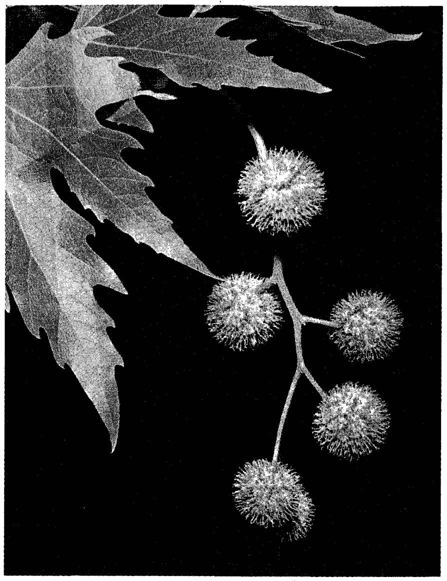
plane, in carpentry, tool made in a wide variety of sizes, used for removing rough surfaces on wood and for reducing it to size. An iron-soled carpenter's plane, found on the site of a Roman town, near Silchester,



Carpenter's hand plane

Hampshire, Eng., dates from before AD 400. Many European guild craftsmen of the Middle Ages worked with beautifully decorated metal planes. Planes today are mostly machine-made, of wood and steel. Plow, or grooving, planes are used for forming channels or grooves; a wide variety of special models are employed for running moldings.

plane tree, any of the 10 species of the genus *Platanus,* the only genus of the family Platanaceae. These large trees are native in North America, eastern Europe, and Asia and are characterized by scaling bark; large, deciduous, usually palmately lobed leaves; and globose heads of flower and seed. The plane trees bear flowers of both sexes on the same tree but in different clusters. The sycamore maple (*Acer pseudoplatanus*), often called sycamore, plane, or mock plane, is distinct (*see* maple).



Leaves and seedballs of the Oriental plane tree (*Platanus orientalis*)
A to Z Botanical Collection—EB Inc.

The American plane tree, or sycamore (*P. occidentalis*), also known as buttonwood, buttonball, or whitewood, is the tallest, sometimes reaching a height of more than 50 m (160 feet). Its pendent, smooth, ball-shaped seed clusters usually dangle singly and often persist after leaf fall. Native from southeastern Europe to India, the Oriental plane (*P. orientalis*) reaches 30 m (100 feet) with huge, often squat boles—some measuring nearly 10 m in circumference (about 10 feet in diameter). Its bristly seedballs hang in clusters of two to six. The London plane (*P. acerifolia*), a hybrid between the American and the Oriental planes, combines characteristics of both in varying degrees. It is a little shorter and more squat than the American tree and usually has bristly, paired seedballs. There are variegated forms of London plane. The California sycamore (*P. racemosa*), about 25 m (80 feet) tall, has contorted branches, thick leaves, and bristly seedballs in groups of two to seven.

The London plane is planted widely in cities for its resistance to air pollution and to diseases that more readily affect other plane trees. All planes grow rapidly and furnish quick shade. Many are picturesque in winter for their patchy bark: as the outer bark flakes off, inner bark shows up in shades of white, gray, green, and yellow.

planer, metal-cutting machine in which the workpiece is firmly attached to a horizontal table that moves back and forth under a single-point cutting tool. The tool-holding device is mounted on a crossrail so that the tool can be fed (moved) across the table in small, discrete, sideward movements at the end of each pass of the table. Since the cutting tool can be moved at almost any angle, a wide variety of grooves and surfaces can be generated. The length and speed of its table travel also may be adjusted.

Mechanical planers, or surfacers, also are used for smoothing wood to an even thickness. The planer consists of a frame, a bed that can be moved up and down, feed rolls, a feeding mechanism, and a cylindrical cutting head holding three or more knives that pare off the excess wood. Models range from the single planer, which smooths one surface of a board at a time, to machines that can finish several surfaces simultaneously. Planer sizes are indicated by the width of work that can be accommodated, ranging from 18 to 50 inches (about 45 to 125 centimetres).

planet (Greek *planētes,* "wanderers"), any body (except a comet, meteoroid, or satellite) revolving in an orbit around the Sun or around some other star. (*See also* individual articles on the solar system's major planets, listed below.) The nine major planets known to revolve around the Sun are (in order of increasing distance from it): Mercury, Venus, Earth, Mars, Jupiter, Saturn, Uranus, Neptune, and Pluto. The inner four are sometimes called the terrestrial planets; and the term giant planets denotes the group Jupiter–Neptune. Between these groups is a belt of numerous, very small bodies called asteroids, or sometimes the minor planets.

In primitive astronomy the term planet was applied to the seven celestial bodies that were observed to move appreciably against the background of the apparently fixed stars. These included the Sun and Moon, as well as the five true planets (Mercury, Venus, Mars, Jupiter, and Saturn) readily visible as celestial wanderers before the invention of the telescope. The names of these seven bodies are still connected, in some languages, with the days of the week.

In astrology great importance is placed on the positions of the various planets in the 12 constellations of the zodiac, the belt around the sky in which the movements of Sun, Moon, and planets are confined.

Deviations in the proper motions—motions relative to the background of apparently fixed, distant stars—of several nearby stars indicate that they may be accompanied by dark, planet-like bodies too faint to be seen directly from the Earth.

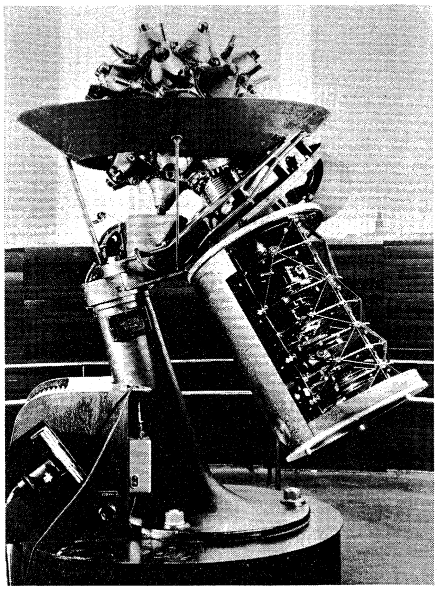
Where the same name may denote a person, place, or thing, the articles will be found in that order

Planet X, supposed planet of the solar system 10th in distance outward from the Sun, surmised on the basis of calculations of its effect on the orbits of Halley's Comet and of the planets Neptune and Pluto.

At the time its existence was proposed (1972), the planet was stated to be located in the direction of the constellation Cassiopeia. Planet X was calculated to have a mass approximately three times that of Saturn and a period of revolution around the Sun of about 500 years; its orbit was believed to be inclined to the ecliptic (the plane of the Earth's orbit) at 120°.

Within a year after the proposal of Planet X, other astronomers demonstrated that a body with the suggested mass and orbit would have perturbed the orbits of the known outer planets by amounts wholly incompatible with the observed paths. In addition, they showed that if the density and the albedo (reflective power) of Planet X had plausible values, it should be visible by standard astronomical techniques. Careful examination of photographic records disclosed no evidence of Planet X.

planetarium, institution devoted to popular education in astronomy and related fields, especially space science, and in which the principal teaching arrangement is a hemispherical screen onto which images of celestial objects as seen from Earth are projected from an instrument also known as a planetarium, or planetarium projector. The term was originally used to describe teaching or exhibit devices designed to portray the orbital motions of the planets and their satellites. Such devices consisted of small globes, representing the planets, that were mounted on wire rods supported and geared at a central pedestal, with a globe for the Sun at the top. Many included the major satellites known at the time of construction. Also called orreries (after the English sponsor of one built in 1712), these devices could be quite elaborate and accurate (*see* orrery).



First modern planetarium projector, built by the Carl Zeiss firm in 1923

By courtesy of Carl Zeiss, Oberkochen, Ger.

Planetarium installations vary greatly. Some have extensive exhibit space, museum collections, and sizable professional and support staffs. The projection dome may have a diameter of 25 metres (82 feet) or more and a seating capacity in excess of 600. Others are large enough to accommodate only a small group of people and might better be described as teaching aids than as institutions.

At the heart of every planetarium is the projection instrument. Here, too, the range is great. Perhaps the best known name in the field is Zeiss; since World War II, projectors have been constructed in a new Zeiss factory in Oberkochen, Ger., as well as in the original Zeiss plant at Jena, Ger., where the first projector was built in 1923. Modern Zeiss instruments are large, technically advanced combinations of lenses, lights, gears, and motors designed to place the planets, Sun, and Moon in their correct locations among the stars for thousands of years past and future. Star images are projected from two spherical units, one for the northern sky and one for the southern sky, while images of the other celestial objects are projected from separate devices supported in a latticework cage between the star balls. The goal is to create a highly realistic artificial sky. Auxiliary projectors produce horizon scenes, the Milky Way, comets, meteors, and the reference lines used for teaching descriptive astronomy and celestial navigation.

Other planetarium projectors are less complex but accomplish the same purpose of creating an artificial sky that can be used for teaching purposes. Manufacturers in Japan and the United States compete with Zeiss, producing an array of instruments appropriate for a variety of dome sizes and for different purposes.

In a typical planetarium, demonstrations—or sky shows, as they are commonly called—are offered to the public on a regular schedule. The astronomy theme is often embellished by music, special effects of all kinds, and a narration that is usually prepared in advance and taped by a professional skilled in this type of dramatic interpretation. There is a trend toward automation of the program to assure that all visitors experience essentially similar presentations on the current theme.

When the first planetarium was opened at the Deutsches Museum in Munich in 1923, it was described as a "schoolroom under the vault of the heavens." Special sky shows for school children remain an essential part of the program in nearly every installation, with the content often integrated with the science curriculum of the local schools. Lectures in the basics of descriptive astronomy are given to college classes, and the facilities are commonly used for courses or lectures in a continuing-education program, sometimes for credit by arrangement with a local college or university.

Although concentric seating around the central projector in the domed theatre remains the most common arrangement, there have been experiments with unidirectional seating. Horizons have been tilted in the construction of some theatres to give audiences a more objective view of the artificial sky. A recent trend in "space theatres" places emphasis on wide-angle motion pictures in a tilted or distorted hemisphere, with projected star fields in a secondary role. Cathode-ray projection systems currently being developed may eventually replace the optical–mechanical planetarium projector. Such electronically controlled systems are readily integrated with computer data banks and have the potential for creating many variations on traditional projected patterns. By taking into account star distances, for example, the system can create the illusion of flying through space among the stars while it maintains an accurate representation of the surroundings from any new perspective.

planetary nebula, any of a class of bright nebulae that may somewhat resemble planets when viewed through a small telescope but are in fact expanding clouds of fluorescent gas far outside the solar system (*see* nebula).

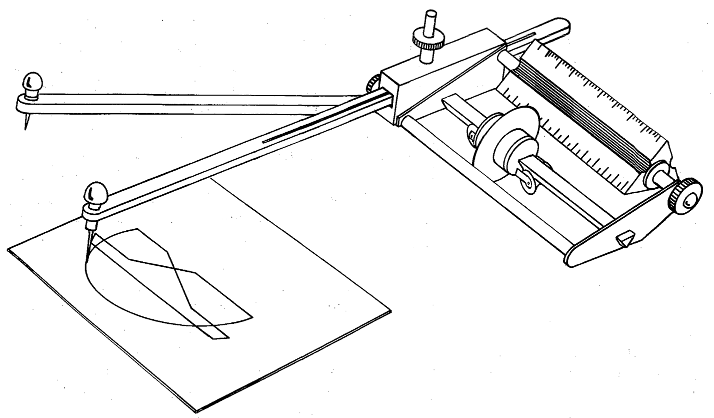
planetesimal, one of a class of hypothetical primitive particles or little bodies that eventually coalesced to form the planets after condensing from gaseous matter early in the history of the solar system. The planetesimal theory was first proposed by the U.S. geologist Thomas Chrowder Chamberlin and the U.S. astronomer Forest Ray Moulton in 1906. Hypotheses of the origin of the solar system involving near-collisions between stars were widely accepted in the early decades of the 20th century but have been superseded by the nebular hypothesis that the planets formed from the same gas cloud that condensed to make the Sun. *See also* protoplanet.

planetoid (astronomy): *see* asteroid.

planigale, common and genus name for certain species of tiny mouselike marsupial animals. *See* marsupial mouse.

planimeter, mathematical instrument for directly measuring the area bounded by an irregular curve, and hence the value of a definite integral (*see* the illustration).

The first such instrument, employing a disk-and-wheel principle to integrate, was invented in 1814 by J.H. Hermann, a Bavarian engineer. Improved mechanisms were invented by the British mathematical physicist James Clerk Maxwell (1855) and the Scottish engineer James Thomson (1876). So far as is known, Maxwell never actually built a working model of his invention, which he called a platometer, but Thomson's principle was not only applied in planimeters but adapted by his brother, the physicist William Thomson (later 1st Baron Kelvin), for a machine used in harmonic analysis of tides. A practical, in-



The Willis planimeter

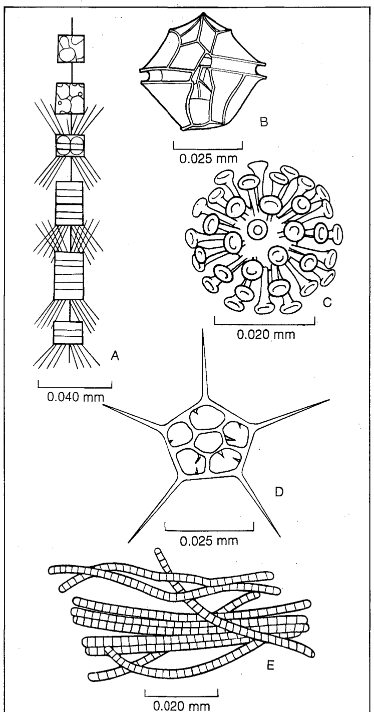
expensive polar planimeter was invented by the Swiss mathematician Jacob Amsler about 1854. It consists of a pole arm, or bar, which has a weight at one end, and a tracer arm, the end of which has a point that the operator guides around the boundary of the area in question. Both arms rest in a carriage that moves as the tracer arm is moved; a vernier wheel within the carriage provides directly the area that is measured, calibration of vernier and area units being undertaken at the outset. *See also* integrator.

plankton, marine and freshwater organisms, which, because they are nonmotile or because they are too small or too weak to swim against the current, exist in a drifting, floating state. The term plankton is a collective name for all such organisms and includes certain algae, bacteria, protozoans, crustaceans, mollusks, and coelenterates, as well as representatives from almost every other phylum of animals. Plankton is distinguished from nekton, which is composed of strong-swimming animals, and from benthos, which include sessile, creeping, and burrowing organisms on the seafloor. Large floating seaweeds (for example, *Sargassum,* which constitutes the Sargasso Sea) and various related multicellular algae are not considered plankton but pleuston. Organisms resting or swimming on the surface film of the water are called neuston (*e.g.,* the alga *Ochromonas*).

Plankton is the productive base of both marine and freshwater ecosystems, providing food for larger animals and indirectly for humans, whose fisheries depend upon plankton. As a human resource, plankton has only begun to be developed and exploited. It may in time be the chief food supply of the world, in view of its high biological productivity and wide extent. It has been demonstrated on several occasions that large-scale cultures of algae are technically feasible. The unicellular green alga *Chorella* has been used particularly in this connection. Through ample culture conditions, production is directed toward protein content greater than 50 percent. Although this protein has a suitable balance of essential amino acids, its low degree of digestibility prevents practical use. Phytoplankton may become increasingly important in space travel as a source for food and for gas exchange. The carbon dioxide released during respiration of spacecraft personnel would be transformed into organic substances by the algae, while the oxygen liberated during this process would support human respiration.

The plantlike community of plankton is called phytoplankton, and the animallike community is known as zooplankton. This convenient division is not without fault, for strictly speaking, many planktonic organisms are neither clearly plant nor animal but rather are better described as protists. When size is used as a criterion, plankton can be subdivided into macroplankton, microplankton, and nannoplankton, though no sharp lines can be drawn between these categories. Macroplankton can be collected with a coarse net, and morphological details of individual organisms are easily discernible. These forms, one millimetre or more in length, ordinarily do not include phytoplankton. Microplankton (also called net plankton) is composed of organisms between 0.05 and 1 mm in size and is a mixture of phytoplankton and zooplankton. The lower limit of its size range is fixed by the aperture of the finest cloth used for plankton nets. Nannoplankton (dwarf plankton) passes through all nets and consists of forms of a size less than 0.05 mm. Phytoplanktonic organisms dominate the nannoplankton.

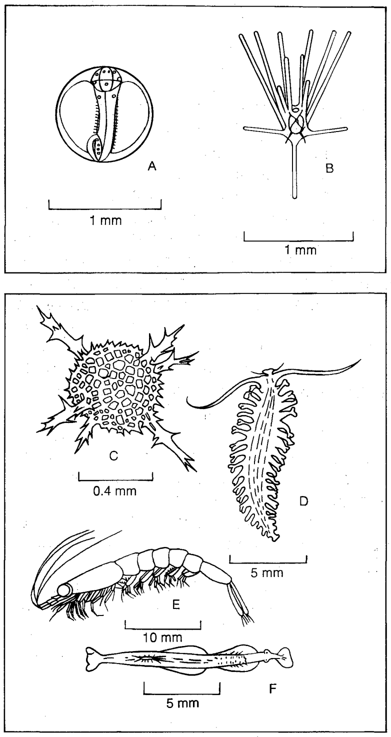
The chief components of marine phytoplankton are found within the algal groups and



Representative types of marine phytoplankton
(A) Diatom (*Thalassiosira*), (B) dinoflagellate (*Gonyaulax*), (C) Coccolithophorid (*Discosphaera*), (D) silicoflagellate (*Distephanus*), (E) blue-green alga (*Trichodesmium*)

include diatoms, dinoflagellates and coccolithophorids. Silicoflagellates, cryptomonads, and green algae are found in most plankton samples. Freshwater phytoplankton, usually rich in green algae, also includes diatoms, blue-green algae, and true flagellates.

The zooplankton is divided into two groups. Temporary plankton consists of planktonic eggs and larvae of members of the benthos and nekton; permanent plankton includes all animals that live their complete life cycles in a floating state. The temporary plankton, particularly abundant in coastal areas, is characteristically seasonal in occurrence, though variations in spawning time of different species ensure its presence in all seasons. Represen-



Representative types of (top) temporary and (bottom) permanent zooplankton
(A) Flounder eggs with embryo, (B) pluteus larva of sea urchin, (C) radiolarian, (D) annelid (*Tomopteris*), (E) crustacean (*Euphausia*), (F) arrowworm (*Sagitta*)

tatives from nearly every phylum of the animal kingdom are found in the permanent plankton. Among the protozoans, planktonic foraminiferans and radiolarians are so abundant and widespread that their skeletons constitute the bulk of bottom sediments over wide ocean areas. They are absent in fresh water. The ciliate protozoans are represented mainly by the tintinnids, which are between 20 and 640 microns in size and sometimes occur in vast numbers. Among the planktonic coelenterates are the beautiful siphonophores (*e.g., Physalia,* the Portuguese man-of-war) and the jellyfishes. Planktonic ctenophores, called comb jellies, or sea walnuts, are also common. Freshwater rotifers may be present in plankton in vast numbers during the warmer seasons. A group of organisms that can be found at all latitudes, both in surface water and at great depths, are the marine arrowworms (*e.g., Sagitta*), important planktonic predators. Oysters, mussels, other marine bivalves, and snails begin life as planktonic larvae. The wing snails (Pteropoda) spend their entire life cycles as plankton.

Crustaceans are the most important members of the zooplankton. They are the marine counterparts of insects on land; on land, as in the sea, the arthropods are the most diverse and numerous of all animal phyla. The copepod *Calanus finmarchicus* is important as food for the herring, and the euphausiid *Euphausia superba,* commonly known as krill, is the main food source for blue and fin whales in the Antarctic Ocean. These whales, particularly blue and finback whales, migrate to waters where spawning of these crustaceans occurs; and the rapid growth of these large mammals, feeding entirely on plankton, is impressive.

There is a pronounced tendency for zooplankton to perform diurnal vertical migrations in both lakes and the sea. This migratory behaviour varies with stages in the life cycle, seasons of the year, latitude, hydrographic structure, and meteorological conditions. Generally, the animals ascend toward the surface at sunset from daytime depths. At midnight, if there is no optical stimulus (*e.g.,* moon, artificial light), some of the animals return to the daytime depths, then approach the surface once again just before dawn. As the sun rises, all descend to their daytime level.

Bacteria and fungi found in water belong by definition to plankton, but because of special techniques required for sampling and identification, they usually are considered separately. These organisms are important in the transformation of dead organic materials to inorganic plant nutrients. Some of these marine and freshwater microorganisms (including blue-green algae) fix molecular nitrogen from water containing dissolved air, forming ammonia or related nutrients important for phytoplankton growth. Although little is known about the extent of nitrogen fixation, bacteria and fungi always are found in water samples. A peculiar situation exists in the Black Sea, where water below 130–180 m contains hydrogen sulfide and no oxygen. Under these conditions only bacteria are found.

The productivity of an area is dependent upon the availability of nutrients and water-stability conditions. Currents that flow near continents are important to plankton production in an area. The California Current (a continuation of the Kuroshio Drift from Japan) causes an outland transport of water and combines with a compensating nutrient-rich current along the coast of California to make this area highly productive. The same situation exists along the west coast of southern Africa, which is influenced by the Benguela Current, and off the west coast of South America, influenced by the Peru Current.

In the sea an adequate supply of nutrients, including carbon dioxide, enables phytoplankton and benthic algae to transform the light energy of the Sun into energy-rich chemical components through photosynthesis. The bottom-dwelling algae are responsible for about 2 percent of the primary production in the ocean; the remaining 98 percent is attributable to phytoplankton. Most of the phytoplankton serves as food for zooplankton, but some of it is carried below the light zone. After death, this phytoplankton undergoes chemical mineralization, bacterial breakdown, or transformation into sediments. Phytoplankton production usually is greatest from 5 to 10 m below the surface of the water. High light intensity and the lack of nutrient in the regions above a depth of 5 m may be the causes for suboptimal photosynthesis. Although bacteria are found at all depths, they are most abundant either immediately below great phytoplankton populations or just above the bottom.

Zooplankton is used directly as food by fish (*e.g.,* herring) or mammals (*e.g.,* whales); but several food chains usually have been passed before plankton is available for human consumption. Because each step in the chain is calculated as a 90 percent loss of the original energy obtained from the Sun, there is considerable energy lost as the number of components in the food chain increases.

planned parenthood, also called FAMILY PLANNING, practice of measures designed to regulate the number and spacing of children within a family.

The history of concern over the uncontrolled growth of populations is as old as recorded history, but it was not until about the 1950s that fears over a rapidly expanding world population came to be combined with fertility practices on the family level. During the 19th century, attempts to educate the public about methods of birth control and the social and economic consequences of sexual ignorance were largely unsuccessful. In the United States it was such persons as Margaret Sanger who eventually overcame initial public resistance. Undeterred by both legal and religious opposition to her activities, Sanger established the first birth control clinic and published scientific information on sex and family planning. Supported by the efforts of Sanger and others—such as Aletta Jacobs in The Netherlands, Marie Stopes in England, and Dhanvanthis Rama Rau in India—clinics for family planning and health care were established in many countries of the world.

Among the associations that are involved in planned parenthood services are The United Nations Fund for Population Activities (UNFPA), the World Health Organization (WHO), and the World Bank. In the United States, the major family planning organization is the Planned Parenthood Federation of America (PPFA), which was formed in 1942 by the merger of Sanger's Birth Control Clinic Research Bureau (established 1923) and the American Birth Control League (established 1921). *See also* contraception; population (in human biology).

Plano, city, Collin and Denton counties, northern Texas, U.S., located about 16 miles (26 km) northeast of Dallas. It is situated in a region of blackland prairie and was first settled (1845–46) by a group called Peters' Colony. The community, originally called Fillmore, was granted a post office in 1851, and its name was changed to Plano. The railroad reached Plano in 1872, and, although the town was almost destroyed by fire in 1881, it continued to develop as a small agricultural centre in the midst of a cotton-producing and cattle-raising area. Plano's main population growth began in the 1960s. It is a financial and commercial centre, and its manufactures include compact discs, printed materials, metals, satellite communication equipment, and bakery equipment. Inc. 1873. Pop. (1988 est.) city, 118,782; Dallas-Fort Worth metropolitan area (CMSA), 3,768,100.

planography, any printing technique in which the printing and nonprinting areas of the plate are in a single plane, *i.e.,* at the same level. *See* offset printing.

plant (kingdom Plantae), multicellular, eukaryotic life form fundamentally characterized by (1) an almost exclusively photosynthetic mode of nutrition, in which the plant produces chemical energy (in the form of sugars) from water, minerals, and carbon dioxide with the aid of pigments and the radiant energy of the Sun, (2) essentially unlimited growth at localized regions of cell divisions called meristems, (3) cells that contain cellulose in their walls and are therefore more or less rigid, (4) the absence of organs of locomotion, resulting in a more or less stationary existence, (5) the absence of sensory and nervous systems, and (6) life histories that show an alternation of haploid and diploid generations (the dominance of one over the other is taxonomically significant).

No definition of the kingdom completely excludes all nonplant organisms or even includes all plants. There are many plants, for example, that are not green and do not produce their own food by photosynthesis but are parasitic on other living plants; others are saprophytic, obtaining their food from dead organic matter. Many animals possess plantlike characteristics, such as the lack of mobility (*e.g.,* sponges) or the presence of a plantlike growth form (*e.g.,* some corals and bryozoans), but in general such animals lack the other characteristics of plants cited earlier and, therefore, cause little confusion. In the past, classification systems have been devised that place such difficult groups as protozoans, bacteria, algae, slime molds, and fungi in the plant kingdom, but morphological and physiological differences between these organisms and plants have caused most scientists to classify them outside the plant kingdom.

Plants are treated in a number of articles in the MACROPAEDIA. For a basic description and analysis, *see* Plants. For descriptions of the various classes and orders of plants, *see* Angiosperms; Bryophytes; Ferns and Other Lower Vascular Plants; Gymnosperms; Trees. For discussions of plants in relation to the biosphere, *see* Biosphere; Growth and Development, Biological; Photosynthesis. For the study of plants, *see* Biological Sciences. *See also* Gardening and Horticulture; Agriculture.

For a description of the place of plants in the circle of learning and for a list of both MACROPAEDIA and MICROPAEDIA articles on the subject, *see* PROPAEDIA: Part Three.

plant breeding, the practical application of genetic principles in agriculture and horticulture to produce plants more useful to humans. Although scientific plant breeding is essentially a 20th-century development, selective cultivation by ancient agriculturists effected a major and rapid evolutionary change in many plants from the wild to the domesticated state.

A brief treatment of plant breeding follows. For full treatment, *see* MACROPAEDIA: Farming and Agricultural Technology.

Not until the mid-18th century was the sexual nature of plants incontrovertibly demonstrated, and the term "plant breeding" did not become widely used until after 1900. Thereafter the intentional breeding of superior plants spread quickly; by the mid-20th century the breeding of field and horticultural crops was so standardized that it was largely in the hands of experts, much of it centred in a few large agronomic and horticultural institutions operated mostly at government expense.

For a variety of reasons the breeding of new and superior ornamental plants, though carried on in part by scientists and by tradesmen, was largely in the hands of gifted amateurs. As the result of their efforts, thousands of new varieties of dahlia, rose, African violet, peony, narcissus, and other plants came into being.

Any successful plant-breeding program must be based upon a sound understanding of the exact mode of reproduction of that plant. Plants reproduce in two ways: vegetatively (that is, asexually), through the growth and development of a small portion (bulbs, tubers, etc.) of the original plant; and sexually, through the flower and seed. Even for those plants in which vegetative reproduction is not highly developed under natural conditions, the artificial rooting of cuttings and the grafting of roots and of stems make it possible to disseminate pieces of a superior individual by vegetative means.

Different kinds of plants vary not only in the extent to which they may be propagated sexually but also in the degree to which they are naturally inbred or outbred. Among the higher plants, both extremes are found. Crops such as wheat, which are naturally very inbred, are almost completely self-pollinated. Others such as corn are mostly cross-pollinated under field conditions, though self-pollination is made possible by artificial means. Still others (many plums for instance) are naturally self-sterile and cannot be self-pollinated, though any particular flower may function effectively as either a male or a female in crosses with other plants.

Mass selection, in which each successive generation of a crop is grown from mixed seeds of the most desirable plants of the preceding generation, is perhaps the simplest and least expensive plant-breeding technique. Great success has been achieved with naturally self-fertilized species using pedigree or pure-line selection. Most of the older varieties of wheat, oats, barley, cotton, beans, and tomatoes have so arisen. However, as the ceiling of remaining variation is reached by selection, hybridization of pure lines is resorted to for further improvement.

Naturally cross-fertilized species are more difficult to handle, because any inbreeding necessary to fix desirable characters often leads to a decline in vigour. One may accordingly use continuous mass selection broadly, avoiding inbreeding. One may, on the other hand, use a combination of inbreeding and controlled hybridization to utilize the phenomenon of hybrid vigour as was done in hybrid corn improvement. *See also* hybrid.

plant bug, any member of two families of the insect order Heteroptera. The family Lygaeidae (*see* lygaeid bug) contains between about 3,000 and 5,000 species. One of the best known members, the chinch bug (*q.v.*), is an important crop pest.

The members of the family Miridae, one of the largest heteropteran families (about 8,000 species), are also called leaf bugs. They are brightly coloured and feed mostly on plant sap, causing serious crop damage. Plant bugs occur throughout the world and have been found north of the Arctic Circle. They are soft-bodied and small, under 10 millimetres (0.4 inch) long, and are easily identified by their four-segmented antennae and their beak.

Among the important species is the four-lined plant bug (*Poecilocapsus lineatus*), which feeds mainly on blueberries, currants, and gooseberries. This yellowish bug has four longitudinal black lines along its back and is about 8 mm long. It feeds on plant juices, producing brown spots on leaves and causing them to wither. The female deposits clusters of six to eight eggs, which hatch the following spring, in plant stems; there is one generation per year. This pest is controlled by pruning or burning contaminated plants.

The tarnished plant bug (*Lygus pratensis*), a well-known pest in North America, feeds on many plants, ranging from trees to grasses and cereals. It is about 6 mm long and is dark in colour—with yellow, black, and red markings. The use of insecticides and the elimination of hibernating spots (*e.g.,* trash piles) help to control this pest.

The apple red bug (*Lygus mendax*) is red and black and about 6 mm long. The front part of the thorax and the wings are usually red, and the posterior thorax and the inner edge of the wings are usually black. It is an important apple orchard pest that causes spotting of leaves and injures the fruit so that it is not marketable.

The garden fleahopper (*Halticus bractatus*) is a small, shiny black jumping bug about 2 mm long. The forewings of this short-winged leaf bug lack a membrane and resemble the hard forewings of a beetle. The fleahopper sucks the juices from garden plants. There are usually five generations every season.

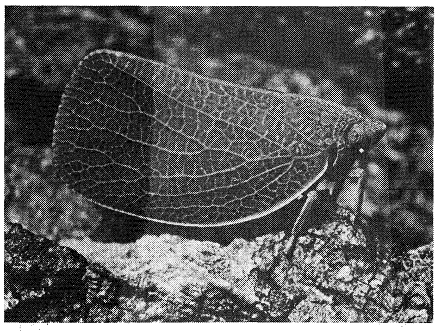
An important cotton pest is the cotton fleahopper (*Psallus seriatus*). The oval-shaped adult is about 3 mm long and pale green in colour, with four black spots on its body. It passes the winter in the egg stage in the plant tissues of weeds. In the spring after the eggs hatch, the nymphs eat the weeds; they then migrate to nearby cotton fields to feed on the cotton plant. Later, the cotton fleahoppers return to the weeds. The life cycle is short, about 22 days, so that there may be seven or eight generations each season. The cotton fleahopper can easily be controlled by insecticide sprays.

Helopeltis theivora is the tea blight bug of Southeast Asia. It is both common and highly destructive.

Although most plant bugs are plant pests, some are beneficial. *Cyrtorhynus mundulus* of Australia feeds on the sugarcane leafhopper's eggs. It has been introduced into certain regions (*e.g.,* Hawaii) as a control for this pest.

plant development: *see* development, plant.

plant hopper, any member of several insect families of the order Homoptera, easily recognized because of the hollow, enlarged head extension that may appear luminous (*see* lanternfly). Plant hoppers feed on plant juices



Plant hopper (*Acanalonia bivattata*)
Richard Parker

and excrete honeydew, a sweet by-product of digestion.

Plant hoppers, ranging in size from one centimetre (0.4 inch) in cooler climates to about five cm in the tropics, are not considered serious economic pests. Some species are covered with either a mealy substance or waxy filaments. Members of this family are variously known as fulgorid, lightning leafhopper, and mealy flata.

plant louse: *see* aphid.

plant virus, any of a number of agents that can cause plant disease. They are of considerable economic importance because many of them infect crop and ornamental plants. Many plant viruses are rodlike and can be extracted readily from plant tissue and crystallized. Most of them lack the fatty membrane found in many animal viruses, and all contain ribonucleic acid (RNA). Plant viruses are transmitted in many ways, the most important of which is through insect bites, primarily by aphids and plant hoppers. One of the most well-studied viruses, tobacco mosaic virus (TMV), is spread mechanically by abrasion with infected sap. Symptoms of virus infection include colour changes, dwarfing, and tissue distortion. The appearance of streaks of colour in certain tulips is caused by virus.

Plantagenet, HOUSE OF, also called HOUSE OF ANJOU, or ANGEVIN DYNASTY, royal house of England, that reigned from 1154 to 1485 and provided 14 kings, six of whom belonged to the cadet houses of Lancaster and York (*qq.v.*). The royal line descended from the union between Geoffrey, count of Anjou (d. 1151), and the empress Matilda, daughter of the English king Henry I. *See* the genealogical table on pages 500–501.

Although well-established, the surname Plantagenet has little historical justification. It seems to have originated as a nickname for Count Geoffrey and has been variously explained as referring to his practice of wearing a sprig of broom (Latin *genista*) in his hat or, more probably, to his habit of planting brooms to improve his hunting covers. It was not, however, a hereditary surname, and Geoffrey's descendants in England remained without one for more than 250 years, although surnames became universal outside the royal family.

Some historians apply the name House of Anjou, or Angevin Dynasty, to Henry II (who was also count of Anjou) and his 13 successors; other historians label only Henry II and his sons, Richard I and John, as the Angevin kings and, for want of a better name, label their successors, notably Edward I, Edward II, and Edward III, as Plantagenets. The first official use of the surname Plantagenet by any descendant of Count Geoffrey occurred in 1460, when Richard, duke of York, claimed the throne as "Richard Plantaginet."

Edward III's numerous children and their marriages greatly affected English history. Edward his heir, the "Black Prince," left an only son, who succeeded his grandfather as Richard II, on whose death (1399) this line became extinct. Lionel, the next surviving son of Edward III, left an only child, Philippa, who married the Earl of March, in whose heirs was the right to the succession. But John of Gaunt, the next son, who had married the heiress of Lancaster and had been created duke of Lancaster in consequence, refounded the Lancastrian line, which obtained the throne in the person of his only son by her, Henry IV, on the deposition of Richard II. The next son of Edward III, Edmund of Langley, who was created duke of York (1385), founded the Yorkist line, and was father of two sons, Edward, second duke, who was slain at Agincourt, and Richard, earl of Cambridge, who by marrying the granddaughter and eventual heiress of Lionel's daughter, Philippa, brought the right to the succession into the House of York.

Between their son and Henry VI (grandson of Henry IV) and the sons and heirs of these rivals was fought out the dynastic struggle known as the Wars of the Roses, which proved fatal to several members of both houses. It did not end until the last Yorkist king, Richard III, was defeated at Bosworth Field in 1485 by Henry Tudor, who became Henry VII and founder of the House of Tudor.

The legitimate male issue of the Plantagenet line became extinct with the execution in 1499 of Edward, earl of Warwick, grandson of Richard, duke of York.

Matilda (1156–89) = Henry the Lion (d. 1195) duke of Saxony and Bavaria

Eleanor (1161–1214) = Alfonso VIII of Castile (1155–1214)

Joan (1165–99) (1) = William II of Sicily (d. 1189) (2) = Raymond VI of Toulouse (d. 1222)

Arthur I (1187–1203) duke of Brittany

Eleanor (d. 1241)

Alexander II (1198–1249) king of Scotland (1) = Joan (1210–38); (2) = Mary de Coucy

HENRY III (1207–72) king of England 1216–72 = Eleanor (d. 1291) dau. of Raymond Berengar IV count of Provence

Richard (1209–72) earl of Cornwall (1) = Isabella (d. 1240) dau. of William Marshal earl of Pembroke (2) = Sanchia (d. 1261) dau. of Raymond Berengar IV of Provence

Isabella (1214–41) = Emperor Frederick II (1194–1250)

Eleanor (1215–75) (1) = William Marshal (d. 1231) earl of Pembroke (2) = Simon de Montfort (d. 1265) earl of Leicester

Alexander III (1241–86) king of Scotland = Margaret (1240–75)

EDWARD I (1239–1307) king of England 1272–1307 (1) = Eleanor of Castile (*see below right*) (2) = Margaret (d. 1317) dau. of Philip III of France

Beatrice (1242–75) = John II (d. 1305) duke of Brittany

Edmund (1245–96) "Crouchback" earl of Lancaster = Blanche of Artois (*see below right*)

5 children died young

Henry of Almain (1235–71)

Edmund (1249–1300) earl of Cornwall

Margaret (1261–83) = Eric II (1268–99) king of Norway

7 daughters and 3 sons, died young, including Alfonso (1273–84)

EDWARD II (1284–1327) king of England 1307–27 = Isabella of France (*see below right*)

Thomas of Brotherton (1300–38) earl of Norfolk

Edmund of Woodstock (1301–30) earl of Kent

Thomas (*c.* 1278–1322) 2nd earl of Lancaster

Henry (*c.* 1281–1345) 3rd earl of Lancaster = Maud Chaworth (d. *c.* 1322)

Margaret (1282/83–90) the Maid of Norway

EDWARD III (1312–77) king of England 1327–77 = Philippa of Hainaut (1314–69)

John (1316–36) earl of Cornwall

Eleanor (1318–55) = Rainald II (d. 1343) count of Gelre

Joanna (1321–62) = David II (1323/24–70/71) king of Scotland

Henry (*c.* 1300–61) 1st duke of Lancaster = Isabel Beaumont

Eleanor (d. 1372) = Richard (1307–76) earl of Arundel

Edward (1330–76) the Black Prince = Joan dau. of Edmund earl of Kent

Lionel of Antwerp (1338–68) duke of Clarence (1) = Elizabeth de Burgh (1332–62) (2) = Violanta Visconti (d. *c.* 1404)

Blanche dau. of Henry duke of Lancaster (*see right*) (1) = John of Gaunt (1340–99) duke of Lancaster (2) = Constance of Castile (d. 1394) (3) = Catherine Swynford (*c.* 1350–1403)

Edmund of Langley (*c.* 1342–1402) duke of York = Isabel of Castile (d. 1392)

Thomas of Woodstock (1355–97) duke of Gloucester

2 sons died young
5 daughters

RICHARD II (1367–1400) king of England 1377–99 (1) = Anne of Bohemia (1366–94) (2) = Isabella (1387–1406) dau. of Charles VI of France

Philippa (1355–81) = Edmund Mortimer (1351–81) 3rd earl of March

HENRY IV (1366–1413) king of England 1399–1413 (1) = Mary de Bohun (*c.* 1370–94) (2) = Joan of Navarre (*c.* 1370–1437)

John Beaufort (*c.* 1371–1410) earl of Somerset = Margaret dau. of Thomas earl of Kent

Henry (*c.* 1374–1447) cardinal bishop of Winchester

Thomas (d. 1426) duke of Exeter

Joan (d. 1440) (1) = Sir Robert Ferrers (2) = Ralph Neville (1364–1425) earl of Westmorland

See LANCASTER, HOUSE OF

Roger Mortimer (1374–98) 4th earl of March = Eleanor dau. of Thomas earl of Kent

HENRY V (1387–1422) king of England 1413–22 (1) = Catherine (1401–37) dau. of Charles VI of France (2) = Owen Tudor (*c.* 1400–61)

Thomas (1388–1421) duke of Clarence

John (1389–1435) duke of Bedford (1) = Jacquetta of Luxembourg (d. 1472) (2) = Sir Richard Woodville (d. 1469)

Humphrey (1390–1447) duke of Gloucester

John Beaufort (1404–44) 1st duke of Somerset = Margaret Beauchamp

Anne Mortimer (1388–before 1414) = Richard earl of Cambridge (*see above right*)

Edmund (1391–1425) 5th earl of March

HENRY VI (1421–71) king of England 1422–61, 1470–71 = Margaret of Anjou (1430–82)

Edmund Tudor (*c.* 1430–56) earl of Richmond = Margaret Beaufort (1443–1509)

EDWARD IV (1442–83) king of England 1461–70, 1471–83 = Elizabeth Woodville (1437–92) dau. of Sir Richard Woodville and Jacquetta of Luxembourg

George (1449–78) duke of Clarence = Isabel (1451–76) dau. of Richard Neville earl of Warwick

Edward (1453–71) = Anne Neville (*see above right*)

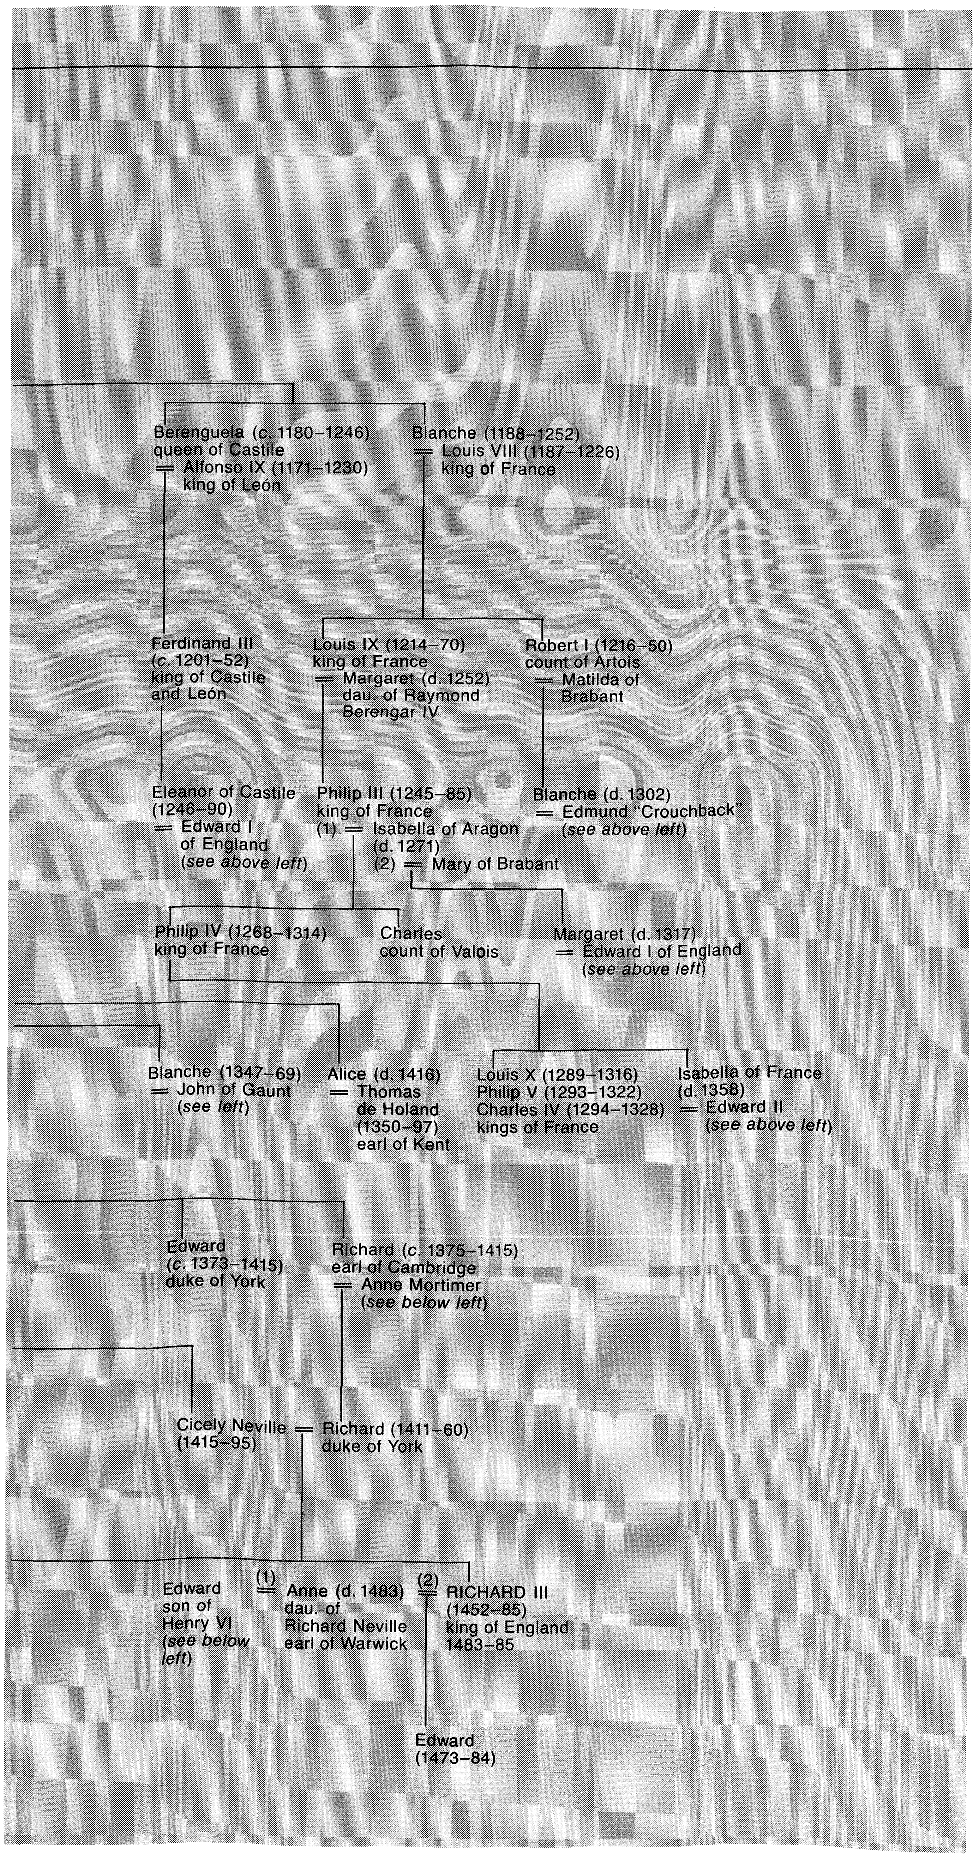
HENRY VII (1457–1509) king of England 1485–1509 = Elizabeth (1465–1503)

EDWARD V (1470–?83) king of England April–June 1483

Richard (1473–?83) duke of York

Margaret (1473–1541) countess of Salisbury = Sir Richard Pole (d. 1505)

Edward (1475–99) earl of Warwick



about 265 species. The small plants usually have a dense tuft of basal leaves and long, leafless stalks bearing a terminal spike of small flowers.

The greater plantain (*Plantago major*) provides seed spikes for bird food. Ribwort and hoary plantain (*P. lanceolata* and *P. media,* respectively) are troublesome weeds. By contrast, *psyllium* and *P. ovata* have been useful in medical science; they produce mucilaginous seeds, which have been used, for example, in laxative preparations known as psyllium, ispaghul, or spogel seeds.

plantain (*Musa paradisiaca*), plant of the banana (*q.v.*) family (Musaceae) closely related to the common banana (*M. sapientum*). The plantain is a tall plant (3–10 metres [10–33 feet]) with a conical false "trunk" formed by the leaf sheaths of its spirally arranged leaves, which are 1.5 to 3 m long and about 0.5 m wide. The fruit, which is green, is typically larger than the common banana. The botanical classification of plantains and bananas is so complicated that plantain is variously viewed as a subspecies of the banana, and the banana as a subspecies of plantain.

The edible fruit of the plantain has more starch than the banana and is not eaten raw. Because plantain has a maximum of starch before it ripens, it is usually cooked green, either boiled or fried, often with coconut juice or sugar as a flavouring. It may also be dried for later use in cooking or ground for use as a meal. The plantain meal can be further refined to a flour. In some parts of East Africa

Plantain (*Musa paradisiaca*)
Phil Clark

the plantain is a staple food and beer-making crop, notably in central and eastern Uganda and Tanzania (formerly Tanganyika), and particularly in the area inhabited by the Chagga people.

The plant is believed to have originated in Southeast Asia. Two groups of plantains are thought to have a common origin: the horn plantain and the French plantain. Both types grow in India, Africa, Egypt, and tropical America. The French plantains also occur in Indonesia and the islands of the Pacific. Plantain is also a common name for plants of the genus *Plantago* (*q.v.*) of the order Scrophulariales.

plantain-eater (bird): *see* turaco.

plantain lily, any ornamental plant of the genus *Hosta* of the family Liliaceae, consisting

Plantain lily (*Hosta fortunei*)
A to Z Botanical Collection—EB Inc.

of about 10 species of perennial garden herbs. They are native to eastern Asia.

Each species has ribbed leaves in a cluster at the base of the plant and tubular white, or bluish-purple flowers that are borne in clusters at the tip of stalks that emerge from the leaves. The fruit is a long capsule.

plantation, a usually large estate in a tropical or subtropical region that is cultivated by unskilled or semiskilled labour under central direction. This meaning of the term arose during the period of European colonization in the tropics and subtropics of the New World, essentially, wherever huge tracts of crops cultivated by slave labour became an economic mainstay.

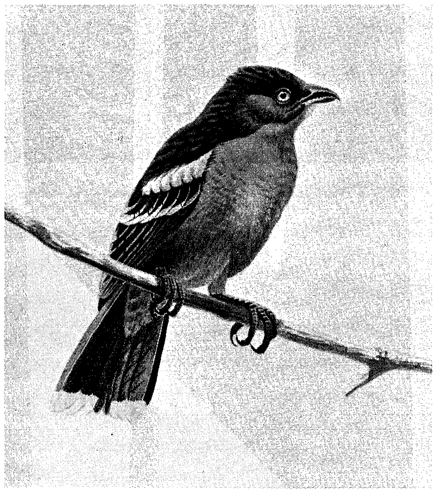
The typical plantation was a self-sustained community, an economic and political institution governed with a monopoly of authority by the planter. Plantation crops were determined by soil and climate, with tobacco, cotton, rice, indigo, and sugarcane, for example, each predominating in a certain zone of the southeastern colonies of North America.

The labour-intensive plantation declined abruptly in the United States with the abolition of slavery. Most plantations were divided into small farms operated by individual owners or tenant farmers; others continued to operate as large plantations that were worked by wage-labourers or sharecroppers, many of whom were held under the tacit bondage of economic insecurity.

In tropical regions worldwide, thousands of square miles of forest land have been cleared since the 18th century for the cultivation of sugarcane, coffee, tea, cacao, rubber trees, oil palms, sisal, and bananas. Such plantations frequently depend on foreign capital and agricultural training and tend to exploit the labour forces of native populations.

plantation walking horse: *see* Tennessee walking horse.

plantcutter, any of three species of South American birds of the family Phytotomidae (order Passeriformes), with finely serrated, stout bills used for snipping off tender shoots, buds, and fruit. In some areas plantcutters do much harm to gardens and orchards. With their broad, squared tails, they resemble streak-backed finches. Males are strongly tinged with reddish brown—especially in the red-breasted, or white-tipped, plantcutter (*Phytotoma rutila*), common from the Patagonian prairies to the uplands of Bolivia. Other species



Peruvian plantcutter (*Phytotoma raimondii*)
Painting by John P. O'Neill

of plantcutter are found in Peru, Argentina, and Chile.

Planté, Francis (b. March 2, 1839, Orthez, Fr.—d. Dec. 19, 1934, St. Avit, Fr.), French pianist active in Paris in the late 19th century.

Planté made his Paris debut as a nine-year-old prodigy. He became a pupil of A.-F. Marmontel at the Conservatoire in 1849 and won the first prize for piano in 1850 after only seven months of tuition. He then became a protégé of Liszt and Rossini, playing in many of the Parisian salons. From 1851 to 1861 he studied piano privately, not appearing in public for about 10 years; on his return to the stage, he was acclaimed as a virtuoso with a finished technique. He gave concerts regularly until 1900, when he abruptly stopped public appearances except for rare concerts for charity. In 1908 he made several recordings.

Planté, Gaston (b. April 22, 1834, Orthez, Fr.—d. May 21, 1889, Paris), French physicist who produced the first electric storage battery, or accumulator, in 1859; in improved form, his invention is widely used in automobiles.

Planté followed an academic career, beginning in Paris as a lecture assistant in physics at the Conservatoire des Arts et Métiers (Conservatory of Arts and Crafts) in 1854 and, six years later, rising to the post of professor of physics at the Association Polytechnique pour le Développement de l'Instruction Populaire.

In 1859 Planté began experiments that resulted in construction of a battery for the storage of electrical energy; his first model contained two sheets of lead, separated by rubber strips, rolled into a spiral, and immersed in a solution containing about 10 percent sulfuric acid. A year later he presented a battery to the Académie des Sciences consisting of nine of the elements described above, housed in a protective box with the terminals connected in parallel. His battery could deliver remarkably large currents.

Plantin, Christophe (b. *c.* 1520, Saint-Avertin, Fr.—d. July 1, 1589, Antwerp), French printer, founder of an important printing house and publisher of the Antwerp Polyglot Bible.

Plantin learned bookbinding and bookselling at Caen, Normandy, and settled in 1549 as a bookbinder in Antwerp. A bad arm wound seems to have led him (about 1555) to turn to typography. His many publications were distinguished by their excellent typography, and he was original in using copper, instead of wood, engravings for book illustrations. His greatest venture, the *Biblia polyglotta,* which would fix the original text of Old and New Testaments, was supported by Philip II of Spain in spite of clerical opposition and appeared in eight volumes during 1569–72. When Antwerp was plundered by the Spaniards in 1576 and Plantin had to pay a ransom, he established a branch office in Paris and then, in 1583, settled in Leiden as the typographer of the new university of the states of Holland, leaving his much-reduced business in Antwerp to his sons-in-law, John Moerentorf (Moretus) and Francis van Ravelinghen (Raphelengius). But in 1585 Plantin returned to Antwerp. After his death, business was carried on by Moretus but declined in the second half of the 17th century. All was religiously preserved, however, and in 1876 the city of Antwerp acquired the buildings and their contents and created the Musée Plantin-Moretus.

Planudes, Maximus, original name MANUEL PLANUDES (b. 1260, Nicomedia, Tur.—d. *c.* 1310, Constantinople), Greek Orthodox humanities scholar, anthologist, and theological polemicist in the controversy between Byzantium and Rome. His Greek translations of works in classical Latin philosophy and literature and in Arabic mathematics publicized these areas of learning throughout the Greek Byzantine cultural world.

After entering political life in Constantinople, Planudes retired to a monastery in 1283 because of factional strife. He later returned to Constantinople and, despite the opposition of the patriarch Athanasius I, established a monastery for laymen and opened a school by the imperial library. Drawing students from the royal family and nobility, the school gained an academic reputation for its thorough humanities curriculum. Planudes' eminence derived in large part from his competence in the Latin language acquired in the wake of the Western occupation of Constantinople (1204–61). This linguistic ability prompted his appointment as the emperor Andronicus II Palaeologus' emissary to Venice in 1295–96.

Notable among his theological writings is a treatise, *De processione Spiritus Sancti* (*c.* 1281; "On the Procession of the Holy Spirit"). Supportive of the Latin Church's teaching on the Holy Spirit, Planudes' first tract was in marked contrast with his second, *Tractatus de Spiritu Sancto adversus Latinos* ("A Treatise on the Holy Spirit Against the Latins"), composed after the accession of the emperor Andronicus II (1282), who reversed his predecessor's policy toward the West. Thus reflecting the variable political atmosphere, Planudes evolved from a Latin Trinitarian (one God in three persons) view that related the Holy Spirit to both the Father and the Son, to the traditional Byzantine dogma that the Spirit proceeds from the Father. In effect, these two works supplied arguments to supporters and opponents of Patriarch John's pro-Latin attitude and, 150 years later, to such Byzantine theological adversaries as Cardinal John Bessarion and George Gemistus Plethon. Related Latin writings that Planudes translated into Greek were *De Trinitate* ("On the Trinity") by the 5th-century Church Father Augustine of Hippo, and logical and theological tracts by the 6th-century philosopher-statesman Boethius. Equally significant were Planudes' translations of the essays and rhetoric of Cicero and the poetry of Ovid.

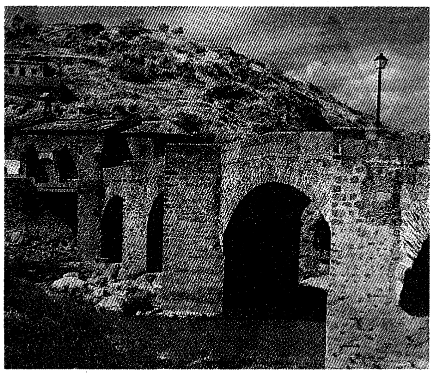
A distinctive contribution to the history of Greek literature was Planudes' revision of the *Anthologia Hellēnikē* ("Greek Anthology"), a renowned collection of Greek prose and poetry comprising authors from *c.* 700 BC to AD 1000, and edited variously from the 1st to the 11th centuries. Although parts of the reconstituted texts show Planudes' personal interpretations, the *Anthologia,* illustrating the continuity of Greek letters for almost 2,000 years, helped the development of modern Italian and French by its influence on 15th-century writers. Similarly, his revision of the *Life and Fables of Aesop* and his commentary on Theocritus, the 3rd-century-BC creator of

Greek pastoral verse, assisted in popularizing this literature throughout Europe.

The evolution of mathematics in Byzantium, and subsequently in Europe, was stimulated by Planudes' *Psephophoria kat' Indous* ("Arithmetic According to the Indians" [*i.e.,* Arabs]). Influenced by the Baghdad school, he encouraged the use of Arabic numerical notation, including the sign for zero, and introduced other mathematical operations (*e.g.,* the extraction of square roots).

planula, plural PLANULAE, free-swimming or crawling larval type common in many species of the phylum Cnidaria (*e.g.,* jellyfish, corals, sea anemones). The planula body is more or less cylindrical or egg-shaped and bears numerous cilia (tiny hairlike projections), which are used for locomotion. Planulae are produced by both of the basic body forms found in cnidarians—polyps, the stalklike, attached adult forms, and medusae, bell- or umbrella-shaped, free-swimming adult forms. *See also* polyp (zoology); medusa.

Plasencia, city, Cáceres *provincia,* in the Extremadura *comunidad autónoma* ("autonomous community"), western Spain. It lies on the Jerte River in the Plasencia Valley northeast of Cáceres city. Although there are Roman ruins at Capera nearby, as well as evidence of Stone Age and Iberian occupations, Plasencia was first known as the Moorish town of Ambroz. When Alfonso VIII of Castile retook it from the Moors in the 12th century, he renamed it Plasencia "that it may be pleasing to God and Man" (*ut Deo placeat et hominibus*) and built a city wall with 68



Bridge of San Lazaro over the Jerte River at Plasencia, Spain

towers. An episcopal see, the city has two cathedrals, the older of which displays 16th-century Plateresque architecture with elaborately carved choir stalls by Rodrigo Alemán. The churches of San Nicolás and San Ildefonso contain interesting tombs. Principal industries are tobacco curing, cotton processing, and meat canning. Olive and soybean oil, peppers, figs, and cattle feed are also produced. Pop. (1981) 32,178.

Plaskett, John Stanley (b. Nov. 17, 1865, Woodstock, Ont., Can.—d. Oct. 17, 1941, Victoria, B.C.), Canadian astronomer remembered for his mastery of the design of instruments and his extensive spectroscopic observations.

Plaskett, a skilled mechanic and photographer, graduated from the University of Toronto in 1899. In 1903 he joined the staff of the Dominion Observatory at Ottawa, where he initiated astrophysical research and devised a new spectrograph that made the telescope at Ottawa equivalent to much larger instruments elsewhere.

In 1913 he persuaded the Canadian government to finance the construction of a 72-inch (183-centimetre) reflector. That instrument, largely designed by Plaskett, was placed in operation near Victoria, B.C., in 1918. Plaskett was appointed director of the observatory at Victoria in 1917. He used the new telescope to study binary stars and the distribution of calcium in interstellar space. In 1922 he resolved a very massive binary star (Plaskett's star), and in 1930 he deduced the distance and direction of the centre of gravity of the Galaxy and the pattern of rotation about it. After his retirement in 1935 he supervised the grinding and polishing of the 82-inch mirror for the telescope of the McDonald Observatory, Fort Davis, Texas.

plasma, in biochemistry, the straw-coloured liquid (including its solutes but excluding the formed elements, such as blood cells and platelets) that constitutes the circulating fluid in animals. Plasma consists of more than 90 percent water, about 7 percent protein, and small percentages of other substances, such as inorganic salts, glucose, and urea and other waste products of metabolism. Plasma serves as a transport system and medium for nutrients, waste products, and blood cells; helps to maintain blood pressure; distributes heat equally throughout the body; and keeps a steady acid–base balance in the bloodstream and body.

Important plasma proteins include fibrinogen, an essential protein necessary for the clotting of blood; albumin, which helps maintain the pressure in blood vessels by its osmotic effect; and a variety of globulins, among which are a hormone that stimulates red blood cell formation and gamma globulin, which is rich in antibodies. *See also* blood.

plasma, in mineralogy, opaque, microgranular or microfibrous, semiprecious variety of the silica mineral chalcedony. Its colour, various shades of green, is due to disseminated silicate particles of different kinds, *e.g.,* amphibole minerals. Other properties are those of quartz (*see* Table 2 under silica mineral). Plasma often has nodules throughout its mass of gray quartz or red jasper (bloodstone). It has long been used for carvings and mosaics. Localities are eastern India, China, Madagascar, Germany, and Egypt.

plasma, in physics, collection of electrically charged particles about equal in number or density that is produced when the atoms in a gas become ionized. It is sometimes referred to as the fourth state of matter, distinct from the solid, liquid, and gaseous states.

A brief treatment of plasma follows. For full treatment, *see* MACROPAEDIA: Matter: Its Properties, States, Varieties, and Behaviour.

When energy (*e.g.,* heat) is continuously applied to a solid, it first melts, then it vaporizes, and finally electrons are removed from some of the neutral gas atoms and molecules to yield a mixture of positively charged ions and negatively charged electrons, while overall neutral charge density is maintained. When a significant portion of the gas has been ionized, its properties will be altered so substantially that little resemblance to solids, liquids, and gases remains. Plasma is unique in the way in which it interacts with itself, with electric and magnetic fields, and with its environment. A plasma can be thought of as a "soup" of ions, electrons, neutral atoms and molecules, and photons, in which some atoms are being ionized simultaneously with other electrons recombining with ions to form neutral particles, while photons are continuously being produced and absorbed.

Scientists have estimated that more than 99 percent of the matter in the universe exists in the plasma state. All of the observed stars, including the Sun, consist of plasma, as do interstellar and interplanetary media and the outer atmospheres of the planets. Although most terrestrial matter exists in a solid, liquid, or gaseous state, plasma is found in lightning bolts, flames, auroras, and in gaseous discharge lamps (neon lights).

plasma cell myeloma: *see* multiple myeloma.

plasma oscillation, the organized motion of electrons or ions in a plasma. Each particle in a plasma assumes positions such that the total force resulting from all the particles is zero, thus producing a uniform neutral-charge state. If an electron is moved from its equilibrium position, the equilibrium position itself takes on a positive charge and exerts an electrostatic attraction on the electron, causing the electron to oscillate about its equilibrium position. Because the interaction between electrons is strong, they will oscillate collectively at a characteristic frequency depending upon the nature of the particular plasma.

plasmapause, portion of the magnetosphere that rotates with the Earth at about four Earth radii (about 26,000 km, or 16,000 miles); beyond this region there is a rapid decrease in electron concentrations, and their circulation pattern is quite different. Under very quiet solar conditions, the plasmapause may extend to six Earth radii, and with very disturbed conditions it contracts to three Earth radii.

plasmid, in microbiology, an extrachromosomal genetic element occurring in many bacterial strains. Plasmids are circular deoxyribonucleic acid (DNA) molecules that are not essential for the bacterium but may confer a selective advantage. One class of plasmids, colicinogenic (or *Col*) factors, determines the production of proteins called colicins, which have antibiotic activity and can kill other bacteria. Another class of plasmids, R factors, confers upon bacteria resistance to antibiotics. Some *Col* factors and R factors can transfer themselves from one cell to another and thus are capable of spreading rapidly through a bacterial population. A plasmid that is attached to the cell membrane or integrated into the bacterial chromosome is called an episome (*q.v.*).

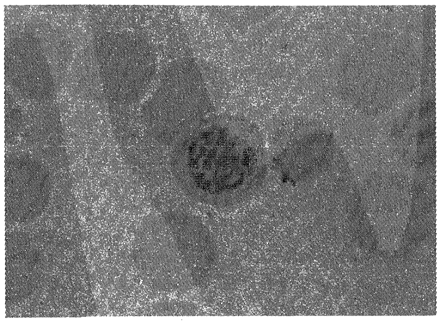
plasmodesma, plural PLASMODESMATA, microscopic cytoplasmic canals that pass through plant-cell walls and allow direct communication of molecules between adjacent plant cells. Plasmodesmata are formed during cell division, when traces of the endoplasmic reticulum (an organelle that synthesizes constituents of the outer cell membrane) become caught in the new wall that divides the parent cell. The two progeny cells may be connected by thousands of plasmodesmata, which contain rings of membrane at each end that are thought to regulate the passage of molecules. By overcoming the barrier posed by the cell wall, plasmodesmata unite plant cells into functioning tissues.

Plasmodiophoromycetes, class of plant parasites in the division Myxomycophyta and referred to as endoparasitic slime molds. Some authors assign them to the fungi (division Mycota). The class contains a single order, Plamodiophorales, a single family, Plasmodiophoraceae, and nine genera, the most important of which are *Plasmodiophora* and *Spongospora.*

All members are obligate parasites of algae, fungi, or higher plants, causing cell enlargement, especially of the roots. They are distinguished by the production of motile cells (zoospores) with two unequal anterior whiplike threads (flagella).

Plasmodiophora brassicae causes clubroot (*q.v.*) of cabbage and related plants. *Spongospora subterranea* causes powdery scab of potato (*see* scab).

Plasmodium, the causative organism of malaria (*q.v.*), a genus of parasitic protozoan of the sporozoan subclass Coccidia. *Plasmodium,* which infects red blood cells in mammals (including humans), birds, and reptiles, occurs throughout the world, especially in tropical and temperate zones. The organism is transmitted by the bite of the female *Anopheles* mosquito. Other insects and some mites may also transmit forms of malaria to animals.



Plasmodium vivax in red blood cell
A.L. Leu

Four species cause human malaria: *P. vivax* (producing the most widespread form), *P. ovale* (relatively uncommon), *P. falciparum* (producing the most severe symptoms), and *P. malariae.* They pass from mosquito to humans as sporozoites in the saliva of the mosquito. The parasites enter liver parenchyma cells first, then red blood cells; there they divide, forming 12 to 24 daughter parasites, and almost simultaneously destroy the red blood cells. They then enter the plasma and infect new red blood cells. The destroyed red cells liberate toxins that cause the periodic chill and fever cycles that are the typical symptoms of malaria. Certain species of *Plasmodium, P. vivax, P. ovale,* and *P. falciparum* repeat the cycle every 48 hours (tertian malaria), and *P. malariae* repeats it every 72 hours (quartan malaria).

Plassey, also called PALĀSHI, historic village, east-central West Bengal state, northeastern India, just east of the Bhāgīrathi River. Plassey was the scene of the decisive victory of British forces under Robert Clive over those of the nawab of Bengal, Sirāj-ud-Dawlah, in 1757. Dispatched from Madras with reinforcements to reestablish British factories (trading stations) in Bengal, Clive was aided in his mission by the treachery of the nawab's generals. The Battle of Plassey helped pave the way for the British acquisition of Bengal. A monument marks the scene of the battlefield, partially washed away by a shift of the Bhāgīrathi.

Plassey battle monument, West Bengal, India
Kaypix—Shostal/EB Inc.

plaster, a pasty composition (as of lime or gypsum, water, and sand) that hardens on drying and is used for coating walls, ceilings, and partitions.

Plastering is one of the most ancient building techniques. Evidence indicates that primitive peoples plastered their reed or sapling shelters with mud, thus developing more durable structures and more effective screens against vermin and inclement weather. More lasting and sightly materials in time replaced mud. Some of the earliest plastering extant is of a quality comparable to that used in modern times. The Pyramids of Egypt contain plasterwork executed at least 4,000 years ago that is still hard and durable. The principal tools of the plasterer of that time were in design and purpose like those used today. For their finest work the Egyptians used a plaster made from calcined gypsum that is identical with plaster of paris. In other respects also the materials and the procedures used by the Egyptians 4,000 years ago were identical with those of today.

Very early in the history of Greek architecture (*e.g.,* at Mycenae), plaster of a fine white lime stucco was used. Greek artisans had achieved high quality earlier than the 5th century BC. Plaster was frequently used to cover the exteriors of temples, a technique commonly known as stucco, in addition to covering the interiors, in some cases even when the building was made of marble. Plaster used in this way provided an excellent ground for decorative painting. The temple of Apollo at Bassae, built of yellow limestone about 450–420 BC, is an excellent example of Grecian use of decoration on stucco and plaster. The ornamental plaster ceilings of England during the reigns of Henry VIII, Elizabeth I, and James I still are admired. Earlier extant specimens of the plasterers' skill in England are the pargeted and ornamented fronts of half-timber houses. Plaster as a medium of artistic expression waned by the 19th century, when imitation and mechanical reproduction usually displaced this creative art. As a surface material for interior walls and ceilings and to a lesser degree for exterior walls, plaster has become common. It facilitates cleanliness and sanitation in building and is a retardant to the spread of fire.

Interior plasterwork is designed according to the type of lathing to which it is applied and the number of applications that are necessary. Ornamental plaster for ceilings and cornices is usually applied with a metal molding tool that has the reverse of the desired profile. Some elements may be formed by hand, while others are precast and stuck in place with plaster of paris. Stucco may be applied directly to concrete, brick, tile, or a supporting metal lath base. Various types of finish, including colours and textures, may be incorporated in the finish coat. Splatter dash and pebble dash are textured surfaces resulting from throwing mortar or pebble with some force on the finish coat while it is still soft.

plaster of paris: *see* paris, plaster of.

plastic, any of numerous synthetic materials that consist of giant molecules called polymers, with extremely long chains of repeating units derived from short molecules. Plastics can be formed into products by molding or otherwise shaping.

A brief treatment of plastics follows. For full treatment, *see* MACROPAEDIA: Industries, Chemical Process.

A significant property of most plastics is that they soften when heated, so that they can be formed into shapes, then become rigid on cooling. This property derives from their physical structure, which consists of a network of polymers, the constituent units of which separate under heat sufficiently to slide apart, but on cooling become firmly entangled again. The first plastic developed was celluloid, consisting of nitrocellulose softened by vegetable oils and camphor, patented in 1870 by an American printer, John W. Hyatt. The first completely synthetic plastic was Bakelite, produced from phenol and formaldehyde by Leo Baekeland in 1909. Advances in basic understanding of molecular physics facilitated the subsequent development of nylon, polyethylene, and other plastics.

All plastics are manufactured by some method of polymerization, the process of forming the long chains and networks of molecules. The two major divisions of plastics are the thermosetting resins and thermoplastic resins. Thermosetting resins become insoluble and infusible on heating. Among thermosetting resins are the phenolic resins, furan resins, aminoplastics, alkyds and polyesters of unsaturated acids, epoxy resins, polyurethanes, and silicones. Thermoplastic resins, which can be melted and solidified repeatedly, unlike thermosetting resins, include cellulose derivatives, addition polymers (polyethylene, polypropylene, vinyls, acrylics, fluorocarbon resins, and polystyrenes), and condensation polymers (nylons, polyethylene terephthalate, polycarbonates, and polyamides). Other types of resins include oil-soluble or modified resins, plastics such as casein and lignin extracted from natural products, and special-application synthetics such as resins used as adhesives and as additives to paper and textiles.

Raw materials for plastics include coal and cellulose, but by far the chief source is petroleum. Plastics are shaped by a variety of means, including extrusion, blow-molding, calendering between rollers, thermosetting in hydraulic presses, injection molding, rotational molding using centrifugal action, thermoforming, vacuum molding, laminating by press, and casting. Foamed plastics are produced by forming gas bubbles in the molten material. Plastic products are further shaped and finished by means ranging from mechanical through laser machining, ultrasonic welding, and radiation processing.

Because of their easy manipulation, economical manufacture, low specific gravity, and resistance to corrosion, plastics have replaced metal, wood, glass, and other materials in many applications. An immense array of plastic industrial and consumer goods is available. *See also* resin.

plastic surgery, surgical specialty concerned with the correction of disfigurement, restoration of impaired function, and improvement of physical appearance. Although surgical reconstruction of the nose was performed by Hindu physicians before the time of Christ, modern techniques of plastic surgery were originated in the post-World War I years by surgeons repairing the wounds and disfigurements of combat veterans.

The term plastic refers to the reshaping of body tissues—bone, fat, muscle, cartilage, and skin. Tissue may be moved to fill a depression; to cover a wound, as in skin grafting; or to improve appearance, as in hair transplantation. Synthetic compounds such as silicone are also used as a substitute for absent or deficient natural tissue. Tissue may be completely removed to alter the contours of a feature, as in rhinoplasty (reconstruction of the nose), otoplasty (ear reduction), and blepharoplasty (the removal of skin and fatty tissue from the eyelids) or to restore youthful appearance, as in rhytidectomy (face-lift, in which excess skin is removed from the face and neck). Among the techniques used in plastic surgery are incision, excision, chemosurgery, electrosurgery, lasar surgery, and dermabrasion. In the late 1970s European doctors developed a technique—known variously as suction lipectomy, lipoplasty, lipodissection, liposuction, or lipolysis—for the removal of diet-resistant fat cells; the procedure involves the use of a blunt, hollow, probelike tool or cannula attached to a mechanical suction machine and inserted through a small incision.

Reconstructive plastic surgery is performed to correct severe functional impairments caused by burns and other traumatic injuries, to correct congenital abnormalities, and to compensate for tissue removed in cancer surgery. The development of microsurgery in the 1960s and '70s greatly expanded the scope of reconstructive surgery, allowing surgeons to reattach severed fingers and limbs. Exceedingly fine needles and sutures make it possible for the surgeon to rejoin small blood vessels and other minute structures under an operating microscope.

The other major impetus to plastic surgery is cosmetic, that is, to improve appearance in otherwise healthy persons. Into this classification fall the majority of the cases of rhinoplasty, rhytidectomy, breast augmentation, hair transplantation, and other procedures.

plasticity, ability of certain solids to flow or to change shape permanently when subjected to stresses of intermediate magnitude between those producing temporary deformation, or elastic behaviour, and those causing failure of the material, or rupture; or the science that describes and explains this behaviour. Plasticity enables a solid under the action of external forces to undergo permanent deformation without rupture, called plastic deformation. Elasticity, in comparison, enables a solid to return to its original shape after the load is removed. Plastic deformation occurs, for example, in many metal-forming processes (rolling, pressing, forging) and in geological processes (rock folding and rock flow within the earth under extremely high pressures and at elevated temperatures).

Plastic deformation is a property of ductile and malleable solids. Brittle materials, such as cast iron, cannot be plastically deformed, though at elevated temperatures some, such as glass, which is not a crystallized solid, do undergo plastic flow.

Plasticity, as a science, refers either to mathematical descriptions of what happens in plastic deformation in terms of stresses, strains, and loads or to physical explanations of plastic flow in terms of atoms, crystals, grains, and motions of structural defects (dislocations) within crystals.

Plaszow, Polish PŁASZOW, German Nazi concentration camp near Kraków, used chiefly as a forced-labour centre.

The camp, opened in June 1942, was the gathering centre for Jews rounded up from the general region of Kraków and, later, for Jews from Hungary; at its peak, it held some 20,000 or more inmates. Brutal labour in local industries and stone quarries, together with poor food and sanitation, caused a heavy death toll. In the final months of 1944 the Nazis attempted to erase evidence of the camp, deporting many prisoners to Auschwitz and other concentration camps, burning some 9,000 exhumed bodies, and destroying many of the installations. When the Soviet army arrived in January 1945, only 600 prisoners remained alive. The commandant of Plaszow, SS officer Amon Goeth, was tried and executed in 1946.

Plata, Río de la (Spanish: "River of Silver"), English RIVER PLATE, estuary on the southeast coast of South America, formed by the Paraná and Uruguay rivers and covering about 13,500 square miles (35,000 square km).

A brief treatment of the Río de la Plata follows. For full treatment, *see* MACROPAEDIA: South America.

Roughly triangular in shape, the Río de la Plata is bounded on the north by Uruguay and on the south by Argentina; it drains eastward into the Atlantic Ocean. Its major tributaries, the Paraná and Uruguay rivers, drain about 1,600,000 square miles (4,144,000 square km), which includes northwestern Argentina, southern Brazil, southeastern Bolivia, Paraguay in its entirety, and most of Uruguay. The combined annual average rate of discharge of the two rivers is nearly 800,000 cubic feet per sec (23,000 cubic m per sec), bringing with it about 2,000,000,000 cubic feet (56,600,000 cubic m) of silt each year. Because the estuary is shallow, constant dredging is required to keep the sand and silt from obstructing the channel to the Argentine port of Buenos Aires. The shoals formed by these deposits are dominant features of the Río de la Plata. The ocean tides, weak though they may be, flow 120 miles (193 km) up the Paraná and the Uruguay rivers from their mouths on the estuary. The average tidal range is 6 inches (15 cm) at Montevideo (in Uruguay) and 2.5 feet (76 cm) at Buenos Aires. The Argentine coast of the estuary is low-lying; its banks are of marine debris and coarse sand. The Uruguayan coast, on the other hand, stands quite high and consists largely of rocks and dunes.

Plataea, ancient city of Boeotia, Greece. Plataea was situated on a triangular ledge 1,000 feet (300 m) above sea level, on the northern side of Mount Cithaeron below the modern village of Plataiaí. It was well-positioned in time of war to threaten the main road from Thebes to the Isthmus of Corinth, which passed east of Plataea over Mount Cithaeron. Plataea was settled by Boeotians who expelled the earlier Bronze Age inhabitants. When Thebes pressed Plataea to join a league of Boeotian cities formed in the 6th century BC, the Plataeans refused and engaged Athens (519) to protect them. Then, when the Persians landed in Attica in 490, the full Plataean levy, numbering about 1,000 men, came to the aid of Athens and fought at Marathon. In 479, Greek forces under Pausanias defeated the invading Persian army of Mardonius on the slopes of Cithaeron below Plataea, decisively crushing Persian ambitions on the Greek mainland. Thereafter the Plataeans offered sacrifice annually to Zeus the Liberator in honour of the Greek dead, and Plataea was declared inviolable by Pausanias. Nonetheless, the city was attacked by Thebans (431), then by Spartans (429), who finally razed it in 427. Thebes occupied the site until 387, then destroyed it again in 373. Athens harboured the survivors until the Macedonian kings Philip II and Alexander the Great rebuilt Plataea after 338 as a symbol of Greek courage in resisting Persia.

Plate, River: *see* Plata, Río de la.

plate glass, form of glass originally made by casting and rolling and characterized by its excellent surface produced by grinding and polishing. Plate glass was first made in the 17th century in France, after which several improvements in the original batch technique culminated in the Bicheroux process (1918), in which the glass was received by power-driven rollers that then delivered it in thinner sheets of greater length to be sheared into sections and annealed (heated, then cooled, to make it less brittle). A continuous process was then developed in which the glass passed through the annealing stage before being cut into lengths, ground, and polished.

A technique developed in Great Britain in the 1950s, called the float-glass method, results in an important economy of space. The molten glass is conveyed onto a bath of a molten metal, such as tin. The high temperature of the molten metal smooths out any irregularities on the surface, making a flat, even sheet. As the glass floats on top of the bath, the temperature of the molten metal is gradually reduced until the glass solidifies.

plate tectonics, theory that present and past earthquakes and volcanism, along with mountain-building processes, can be explained by the relative movement and jostling of enormous, rigid blocks (plates) comprising the Earth's surface.

A brief treatment of plate tectonics follows. For full treatment, *see* MACROPAEDIA: Plate Tectonics.

The surface of the Earth is composed of about a dozen large plates and several small ones. Within each plate the rocks of the terrestrial crust move as a rigid body, with only minor flexuring and few manifestations of seismicity and volcanism. The margins of the plates are defined by narrow bands in which 80 percent of the world's earthquakes and volcanoes occur. There are three types of boundaries. The first of these is a very narrow band of shallow earthquakes caused by tensile stresses that follow exactly the crest of the 48,000-mile- (80,000-kilometre-) long, active midocean ridges. The second boundary type occurs in areas where these ridges are offset. Earthquakes are much more violent along faults at such sites and result from the plates on either side of the faults grinding laterally past one another in opposite directions. Earthquakes forming the third boundary are distributed more diffusely but include all of the world's deep earthquakes (*i.e.,* those originating at depths greater than 90 miles [145 km]) and are associated with extremely narrow zones in which the ocean floor descends below its normal depth to as much as 6.6 miles (10.5 km) below sea level—the oceanic trenches. Across this margin, the maximum earthquake depths systematically increase along a dipping plane, with shallower earthquakes associated principally with the volcanic activity that borders each trench.

The ridge-crest earthquakes originate because of the tension created when the plates on either side move in opposite directions. This movement also releases the pressure on the underlying hot rocks, causing them to begin melting. The resulting magmas rise to form volcanoes (such as those in Iceland), which then solidify and later fracture as the tensional forces reassert themselves. Such new volcanic rocks thus become added to the edge of each plate, which grows at these "constructive" margins. The evidence for plate motion is not only the nature of the earthquakes but also the age of the volcanic oceanic rocks. Dating can be achieved by using both the fossil content of the sediments overlying the volcanic rocks and the time record represented by the anomalies in the magnetism of the rocks, which can be detected by ships sailing on the ocean surface. These show that the youngest volcanic rocks are at the crests of the midocean ridges and the oldest are in the deepest areas, *i.e.,* the oceanic trenches. Nowhere, however, are such rocks older than 190,000,000 years, indicating that all older oceanic rocks must have been destroyed.

The trench margin is termed "destructive" because this is the region where the oceanic rocks are subducted (carried down) into the mantle along the dipping plane. Where subduction occurs along a continental edge, volcanism distorts the continental rocks, forming such mountain chains as the Andes. Elsewhere, volcanism creates island arcs, as in the southwestern Pacific. The composition of the volcanoes and their mineralization changes systematically with depth to the dipping plane, but their overall composition is that of continental crustal rocks. The destructive margins are thus regions where continental crustal rocks are created but oceanic rocks are recycled back to the mantle. The density of continental rocks is too low for them to be subducted, so if they are carried to a trench they will eventually collide, giving rise to mountain chains such as the Alps and Himalayas, which formed when Africa and India, respectively, collided with Europe and Asia.

Although the lateral extent of the plates is well defined, their thickness is less certain. At the crest of the oceanic ridge they are very thin, but heat-flow and seismic evidence suggest that their base increases rapidly with depth, reaching 30–36 mi (48–57 km) within about 6–12 mi (9–19 km) of the crest. By about 600 mi (960 km) distance from the crest the base has increased to 72 mi (115 km). A plate may be subducted at any thickness but rarely exceeds 90 mi (145 km). Each plate is composed of rigid mantle rocks with oceanic crustal rocks, but not necessarily those of the continental variety (*e.g.,* the Pacific plate is devoid of continental rocks). The zone of rigid crustal and mantle rocks is termed the lithosphere to distinguish it from the deeper asthenosphere, where mantle rocks are at a higher temperature and so deform plastically when subjected to tectonic stresses. The continental lithosphere is not consistently underlain by an asthenosphere. Moreover, the presence of volcanic rocks such as diamond-bearing kimberlites indicates that here the Earth's lithosphere is at least 120 mi (190 km) thick, so that mantle flow, which causes plate motions, must occur at even greater depths.

The movements of the mantle result from the need to transfer to the Earth's surface the heat generated within it by radioactive decay, and hence convective patterns vary with time. This is shown by changes in the location of past plate margins. The subduction that formed the Western Cordillera of North America largely ceased 10,000,000 years ago, although some activity continues to produce volcanoes (*e.g.,* the continuing eruptions of Mt. Saint Helens in Washington) and earthquakes in Alaska.

Over time scales of hundreds of millions of years, changes in mantle convection initiated the formation of the Atlantic and Indian Oceans by splitting preexisting continents that were grouped as two major blocks, Laurasia and Gondwanaland (*qq.v.*), some 160,000,000 to 180,000,000 years ago. Similarly, past continental collisions are recorded by largely eroded mountain chains, such as the Appalachian Mountains of eastern North America and the Caledonian-Hercynian Mountains of Europe and Africa, which were formed when these continents collided on successive occasions. The rate of mantle convection depends essentially on the square root of heat production within the mantle. This means that convection rates must have been at least twice as fast about 3,000,000,000 years ago, when the radiogenic heat being produced was about five times greater than today. The surface expressions of such motions, however, may have been different. There are no continental rocks more than 4,000,000,000 years old, possibly because the lithosphere was thin and was recycled without generating continental rocks. The nature of plate tectonic activity during most of the Earth's history is still uncertain, and models of the way in which it would be reflected in the continental rocks are highly speculative.

platea, in medieval theatre, the neutral acting area of a stage. In medieval staging, a number of mansions, or booths, representing specific locations, were placed around the acting area. The actors would move from mansion to mansion as the play demanded. The *platea* would assume the scenic identity of the mansion that was being used. The *platea* was also used as the acting area for places not specified by individual mansions, such as streets and open country.

Plateau, state, east central Nigeria, created in 1976 out of the northern half of former Benue-Plateau state. It occupies an area of 22,405 sq mi (58,030 sq km) and is bounded by the states of Bauchi and Kaduna on the north, Benue on the south, Gongola on the east, and Kwara and the Abuja Federal Capital Territory on the west. The Jos Plateau rises to about 5,250 ft (1,600 m) above sea level in the north central part, and the Benue River Valley stretches along the southwestern border. Although there are wooded valleys in the southeast, the vegetation is mostly open grassland (formerly wooded but now with only occasional hedges of cacti and scattered trees), which is used for grazing and farming. Although the state is best known for its mining production, agriculture is the major occupation of the people. Acha (a grain known as "hungry rice") and millet are the chief cash crops; yams, sorghum, corn (maize), potatoes, cowpeas, rice, fruits, and vegetables are the staple crops. Fulani herdsmen graze their cattle on the tsetse-free plateau and supply milk to the dairy at Vom. Among the major exports of the state are hides and skins.

Plateau state is the most important mining area in Nigeria and is a major exporter of tin and columbite. Previously shipped to Britain for treatment, the tin (also mined in neighbouring Bauchi, Kaduna, Benue, and Kano states) has been smelted since 1962 just outside Jos, the state capital and its largest town. The metals are shipped by rail to Port Harcourt for export. Other minerals, notably tantalite, kaolin, tungsten (wolfram), zircon, and thorium compounds, are also exploited on the plateau. Lead, zinc, and silver are mined on a small scale in the eastern part of the state around Wase, Zurak, and Kigom.

Known for its heterogeneity, the state has about 40 ethnic groups, including the Vergam, Ankwei, Angas, Jawara (Jarauci), Birom, Mango, Fulani, Hausa, and Eggen. The mining industry has attracted European, Ibo, and Yoruba immigrants into the state. Jos is connected by road with Wamba, Akwanga, Keffi, and Lafia and has an airport. Lafia, Pankshin, Wamba, Shendam, and Akwanga are also sizeable market and mining centres. Places of interest include a museum, with Nok terra-cotta sculptures, and a zoo, both located at Jos. There is a federal university at Jos and a college of technology at Bukuru. Major research institutes are located at Vom (veterinary sciences) and at Bukuru (strategic studies). Pop. (1983 est.) 3,313,600.

plateau, extensive area of flat upland usually bounded by an escarpment on all sides but sometimes enclosed by mountains. The essential criteria for plateaus are low relative relief and altitude. Plateaus are extensive, and together with enclosed basins they cover about 45 percent of the Earth's land surface.

A brief treatment of plateaus follows. For full treatment, *see* MACROPAEDIA: Continental Landforms.

Classifications of different plateaus reflect their origins and subsequent erosional history. Tectonic plateaus are the most common. Most of Africa is such an uplifted continental block. The Arabian Peninsula and the Deccan Plateau of the Indian subcontinent are similar landforms. On a rather smaller scale, fault blocks and horsts are plateaus uplifted along marginal fault systems or left standing high when neighbouring blocks have sunk. Horsts are usually more distinctive than the larger fault block. A variation is the tilted block in which the plateau has one steeper edge and a gently tilted surface.

Plateaus enclosed within mountain systems are termed intermontane plateaus. In the United States the term basin and range is often used for this type of landscape, which extends between the Sierra Nevada and the Rockies. Basin-and-range topography, however, has a worldwide distribution. It includes much of Central Asia, Tibet, part of Szechwan, and Mongolia. Anatolia, Armenia, and Iran consist of intermontane plateaus, and some writers have gone so far as to class the Mediterranean, Aegean, and Black seas as intermontane basins. Intermontane plateaus are also common in the Andes; Lake Titicaca, the highest navigable water in the world at 12,500 ft (3,810 m), lies on such a plateau. Intermontane plateaus, horsts, and fault blocks are usually associated with young fold mountains.

Other plateau types consist of resistant rocks. Volcanoes pouring out extensive areas of basaltic lava have created a number of plateaus. Examples include the Antrim basaltic plateau in northern Ireland, the Cumberland–Snake basin in the northwestern United States, Ethiopia, and the northwestern part of the Deccan in India.

Low relief distinguishes plateaus from mountains, although modes of origin may be the same. Plateau areas, however, are subject to erosion and dissection by streams and glaciers. Ancient fold systems, once eroded, have been uplifted as plateaus and begin to undergo erosion once again. The Ardennes of Belgium, the Fjeld-plateaus of Scandinavia, and the Allegheny-Cumberland plateaus in the Appalachians are examples of this. In other places dissection has been more thorough and little remains of the original plateau surface. Such surfaces are inferred from accordant summits and have aroused debate among geomorphologists as to the existence of such erosional surfaces. The Highlands of Scotland are one area where surfaces have been postulated but where the existence of particular levels is often disputed. Apart from presenting problems in sampling surfaces, uplifted areas may have undergone substantial warping, and one cannot be sure that a former low-lying plain has been uplifted.

In arid and semiarid areas dissection often leads to the formation of tabular masses, especially if there is a resistant cap-rock. This is the typical frontier scenery of the southwestern United States where surfaces have been eroded into mesas (tablelands) and buttes (smaller flat-topped hills).

Plateaus, being high, often create their own local climates. In basin-and-range topography, height together with the rain-shadow effect created by surrounding mountains work to produce arid and semiarid conditions.

plateau, oceanic: *see* oceanic plateau.

Plateau Indian, member of any of a group of North American tribes who inhabited the high plateau between the Rocky Mountains on the east and the Cascade Range on the west. Linguistically they belonged to four main families: the Salish, Kutenai, Sahaptin and Klamath-Modoc (Lutuami), although the majority languages were Salish and Sahaptin. Their tribes included the Shuswap, Lillooet, and Thompson of the Northern Plateau group and the Okanagon, Lake, Wenatchee, Sanpoil, Nespelim, Spokan, Kalispel (with the Pend d'Oreille), Coeur d'Alene, and Flathead of the Interior group. There were also the Nez-Percé, the Cayuse-Molala, and other subdivisions of the Central Sahaptin.

A brief treatment of the Plateau Indians follows. For full treatment, *see* MACROPAEDIA: American Indians.

The Plateau Indians in the main were seasonal people, spending their winters in permanent villages along the waterways of the area and their summers in camps on the upland hunting grounds. Winters were harsh (as cold as −30° F [−34° C]) and summers hot (as high as 100° F [38° C]), but the area had plentiful opportunities for fishing (mostly salmon), hunting, and gathering. The Plateau Indians lived in earth lodges in the winter and in mat-covered conical lodges on the summer camping grounds. The basic unit was the village, but, beyond that, customs varied. The Thompson Indians based their decisions on informal village meetings, deferring to the consent of all the villagers. The Sanpoils had a more formal structure based on a chief, a subchief, and a general assembly including all adults except unmarried young men. The Nez Percé had a similar structure with a hereditary chief; the Flathead had a powerful head chief with subordinate band chiefs.

There were annual firstling rites on the occasion of the first salmon catch and the first root or berry harvest. Trickster, or transformer, figures such as the Coyote and the Bluejay were central elements of the mythology. Plateau Indian art is undistinguished, consisting largely of pictographic representations of supernatural beings and cosmic phenomena.

The demise of the old culture and traditions began with the penetration of the Northwest by fur traders and trappers from the east. Among these were Iroquois Christians who spread Christian culture through the area. The fur traders brought modern tools and weapons as well as diseases to which the Indians had no resistance. The horse was introduced at the beginning of the 18th century by the neighbouring Plains Indians and became more widely used than among the Plains Indians themselves.

The great invasion by the white man began with the first wagon train led into the Northwest area by Marcus Whitman, an eastern missionary-doctor, early in the mid-19th century. In the 1850s and '60s there were great waves of settlers and gold seekers, with the result that a series of wars broke out with the Indian tribes. The most famous of these was the Nez Percé War of 1877. By the end of the century the tribes were reduced to living on small reservations, and most of the old culture and the traditional economic ways of life have now been lost.

Plateau Indian cultures in the 20th century represent a mixture of aboriginal and white elements. The members of some tribes have become ranchers or ranch hands while continuing to engage in seasonal fishing; others have become farmers. The Indians have partly retained their religion and group identification but adopted modern technology and material culture.

Plateau Shoshonean languages: *see* Numic languages.

platelet, also called THROMBOCYTE, small, colourless, nonnucleated, usually round body that is important in blood-clot formation and is found only in the blood of mammals. Platelets are formed when cytoplasmic fragments of megakaryocytes, which are very large cells in the bone marrow, pinch off into the circulation as they age. The platelet is metabolically more active than the red blood cell and has a variety of functions. Platelets play an important and not fully understood role in the formation of the blood clot by coagulating to occlude a cut blood vessel and provide a surface on which strands of fibrin (*q.v.*) form an organized clot, by contracting to pull the fibrin strands together to make the clot firm and permanent, and, perhaps most important, by providing or mediating a series of coagulation factors necessary to the formation of the clot. Platelets also store and transport several chemicals, including serotonin, epinephrine, and histamine (the importance of which in this capacity is unknown), and they phagocytose (absorb) foreign bodies, including viruses, as well.

At birth the number of platelets is low, but by three months of age the adult level is reached. The number of platelets rises following trauma or asphyxiation, at high altitudes, after exercise, and in cold weather; the number may be temporarily lowered by menstruation in women. Certain chemicals may prolong the life of platelets; smoking is believed to shorten their life spans.

Platelets are produced in the bone marrow and stored in the spleen. Some evidence suggests they may also be produced or stored in the lungs, where megakaryocytes are frequently found. Individuals may develop antibodies to platelets following repeated platelet or whole-blood transfusion.

Platen(-Hallermünde), August, Graf von (count of), Hallermünde also spelled HALLERMUND (b. Oct. 24, 1796, Ansbach, principality of Ansbach [Germany]—d. Dec. 5, 1835, Syracuse, Sicily), German poet and dramatist

Platen, engraving by C. Barth, second quarter of the 19th century

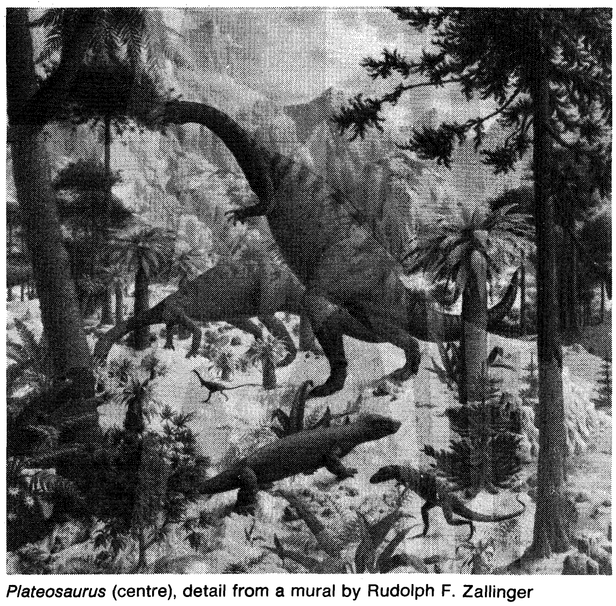
By courtesy of the Germanisches Nationalmuseum, Nurnberg

who was almost unique among his contemporaries in aiming at classical purity of style; although he was schooled in the Romantic tradition, he opposed its undisciplined flamboyance.

Platen entered the Bavarian life guards in 1814 and attended the University of Würzburg in 1818. In 1819 he moved to Erlangen, where he studied under the philosopher of Romanticism, Friedrich Schelling, and made the acquaintance of many of the leading writers of the time, including Johann Wolfgang von Goethe. He became a first-rate scholar and published a little book of poems, *Ghaselen* (1821; "Ghazels"), in which he imitated the style of his friend Friedrich Rückert. This was soon followed by other volumes.

Though Platen was at first influenced as a dramatist by the Romantics and particularly by Spanish models, the plays that he wrote while he was at Erlangen show a clearness of plot and expression that is foreign to the Romantic style. His antagonism to Romanticism became more pronounced, and he attacked its extravagances, particularly the *Schicksaldrama,* or fate drama, in his witty comedies in the manner of Aristophanes: *Die verhängnisvolle Gabel* (1826; "The Fateful Prong") and *Der romantische Oedipus* (1829; "The Romantic Oedipus"). *Der romantische Oedipus* earned him the enmity of two other eminent German writers—Karl Immermann, whose work was ridiculed in it, and Immermann's close friend Heinrich Heine. Platen, however, possessed many admirers who delighted in the classical purity of his plays and their polished form and diction. After 1826 he lived in Italy, and his last play, *Die Liga von Cambrai* (1833; "The League of Cambrai"), and the epic fairy tale *Die Abbassiden* (1834; "The Abbasids") were written at Naples. Platen's odes and sonnets and his *Polenlieder* (1831; "Songs of the Poles"), which expressed sympathy for the Poles in their rising against the tsar's rule, are counted among the best classical poems of their time.

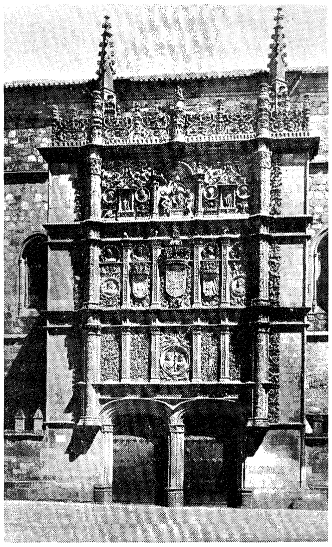
Plateosaurus, genus of early dinosaurs known from extensive Late Triassic fossil material found in Europe (the Triassic period began 245,000,000 years ago and lasted 37,-000,000 years). *Plateosaurus,* a representative of the prosauropods, an early group that might be ancestral to the giant sauropod dinosaurs of later time periods, was among the earliest dinosaurs to attain a relatively large size. It grew to be about 7 m (23 feet) long and was more massive than earlier dinosaurs. The bones were no longer hollow since hollow bones could not support the increasing bulk of the animal. Although *Plateosaurus* walked on its two very strong hind legs, its forelimbs also were relatively well-developed and strong, and thus it would have been able to walk on all four legs as well. The small skull was perched atop a long and flexible neck and contained compressed and spatulate teeth serrated on the front and back edges. Although it has been suggested that *Plateosaurus* was carnivorous, the teeth and jaw musculature seem much better suited to a plant diet. It also has been suggested that *Plateosaurus* was at least partially aquatic, but this, too, is uncertain. Specimens that resemble *Plateosaurus* have been found in South Africa and China, and



Plateosaurus (centre), detail from a mural by Rudolph F. Zallinger

By courtesy of the Peabody Museum of Natural History, Yale University it is possible that the genus had a very wide distribution.

Plateresque, Spanish PLATERESCO ("Silversmith-like"), main architectural style in Spain during the late 15th and the 16th centuries, also used in Spain's American colonies. Cristóbal de Villalón first used the term in 1539 while comparing the richly ornamented facade of the Cathedral of Leon to a silversmith's intricate work. Later the name came to be generally applied to late Gothic and early Renaissance Spanish architecture, since it was characterized by an intricate and minutely detailed relief ornament that is generally applied to the surface of buildings for extravagant decorative effect and without regard for structural articulation. Favourite motifs of this florid ornament include twisted columns, heraldic escutcheons, and sinuous scrolls. Clusters of this jewelry-like ornament contrast with broad expanses of flat wall surface.



Plateresque facade of the University of Salamanca, Spain, early 16th century
Archivo Mas, Barcelona

The Plateresque style went through two distinguishable phases. The first phase, termed the Isabelline style because it flourished during the reign of Isabella I, lasted from about 1480 to about 1540. In this phase (also known as the Gothic-Plateresque style), the forms of late Flamboyant Gothic still predominate, and Renaissance elements are used with only imperfect understanding. The first phase, like its successor, utilized Mudejar ornament—*i.e.,* the intricate and elegant decorative patterns used by Moorish artists working in Christian-ruled Spain. The Isabelline style is well represented in the buildings of Enrique de Egas and Diego de Riaño and is typified by the facade of the College of San Gregorio in Valladolid (1488), in which architectural ornamentation seems free from all external dictates and pursues its own life without regard to scale, composition, placement, or appropriateness.

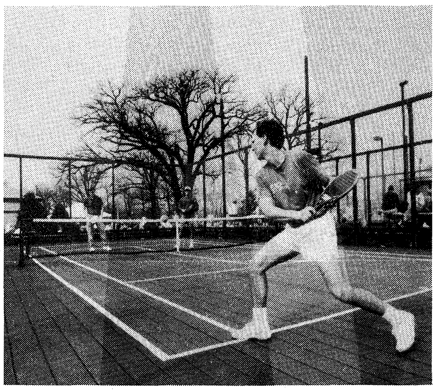
The second phase, the Renaissance-Plateresque, or simply the Plateresque, lasted from about 1525 to 1560. The architect and sculptor Diego de Siloé (d. 1563) helped inaugurate this phase, in which High Renaissance structural and decorative elements clearly predominated over late Gothic ones. In the Granada Cathedral (1528–43) and other buildings, Diego evolved a purer, more severe, harmonious, and unified style using massive geometric forms; correct classical orders became frequent, and nonstructural Gothic ribbing tended to disappear in favour of Italianate round arches and domical vaults. The buildings of Alonso de Covarrubias and of Rodrigo Gil de Hontañón, particularly the latter's facade of the University of Alcalá de Henares (1541–53), are the masterworks of the second style, which lasted only a few decades. Even the balance and correctness of the style seemed excessively rich to the sombre young man who became King Philip II in 1556 and supervised construction of the severe El Escorial.

platform, wave-cut, also called ABRASION PLATFORM (coastal feature): *see* wave-cut platform.

platform rocker, also called SWING ROCKING CHAIR, rocking chair with rockers fixed to move on a stationary base instead of on the floor. Introduced in the United States about 1870, it achieved quick popularity, partly because the movable section of the chair could be kept at a comfortable angle without oscillating. The base of the platform rocker was often of considerable structural complexity, but this meant that the seating portion could be made of lighter material, such as bamboo. The backs were invariably rectangular, never curved, and the general decorative pattern was usually based on 17th-century prototypes.

platform stage: *see* open stage.

platform tennis, also called PLATFORM PADDLE TENNIS, or PADDLE TENNIS, sport that is a combination of tennis and squash, devised in 1928 by American sports enthusiasts Fessenden Blanchard and James Cogswell at Scarsdale, N.Y. It is played on specially constructed platforms, 60 by 30 feet (18 by 9 m), surrounded by back and side walls of tightly strung wire netting 12 feet (3.7 m) high. The actual court measures 44 by 20 feet (13.4 by 6 m), and the net is 2 feet 10 inches (86 cm) high at its centre. The paddles, or bats, used instead of rackets, are made of oval plywood, metal-bound and perforated, and have short handles. Balls are made of sponge rubber. The rules are the same as for tennis, except that balls may be taken off the back or side walls after first striking inside the court proper, and only one serve is allowed.



Men's National Championships in platform tennis
Cathy Melloan

The sport has gained some popularity in the United States. The American Platform Tennis Association, founded in 1934, regulates the game.

Plath, Sylvia (b. Oct. 27, 1932, Boston, Mass., U.S.—d. Feb. 11, 1963, London, Eng.), American poet and novelist whose best-known works are noted for their preoccupation with alienation and with death and self-destruction. Little-known at the time of her death by suicide, her reputation and popularity grew rapidly afterward, and by the mid-1970s she was considered a major contemporary poet.

Plath's early life was dominated by a drive to excel at writing, and she published her first poem at age eight. She entered and won many literary contests and received a scholarship to Smith College. From 1955 to 1957 she attended the University of Cambridge on a Fulbright grant; there she met and in 1956 married the English poet Ted Hughes.

Her first major publication was *The Colossus* (1960), a collection of poems written from 1956 to 1960. This was followed by her only novel, *The Bell Jar* (1963), which first appeared under the pseudonym Victoria Lucas. Drawn from Plath's own experiences, the book describes the mental breakdown, attempted suicide, and eventual recovery of a young college girl. Works published posthumously include *Ariel* (1965) and *Crossing the Water* (1971), both poetry collections, and *Johnny Panic and the Bible of Dreams* (1977), a book of short stories and prose. *The Collected Poems,* which includes many previously unpublished poems, appeared in 1981.

plating, coating a metal or other material such as plastic or china with a hard, nonporous metallic surface to improve durability and beauty. Such surfaces as gold, silver, stainless steel, palladium, copper, and nickel are formed by dipping an object into a solution containing the desired surface material, which is deposited by chemical or electrochemical action. While much plating is done for decorative purposes, still more is done to increase the durability and corrosion-resistance of softer materials. Most automotive parts, appliances, housewares and flatware, hardware, plumbing and electronic equipment, wire goods, aircraft and aerospace products, and machine tools are plated for durability.

Several processes are used for plating: electroplating, electroless plating, and anodizing are the major processes used today, but other methods also have been developed.

In electroplating, the article to be plated serves as the cathode in an electrolytic bath composed of a solution of the salt of the metal to be deposited. The other terminal, the anode, may be of the same metal or another chemically unaffected conductor. A low-voltage current is passed through the solution and causes the metal in solution to plate the article. Electroless plating (*q.v.*) relies on reactions in a chemical bath that may or may not be aqueous and may or may not be heated. Anodizing (*q.v.*) is similar to electroplating, but the article to be plated serves as the anode in the electrical circuit.

platinum (Pt), chemical element, the best known and most widely used of the six platinum metals of Group VIII of the periodic table. A very heavy, precious, silver-white metal, platinum is soft and ductile, has a high melting point and good resistance to corrosion and chemical attack. For example, its surface remains bright after being brought to white heat in air and, though it readily dissolves in aqua regia, it is scarcely attacked by simple acids. Small amounts of iridium are commonly added to give a harder, stronger alloy that retains the advantages of pure platinum.

Platinum and its alloys are indispensable in the chemical laboratory for electrodes and for crucibles and dishes in which materials can be heated to high temperatures. Platinum is used for electrical contacts and sparking points because it resists both the high temperatures and chemical attack of electric arcs. Jewelry and dental alloys account for much of its use; platinum–iridium is used for surgical pins. The prototype international standard kilogram of mass was made from an alloy of 90 percent platinum and 10 percent iridium. The electrical resistivity of platinum is relatively high and depends markedly upon the temperature; the international temperature scale from −183° C to 630° C (−297° to 1,166° F) is defined in terms of a resistance thermometer made with platinum wire. As a catalyst, platinum has many applications.

The Italian-French physician Julius Caesar Scaliger alluded (1557) to a refractory metal, probably platinum, found between Darién and

Mexico. The Spanish mathematician Antonio de Ulloa (1735) and the British metallurgist and assayer Charles Wood (*c.* 1741) found platinum in South America, whence it was taken to Europe. The first certain discovery was in the alluvial deposits of the Río Pinto, Colombia. The Spaniards called the new metal *platina del Pinto* for its resemblance to silver. The world's most important deposits were found (1822) in the Ural Mountains of Russia. It occurs in Finland, Ireland, Borneo, New South Wales, New Zealand, Brazil, Peru, Madagascar, and in the Transvaal of South Africa. Native platinum also is found in Alaska, California, and Oregon, in British Columbia, and in Alberta. Platinum-bearing igneous rocks give rise to the associated placer deposits, the most productive sources of the native element. The ordinary variety of native platinum is called polyxene; it is 80 percent to 90 percent platinum, with 3 percent to 11 percent iron, plus the other platinum metals, and gold, copper, and nickel. For mineralogical properties, *see* native element (table). Platinum is also found in the very rare native alloy platiniridium. Platinum occurs combined with arsenic as sperrylite ($PtAs_2$) in the copper–nickel-mining district near Sudbury, Ont., and with sulfur as cooperite (PtS) in the Transvaal.

For information about the mining, recovery, and production of platinum, *see* MACROPAEDIA: Industries, Extraction and Processing. Additional details on the application of pure platinum and its alloys are also provided in the same article.

Platinum forms an important series of compounds with the oxidation states of +2 and +4 (and some compounds of 0, +5, and +6 states). Many of these compounds contain coordination complexes in which chloride ion (Cl^-), ammonia (NH_3), or other groups are bonded to a central platinum atom. Among the transition metals, platinum has one of the greatest tendencies to form bonds directly with carbon. Natural platinum is a mixture of six isotopes: platinum-190 (0.0127 percent), platinum-192 (0.78 percent), platinum-194 (32.9 percent), platinum-195 (33.8 percent), platinum-196 (25.3 percent), and platinum-198 (7.21 percent). All are stable except platinum-190 and platinum-192, which have been reported as long-lived alpha emitters.

Plato (b. 428/427 BC, Athens, or Aegina, Greece—d. 348/347, Athens), ancient Greek philosopher, the second of the great trio of ancient Greeks—Socrates, Plato, and Aristotle. He developed a wide-ranging system of philosophy that was strongly ethical, resting on a foundation of eternal Ideas or Forms that represented universals or absolutes. Platonism influenced currents of philosophy up to the 20th century.

A brief account of the life and works of Plato follows; for a full biography, *see* MACROPAEDIA: Platonism.

Born of a distinguished Athenian family, Plato had political ambitions until he became convinced that there was no place for men of conscience in active politics. After the execution of Socrates (399 BC), he and other Socratic men took temporary refuge at Megara and then spent the next few years traveling in Greece, Egypt, Italy, and Sicily, where he found a kindred spirit in Dion, brother-in-law of Dionysius I, the tyrant of Syracuse. About 387 he founded the Academy in Athens as an institute for the systematic pursuit of philosophical and scientific research. He presided over it for the rest of his life, making it the recognized authority also in mathematics and jurisprudence. On the death of Dionysius I in 367, Plato went to Syracuse at the request of Dion to be the tutor for Dionysius II, but the plan to educate a constitutional king failed, and Plato returned to the Academy.

Although Plato considered the foundation and organization of the Academy his chief work, his importance to later generations has been as one of the greatest of philosophical writers. His dialogues are divided into two groups—the earlier and the later—on the basis of a real difference in thought, perhaps indicating the distinction between the more Socratic thought and the more distinctively Platonic thought.

Platonic Academy, Italian ACCADEMIA PLATONICA, a group of scholars in mid-15th-century Florence who met under the leadership of the outstanding translator and promulgator of Platonic philosophy Marsilio Ficino (*q.v.*), to study and discuss philosophy and the classics. The influence of their modernized and Christianized Platonism on Italian Renaissance thought was profound and still survives in the popular concept of "Platonic love." Although the group was never formally organized, its members considered themselves a re-creation of the Academy that had been formed by Plato in Athens. The most important members of the group, most of them connected with the courts of Cosimo and Lorenzo de' Medici, were Politian (or Poliziano), the outstanding poet and classical scholar of the Renaissance; the professor of poetry and oratory at the University of Florence, Cristofero Landino; and the scholars and philosophers Pico della Mirandola and Gentile de' Becchi.

Platonism, family of philosophic movements that derive their ultimate inspiration from the *Dialogues* of Plato and embrace his belief in absolute values rooted in a realm of unchanging and eternal realities independent of the world perceived by the senses. As here construed, Platonism does not include the work of Plato himself. *See also* Plato.

A brief treatment of Platonism and Neoplatonism follows. For full treatment, *see* MACROPAEDIA: Platonism.

After Plato's death, his greatest scholar, Aristotle, went his own way and eventually organized a school of his own in the Lyceum, claiming that he was preserving the essential spirit of Platonism while rejecting the difficult doctrine of the forms. It was under Arcesilaus (*c.* 276–241 BC) that the Academy began its polemic against the sensationalist dogmatism of the Stoics, which was to culminate a century later under the leadership of Philo of Larissa.

The history of the Academy after Philo is obscure, but in the late 1st century AD there arose a popular literary, somewhat corrupted, Platonism of which the writings of Plutarch of Athens are the best example. Genuine Platonism was revived in the 3rd century AD, in Rome, and independently of the Academy, by Plotinus. His Neoplatonism represents a real effort to do justice to the whole thought of Plato. Two aspects of Plato's thought, however, inevitably fell into the background: the mathematical physics and the politics. The 3rd century AD had no understanding for the former, and the Roman Empire under a succession of military chiefs had no place for the latter.

Plotinus lived in an atmosphere too pure for sectarian polemic, but in the hands of his successors, Neoplatonism was developed in conscious opposition to Christianity. Porphyry, his disciple and biographer, was the most formidable of the anti-Christian controversialists; in the next century, "Platonists" were among the allies and counselors of the emperor Julian in his attempts to invent a Hellenic counterpart to Christianity.

Early in the 5th century, Neoplatonism flourished for a short time in Alexandria and captured the Athenian Academy itself, where its last great representative was the acute Proclus (AD 410–485). Traces of Plato are probably to be detected in the Alexandrian *Wisdom of Solomon;* the thought of the Alexandrian Jewish philosopher and theologian Philo, in the 1st century AD, is at least as much Platonic as Stoic. There are, perhaps, no certain marks of Platonic influence in the New Testament, but the earliest apologists (Justin, Athenagoras) appealed to the witness of Plato against the puerilities and indecencies of mythology.

In the 3rd century, Clement of Alexandria and, after him, Origen made Platonism the metaphysical foundation of what was intended to be a definitely Christian philosophy. Although the church could not, in the end, conciliate Platonist eschatology with the dogmas of the resurrection of the flesh and the final judgment, the platonizing tendency was continued through the Middle Ages under the influence of St. Augustine and Boethius. A further powerful influence was exerted by the writings of the so-called Dionysius the Areopagite, which laid down the main lines of medieval mystical theology and angelology.

Apart from this theological current, Plato dominated the thought of the earlier Renaissance by virtue of numerous translations and commentaries. For a time, the work of Aristotle was comparatively unknown in the West. The 13th century saw a change, however, with the recovery of Aristotle's physics and metaphysics from the Moors, Persians, and Jews. Aristotle came to displace Plato in philosophy, partly in consequence of the immediately perceived value of his scientific works as a storehouse of well-digested natural facts, and partly from the brilliant success of the enterprise carried through by St. Thomas Aquinas, the reconstruction of philosophical theology on an Aristotelian basis. Plato is, however, by no means supplanted in the Thomist system; the impress of Augustine on Western thought has been far too deep for that.

Two Platonist revivals in particular are famous. The first is that of the 16th century, marked most notably by the foundation of Lorenzo de' Medici's Florentine Academy. In the 17th century, Plato, seen chiefly through the medium of Plotinus, supplied the inspiration of the so-called Cambridge Platonists (*q.v.*). In the 20th century, on the one hand A.N. Whitehead tried to work out a philosophy of the sciences that confessedly connected itself with the ideas of the *Timaeus;* and on the other the rise of totalitarian governments produced a number of publications confronting Plato with the theories inherent in their policies. Neo-Kantianism, Existentialism, and Analytic philosophy produced their own interpretations of Plato.

Platonov, Sergey Fyodorovich (b. June 28 [June 16, old style], 1860, Chernigov, Russia—d. Jan. 10, 1933, Samara), leading Russian historian of the early 20th century.

Having graduated from the University of St. Petersburg in 1882, Platonov held various academic posts at that institution and elsewhere. After 1920 he was a member of the U.S.S.R.'s Academy of Sciences. Most of Platonov's scholarly work dealt with the Time of Troubles, the chaotic interregnum (1598–1613) between the demise of the Rurik dynasty and the election of the first Romanov tsar. His major work on this subject was the monumental *Studies in the History of the Time of Troubles in the Muscovite State During the 16th and 17th Centuries* (1899). Platonov founded a new school of historiography in Russia based on careful and exhaustive archival research and analysis. His *History of Russia* (1909) and *Lectures on Russian His-*

tory (1899) remained, respectively, the standard high school and university textbooks on the subject for more than 20 years. Platonov's enormous prestige ensured his toleration by the Bolsheviks in the years immediately after the Revolution of 1917, and he continued to teach at Leningrad University (formerly the University of St. Petersburg) as he had since becoming a professor there in 1899. However, the apolitical Platonov came increasingly under attack from Marxist critics in the late 1920s, and in 1930 he was arrested, tried, and convicted on trumped-up charges of participating in a plot to restore the monarchy. He was exiled to Samara (now Kuybyshev), where he died.

platoon, principal subdivision of a military company, battery, or troop. Usually commanded by a lieutenant, it consists of from 25 to 50 men organized into two or more sections, or squads, led by noncommissioned officers.

In the 17th century the term referred to a small body of musketeers who fired together in a volley alternately with another platoon, and it has always retained some sense of systematic alternate employment. Hence "platoon fire" meant a regulated fire of alternating platoon volleys, and "platoon" sometimes referred to the volley itself. In the 18th century, battalions were often organized for tactical purposes into 16 platoons of about 24 men each, plus 2 or 4 platoons of grenadiers or light infantry.

The term platoon has been used in U.S. military manuals since 1779 and throughout the 19th century meant half a company. The platoon was reintroduced into the British Army in 1913.

The "platoon system" in municipal police and U.S. baseball and football organizations signifies the use of two or more shifts or teams of comparable strength that alternate on duty.

Platt, Orville Hitchcock (b. July 19, 1827, Washington, Conn., U.S.—d. April 21, 1905, Washington), U.S. senator from Connecticut (1879–1905) who introduced the Platt Amendment (*q.v.*), which became the basis for the withdrawal of U.S. troops from Cuba following the Spanish–American War of 1898.

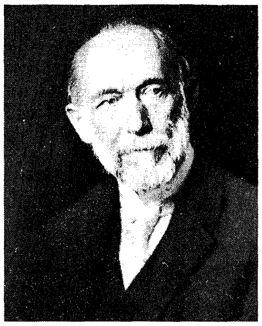
Platt began the practice of law in Meriden, Conn., in 1850 and was active in Connecticut politics, serving as secretary of state (1857), state senator (1861–62), and member of the state House of Representatives (1864, 1869). In 1879 he was elected as a Republican to the U.S. Senate. Although principally remembered in connection with the Platt Amendment, he also sponsored important legislation relating to patents and copyrights, including the international copyright act of 1891, and was chairman of the committee on territories (1887–93), which recommended the admission to the Union of six new Western states. He was also instrumental in the passage of the Sherman Silver Purchase Act of 1890. One of the "Big Four" leaders of the Senate—with Nelson W. Aldrich, William B. Allison, and James C. Spooner—Platt was regarded as a "stand-pat" conservative and was admired for his integrity and independence.

Platt, Thomas Collier (b. July 15, 1833, Owego, N.Y., U.S.—d. March 6, 1910, New York City), U.S. representative and senator from New York, who unwillingly furthered the rise to the U.S. presidency of Theodore Roosevelt (whom he called "a perfect bull in a china shop").

Educated at Owego Academy and at Yale (1849–50), Platt entered banking and lumbering, served in the U.S. House of Representatives (1873–77), and became president (1880) of the United States Express Company.

He first entered the Senate in March 1881. Two months later, both he and Roscoe Conkling, Republican Party boss of New York state, resigned from the Senate to protest the refusal of Pres. James A. Garfield to accept their recommendations for appointments to federal positions in New York State. Platt had to wait more than 15 years to regain his seat. (He then served two full terms, 1897–1909.) Meanwhile, Conkling retired from politics, and Platt assumed control of the Republican machinery in New York.

In 1898 Platt reluctantly accepted the candidacy for governor of the popular young reformer Theodore Roosevelt. Finding that he could not control Roosevelt, he contrived to eliminate him from state politics by persuading the Republican national convention in 1900 to nominate him for vice president. This maneuver backfired when the assassination of



Thomas Collier Platt, *c.* 1903
By courtesy of the Library of Congress, Washington, D.C.

Pres. William McKinley elevated Roosevelt to the presidency in 1901. By the time of the next presidential election, Platt's power had begun a decline that he was unable to reverse.

Platt Amendment, rider appended to the U.S. Army appropriations bill of March 1901, stipulating the conditions for withdrawal of U.S. troops remaining in Cuba since the Spanish–American War, and molding fundamental Cuban–U.S. relations until 1934. Formulated by the secretary of war, Elihu Root, the amendment was presented to the Senate by Sen. Orville H. Platt of Connecticut. By its terms, Cuba would not transfer Cuban land to any power other than the United States, Cuba's right to negotiate treaties was limited, rights to a naval base in Cuba (Guantánamo Bay) were ceded to the United States, U.S. intervention in Cuba "for the preservation of Cuban independence" was permitted, and a formal treaty detailing all the foregoing provisions was provided for. To end the U.S. occupation, Cuba incorporated the articles in its constitution. Although the United States intervened militarily in Cuba only twice, in 1906 and 1912, Cubans generally considered the amendment an infringement of their sovereignty. In 1934, as part of his Good Neighbor policy, Pres. Franklin D. Roosevelt supported abrogation of the amendment's provisions except for U.S. rights to the naval base.

Platte River, river formed at the city of North Platte, Neb., U.S., by the confluence of the North Platte and South Platte rivers (*qq.v.*). The 310-mi (500-km) Platte flows southeast into a big bend at Kearney, Neb., turns northeast, and empties into the Missouri River at Plattsmouth, 15 mi south of Omaha. During the spring runoff, the Platte is a mile wide in many places, but it is almost dry the remainder of the year. The extreme shallowness of the river (named from the French *plat*, "shallow") prevents navigation. It drains an area of 90,000 sq mi (233,000 sq km). The vast quantities of water diverted for irrigation agriculture and for municipal use are the most significant aspects of the Platte River system. The Loup River is the largest tributary to the Platte.

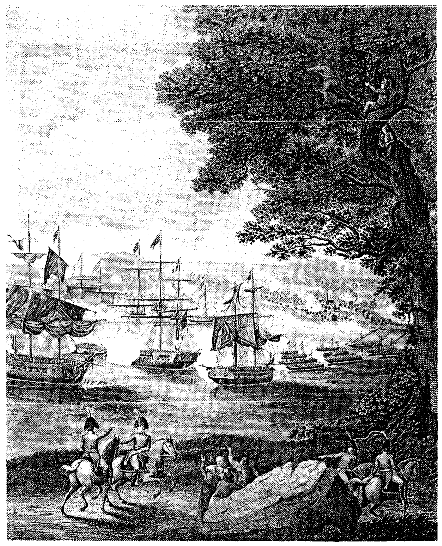
Platter, Thomas (b. Feb. 10, 1499, Grächen, Switz.—d. Jan. 26, 1582, Basel), Swiss writer and humanist known for his autobiography.

After years of hardship, spent as a goatherd

Platter, detail of an engraving by P. Aubrey
By courtesy of the Bibliotheque Nationale Suisse, Bern

in the Alps and as a scholar's assistant in Germany, Platter was initiated at Zürich into Huldrych Zwingli's teachings and the newly discovered world of Greek, Latin, and Hebrew culture. Moving to Basel, Platter first made his living as a ropemaker but contributed to the renown of this great centre of humanistic learning by teaching Hebrew, working as partner to the printer Andrew Cratander, and, after 1541, reforming Basel grammar school. His autobiography, completed in 1576, an important document of the period, tells the story of his lifelong struggle against heavy odds in self-education.

Plattsburgh, historically PLATTSBURG, city, seat (1788) of Clinton County, northeastern New York, U.S., on the west shore of Lake Champlain, at the mouth of the Saranac



"Macdonough's Victory on Lake Champlain in the War of 1812"; detail of an engraving by B. Tanner after a painting by H. Reinagle
By courtesy of the Library of Congress, Washington, D.C.

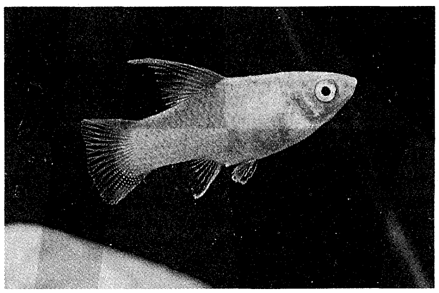
River, 60 mi (97 km) south of Montreal. Founded by Zephaniah Platt in 1784, it was the scene of an important U.S. victory during the War of 1812 on Lake Champlain that saved New York from possible British invasion via the Hudson Valley. A British army of 14,000 troops under Sir George Prevost reached Plattsburg in a joint land and sea operation. U.S. defenders included 1,500 regulars and 2,500 militia commanded by Gen. Alexander Macomb, supported by a 14-ship U.S. naval squadron under Comdr. Thomas Macdonough. The outcome of the battle was determined on water when the British fleet was decisively defeated on Sept. 11, 1814. Deprived of naval support, the invading army was forced to retreat. The victory at Plattsburg influenced the terms of peace drawn at the Treaty of Ghent the following December. The Macdonough Memorial commemorating the battle is in front of the city hall. The Kent-Delord House (1797) served successively as British and American headquarters and is maintained as a museum.

Abundant waterpower influenced the development of lumber and paper mills, and the city is a base for the Champlain resort area. The State University of New York College at Plattsburgh (established as a normal school, 1899), Clinton Community College (1966), and Plattsburgh Air Force Base (activated 1955) are additional economic factors. Recognized as a village in 1785, it was incorporated as a city in 1902. Pop. (1988 est.) 21,013.

Plattsmouth, city, seat (1855) of Cass county, eastern Nebraska, U.S., near the confluence of the Platte and Missouri rivers. Founded in 1854, it developed as a trading post, stagecoach stop, and terminus and shipping point for farmers. With the arrival of the Burlington and Missouri River Railroad in 1869, river traffic declined.

After 1940 Plattsmouth evolved into a commuter suburb of Omaha but retained some industries, the largest being the manufacture of freight cars. The King Korn Karnival, a harvest fair, is held each September. Inc. 1855. Pop. (1986 est.) 6,860.

platy (species *Xiphophorus maculatus*), popular tropical aquarium fish of the live-bearer family, Poeciliidae (order Atheriniformes). The platy is a compact fish, about 5 cm (2 inches)



Platy (*Xiphophorus maculatus*)
Jane Burton—Bruce Coleman Ltd.

long and extremely variable in colour. It has been bred in many attractive colour varieties, and, like the related swordtail (*Xiphophorus helleri*) with which it has been crossed, has been used in a variety of genetic and medical studies.

Platyceras, genus of extinct gastropods (snails) that occurs as fossils in rocks of Silurian to Permian age (438 to 245 million years ago). Its distinctive shape is easily recognized. The caplike shell is high and broad anteriorly. The posterior portion of the shell, at the apex, is slightly coiled in an asymmetrical fashion. Frequently, the front portions of the shells are broken, though the posterior sections are relatively well preserved. *Platyceras* is particularly abundant in Devonian deposits (360 to 408 million years old).

Platycrinites, genus of extinct crinoids, or sea lilies, especially characteristic as fossils of Early Carboniferous marine deposits (360 to 320 million years ago). *Platycrinites,* of moderate size, had a columnar stem with a twisted pattern, an unusual feature.

platyhelminth: *see* flatworm.

platypus, also called DUCKBILL (species *Ornithorhynchus anatinus*), a small, semiaquatic, oviparous mammal, the sole member of the family Ornithorhynchidae, order Monotremata. It lives in lakes and streams of eastern Australia and Tasmania. The platypus is notable in having a broad, flat, rubbery

Platypus (*Ornithorhynchus anatinus*)
By courtesy of the Australian Information Service

snout and in laying eggs. It has a squat body, short splayed legs, webbed feet, and a flat beaverlike tail. Its total length is about 60 cm (24 inches). The dense soft fur varies from yellowish to dark brown. The male of the species has a poison spur on each hindfoot for sexual combat; the poison is intensely painful to humans.

The platypus' sensitive snout has been shown by researchers to contain electroreceptors, which enable it to detect the electrical field produced by the moving muscles of its prey. The platypus finds its food chiefly in underwater mud, and it consumes daily nearly its own weight in crustaceans, fishes, frogs, mollusks, tadpoles, and earthworms. It burrows above the waterline; the long twisting passage dug by the female contains a nest in which she lays one, two, or three sticky soft-skinned eggs. Incubation takes about 10 to 12 days. The young platypus has elongated lips (the incipient bill) for sucking milk, exuded from the nippleless mammae. Weaning occurs four months after hatching.

Because of their enormous appetites, platypuses are difficult to maintain in captivity; one is known to have survived in a zoo, however, for 17 years. Their natural enemies are large fishes and, perhaps, snakes. Platypuses formerly were trapped for their pelts but are now protected by law.

platyrrhine: *see* New World monkey.

Platystrophia, genus of extinct brachiopods (lamp shells) occurring as fossils in marine rocks of the Middle Ordovician epoch to about the middle of the Silurian period (*i.e.,* from about 478 to 421 million years ago). Each valve of the shell is convex in profile, and the hinge line between the valves is wide. Surface markings on the shell include prominent angular ridges and intervening linear depressions. *Platystrophia* is a common Late Ordovician fossil that is useful for stratigraphic correlations.

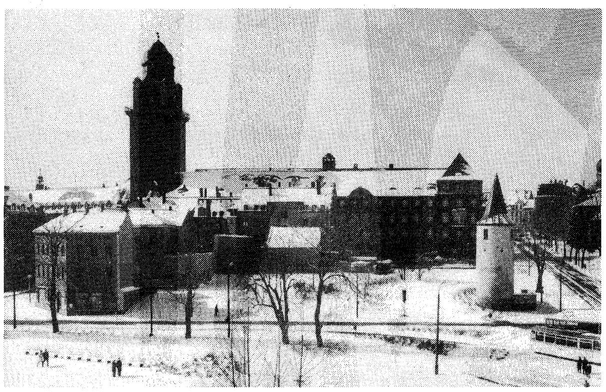
Plauen, city, Saxony *Land* (state), east-central Germany, on the slopes of the Weisse Elster River valley, in the Vogtland. Chartered in 1220, it is the centre of the Vogtland region, which in the Middle Ages was directly administered by the *Vögte* (imperial advocates) of Weida. Plauen became the centre of a flourishing textile industry as early as the 15th century. It was severely damaged by air raids in World War II. Notable landmarks include the old town hall (rebuilt 1548) with the adjoining new town hall, the 12th-century Johanneskirche (John's Church, restored), the Luther Church (1693–1708), and the former castle of the *Vögte* (1250), now a lawcourt.

The contemporary city has a textile craft school. A rail junction, Plauen is known for lace making, but a variety of other textile products are manufactured, and there are also a variety of heavy and light industries in the city. Pop. (1989 est.) 77,593.

Plautus (b. *c.* 254 BC, Sarsina, Umbria? [Italy]—d. 184), great Roman comic dramatist, whose works, loosely adapted from Greek plays, established a truly Roman drama in the Latin language.

Life. Little is known for certain about the life and personality of Plautus, who ranks with Terence as one of the two great Roman comic dramatists. His work, moreover, presents scholars with a variety of textual problems, since the manuscripts by which his plays survive are corrupt and sometimes incomplete. Nevertheless, his literary and dramatic skills make his plays enjoyable in their own right, while the achievement of his comic genius has had lasting significance in the history of Western literature and drama.

According to the grammarian Festus (2nd or 3rd century AD), Plautus was born in northeastern central Italy. His customarily assigned birth and death dates are largely based on statements made by later Latin writers, notably Cicero in the 1st century BC. Even the three names usually given to him—Titus Maccius Plautus—are of questionable historical authenticity. Internal evidence in some of the plays does, it is true, suggest that these were the names of their author, but it is possible that they are stage names, even theatrical jokes or allusions. ("Maccus," for example, was the traditional name of the clown in the "Atellan farces," a long-established popular burlesque, native to the Neapolitan region of southern Italy; "Plautus," according to Festus, derives from *planis pedibus, planipes* [flat-footed] being a pantomime dancer.) There are further difficulties: the poet Lucius Accius (170–*c.* 86 BC), who made a study of his fellow Umbrian, seems to have distinguished between one Plautus and one Titus Maccius. Tradition has it that Plautus was associated with the theatre from a young age. An early story says that he lost the profits made from his early success as a playwright in an unsuccessful business



Clock tower of the old town hall and (right) the Nonnenturm ("Nun's Tower"), Plauen, Ger.
W. Krammisch—Bruce Coleman Inc./EB Inc.

venture, and that for a while afterward he was obliged to earn a living by working in a grain mill.

Approach to drama. The Roman predecessors of Plautus in both tragedy and comedy borrowed most of their plots and all of their dramatic techniques from Greece. Even when handling themes taken from Roman life or legend, they presented these in Greek forms, setting, and dress. Plautus, like them, took the bulk of his plots, if not all of them, from plays written by Greek authors of the late 4th and early 3rd centuries BC (who represented the "New Comedy," as it was called), notably by Menander and Philemon. Plautus did not, however, borrow slavishly; although the life represented in his plays is superficially Greek, the flavour is Roman, and Plautus incorporated into his adaptations Roman concepts, terms, and usages. He referred to towns in Italy; to the gates, streets, and markets of Rome; to Roman laws and the business of the Roman law courts; to Roman magistrates and their duties; and to such Roman institutions as the Senate.

Not all references, however, were Romanized: Plautus apparently set little store by consistency, despite the fact that some of the Greek allusions that were left may have been unintelligible to his audiences. Terence, the more studied and polished playwright, mentions Plautus' carelessness as a translator and upbraids him for omitting an entire scene from one of his adaptations from the Greek (though there is no criticism of him for borrowing material, such plagiarism being then regarded as wholly commendable). Plautus allowed himself many other liberties in adapting his material, even combining scenes from two Greek originals into one Latin play (a procedure known as *contaminatio*).

Even more important was Platus' approach to the language in which he wrote. His action was lively and slapstick, and he was able to marry the action to the word. In his hands, Latin became racy and colloquial, verse varied and choral.

Whether these new characteristics derived from now lost Greek originals—more vigorous than those of Menand—or whether they stemmed from the established forms and tastes of burlesque traditions native to Italy, cannot be determined with any certainty. The latter is the more likely. The result, at any rate, is that Plautus' plays read like originals rather than adaptations, such is his witty command of the Latin tongue—a gift admired by Cicero himself. It has often been said that Plautus' Latin is crude and "vulgar," but it is in fact a literary idiom based upon the language of the Romans in his day.

The plots of Plautus' plays are sometimes well organized and interestingly developed, but more often they simply provide a frame for scenes of pure farce, relying heavily on intrigue, mistaken identity, and similar devices. Plautus is a truly popular dramatist, whose comic effect springs from exaggeration, burlesque and often coarse humour, rapid action, and a deliberately upside-down portrayal of life, in which slaves give orders to their masters, parents are hoodwinked to the advantage of sons who need money for girls, and the procurer or braggart soldier is outwitted and fails to secure the seduction or possession of the desired girls. Plautus, however, did also recognize the virtue of honesty (as in *Bacchides*), of loyalty (as in *Captivi*), and of nobility of character (as in the heroine of *Amphitruo*).

Plautus' plays, almost the earliest literary works in Latin that have survived, are written in verse, as were the Greek originals. The metres he used included the iambic six foot line (*senarius*) and the trochaic seven foot line (*septenarius*), which Menander had also employed. But Plautus varied these with longer iambic and trochaic lines and more elaborate rhythms. The metres are skillfully chosen and handled to emphasize the mood of the speaker or the action. Again, it is possible that now lost Greek plays inspired this metrical variety and inventiveness, but it is much more likely that Plautus was responding to features already existing in popular Italian dramatic traditions. The *Senarii* (conversational lines) were spoken, but the rest was sung or chanted to the accompaniment of double and fingered reed pipes. It could indeed be said that, in their metrical and musical liveliness, performances of Plautus' plays somewhat resembled musicals of the mid-20th century.

Plautus' original texts did not survive. Even by the time that Roman scholars such as Varro, a contemporary of Cicero, became interested in the playwright, only acting editions of his plays remained. These had been adapted, modified, cut, expanded, and generally brought up-to-date for production purposes. Critics and scholars have ever since attempted to establish a "Plautine" text, but 20th-century editors have admitted the impossibility of successfully accomplishing such a task. The plays had an active stage life at least until the time of Cicero and were occasionally performed afterward. Whereas Cicero had praised their language, the poet Horace was a more severe critic and considered the plays to lack polish. There was renewed scholarly and literary interest in Plautus during the 2nd century AD, but it is unlikely that this was accompanied by a stage revival, though a performance of *Casina* is reported to have been given in the early 4th century. St. Jerome, toward the end of that century, says that after a night of excessive penance he would read Plautus as a relaxation; in the mid-5th century, Sidonius Apollinaris, a Gallic bishop who was also a poet, found time to read the plays and praise the playwright amid the alarms of the barbarian invasions.

During the Middle Ages, Plautus was little read—if at all—in contrast to the popular Terence. By the mid-14th century, however, the Humanist scholar and poet Petrarch knew eight of the comedies. As the remainder came to light, Plautus began to influence European domestic comedy after the Renaissance poet Ariosto had made the first imitations of Plautine comedy in the Italian vernacular. His influence was perhaps to be seen at its most sophisticated in the comedies of Molière (whose play *L'Avare,* for instance, was based on *Aulularia*), and it can be traced up to the present day in such adaptations as Jean Giraudoux's *Amphitryon 38* (1929), Cole Porter's musical *Out of This World* (1950), and the musical and motion picture *A Funny Thing Happened on the Way to the Forum* (1963). Plautus' stock character "types" have similarly had a long line of successors: the braggart soldier of *Miles Gloriosus,* for example, became the "Capitano" of the Italian commedia dell'arte, is recognizable in Nicholas Udall's *Ralph Roister Doister* (16th century), in Shakespeare's Pistol, and even in his Falstaff, in Rostand's *Cyrano de Bergerac* (1897), and in Bernard Shaw's Sergius in *Arms and the Man* (1894), while a trace of the character perhaps remains in Bertolt Brecht's Eilif in *Mother Courage and Her Children* (1941). Thus, Plautus, in adapting Greek "New Comedy" to Roman conditions and taste, also significantly affected the course of the European theatre.

MAJOR WORKS. Twenty-one comedies (most dates uncertain) have survived: *Amphitruo* (*Amphitryon*); *Asinaria* (*The Comedy of Asses*); *Aulularia* (*The Pot of Gold*); *Bacchides* (*The Two Bacchuses*); *Captivi* (*The Captives*); *Casina; Cistellaria* (*The Casket Comedy*); *Curculio; Epidicus; Menaechmi* (*The Two Menaechmuses*); *Mercator* (*The Merchant*); *Miles Gloriosus* (*The Braggart Warrior*); *Mostellaria* (*The Haunted House*); *Persa* (*The Persian*); *Poenulus* (*The Little Carthaginian*); *Pseudolus* (first produced 191 BC); *Rudens* (*The Rope*); *Stichus* (first produced 200 BC); *Trinummus* (*Three Bob Day*); *Truculentus; Vidularia* (fragmentary; *The Tale of a Travelling Bag*).

There is an English translation of all the extant plays in the "Loeb Series" (1916–38) and a French translation in the "Budé Series" (1932–40). Several of the plays have been translated in the "Penguin Classics Series." Many other translations of specific plays are available.

BIBLIOGRAPHY. Full bibliography is in G.E. Duckworth, *The Nature of Roman Comedy,* pp. 447–464 (1952); a more recent but selective one may be found in Mason Hammond, Arthur M. Mack, and Walter Moskalew, *Plautus: Miles Gloriosus,* rev. ed., pp. 59–66 (1970). Still fundamental are the collections of ancient evidence and the discussions in Martin Schanz, 4th ed. by Carl Hosius, *Geschichte der römische Literatur I: Die römischen Literatur in der Zeit der Republik,* pp. 55–86 (1927); and the article "Maccius" by A.F. Sonnenberg in *Pauly-Wissowa Realencyclopädie,* vol. 14, col. 95–126 (1928). Useful is the briefer article "Plautus" by G.W. Williams in the *Oxford Classical Dictionary,* 2nd ed., pp. 843–844 (1970). In addition to Duckworth (above), a good account is in William Beare, *The Roman Stage,* 3rd ed. (1964). A standard text is that by M.W. Lindsay, 2 vol. (1904 and reprints). The Loeb edition with English translation by Paul Nixon, 5 vol. (1916–38 and reprints), unfortunately used the text of Friedrich Leo, 2nd ed. (1895–96).

play, in zoology, behaviour performed in the absence of normal stimuli or behaviour elicited by normal stimuli but not followed to the completion of the ritualized behaviour pattern. Play has been documented only among mammals and birds. Play is common among immature animals, apparently part of the process of learning adult behaviour. Much of the play of kittens and other young predators serves to develop hunting skills. The movements of a kitten following a ball or string prepare the animal for stalking prey; likewise leaping and jumping in play are preparation for springing after a bird in flight.

Adult animals also engage in play. Horses, cattle, and other hooved mammals sometimes run, chase each other, and kick up their heels for no obvious reason. Dogs have postural signals of mock aggression used to entice others into play fighting. In play all the elements of ritualized behaviour may be present, but they do not follow the pattern or sequence necessary to communicate serious intent.

Play and Pay (card game): *see* Fan-Tan.

playa, also called PAN, FLAT, or DRY LAKE, flat-bottom depression found in interior desert basins and adjacent to coasts within arid and semiarid regions, periodically covered by water which slowly filtrates into the ground water system or evaporates into the atmosphere, causing the deposition of salt, sand, and mud along the bottom and around the edges of the depression.

A brief treatment of playas follows. For full treatment, *see* MACROPAEDIA: Continental Landforms.

Playa (Spanish: shore or beach) is applied in the English-speaking world to a wide range of topographic depressions and desiccated lakes, but its nomenclature will vary according to individual depressions and regions of the world. Playas are called *shotts* or *sabkhas* in North Africa and Arabia, *kavirs* in Iran, *takyrs* in the Soviet Union, *solonchaks* in the Caspian Sea region, and pans in South Africa and Australia. In North America the terms salt flat, salt marsh, salt plain, and salina are used in reference to playas containing saline deposits, while a salt-free playa is sometimes called a clay pan, hardpan, or dry lake, and the term alkali flat is used for both saline and non-saline playas.

Playas found within interior drainage basins vary in size from tens of metres to tens of kilometres across. Coastal playas or saline flats are usually only a few hundred feet wide, but sometimes they may extend several hundred miles along a coastal plain with widths exceeding 18 mi (30 km). The majority of the approximately 50,000 playas in the world are small. Fewer that 1,000 exceed 25 sq mi (65 sq km) and fewer that 100 exceed 200 sq mi. Most small playas are almost circular in shape and the typical playa will have a length–width ratio of 2:1 or 3:1. Coastal playas will usually be elongated parallel to the shoreline, but the configuration of all playas will vary according to the local topography and climate. Playas can be distinguished from intermittent lakes by the amount of time water is contained in the depression. A depression in which water is present for less than one-fourth of the year should be called a playa. Perhaps the most famous playas are those of Lake Bonneville in Utah, where the almost horizontal surface is ideal, when dry, for automobile speed trials.

Playboy, U.S. monthly magazine for men, the first to feature female nudity and sexually oriented material in a sophisticated format. Famous for its photo features, the magazine combines nude photography with topical general articles and fiction that both are frequently of high quality. Its interviews with celebrities and other newsworthy persons have won wide attention. Founded by Hugh Hefner in 1953, the periodical emphasizes progressive sexual views. The "Playboy philosophy" it enunciates supports the view that man should maintain complete freedom in all things, including sex. It has had a significant influence on the sexual mores of the young U.S. middle-class male, and in format and approach has been widely imitated.

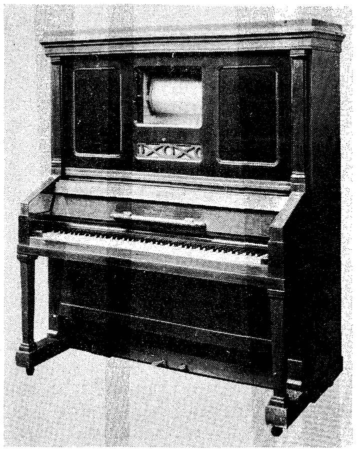
A list of the abbreviations used in the MICROPAEDIA *will be found at the end of this volume*

Player, Gary (Jim) (b. Nov. 1, 1935, Johannesburg), South African who was one of the world's best professional golfers in the post-World War II era. He was the third man (after Gene Sarazen and Ben Hogan, both of the U.S.) to win the four tournaments composing the modern golf Grand Slam.

In 1955 Player entered competition on the U.S. Professional Golfers' Association (PGA) circuit of tournaments, and in 1961 he was the leading winner of prize money on the circuit. His international record, unsurpassed by any golfer, was a tribute to his remarkable fitness and love of competition. He won the British Open (1959, 1968, 1974), the Masters (1961, 1974, 1978), the U.S. PGA (1962, 1972), and the U.S. Open (1965). He also won the South African Open 13 times, the Australian Open 7 times, and the World Series of Golf 3 times (1965, 1968, 1972). When he won the Masters in 1978 the span of his major championship victories covered three decades, longer than any previous golfer.

player piano, musical instrument equipped with a device for playing music automatically by pedals and hand levers. The original mechanism—the Pianola, patented in 1897 by a U.S. engineer, Edwin S. Votey—was placed in front of the keyboard. Music was notated in perforations on a paper roll that passed over a tracker bar. Pedals and levers controlled pneumatic devices that released air, moving hammers that struck the piano keys. Later the mechanism was built into the piano body. The pedals and levers made available a considerable range of dynamics and tempo.

In the early 20th century, some companies manufactured player-piano rolls that reproduced with considerable accuracy performances by distinguished figures, such as Alfred Cortot and Claude Debussy. The player piano also attracted composers, who could write pieces without concern for the limitations of the human hand. Such works include Stra-



Steinway-Welte player piano, 1910; in the British Piano and Musical Museum, Brentford, Middlesex, Eng.

vinsky's *Étude* for Pianola (1917) and Hindemith's *Toccata* for mechanical piano (1926).

Playfair, John (b. March 10, 1748, Benvie, Forfarshire, Scot.—d. July 20, 1819, Edinburgh), Scottish geologist and mathematician known for his explanation and expansion of ideas on uniformitarianism—the theory that the Earth's features generally represent a response to former processes similar in kind to processes that are operative today.

A professor of natural philosophy at the University of Edinburgh, Playfair was the first to propose that a river cuts its own valley and was also the first to recognize the transport role of glaciers. He wrote *Elements of Geometry* (1795), *Illustrations of the Huttonian Theory of the Earth* (1802), and *Outlines of Natural Philosophy* (1812–16).

Playford, John (b. 1623, Norwich, Norfolk, Eng.—d. November 1686?, London), English music publisher and bookseller whose popular and frequently expanded collection of music and dance steps remains the principal source of knowledge of English country dance steps and melodies. His book, *The English Dancing-Master* (1650, but dated 1651; critical ed., M. Dean-Smith, 1958), originally contained 104 dances and accompanying tunes set to the fiddle; its 18th and last edition (1728, published by John Young) held about 700. Many of the Playford dances were revived in the 20th century. Playford had established his business in London by 1648. He often included his own song and psalm music in his collections of music. His *Brief Introduction to the Skill of Musick*, a handbook on music theory and practice, went into many editions between 1654 and 1730 and was revised in 1694 by Henry Purcell. An elegy on Playford's death, "Gentle shepherds, you that know," by Nahum Tate, was set to music by Purcell.

Playford's son Henry Playford (1657–1709) continued the family business. His publications include two posthumous collections of music by Purcell.

playground, area especially designed for games. The incorporation of play areas in public and private pleasure grounds dates from early antiquity; a training ground for athletes was part of a complex in ancient Athens that included a public promenade and an open-air, informal assembly place. The most ambitious Roman gardens contained tracks for horse racing. Except for bowling greens and occasional accommodations for archery and pall-mall (a game played with a wooden ball and mallet), there was little provision for games in the average 17th- and 18th-century gardens. Formal open-air games took place on common ground, such as the village green or, if walls were needed, in churchyards and city streets. Not until the 19th century was it common to provide for games and to incorporate all open-air pastimes in one central area. In the 20th century there are public playgrounds for team games, such as baseball and cricket, and for children's play; and the private homeowner often arranges facilities in his own garden for tennis, bowls, croquet, and golf.

playing card, one of a set of cards that are numbered or illustrated (or both) and are used for playing games, for education, for divination, and for conjuring. Modern cards are

(Top) The *avatāra* and ten of Paraśurāma, round, painted ivory Indian cards, probably from Deccan, 18th century

divided into four suits—spades, hearts, diamonds, and clubs—with 13 cards in each suit. The set of 52 cards together is known variously as the pack or the deck, the term used in Shakespeare's day. Two jokers, bearing the image of a medieval court jester, are usually included with the standard 52-card deck, although they are not always used in play.

Though where and when cards originated is uncertain, China seems the most likely place, and the 7th to the 10th century the earliest probable time. An Indian origin has been suggested by the resemblance of symbols on some early European decks to the ring, sword, cup, and baton classically depicted in the four hands of Hindu statues. Yet another theory

Deuce of bells from a German deck, Dresden, 1848; bells are equivalent to diamonds

By courtesy of the Deutsches Spielkarten-Museum, Leinfelden-Echterdingen, Zweigmuseum des Wurttembergischen Landesmuseums Stuttgart, Federal Republic of Germany

is that both cards and chess are derived from ancient divinatory procedures used by primitive peoples.

Nor is it known how cards were introduced to Europe. Some early decks had symbols resembling the Chinese markings and may have been taken back by a Venetian, possibly Niccolò Polo or his more famous son, Marco, during travels to and from China in the latter half of the 13th century. Another speculation is that cards may have been brought from Arabia by the Gypsies, but the Gypsies did not reach western Europe in appreciable numbers until after cards had become firmly established. If an Arab origin is to be sought, the Saracen invasion of Sicily or the Moorish conquest of Spain could provide a link. The Spanish word for cards, which is *naipes,* and an earlier Italian word, which is *naibi,* are probably of Arab origin.

There are references to cards in Italy from 1299; in Spain, from as early as 1371; in the Low Countries, from 1379; and in Germany, from 1380. A French manuscript of the early 14th century contains a reference to cards, and in 1392 the registers of the Chambre des Comptes of Charles VI recorded the purchase of three games of cards "in gold and diverse colours." In England by 1465 the use of cards was well enough established for manufacturers to petition for protection against imports.

Cards may have first reached the Americas with Columbus, and they became firmly established there with the arrival of the English, French, and Dutch colonists. Cards are now played throughout the world.

The 52-card French deck, now standard throughout the world, evolved from the numbered cards of the Tarot (*q.v.*) deck. The deck, in usual descending order of rank, consists of an ace, king, queen, jack (formerly knave), and nine numerals (10 to 2) in each of four suits. A German deck of 32 cards and a Spanish deck of 40 also evolved, but modern games requiring a short deck are usually played by removing cards from a standard deck.

The suits had different names and often different symbols in the various countries. The English adopted the French symbols: the French *pique* ("pike") looked like a spade to the English; the *carreau* ("square") became the English diamond, the *trèfle* ("trefoil") became the English club, and the *coeur* ("heart") remained heart. Other traditional suit designations are shown in the Table. The spread of games such as Whist and Piquet, and later Contract Bridge, made the 52-card deck current among card players throughout the world.

The making of cards has been closely linked with the development of printing. The earliest cards were hand-painted, but it would appear that German production in the 15th century almost certainly was so large as to mean that wood-block printing must have been employed. German cardmakers may, in fact, have been the first wood-block engravers in Europe.

The great diversity of early decks gradually lessened, influenced by 15th-century French exporters, whose simple designs became widely popular. Modern variations of those designs may be found primarily in the design of the court cards (kings, queens, and jacks); those in English decks, for instance, show figures dressed in the style of Henry VII. The traditional superstition of gamblers and the more modern tendency to preserve fragments of the past have tended to prevent change, including official attempts in some countries to provide proletarian substitutes for the court cards.

The standard modern card measures about $2\frac{1}{2} \times 3\frac{1}{2}$ inches (6×9 cm) and is double-headed to aid recognition, with indices at two opposite corners. The backs are printed with identical designs, patterns, or pictures. A full deck, including two jokers, is printed on pasteboard consisting of two sheets gummed together with black paste to ensure opaqueness. The spades and clubs normally are printed in black, the hearts and diamonds in red. Each card is stamped out with a die and simultaneously given a knife edge; sometimes the edges are lacquered. Almost invariably the manufacturer's seal is affixed to the wrapped deck.

Governments have often found cards to be a useful source of revenue. In 1615 James I of England granted letters patent for a duty on imports, and in 1628 Charles I taxed manufacturers at a rate gradually increased to the considerable sum of half-a-crown per pack. After 1765 the tax paid was shown in the design of the ace of spades, printed officially by the commissioner of stamps. The heavy impost caused a boom in second-hand sales and a traffic in forged aces of spades, but since 1862 the tax has been moderate. In some countries, however, manufacture is a state monopoly. The high taxes imposed in Austria led to the printing of oversized cards, which were trimmed and cleaned when their edges became soiled. High taxes also encouraged the invention in the 1930s of playing cards printed on plastic, which far outlasted those printed on pasteboard.

Traditional suit designations

English	French	German	Spanish	Italian
spade	pique	Grün ("leaf")	espada	spada ("sword")
heart	coeur	Herz	copa ("cup")	coppa ("cup")
diamond	carreau	Schelle ("bell")	oro ("gold")	denaro ("money")
club	trèfle	Eichel ("acorn")	basto	bastone ("rod")

Playing Cards, Master of the (fl. *c.* 1430–50), anonymous German artist who is one of the most important of the early engravers in the Rhineland. He is known for a set of playing cards (60 remain) that are distinguished for the manner in which the technique of soft-ground engraving has been handled, as well as for an exquisite use of line and the realistic observation evident in the human figures, plants, and animals that have been depicted. Some of the decorative devices employed have been stylistically related to those used by the printer Johannes Gutenberg.

pleached alley, garden path, on each side of which living branches have been intertwined in such a way that a wall of self-supporting living foliage has grown up. To treat each side of a garden walk, or alley, with pleaching and thus make a secluded walk was a favourite device of the 16th and 17th centuries. Although

Pleached alley, Schönbrunn Palace, Vienna

Mary Bacon

most pleaching is done by gardeners, it can also occur naturally. Maples, sycamores, and lindens are commonly pleached.

pleading, in law, presentation by a litigant in a lawsuit setting forth the facts upon which he claims legal relief or challenges the claims of his opponent. A pleading includes both written and oral claims and counterclaims but not the evidence by which the litigant intends to prove his case.

After both the plaintiff and the defendant have made their initial statements, there may be further proceedings, such as a reply, a rejoinder, and even a surrejoinder. It is open to either party to apply to strike out his opponent's pleading, or part thereof, on the grounds that it discloses no cause of action or of defense or on certain other grounds. It is likewise open to either party to apply for further particulars of his opponent's pleading, and the court may order that these be furnished.

The rules make provision for the joinder of other parties whose participation is considered necessary by the court (*see* joinder and impleader). Thus, a defendant under English law may issue a notice—called a third-party notice—containing a statement of the nature of the claim made by him against a third party, relevant to the original subject matter of the action or of issues to be determined. A third party has the same rights against the defendant as the latter has against the plaintiff; he may bring in a fourth party, who may bring in a fifth, and so on.

Whereas pleadings in common-law countries tend to be formal, those in civil-law countries are very informal. In England, for example, the parties, following stated forms, alternately present written statements until all issues of law and fact in question have been brought out. The aim is to separate the legal issues from the factual ones so that the latter, clearly delineated, can be given to a jury.

In civil-law countries, where juries do not exist except in certain criminal cases, it is not necessary to make an early delineation of factual and legal issues. Oral pleadings are stressed; written pleadings are only preparatory to the main hearing in open court, where allegations are clarified and proofs offered.

pleasing fungus beetle, any member of any of the more than 1,400 species of the insect family Erotylidae (order Coleoptera). Some bore into the stems of plants or wood rather than feed on fungi.

Most species in this widely distributed family are tropical. They range in size from 3 to 20 millimetres (up to 4/5 inch) and are often brightly coloured with orange, red, and black patterns.

plebeian, also spelled PLEBIAN, Latin PLEBS, plural PLEBES, member of the general citizenry in ancient Rome as opposed to the privileged patrician class. The distinction was probably originally based on the wealth and influence of certain families who organized themselves into patrician clans under the early republic, during the 5th and 4th centuries BC. Plebeians were originally excluded from the Senate and from all public offices except that of military tribune. Before the passage of the law known as the Lex Canuleia (445 BC), they were also forbidden to marry patricians. Until 287 BC the plebeians waged a campaign (Conflict of the Orders) to have their civil disabilities abolished. They organized themselves into a separate corporation and withdrew from the state on perhaps as many as five or more critical occasions to compel patrician concessions; such a withdrawal was termed a *secessio.* The plebeian corporation held its own assemblies (*concilia plebis*), elected its own officials (tribunes and plebeian aediles), who were usually more well-to-do plebeians, and kept its own records. An important step in the plebeian campaign was the achievement of inviolability of their tribunes.

The Conflict of the Orders was finally resolved in the final secession of 287 BC when a plebeian dictator, Quintus Hortensius, was appointed. He instituted a law (Lex Hortensia) making *plebiscita* (measures passed in the plebeian assembly) binding not only on plebeians but also on the rest of the community. In the later republic and under the empire (after 27 BC), the name plebeian continued to be used in the sense of commoner.

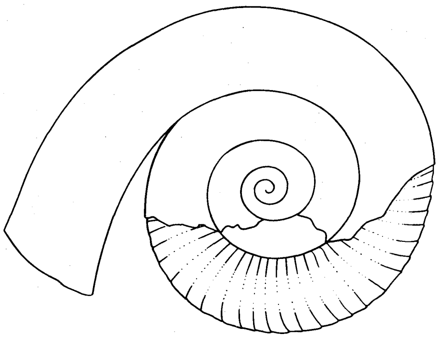
plebiscite, a vote by the people of an entire country or district to decide on some issue, such as choice of a ruler or government, option for independence or annexation by another power, or a question of national policy.

In a plebiscite, voters are asked not to choose between alternate regimes or proposals but to confirm or reject the legitimacy of a certain form of government or course of action. Plebiscites are seen as a way for a government to go directly to the people, bypassing intermediaries such as political parties. After the Revolution of 1789, the plebiscite was popular in France because it was seen as an expression of popular sovereignty. In 1804, a plebiscite made Napoleon emperor.

Plebiscites have been used to establish political boundaries when it is a question of nationality. For example, in 1935, the Saar chose to remain part of Germany rather than become part of France.

Because a plebiscite offers a way of claiming a popular mandate without officially sanctioning an opposition party, totalitarian regimes also use them to legitimize their power.

Plectoceras, extinct genus of small marine nautiloid cephalopods, forms related to the modern pearly nautilus, that had a coiled shell composed of a series of chambers; *Plectoceras* is an Ordovician form (between 430,000,000 and 500,000,000 years old). The junctures between successive chambers of *Plectoceras* were simple in character.



Plectoceras occidentale

Plectomycetes, name often given fungi constituting a series of the class Ascomycetes (sac fungi) within the division Mycota. Its more than 2,500 species produce saclike structures (asci) containing ascospores in either a closed fruiting body (ascocarp) or spore balls. Economically important genera include *Ceratocystis,* which includes the agents of Dutch elm disease and oak wilt, and *Trichophyton,* species of which cause skin disease in animals including man.

Pledge of Allegiance to the Flag of the United States of America, pledge to the flag of the United States. It was first published in the juvenile periodical *The Youth's Companion* on Sept. 8, 1892, in the following form: "I pledge allegiance to my Flag and the Republic for which it stands; one nation indivisible, with liberty and Justice for all." The words "the flag of the United States of America" were substituted for "my Flag" in 1924, and the pledge was officially recognized by the U.S. government in 1942. In 1954, at Pres. Dwight D. Eisenhower's urging, the Congress legislated that "under God" be added, making the pledge read:

> I pledge allegiance to the flag of the United States of America and to the Republic for which it stands, one nation under God, indivisible, with liberty and justice for all.

A controversy arose concerning the authorship of the pledge of 1892. Claims were made on behalf of both James B. Upham, one of the editors of *The Youth's Companion,* and Francis Bellamy, an assistant editor. In 1939 a committee of the U.S. Flag Association ruled in favour of Bellamy, and a detailed report issued by the U.S. Library of Congress in 1957 supported the committee's ruling.

According to the legislation of 1954, one is supposed to stand upright, remove any headdress, and place the right hand over the heart while reciting the pledge.

Plehve, Vyacheslav Konstantinovich, Plehve also spelled PLEVE (b. April 20 [April 8, old style], 1846, Kaluga province, Russia—d. July 28 [July 15, O.S.], 1904, St. Petersburg), Russian imperial statesman whose efforts to uphold autocratic principle, a police-bureaucratic government, and class privilege resulted in the suppression of revolutionary and liberal movements as well as minority nationality groups within the Russian Empire.

Appointed director of the police department in the Ministry of the Interior after the assassination of Emperor Alexander II (1881), Plehve became head of the Imperial Chancellery (1894) and acting minister and state secretary for the Grand Duchy of Finland (1899). In 1902 he became minister of interior. From these positions he obstructed liberal local governmental (*zemstvo*) activity, harshly pursued Russification policies, particularly against the Armenians and the Finns, and encouraged anti-Semitic propaganda that led to a violent pogrom (April 1903) at Kishinev, now in the Moldavian S.S.R. To assuage labour discontent, he backed police-controlled patriotic labour unions. He supported the Russian policy in Korea that provoked conflict with Japan. Plehve was assassinated by a member of the Socialist Revolutionary Party.

Pléiade, La, group of seven French writers of the 16th century, led by Pierre de Ronsard, whose aim was to elevate the French language to the level of the classical tongues as a medium for literary expression. La Pléiade, whose name was taken from that given by the ancient Alexandrian critics to seven tragic poets of the reign of Ptolemy II Philadelphus (285–246 BC), also included Joachim du Bellay, Jean Dorat, Jean-Antoine de Baïf, Rémy Belleau, Pontus de Tyard, and Étienne Jodelle.

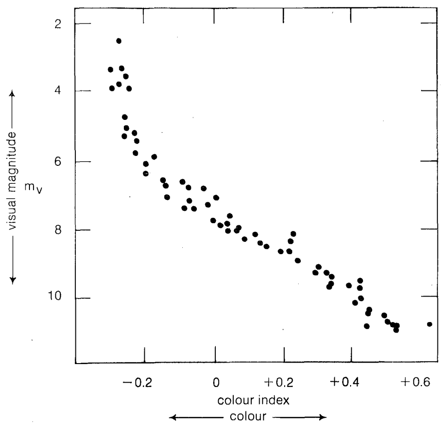
The principles of La Pléiade were authoritatively set forth by du Bellay in *Défense et illustration de la langue françoise* (1549), a document that advocated the enrichment of the French language by discreet imitation and borrowing from the language and literary forms of the classics and the works of the Italian Renaissance—including such forms as the Pindaric and Horatian ode, the Virgilian epic, and the Petrarchan sonnet. Du Bellay also encouraged the revival of archaic French words, the incorporation of words and expressions from provincial dialects, the use of technical terms in literary contexts, the coining of new words, and the development of verse forms new to French literature.

The writers of La Pléiade are considered the first representatives of French Renaissance poetry, one reason being that they revived the alexandrine verse form (composed of 12-syllable lines, rhyming in alternate masculine and feminine couplets), the dominant poetic form of the French Renaissance. The members of La Pléiade are sometimes charged with attempting to Latinize the French language and are criticized for inspiring the slavish imitation of the classics that occasionally occurred among their followers.

Pleiades, in Greek mythology, the seven daughters of the Titan Atlas and the Oceanid Pleione: Maia, Electra, Taygete, Celaeno, Alcyone, Sterope, and Merope. They all fell in love with gods (except Merope, who loved a mortal) and were the mothers of gods.

The Pleiades eventually formed a constellation. One myth recounts that they all killed themselves out of grief over the death of their sisters, the Hyades. Another explains that after seven years of being pursued by Orion, a Boeotian giant, they were turned into stars by Zeus. Orion became a constellation, too, and continued to pursue the sisters across the sky. The faintest star of the Pleiades was thought to be either Merope, who was ashamed of loving a mortal, or Electra, grieving for Troy, her son's city.

Pleiades (catalog number M 45), open cluster of stars in the zodiacal constellation Taurus, about 400 light-years from the solar system. It contains a large amount of bright nebulous material and several hundred stars, of which six or seven can be seen by the unaided eye and have figured prominently in the myths and literature of many cultures. In Greek mythology the Seven Sisters (Alcyone, Maia, Electra, Merope, Taygete, Celaeno, and Sterope, names now assigned to individual stars), daughters of Atlas and Pleione, were changed into the stars. The heliacal (near dawn) rising of the Pleiades in spring of the Northern Hemisphere has marked from ancient times the opening of seafaring and farming seasons, as the morning setting of the group in autumn signified the seasons' ends. Some South American Indians use the same word for "Pleiades" and "year."



Colour-luminosity array of the Pleiades

The cluster was first examined telescopically by Galileo, who found more than 40 members; it was first photographed by Paul and Prosper Henry in 1885.

Pleiku, town, central Vietnam, located in the central highlands. The town has a hospital, a commercial airfield, and several airbases that are a legacy of its strategic importance during the later stages of the Vietnam War (1965–75). It lies in a mountainous region inhabited mainly by Bahnar and Jarai peoples, sometimes referred to as Montagnards (French: "Mountain Dwellers"). Tea, coffee, handicrafts, timber, and upland rice are the main products of the region. The town is at the crossroads of several upland highways, including the road north to Cong Tum and the road west to Stœng Trêng, Kampuchea (Cambodia). Pop. (latest est.) 34,867.

plein air painting, in its strictest sense, the practice of painting landscape pictures out-of-doors; more loosely, the achievement of an intense impression of the open air (French: *plein air*) in a landscape painting.

Until the time of the painters of the Barbizon school in mid-19th-century France, it was normal practice to execute rough sketches of landscape subjects in the open air and produce finished paintings in the studio. Some of the Barbizon painters continued this practice, and not until the late 1860s, with the work of Claude Monet, Pierre-Auguste Renoir, and Camille Pissarro, the leaders of Impressionism, did painting out-of-doors become more popular. From 1881 Monet, in his efforts to capture the true effects of light on the colour of landscape at any given moment, began to carry several canvases at once into the out-of-doors. On each he began a painting of the same subject at a different time of day; on subsequent days, he continued to work on each canvas in succession as the appropriate light appeared.

Pleione, star in the Pleiades, thought to be typical of the shell stars, so called because in their rapid rotation they throw off shells of gas. In 1938 sudden changes in the spectrum of Pleione were attributed to the ejection of a gaseous shell, which by 1952 had apparently dissipated. Pleione is a blue-white star of about the fifth magnitude. Some astronomers conjecture that it may have been brighter in the past; it would then have made a seventh bright star in the Pleiades cluster, which is named for seven mythological sisters.

Pleistocene Epoch, the earlier and major of the two epochs that constitute the Quaternary Period of Earth history, and the time period during which a succession of glacial and interglacial climatic cycles occurred. The Pleistocene began about 1.6 million years ago and ended roughly 10,000 years ago. It is preceded by the Pliocene Epoch of the Tertiary Period and is followed by the Holocene Epoch.

A brief treatment of the Pleistocene Epoch follows. For full treatment, *see* MACROPAEDIA: Geochronology.

Originally, the Pleistocene Epoch was envisaged as covering the period of the Great (or Quaternary) Ice Age. The onset of this ice age, however, was marked by a sharp climatic cooling dated about 2,500,000 years ago, and it is now placed within the Pliocene Epoch. Additionally, the Holocene Epoch is now regarded as the latest interglacial stage of the ice age. Some authorities would like to extend the Pleistocene up to the present time, but others feel that the present subdivision of the Quaternary Period into Pleistocene and Holocene epochs is justified by the much-intensified role of man during the latter epoch.

At the height of the Pleistocene glacial ages, more than 30 percent of the land area of the world was covered by glacial ice. At present only about 10 percent is so covered, and much of the ice is in the higher latitudes. The same was probably true for the interglacial stages. Some differences between the present-day conditions and the conditions of at least one of the interglacials are apparent, however, from comparison of fossil faunal forms with the animals of today.

Glacial cirques (theatre-like valley heads fashioned by the action of snowfields at the heads of individual glaciers in mountainous terrain) bear a rough general relation to the snow line (lower limit of perennial snow). Through measurements of the altitudes of cirques in many parts of the world, the approximate position of the snow line at the height of the latest glaciation has been determined. Wherever measured, this former snow line is lower than the snow line of today—at the equator as well as in polar latitudes. The subpolar climate belts were shifted toward the equator during the glacial episodes. This shift may have amounted to as much as 15° of latitude for the boreal, or northern, belt but somewhat less for the warmer belts.

The pluvial conditions of the dry regions of middle and low latitudes support this conclusion in that they appear to show equatorward shifting of the middle-latitude belts of rain-bearing cyclonic storms. Fossil flora and fauna likewise indicate southward shifting of the cold northern climatic zone through many degrees of latitude.

The areas within the Northern Hemisphere that were formerly glaciated include the mountainous western part of North America. This region was occupied by a vast complex of glaciers that, throughout most of the Canadian sector, formed a nearly continuous covering of ice. The vast area from the Atlantic to the Rocky Mountains, Canada and the northern part of the United States (as far south as New York City; Cincinnati, Ohio; Carbondale, Ill.; St. Louis, Mo.; Kansas City, Mo.; and Pierre, S.D.) were buried beneath the Laurentide Ice Sheet that had its source in Canada. This enormous continental glacier is thought to have originated on the Labrador-Ungava plateau and on the Arctic islands of Canada. Greenland and Iceland were almost entirely ice-covered. Nearly half of Europe—from the North Cape off the north coast of Norway south to Kiev on the banks of the Dnepr—was covered by the Scandinavian Ice Sheet. Much of Siberia was overspread by mountain glaciers and by the Siberian Ice Sheet on its northwestern plain. The Alps, the Caucasus, and the Pyrenees in Europe and most of the high mountains on other continents carried glaciers of varying dimensions. The Antarctic continent was even more nearly completely ice-covered than now, and the glaciers of the southern Andes spread westward to tidewater in Chile and eastward onto the pampas of Argentina. The highest mountains of Hawaii, Japan, and New Guinea supported valley glaciers.

The effects of the glacial climate and continental ice sheets included the fall and rise of the sea level throughout the world. The moisture that formed glaciers came from the sea, resulting in the lowering of the sea level. Under warming climates the existing glaciers melted and large volumes of meltwater were returned to the sea, thereby raising its level. The alternation of glacial and interglacial episodes, therefore, resulted in fluctuation of the sea level through a range of more than a hundred metres, including levels both somewhat higher and much lower than today. Glaciation also caused extensive warping of the Earth's crust. The crust yields to excessive loading such as that induced by great ice sheets. In the substratum below the rocky crust, plastic flow transfers rock material outward away from the weighted area, causing basinlike subsidence. When the ice sheet melts, the load is removed,

"Monet Painting in His Garden," oil painting by Pierre-Auguste Renoir, 1873; in the Wadsworth Atheneum, Hartford, Conn.

By courtesy of the Wadsworth Atheneum, Hartford, Conn., bequest of Anne Parrish Titzell causing the crust to rebound. Such uplift is initially rapid, but it decreases with time. The eastern area of Hudson Bay is known to have been uplifted by over 300 m (985 feet) since the last major glaciation.

In the dry regions in low and middle latitudes on all the continents, there is impressive evidence both of former lakes where none now exist and of the formerly much larger size of existing lakes. A good example of the latter is Lake Bonneville, the predecessor of the present-day Great Salt Lake in Utah in the western United States. At its highest stage some 15,000 years ago during the last glaciation, Lake Bonneville covered an area of approximately 51,000 square km (19,700 square miles) and was about 370 m (1,215 feet) deep.

A conspicuous effect of the glacial climates in areas that lay a short distance beyond the ice sheets is the effect of frost heaving and solifluction. Solifluction is the slow creeping of soil, even on gentle slopes, as a result of freezing and thawing. It takes place today in Arctic and Antarctic regions and on high mountain summits in lower latitudes. The effects of solifluction in producing contortion of stratification and the patterned arrangements of stones resulting from frost-heaving of the soil are distinctive.

The flora and fauna of the Pleistocene began to resemble those of today. Angiosperms (flowering plants), particularly the deciduous forms, proliferated in the temperate and colder regions. New groups of land mammals appeared in Europe during the early Pleistocene; these included true elephants, zebrine horses, and cattle. Later in the epoch, there emerged various "Arctic" mammalian forms, such as reindeer, musk-oxen, and lemmings, followed by woolly mammoths, woolly rhinoceroses, and moose. North American fauna of the early and middle Pleistocene was quite similar. It included a large number of immigrants from Asia, notably mammoths, caballine horses, antelopes, and many rodents. By the late Pleistocene, bison, skunks, and bats appeared on the scene.

Among the significant mammals that evolved during the Pleistocene were humans. *Homo erectus,* usually considered to be the direct ancestor of modern humans, had appeared in Africa at the outset of the Pleistocene and became extinct late in the epoch. By the mid-Pleistocene, *Homo sapiens,* the species of modern humans, evolved in Africa and Europe. *H. sapiens* spread to Asia and the Americas before the end of the epoch.

The striking difference between the present-day fauna of large terrestrial mammals and the far richer fauna that existed at the height of the last glaciation is the direct result of mass extinctions. In North America more than 30 genera of large mammals became extinct within a span of roughly 2,000 years during the late Pleistocene. The number in Eurasia was considerably smaller, as was the case in Africa and South America. The extinctions involved not only large mammalian forms but also large flightless birds (*e.g.,* in New Zealand). Of the many causes that have been proposed by scientists for these faunal extinctions, the two most likely are changing environment with changing climate, and the disruption of the ecological pattern by early humans.

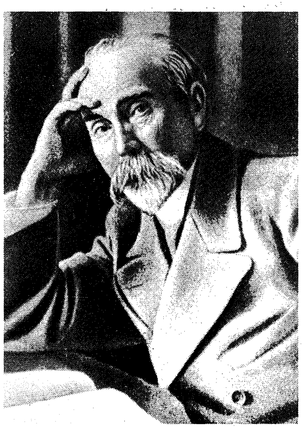
Plekhanov, Georgy Valentinovich (b. Dec. 11 [Nov. 29, Old Style], 1856, Gudalovka, Russia—d. May 30 [May 17], 1918, Terioki, Fin.), Marxist theorist, the founder and for many years the leading exponent of the Marxist movement in Russia. A Menshevik, he opposed the Bolshevik seizure of power in Russia in 1917 and died in exile.

Early life. Plekhanov was born into a family of the minor gentry. In 1873, after completing his studies at the Voronezh Military Academy, he enrolled in St. Petersburg's Konstantinovskoe Military School, with the intention of becoming an army officer.

He soon transferred to the Mining Institute and then, during his second year there, abandoned his studies to devote himself entirely to a populist revolutionary movement. Although this movement aimed to foment a peasant upheaval and to establish an agrarian socialist society, Plekhanov's activity involved him particularly with urban factory workers. After becoming a leader of the populist organization Land and Freedom in 1877, he engaged in underground political agitation. His writings appeared in Land and Freedom's publication of the same name; some of them showed Marxist influence. When Land and Freedom turned increasingly to terrorist methods, Plekhanov formed an antiterrorist splinter group to continue mass agitation. This faction was, however, short-lived, and in 1880 Plekhanov went abroad to avoid arrest. He did not return to Russia until 1917.

Formulation of Russian Marxism. For the greater part of his exile, Plekhanov resided in Geneva. In 1883, with several friends, he established the first Russian Marxian revolutionary organization, Liberation of Labour. In two major works, *Socialism and Political Struggle* (1883) and *Our Differences* (1885),



Plekhanov
Sovfoto

he launched a destructive critique of populism and laid the ideological basis of Russian Marxism. Russia, he argued, had been caught up in a capitalistic development that was altering its social structure and creating the conditions for the overthrow of Russian autocracy and the establishment of a bourgeois-democratic regime. The Marxists, according to Plekhanov, were obliged to organize the emerging industrial proletariat for the struggle against autocracy. After its overthrow further capitalistic development would multiply the numbers of the proletariat; and, under the leadership of a social-democratic labour party, the working class would ultimately liberate itself through a socialist revolution. This two-phase revolutionary scheme lay at the centre of Russian Marxian thought through several decades.

During the 10 years or so after the publication of *Socialism and Political Struggle,* Plekhanov's group produced a mass of socialist literature, but the Marxists remained isolated from the Russian working class. Toward the mid-1890s, however, after a renewal of antigovernment activity, the group won some notable followers, including Vladimir Lenin. Revolutionaries from the intelligentsia established relationships with workingmen to promote labour struggles against management. Plekhanov and his friends joined with these groups, whose activities culminated in 1898 in the formation of the Russian Social Democratic Workers' Party.

In the 1890s Plekhanov continued his polemics against the populists, most importantly with his book *On the Development of the Monistic Conception of History.* In 1898 he began publishing a series of tracts defending Marxian orthodoxy from those who proposed modifications or deviations. His principal targets were the reformist revisionism propounded by the German Social Democrat Eduard Bernstein, and a Russian tendency called "economism," which purportedly deprecated the importance of the direct political struggle and, rather, encouraged efforts to improve the position of the working class through labour pressure on the factory owners.

Break with Lenin. These campaigns were waged in concert with Lenin and some others, who, in 1900, had joined hands to publish the militant journal *Iskra* ("The Spark"). By 1903 their foes in the Russian movement had apparently been routed, and the second congress of the Russian Social Democratic Workers' Party was held. Unexpectedly, a controversy over the character of the party split the congress into what became known as the Bolshevik and Menshevik factions. Plekhanov initially sided with Lenin, the Bolshevik leader, but soon drew away and joined the Mensheviks in attacks upon him. For the remainder of his political life, and especially between 1906 and 1914, Plekhanov strove in vain to reunite the party.

In the last two decades of his life, Plekhanov was deeply absorbed in philosophical, artistic, literary, and historical studies. In all these fields he made significant contributions. But he did not completely retire from political life. A prominent member of the Second International, he assumed a "defeatist" stance toward his country in the Russo-Japanese War of 1904–05. By contrast, he supported the Entente during World War I, as he believed that the victory of German militarism would unquestionably spell disaster for the progressive workers' movement in Russia and elsewhere.

The Revolution of 1905 tested the revolutionary scheme Plekhanov had devised in the 1880s and found it wanting. The bourgeoisie did not act as he had anticipated they would. The peasantry, whose role he had underestimated, proved to be a potent revolutionary force. Yet he did not modify his theory in any fundamental respect. His influence declined noticeably between the two revolutions.

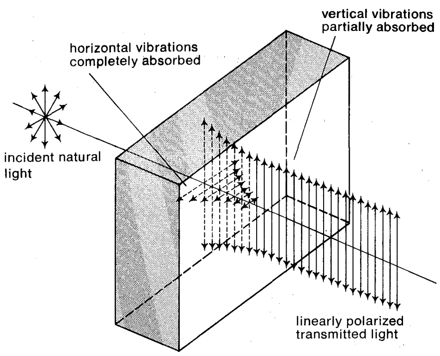
In 1917 Plekhanov greeted the February upheaval as the long-awaited "bourgeois" revolution. Returning to Russia in 1917, he urged continuation of the war to victory. The soldiers heeded him no more than did the peasants and workers whom he urged to subordinate their political demands to the more pressing need for national survival. Though critical of the Provisional Government, he supported many of its key policies. He was impotent to stop the Bolsheviks' march to power, and as a consequence of his attacks on them he was harassed by overzealous Red Guards as "an enemy of the people." (S.H.B.)

BIBLIOGRAPHY. For biographical information, see Samuel H. Baron, *Plekhanov: The Father of Russian Marxism* (1963).

Plenty, Bay of, bay of the South Pacific Ocean, eastern North Island, New Zealand. About 100 miles (160 km) wide, it extends along a narrow lowland strip from Waihi Beach eastward to Opotiki. The Rangitaiki and Whakatane rivers empty into the bay, the largest islands of which are White and Motiti. Matakana Island shelters Tauranga Harbour to the west.

The Bay of Plenty was named in 1769 by Captain James Cook, in recognition of the generous provisions and water received from Maoris living along its shore. Principal settlements are Mount Maunganui, Maketu, Matata, Whakatane, and Opotiki. The region supports dairy and sheep farming.

pleochroism (from Greek *pleiōn,* "more," and *chrōs,* "colour"), in optics, the selective absorption in crystals of light vibrating in different planes. Pleochroism is the general term for both dichroism, which is found in uniaxial crystals (crystals with a single optic axis), and trichroism, found in biaxial crystals



Plane-polarized light transmitted by a dichroic crystal
From F.W. Sears, *Optics*

(two optic axes). It can be observed only in coloured, doubly refracting crystals. When ordinary light is incident on a crystal exhibiting double refraction, the light is split into two polarized components, an ordinary ray and an extraordinary ray, vibrating in mutually perpendicular planes. A dichroic substance such as tourmaline transmits only the extraordinary ray, having absorbed the ordinary ray (*see* illustration).

When a ray of unpolarized (ordinary) light falls on a dichroic uniaxial crystal, any given wavelength will be absorbed differently according to which plane it is vibrating in, except along the optic axis for which there is no distinction between an ordinary ray and an extraordinary ray. Thus, the dichroic crystal will appear to have one colour in the direction of the optic axis and a different one at other angles. A biaxial crystal, one having two optic axes, will exhibit trichroism, in which three colours, sometimes called face colours, may be observed. As an example, in the crystal cordierite, when white light travels through the crystal parallel to one of the three crystal axes, either violet, blue, or yellow light will be absorbed. If a cube is cut having the crystal axis for edges, the three residual colours will be mixtures of blue plus yellow, violet plus yellow, and violet plus blue.

A pleochroic halo is a spherical shell of colour produced around a radioactive impurity included in a mineral. Such a shell—observed as a ring, or halo, if the specimen is cleaved along a plane passing through the sphere—is believed to represent a region in which the crystal structure has been modified by the absorption of the energy of alpha particles emitted by the radioactive elements. Because most of the energy of an alpha particle is absorbed at the end of its path length in a mineral, these colour centres are produced most intensely around the inclusion. Pleochroic halos are commonly found in rock-forming minerals—for example, biotites, fluorites, and amphiboles. The most common inclusions are the minerals zircon, xenotime, apatite, and monazite.

The distance of the rings from the central radioactive inclusion depends upon the range of the alpha particles. Consequently each ring may be identified with alpha emission by a specific element.

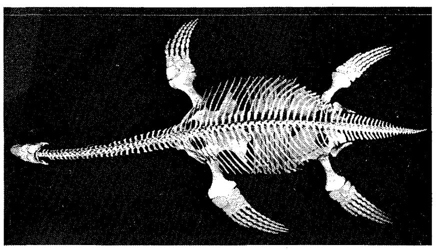
pleomorphism, the existence of irregular and variant forms in the same species or strain of microorganisms, a condition analogous to polymorphism in higher organisms. Pleomorphism is particularly prevalent in certain groups of bacteria and in yeasts, rickettsias, and mycoplasmas and greatly complicates the task of identifying and studying them.

Consult the INDEX *first*

plesiosaur, also called PLESIOSAURUS, plural PLESIOSAURI (genus *Plesiosaurus*), any of a group of extinct long-necked, marine reptiles that are found as fossils in rocks of the Late Triassic through the Late Jurassic epochs (230 to 144 million years old). The plesiosaur had a wide distribution throughout the Eastern Hemisphere and also may be represented in South American deposits. Related forms known from North America and elsewhere persisted until the end of the Cretaceous Period (66.4 million years ago).

The plesiosaur was about 4.5 m (15 feet) long, with a broad and flat body and relatively short tail. The neck was long and flexible. The nostrils were far back near the eyes, and the palate was almost solid. Long, sharp teeth were present in the jaws; the plesiosaur probably fed by swinging its head from side to side through a school of fish. The plesiosaur apparently was able to employ its large, paddle-like limbs to swim backward or forward or even to rotate itself about the body axis.

Early in their evolutionary history, the plesiosaurs split into two main groups: pliosaurs, the short-necked forms, in which the neck was short and the head elongated; and elasmosaurs, in which the head remained relatively small and the neck assumed snakelike proportions and became very flexible. The late evolution of plesiosaurs was marked by a great increase in size. *Kronosaurus,* an Early Cretaceous pliosaur from Australia, was about 12 m (40 feet) long; the skull alone was about



Cryptocleidus, showing dorsal aspect of a plesiosaur skeleton
By courtesy of the American Museum of Natural History, New York

3.7 m (12 feet) long. *Elasmosaurus* had as many as 76 vertebrae in its neck and reached a length of about 13 m (43 feet), fully half of which consisted of the head and neck.

Plessis-Marly, Philippe de Mornay, seigneur du (lord of): *see* Mornay, Philippe de.

Plessner, Helmuth (b. Sept. 4, 1892, Wiesbaden, Ger.—d. June 12, 1985, Göttingen, W.Ger.), German philosopher credited with establishing European philosophical anthropology, the study of the nature of individuals through their experiences. In his theory of existence based on a balance between an "inner" and an "outer" self, he differentiated humans from animals. When individuals transcend their outer self and realize their inner life, he believed, they are open to perceptions, experiences, and expressions that have a greater sociological and historical significance.

Educated in medicine, zoology, and philosophy at the universities of Freiburg, Heidelberg, and Berlin, he acquired a doctorate in philosophy from Erlangen (1916). He was a professor at Cologne from 1926 to 1934, when the Nazi political climate compelled his move to Groningen, Neth., where he became professor of sociology (1934–42). Ousted by the Nazis during the occupation, he taught again at Groningen (1946–51), as professor of philosophy, before returning to the University of Göttingen (1951), where he became professor emeritus in 1962. His principal works include *Die wissenschaftliche Idee* (1913; "The Scholarly Idea"), *Die Einheit der Sinne* (1923; "The Unity of Senses"), *Macht und menschliche Natur* (1931; "Might and Human Nature"), *Das Schicksal deutschen Geistes im Ausgang seiner bürgerlichen Epoche* (1935; "The Destiny of the German Spirit at the End of Its Bourgeois Epoch"), *Lachen und Wienen* (1941; *Laughing and Crying*), *Zwischen Philosophie und Gesellschaft* (1953; "Between Philosophy and Society"), and *Grenzen der Gemeinschaft: Eine Kritik des sozialen Radikalismus* (1972; "Limits of Society: A Critique of Social Radicalism").

Plethon, George Gemistus: *see* Gemistus Plethon, George.

pleura, plural PLEURAE, or PLEURAS, membrane lining the thoracic cavity (parietal pleura) and covering the lungs (visceral pleura). The parietal pleura folds back on itself at the root of the lung to become the visceral pleura. In health the two pleurae are in contact. When the lung collapses, however, or when air or liquid collects between the two membranes, the pleural cavity or sac becomes apparent (*see* pleurisy). There are actually two pleural cavities, the right and the left; each constitutes a closed unit not connected to the other. The glistening surface of the pleura is made up of a sheet of flat cells, the mesothelium, which covers an underlying layer of loose elastic tissue. The pleura exudes a thin fluid that keeps it moist and lubricated.

Major disorders of the pleura include pleurisy, the inflammation of the pleura; pleural effusion, the accumulation of excess fluid between the visceral and parietal pleurae; empyema, the collection of pus in the pleural space; tumours of the pleura; chylothorax, the rupture of the thoratic duct; hemothorax, the accumulation of blood in the pleural space; and fibrothorax, resulting from the presence of large amounts of fibrin in the pleural fluid.

pleurisy, inflammation of the pleura, the membrane that lines the thoracic cavity and folds in to cover the lungs. The inflamed membrane exudes varying quantities of fluid into the pleural cavity, between these two surfaces of the folded membrane. Depending on the amount of exudate, the pleurisy is described as simple or dry or fibrinous (in which case the amount of fluid is normal) or as pleurisy with effusion (in which case the amount of fluid accumulating in the pleural cavity is often extremely large). Because the pleura is well supplied with nerves, pleurisy can be very painful. The disease is commonly caused by infection in the underlying lung and, more rarely, by diffuse inflammatory conditions such as rheumatoid arthritis. Treatment of the disease includes pain relief and fluid evacuation; its main objective is correction of the underlying cause.

pleurisy root: *see* butterfly weed.

Pleurococcus, also called PROTOCOCCUS, or MOSS, genus of green algae. Several other algae and a number of lichens are also popularly called "mosses" (*e.g.* Irish moss, oak moss), as are all members of the plant class Bryopsida (*see* moss).

Pleurococcus is found as a thin, green covering on the moist, shaded side of trees, rocks, and soil. Because it grows on the north (or shaded) side of trees, stone walls, and fences, *Pleurococcus* is an important compass direction indicator. The spherical cells, either solitary or clumped together forming short false filaments, have heavy cell walls that protect the cells against excessive water loss. Each cell contains a large dense chloroplast, either lobed or plate-shaped. Reproduction is by cell division only. The taxonomic position of *Pleurococcus* is uncertain.

pleurodynia, also called BORNHOLM DISEASE, viral (coxsackie B) epidemic disease with an incubation period of two to four days, marked by a fever of brief duration, severe chest and lower back pain aggravated by deep breathing and movement, and a tendency to recur at intervals of a few days. The disease is usually self-limiting, terminating in complete recovery. Pain and fever can usually be relieved by aspirin.

Pleuromeia, a genus of extinct club mosses, order Pleuromeiales (class Lycopsida). It represents a curious line of small, treelike Late Triassic epoch (starting 230 million years ago) lycopsids, perhaps related to members of the present-day quillwort genus (*Isoetes*). *Pleuromeia*'s unbranched trunk reached to more than 1 m (40 inches) in height and about 10 cm (4 inches) in diameter; it bore a zone of elongated leaves near its tip, at which one large terminal cone was produced. Its rootlets were spirally arranged on four or more lobes that flared out at the base of the trunk, inviting comparisons with several other treelike lycopsids (*e.g., Lepidodendron, Sigillaria*).

Pleuronectiformes (fish order): *see* flatfish.

pleuropneumonia, lung disease of cattle and sheep, characterized by inflammation of the lungs and caused by the bacterium *Mycoplasma mycoides*. Fever, thirst, loss of appetite, and difficult breathing are signs of the disease. The United States and Europe eradicated the disease near the end of the 19th century. Vaccines offer protection in places where the disease still exists—Asia, Australia, and parts of Africa.

Pleurothallis, genus of more than 1,000 species of tropical American orchids, family Orchidaceae, that grow on other plants and range greatly in size. The flowers may be solitary or borne on a short spike.

The flowers are primarily in tints and shades of yellow combined with white, red, green, or brown. The widow orchid (*P. macrophylla*) is a dark, deep purple.

Pleve, Vyacheslav Konstantinovich: *see* Plehve, Vyacheslav Konstantinovich.

Pleven, town, northern Bulgaria. It lies a few miles east of the Vit River, which is a tributary of the Danube. At one time a Thracian settlement called Storgosia, the town was destroyed by Huns and was restored by the emperor Justinian I in the 6th century. Renamed Kajluka by Slavs, it became Hungarian in 1266, and the name Pleven was used from 1270 onward. As a key fortress of the Ottoman Empire, it became an important trade centre in the 15th–19th century.

Pleven is now a service town for an agricultural hinterland and also has food-processing, textile, engineering, cement, woodworking, rubber, and tobacco industries. Pleven has good road and rail connections. Innumerable monuments and eight museums in the area are devoted to the Siege of Pleven (*see* Pleven, Siege of), a lengthy and important engagement of the Russo-Turkish War of 1877–78. There is also the important Liberation Museum, which was established in 1905–07. The fertile agricultural area in which Pleven is located is well-irrigated by the Danube and several tributaries. Grains, grapes, fruits, and cattle are the area's major products. Pop. (1987 est.) town, 132,206.

Pleven, René (b. April 13, 1901, Rennes, Fr.), politician, twice premier of the French Fourth Republic (1950–1951, 1951–52), who is best-known for his sponsorship of the Pleven Plan for a unified European army. His efforts spurred the creation of the North Atlantic Treaty Organization (NATO).

After receiving a law degree from the University of Paris, Pleven became an industrial executive. During World War II, he joined General Charles de Gaulle's Free French government, serving successively as commissioner of finance, colonies, and foreign affairs and becoming colonial minister in 1944. After the liberation of France he became minister of finance in de Gaulle's Cabinet and in 1945 was elected deputy to the National Assembly. From 1946 to 1953 he was president of the left-centre Democratic and Socialist Union of the Resistance (Union Dêmocratique et Socialiste de la Résistance; UDSR); he was twice minister of defense (1949–50, 1952–54) and twice premier (July 1950–February 1951 and August 1951–January 1952).

Pro-American in outlook, Pleven convened a conference in Paris in July 1950 to draw up a plan for a European army, the European Defense Community, to unify North Atlantic and western European defense under a single high command. Although the plan was opposed by the French Communists, Socialists, and Gaullists, and none of the governments to which Pleven belonged was willing to ratify the necessary treaty, he had helped lay the foundations of NATO. In Indochina he carried on the war against the nationalist Viet Minh with American aid.

Pleven quit the UDSR in 1958 to support de Gaulle's new constitution and the Fifth Republic. He formed a new party, the Union for a Modern Democracy, in 1959. In 1966 he criticized de Gaulle for withdrawing France from NATO but he supported the Gaullist government after de Gaulle's resignation in April 1969. He was minister of justice (1969–73) and president of the council of Bretagne (1974–76).

Pleven, Siege of, also called SIEGE OF PLEVNA (July 20–Dec. 10, 1877), in the Russo-Turkish War of 1877–78, the Russian siege of the Turkish-held Bulgarian town of Pleven (Russian: Plevna). Four battles were fought, three being repulses of Russian attacks and the fourth being a defeat of the Turks in their attempt to escape.

In the opening weeks of the war of 1877–78 the Russians achieved some successes. On the Bulgarian front they crossed the Danube in June 1877, and a flying column seized the Shipka Pass through the Balkan Mountains on July 19. At this point the Russian plans received a setback. On July 20 a Turkish force under Osman Nuri Paşa repulsed the Russians at newly fortified Pleven and stemmed their advance (First Battle of Pleven). Attempts to break the resistance of Osman Nuri Paşa failed. The Russian assaults of July 30 (Second Battle) and September 11–12 (Third Battle) were repulsed with severe losses. The Russian commander then called up Colonel Count E.I. von Todleben, the engineer officer who had organized the defense of Sevastopol during the Crimean War, and Todleben pronounced in favour of a siege of Pleven. The other Turkish commanders did little to relieve the pressure on Osman Nuri Paşa, who at last perceived that his position was hopeless and attempted to break through the Russian cordon but was defeated and compelled to surrender (Dec. 10, 1877).

The Russians then tried to execute their original plan of penetration deep into European Turkey, but the Great Powers, especially Britain, forced a truce and the signing of the Treaty of San Stefano.

Pleyel, Ignace Joseph, also spelled IGNAZ JOSEF PLEYEL (b. June 18, 1757, Ruppersthal, Austria—d. Nov. 14, 1831, Paris), Austro-French composer, music publisher, and piano builder.

Trained in music while still a very young child, he was sent in 1772 to Eisenstadt to become a pupil and lodger of Joseph Haydn's. Pleyel later claimed a close, warm relationship

Ignace Joseph Pleyel, watercolour by an unknown artist
J.P. Ziolo

had existed between them, and there is evidence of the master's esteem for his student's compositional talents in the overture (or at least the first two movements) of Haydn's puppet opera *Das abgebrannte Haus* (1776?), now generally accepted as being Pleyel's work. His first position was probably as Kapellmeister to Count Erdödy at Pressburg, to whom he gratefully dedicated his string quartets, Opus 1 (1782–83). By 1784 Pleyel had become an assistant Kapellmeister at Strasbourg Cathedral, succeeding as principal Kapellmeister when his predecessor died in 1789. In 1786 he also organized and conducted a series of public concerts, which provided him with additional opportunities to popularize his compositions. The Strasbourg period was his most musically productive, and most of his compositions date from the years 1787–95. Many of his works were widely known in Europe and North America. Because of the interruptions to religious and musical life caused by the French Revolution, Pleyel left Strasbourg in 1791 for London, where his concerts were also well-attended and his compositions—especially the *symphonies concertantes* and quartets—received high praise from the critics. Early in 1795 Pleyel settled in Paris, where he opened a music shop and founded a publishing house; it issued about 4,000 works during the 39 years it existed, including many by Luigi Boccherini, Beethoven, Muzio Clementi, Jan Ladislav Dussek, and Haydn. Pleyel published the first miniature scores, beginning with Haydn's string quarters and symphonies. Though Pleyel attempted to divest himself of the entire business in 1813, the Maison Pleyel continued until 1834, when it ceased publishing completely, selling its stocks of plates and printed works to various Paris music publishers.

The piano-manufacturing company Pleyel had founded in Paris in 1807 continued to prosper. In 1815 Pleyel's eldest son, Camille (1788–1855), became a legal partner of the firm, which then adopted the name "Ignace Pleyel et fils aîné." Recognized as a fine and sensitive pianist as well as an able administrator, Camille was a close friend of Frédéric Chopin, who made his Paris debut and also gave his final Paris concert in the Salle Pleyel. (Chopin later owned a Pleyel grand piano constructed in 1839.)

In 1855 Camille died and was succeeded by his son-in-law, Auguste Wolff (1821–87), the firm becoming Pleyel, Wolff & Cie. After Wolff's death, his son-in-law Gustave Lyon (1857–1936) assumed control of the company, which he renamed Pleyel, Lyon et Cie, best-known for the development of a chromatic harp at the end of the 19th century.

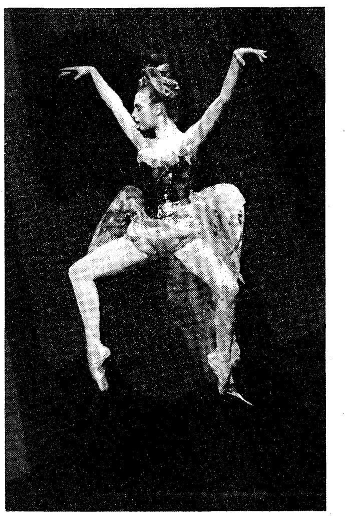
Pleyel, Marie-Félicité-Denise, also called CAMILLE MOKE (b. Sept. 4, 1811, Paris—d. March 30, 1875, St.-Josse-ten-Noode, near Brussels), French pianist and teacher, one of the most celebrated virtuosos of the 19th century.

She studied with Henri Herz, Frédéric Kalkbrenner, and Ignaz Moscheles, and by the age of 15 she was known in Belgium, Austria, Germany, and Russia as an accomplished virtuoso. She was engaged to Berlioz in 1830, but after three months, while Berlioz was in Italy, she broke the engagement to marry Camille Pleyel (1788–1855), scion of the piano-manufacturing family. After their separation in 1835 (her many love affairs were notorious), her concert career flourished. She received praise from Mendelssohn, Liszt, Chopin, and François-Joseph Fétis. From 1848 to 1872 she was professor of piano at the Brussels Conservatory, where she established a true school of piano playing in Belgium. Her few compositions for piano are of minor importance.

plica circularis, plural PLICAE CIRCULARES, also called VALVE OF KERCKRING, any of the crescent or circular folds in the surface of the small-shaped intestine that triple its absorption area, slow down the passage of food, and give it a characteristically pleated appearance. The folds usually run one-half to two-thirds of the way around the inside of the intestinal wall; occasionally, a single fold may spiral the wall for three or four complete turns. The folds are largest and most prevalent in the beginning of the intestinal tract; toward the middle they are more widely spaced and shortened, and near the end they totally disappear.

The tissue that forms these structures is the surface mucous-membrane lining and the deeper submucosa. The mucous membrane further divides into small projections called villi (*q.v.*) and is the predominant site of nutritional absorption, while the submucosa is composed of supportive tissue and blood vessels. Unlike the transient folds in the stomach, these intestinal folds are permanent structures not obliterated by distention.

plié (French: "bent"), knee bend in ballet. It is used in jumps and turns to provide spring, absorb shock, and as an exercise to loosen muscles and to develop balance. Performed in all of the five basic foot positions, pliés may be shallow, so that the dancer's heels remain on the floor (*demi-plié*), or deep, so that in all foot positions except the second the heels rise (*grand plié*).



Plié in second position *en pointe* executed by Gelsey Kirkland in *The Firebird*
Martha Swope

Pliekšāns, Jānis: *see* Rainis.

Pliensbachian Stage, standard, worldwide division of Jurassic rocks and time. (The Jurassic Period began about 190,000,000 years ago and lasted about 54,000,000 years.) The Pliensbachian is characterized by the marly limestones near the village of Pliensbach, in the Swabian Alps. Several ammonite zones (shorter periods of time characterized by kinds of fossil mollusks) have been recognized. Rocks of the Pliensbachian Stage overlie those of the Sinemurian Stage and underlie those of the Toarcian Stage.

pliers, hand-operated tool for holding and gripping small articles or for bending and cutting wire. Slip-joint pliers have grooved jaws, and the pivot hole in one member is elongated so that the member can pivot in either of two positions in order to grasp objects of different size in the most effective way. On some pliers the jaws have a portion that can cut soft wire and nails.

For bending wire and thin metal, round-nose pliers with tapering, conical jaws are used. Diagonal cutting pliers are used for cutting wire and small pins in areas that cannot be reached by larger cutting tools. Because the cutting edges are diagonally offset about 15 degrees, these can cut objects flush with a surface.

Plievier, Theodor, pseudonym (until 1933) THEODOR PLIVIER (b. Feb. 12, 1892, Berlin—d. March 12, 1955, Avegno, near Locarno, Switz.), German war novelist who was one of the first native writers to begin examining Germany's role in World War II and assessing the national guilt.

Plievier, the son of a labourer, left home at 17. He led a vagrant life until serving in the German Navy in World War I, during which time he participated in the 1918 naval mutiny. An ardent Communist, Plievier worked as a left-wing publicist during the 1920s. He described his war experiences in *Des Kaisers Kulis* (1930; *The Kaiser's Coolies,* 1931), *Zwölf Mann und ein Kapitän* (1930; "Twelve Men and a Captain"), *Der Kaiser ging, die Generäle blieben* (1932; *The Kaiser Goes, the Generals Remain,* 1933), *Der 10. November 1918* (1935; "The 10th of November 1918"), and *Das grosse Abenteuer* (1936; "The Great Adventure"). These novels received little recognition, as did a 1935 play. The only notice his war novels attracted came from the Nazi Party, which banned his books in 1933 and revoked his citizenship in 1934. Plievier fled to Moscow in 1933, to the Soviet Zone in 1945, and returned to the West in 1947. His famous and most important work is a World War II trilogy that deals with the war on the eastern front. The first volume, *Stalingrad* (1945; Eng. trans. 1948), which describes the crushing defeat of the German Sixth Army, became an international bestseller. The trilogy was completed by *Moskau* (1952; *Moscow,* 1953) and *Berlin* (1954; Eng. trans. 1956). The novels are shocking in their graphic naturalistic detail, yet hold out some hope for a reborn humanity.

Plimsoll line, also called PLIMSOLL MARK, official name INTERNATIONAL LOAD LINE, internationally agreed-upon reference line marking the loading limit for cargo ships. At the instigation of one of its members, Samuel Plimsoll, a merchant and shipping reformer, the British Parliament, in the Merchant Shipping Act of 1875, provided for the marking of a load line on the hull of every cargo ship, indicating the maximum depth to which the ship could be safely loaded. Application of the law to foreign ships leaving British ports led to general adoption of load-line rules by maritime countries. An International Load Line was adopted by 54 nations in 1930, and in 1968 a new line, permitting a smaller freeboard (hull above waterline) for the new, larger ships, went into effect.

Pliny THE ELDER, Latin in full GAIUS PLINIUS SECUNDUS (b. AD 23, Novum Comum, Transpadane Gaul—d. Aug. 24, 79, Stabiae, near Mt. Vesuvius), Roman savant and author of the celebrated *Natural History,* an encyclopaedic work of uneven accuracy that was an authority on scientific matters up to the Middle Ages.

Life. Pliny was descended from a prosperous family, and he was enabled to complete his studies in Rome. At the age of 23, he began a military career by serving in Germany, rising to the rank of cavalry commander. He returned to Rome, where he possibly studied law. Until near the end of Nero's reign, when he became procurator in Spain, Pliny lived in semi-retirement, studying and writing. His devotion to his studies and his research technique were described by his nephew, Pliny the Younger. Upon the accession in AD 69 of Vespasian, with whom Pliny had served in Germany, he returned to Rome and assumed various official positions.

Pliny's last assignment was that of commander of the fleet in the Bay of Naples, where he was charged with the suppression of piracy. Learning of an unusual cloud formation—later found to have resulted from an eruption of Mt. Vesuvius—Pliny went ashore to ascertain the cause and to reassure the terrified citizens. He was overcome by the fumes resulting from the volcanic activity and died on Aug. 24, 79, according to his nephew's report. Pliny was unmarried and was survived by his only sister.

The Natural History. Seven writings are ascribed to him, of which only the *Natural History* is extant. There survive, however, a few fragments of his earlier writings on grammar, a biography of Pomponius Secundus, a history of Rome, a study of the Roman campaigns in Germany, and a book on hurling the lance. These writings probably were lost in antiquity and have played no role in perpetuating Pliny's fame, which rests solely on the *Natural History.*

The *Natural History,* divided into 37 *libri,* or "books," was completed, except for finishing touches, in AD 77. In the preface, dedicated to Titus (who became emperor shortly before Pliny's death), Pliny justified the title and explained his purpose on utilitarian grounds as the study of "the nature of things, that is, life" ("Preface," 13). Heretofore, he continued, no one had attempted to bring together the older, scattered material that belonged to "encyclic culture" (*enkyklios paideia,* the origin of the word encyclopaedia). Disdaining high literary style and political mythology, Pliny adopted a plain style—but one with an unusually rich vocabulary—as best suited to his purpose. A novel feature of the *Natural History* is the care taken by Pliny in naming his sources, more than 100 of which are mentioned. Book I, in fact, is a summary of the remaining 36 books, listing the authors and sometimes the titles of the books (many of which are now lost) from which Pliny derived his material.

The *Natural History* properly begins with

Book II, which is devoted to cosmology and astronomy. Here, as elsewhere, Pliny demonstrated the extent of his reading, especially of Greek texts. By the same token, however, he was sometimes careless in translating details, with the result that he distorted the meaning of many technical and mathematical passages. In Books III through VI, on the physical and historical geography of the ancient world, he gave much attention to major cities, some of which no longer exist.

Books VII through XI treat zoology, beginning with man (VII), then mammals and reptiles (VIII), fishes and other marine animals (IX), birds (X), and insects (XI). Pliny derived most of the biological data from Aristotle, while his own contributions were concerned with legendary animals and unsupported folklore.

In Books XII through XIX, on botany, Pliny came closest to making a genuine contribution to science. Although he drew heavily upon Theophrastus, he reported some independent observations, particularly those made during his travels in Germany. Pliny is one of the chief sources of modern knowledge of Roman gardens, early botanical writings, and the introduction into Italy of new horticultural and agricultural species. Book XVIII, on agriculture, is especially important for agricultural techniques such as crop rotation, farm management, and the names of legumes and other crop plants. His description of an ox-driven grain harvester in Gaul, long regarded by scholars as imaginary, was confirmed by the discovery in southern Belgium in 1958 of a 2nd-century stone relief depicting such an implement. Moreover, by recording the Latin synonyms of Greek plant names, he made most of the plants mentioned in earlier Greek writings identifiable.

Books XX through XXXII are concerned with medicine and drugs. Like many Romans, Pliny criticized luxury on moral and medical grounds. His random comments on diet and on the commercial sources and prices of the ingredients of costly drugs provide valuable historical evidence relevant to contemporary Roman life. The subjects of Books XXXIII through XXXVII include minerals, precious stones, and metals, especially those used by Roman craftsmen. In describing their uses, he referred to famous artists and their creations and to Roman architectural styles and technology.

Assessment. In retrospect, Pliny's influence is based on his ability to assemble in a methodical fashion a number of previously unrelated facts, his perceptiveness in recognizing details ignored by others, and his readable stories, with which he linked together both factual and fictional data. Along with unsupported claims, fables, and exaggerations, Pliny's belief in magic and superstition helped to shape scientific and medical theory in subsequent centuries. Perhaps the most important of the pseudoscientific methods advocated by him was the doctrine of signatures: a resemblance between the external appearance of a plant, animal, or mineral and the outward symptoms of a disease was thought to indicate the therapeutic usefulness of the plant. With the decline of the ancient world and the loss of the Greek texts on which Pliny had so heavily depended, the *Natural History* became a substitute for a general education. In the European Middle Ages many of the larger monastic libraries possessed copies of the work; these and many abridged versions ensured Pliny's place in European literature. His authority was unchallenged, partly because of a lack of more reliable information and partly because his assertions were not and, in many cases, could not be tested.

The first attack on Pliny's work—Niccolò Leoniceno's tract on the errors of Pliny—was published in Ferrara in 1492. Thereafter, Pliny's influence diminished, as more writers questioned his statements. By the end of the 17th century, the *Natural History* had been rejected by the leading scientists. Up to that time, however, Pliny's influence, especially on nonscientific writers, was undiminished; he was, for example, almost certainly known to William Shakespeare and John Milton. Although Pliny's work was never again accepted as an authority in science, 19th-century Latin scholars conclusively demonstrated the historical importance of the *Natural History* as one of the greatest literary monuments of classical antiquity. It is still of value to those who wish an honest résumé of 1st-century Rome.

(Je.St.)

BIBLIOGRAPHY. The role of Pliny in the preservation and interpretation of the early views of the natural world is assessed in Roger French and Frank Greenaway (eds.), *Science in the Early Roman Empire: Pliny the Elder, His Sources and Influence* (1986), a collection of informative, authoritative essays.

Pliny THE YOUNGER, Latin in full GAIUS PLINIUS CAECILIUS SECUNDUS (b. AD 61 or 62, Comum, Italy—d. *c.* 113, Bithynia), Roman author and administrator who left a collection of private letters of great literary charm, intimately illustrating public and private life in the heyday of the Roman Empire.

Born into a wealthy family and the adopted son of his uncle, Pliny the Elder, Pliny began to practice law at 18. His reputation in the civil-law courts placed him in demand in the political court that tried provincial officials for extortion. His most notable success (100) was securing condemnation of a governor in Africa and a group of officials from Spain. Meanwhile he had attained the highest administrative posts, becoming praetor (93) and consul (100).

Pliny had financial ability and successively headed the military treasury and the senatorial treasury (94–100). After administering the drainage board of the city of Rome (104–106), he was sent (*c.* 110) by Emperor Trajan to investigate corruption in the municipal administration of Bithynia, where apparently he died two years later.

Like his contemporary, the historian Tacitus, Pliny was conventional, accepting the Roman Empire, serving under "good" and "bad" emperors, and making the conventional complaints against the latter in his writings. Between 100 and 109 he published nine books of selected, private letters, beginning with those covering events from the death of Emperor Domitian (October 97) to the early part of 100. The 10th book contains addresses to Emperor Trajan on sundry official problems and the emperor's replies.

The private letters are carefully written, occasional letters on diverse topics. Each holds an item of recent social, literary, political, or domestic news, or sometimes an account of an earlier but contemporary historical event, or else initiates moral discussion of a problem. Each has a single subject and is written in a style that mixes, in Pliny's terminology, the historical, the poetical, and the oratorical manner, to fit the theme. The composition of these *litterae curiosius scriptae* ("letters written with special care") was a fashion among the wealthy, and Pliny developed it into a miniature art form.

There are letters of advice to young men, notes of greeting and inquiry, and descriptions of scenes of natural beauty or of natural curiosities. Pliny also left a detailed picture of the amateur literary world with its custom of reciting works to seek critical revision from friends. Estate business is a frequent theme, and letters concerned with such matters reveal the abilities for which Trajan chose him to reorganize the municipal finances and local government of Bithynia.

Pliny's letters introduce many of the leading figures of Roman society in the 12 years after the death of Domitian—men of letters, politicians, administrators, generals, and rising young men of rank. They make possible the social reconstruction of an age for which there is otherwise no serious historical record. He was an adept at brief character sketches, his works being less satirical, more kindly, and possibly more complete than those of Tacitus. He was also a devotee of literature. He has left a detailed picture of the amateur literary world of his time and of the salons in which it was the custom to recite one's work and to seek critical revision from one's friends.

Pliny published his forensic and literary speeches with care, and late in life he took to the contemporary fashion for light verse in the style of Martial. Though fulsome in the praise of contemporary writers, his judgment of the dead Statius was fair: "He was ever writing poems with greater pains than ability." His letters addressed to his fellow advocate Tacitus, then occupied with his first major work, tell the little that is known about the date and circumstances of the composition of the *Historiae,* to which Pliny contributed his famous account of the eruption of Vesuvius. The biographer Suetonius was among his protégés.

One of the best modern editions of the letters and his panegyric to Trajan is by M. Schuster in the Teubner series (2nd ed., 1952). W. Melmoth's English translation, *The Letters of Pliny the Consul* (1746), was revised by W.M. Hutchinson for the Loeb Classical Library (2 vol., 1915).

BIBLIOGRAPHY. An important scholarly commentary on the political, social, literary, and legal background of Pliny's writings is given in A.N. Sherwin-White, *The Letters of Pliny* (1966, reissued 1985). Federico Gamberini, *Stylistic Theory and Practice in the Younger Pliny* (1983), offers an analysis of the language of the writer.

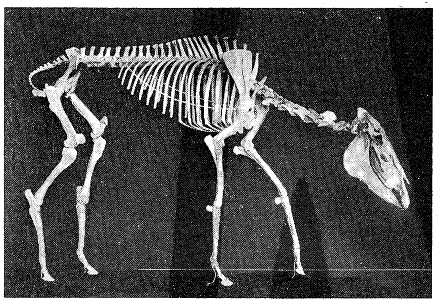
Consult the INDEX *first*

Pliocene Epoch, major worldwide division of the Tertiary Period extending from about 5.3 to 1.6 million years ago. It is often divided into the Early Pliocene Epoch (5.3 to 3.4 million years ago) and the Late Pliocene Epoch (3.4 to 1.6 million years ago). The Pliocene Epoch is the last and shortest epoch of the Tertiary Period. It follows the Miocene Epoch of the Tertiary Period and precedes the Pleistocene Epoch of the Quaternary Period. The Pliocene is also subdivided into two ages and their corresponding rock stages—namely, the Zanclean and the Piacenzian.

Pliocene deposits are known throughout the world. Early Pliocene deposits are well known from the Mediterranean region, the Siwālik Hills of India (*see* Siwalik Series), and the Honan and Shansi provinces of China. Pliocene environments were generally cooler and drier than those of preceding Tertiary epochs, as revealed by the remains of plants and trees.

A very modern aspect is seen in the vertebrate faunas of the Northern Hemisphere. Older groups of animals became extinct throughout the preceding Miocene Epoch. Although similarities are evident between the faunas of Eurasia and North America, little faunal interchange appears to have occurred between the two regions. The similarities are probably due to the continuation of forms that migrated between the two areas late in the Miocene Epoch. It is likely that during the early Pliocene a remarkably homogeneous fauna existed from Spain and Africa to China. Mastodons (elephant-like animals) underwent a great evolutionary diversification during the Pliocene, and many variant forms developed, adapted to varying ecological environments. In North America rhinoceroses became extinct. Camels, some of large size, were abundant and diverse, as were horses. In general, Pliocene mammals grew larger than those of earlier epochs. The more advanced primates continued to evolve in the Pliocene, and it is possible that the australopithecines, the first creatures that can be termed men, developed late in the Pliocene. The land connection between North and South America probably became reestablished in the Pliocene. Species of sloths and glyptodonts, large, armadillo-like, armoured animals, appear in the Pliocene fossil record of North America (previously, they had been isolated on the South American continent).

Pliohippus, extinct genus of primitive horses that inhabited North America during the Pliocene Epoch, between 2,500,000 and 7,000,000 years ago. *Pliohippus,* the first of the one-toed horses, evolved from *Merychippus,* an ancestor that lived in the preceding Miocene Epoch. The teeth in *Pliohippus* are



Pliohippus leidyanus

ing surface as in cloisonné. The unattached support, usually a sheet of metal or mica, can be easily removed after the enamels have been annealed and cooled, producing an effect not unlike a stained-glass window in miniature. Developed in France and Italy in the 14th century, this technique has been used largely for making vessels, jewelry, and, in Russia, demitasse spoons.

Plisetskaya, Maya (Mikhaylovna) (b. Nov. 20, 1925, Moscow), prima ballerina of the Bolshoi Ballet of Moscow, admired particularly for her technical virtuosity, expressive use of her arms, and ability to integrate acting with dancing.

A niece of the dancers Asaf and Sulamith

Maya Plisetskaya in *Swan Lake*, 1961
Paris Match—Pictorial Parade/EB Inc.

Messerer, she studied with Paul Gerdt's daughter Yelizaveta and with Agrippina Yakovlevna Vaganova and graduated from the Bolshoi school in 1943. Plisetskaya is noted for her unique, individualistic portrayals in both Soviet and classic ballets; her repertory includes Zarema in *The Fountain of Bakhchisaray, Laurencia,* the Mistress of the Copper Mountain in *The Stone Flower,* Kitri in *Don Quixote, Giselle,* Aurora in *The Sleeping Beauty,* and the dual character Odette-Odile in *Swan Lake,* often considered her greatest role. She has performed in many countries, including the U.S., India, and China, and was a guest artist with the Paris Opéra in 1961 and 1964. Her performances have been recorded in the films *Stars of the Russian Ballet* (1953), *Swan Lake* (1957), and *Plisetskaya Dances* (1966). In 1964 she received a Lenin Prize for outstanding work in the arts. She has appeared in ballets by such non-Soviet choreographers as Roland Petit, Maurice Béjart, and Alberto Alonso. Since 1975 she has also performed with the Ballet de XXe Siècle of Brussels. Her first choreography was *Anna Karenina* (1972).

Plitvice Lakes, Serbo-Croatian PLITVIČKA JEZERA, continuous chain of 16 lakes and many waterfalls in western Croatia, Yugoslavia. The chain, 5 mi (8 km) in length, begins two mountain streams that join near Plitvički Ljeskovac to form the Matica River. The river feeds Lake Prošće, the highest in elevation; it then flows by a number of waterfalls and smaller lakes into Lake Kozjak, the largest. Of the many cascades and falls, Plitvice and the Sastavci falls are the most spectacular, particularly during the spring snow melt. The lakes are the focal point of Plitvice National Park, which is also a nature reserve.

Plivier, Theodor: *see* Plievier, Theodor.

PLO: *see* Palestine Liberation Organization.

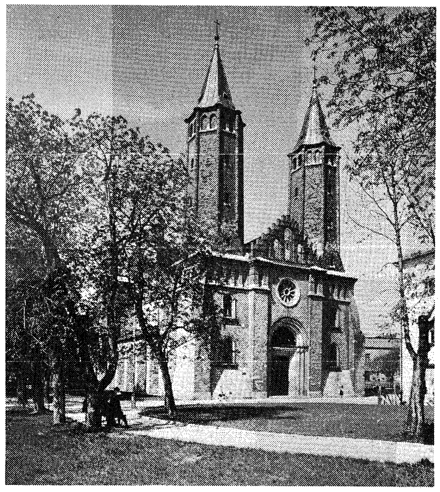
Ploceidae, songbird family, order Passeriformes, including the bishop, weaver, and whydah groups and Old World sparrows. The 135 to 155 species are native chiefly to Africa—but several have been introduced elsewhere. Ploceids are small, compact birds with short, stout bills. In many species the males are brightly coloured; some acquire, in nonbreeding season, dull plumage resembling that of females.

Ploceids are commonest in dry, hot country, where they forage on the ground for seeds and insects. Most are highly gregarious, and many are polygamous. They chirp and chatter incessantly. Except for the parasitic whydahs and certain sparrows, all weave covered nests, typically in colonies. The usually five or six eggs are tinted and speckled in most species.

The relationships of these and other seedeaters are very uncertain, and authorities disagree widely on the classification of the groups.

Płock, *województwo* (province), central Poland, established 1975, comprising an area of 1,976 sq mi (5,117 sq km). It is bordered by the provinces of Ciechanów on the northeast; Warsaw and Skierniewice on the southeast; Łódź and Sieradz on the south; and Konin and Włocławek on the west. The province is crossed from east to west by the Vistula River. Płock (*q.v.*) city, the provincial capital, is located on both banks of the Vistula. The mostly level terrain is broken by 548-ft- (167-m-) high morainal hills in the south. The Łąck Forest (Lasy Łąckie) in the western part of the province is the site of numerous health spas; otherwise, the province is not heavily forested. The soil is arable and supports large crops of wheat, rye, potatoes, and sugar beets. Provincial industry includes food processing, iron mining, oil refining, lumber milling, agricultural-machinery manufacturing, and chemical and petrochemical production. Pop. (1982 est.) 497,100.

Płock, city, capital of Płock *województwo* (province), central Poland, on the Vistula River. First chronicled in the 10th century, Płock is the oldest community in Mazowsze (Mazovia), having served as the seat of Polish



The cathedral at Płock, Poland
Z. Siemaszko

rulers from 1079 to 1138. It received town privileges in 1237 and prospered as a trading centre through the 17th century. In 1793 Płock passed to Prussia; it was returned to Poland in 1918. The town was badly damaged during World War II, at which time it was known as Schröttersburg. The economy is based on oil refining and modern petrochemical and plastics works, supplied by the Druzhba (Friendship) pipeline from the U.S.S.R. There is also production of agricultural machinery and foodstuffs. It is located on a rail line and has riverboat service and good road links with the rest of Poland. It contains the state and diocesan museums. Pop. (1982 est.) 103,800.

ploidy, in genetics, the number of chromosomes occurring in the nucleus of a cell. In normal somatic (body) cells, the chromosomes exist in pairs. The condition is called diploidy. During meiosis the cell produces gametes, or germ cells, each containing half the normal or somatic number of chromosomes. This condition is called haploidy. When two germ cells (*e.g.,* egg and sperm) unite, the diploid condition is restored.

Polyploidy refers to cells the nuclei of which have three or more times the number of chromosomes found in haploid cells. This condition frequently occurs in plants and may result from chromosome duplication without division of the cytoplasm or from the union of two diploid gametes. Polyploid animals, because they have more than the normal number of sex chromosomes, are usually sterile.

Some cells have an abnormal number of chromosomes that is not a whole multiple of the haploid number. This condition, called aneuploidy, is most often caused by some error resulting in an unequal distribution of chromosomes to the daughter cells. Organisms in which aneuploidy occurs may deviate noticeably from the norm in appearance and behaviour.

Ploieşti, also spelled PLOEŞTI, city, capital of Prahova *judeţ* (district), southeastern Romania. It is situated between the valleys of the Prahova and Teleajen rivers, north of Bucharest. According to legend the city was named after its founder, Father Ploaie, an escapee from Transylvania. The city is first documented in the 16th century as a military camp for the army of Michael the Brave (Mihai Viteazul), but not until the mid-19th century did Ploieşti begin to develop rapidly. In 1856 one of the first oil refineries in the world was opened near Ploieşti, and the city's growth since that time has been directly related to that of the expanding Romanian petroleum industry. Ploieşti is the country's primary petroleum centre, having refineries, storage tanks, oil-field equipment works, and a distillery. While under German occupation during World War II, it was the target of repeated massive bombing raids. At Brazi, south of the city, is a giant petrochemical complex. Also in Ploieşti are textile and food-processing factories. Also a cultural centre, the city has six museums, including the Oil Museum, which traces the development of the Romanian petroleum industry. Pop. (1982 est.) 211,657.

Plomer, William (Charles Franklyn) (b. Dec. 10, 1903, Transvaal, S.Af.—d. Sept. 21, 1973, Lewes, East Sussex, Eng.), South African-born British man of letters, whose writing covered many genres: poetry, novels,

Plomer
Camera Press—Pictorial Parade/EB Inc.

short stories, memoirs, and even opera librettos.

Plomer was educated in England but returned with his family to South Africa after World War I. His experience as an apprentice on a remote farm in the eastern Cape when he was 17 alerted him to the literary possibilities of the South African landscape and established the sensibility of his early works. His first novel, *Turbott Wolfe* (1925), caused a scandal because it touched upon miscegenation and dared to criticize the supposed benevolence of whites toward blacks, even casting some white characters in the role of villains. *I Speak of Africa* (1927), a collection of short stories, exacerbated his reputation. In collaboration with Laurens Van Der Post and the iconoclastic poet Roy Campbell, he founded a magazine called *Voorslag* ("Whiplash") with which he intended to excoriate South African racist society. Public outrage silenced the journal, and Plomer and Campbell left the country.

Plomer travelled in Japan and Europe before returning to England, where to all intents he became a British man of letters, though some of his work continued to draw upon his travels. In England he wrote two dramatic novels about London, *The Case Is Altered* (1932) and *The Invaders* (1934). Additional publications included a semifictional memoir, *Museum Pieces* (1952), and three volumes of family and personal memoirs, *Double Lives* (1943), *At Home* (1958), and *Autobiography of William Plomer* (1975). Between 1938 and 1940 he edited three volumes of the diaries of the Victorian clergyman Francis Kilvert. His association with the British composer Benjamin Britten began with the opera *Gloriana* (1953) and continued with librettos for the cantatas *Curlew River* (1964), *The Burning Fiery Furnace* (1966), and *Prodigal Son* (1968). One of his major achievements was *Collected Poems* (1960).

His assimilation into English society is indicated by his service in Naval Intelligence during World War II and his years as senior editor with the publishing house Jonathan Cape. In 1968 he was made Commander of the Order of the British Empire.

plosive (phonetics): *see* stop.

plot, in fiction, the structure of interrelated actions, consciously selected and arranged by the author. Plot involves a considerably higher level of narrative organization than normally occurs in a story or fable. According to E.M. Forster in *Aspects of the Novel* (1927), a story is a "narrative of events arranged in their time-sequence," whereas a plot organizes the events according to a "sense of causality."

In the history of literary criticism, plot has undergone a variety of interpretations. In the *Poetics,* Aristotle assigned primary importance to plot (*mythos*) and considered it the very "soul" of a tragedy. Later critics tended to reduce plot to a more mechanical function, until, in the Romantic era, the term was theoretically degraded to an outline on which the content of fiction was hung. Such outlines were popularly thought to exist apart from any particular work and to be reusable and interchangeable. They might be endowed with life by a particular author through his development of character, dialogue, or some other element. The publication of books of "basic plots" brought plot to its lowest esteem.

In the 20th century there have been many attempts to redefine plot as movement, and some critics have even reverted to the position of Aristotle in giving it primary importance in fiction. These neo-Aristotelians (or Chicago school of critics), following the leadership of the critic Ronald S. Crane, have described plot as the author's control of the reader's emotional responses—his arousal of the reader's interest and anxiety and the careful control of that anxiety over a duration of time. This approach is only one of many attempts to restore plot to its former place of priority in fiction.

Plotina, Pompeia (d. *c.* AD 122), wife of the Roman emperor Trajan. She earned great respect in her lifetime by her virtue and her advocation of the people's interests. During the ceremony of Trajan's accession, she is supposed to have turned around as she climbed the palace steps and addressed the crowd, saying that she desired always to be the same as she was then. One of her accomplishments was to curb the excesses of the procurators, the state's revenue agents.

Plotina was childless. She induced Trajan to adopt Hadrian, with whom she was on close terms. Plotina survived Trajan, and, upon her death, the emperor Hadrian had temples erected in her honour at Rome and at Nemausus (Nîmes) in Gaul.

Plotinus (b. AD 205, Lyco, or Lycopolis, Egypt?—d. 270, Campania), ancient philosopher, the centre of an influential circle of intellectuals and men of letters in 3rd-century Rome, who is regarded by modern scholars as the founder of the Neoplatonic school of philosophy.

Origins and education. The only important source for the life of Plotinus is the biography that his disciple and editor Porphyry wrote as a preface to his edition of the writings of his master, the *Enneads.* Other ancient sources add almost no reliable information to what Porphyry relates. This must be mentioned because, though Porphyry's "Life of Plotinus" is the best source available for the life of any ancient philosopher, it has some important deficiencies that must necessarily be reflected in any modern account of the life of Plotinus that does not use a great deal of creative imagination to fill in the gaps. The "Life" is the work of an honest, accurate, hero-worshipping, and serious-minded friend and admirer. Apart from a few fascinating scraps of information about the earlier parts of the life of Plotinus, Porphyry concentrates on the last six years, when he was with his master in Rome. Thus, a fairly complete picture is available only of the last six years of a man who died at the age of 65. It is the elderly Plotinus, as it is the elderly Socrates, who alone is known. Plotinus' own writings contain no autobiographical information, and they can give no unintentional glimpses of his mind or character when he was young; they were all written in the last 15 years of his life. Nothing is known about his intellectual and spiritual development.

Plotinus was born in AD 205. Porphyry states that he never spoke about his parents, his race, or his country. Eunapius, a late 4th-century writer, and later authors wrote that his birthplace was Lyco, or Lycopolis, in Egypt, either the modern Asyūt in Upper Egypt or a small town in the Nile Delta. Though this may be true, there is no real evidence in the "Life" or in his own writings to suggest that Plotinus had any special knowledge of or affinity with Egypt; the fact that he later studied philosophy in the great cosmopolitan city of Alexandria is not necessarily evidence that he was an Egyptian. His name is Latin in form, but, in the 3rd century AD, this gives no clue to his ethnic origins. All that can be said with reasonable certainty is that Greek was his normal language and that he had a Greek education. For all his originality, he remains Hellenic in his way of thinking and in his intellectual and religious loyalties.

In his 28th year—he seems to have been rather a late developer—Plotinus felt an impulse to study philosophy and thus went to Alexandria. He attended the lectures of the most eminent professors in Alexandria at the time, which reduced him to a state of complete depression. In the end, a friend who understood what he wanted took him to hear the self-taught philosopher Ammonius "Saccas." When he had heard Ammonius speak, Plotinus said, "This is the man I was looking for," and stayed with him for 11 years.

Ammonius is the most mysterious figure in the history of ancient philosophy. He was, it seems, a lapsed Christian (yet even this is not quite certain), and the one or two extant remarks about his thought suggest a fairly commonplace sort of traditional Platonism. A man who could attract such devotion from Plotinus and who may also have been the philosophical master of the great Christian theologian Origen, must have had something more to offer his pupils, but what it was is not known. That Plotinus stayed with him for 11 years is in no way surprising. One did not enter an ancient philosophical school to take courses and obtain a degree, but rather to join in what might well be a lifelong cooperative following of the way to truth, goodness, and the ultimate liberation of the spirit.

Expedition to the East. At the end of his time with Ammonius, Plotinus joined the expedition of the Roman emperor Gordian III against Persia (242–243), with the intention of trying to learn something at first hand about the philosophies of the Persians and Indians. The expedition came to a disastrous end in Mesopotamia, however, when Gordian was murdered by the soldiers and Philip the Arabian was proclaimed emperor. Plotinus escaped with difficulty and made his way back to Antioch. From there he went to Rome, where he settled at the age of 40. That a Greek philosopher, especially at this period, should be interested in Oriental thought is not extraordinary. Plotinus' own thought shows some striking similarities to Indian religious philosophy, but he never actually made contact with Eastern sages because of the failure of the expedition. Though direct or indirect contact with Indians educated in their own religious-philosophical traditions may not have been impossible in 3rd-century Alexandria, the resemblances of the philosophy of Plotinus to Indian thought were more likely a natural development of the Greek tradition that he inherited. That Plotinus was able to join the expedition of the senatorial emperor Gordian, that he went to Rome (an unusual place for a philosopher to settle), and that Porphyry found him, 19 years later, at the centre of a circle of friends and disciples—many of whom were members of the senatorial aristocracy—has been interpreted (probably erroneously) as meaning that he or his family had strong personal connections with Roman senators.

Life in Rome. Whatever may have been the circumstances of Plotinus when he first came to Rome, by the time Porphyry made his acquaintance in AD 263 he was living in dignified and comfortable conditions, though maintaining a considerable degree of personal austerity. His reputation in society was excellent and earned by practical activity as well as by teaching. He acted as an arbitrator in disputes, without ever being known to make an enemy, and many of his aristocratic friends, when they were approaching death, appointed him guardian of their children. "His house," Porphyry says, "was full of young lads and maidens," and he most conscientiously fulfilled his obligations under Roman law as their guardian, taking care of their education and their property. Like other great contemplatives, he had plenty of time for other people and could attend to their worries (sometimes quite trivial) without losing his inward concentration. He heard a boy's lessons, found who had stolen a lady friend's necklace, or noticed that Porphyry was in a state of depression and contemplating suicide and so sent him away for a change of scenery and companionship. "Present at once to himself and others" and "gentle and at the disposal of all who had any sort of acquaintance with him" are ways in which Porphyry described him. He was, it seems, a man who gave the impression of being in touch with the eternal without losing awareness of the earthly needs of his many friends.

His circle of friends was cosmopolitan, including men from the eastern half of the empire as well as Roman senators, their wives, and widows. Among those who venerated Plotinus, according to Porphyry, were the emperor Gallienus (reigned 253–268) and his wife Salonina, and this led Plotinus on one occasion to attempt practical activity on a larger scale. He asked the emperor to restore a ruined city in Campania and endow it with the surrounding land; the restored city was to be called Platonopolis, and its citizens were to live according to the laws and customs of Plato's ideal states. Plotinus promised that he would go and live there himself with his friends. That a philosopher who shows in his writings such a total lack of interest in the political side of Plato's thought and who preached withdrawal from public life should have made such a proposal is interesting. He may well have thought it his duty as a Platonic philosopher to attempt the foundation of a Platonic city, if opportunity offered—however personally disinclined he might have been to such activity. The emperor refused his request, and in the political circumstances of the time there was no chance of its being granted. Gallienus and the Senate were not on good terms. He had excluded members of the senatorial order from all military commands, and they took their revenge by successfully blackening his memory after his death. However much he might have respected Plotinus personally, the emperor would inevitably have regarded Platonopolis as a most undesirable senatorial strongpoint and a centre of intrigue against his authority.

Plotinus' teachings and writings. The main activity of Plotinus, to which he devoted most of his time and energy, was his teaching and, after his first 10 years in Rome, his writing. There was nothing academic or highly organized about his "school," though his method of teaching was rather scholastic. He would have passages read from commentaries on Plato or Aristotle by earlier philosophers and then expound his own views. The meetings, however, were friendly and informal, and Plotinus encouraged unlimited discussion. Difficulties, once raised, had to be discussed until they were solved. The school was a loose circle of friends and admirers with no corporate organization. It was for these friends that he wrote the treatises that Porphyry collected and arranged as the *Enneads.* Some, it seems from their complexity, were destined for an inner circle of his closest friends and philosophical collaborators, such as Porphyry, Amelius Gentilianus from Tuscany (the senior member of the school), and Eustochius, who was Plotinus' physician and who may have produced another edition of his works, now lost.

Some stories in the "Life," and some passages in the *Enneads,* give an idea of Plotinus' attitude to the religions and superstitions of his intensely religious and superstitious age, an attitude that seems to have been unusually detached. Like all men of his time, he believed in magic and in the possibility of foretelling the future by the stars, though he attacked the more bizarre and immoral beliefs of the astrologers. His interest in the occult was philosophical rather than practical, and there is no definite evidence that he practiced magic. A person called Olympius is reported to have once tried to use magic against Plotinus, but he supposedly found that the malignant forces he had evoked were bouncing back from Plotinus to himself. Plotinus was once taken to the Temple of Isis for a conjuration of his guardian spirit; a god, Porphyry stated, appeared instead of an ordinary guardian angel but could not be questioned because of a mishandling of the conjuring process which broke the spell. What Plotinus himself thought of the proceedings is not known, but apparently he was not deeply interested.

His attitude toward the traditional pagan cults was one of respectful indifference. Amelius, his closest friend and coworker in philosophy, was a pious man, addicted to attendance at sacrifices. Plotinus refused to join him in his devotions but seems to have thought none the worse of him. Despite his rather aggressive piety, Amelius remained Plotinus' friend and collaborator. Some members of his circle of friends were Gnostics (heretical Christian dualists who emphasized esoteric salvatory knowledge), and they provoked him not only to write a vigorous attack on their beliefs but to organize a polemic campaign against them through the activities of Porphyry and Amelius. Plotinus' reasons for detesting Gnosticism also would have applied, to some extent, to orthodox Christianity—though there is no evidence that he knew anything about it or that he had any contact with the church in Rome. Gnosticism appeared to him to be a barbarous, melodramatic, irrational, immoral, un-Greek, and insanely arrogant superstition. Plotinus' own religion, which he practiced and taught with calm intensity, was the quest for mystical union with the Good through the exercise of pure intelligence.

Last years. In his last years Plotinus, whose health had never been very good, suffered from a painful and repulsive sickness that Porphyry describes so imprecisely that one modern scholar has identified it as tuberculosis and another as a form of leprosy. This made his friends, as he noticed, avoid his company, and he retired to a country estate belonging to one of them in Campania and within a year died there (270). The circle of friends had already broken up. Plotinus himself had sent Porphyry away to Sicily to recover from his depression. Amelius was in Syria. Only his physician Eustochius arrived in time to be with Plotinus at the end. His last words were either "Try to bring back the god in you to the divine in the All" or "I am trying to bring back the divine in us to the divine in the All." In either case, they express very simply the faith that he shared with all religious philosophers of late antiquity. (A.H.A.)

BIBLIOGRAPHY. The text of Porphyry's *Life of Plotinus* may be found prefixed to most of the editions of the *Enneads* of Plotinus. *Plotins Schriften,* vol. 5c, ed. and trans. by R. Harder (1958), is a critical edition of the Greek text with German translation and notes. A Greek text with English translation and short notes is in *Plotinus,* vol. 1, trans. by A.H. Armstrong (1966). An English translation is in *The Enneads,* trans. by Stephen MacKenna, 4th ed. rev. by B.S. Page, pp. 1–20 (1969). The best character study of Plotinus, and also an excellent introduction to his thought, is Pierre Hadot, *Plotin, ou la simplicité du regard* (1963). See also A.H. Armstrong in the *Cambridge History of Later Greek and Early Mediaeval Philosophy,* part 3, "Plotinus," ch. 12, "Life," and 13, "Teaching and Writing" (1967), with bibliography.

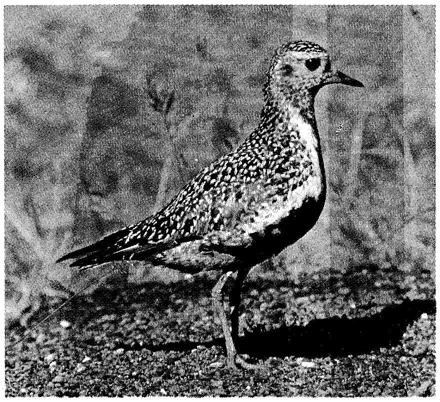
A list of the abbreviations used in the MICROPAEDIA *will be found at the end of this volume*

Plovdiv, second largest city of Bulgaria, situated in the south-central part of the country. It lies along the Maritsa River and is situated amid six hills that rise from the Thracian Plain to a height of 400 feet (120 m). Called Pulpudeva in Thracian times, it was renamed Philippopolis in 341 BC after its conquest by Philip II of Macedonia. From AD 46 it was called Trimontium and was the capital of the Roman province of Thrace. Plovdiv repeatedly changed hands during the Middle Ages until 1364, when it was taken by the Turks, who called it Philibé. After the Russo-Turkish War (1877–78), it became capital of Turkish Eastern Rumelia, which united with Bulgaria in 1885. It officially assumed its present name after World War I.

In the old Trimontium quarter of the city, parts of the Roman walls remain. The medieval ruins of Tsar Ivan Asen II's fortress and Bachkovo monastery are nearby. Cultural institutions include a museum housing a collection of Thracian gold vessels.

The city, a junction on the Belgrade–Sofia–Istanbul rail line, is a food-processing centre with diversified industries, including the manufacture of nonferrous metals, machinery parts, textiles, carpets, and fertilizers. The city is the chief market of a fertile region that produces tobacco, rice, vegetables, and fruit. An international trade fair is held biennially. Pop. (1987 est.) city, 349,148.

plover, any of numerous species of plump-breasted birds of the shorebird family Charadriidae (order Charadriiformes). There are about three dozen species of plovers, 15 to 30 centimetres (6 to 12 inches) long, with



Golden plover (*Pluvialis apricaria*)
Kenneth W. Fink—Root Resources

long wings, moderately long legs, short necks, and straight bills that are shorter than their heads. Many species are plain brown, gray, or sandy above and whitish below. The group of so-called ringed plovers (certain *Charadrius* species) have white foreheads and one or two black bands ("rings") across the breast. Some plovers, like the golden (*Pluvialis* species) and black-bellied (*Squatarola squatarola*), are finely patterned dark and light above and black below in breeding dress. These two genera are sometimes included in *Charadrius.*

Many plovers feed by running along beaches and shorelines, snapping up small, aquatic, invertebrate animals for food. Others, like the killdeer (*q.v.*), of upland meadows and grasslands, are chiefly insectivorous. Plovers and their relatives are quick to give alarm. When flushed, they take swift and direct flight. Many utter melodious whistled calls, which can be used to distinguish the species. The nest is in a slight hollow in the ground where two to five (usually four) spotted eggs are laid. Both parents incubate and care for the downy young, which run about and accompany their parents soon after hatching.

Plovers are found in most parts of the world. Those nesting in the north are strongly migratory, and they travel and feed in flocks. Most notable as long-distance migrants are the golden plover of Eurasia (*Pluvialis apricaria*) and the American golden plover (*P. dominica*), which breed in the Arctic and winter in the Southern Hemisphere. The American golden plovers of the eastern range fly over the Atlantic and South America as far south as Patagonia, and most return via the Mississippi Valley; those in the western range travel, presumably nonstop, to groups of islands in the South Pacific. *See also* crab plover.

plow, also spelled PLOUGH, most important agricultural implement since the beginning of history, used to turn and break up soil, to bury crop residues, and to help control weeds.

The antecedent of the plow is the prehistoric digging stick. The earliest plows were doubtless digging sticks fashioned with handles for pulling or pushing. By Roman times, light, wheelless plows with iron shares (blades) were drawn by oxen; these implements could break up the topsoil of the Mediterranean regions but could not handle the heavier soils of northwestern Europe. The wheeled plow, at first drawn by oxen but later by horses, made possible the northward spread of European agriculture. The 18th-century addition of the moldboard, which turned the furrow slice cut by the plowshare, was an important advance. In the mid-19th century the black prairie soils of the American Midwest challenged the strength of the existing plow, and American mechanic John Deere invented the all-steel one-piece share and moldboard. The three-wheel sulky plow followed and, with the introduction of the gasoline engine, the tractor-drawn plow.

In its simplest form the moldboard plow consists of the share, the broad blade that cuts through the soil; the moldboard, for turning the furrow slice; and the landside, a plate on the opposite side from the moldboard that absorbs the side thrust of the turning action. Horse-drawn moldboard plows, still widely used, have a single bottom (share and moldboard), while tractor-drawn plows have from one to five hydraulically lifted and controlled bottoms staggered in tandem. Listers and middlebusters are double-moldboard plows that leave a furrow by throwing the dirt both ways.

Disk plows usually have three or more individually mounted concave disks that are inclined backward to achieve maximum depth. They are particularly adapted for use in hard, dry soils, shrubby or bushy land, or on rocky land. Disk tillers, also called harrow plows or one-way disk plows, usually consist of a gang of many disks mounted on one axle (*see* harrow). Used after grain harvest, they usually

A three-bottom, tractor-mounted moldboard plow

leave some stubble to help reduce wind erosion and often have seeding equipment. Two-way (reversible) plows have disks or moldboards that can be either opposed, so that one fills the trench made by the other, or set to throw the soil entirely to the right or left.

Rotary plows or tillers (sometimes called rototillers) have curved cutting knives mounted on a horizontal power-driven shaft. The pronged rotary hoe, a plow used chiefly for seedbed and weed control, works well at high speed. Garden sizes cut swaths from 1 to $2\frac{1}{2}$ feet (about $\frac{1}{3}$ to $\frac{4}{5}$ metre) wide; tractor types, up to 4 feet.

Deep tillage implements, used chiefly to break up hardpan and packed soils, include the subsoiler and the chisel plow. The subsoiler must be pulled by a heavy tractor, for its steel-pointed shank is capable of penetrating the subsoil to a depth of three feet. The chisel plow, or ripper, has several rigid or spring-toothed shanks with double pointed shovels mounted on a transverse bar at intervals of one to three feet. Plowing depths vary from a few inches to $1\frac{1}{2}$ feet.

Plowright, Joan (Anne) (b. Oct. 28, 1929, Scunthorpe, Lincolnshire, Eng.), English dramatic actress.

Plowright received her dramatic training at the Laban Art of Movement Studio in Manchester and at the Old Vic Theatre School in London. She made her first appearances on stage in 1951, played with an Old Vic touring company in South Africa in 1952, and made her debut in London in *The Duenna* in 1954. She continued to perform on the London stage until 1958, when she made her first appearance in New York City. Her dual performances in two plays by Eugene Ionesco as both an old woman and a 17-year-old girl demonstrated her range and versatility as an actress and brought her wide critical acclaim.

Plowright's most notable stage performances included those in *A Taste of Honey* (1960), *Saint Joan* (1963), and *Saturday, Sunday, Monday* (1973). She also performed in such motion pictures as *Moby Dick* (1956), *The Entertainer* (1960), *Three Sisters* (1974; the latter two with her husband, Sir Laurence Olivier), and *Equus* (1977), and on television.

Plücker, Julius (b. June 16, 1801, Elberfeld, Duchy of Berg—d. May 22, 1868, Bonn), German mathematician and physicist whose work suggested the far-reaching principle of duality, which states the equivalence of certain related types of theorems. He also discovered that cathode rays (electron rays produced in a vacuum) are diverted from their path by a magnetic field. This effect is a principle vital to the development of modern electronic devices, such as television.

Plücker attended the universities of Heidelberg, Berlin, and Paris. In 1829, after four years as an unsalaried lecturer, he became extraordinary professor at the University of Bonn. From his lectures came his first great work, *Analytisch-geometrische Entwicklungen,* 2 vol. (1828–31; "The Development of Analytic Geometry"), in which he introduced the abridged notation in analytic geometry.

In 1829 Plücker proposed a revolutionary idea in analytic geometry: that the fundamental geometric element need not be the point but could be the straight line. Through this idea he developed the principle of duality. In 1834 Plücker became professor of mathematics at the University of Halle and two years later professor of mathematics at the University of Bonn. *Theorie der algebraischen Curven* (1839; "Theory of Algebraic Curves"), his greatest work, contains equations detailing the number of singularities (points at which there is no unique tangent line) on algebraic curves, and his *System der analytischen Geometrie* (1835; "System of Analytic Geometry") introduced the use of linear functions in place of the usual coordinate points. Plücker's *System der Geometrie des Raumes in neuer analytischer Behandlungsweise* (1846; "System of the Geometry of Space in a New Analytical Treatment") contains a more systematic and polished rendering of his earlier results.

After his appointment as professor of physics at Bonn in 1847, Plücker began research on the behaviour of crystals in a magnetic field and then studied the properties of magnetic bodies, establishing results integral to knowledge of magnetism. He discovered and investigated the magnetic deflection of cathode rays and thus stimulated research in electronics and atomic physics.

At first alone and later with the German physicist Johann W. Hittorf, Plücker made many important discoveries in spectroscopy. He anticipated Robert Bunsen and Gustav R. Kirchhoff, both of Germany, in announcing that spectral lines were characteristic for each chemical substance and in indicating the value of this discovery to chemical analysis. According to Hittorf, Plücker was the first who saw the three lines of the hydrogen spectrum that a few months after his death were recognized in the spectrum of the solar prominences, thus solving a mystery of modern astronomy. In 1862 he pointed out that the same element may exhibit different spectra at different temperatures.

In 1865 he returned to the study of mathematics and later published his work on modern pure geometry of space, *Neue Geometrie* *des Raumes gegründet auf die Betrachtung der geraden Linie als Raumelement* (1868–69; "New Geometry of Space Founded on the Treatment of the Straight Line as Space Element").

plum, fruit of the genus *Prunus* of the rose family (Rosaceae). Like the peach and cherry, it is a stone, or drupe, fruit. Trees of some plum species reach a height from 6 to 10

Plum (*Prunus*)
Grant Heilman—EB Inc.

metres (20 to 33 feet), while others are much smaller; some species are small shrubs with drooping branches. The flower buds on most varieties are borne on short spurs or along the terminal shoots of the main branches. Each bud may contain from one to five flowers, two or three being most common; where the buds are close together, they give an appearance of densely packed, showy flower clusters when the trees are in full bloom. The individual flower is made up of a receptacle forming a hollow cup bearing sepals, petals, and stamens on the outer rim, surrounding a single pistil attached at the bottom of the cup. After fertilization the receptacle and attachments fall off, and the style withers and drops off, leaving the enlarged basal portion of the pistil, the ovary, which develops into the fruit.

As the fruit grows, the outer part of the ovary ripens into a fleshy, juicy exterior, making up the edible part of the fruit, and a hard interior, called the stone, or pit. The seed is enclosed within the stone. The fruits show a wide range of size, flavour, colour, and texture.

The common European plum (*Prunus domestica*) probably originated in the region around the Caucasus and the Caspian Sea. According to the earliest writings in which the plum is mentioned, the species is at least 2,000 years old. Another Old World plum species, probably of European or Asiatic origin, is the Damson plum (*Prunus institia*). Ancient writings connect early cultivation of these plums with the region around Damascus. It is not known when European plums were introduced into North America, but pits were probably brought over by the first colonists.

In the United States and Europe the plum has long been recognized as one of the most delicious fruits. It is widely eaten fresh as a dessert fruit, cooked as compote or jam, or baked in a variety of pastries. Among the stone fruits, the plum ranks next to the peach in commercial production. Many varieties cultivated in the United States have been introduced from elsewhere; when these are added to the native varieties, they give plums the largest number of kinds and species among the stone fruits. Different varieties are adapted to a wide range of soils and climatic conditions. Plums respond to good soil-management practices. As trees come into bearing, they do not require much pruning and in the home fruit garden can be grown satisfactorily if diseases and pests are controlled.

Plums are the most widely distributed of the stone fruits. The fruit is grown over a wide region in Europe, from Italy on the south to Norway and Sweden on the north. The Soviet Union is the leading European producer of plums, followed by Yugoslavia and Romania. A popular distilled liquor called *šljivovica* made from plums is an important article of commerce in Yugoslavia. Germany is the next-largest producer of plums in Europe, with a tree potential that in some years has equalled that of the United States in production. Turkey and China are leading countries in plum production in Asia.

Plum varieties that can be or have been dried without resulting in fermentation are called prunes. Such plums have firm flesh and contain a sufficiently high level of sugar, qualities that favour their being preserved by drying, which is done in dehydrators or in the sun. Dried prunes keep far longer than do fresh plums.

plum curculio, also called AMERICAN PLUM WEEVIL (*Conotrachelus nenuphar*), North American insect pest of the family Curculionidae (order Coleoptera); it does serious damage to a variety of fruit trees. The adult has a dark brown body, about six millimetres (¼ inch) long, with gray and white patches and conspicuous humps on each wing case. It has the typical weevil's snout, strongly down-curved for puncturing the skin of young fruit (apple, plum, peach, or cherry) so that an egg can be deposited in each wound. An average of less than 100 eggs are produced by each female. After hatching, the legless larva burrows into the centre of the fruit, spoiling it. The larva then leaves the fruit and enters the soil, where it pupates and eventually emerges as an adult. Up to two generations occur annually. Both sexes of the adult plum curculio pass the winter in hibernation.

plum-yew (*Cephalotaxus* species), any of about seven species of small coniferous trees and shrubs in the genus *Cephalotaxus,*

Plum-yew (*Cephalotaxus drupacea*)
Joan E. Rahn—EB Inc.

comprising the plum-yew family (Cephalotaxaceae). Native to central and eastern Asia, these plants are used in many temperate-zone areas as ornamentals. The small, fleshy, plumlike fruit contains a single, hard seed. The Japanese plum-yew, or cow's tail pine (*C. harringtonia*), grows only in cultivation; it may reach 3 metres (about 10 feet). The Chinese plum-yew (*C. fortuni*) grows to 12 m (40 ft) in the wild and up to 6 m (20 ft) under cultivation.

plumage, collective feathered covering of a bird. It provides protection, insulation, and adornment and also helps streamline and soften body contours, reducing friction in air and water. Plumage of the newborn chick is downy, called neossoptile; that which follows is termed teleoptile. Juvenal plumage, frequently distinct from that of the adult bird, is often drab, streaked, or spotted and thus camouflages the young.

Sexual differences are common, the plumage of the male usually showing more brilliance and pattern than that of the female. Feathers are normally lost and replaced at least once a year through molt and regrowth. Eclipse plumage, typical of ducks but found in other birds as well, is dull, female-like plumage worn by the male for a month or more in summer after breeding. It "eclipses" his usual bright plumage. He soon molts and is flightless until he grows new wing feathers. *Compare* pelage.

Plumbaginales, the plumbago, or leadwort, order of dicotyledonous flowering plants comprising the family Plumbaginaceae, with 10 genera of herbs and shrubs, found throughout the world but especially in semi-arid salt steppes and seacoasts of Europe, Asia, Africa, and Australia. The plants are characterized by alternating, simple leaves that often bear glands on the surface and by radially symmetrical, bisexual flowers, the petals of which are fused into a tube, and the sepals of which remain attached to the fruit until maturity.

Thrift (*Armeria*)
Kenneth W. Fink from Root Resources—EB Inc.

The male flower parts (stamens) number five and arise from the inner surface of the corolla (fused petal tube) opposite the petal lobes. The female structure (pistil) is superior, *i.e.,* positioned above the other flower parts, and is composed of five carpels (structural segments), which enclose one chamber containing a single ovule. The upper part of the pistil consists of five more or less united styles topped by their stigmas, the pollen-receptive surfaces. The largest genera include *Limonium* (300 species), *Acantholimon* (150 species), *Armeria* (80 species), *Plumbago* (12 species), *Limoniastrum* (10 species), and *Ceratostigma* (8

Plumbago capensis
L.J. Uttal

species). The remaining four genera (*Dyerophytum, Aegialitis, Plumbagella,* and *Limoniopsis*) contain only one or two species each.

Economically the group is important mainly for the many garden ornamentals it contains. Among these are a number of species of *Armeria* that go by the common name thrift, especially *A. maritima,* also called sea pink, a plant with small red flowers that is common on sea cliffs and in high mountains in western Europe. Sea lavender (*Limonium vulgare*), with small flowers in dense spikes, grows in large tracts that sometimes turn acres of ground lilac-coloured during the late summer blooming season. The flower spikes of *L. vulgare* and other *Limonium* species, also known as sea lavender, are often used in dry-flower arrangements for their lasting qualities and permanent colours. Prickly thrifts (species of *Acantholimon*, especially *A. glumaceum*) are favourite rock-garden plants. The sap of leadwort (*Plumbago europea*) is irritating and caustic, as are the juices of other *Plumbago* species, for example, *P. indica* (or *P. rosea*) and *P. scandens,* which are grown in the cool greenhouse for their rose and white or blue flowers, respectively. The leaves and roots of *P. zeylanica* have been used as a remedy for skin disease, especially in the tropical Far East. The active principle extracted from *Plumbago* roots, used in several medicinal drugs, is a yellow pigment called plumbagin.

plumbago (mineral): *see* graphite.

plumbing, system of pipes and fixtures installed in a building for the distribution and use of potable (drinkable) water and the removal of waterborne wastes. It is usually distinguished from water and sewage systems that serve a group of buildings or a city.

One of the problems of every civilization in which the population has been centralized in cities and towns has been the development of adequate plumbing systems. In certain parts of Europe the complex aqueducts built by the Romans to supply their cities with potable water can still be seen. However, the early systems built for the disposal of human wastes were less elaborate. Human wastes were often transported from the cities in carts or buckets or else discharged into an open, water-filled system of ditches that led from the city to a lake or stream.

Improvement in plumbing systems was very slow. Virtually no progress was made from the time of the Romans until the 19th century. The relatively primitive sanitation facilities were inadequate for the large, crowded population centres that sprang up during the Industrial Revolution, and outbreaks of typhoid fever and dysentery were often spread by the consumption of water contaminated with human wastes. Eventually these epidemics were curbed by the development of separate, underground water and sewage systems, which eliminated open sewage ditches. In addition, plumbing fixtures were designed to handle potable water and water-borne wastes within buildings.

The term plumbing fixture embraces not only showers, bathtubs, lavatory basins, and toilets but also such devices as washing machines, garbage-disposal units, hot-water heaters, dishwashers, and drinking fountains.

The water-carrying pipes and other materials used in a plumbing system must be strong, noncorrosive, and durable enough to equal or exceed the expected life of the building in which they are installed. Toilets, urinals, and lavatories usually are made of stable porcelain or vitreous china, although they sometimes are made of glazed cast iron, steel, or stainless steel. Ordinary water pipes usually are made of steel, copper, brass, plastic, or other nontoxic material; and the most common materials for sewage pipes are cast iron, steel, copper, and asbestos cement.

Methods of water distribution vary. For towns and cities, municipally or privately owned water companies treat and purify water collected from wells, lakes, rivers, and ponds and distribute it to individual buildings. In rural areas water is commonly obtained directly from individual wells.

In most cities, water is forced through the distribution system by pumps, although, in rare instances, when the source of water is located in mountains or hills above a city, the pressure generated by gravity is sufficient to distribute water throughout the system. In other cases, water is pumped from the collection and purification facilities into elevated storage tanks and then allowed to flow throughout the system by gravity. But in most municipalities water is pumped directly through the system; elevated storage tanks may also be provided to serve as pressure-stabilization devices and as an auxiliary source in the event of pump failure or of a catastrophe, such as fire, that might require more water than the pumps or the water source are able to supply.

The pressure developed in the water-supply system and the friction generated by the water moving through the pipes are the two factors that limit both the height to which water can be distributed and the maximum flow rate available at any point in the system.

A building's system for waste disposal has two parts: the drainage system and the venting system. The drainage portion comprises pipes leading from various fixture drains to the central main, which is connected to the municipal or private sewage system. The venting system consists of pipes leading from an air inlet (usually on the building's roof) to various points within the drainage system; it protects the sanitary traps from siphoning or blowing by equalizing the pressure inside and outside the drainage system.

Sanitary fixture traps provide a water seal between the sewer pipes and the rooms in which plumbing fixtures are installed. The most commonly used sanitary trap is a U bend, or dip, installed in the drainpipe adjacent to the outlet of each fixture. A portion of the waste water discharged by the fixture is retained in the U, forming a seal that separates the fixture from the open drainpipes.

plumbism: *see* lead poisoning.

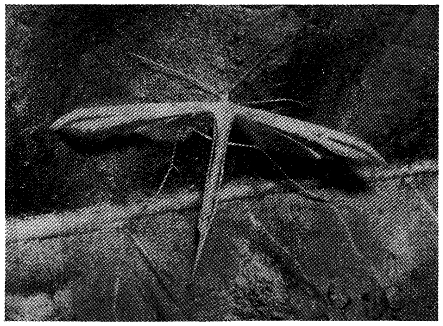
plumbojarosite, a widespread iron and lead sulfate mineral, $PbFe_6(SO_4)_4(OH)_{12}$, that has been found in the oxidized zone of lead deposits, particularly in arid regions. It is an important ore mineral of lead in Bolkar Daği, Tur., and in Clark County, Nev. It also occurs in many places in the western United States. For detailed physical properties, *see* sulfate mineral (table).

Consult the INDEX *first*

plume grass, any of about 20 species of grasses constituting the genus *Erianthus* (family Poaceae), native to warm regions of the Northern and Southern hemispheres. Plume grasses are tall, reedlike perennials with dense, cylindrical, plumelike panicles. Most species are 1 to 3 m (3 to 10 feet) tall, but Ravenna grass (*E. ravennae*), native to southern Europe, grows to 4 m (13 feet). It is cultivated as an ornamental for its long (0.6 m [2 feet]) panicle.

plume moss: *see* feather moss.

plume moth, any of the approximately 600 species of the cosmopolitan insect family Pterophoridae (order Lepidoptera), named for the deep wing divisions that resemble plumes or lobes. It differs from the many-plumed moth, an Orneodidae-family member, in that its forewings and hindwings are not split down to their base into six plumes but are divided only to their middle, the forewings usually into two plumes, the hindwings into three. Plume moths have slender bodies with long, fragile legs. The moths vary in wingspan from 6 to 50 mm (0.25 to 2 inches) and are weak fliers. Active at night, they usually rest in plants during the day, stretching their wings



Plume moth (*Platyptilia ochrodactyla*)

out and rolling them into the shape of a rod, rather than folding them back. Larval habits range from rolling leaves to boring in stems.

plumebird, any of several bird-of-paradise species. *See* bird-of-paradise.

Plummer, Christopher, byname of ARTHUR CHRISTOPHER ORME PLUMMER (b. Dec. 13, 1929, Toronto), Canadian actor known for his interpretations of classical roles on the stage as well as his starring and supporting roles in motion pictures.

Plummer made his first professional appearance in 1950 in Ottawa and spent several years performing with Canadian repertory theatre groups. In 1954 he made his New York City debut and soon attracted wide critical praise. He joined the American Shakespeare Festival Company in Stratford, Conn., in 1955—quickly establishing a reputation as a leading Shakespearean actor and performing in repertory in Canada and England as well as the United States. His nonclassical roles included those in such plays as *The Dark is Light Enough* (1955), *The Lark* (1955), *Arturo Ui* (1963), *The Royal Hunt of the Sun* (1965), and *The Good Doctor* (1973). In 1981 he returned to Shakespeare to play Iago, opposite the Othello of James Earl Jones.

Plummer's first motion picture was *Stage Struck* (1956), and later notable film performances were in *The Sound of Music* (1965), *The Battle of Britain* (1968), *The Man Who Would Be King* (1975), *The Silent Partner* (1978), *Murder by Decree* (1980), and *Eyewitness* (1981).

Plummer's disease, also called TOXIC MULTINODULAR GOITRE, thyroid condition characterized by marked enlargement of the thyroid gland (goitre), firm thyroid nodules, and mild overproduction of thyroid hormone (hyperthyroidism). Plummer's disease, which usually occurs in older people, is of unknown etiology. Its symptoms resemble those of Graves' disease (*q.v.*), a condition believed to be an autoimmune disorder caused by antibodies to the thyroid.

Typically, persons affected by Plummer's disease develop a goitre many years before the onset of symptoms of hyperthyroidism; most patients are over age 50 before the characteristic accelerated heart rate and other cardiac conditions appear. Unlike other forms of hyperthyroidism, the disease seldom causes bulging of the eyes (exophthalmos). Swelling of the thyroid gland may obstruct breathing or swallowing, requiring surgery to remove the excess tissue; the cardiac symptoms, resulting in congestive heart failure in some cases, can also be fatal. In the absence of obstruction or cosmetic reasons for removing the gland, the goitre may be treated with drugs that block thyroid activity or with radioactive iodine therapy; however, the multiple thyroid nodules characteristic of the disease may raise suspicion of cancer, necessitating surgical excision of the gland.

Plumtree, town, Matabeleland North Province, southwestern Zimbabwe. At the Botswana border, it is the last major Zimbabwean station on the Bulawayo–Cape Town railway and has customs, immigration, and quarantine facilities. Founded in 1897, it serves the Bulalima-Mangwe district as administrative centre. Local industries include grain milling and brickmaking. Pop. (latest census) 2,040.

Plunket, Saint Oliver, Plunket also spelled PLUNKETT (b. 1629, Loughcrew, County Meath, Ire.—d. July 1, 1681, London; canonized 1975; feast day July 11), Roman Catholic primate of all Ireland and the last man to

St. Oliver Plunket, engraving by R. Collin, 1681

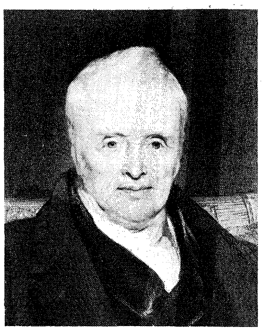
By courtesy of the trustees of the British Museum; photograph, J.R. Freeman & Co. Ltd.

suffer martyrdom for the Catholic faith in England.

Plunket was educated and ordained in Rome, serving there as professor of theology at the College of Propaganda Fide and as the representative of the Irish bishops at the Holy See. Appointed archbishop of Armagh and primate of all Ireland in 1669, he arrived in the following year at a time when, after prolonged repression, the Catholic Church was greatly disorganized, with only one aged bishop at liberty. Setting himself to restore order and discipline in accordance with the precepts of the Council of Trent, Plunket kept on good terms with the English and the Protestants until in 1673 when, under renewed persecution, he was obliged to go into hiding. For the next five years he laboured under conditions of increasing difficulty, brought to a climax by the terror inspired by the Titus Oates plot of 1678. In the following year he was betrayed, arrested, and imprisoned in Dublin Castle. His trial at Dundalk was made absurd by the ignominious witnesses for the prosecution; he was taken to London, where, after protracted and farcical legal proceedings, he was sentenced to be hanged, disembowelled, and quartered; the sentence was carried out at Tyburn before a large crowd. Plunket was beatified by Benedict XV in 1920 and canonized by Pope Paul VI on Oct 12, 1975. His head is preserved at Drogheda and his body at Downside Abbey, near Bath.

Plunket (of Newton), William Conyngham Plunket, 1st Baron (b. July 1, 1764, Enniskillen, County Fermanagh, Ire.—d. Jan. 4, 1854, near Bray, County Wicklow), Anglo-Irish lawyer, parliamentary orator, successor to Henry Grattan (died 1820) as chief spokesman for Roman Catholic emancipation—*i.e.,* admission of Catholics to the British House of Commons, a goal that was achieved in 1829.

Called to the Irish bar in 1787, Plunket was highly successful as an equity lawyer. Entering the Irish Parliament in 1798, he found that the British prime minister, William Pitt the Younger, was planning an Anglo-Irish



1st Baron Plunket, engraving by David Lucas, 1844, after a painting by Richard Rothwell

By courtesy of the trustees of the British Museum; photograph, J.R. Freeman & Co. Ltd.

legislative union that would abolish the Irish Parliament. During Grattan's temporary retirement from politics (1797–1800), Plunket was the most vehement opponent of Pitt's design, speaking often in the Irish legislature and writing articles for the newspaper *Anti-Union* (1798–99). On the passage of the Act of Union (Aug. 1, 1800), he returned to his law practice. In 1803 he acted for the crown in prosecuting the Irish nationalist Robert Emmet for his futile rising in Dublin. Emmet was executed, and later in the year Pitt appointed Plunket solicitor general of Ireland. Charged with disloyalty to the Irish cause by a writer in the *Weekly Register,* Plunket in 1804 recovered damages for libel from that periodical's editor, the English radical William Cobbett.

After serving as Irish attorney general (1805–07), Plunket sat in the British House of Commons (1807, 1812–27). Himself a Presbyterian minister's son, he unsuccessfully introduced bills (1821, 1825) for increased political rights for Catholics. He disliked popular agitation, however, and opposed the Irish leader Daniel O'Connell's Catholic Association. The Emancipation Act of 1829 was passed two years after Plunket had been created baron (1827). From 1830 to 1841 he was lord chancellor of Ireland, his term proving largely uneventful.

Plunkett, Edward John Moreton Drax: *see* Dunsany, Edward John Moreton Drax Plunkett, 18th Baron.

Plunkett, Sir Horace Curzon (b. Oct. 24, 1854, Sherborne, Gloucestershire, Eng.—d. March 26, 1932, Weybridge, Surrey), pioneer of Irish agricultural cooperation who strongly influenced the rise of the agricultural cooperative movement in Great Britain and the Commonwealth.

Educated in England, he went to the United States in 1879 and spent 10 years as a cattle rancher in Wyoming. He returned to Ireland in 1889 and devoted himself to the agricultural cooperative movement, first organizing creameries and then, in 1894, the Irish Agricultural Organization Society, a forerunner of similar societies in England, Wales, and Scotland. A Unionist member of Parliament for South County Dublin from 1892 to 1900, he became president in 1899 of the new Department of Agriculture and Technical Instruction for Ireland, which he had been instrumental in creating.

His later experience convinced him of the need for the independence of an Ireland without partition inside the Commonwealth, and he fought strongly for this goal, although from 1922 to 1923 he was a senator of the Irish Free State. In 1919, in London, he endowed a trust, now the Plunkett Foundation for Cooperative Studies, as a commonwealth agricultural research and information centre. He was made a fellow of the Royal Society in 1902 and Knight Commander of the Royal Victorian Order in 1903. His writings include *Ireland in the New Century* (1904) and *The Rural Life Problem of the United States* (1910).

pluralism, in social and political thought, the autonomy enjoyed by disparate groups within a society—such groups as religious groups, trade unions, professional organizations, or ethnic minorities.

The term also refers to the doctrine that the existence of such groups is beneficial, a major element in the ideologies of both the liberal Western nations and the Communist nations. Pluralism was stressed most vigorously in England during the early 20th century by a group of writers (including F. Maitland, S.G. Hobson, Harold Laski, R.H. Tawney, and G.D.H. Cole) reacting against what they alleged to be the alienation of the individual under conditions of unrestrained capitalism. It was necessary, they argued, to integrate the individual in a social context that would give him a sense of community; a historical example of such a society was held to be the medieval structure of guilds, chartered cities, villages, monasteries, and universities. Some of the negative aspects of modern industrial society might be overcome, the pluralists argued, by economic and administrative decentralization.

pluralism and monism, philosophical theories that answer "many" and "one," respectively, to the distinct questions: how many kinds of things are there? and how many things are there? Different answers to each question are compatible, and the possible combination of views provide a popular way of viewing the history of philosophy.

All philosophy as well as science may be regarded as a search for unity in the attempt to comprehend the diversity of things under general principles or laws. But some thinkers have been so attracted to unity that they have denied the multiplicity of things and asserted some form of monism. Thus, Parmenides in the ancient world held that all is being, since whatever is is; Spinoza at the beginning of modern philosophy asserted that there is but one infinite divine substance in which everything else has its finite being as a mode or affect; whereas for Hegel all that is is the Absolute Idea developing through time.

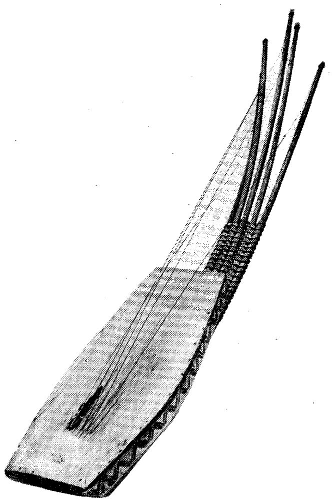
Opposed to such monistic theories are those philosophers for whom the multiplicity and diversity of things rather than their unity is the more striking and important fact. Thus William James, who titled one of his books *A Pluralistic Universe,* held that it is characteristic of empirically minded thinkers to note and take into account the changeability of things, their multiplicity in being as well as in their relations with one another, and the unfinished character of the world as in process. James asserted that the problem of the one and the many is "the most central of all philosophical problems" in that the answer given to it influences so greatly the approach to other problems and the answers given to them.

plurality system, electoral process in which the candidate who polls more votes than any other candidate is elected. It is distinguished from the majority system, in which, to win, a candidate must receive more votes than all other candidates combined. Election by a plurality is the most common method of selecting candidates for public office.

Advantages of the plurality system are that it is easily understood by voters, provides a quick decision, and is more convenient and less costly to operate than other methods. The main argument against it is that in an election with more than two candidates, it may result in the election of a candidate who has received only a minority of the votes cast: for example, in a closely contested election with four candidates, the total required to win by a plurality could be as little as 25 percent of the total vote plus one. To overcome this disadvantage, alternative devices, such as election by an absolute majority and proportional representation (*q.v.*), are used. The plurality method operates best under a two-party system.

Election by a plurality is not limited to government; it is commonly used in the selection of officers in such large organizations as trade unions and professional associations and also in arriving at decisions at meetings of boards of directors and trustees.

pluriarc, also called BOW LUTE, west African stringed musical instrument having a deep boxlike body from which project between two and eight slender, curved arms; one string runs from the end of each arm to a string holder on



West African *pluriarc;* in the Pitt-Rivers Museum, Oxford
By courtesy of the Pitt-Rivers Museum, Oxford

the belly. The strings are plucked, usually by the fingers, occasionally by plectra attached to the fingers. They are generally played open, as on a harp; in some regions they are stopped, as on a lute. The *pluriarc,* possibly derived from the musical bow, is known by various names among many peoples of the Congo and Gabon and a few of southern Africa; as the *kissanga* it was taken to Cuba by African slaves. As early as the 16th century it was described by the German composer Michael Praetorius.

Plutarch, Greek PLUTARCHOS, Latin PLUTARCHUS (b. *c.* AD 46, Chaeronea, Boeotia [Greece]—d. after 119), biographer and author whose works strongly influenced the evolution of the essay, the biography, and historical writing in Europe from the 16th to the 19th century. Among his approximately 227 works, the most important are the *Bioi parallēloi* (*Parallel Lives*), in which he recounts the noble deeds and characters of Greek and Roman soldiers, legislators, orators, and statesmen, and the *Moralia,* or *Ethica,* a series of more than 60 essays on ethical, religious, physical, political, and literary topics.

Life. Plutarch was the son of Aristobulus, himself a biographer and philosopher. In 66–67, Plutarch studied mathematics and philosophy at Athens under the philosopher Ammonius. Public duties later took him several times to Rome, where he lectured on philosophy, made many friends, and perhaps enjoyed the acquaintance of the emperors Trajan and Hadrian. According to the Suda lexicon (a Greek dictionary dating *c.* AD 1000), Trajan bestowed the high rank of an ex-consul upon him. Although this may be true, a report of a 4th-century church historian, Eusebius, that Hadrian made Plutarch governor of Greece is probably apocryphal. A Delphic inscription reveals that he possessed Roman citizenship; his *nomen,* or family name, Mestrius, was no doubt adopted from his friend Lucius Mestrius Florus, a Roman consul.

Plutarch traveled widely, visiting central Greece, Sparta, Corinth, Patrae (Patras), Sardis, and Alexandria, but he made his normal residence at Chaeronea, where he held the chief magistracy and other municipal posts and directed a school with a wide curriculum in which philosophy, especially ethics, occupied the central place. He maintained close links with the Academy at Athens (he possessed Athenian citizenship) and with Delphi, where, from about 95, he held a priesthood for life; he may have won Trajan's interest and support for the then-renewed vogue of the oracle. The size of Plutarch's family is uncertain. In the *Consolatio* to his wife, Timoxena, on the death of their infant daughter, he mentions four sons; of these at least two survived childhood, and he may have had other children.

Plutarch's literary output was immense. The 227 titles in the so-called catalog of Lamprias, a list of Plutarch's works supposedly made by his son, are not all authentic, but neither do they include all he wrote. The order of composition cannot be determined.

The Lives. Plutarch's popularity rests primarily on his *Parallel Lives.* These, dedicated to Trajan's friend Sosius Senecio, who is mentioned in the lives "Demosthenes," "Theseus," and "Dion," were designed to encourage mutual respect between Greeks and Romans. By exhibiting noble deeds and characters, they were also to provide model patterns of behaviour.

The first pair, "Epaminondas and Scipio," and perhaps an introduction and formal dedication, are lost. But Plutarch's plan was clearly to publish in successive books biographies of Greek and Roman heroes in pairs, chosen as far as possible for their similarity of character or career, and each followed by a formal comparison. Internal evidence suggests that the *Lives* were composed in Plutarch's later years, but the order of composition can be only partially determined; the present order is a later rearrangement based largely on the chronology of the Greek subjects, who are placed first in each pair. In all, 22 pairs survive (one pair being a double group of "Agis and Cleomenes" and the "Gracchi") and four single biographies, of Artaxerxes, Aratus, Galba, and Otho.

The *Lives* display impressive learning and research. Many sources are quoted, and, though Plutarch probably had not consulted all these at first hand, his investigations were clearly extensive, and compilation must have occupied many years. For the Roman *Lives* he was handicapped by an imperfect knowledge of Latin, which he had learned late in life, for, as he explains in "Demosthenes," political tasks and the teaching of philosophy fully engaged him during his stay in Rome and Italy. The form of the *Lives* represented a new achievement, not closely linked with either previous biography or Hellenistic history. The general scheme was to give the birth, youth and character, achievements, and circumstances of death, interspersed with frequent ethical reflections, but the details varied with both the subject and the available sources, which include anecdote mongers and writers of memoirs as well as historians. Plutarch never claimed to be writing history, which he distinguished from biography. His aim was to delight and edify the reader, and he did not conceal his own sympathies, which were especially evident in his warm admiration for the words and deeds of Spartan kings and generals; his virulent and unfair attack on Herodotus, the Greek historian of the 5th century BC, probably sprang from his feeling that he had done Athens more and Boeotia less than justice.

The Moralia. Plutarch's surviving writings on ethical, religious, physical, political, and literary topics are collectively known as the *Moralia,* or *Ethica,* and amount to more than 60 essays cast mainly in the form of dialogues or diatribes. The former vary from a collection of set speeches to informal conversation pieces set among members of Plutarch's family circle; the date and dramatic occasion are rarely indicated. The diatribes, which often show the influence of seriocomic writings of the 3rd-century-BC satirist Menippus, are simple and vigorous. The literary value of both is enhanced by the frequent quotation of Greek poems, especially verses of Euripides and other dramatists.

The treatises dealing with political issues are of especial interest. "Political Precepts" is an enlightening account of political life in contemporary Greece; in "Whether a Man Should Engage in Politics When Old," Plutarch urged his friend Euphanes to continue in public life at Athens; Stoic ideas appear in the short work "To the Unlearned Ruler" and the fragmentary argument that "The Philosopher Should Converse Especially with Princes."

Plutarch's interest in religious history and antiquarian problems can be seen in a group of striking essays, the early "Daemon of Socrates," and three later works concerning Delphi, "On the Failure of the Oracles," in which the decline of the oracle is linked with the decline in the population, "On the E at Delphi," interpreting the word EI at the temple entrance, and "On the Pythian Responses," seeking to reestablish belief in the oracle. Contemporary with these is "On Isis and Osiris," with its mystical tones. "Convivial Questions" (nine books) and "Greek and Roman Questions" assembled a vast collection of antiquarian lore.

Among the more important works no longer accepted as authentic are the *Consolatio* to Apollonius for his son, the "Lives of the Ten Orators," "On Fate," the "Short Sayings of Kings and Commanders," the "Short Sayings of Spartans," and "Proverbs of the Alexandrines."

Assessment. Plutarch's perennial charm and popularity arise in part from his treatment of specific human problems in which he avoids raising disquieting solutions. He wrote easily and superficially, with a wealth of anecdote. His style is predominantly Attic, though influenced by the contemporary Greek that he spoke; he followed rhetorical theory in avoiding hiatus between words and was careful in his use of prose rhythms. He is clear, but rather diffuse. Plutarch's philosophy was eclectic, with borrowings from the Stoics, Pythagoreans, and Peripatetics (but not the Epicureans) grouped around a core of Platonism. His main interest was in ethics, though he developed a mystical side, especially in his later years; he reveals that he had been initiated into the mysteries of the cult of Dionysus, and both as a Platonist and as an initiate he believed in the immortality of the soul. He believed too in the superiority of Greek culture and in the meritoriousness and providential character of the Roman Empire. Personally, he preferred a quiet and humane civic life as a citizen of a small Boeotian town, where his writing and teaching did much to illuminate the darkness of provincial life in 1st-century Greece.

Reputation and influence. Plutarch's later influence has been profound. He was loved and respected in his own time and in later antiquity; his *Lives* inspired a rhetorician, Aristides, and a historian, Arrian, to similar comparisons, and a copy accompanied the emperor Marcus Aurelius when he took the field against the Marcomanni. Gradually, Plutarch's reputation faded in the Latin West, but he continued to influence philosophers and scholars in the Greek East, where his works came to constitute a schoolbook. Proclus, Porphyry, and the emperor Julian all quote him, and the Greek Church Fathers Clement of Alexandria and Basil the Great imitate him without acknowledgment. His works were familiar to all cultivated Byzantines, who set no barrier between the pagan past and the Christian present. It was mainly the *Moralia* which appealed to them; but in the 9th century the Byzantine scholar and patriarch Photius read the *Lives* with his friends.

Plutarch's works were introduced to Italy by Byzantine scholars along with the revival of classical learning in the 15th century, and Italian humanists had already translated them into Latin and Italian before 1509, when the *Moralia,* the first of his works to be printed in the original Greek, appeared at Venice published by the celebrated Aldine Press. The first original Greek text of the *Lives* was printed at Florence in 1517 and by the Aldine Press in 1519. The *Lives* were translated into French in 1559 by Jacques Amyot, a French bishop and classical scholar, who also translated the *Moralia* (1572). The first complete edition of the Greek texts by a French humanist in 1572 marked a great improvement in the text.

That Rabelais knew Plutarch well is proved by the frequency with which he quotes from both the *Lives* and the *Moralia.* It was Montaigne, however, who read Plutarch in Amyot's version, who first made his influence widely felt. The style of Montaigne's *Essays* (1580–88) owed much to the *Moralia,* and from the *Lives* he adopted Plutarch's method of revealing character by illustrative anecdote and comment, which he applied to self-revelation. Moreover, the *Essays* made known the ideal, derived from Plutarch's presentation of character and openly expressed opinion, of "high antique virtue and the heroically moral man" which became the humanist ideal of the Renaissance period.

The *Lives* were translated into English, from Amyot's version, by Sir Thomas North in 1579. His vigorous idiomatic style made his *Lives of the Noble Grecians and Romans* an English classic, and it remained the standard translation for more than a century. Even when superseded by more accurate translations, it continued to be read as an example of Elizabethan prose style. North's Plutarch was Shakespeare's source for his Roman plays and influenced the development of his conception of the tragic hero. The literary quality of North's version may be judged from the fact that Shakespeare lifted whole passages from it with only minor changes.

In 1603 the complete *Moralia* was first translated into English directly from the Greek. Its influence can be seen in the 1612 edition of Bacon's *Essays,* which contain counsels of public morality and private virtue recognizably derived from Plutarch. Francis Bacon was more attracted by Plutarch the moralist than by Plutarch the teller of stories or painter of character, but to the Renaissance mind it was the blend of these elements that gave him his particular appeal. His liking for historical gossip, for the anecdote and the moral tale, his portrayal of characters as patterns of virtue or vice (in the manner of the morality play and the character), and his emphasis on the turn of fortune's wheel in causing the downfall of the great, all suited the mood of the age, and from him was derived the Renaissance conception of the heroic and of the "rational" moral philosophy of the ancients.

Historians and biographers in the 16th and 17th centuries followed Plutarch in treating character on ethical principles. The 17th-century English biographer Izaak Walton knew Plutarch well, and his own *Lives* (collected 1670, 1675) imitated Plutarch by dwelling on the strength, rather than the weakness, of his subjects' characters.

Plutarch was read throughout the 17th and 18th centuries. The English poet and dramatist John Dryden edited a new translation of the *Lives* first published in 1683–86, and abridged editions appeared in 1710, 1713, and 1718. The *Moralia* was retranslated in 1683–90 and also frequently reprinted. In France, Amyot's translations were still being reprinted in the early 19th century, and their influence on the development of French classical tragedy equaled that of North's version on Shakespeare. Admiration for those heroes of Plutarch who overthrew tyrants, and respect for his moral values, inspired the leaders of the French Revolution; Charlotte Corday, who assassinated the revolutionary leader Jean-Paul Marat, spent the day before that event in reading Plutarch. The German classical poets—Johann Wolfgang von Goethe, Friedrich von Schiller, and Jean Paul (Johann Paul Richter) especially—were influenced by his works, and he was read also by Beethoven and Nietzsche.

In the 19th century, Plutarch's direct influence began to decline, in part as a result of the reaction against the French Revolution, in part because the rise of the Romantic movement introduced new values and emphasized the free play of passions rather than their control, and in part because the more critical attitude of scholars to historical accuracy drew attention to the bias of his presentation of fact. He was still admired, however, notably by the American poet, philosopher, and essayist Ralph Waldo Emerson, and, although in the 20th century his direct influence was small, the popular ideas of Greek and Roman history continued to be those derived from his pages. (F.W.W./Ed.)

BIBLIOGRAPHY. R.H. Barrow, *Plutarch and His Times* (1967), is a good general introduction that lists further reading. An excellent study (in German), with comprehensive bibliography, is K. Ziegler in *Pauly-Wissowa's Real-encyclopädie der classischen Altertumswissenschaft,* vol. 41, col. 636–962 (1951). T.J.B. Spencer, *Shakespeare's Plutarch* (1964), prints North's *Lives* of Caesar, Brutus, Antony, and Coriolanus, with the relevant parts of Shakespeare.

Editions and translations. Lives. Vitae Parallelae by C. Lindskog and K. Ziegler in the "Teubner Series" (1914–39), is being revised (from 1957); *Plutarch's Lives* by B. Perrin in the Loeb edition, 11 vol. (1914–26), gives a text and translation. *Moralia. Moralia* by G. Bernadakis in the "Teubner Series," 7 vol. (1888–96), is being revised by various authors (from 1925). *Plutarch's Moralia* in the Loeb edition, with text and translation, was revised in 16 vol. (1928–69).

Pluto (Greek god): *see* Hades.

Pluto, in astronomy, ninth major planet of the solar system. It is named after the Greek and Roman god of the lower world.

A brief treatment of Pluto follows. For full treatment, *see* MACROPAEDIA: Solar System, The.

Pluto is normally the outermost of the known planets and the most distant from the Sun; its mean distance from the latter is calculated at about 5,913,000,000 km (3,666,060,000 miles). Pluto's orbit, however, is so eccentric (0.246) that the planet comes closer to the Sun than Neptune does at times around perihelion (about every 248 years), as for example between 1979 and 1999. During this 20-year interval Pluto will remain inside Neptune's orbit.

Pluto has an inclination of 17°8′ to the mean plane of the solar system, the highest of any of the major planets. Because of its great distance from the Earth, Pluto always appears relatively faint even when viewed with a telescope—no more than 14th magnitude. Pluto's brightness level varies regularly by about 12 percent in a period of 6.39 days, which indicates that the surface reflection properties of the planet are not uniform and that the planet rotates on its axis every 6.39 days.

Having a diameter of slightly more than 2,200 km (1,370 miles), Pluto is roughly two-thirds the size of the Moon. Its mean density ranges from 0.5 to 0.9 gram per cubic centimetre. Because of this low density value, many astronomers theorize that the planet consists largely of solid methane rather than of the denser rocky matter found in the inner (or terrestrial) planets. Infrared observations suggest strongly that Pluto has polar caps composed of methane ice. These ice caps sometimes appear to extend halfway to Pluto's equator. That the surface materials are frozen is supported by evidence of extremely low temperatures on the planet. It is estimated that the average surface temperature on the sunlit side of Pluto is less than 60 K when the planet is at perihelion and only about 47 K at aphelion. The far side of the planet may have a temperature as low as 20 K. The planet appears to have a thin atmosphere, also composed of methane.

Pluto's origin and evolution are obscure. Pluto differs significantly from the outer planets in such physical properties as size, mass, axial rotation, orbital eccentricity, and inclination. Thus, it most likely formed and evolved in a different manner. Some investigators have proposed that Pluto may be a runaway satellite that was originally part of Neptune's system. Not only do Pluto's properties resemble those of Triton but its orbit almost intersects Neptune's periodically. (Pluto's orbit clears that of its neighbour by only about 385,000,000 km [240,000,000 miles]). Moreover, recent computer simulations show that if a planet three times as massive as the Earth had plunged into a hypothetical proto-Neptunian satellite system of four members, one of the moons would have been perturbed away from the planet into a Pluto-like orbit.

Pluto was discovered in 1930 by the American astronomer Clyde W. Tombaugh during a systematic search for a trans-Neptunian planet predicted by Percival Lowell and William H. Pickering. In a series of photographs he had taken at the Lowell Observatory in Flagstaff, Ariz., Tombaugh recognized the new planet by its motion, which was much slower than that of numerous asteroids also recorded on the same photographs.

Pluto has one satellite, an object of less than half its size and one-tenth its mass. The satellite was discovered in 1978 by two American astronomers, James W. Christy and Robert S. Harrington, and was named Charon (*q.v.*) after the mythological boatman who ferried souls across the river Styx to Pluto for judgment.

pluton, body of intrusive igneous rock the size, composition, shape, or exact type of which is in doubt; when such characteristics are known, more limiting terms can be used. Thus, plutons include dikes, laccoliths, batholiths, sills, and other forms of intrusions. Most plutons are thought to be the result of igneous activity in which a magma is involved; the controversial origin of some large granitic bodies, however, requires that metasomatic processes or granitization be included when discussing many plutons.

Articles are alphabetized word by word, not letter by letter

plutonium (Pu), radioactive chemical element of the actinide series in Group IIIb of the periodic table, atomic number 94. It is the most important transuranium element because of its use as fuel in certain types of nuclear reactors and as an ingredient in nuclear weapons. Plutonium, warm because of energy released in alpha decay, is a silvery metal that takes on a yellow tarnish in air. The element was first detected (1940) as the isotope plutonium-238 by Glenn T. Seaborg, Joseph W. Kennedy, and Arthur C. Wahl, who produced it by deuteron bombardment of uranium-238 in the 60-inch cyclotron at Berkeley, Calif. Traces of plutonium have subsequently been found in uranium ores, where it is not primeval but naturally produced by neutron irradiation.

All plutonium isotopes are radioactive. The most important is plutonium-239 because it is fissionable, has a relatively long half-life (24,360 years), and can be readily produced in large quantities in breeder reactors by neutron irradiation of plentiful but nonfissile uranium-238. Critical mass (the amount that will spontaneously explode when brought together) must be considered when handling quantities in excess of 300 grams (2/3 lb). The critical mass of plutonium-239 is only about one-third that of uranium-235.

Plutonium and all elements of higher atomic number are radiological poisons because of their high rate of alpha emission and their specific absorption in bone marrow. The maximum amount of plutonium-239 that can be indefinitely maintained in an adult without significant injury is 0.008 microcuries (equal to 0.13 micrograms). Longer lived isotopes plutonium-242 and plutonium-244 are valuable in chemical and metallurgical research. Plutonium-238 can be manufactured to harness its heat of radioactive decay to operate thermoelectric and thermionic devices that are small and lightweight but long-lived (the half-life of plutonium-238 is 86 years).

Plutonium exhibits six forms differing in crystal structure and density (allotropes); the alpha form exists at room temperatures. It has the highest electrical resistivity of any metallic element (145 microhm-centimetres). Chemically reactive, it dissolves in acids and can exist in four oxidation states as ions of characteristic colour in aqueous solution: Pu^{3+}, blue-lavender; Pu^{4+}, yellow-brown; PuO_2^+, pink (?); PuO_2^{2+}, pink-orange. Very many compounds of plutonium have been prepared, often starting from the dioxide (PuO_2), the first compound of any synthetic element to be separated in pure form and in weighable amounts (1942).

atomic number	94
stablest isotope	244
melting point	639.5° C (1,183.1° F)
boiling point	3,235° C (5,855° F)
specific gravity (alpha)	19.84 (25° C)
valence	3,4,5,6
electronic config.	2-8-18-32-24-8-2 or (Rn)$5f^67s^2$

Plutus, in Greek religion, god of abundance or wealth, a personification of *ploutos* (Greek: "riches"). According to Hesiod, Plutus was born in Crete, the son of the goddess of fruitfulness, Demeter, and the Cretan Iasion. In art he appears chiefly as a child with a cornucopia. He was sometimes confused with Pluto (Hades), god of the underworld.

pluvial regime, a regular seasonal and annual pattern of rainfall and other precipitation in a specified region or locality.

Averaged zonally, regions of excessive precipitation, in which annual precipitation exceeds annual evaporation, exist in the tropics and at latitudes poleward of 40° in both hemispheres. In the subtropics, dominated by high atmospheric pressure, annual evaporation exceeds annual precipitation, at least over the oceans. At high-latitude coastal locations, precipitation tends to peak in winter; in the continental interior and in regions affected by monsoon winds, the maximum usually occurs in summer. Many points near the Equator have two rainy seasons, in response to the northward and southward movement of the equatorial trough with the Sun. The trough separates the trade winds of the two hemispheres and is a zone of strong convergence, rising motion, and heavy precipitation.

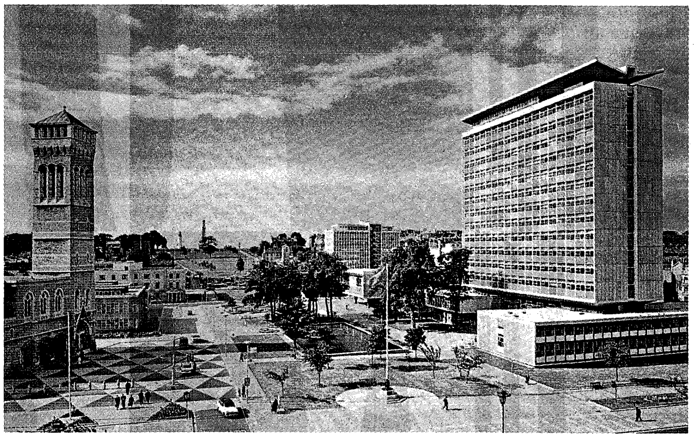
In paleoclimatology, pluvial regimes are usually associated with periods of unusually heavy precipitation as deduced from geologic evidence, especially in tropical and subtropical latitudes. The best evidence for pluvial phases in the ancient past comes from splendidly preserved lake terraces in present desert areas. Lake Bonneville in western Utah is an excellent example. The level of this lake has fluctuated greatly and rapidly during at least the last 500,000 years, with the latest pluvial stage occurring about 10,000 years ago, when the lake level was 180 metres (600 feet) above the present elevation of the lake bed. Lake Chad, in the southern Sahara, is another notable example of this widespread phenomenon.

Most authorities equate pluvial regimes in the subtropics with periods of glacial advance at higher latitudes, though, during these cold periods, global precipitation and evaporation may decrease. Because of the advancing ice sheets, the middle-latitude storm track is shifted Equatorward, thus bringing heavy precipitation to the subtropics, especially in winter. In contrast, recent evidence indicates a correspondence between glacial and interpluvial periods in the tropics. Tropical lowlands were apparently dry during the last glaciation and wet during the postglacial period.

Plymouth, district (city), county of Devon, England. It lies between the Rivers Plym and Tamar, which flow into Plymouth Sound, covering 4,500 ac (1,821 ha) and providing an extensive anchorage used principally by the Royal Navy.

Named Sudtone in Domesday Book (1086), Plymouth's original harbour is still called Sutton Harbour. A developing trade and the shipment of armies to France led to its early growth. In the 16th century the attempts of Sir Walter Raleigh to colonize Virginia were made from Plymouth; it was the home port of other famous Elizabethan adventurers, and the British fleet sailed from there to attack the Spanish Armada (1588). The Hoe (the southern waterfront) is dominated by the Citadel, built by Charles II (reigned 1660–85) to replace a Tudor castle. In 1690 the Royal Dockyard was begun on the eastern bank of the Tamar, and the town of Plymouth Dock (renamed Devonport in 1824) was founded. A third town, Stonehouse, developed between Devonport and Plymouth, and all were amalgamated in 1914.

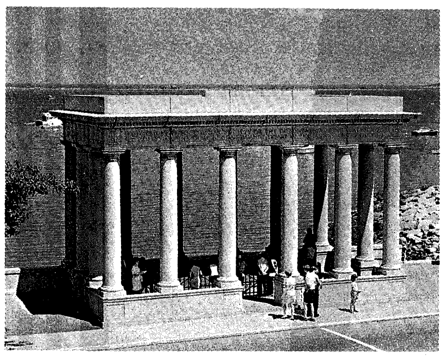
During World War II, Plymouth suffered severe bomb damage from air raids. The new Plymouth has some of the finest commercial, shopping, and civic centres in Britain. New approach roads link the city with new bridges over the Plym and Tamar. The reconstruction included the building of several satellite communities in which light industries were introduced. Others include the manufacture of machine tools, precision instruments, lubrication equipment, chemicals, and engineering products. The district has an area of 30 sq mi (79 sq km). Pop. (1983 est.) 255,200.



The Guildhall (left) and the Civic Centre (right), Plymouth, Devon
Kenneth Scowen

Plymouth, city, seat (1836) of Marshall County, northern Indiana, U.S., 23 mi (37 km) south of South Bend. Founded in 1834 and apparently named for Plymouth, Mass., it is near the site of the area's last Potawatomi Indian village from where, in 1838, more than 800 Indians were dispossessed and moved to a reservation on the Osage River in Kansas. Many of them died of malaria before reaching their destination. Plymouth is now the trade centre for an extensive agricultural area (livestock, dairy products, soybeans, and grain) and has acquired some industry. Manufactures include light machinery, batteries, and chemical fertilizers. Marshall County Historical Museum exhibits Indian artifacts. Culver Military Academy is 11 mi southwest, and Ancilla College (1937) is in nearby Donaldson. Inc. 1872. Pop. (1980) 7,693.

Plymouth, town (township), seat (1685) of Plymouth County, southeastern Massachusetts, U.S., on Plymouth Bay, 37 mi (60 km) southeast of Boston. Site of the first permanent settlement by Europeans in New England Plymouth Colony (formally, the colony of New Plymouth), it was founded by Pilgrims (separatists from the Church of England) who, in their search for religious toleration, had emigrated first to the Netherlands and then to North America. Sailing in the "Mayflower" (*q.v.*) from Plymouth, Eng., the settlers reached the shores of Cape Cod in November 1620, and an exploring party arrived in the Plymouth area on December 21 (now celebrated as Forefathers' Day). The Pilgrims landed (according to tradition) on Plymouth



Granite portico protecting Plymouth Rock, Mass.
R.E. Dietrich—Shostal/EB Inc.

Rock on December 26 and built their first fort and watchtower on Burial Hill (so called because it contains the graves of Gov. William Bradford and others of the original group). Half their number died that first winter and were buried on Cole's Hill, which was later levelled and planted to grain so that the Indians could not judge the extent of the colony's depletion. Although never officially incorporated, the town was recognized in 1633 as the seat of Plymouth Colony (absorbed into Massachusetts Bay Colony in 1691).

Its seaside location and historic associations make Plymouth an outstanding summer resort. A tourist-based economy is supplemented by light manufacturing (cordage), fishing, and cranberry growing. Seafaring was the heart of the early economy of the community, and active wharves and boatyards remain. Numerous historic attractions include Plimoth Plantation (a re-creation of the original Pilgrim village), Pilgrim Hall Museum (built in 1824), Harlow Old Fort House (a building depicting 17th-century household occupations of Plymouth women), and "Mayflower II," a goodwill ship built at Brixham, in England, that sailed across the Atlantic in 53 days in 1957. Many early colonial houses in the town have been restored, including the Edward Winslow House (now the headquarters of the Mayflower Society). Plymouth Rock, first identified in 1741, became a symbol of freedom in 1774 when it was split by being dragged to Liberty Pole Square in pre-Revolutionary agitation. It now rests on its original waterfront site under a portico of granite. On a hill behind the town is the 81-ft (25-m) National Monument to the Forefathers (Pilgrim Monument), dedicated in 1889. Plymouth includes most of Myles Standish State Forest (10,910 ac [4,415 ha]). Pop. (1980) 35,913.

Plymouth, town (township), Grafton County, central New Hampshire, U.S., on the Pemigewasset River, north-northwest of Laconia, west of Squam Lake and overlooked (southwest) by Plymouth Mountain (2,187 ft [667 m]). Chartered in 1763, it annexed parts of Hebron and Campton in 1845 and 1860. Agriculture, lumbering, and the manufacture of pig-iron, gloves, mattresses, and sporting goods are local economic activities, and since the mid-19th century the town has been a popular resort centre. The Plymouth State Fair is an annual (August) event. Plymouth State College originated in 1871 as a state normal school. Nathaniel Hawthorne died (1864) in Pemigewasset House (burned down; site near the railroad station) while on a trip to improve his health. The Tenney Mountain Ski Area and Polar Caves are nearby. Pop. (1980) 5,094.

Plymouth, town (includes Plymouth Notch, Plymouth Union, and Tyson), in Windsor County, south central Vermont, U.S. It was chartered in 1761 as Saltash and renamed in 1797. Calvin Coolidge, 30th president of the United States, was born (July 4, 1872) in Plymouth in a small house behind the crossroads village store. The homestead in Plymouth Notch where he took the presidential oath of office, on Aug. 3, 1923, and six other buildings, are preserved. Coolidge's grave is in a local church cemetery. The Calvin Coolidge State Forest is nearby. Pop. (1980) 405.

Plymouth Brethren, community of Christians whose first congregation was established in Plymouth, Devon, Eng., in 1831. The movement originated in Ireland and England a few years earlier with groups of Christians who met for prayer and fellowship. Biblical prophecy and the Second Coming of Christ were emphasized. John Nelson Darby, a former clergyman in the Church of Ireland (Anglican), soon became the dominant personality in the movement. He founded groups of Brethren in many parts of the British Isles and in continental Europe, especially in French Switzerland, where he spent the greater part of the period 1838–45.

After Darby returned to England in 1845, disputes over doctrine and church government split the Brethren. Darby's followers formed a closely knit federation of churches and were known as Exclusive Brethren; the others, called Open Brethren, maintained a congregational form of church government and less rigorous standards for membership. Exclusive Brethren have suffered further divisions.

Brethren of all parties recognize no order of clergy or ministers as distinct from the laity. A communion service is celebrated every Sunday. Practically all groups practice believer's Baptism, although some Exclusives, following Darby's practice, baptize children of members.

The Plymouth Brethren have been active in foreign missionary work, principally in Central Africa, India, and Latin America. Brethren are found throughout the English-speaking world and in most European countries. In the U.S., which they reached in the early 1860s, there are eight groups, distinguished for statistical purposes by roman numerals I through VIII.

Plymouth Company, also called VIRGINIA COLONY OF PLYMOUTH, commercial trading company chartered by England's King James I in April 1606 for the purpose of colonizing the eastern American coast between parallels 38° and 45° N. Its shareholders were men of Plymouth, Bristol, and Exeter.

The Plymouth Company was less successful than its twin, the London Company (*q.v.*). In 1606 it established two colonies, and in 1607 settlers landed at the mouth of the Kennebec River (Maine), only to abandon the enterprise the next spring. The failure of the Plymouth Company led in 1620 to its reorganization as a new company under a new charter the Council for New England, (*q.v.*).

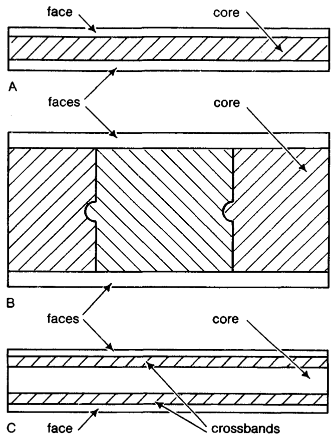
Plymouth porcelain, first hard-paste, or true, porcelain made in England, produced at a factory in Plymouth, Devon, from 1768 to 1770. Formulated by a chemist, William Cookworthy, it is distinguishable from the Bristol porcelain that he produced later by its imperfections.

Cookworthy found deposits of kaolin (a soft, white clay, also called china clay) and china stone (or petuntse, a partly decomposed granite) near St. Austell in Cornwall and began experimenting. His first porcelain was coarse, with many faults, and it was liable to smoke staining during firing. Later, both body and decoration were improved. Chinese motifs were copied from Worcester porcelain, and the shapes of the wares generally were inspired by silver work or shells, mainly from early Bow wares. Plymouth porcelain is marked in underglaze blue, blue enamel, red, or gold, with the alchemical sign for tin.

Plynlimon, Welsh PUMLUMON, ridge on the gritstone plateau of central Wales, rising to 2,468 ft (752 m) at Plynlimon Fawr. The ridge marks the watershed between drainage westward to Cardigan Bay and east to the Rivers Severn and Wye, flowing toward England and ultimately the Bristol Channel. It forms part of the administrative boundary between the counties of Dyfed and Powys. It is known for its mists and general wetness. Much of the surface is boggy and of little agricultural value except for sheep grazing. Extensive planting of conifers has been carried out by the British Forestry Commission, and the heavy rainfall sustains reservoirs supplying water to the industrial cities of England. Mining for lead was active in the 19th century and led to an extension of settlement; abandoned lead mines dot the slopes of the ridge. The area now suffers from severe rural depopulation.

plywood, composite wood panel made of three or more layers glued together with the grain of adjoining plies at right angles to each other. Thin panels are built up of veneer (thin sheet wood) exclusively. For thicker panels, sawed lumber often is used as the centre ply, or core, the product being called lumber-core plywood.

Two types of plywood are made: interior plywood, for use only in dry locations, and exterior plywood, for which water-resistant glues are used. Wherever a material is required to cover large areas with a light but strong and rigid sheeting, plywood may be used; for example, in cabinetmaking, for chests, dressers, wardrobes, and tables; in housebuilding, for walls, ceilings, floors, doors, cupboards, and cement forms; in coachbuilding, for trucks, vans, and trailers; in shipbuilding, for small boat hulls, decks, and cabins; and in boxmaking, for shipping and storage chests and cases.



Three types of plywood construction
(A) Three-ply, all veneer; (B) three-ply, lumber core; (C) five-ply, all veneer (edge views)

From "Wood Handbook," Forest Products Laboratory, U.S. Department of Agriculture

Plywood has a number of advantages over solid wood: it can be manufactured into large sheets with few defects; it is stronger than boards of the same thickness; shrinking and swelling are almost eliminated because the plies cross each other; splitting in handling and nailing is greatly reduced; and wood of lower grades can be used for the interior plies. Since veneer can be dried in a few minutes, dry plywood can be produced from green logs in a day. Plywood is almost always composed of an odd number of plies so that the grain of corresponding plies, counting from the outside in, runs in the same direction, balancing and stabilizing the construction.

Veneer used for plywood usually varies in thickness from $^1/_{28}$ to $^1/_8$ inch (0.09 to 0.32 centimetres), but both thinner and thicker veneers often are used. Thin veneers have an advantage, especially for the outer, or face, plies, in that they set up less severe transverse stresses with changes in moisture content, thereby reducing warping and surface checking (superficial cracking) of panels. The use of thin veneer also makes valuable wood go farther. Since successively cut layers of thin veneers are similar in appearance, identical areas from adjacent sheets can be matched to make highly symmetrical ornamental patterns. In lumber-core panels, the plies next to the faces or the crossbands usually are thicker than the face plies and largely control the stability of the panel.

In sandwich construction, thin facings are bonded on a thick core. The facings are made of strong material, such as thin, dense plywood, and the core of a lightweight material, such as balsa wood, cellular cellulose acetate, or paper honeycomb. The core serves primarily to separate and stabilize the thin faces, which are the principal load-carrying portions. The complete assembly is exceedingly strong and stiff for its weight.

Plzeň, German PILSEN, city, capital of Západočeský *kraj* (Western Bohemia region), Czechoslovakia; it lies in the fertile Plzeň basin, where several tributaries gather to form the Berounka River. Situated on a busy trade route between Prague and Bavaria, it was first recorded in the 10th century, chartered in 1292, and fortified in 1295 by King Wenceslas II. Plzeň was a Roman Catholic stronghold in the 15th century during the Hussite Wars and withstood long sieges.

The medieval town square forms the centre of Plzeň and is dominated by St. Bartholomew's church, with its slender steeple (335 ft [102 m]), the highest in Bohemia; the Franciscan church of the Virgin Mary; and the Renaissance town hall (1556) and burgher houses.

The coalfields at nearby Nýřany and local iron-ore deposits gave rise in the 19th century to Plzeň's engineering industry, symbolized by the Škoda (now officially the V.I. Lenin) Works, which occupy most of the city's western sector. Severely damaged in World War II, the factories were rebuilt and restored to production. Best known for munitions, the Škoda Works also manufacture heavy machinery, military aircraft, railway locomotives, and cars. Škoda pioneered the development of electric-railway locomotives, with plastic body panels to reduce axle loadings. Since the Middle Ages, Plzeň has been famous for its Pilsner beer; its Měšťanský pivovar (Citizen's Brewery) was built in 1842. Other manufactures include chemicals, pottery, hardware, and paper. The city is the transportation hub and the economic and cultural centre of western Bohemia. It is the site of the College of Mechanical and Electrical Engineering (1949; reconstituted 1953–60) and the West Bohemian Gallery and Museum. Pop. (1984 est.) 174,094.

pneumatic device, any of various tools and instruments that generate and utilize compressed air. Examples include rock drills, pavement breakers, rivetters, forging presses, paint sprayers, blast cleaners, and atomizers.

Compressed-air power is flexible, economic, and safe. An air device creates no spark hazard in an explosive atmosphere and can be used under wet conditions without electric shock hazard. A relatively small compressor suffices to fill a storage tank for intermittent use, and no return lines are needed. Other characteristics of a compressed-air system are important in meeting special service requirements. It is relatively easy to connect one device (such as a valve or a cylinder and piston) to another by pipe, tubing, or flexible hose. Many actions can be controlled by a simple manipulation of valves. The motion of an actuating piston in a cylinder can be changed quickly and in small steps with practically no shock. An air system can provide great flexibility in speed and motion control. Relief valves are easily arranged to protect a system and avoid damage. Control of operations is simple, efficient, and centralized. In general, air systems have relatively few moving parts, contributing to high reliability and low maintenance costs.

Development of pneumatic devices. The ordinary hand bellows, used by early smelters and blacksmiths for working iron and other metals, was a simple type of air compressor. The air intake consisted of several holes in a piece of wood, covered with flaps that served as valves. A simple check valve in the discharge prevented air from being drawn back into the bellows during the suction stroke. In the time of Hero (probably 1st century AD) a simple jet-type compressor was used to provide air for smelting and forging.

In the 17th century, Otto von Guericke, of Magdeburg, Ger., carried out notable experiments and made significant improvements in compressors. In 1829 a stage, or compound, compressor which involved compressing air in successive cylinders was patented. Cooling by jets of water sprayed into the cylinder during compression was introduced about 1872; later, a better system of cooling by the use of water-jacketed cylinders was developed. In the United States the first compressor used in large-scale work was a four-cylinder unit for the Hoosac Tunnel, at North Adams, Mass., in 1866.

The 20th century witnessed a large increase in the use of compressed air and of compressed-air devices. The introduction of jet engines for military and passenger aircraft stimulated the use and improvement of centrifugal and axial-flow compressors. The further development of automatic machinery, labour-saving devices, and automatic-control systems led to an increase in the use of pneumatics. In the late 1960s there began a significant development of a new class of compressed-air devices: digital-logic pneumatic-control components, which can be used in various power and control systems.

Major types of pneumatic devices. Air compressors and pneumatic tools constitute the principal classes of pneumatic devices. Other kinds of apparatus that make use of compressed air are paint-spray equipment, pneumatic tubes for conveying materials, and train brake systems.

An air compressor is a power-driven machine for compressing air from some initial intake pressure (usually atmospheric) to a higher pressure. Compressors (as well as other fluid machines) can be classified into two main types, depending on the air or fluid action: (1) the positive-displacement type and (2) the velocity, or dynamic, type.

In the positive-displacement, or static-pressure, type, the characteristic action is a volumetric change or displacement action. Successive volumes of air are confined within a closed space, and the pressure is increased by reducing the volume of the space. In the simple hand tire pump, pressure is developed by moving a piston in a cylinder. The positive-displacement type may be subdivided into reciprocating (back-and-forth straight-line motion) and rotary (motion in a circular path) compressors. In a positive-displacement machine, neglecting leakage, the volume rate of flow (cubic feet per second) through the compressor is essentially constant over a wide range of discharge pressures.

The dynamic type of compressor may be subdivided into the centrifugal type (with flow through a rotating runner or rotor primarily in a radial direction), the axial-flow type (with flow through a runner primarily in a direction parallel to the axis of rotation), and the fluid-jet type.

Pneumatic tools can be separated into two broad categories on the basis of the driving method: rotor and reciprocating piston. Both kinds are known as air motors. A rotating type of compressor, operating in reverse, serves as one type of motor. Compressed air enters the housing, pushes on the vanes, and rotates a central shaft or spindle. A drill, grinding wheel, or other device is fastened to the spindle. A reciprocating compressor, operating in reverse, also functions as a motor. Compressed air enters the cylinder, expands, and forces the piston to move. The return stroke may be actuated by compressed air on the other side of the piston or by spring action. A tool, such as a rivetting hammer, may be connected to the reciprocating piston. Pneumatic tools are normally supplied with compressed air at about 90 psig (pounds per square inch gauge).

With compressed air as the power source, tools have been designed that are relatively lightweight, compact, portable, easy to operate, and free from electrical shock and spark hazards. In underwater operations, compressed air prevents water from entering the air motor.

Pneumatic tools can also be divided into two groups according to the type of tools: portable tools and rock drills. Portable pneumatic tools include abrasive devices (*e.g.*, grinders, buffers, and sanders), drills, reamers, tappers, stud setters, screwdrivers, nutsetters, shears, wrenches, and impact tools. They are normally powered by a rotary-vane type of air motor. Operating speeds can be varied by throttling the air to the motor. Air motors do not become hot when overloaded; they will stand repeated stalling and rapid reversals without damage. Figure 1 illustrates a grinder; the air motor is typical for this class of device.

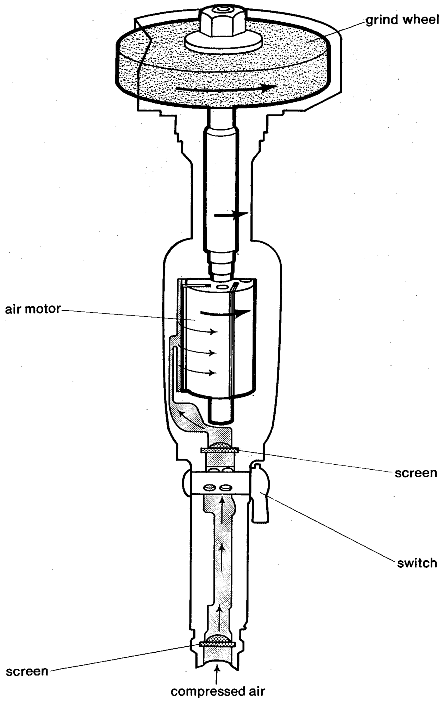


Figure 1: Pneumatic grinder

Reprinted from the *CAGI Fundamentals of Compressed Air Power* with permission of Compressed Air and Gas Institute

Portable tools also include chipping hammers and air hoists. Pneumatic chipping hammers contain an air-operated piston that delivers successive blows to a chisel or forming tool at the end of the hammer. The valve type of tool has a separate mechanism to control the airflow to the piston, thus allowing the operator to control the speed and force of the blows. In a compression rivetter the compression, or squeezing action, on the rivet is obtained from an air piston connected to a cam, wedge, or toggle. A yoke rivetter has an air-operated clamp or vise that holds the work in place; the yoke absorbs the hammering action and thus reduces operator fatigue. Hoists operated by compressed air are employed in operations requiring accurate control of lifting or lowering speeds. In most cases, they are used outdoors and under conditions in which corrosive fumes, explosive gases, or inflammable fluids are present.

There are also various portable specialty tools, such as concrete vibrators, countersinking tools, spikedrivers, paint mixers, air cranking motors, railway roadbed tampers, valve grinders, reciprocating filing machines, and shank grinders.

Rock drills are used for mining and rock excavation. An example of such a pneumatic tool is the hammer drill, or percussion hammer, which is composed of a piston and a drill made of high-carbon steel. The drill is held loosely in a chuck at the end of the cylinder and is struck by rapid blows from the freely moving piston. For downward-sloping holes, some means must be provided for removing drill cuttings, dust, and sludge. A hollow drill is usually used, and water or air is passed through it to remove the cuttings and cool the drill bit. Another kind of rock drill, called the drifter drill, is used for horizontal holes in mining operations and tunnel driving. It is mounted on some type of rig or frame and is mechanically fed into the work. Stoper drills are used primarily on up-hole or overhead drilling because of the automatic-feed characteristics. The usual stoper is a hammer drill with a self-rotating drill bit and an automatic feed by means of an air piston. Large air-operated earth drills, mounted on motor trucks on trailers, are utilized for digging water wells and blast holes for quarry operations. A high-capacity compressor provides air not only to power the drill tool but also to raise the tools in the hole and to remove drill cuttings from the hole. Such machines are used to advantage in areas where surface water supplies are insufficient to provide the drilling fluid needed for standard rotary and cable-tool well-drilling machines.

Hand-operated pneumatic paving breakers usually use solid steel drills and are not equipped for automatic rotation. Figure 2 shows a portable paving breaker. One type of tool is valve actuated, another is valveless. Heavy machines of about 80 pounds (36 kilograms) are used to break concrete pavement, foundations, and boulders. Medium breakers, weighing about 50 to 70 lbs (23 to 32 kg), are employed when breaking light concrete floors, macadam, and frozen ground. Light tools, weighing less than 50 lbs, are used to break floors, paving, and masonry walls. Heavy and medium-weight breakers can be adapted for driving spikes.

Compressed air is a good vehicle for conveying a paint spray. In a spray gun, the paint (*e.g.*, lacquer, enamel, or plastic coating) is atomized and mixed with compressed air. The principle of operation is similar to that of the jet compressor, with the compressed air serving as the motive fluid to draw the paint into the mixing area. *Spray painting* usually implies covering relatively large surfaces, such as a building. The term *airbrush*, by contrast, implies a device for developing a fine, small diameter spray of paint, protective coating, or liquid colour. The airbrush can be a pencil-shaped atomizer used for a variety of much more detailed activities such as shading drawings and retouching photographs.

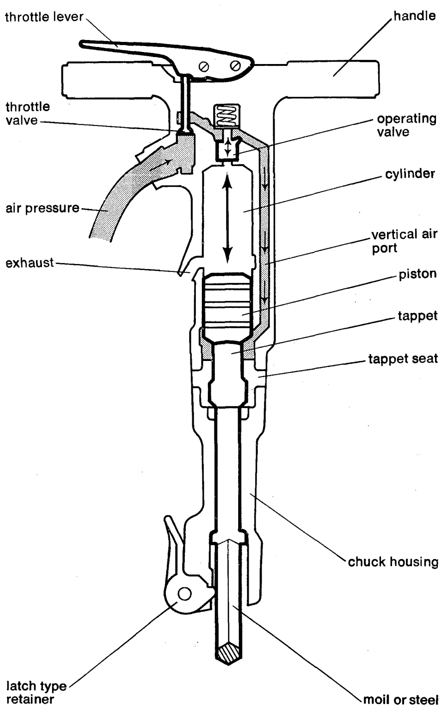

Figure 2: Pneumatic paving breaker

Pneumatic conveyers are used in various applications for handling materials. In a pressure system the outlet of the compressor leads into the inlet of the conveyer system. In a vacuum system the compressor inlet is at the end of the system. The air-pressure difference across the system depends on the material to be handled. In many places, mail is transferred from one site to another by pneumatic transport capsules in tubes. All sorts of materials may be conveyed by pneumatic systems, from ashes and cement to frozen foods, minerals, nuts, and seeds. Pneumatic handling is safe, fast, clean, automatic, and flexible.

Certain recently developed vehicles are supported by a cushion of air. The most successful of these air-cushion vehicles (ACVs) is the British-made Hovercraft. It is used commercially as a passenger- and car-carrying ferry; a number of them ply the English Channel. Experimental "tracked skimmers" (air-cushion trains) are under development in a number of countries, but they are not yet used commercially to any great extent. In the planning of many city transit systems, consideration is being given to air-cushion vehicles capable of speeds up to 300 miles (480 kilometres) per hour. Other specialized forms of air-cushion vehicles have been designed for use over rough terrain—such as that in Arctic regions—and for other uncommon applications.

Brakes on trains and most buses and large trucks are operated by air pressure. A piston rod from an air cylinder exerts force on the braking device. On railroad cars the air-brake system includes a compressor, pneumatic valves, regulators, piping, reservoir, and other accessories. There are levers, cylinders, and other rigging to apply forces to the brake shoe, which bear directly on the rim of the wheel. Various automatic-control safety arrangements assure a definite braking action should some malfunction develop.

pneumatism, in medicine, Alexandrian medical school, or sect, based on the theory that life is associated with a subtle vapour called the pneuma; it was, in essence, an attempt to explain respiration.

Pneumatism was expounded by the Greek anatomist and physiologist Erasistratus in about 300 BC, though the concept had been suggested earlier by other commentators. Unlike his contemporary, the Alexandrian anatomist Herophilus, who accepted the old theory of humoral pathology (*i.e.*, that human temperament and features were determined by certain combinations of body fluids), Erasistratus held that health and disease and, in fact, the nature of life were intimately connected with the pneuma, which had affinities with the air man breathes. Erasistratus drew a distinction between two kinds of pneuma: one was a "vital spirit" formed in the heart from air; the second type was formed in the brain from the first kind. The former was transported by arteries to the parts of the body and the latter, the "animal spirit," by the nerves, being the prime cause of movement. Although Erasistratus held that hindrance of the action of the pneuma, or an excess of blood, was the essential cause of certain diseases, he did not follow the contemporary practice of bloodletting, preferring to attempt to control the blood supply by diet and other less drastic measures.

Pneumatomachian, also called PNEUMATOMACHIST, Greek PNEUMATOMACHOS, plural PNEUMATOMACHOI ("Opponents of the Spirit"), any of the Christian heretics of the 4th century AD who denied the consubstantiality of the Holy Spirit with the Father in the divine Trinity. *See* Macedonianism.

pneumococcus (*Streptococcus pneumoniae*), spheroidal bacterium in the family Streptococcaceae that causes human diseases such as pneumonia, sinusitis, otitis media, and meningitis. It is microbiologically characterized as a gram-positive coccus, 0.5 to 1.25 μm (micrometre; 1 $\mu m = 10^{-6}$ metre) in diameter, often found in a chain configuration and surrounded by a capsule consisting of complex carbohydrate (polysaccharide). Many serological types have been differentiated. Pneumococci normally occur in the upper respiratory tract.

Pneumococci have proved useful in elucidating microbial genetics. The phenomenon of transformation—an alteration of one cell by another—was first observed in these microorganisms in 1928. For the most part, colonies formed by pneumococci are small, round, and smooth. Occasional mutant rough colonies are produced by organisms incapable of synthesizing the capsular material. When a rough colony is grown in the presence of genetic material (deoxyribonucleic acid) from a smooth colony, the rough colony is transformed into a smooth one.

Pneumococci are separated into types depending on the specific capsular polysaccharide formed. The disease-causing ability of pneumococci resides in the capsule, which delays or prevents their destruction by phagocytes, cells in the bloodstream that normally engulf foreign material.

pneumoconiosis, any of many lung diseases caused by the inhalation of a variety of organic or inorganic dusts or chemical irritants, usually over a prolonged period of time. The type and severity of disease depends on the composition of the dust; small quantities of some substances, notably silica and asbestos, produce grave reactions, while milder irritants produce symptoms of lung disease only with massive exposure. Much evidence indicates that the smoking of cigarettes in particular aggravates the symptoms of many of the pneumoconiosis diseases.

Typically, the early symptoms of mild pneumoconioses include chest tightness and shortness of breath, progressing to more serious breathing impairment, chronic bronchitis, and emphysema in the most severe cases. Inhaled dust collects in the alveoli, or air sacs, of the lung, causing an inflammatory reaction that converts normal lung tissue to fibrous scar tissue and thus reduces the elasticity of the lung. If enough scar tissue forms, lung function is seriously impaired, and the clinical symptoms of pneumoconiosis are manifested. The total dust load in the lung, the toxic effects of certain types of dust, and infections of the already damaged lung can accelerate the disease process.

Among inorganic dusts, silica, encountered in numerous occupations including mining, quarrying, sand blasting, and pottery making, is the most common cause of severe pneumoconiosis. As little as 5 or 6 grams (about 0.2 ounce) in the lung can produce disease (*see* silicosis).

Graphite, tin, barium, chromate, clay, iron, and coal dusts (*see* anthracosis) are other inorganic substances known to produce pneumoconiosis, although silica exposure is also involved in many cases. Pneumoconioses associated with these substances usually result only from continued exposure over long periods. Asbestos (*see* asbestosis), beryllium (*see* berylliosis), and aluminum dusts can cause a more severe pneumoconiosis, often after relatively brief exposure to massive amounts of dust. Asbestosis has also been associated with cancers of the lung and other organs.

Prolonged exposure to organic dusts such as spores of molds from hay, malt, sugarcane, mushrooms, and barley can produce lung disease through a severe allergic response within a few hours of exposure, even in previously nonallergic persons. Brown lung disease (*see* byssinosis) in textile workers is also a form of pneumoconiosis, caused by fibres of cotton, flax, or hemp, which, when inhaled, stimulate histamine release. Histamines cause the air passages to constrict, impeding exhalation.

Chemical irritants that have been implicated in lung disease include sulfur dioxide, ammonia, acid, and chloride, which are quickly absorbed by the lining of the lungs. The chemicals themselves may scar the delicate lung tissues, and their irritant effect may cause large amounts of fluid to accumulate in the lungs. Once exposure to the chemical ceases, the patient may recover completely or may suffer from chronic bronchitis.

pneumonia, inflammation and consolidation of the lung tissue as a result of infection, inhalation of foreign particles, or irradiation. Many organisms, including viruses and fungi, can cause pneumonia, but the most common causes are bacteria, in particular species of *Streptococcus* and *Mycoplasma.* Although viral pneumonia does occur, viruses more commonly play a part in weakening the lung, thus inviting secondary pneumonia caused by bacteria. Fungal pneumonia can develop very rapidly and may be fatal, but it usually occurs in hospitalized persons who, because of impaired immunity, have reduced resistance to infection. Contaminated dusts, when inhaled by previously healthy individuals, can sometimes cause fungal lung diseases such as histoplasmosis.

Mycoplasmal pneumonia, caused by *Mycoplasma pneumoniae,* an extremely small organism, usually affects children and young adults; few cases beyond the age of 50 are seen. Most outbreaks of this disease are confined to families, small neighbourhoods, or institutions, although epidemics can occur. *M. pneumoniae* grows on the mucous membrane that lines the surfaces of internal lung structures; it does not invade the deeper tissues—muscle fibres, elastic fibres, or nerves. The bacteria can produce an oxidizing agent that might be responsible for some cell damage. Usually the organism does not invade the membrane that surrounds the lungs, but it does sometimes inflame the bronchi and alveoli.

Symptoms do not appear until about three weeks after the initial infection. Headaches and a run-down feeling increase to feverishness, muscle pain, and sore throat. As the disease progresses, coughing becomes the major symptom. Sputum discharge may contain flecks of blood. Any chest pains result from the tenderness of the trachea (windpipe) and muscles from severe coughing. The illness may be severe but there are few fatalities. Recovery generally occurs in a few weeks with the help of antibiotic drugs.

Streptococcal pneumonia, caused by *Streptococcus pneumoniae,* is the single most common form of pneumonia, especially in hospitalized patients. The bacteria may live in the bodies of healthy persons and cause disease only after resistance has been lowered by other illness or infection. Viral infections such as the common cold promote streptococcal pneumonia by causing excessive secretion of fluids in the respiratory tract. These fluids provide an environment in which the bacteria flourish. This is generally a more severe illness than mycoplasmal pneumonia, although most patients recover with antibiotic treatment.

Another bacterium, *Klebsiella pneumoniae,* although it has little ability to infect the lungs of healthy persons, produces a highly lethal pneumonia that occurs almost exclusively in hospitalized patients with impaired immunity. Other bacterial pneumonias include Legionnaires' disease (*q.v.*), caused by *Legionella;* pneumonia secondary to other illnesses caused by *Staphylococcus aureus* and *Hemophilus influenzae;* and psittacosis (*q.v.*), an atypical infectious form.

Pneumonia can also result from inhalation of oil droplets, which scar the lung surfaces. This type of disease occurs most frequently in workers exposed to large quantities of oily mist and in the elderly. Oil that is being swallowed may be breathed into the respiratory tract, or, less often, it may come from the body itself when the lung is physically injured. Scar tissue forms as a result of the presence of the oil. Ordinarily no treatment is necessary. Inflammation of lung tissues may result from X-ray treatment of structures within the chest. The disease makes its appearance from one to 16 weeks after exposure to the X-rays has ceased. Recovery is usual unless too great an area of lung tissue is involved.

pneumothorax, condition in which air accumulates in the pleural sac, causing it to expand and thus compress the underlying lung, which may then collapse. (The pleural sac is a cavity formed by the two pleural membranes that line the thoracic cavity and cover the lungs.) Traumatic pneumothorax is the accumulation of air caused by penetrating wounds (knife stabbing, gunshot) or other injuries to the chest wall, after which air is sucked through the opening and into the pleural sac. Spontaneous pneumothorax is the passage of air into the pleural sac from an abnormal connection created between the pleura and the bronchial system as a result of tuberculosis or some other lung disease. The symptoms of spontaneous pneumothorax are a sharp pain in one side of the chest and shortness of breath. Artificial pneumothorax, which now is of strictly historical interest, was achieved by injecting air into the sac by means of a needle inserted into the chest wall. This procedure was used in the treatment of tuberculosis; the injected air served to compress the underlying lung and thus stop its movement, giving it time to heal free of the stress of breathing.

Pnom Penh (Kampuchea): *see* Phnom Penh.

Po (people): *see* Pai.

p'o, Pinyin PO, in Chinese Taoism, the earthly (inferior, material) human soul as distinguished from the heavenly *hun* (superior, spiritual) soul; the distinction is based on the Chinese concept of yin–yang, the inescapable principle of duality in all things. When the two souls of man are joined in harmonious union, health and life flourish; separation causes sickness and death. The Chinese assigned organic functions to *p'o.*

Although right order demands that the *p'o* (yin) soul be subservient to the *hun* (yang), in many cases the passions of *p'o* dominate men's lives. Because the *p'o* soul can turn into a *kuei* (malevolent spirit) if the deceased is not properly interred or sacrificed to, fitting burial rites not only ensure peaceful rest for the dead but further guarantee that the *hun* soul will impart special blessings to surviving family members.

Po Chü-i, Pinyin BO JUYI (b. 772, Hsin-cheng, Shensi Province, China—d. 846, Lo-yang, now Honan, Honan Province), Chinese poet of the T'ang dynasty (618–907) in China, who used his elegantly simple verse to protest the social evils of his day.

Po Chü-i began composing poetry at the age of five. Because of his father's death in 794 and straitened family circumstances, Po did not take the official examinations for the bureaucracy until the late age of 28. He did extremely well and was given a minor post at the palace library, as was another successful examination candidate and poet, Yüan Chen. Their friendship became perhaps the most famous in Chinese history. Po became a member of the prestigious Han-lin Academy in Ch'ang-an, the capital, in 807 and rose steadily in official life except for his banishment in 814 to a minor post at Chiu-chiang, the cause

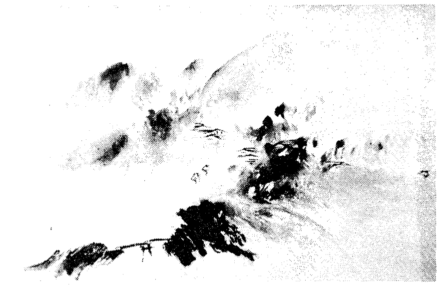
for which remains unclear. He assumed the important posts of governor of Chung-chou (818), Hangchow (822), and, later, Soochow. In 829 he became mayor of Lo-yang, the eastern capital, but retired from that post in 833 because of illness.

Po Chü-i was the informal leader of a group of poets who rejected the courtly style of the time and emphasized the didactic function of literature, believing that every literary work should contain a fitting moral and a well-defined social purpose. Po considered his most important contributions to be his satirical ballads and social-protest poems, which usually took the form of free verse based on old folk ballads, or "new *yüeh-fu,*" as he entitled a series of 50 of these poems. The most prolific of the T'ang poets, Po aimed for simplicity in his writing and, like Tu Fu, a great T'ang poet of the preceding generation, whom Po greatly admired, was deeply concerned with the social problems of the times. His poetry is marked by humour, compression, and clarity.

P'o-hai (ancient Chinese state): *see* Parhae.

Po Hai, Pinyin BO HAI, also called GULF OF CHIHLI, shallow northwestern arm of the Yellow Sea, off the North China coast. It is enclosed by the Liaotung Peninsula (northeast) and the Shantung Peninsula (south). The broad Gulf of Liaotung on the northeast is generally considered part of the Po Hai. Within these limits, the gulf's maximum dimensions are 300 miles (480 km) from northeast to southwest and 190 miles (306 km) east–west. The strait leading to the gulf is about 65 miles (105 km) in width. The Huang Ho (Yellow River), China's second longest river, discharges into the gulf. The gulf has long been used as a source of prawns and salt. There are both onshore and offshore petroleum deposits, and several oil refineries are located there.

p'o-mo, Pinyin BOMO, either of two different phrases (two different Chinese characters are pronounced *p'o*) that describe two kinds of textured surface given to Chinese paintings (*see* ts'un). The more common interpretation of *p'o-mo* is "broken ink," which, though it is now difficult to identify, was supposedly an innovation of the 8th-century painter Wang Wei. The brush was used to render and build up a series of dense ink washes (diluted ink applied in broad sweeps) to give a sense of the solid surface of landforms first defined by line. The other interpretation of *p'o-mo,* "splashed ink," was probably similar in effect but with forms unconfined by an outline and rendered by more freely and actively maneuvering the ink over the surface. "Splashed ink" is associated with the art of the eccentrics of the later T'ang dynasty and with some Ch'an artists of the 13th century.



"Village in Clearing Mist," ink painting in the *p'o-mo* technique by Ying Yü-chien, early 13th century, Sung dynasty, in the Yoshikawa Eiji Collection, Tokyo

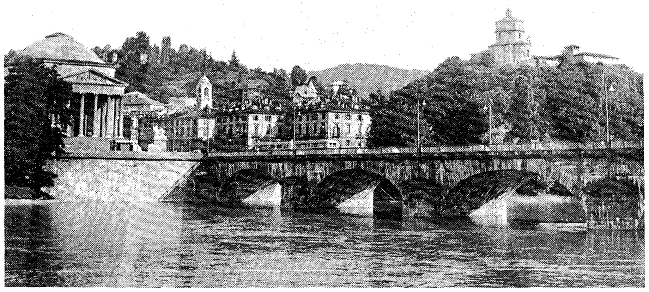
Po River, Latin PADUS, longest river in Italy, rising in the Monte Viso group of the Cottian Alps on Italy's western frontier and emptying into the Adriatic Sea in the east after a course of 405 miles (652 km). Its drainage basin covers 27,062 square miles (70,091 square km), forming Italy's widest and most fertile plain.

Flowing eastward in its upper course, the Po is rapid and precipitous, descending about 5,500 feet (1,700 m) in its first 22 miles (35 km). Just west of Saluzzo the Po turns sharply northward, flows through Turin and skirts the Monferrato upland, then turns east at Chivasso and continues in a generally easterly course to its delta on the Adriatic.

The Po forms the boundary between the regions of Lombardy and Veneto (north) and Emilia-Romagna (south). The Po receives the waters of the Dora Riparia and the Dora Baltea below Turin, and its other principal tributaries are the Sesia, Ticino, Adda, Oglio, and Mincio from the north. Among the numerous streams that drain into the Po from the south, the Tanaro (from the Maritime Alps) and the Scrivia and Trebbia (from the Apennines) are important; but many of the others are rain fed and torrential and carry little water through much of the year. Throughout its middle and lower courses the Po describes many meanders, which have left numerous oxbows (circular lakes).



The Po River flowing through Turin, Italy
Authenticated News International

Its delta is among the most complex of any European river, with at least 14 mouths, usually arranged in five groups (from north to south): the Po di Levante, Po di Maestra, Po della Pila, Po delle Tolle, and Po di Goro e di Gnocca. Of these mouths, the Po della Pila carries the greatest volume of water and is the only navigable one.

The river is navigable from its mouth to Pavia. At Pontelagoscuro, 60 miles (96 km) from the sea, the Po's average discharge is 48,400 cubic feet (1,370 cubic m) per second, with variations from 910 to 340,000 cubic feet (26 to 9,630 cubic m), although in the great flood of 1951 the discharge was estimated at 424,000 cubic feet (12,000 cubic m) per second. The most devastating floods have been those of 589, 1150, 1438, 1882, 1917, 1926, 1951, 1957, and 1966, all in the autumn.

The sediment load carried by the river is considerable, and the extension of the delta is estimated at 200 acres (80 hectares) per year. Certain ancient ports south of the delta, such as Ravenna, now find themselves as much as 6 miles (10 km) from the sea as a result of silt from the Po carried down by currents in the Adriatic. The floods of the river and the silt load carried by it have long challenged hydraulic engineers. The Venetian Republic built dikes to control floods and canals to divert silt, and in the area between Ferrara and the Adriatic numerous undertakings have reclaimed thousands of acres during the past three centuries. The latest of these projects, undertaken in 1953 by the Italian Land Reform, was devoted to soil improvements, reclamation of marshy areas such as the Valli di Comacchio, and the creation of small peasant farms in the delta area, or *polesine,* which, nevertheless, suffered enormously in the great floods of 1951 and 1966.

The lower valley of the Po was, during prehistoric times, occupied by people of the Paleolithic and Neolithic stages of civilization, who built houses on piles along the swampy banks. The river regulation works originated in pre-Roman times. The reclamation and protection of the riparian lands went on rapidly under the Romans, and in several places their rectangular divisions of the ground are still visible. During the barbarian invasions much of the protective system decayed, but the later Middle Ages saw the works resumed so that the present arrangement existed in the main by the close of the 15th century.

The Ligurian name of the Po was Bodincus, or Bodencus, meaning "bottomless." The name Padus was taken from the Celts or the Veneti of Brittany. Thus, Bodincomagus is found as a town name on the upper course and Padua as a name of one of the mouths of the river.

Po-se (China): *see* Pai-se.

P'o-yang Lake, Wade–Giles romanization P'O-YANG HU, Pinyin POYANG HU, large lake in northern Kiangsi Province, China. It lies in a depression south of the Yangtze River and is fed by various rivers from Kiangsi, the most important being the Kan River, which drains almost the whole of Kiangsi. P'o-yang Lake itself drains into the Yangtze at Hu-k'ou. The lake's size is ill defined, a whole system of lakes and marshes being subject to very great seasonal variation. At its greatest extent it is about 95 miles (150 km) in length from north to south and has a breadth of 19 miles (31 km) from east to west. In winter the whole area becomes a huge marsh, intersected by waterways and dotted with hills surmounted by villages. In summer the whole area is flooded, and the hills become islands. The water level depends on complex factors, including the level of the Yangtze River as well as the level of its tributaries. The P'o-yang has always been an important retention lake that receives some of the excess of the Yangtze in flood time; consequently, the surrounding farmland is often extensively flooded.

The lake has been silting up in recent centuries. Even in summer there is a wide margin of reedbeds and swamp around the lake itself, and over the centuries large areas of farmland have been reclaimed from the lacustrine deposits. Nan-ch'ang, capital of Kiangsi, was once on the shore of the lake but is now some 15 miles (24 km) from it. The lake is divided into two sections by a narrow neck of land known as Ying-tzu-k'ou. The northern section is sometimes known as the Lo-hsing Lake. The much larger southern section is sometimes known as the Tzu-t'ing Lake or Kung-t'ing Lake.

The total area of the lake is about 1,383 square miles (3,583 square km), but precise measurement is impossible because the difference between flood level and low-water level is sometimes as much as 25 feet (8 m). Unlike Tung-t'ing Lake in Hunan Province, P'o-yang Lake has no artificial retention basin to increase its capacity to receive the Yangtze's floodwaters.

Poaceae, also called GRAMINEAE, the grass family comprising the flowering plant order Poales, containing about 600 genera with an estimated 5,000 to 10,000 species. It is economically the most important of all plant families.

A brief treatment of grasses follows. For full treatment, *see* MACROPAEDIA: Angiosperms.

Grasses thrive in all climates and are found throughout the world. Their long, narrow leaves form sheaths around the stem; the sheaths are usually split and have overlapping edges. The round or flattened stems are often hollow between the joints. The stems may grow upright or be bent at their bases; they may lie on the ground, producing new plants at each joint, or grow just below the surface. Cell division above each joint causes stem elongation. The small flowers lack petals and sepals, are located between two bracts, and are arranged into units called spikelets. The seeds store oil, starch, and protein. The fibrous roots are often greatly branched; when combined with underground or extensive surface stems in perennial species, they prevent erosion.

Cereal grasses such as rice, millet, corn (maize), and wheat (*qq.v.*) are cultivated for the nutritional value of their seeds. Many grass species provide forage for wild and domestic animals; others are used by man for shelter construction, industrial purposes, erosion control, and ornamentation.

Traditionally, botanists divide the Poaceae into two subfamilies, Festucoideae and Panicoideae, on the basis of spikelet arrangement. More recent workers prefer a system of six subfamilies (Pooideae, Panicoideae, Bambusoideae, Chloridoideae, Arundinoideae, and Oryzoideae), separated by both anatomic and microscopic characteristics. Each classification system is further subdivided into a number of tribes.

poacher, also called POGGE, or ALLIGATOR FISH, any of the marine fish of the family Agonidae (order Scorpaeniformes). Poachers live in cold water, on the bottom, and are found mainly in the northern Pacific. They are small fish, about 30 cm (12 inches) or less in length, and are distinguished by the bony, often saw-edged armour plates covering their bodies.

Notable species include the sturgeon poacher (*Agonus acipenserinus*), a large, common, northern Pacific poacher, and the hook-nose, pogge, or armed bullhead (*A. cataphractus*), a small fish, common in northern Europe and one of the few poachers found outside the Pacific. Little is known about the natural history of the poachers. The various species are of little commercial value to man.

poaching, in law, the shooting, trapping, or taking of game or fish from private property or from a place where such practices are specially reserved or forbidden.

Until the 20th century most poaching was subsistence poaching—*i.e.,* the taking of game or fish by impoverished peasants to augment a scanty diet. In medieval Europe feudal landowners from the king downward stringently enforced their exclusive rights to hunt and fish on the lands they owned, and poaching was a serious crime punishable by imprisonment. Large stretches of forested countryside were subject to special laws to preserve in them the deer, wild boars, and other beasts of the chase who provided the nobles and royalty with sport. With the cumulative destruction of forests over the centuries and the taking of communal or royally owned lands into private use, laws were passed in the 17th and 18th centuries restricting hunting and shooting rights on private property to the landowner and his sons, and the practice of hiring gamekeepers to protect the wildlife on one's own land became common. Given these obstacles, subsistence poaching necessarily became a more specialized activity; during the 18th and 19th centuries gangs of organized poachers frequently engaged in fierce battles against gamekeepers, and mantraps and spring guns were hidden in the underbrush to catch intruders.

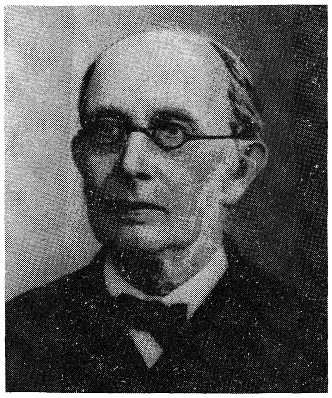
Present-day poaching is usually done for sport or commercial profit, but it can be a serious threat to many species of wild animals, particularly those protected in wildlife preserves or national parks. Many animal species have been limited in range or severely depleted in numbers, sometimes to the point of extinction, by the depredations of market hunters and unregulated sportsmen. In Africa the difficulty of enforcing game codes has led to the critical depletion of the rhinoceros, which is hunted for its horn. The Bengal tiger of India and the gorilla of central Africa have similarly been threatened with extinction by hunters operating illegally. River poaching has also been a problem in some countries, causing the depletion of stocks of fish in many areas.

Game management and other conservation programs throughout the world have been instituted to counteract the effects of poaching and other threats to wildlife, reinforced by the patrolling of game wardens to restrain poaching for commercial profit.

Poales, grass order of flowering plants, containing the family Poaceae (or Gramineae), economically the most important order of plants, with a worldwide distribution in all climates. *See* grass; Poaceae.

Pobedonostsev, Konstantin Petrovich (b. May 21, 1827, Moscow—d. March 23, 1907, St. Petersburg, Russia), Russian civil servant and conservative political philosopher, who served as tutor and adviser to the Russian emperors Alexander III and his son Nicholas II. Nicknamed the "Grand Inquisitor," he came to be the symbol of Russian monarchal absolutism.

The youngest son of a Russian Orthodox priest who was also professor of Russian literature at Moscow University, Pobedonostsev was educated at home and at the Oldenburg School of Law in St. Petersburg (now Leningrad), from 1841 to 1846. His adult life was devoted to service at the centre of the Russian state bureaucracy, beginning in the Moscow office of the senate. The publications he produced in his spare time there on the history of Russian civil law and institutions led to his being invited in 1859 also to lec-



Pobedonostsev
H: Roger-Viollet

ture on civil law in Moscow University. His courses were so distinguished in organization, learning, and clarity that in 1861 Alexander II asked him to serve also as a tutor to his sons during the time they spent in Moscow each year. At the same time, he was an important contributor to the 1864 reform of the Russian judicial system. In 1865 he accepted the tsar's invitation to leave Moscow University and the senate to serve as a tutor to the tsar's sons and their families in St. Petersburg. Gradually he turned against all the reforms of Alexander II, particularly that of the courts. His service as one of the tutors and closest advisers of Alexander III helped make the latter a most reactionary ruler. Pobedonostsev was appointed to the senate in 1868, to the council of state (a high advisory body) in 1872, and in 1880 to the director generalship, or chief administrative position, of the Most Holy Synod of the Russian Orthodox Church, a position he held until the fall of 1905. This post gave him immense power over domestic policy, particularly in matters affecting religion, education, and censorship.

Pobedonostsev considered man to be by nature "weak, vicious, worthless, and rebellious." He denounced the 18th-century Enlightenment view of the perfectibility of man and of society, and therefore strongly supported paternalistic and authoritarian government. He looked upon each nation as being based on the land, the family, and the national church, and he regarded the maintenance of stability as the principal purpose of government. He sought, therefore, to defend Russia and the Russian Orthodox Church against all rival religious groups, such as the Old Believers, Baptists, Catholics, and Jews. He also defended Russian rule over the various minority groups and supported their Russification. As lay head of the church, he promoted the rapid expansion of primary education in parish schools because he saw it, with its emphasis upon religion, as a strong bulwark of the autocracy. He sought to keep each person in that station in life into which he had been born and to restrict higher education to the upper classes and exceptionally talented. He tried also to prohibit and to banish all foreign influences, especially western European ideas concerning constitutional and democratic government. He was thus largely responsible for the government's repressive policies toward religious and ethnic minorities and toward Western-oriented liberal intellectuals.

Pobedonostsev had great influence in 1881, immediately after the assassination of Alexander II, when he persuaded Alexander III to reject the so-called Loris-Melikov constitution that was designed to bridge the gap between the government and the leading elements of society. He influenced the government's reactionary domestic policies throughout the rest of the 1880s but exercised little authority during the last 15 years of his life. His role, however, was exaggerated during his lifetime by critics of the regime and since then by historians, largely because his personality, appearance, and known views superbly qualified him as the symbol of a system of government deeply unpopular among many educated Russians and among all liberals and radicals.

Pobedonostsev was a childless, dry, reserved, and deeply pessimistic ascetic with almost no close friends, except for the novelist Dostoyevsky, who died in 1881. At the same time, he was a man of immense learning and scholarship who was widely respected among foreign diplomats. He read and spoke most European languages and was deeply familiar with the great body of European and American literature and philosophy—although he strongly supported censorship and tight controls for other Russians. Especially after 1890 he was convinced the regime would be overthrown by revolution. His deep hatred and fear of constitutional and democratic government, freedom of the press, religious freedom, trial by jury, and free secular education was best expressed in a collection of essays, *Moskovskyy sbornik,* published in 1896.

Pocahontas, personal name MATOAKA, Christian name REBECCA (b. *c.* 1595 [near future Jamestown, Va., U.S.]—d. March 1617, Gravesend, Kent, Eng.), Powhatan Indian woman who helped maintain peace between English colonists and native Americans by be-

Pocahontas, detail of a portrait by an unknown artist, 1616
By courtesy of the Library of Congress, Washington, D.C.

friending the settlers at Jamestown, Va., and eventually marrying one of them; dramatic accounts of her unusual role have immortalized her name in American folk history.

Daughter of the powerful intertribal leader Powhatan, Pocahontas was a young girl when she first became acquainted with the colonists who settled in the Chesapeake Bay area in 1607. The following year, according to a later account written by Capt. John Smith, founder and leader of the colony, she saved Smith's life after he had been captured by the tribe. Just as he laid his head on the sacrificial stone to await death, Pocahontas supposedly flung herself down and, embracing the captain's head, successfully implored her father to spare him.

After Smith returned to England in 1609, relations between the Virginians and Powhatan deteriorated. Capt. Samuel Argall therefore seized the opportunity to kidnap Pocahontas, hoping to use her to negotiate permanent peace. Treated with great respect and courtesy during her captivity, Pocahontas was converted to Christianity and was baptized Lady Rebecca. She was ransomed by her father but had in the meantime fallen in love with John Rolfe, a distinguished settler; both the Virginia governor, Sir Thomas Dale, and Chief Powhatan agreed to a marriage, and peace prevailed as long as Powhatan lived.

In 1616 Governor Dale, seeing in the adaptable and charming Indian princess a pleasing advertisement for the London Company of Virginia, took Pocahontas and her husband to England, where she was received at court and lionized by English society. About to embark for home, she contracted smallpox and died. Her only son, Thomas Rolfe, was educated in England and later migrated to Virginia, where he became a leading citizen.

Pocatello, city, seat (1893) of Bannock County, southeastern Idaho, U.S., in the Portneuf Valley. Originally an intermontane stopover point on the Oregon Trail, it was settled in 1882 and named for a Bannock Indian chief who granted rights-of-way to the railroads. It grew slowly at first because of its location on the Fort Hall Indian Reservation. The opening of the reservation to settlement in 1902 provided impetus for development, and Pocatello became a prominent railway depot on the Union Pacific line between Omaha, Neb., and Portland, Ore. It progressed as a processing and distribution centre for an irrigated agricultural area, with trucking augmenting rail freight transportation. An Army air base reverted to a municipal airport after World War II, and the community expanded industrially with the acquisition in the 1940s of a large naval ordnance plant and a phosphate reduction works. In 1962 it annexed Alameda. The city is the seat of Idaho State University (established as the Academy of Idaho, 1901). It is the headquarters for the Caribou National Forest. Inc. village, 1889; city, 1893. Pop. (1985 est.) 47,937.

pochard, any of the 14 to 16 species of diving ducks of the tribe Aythyini (family Anatidae, order Anseriformes), often called bay ducks.

Pochards are round-bodied, big-headed, rather silent birds of deep water; they dive well, with closed wings, to feed chiefly on aquatic plants. All lack a metallic wing mark, but most species show some white in the wings. Drakes commonly are black or gray with red heads, hens are plain brown. The nest is either a scraped hollow or a mound of reeds, and the hen lays 7–17 buff or dark-greenish eggs. Along seacoasts and on the bigger lakes, where most species spend the winter, "rafts" of pochards are a familiar sight.

The common, or European, pochard (*Aythya ferina*) breeds along northern reedy lakes; some winter in Egypt, India, and southern China. The drake of the red-crested pochard (*Netta rufina*) has a puffy yellowish-red head with fuzzy erectile crown feathers, black throat and breast, and white sides. This is a more southerly species of inland waters. Mahogany-coloured relatives are the pochards of South America and Africa (*N. erythrophthalma*).

The canvasback (*Aythya valisineria*) is a mallard-sized North American pochard, red-headed and black-breasted with its back and sides white, finely penciled with gray (like canvas). The redhead (*A. americana*) of North America resembles the common pochard of Europe but is larger and darker. Its round-headed, short-billed profile distinguishes it from the similarly coloured canvasback. Hunters call redheads "fool ducks" because they can be lured with decoys so easily. Scaups, or bluebills, are smaller than mallards. In the greater scaup (*A. marila*), a white stripe extends nearly to the wing tip; in the lesser scaup (*A. affinis*), the wing stripe is about half as long. Scaups gather in huge flocks offshore in winter and dive for shellfish (hence "scaup," from "scallop").

Poch'ŏngyo (Korean: "Universal Religion"), indigenous Korean religion, also popularly called Humch'igyo from the distinctive practice of chanting *humch'i,* a word said to have mystical significance.

Poch'ŏngyo was founded by Kang Il-sun (1871–1909), who initially gained a following by offering to cure illnesses through incantations and by medicine. The Japanese rulers of Korea, fearful that Poch'ŏngyo was an underground political movement, so restricted Kang's activities that only a weak organization was established before his death. Leadership of the religion was subsequently assumed by Cha' Kyŏng-sŏk, an early associate of Kang. During the March 1 independence movement of 1919, Cha' and 30,000 of the religion's adherents were imprisoned by the Japanese. Cha' escaped two years later and established Pohwagyo ("Religion of Universal Enlightenment"), which was registered with the government the following year as Poch'ŏngyo.

The religion's belief centres on Okhwang-sangje, or "Great Lord of Okhwang (Heaven)." Poch'ŏngyo professes the four principles of one mind, coexistence, forgiveness, and conquest of disease. By practicing one mind, adherents are led to God through the unity of mind and body and thus conquer disease. By dissolving divine and human anger, coexistence and forgiveness prevail. Confucianism later influenced Cha's espousal of benevolence and righteousness and his four principles: respect for heaven, bright virtue, proper conduct, and love of mankind.

The religion's incantations are said to induce trembling and to produce a trancelike sense of selflessness. More recently, meditation on the Tao ("Way") has been emphasized as the path to self-enlightenment and as an effective means of inducing a state of selfless trance, which is the highest of all goals. To this end, group sessions are held once a year. Adherents pay reverence to a tablet of Okhwang every morning and evening by offering fresh water, burning incense, lighting a candle, and bowing four times. Temple services have more elaborate rituals.

pocket billiards, also called POOL, a billiards game, most popular in the United States and Canada, played with a white cue ball and 15 consecutively numbered coloured balls on a rectangular table with six pockets (one at each corner and one at the midpoints of both longer sides). The dimensions of the table are usually 4 by 8 feet (122 by 244 cm) or 4½ by 9 feet (137 by 274 cm).

To begin play, the 15 object balls are arranged (racked) in a pyramid formation with its apex on a spot near the foot of the table. The first player then stands at the head of the table and drives the cue ball into the formation to break it apart. To continue play, he is usually required either to pocket a ball or to drive two object balls in addition to the cue ball against the cushions. When a player fails to pocket a ball, his opponent begins play. The first player or side to pocket eight balls wins the round.

After the break (first) shot, a player must designate (call) the ball that he intends to pocket, although in this form of the game he need not indicate the pocket into which the ball will go. If the ball called is pocketed, any other balls pocketed on that stroke are also credited to the player. If the ball called is not pocketed, any other balls pocketed on that shot are replaced on the table on the spot where the rack is made or, if more than one ball is replaced, in a line from that spot; the player then loses his turn.

Penalties of one ball replaced on the table in addition to those pocketed on the foul stroke are assessed for such infractions as failure to comply with rules for the break shot; touching the cue ball twice with the cue on the same stroke; pocketing the cue ball ("scratching") or knocking it off the table; and failing either to pocket a ball, to drive an object ball to a cushion, or to drive the cue ball to a cushion after contacting an object ball. For a double foul on a single stroke, only one penalty is assessed. *See* Sporting Record: *Billiards.*

pocket borough, election district that is controlled by, or "in the pocket" of, one person or family. The term was used by 19th-century English parliamentary reformers to describe the many boroughs in which a relatively small population was either bribed or coerced by the leading family or landowners to elect their representatives to Parliament. As a result, Parliament was controlled by the landed gentry and seats were filled by representatives who wanted to please their patrons rather than their constituents. Reforms passed in 1832 and 1867 ended this practice by widening the franchise and redistributing parliamentary seats to reflect the population shift from rural areas to the industrial towns.

pocket gopher: *see* gopher.

pocket mouse (*Perognathus*), any of about 30 species of small North American rodents, belonging to the family Heteromyidae (order Rodentia), characterized by fur-lined, external cheek pouches that open alongside the mouth. Pocket mice are pale yellowish brown to dark gray in colour, and they measure 6 to 13 cm (about 2½ to 5 inches) long, excluding a tail of about the same length. They are nocturnal and usually solitary and are found in dry and desert regions. They carry food (mainly seeds) in their cheek pouches and store it in their burrows. They breed in spring and summer, the female bearing one or more litters of about four young.

Spiny pocket mice (*Liomys* and *Heteromys*), also of the family Heteromyidae, are harsh-furred, gray, brown, or black rodents found from Mexico through Central America. They are nocturnal burrowers and are inhabitants of wet, forested regions as well as of dry or desert country.

pocketbook flower: *see* slipper flower.

Pocock, Lena Margaret (English actress): *see* Ashwell, Lena (Margaret).

Pocomam, also spelled POKOMAM, Mayan Indians of the highlands of eastern Guatemala. The Pocomam are primarily agriculturists; they cultivate corn (maize) and beans and manufacture pottery and charcoal. Houses are built of poles or adobe, with thatch, tile, or tin roofs. The houses are scattered over the countryside, with little congregation even around a church or town hall; territory is divided into cantons, which act as administrative districts and social barriers.

The Pocomam practice ritual kinship involving the choosing of godparents for children at baptism, marriage, or other major occasions. Young unmarried men also enter into ritual friendships called *camaradería.* There is a rigid class system, status being based on age and wealth. The Pocomam adhere to an admixture of Roman Catholicism, pagan mythology, and belief in sacred places and sacred objects.

Poços de Caldas, city, southern Minas Gerais state, Brazil. It lies along a stream called Poços de Caldas, near the Pardo River. Known principally for its thermal baths, the city has resort hotels and casinos. The local soils are rich in minerals and yield thorium, zirconium, and bauxite, which is converted into aluminum there. The city has Brazil's first uranium-ore concentration plant, for use in the Angra I nuclear power facility in Angra dos Reis. Poços de Caldas is accessible by air from São Paulo, Belo Horizonte, and other cities. Pop. (1980 prelim.) 81,448.

pod (botany): *see* legume.

podesta, Italian PODESTÀ, or POTESTÀ ("power"), in medieval Italian communes, the highest judicial and military magistrate. The office was instituted by the emperor Frederick I Barbarossa in an attempt to govern rebellious Lombard cities. From the end of the 12th century the communes became somewhat more independent of the emperor, and they began to elect their own podesta, who gradually superseded the collegiate government of consuls. The podesta was usually a nobleman with legal training. He was selected from another city to ensure his neutrality in local disputes. Though the office was subject to strict statutory limitations, it sometimes served as a starting point for the establishment of a despotic government, or signoria. After the 13th century the office declined in importance; in 15th-century Florence its principal functions were judicial.

Podesta was the title of mayors in the Austrian territories of Italy from 1815 to 1918 and of mayors appointed by the Italian government during the Fascist regime.

Podgorica (Yugoslavia): *see* Titograd.

Podgorny, Nikolay Viktorovich (b. Feb. 18 [Feb. 5, Old Style], 1903, Karlovka, Ukraine, Russian Empire—d. Jan. 12, 1983, Moscow), Soviet statesman and Communist Party official.

As a youth, Podgorny served as secretary in his district's Komsomol committee. He attended Kiev Technological Institute for the Food Industry, graduating in 1931 and subsequently working in engineering jobs in the sugar industry. Podgorny's first government appointment came in 1939, as deputy people's commissar of the food-processing industry in the Ukraine; he was promoted in 1940 to deputy commissar of the Soviet food-processing industry. His first important Communist Party appointment was as first secretary of the Kharkov regional party committee (1950–53), and he soon rose to first secretary of the Ukraine party committee (1957–63). He became a full member of the Politburo in 1960, and he was later promoted to secretary of the Central Committee of the Communist Party of the Soviet Union (1963–65).

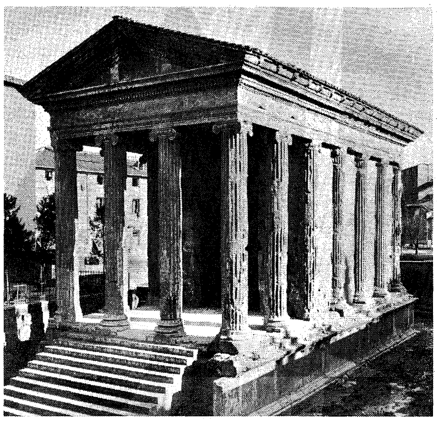
Podgorny became involved in a power struggle with Leonid Brezhnev, who had become party first secretary in 1964. The apparent loser, Podgorny relinquished his secretaryship in 1965 and was given the less-influential post of chairman of the Presidium of the Supreme Soviet from 1965 to 1977. Podgorny enhanced his position of ceremonial head of state and traveled widely, but real power was in the hands of Brezhnev, general secretary of the Communist Party. On May 24, 1977, as a result of his resistance to Brezhnev's wish to hold both the party secretaryship and the Presidium chairmanship, Podgorny was ousted from the Politburo and "relieved" of his duties as chairman of the Presidium, with Brezhnev assuming the latter title. Thereafter Podgorny lived in retirement in Moscow.

podiatry, also called CHIROPODY, medical specialty dealing with the diagnosis and treatment of diseases and disorders of the human foot. The ancient Egyptian Ebers medical papyrus (*c.* 1500 BC) records some of the earliest remedies for foot problems, and other references to foot treatment are found in the medical literature of most succeeding centuries. The word *chiropody* derives from the first modern work that was primarily devoted to the medical care of the foot, a 1774 treatise by D. Low of London entitled *Chiropodologia.* Doctors specializing in foot care appeared in England in the late 18th century, and itinerant "corn cutters" became a fixture of North American rural life during the 19th century. The National Association of Chiropodists was founded in the United States in 1912 and was renamed the American Podiatry Association in 1958. The term *podiatry* was coined by M.J. Lewi of New York in 1917.

Podiatrists diagnose and treat the diseases, disabilities, and deformities of the foot by physical therapy, special shoes and other mechanical devices, pharmaceuticals, and minor surgery. After a prerequisite of at least two years of college education, the podiatry student must usually complete a four-year educational curriculum that embraces the fundamental medical sciences with an emphasis on their application to the human foot.

podicipediform: *see* grebe.

podium, in architecture, term referring to various structural elements, namely a raised pedestal or base; a low wall supporting columns; or the structurally or decoratively emphasized lowest portion of a wall. Sometimes the basement story of a building may be treated as a podium. The podium is usually designed with a modeled base and plinth at the bottom; a central surface known as a die, or dado; and a projecting cornice, or cap. Major Roman examples can be seen in the Maison Carrée (*c.* 12 BC) in Nîmes, Fr., and the Temple of Fortuna Virilis (*c.* 40 BC) in the Forum Boarium at Rome.



Podium upon which the Temple of Fortuna Virilis stands, in the Forum Boarium, Rome, *c.* 40 BC
Anderson—Alinari from Art Resource/EB Inc.

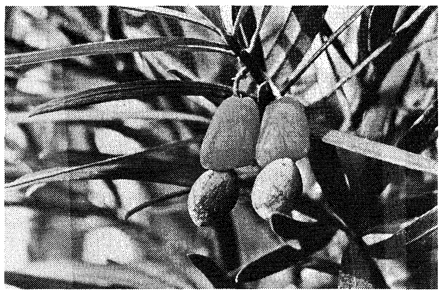
The term podium is also applied to raised platforms in general, especially those used by orchestra conductors and lecturers.

Podkamennaya Tunguska River, also spelled PODKAMENNAJA TUNGUSKA, English STONY TUNGUSKA, also called SREDNYAYA TUNGUSKA, tributary of the Yenisey River in Western Siberia, Irkutsk *oblast* (administrative region), Russian S.F.S.R. It has a total length of 1,159 miles (1,865 km) and a drainage basin of 96,100 square miles (249,000 square km). Known in its upper section as the Katanga, it rises on the Central Siberian Plateau near the watershed with the Lena–Angara system and flows generally northwestward to join the Yenisey at Podkamennaya Tunguska village. Its upper part has a wide, swampy valley; its lower section has numerous falls and rapids. The river is navigable for 710 miles (1,140 km) to the village of Vanavara.

Podluží, agricultural and cultural area of southeastern Jihomoravský *kraj* (region), Czech Socialist Republic. It is situated along the borders of Austria and the Slovak Socialist Republic, in south-central Czechoslovakia. Located in the lower Morava River Valley, Podluží's rich soils and warm climate support wheat, barley, corn (maize), sugar beets, and vegetable cultivation, and the area is noted for its vineyards. Small oil and natural-gas fields were found in the 1960s; and brown-coal (lignite) extraction began in the early 1980s at Mikulčice. Industry, centred in the main cities of Břeclav and Hodonín, consists of oil refining and the production of synthetic rubber, petrochemicals, machinery, textiles, and brick. There is woodworking, and food processing includes sugar refining, dairy products, and wine, slivovice (a plum brandy), and beer production. Mikulov and Valtice are wine centres. In Mikulov, the Dietrichstein Castle has a noted wine cellar with one of Europe's largest wine tuns, made in 1643 and holding 26,400 gallons (99,932 l).

Podluží's population is mixed Czech (Moravian) and Slovak but speaks a dialect closest to Slovak. Podluží has two noted archaeological sites: Mikulčice, where a 9th-century Slavic settlement was excavated in 1957, and Dolní Věstonice, where a prehistoric site has been excavated, yielding the renowned Věstonice Venus, a clay and ash female figurine dated *c.* 20,000 BC. The Moravian Slovak Museum in Uherské Hradiště has exhibits with artifacts from the two sites, as well as costumes and folk art of the Podluží area.

Podocarpaceae, family of seven genera in the conifer order (Coniferales), containing over 125 species of ornamental and timber evergreen trees and shrubs, distributed mainly in the Southern Hemisphere. The largest genus, *Podocarpus,* contains more than 100 species, commonly called yellowwood, found throughout Australasia, Africa, and South America. *Dacrydium* has about 20 species of Australasian trees and shrubs, including the Huon pine, or Macquarie pine (*D. franklinii*), and the rimu, or New Zealand red pine. The celery-top pine is the best-known of the six species of Australasian trees and shrubs in the genus *Phyllocladus.* The Prince Albert yew, a timber tree native to South America, is the only species in the genus *Saxegothaea.*



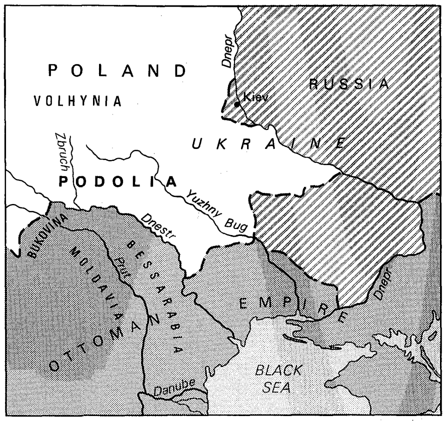
Podocarpus
W.H. Hodge

Podokesaurus, very small carnivorous dinosaur found as fossils in Late Triassic rocks of North America (the Triassic Period began 225,000,000 years ago and lasted 35,000,000 years). *Podokesaurus,* representative of the coelurosaurs, was about 1.5 m (5 feet) long and was very light. *Coelophysis,* a very slender relative, was about 2.5 m (8 feet) long and weighed 18 to 23 kg (40 to 50 pounds).

The skull of the coelurosaur was small, the eyes large, and the neck long and slender. In general, the coelurosaurs were primitive bipeds probably capable of rapid movement. *Podokesaurus* and the other coelurosaurs were active predators; it is possible that they fed on other small reptiles and the very early mammals. This group is well-representative of the basal stock from which the sauropod dinosaurs evolved; clear relationships are evident in the structure of the pelvis.

Podolia, western Ukrainian region, south of Volhynia and extending between the rivers

Dnestr and southern Bug. The name Podolia appeared in the 14th century when the Poles began to colonize the area. Except for a period



Podolia in the 18th century

in the late 17th century when it was held by the Ottoman Turks, it was under Polish rule until 1772. Then the part west of the Zbruch River became Austrian; the rest became the Podolian *guberniya* (province) in Russia in 1793. After World War I the region continued to be divided at the Zbruch, between Poland and the U.S.S.R. After World War II it was entirely incorporated into the U.S.S.R. and divided among the *oblasti* (provinces) of Ternopol (Tarnopol), Khmelnitski, and Vinnitsa.

Podolsk, city, Moscow *oblast* (province), western Russian Soviet Federated Socialist Republic, south of Moscow on the Pakhra River, a tributary of the Moskva. The village of Podol, created a town in 1781, owed its development to its position on a main highway and, after the 1860s, on a railway running south from Moscow. It has engineering, nonferrous-metallurgical, cement, and food-processing industries. Pop. (1989 prelim.) 210,000.

Podostemales, riverweed order of dicotyledonous flowering plants comprising the family Podostemaceae, with 45 genera of aquatic plants that look like mosses, liverworts, algae, and even lichens and live on rocks in rushing rivers and waterfalls. Many species lack both stems and leaves; photosynthesis takes place instead in a highly modified, ribbonlike thallus (vegetative plant body) upon which flowering and leaf-bearing secondary shoots sometimes develop. The juice of many species is milky. Few species are found outside the tropics and subtropics. One representative, the riverweed (*Podostemum ceratophyllum*), grows in shallow streams from western Quebec southward to Georgia and Arkansas.

Flowers are produced only after the plants are exposed to the air for a specific period as a result of a drop in water level. After the seeds mature they are shed on the rocks during the dry season, and they germinate when the wet season returns. The seeds of many are sticky and adhere to the rocks and to the feet of birds, by which means they are distributed to new habitats. The petalless flowers, which are bisexual, are solitary or occur in clusters, are very tiny, and stand on a relatively long stalk inside a cuplike sheath. The stamens (male pollen-producing parts) are usually one to four in number and are all on one side of the flower. The ovary is two- or three-chambered with a like number of styles (prolonged pollen-receptive upper parts of the ovary), and there are many ovules in each chamber. The fruits are many-seeded capsules.

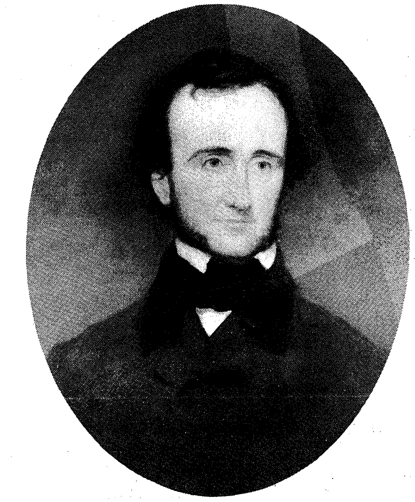
The principal genera are *Apinagia* (50 species, tropical South America), *Inversodicraea* (35 species, tropical Africa and Madagascar), *Rhyncholacis* (25 species, northern tropical South America), *Marathrum* (25 species, Central America and northwestern tropical South America), *Podostemum* (17 species, worldwide tropics and subtropics), *Dicraea* (12 species, tropics of Asia and Africa), *Castelnavia* (9 species, Brazil), *Mourera* (6 species, northern tropical South America), *Oserya* (6 species, Mexico to northern tropical South America), and *Hydrobryum* (3 species, eastern Nepal, Assam, and southern Japan). Most of the remaining 35 genera have only one or 2 species each. The order is considered to have evolved from an ancestor in the stonecrop family (Crassulaceae) of the order Saxifragales.

podzol, also spelled PODSOL, also called PODZOL SOIL, or PODSOL SOIL, soil that typically forms in very cold climates under coniferous forests, heaths, or tundra. The humus formed is very rich in slightly polymerized substances (*e.g.,* fulvic acid), which descend through the soil, form complexes with the clay minerals and iron, and leach out all the weathering products—*i.e.,* bases, iron, alumina (aluminum oxide), and silica (silicon dioxide). Podzols are characterized by one or more of the following horizons (layers): a bleached horizon that resembles ash; a spodic horizon, one formed by the accumulation (illuviation) of clay or organic matter, or both, which is transported by water and which, because it is rich in amorphous clay (allophane), iron, and organic matter, has a high cation-exchange capacity (ability of a charged metal atom in the structure to exchange places with another in aqueous solution); a horizon in which the soil grains are coated with organic matter and bound together; and hard horizons (pans) cemented together by organic matter or iron and resistant to breakdown in water. *See also* podzolic soil.

podzolic soil, podzolic also spelled PODSOLIC, also called LESSIVÉ SOIL, soil usually forming in a broadleaf forest and characterized by moderate leaching, which produces an accumulation of clay and, to some degree, iron that have been transported (eluviated) from another area by water. The humus formed produces a textural horizon (layer) that is less than 50 cm (20 inches) from the surface. Podzolic soils may have laterite (a soil layer cemented together by iron) in place of the humic horizon or along with it. A podzolic soil may be distinguished from a podzol (*q.v.*) because the main effect of the humic acid in podzolic soils is clay eluviation, whereas in podzols it is iron eluviation or the leaching of all weathering products, or both, which leaves a bleached, ashy horizon.

Poe, Edgar Allan (b. Jan. 19, 1809, Boston, Mass., U.S.—d. Oct. 7, 1849, Baltimore, Md.), American poet, critic, and short-story writer famous for his cultivation of mystery and the macabre in fiction, illustrated in such pieces as "The Murders in the Rue Morgue" (1841) and "The Raven" (1845).

Life. Poe was the son of the English-born actress Elizabeth Arnold Poe and David Poe, Jr., an actor from Baltimore. After his mother died in Richmond, Va., in 1811, he was taken into the home of John Allan, a Richmond merchant (presumably his godfather) and of his childless wife. He was taken to Scotland and England (1815–20), where he was given a classical education that was continued in Richmond. For 11 months in 1826 he attended the University of Virginia, where he studied Greek, Latin, French, Spanish, and Italian; but his gambling losses at the university so incensed his guardian that he refused to let him continue, and Poe returned to Richmond to find his sweetheart, (Sarah) Elmira Royster, engaged. He went to Boston, where in 1827 he published a pamphlet of youthful Byronic poems, *Tamerlane, and Other Poems,* some of which allude to Elmira. Poverty forced him to join the army under the name of Edgar A. Perry, but on the death of Poe's foster mother, John Allan purchased his release from the army and helped in getting him an appointment to the U.S. Military Academy at West Point. Before going, Poe published a new volume at Baltimore, *Al Aaraaf, Tamerlane, and Minor Poems* (1829), showing the influence of the English poet John Milton and the Irish poet Thomas Moore, as well as of a local Maryland poet, Edward Coote Pinkney. He successfully sought expulsion from the academy, where he was absent from all drills and classes for a week. He proceeded to New York City and brought out a volume of *Poems,* containing several masterpieces, some showing the influence of John Keats, Percy Bysshe Shelley, and Samuel Taylor Coleridge. He then returned to Baltimore, where he began to write stories. In 1833 his "MS. Found in a Bottle" won $50 from a Baltimore weekly, and by 1835 he was in Richmond as editor of the *Southern Literary Messenger.* There he



Poe, oil portrait by S.S. Osgood, 1845
By courtesy of The New-York Historical Society

made a name as a critical reviewer and married his young cousin Virginia Clemm, who was only 13. Poe seems to have been an affectionate husband and son-in-law. He wrote a tribute "To My Mother" to his aunt, Mrs. Clemm, in 1849.

Poe was dismissed from his job in Richmond, apparently for drinking, and went to New York City. Drinking was in fact to be the bane of his life. To talk well in a large company he needed a slight stimulant, but a glass of sherry might start him on a spree; and, although he rarely succumbed to intoxication, he was often seen in public when he did. This gave rise to the conjecture that Poe was a drug addict, but according to medical testimony he had a brain lesion. While in New York City in 1838 he published a long prose narrative, *The Narrative of Arthur Gordon Pym,* combining (as so often in his tales) much factual material with the wildest fancies. It is considered one inspiration of Herman Melville's *Moby Dick.* In 1839 he became coeditor of *Burton's Gentleman's Magazine* in Philadelphia. There a contract for a monthly feature stimulated him to write "William Wilson" and "The Fall of the House of Usher," stories of supernatural horror. The latter contains a study of a neurotic now known to have been an acquaintance of Poe, not Poe himself.

Later in 1839 his *Tales of the Grotesque and Arabesque* appeared (dated 1840). He resigned from *Burton's* about June 1840 but returned in 1841 to edit its successor, *Graham's Lady's and Gentleman's Magazine,* in which he printed the first detective story, "The Murders in the Rue Morgue." In 1843 his "The Gold

Bug" won a prize of $100 from the Philadelphia *Dollar Newspaper,* which gave him great publicity. In 1844 he returned to New York, wrote the "Balloon Hoax" for the *Sun,* and became subeditor of the *New York Mirror* under N.P. Willis, thereafter a lifelong friend. In the *New York Mirror* of Jan. 29, 1845, appeared, from advance sheets of the *American Review,* his most famous poem, "The Raven," which gave him national fame at once. Poe then became editor of the *Broadway Journal,* a short-lived weekly, in which he republished most of his short stories, in 1845. During this last year the now forgotten poet Frances Sargent Locke Osgood pursued Poe. Virginia did not object, but "Fanny's" indiscreet writings about her literary love caused great scandal. His *The Raven and Other Poems* and a selection of his *Tales* came out in 1845, and in 1846 Poe moved to a cottage at Fordham (now part of New York City), where he wrote for *Godey's Lady's Book* (May–October 1846) "Literati of New York"—gossipy sketches on personalities of the day, which led to a libel suit.

His wife, Virginia, died in January 1847. The following year Poe went to Providence, R.I., to woo Sarah Helen Whitman, a poet. There was a brief engagement. Poe had close but platonic entanglements with Annie Richmond and with Sarah Anna Lewis, who helped him financially. He composed poetic tributes to all of them. In 1848 he also published the lecture "Eureka," a transcendental "explanation" of the universe, which has been hailed as a masterpiece by some critics and as nonsense by others. In 1849 he went south, had a wild spree in Philadelphia, but got safely to Richmond, where he finally became engaged to Elmira Royster, by then the widowed Mrs. Shelton, and spent a happy summer with only one or two relapses. He enjoyed the companionship of childhood friends and an unromantic friendship with a young poet, Susan Archer Talley.

Poe had some forebodings of death when he left Richmond for Baltimore late in September. There, after toasting a lady at her birthday party, he began to drink heavily. The indulgence proved fatal, for Poe had a weak heart. He was buried in Westminister Presbyterian churchyard in Baltimore.

Appraisal. Poe's work owes much to the concern of Romanticism with the occult and the satanic. It owes much also to his own feverish dreams, to which he applied a rare faculty of shaping plausible fabrics out of impalpable materials. With an air of objectivity and spontaneity, his productions are closely dependent on his own powers of imagination and an elaborate technique. His keen and sound judgment as appraiser of contemporary literature, his idealism and musical gift as a poet, his dramatic art as a storyteller, considerably appreciated in his lifetime, secured him a prominent place among universally known men of letters.

The outstanding fact in Poe's character is a strange duality. The wide divergence of contemporary judgments on the man seems almost to point to the coexistence of two persons in him. With those he loved he was gentle and devoted. Others, who were the butt of his sharp criticism, found him irritable and self-centred and went so far as to accuse him of lack of principle. Was it, it has been asked, a double of the man rising from harrowing nightmares or from the haggard inner vision of dark crimes or from appalling graveyard fantasies that loomed in Poe's unstable being?

Much of Poe's best work is concerned with terror and sadness, but in ordinary circumstances the poet was a pleasant companion. He talked brilliantly, chiefly of literature, and read his own poetry and that of others in a voice of surpassing beauty. He admired Shakespeare and Alexander Pope. He had a sense of humour, apologizing to a visitor for not keeping a pet raven. If the mind of Poe is considered, the duality is still more striking. On one side, he was an idealist and a visionary. His yearning for the ideal was both of the heart and of the imagination. His sensitiveness to the beauty and sweetness of women inspired his most touching lyrics ("To Helen," "Annabel Lee," "Eulalie," "To One in Paradise") and the full-toned prose hymns to beauty and love in "Ligeia" and "Eleonora." In "Israfel" his imagination carried him away from the material world into a dreamland. This Pythian mood was especially characteristic of the later years of his life.

More generally, in such verses as "The Valley of Unrest," "Lenore," "The Raven," "For Annie," and "Ulalume" and in his prose tales his familiar mode of evasion from the universe of common experience was through eerie thoughts, impulses, or fears. From these materials he drew the startling effects of his tales of death ("The Fall of the House of Usher," "The Masque of the Red Death," "The Facts in the Case of M. Valdemar," "The Premature Burial," "The Oval Portrait," "Shadow"), his tales of wickedness and crime ("Berenice," "The Black Cat," "William Wilson," "Imp of the Perverse," "The Cask of Amontillado," "The Tell-Tale Heart"), his tales of survival after dissolution ("Ligeia," "Morella," "Metzengerstein"), and his tales of fatality ("The Assignation," "The Man of the Crowd"). Even when he does not hurl his characters into the clutch of mysterious forces or onto the untrodden paths of the beyond, he uses the anguish of imminent death as the means of causing the nerves to quiver ("The Pit and the Pendulum"), and his grotesque invention deals with corpses and decay in an uncanny play with the aftermath of death.

On the other side, Poe is conspicuous for a close observation of minute details, as in the long narratives and in many of the descriptions that introduce the tales or constitute their settings. Closely connected with this is his power of ratiocination. He prided himself on his logic and carefully handled this real accomplishment so as to impress the public with his possessing still more of it than he had; hence the would-be feats of thought reading, problem unravelling, and cryptography that he attributed to his Legrand and Dupin. This suggested to him the analytical tales, which created the detective story, and his science fiction tales.

The same duality is evinced in his art. He was capable of writing angelic or weird poetry, with a supreme sense of rhythm and word appeal, or prose of sumptuous beauty and suggestiveness, with the apparent abandon of compelling inspiration; yet he would write down a problem of morbid psychology or the outlines of an unrelenting plot in a hard and dry style. In Poe's masterpieces the double contents of his temper, of his mind, and of his art are fused into a oneness of tone, structure, and movement, the more effective, perhaps, as it is compounded of various elements.

As a critic, Poe laid great stress upon correctness of language, metre, and structure. He formulated rules for the short story, in which he sought for the ancient unities: *i.e.,* the short story should relate a complete action and take place within one day in one place. To these unities he added that of mood or effect. He was not extreme in these views, however. He praised longer works and sometimes thought allegories and morals admirable if not crudely presented. Poe admired originality, often in work very different from his own, and was sometimes an unexpectedly generous critic of decidedly minor writers.

Poe's genius was early recognized abroad. No one did more to persuade the world and, in the long run, the United States, of Poe's greatness than the French poets Charles Baudelaire and Stéphane Mallarmé. Indeed his role in French literature was that of a poetic master model and guide to criticism. French Symbolism relied on his "Philosophy of Composition," borrowed from his imagery, and used his examples to generate the modern theory of "pure poetry." (C.Ce./T.O.M./J.Ba.)

MAJOR WORKS. *Poems. Tamerlane and Other Poems* (1827); *Al Aaraaf, Tamerlane, and Minor Poems* (1829); *Poems by Edgar Allan Poe* (1831); *The Raven and Other Poems* (1845); "Ulalume" (1847); "Annabel Lee" (1849); "The Bells" (1849).

Short stories. Tales of the Grotesque and Arabesque (1840); *The Prose Romances of Edgar A. Poe* (1843), includes "The Murders in the Rue Morgue" and "The Man That Was Used Up"; *Tales* (1845), includes "The Fall of the House of Usher," "The Mystery of Marie Roget," "The Gold Bug," "The Black Cat," and "The Purloined Letter"; "The Masque of the Red Death" (1842); "The Pit and the Pendulum" (1843); "The Tell-Tale Heart" (1843); "The Premature Burial" (1844); "The Cask of Amontillado" (1846).

(1933; *The Life and Works of Edgar Allan Poe,* with an introduction by Sigmund Freud, 1949), often farfetched in its interpretations.

Poel, William, original name WILLIAM POLE (b. July 22, 1852, London—d. Dec. 13, 1934, London), English actor, theatre manager, and producer who revolutionized modern Shakespearean production by returning to Elizabethan staging.

As a child, Poel was reared among the Pre-Raphaelite artists and early decided to go on the stage. After working as an actor, stage manager, and theatre manager, he founded the Elizabethan Stage Society (1894–1905), which demonstrated the importance of the theatrical conditions under which Shakespeare wrote. Using largely amateur casts, no scenery, and an Elizabethan open-platform stage, Poel's productions were distinguished by swift and musical speech, continuity of action in nonlocalized scenes, fidelity to Shakespeare's words, and a more intimate relationship between the actors and the audience. Poel's staging methods were perhaps the single most important influence on what became the accepted approach to Shakespearean production in the 20th century. At the Elizabethan State Society, Poel revived works by Christopher Marlowe, Ben Jonson, and Beaumont and Fletcher, in addition to presenting Shakespeare's plays.

Poelzig, Hans (b. April 30, 1869, Berlin—d. June 14, 1936, Berlin), German architect who is remembered for his Grosses Schauspielhaus

Poelzig, 1932
Bavaria-Verlag

(1919), an auditorium in Berlin that is one of the finest architectural examples of German Expressionism.

Poelzig taught at the Breslau Art Academy (1900–16) and the Technical Academy in Berlin (1920–35). His Luban Chemical Factory, situated near Posen, and office building at Breslau (both 1911–12) contained novel elements, but nothing suggesting the imagination evident in his Grosses Schauspielhaus. This structure, a rebuilding of the Schumann Circus, has as its most notable feature an interior lined with stalactite shapes that, particularly under changing lighting conditions, create a grottolike atmosphere. Poelzig's later works, such as the administrative building of I.G. Farben in Frankfurt am Main (1930), although monumental in design, are held to be conventional.

Poema de Mio Cid (Spanish epic): *see* Cantar de Mio Cid.

Poerio, Carlo (b. Oct. 13, 1803, Naples—d. April 28, 1867, Florence), Italian revolutionary, distinguished for his services to liberalism during the Risorgimento.

The son of the Neapolitan lawyer and liberal Baron Giuseppe Poerio and the brother of the poet and soldier Alessandro Poerio, Carlo shared in the exiles of his family from Naples by the Bourbons; and, when he returned to Naples in 1833, he was an object of constant suspicion, though he was careful to play no part in politics. He was arrested in 1837, 1844, and 1847. In the Revolution of 1848 he helped to formulate the demands of the constitutionalists and then became at first director of police and afterward minister of education in the Liberal government. After his resignation in May 1848 he led the constitutional opposition. He was again arrested in July 1849 but was not tried until February 1851, when he was sentenced with his fellow Liberals to 24 years in irons. The illegality of the trials, the atrocious sentences, and the sufferings of the prisoners horrified the visiting English politician William Ewart Gladstone, who denounced the conditions of the Neapolitan prisons in his two *Letters to Lord Aberdeen* (July 1851) and so made Poerio's case notorious throughout Europe. Poerio was not released until January 1859 and then made his way to London.

After the outbreak of war between Sardinia–Piedmont and Austria, he went to Turin. He served as a deputy in the Parliament of the new Kingdom of Italy (1861) but later refused a governmental portfolio.

poet laureate, title first granted in England for poetic excellence. Its holder is a salaried member of the British royal household, but the post has come to be free of specific poetic duties.

The office is remarkable for its continuity. It began with a pension granted to Ben Jonson by James I in 1616, confirmed and increased by Charles I in 1630 (when an annual "butt of canary wine" was added, to be discontinued at the request of Henry James Pye—made laureate in 1790—who preferred the equivalent in money). Jonson's pension specifically recognized his services to the crown as a poet and envisaged their continuance, but not until 16 months after Jonson's death in 1637 was a similar pension for similar services granted to Sir William Davenant. It was with John Dryden's appointment in 1668, within a week of Davenant's death, that the laureateship was recognized as an established royal office to be filled automatically when vacant.

At the Revolution of 1688, Dryden was dismissed for refusing the oath of allegiance, and this gave the appointment a political flavour, which it retained for more than 200 years. Dryden's successor, Thomas Shadwell, inaugurated the custom of producing New Year and birthday odes; this hardened into a tradition between 1690 and about 1820, becoming the principal mark of the office. The odes were set to music and performed in the sovereign's presence. On his appointment in 1813, Robert Southey sought unsuccessfully to end this custom, but, although it was allowed tacitly to lapse, it was only finally abolished by Queen Victoria. Her appointment of William Wordsworth in 1843 signified that the laureateship had become the reward for eminence in poetry, and the office since then has carried no specific duties. The laureates from Alfred Tennyson onward have written poems for royal and national occasions as the spirit has moved them.

The list of poets laureate (with dates of tenure) follows: John Dryden (1668–89), Thomas Shadwell (1689–92), Nahum Tate (1692–1715), Nicholas Rowe (1715–18), Laurence Eusden (1718–30), Colley Cibber (1730–57), William Whitehead (1757–85), Thomas Warton (1785–90), Henry James Pye (1790–1813), Robert Southey (1813–43), William Wordsworth (1843–50), Alfred Tennyson (1850–92), Alfred Austin (1896–1913), Robert Bridges (1913–30), John Masefield (1930–67), C. Day-Lewis (1968–72), Sir John Betjeman (1972–84), and Ted Hughes (1984–).

In 1985 the U.S. government created a title of poet laureate, to be held by the same person who holds the post of consultant in poetry for the Library of Congress. Both appointments are annual ones. The American poet laureate receives a modest stipend and is expected to present one major poetic work and to appear at certain national ceremonies.

The title of the office stems from traditions concerning the laurel dating to the earliest Greek and Roman times.

poète maudit (French: "accursed poet"), in literary criticism, the poet as an outcast of modern society, despised by its rulers who fear his penetrating insights into their spiritual emptiness. The phrase was first applied by Paul Verlaine in *Les Poètes maudits* (1884), a collection of critical and biographical studies that focused on the tragedy of the lives of the then little-known Symbolist poets Tristan Corbière, Marceline Desbordes-Valmore, Villiers de l'Isle-Adam, Stéphane Mallarmé, and Arthur Rimbaud. Verlaine may have taken *les poètes maudits* from Baudelaire's "Bénédiction," in which a poet is described as untouched by the suffering and contempt he experiences. The term carries the implication of the low estate into which the poet has fallen from his ancient position as seer and prophet.

poetry, literature that evokes a concentrated imaginative awareness of experience or a specific emotional response through language chosen and arranged for its meaning, sound, and rhythm.

A brief treatment of the art of poetry follows. For full treatment, *see* MACROPAEDIA: Literature, The Art of.

For a description of the place of poetry in the circle of learning, and for a list of both MACROPAEDIA and MICROPAEDIA articles on the subject, including those on the poetry of specific languages and cultures, *see* PROPAEDIA: Part Six, Division II.

Poetry may be distinguished from prose literature in terms of form by its compression, by its frequent (though not prescribed) employment of the conventions of metre and rhyme, by its reliance upon the line as a formal unit, by its heightened vocabulary, and by its freedom of syntax. The characteristic emotional content of poetry finds expression through a variety of techniques, from direct description to highly personalized symbolism. One of the most ancient and universal of these techniques is the use of metaphor and simile to alter and expand the reader's imaginative apprehension through implicit or explicit comparison. This may involve an appeal to sense experience, especially visual sensation, or to emotional experience or cultural and historical awareness. Thus, by conjuring up pictures or images and by invoking different kinds of imaginative associations, the poet elicits in others something of his own feeling and consciousness.

Poetry encompasses many modes: narrative, dramatic, aphoristic, celebratory, satiric, descriptive, didactic, erotic, and personal. Within a single work the poet may move from one mode to another, preserving overall unity through the consistency of the formal pattern. The formal patterns available to the poet vary considerably: in English poetry the formal unit may be the single unrhymed line (as in blank verse), the rhymed couplet, the rhymed stanza of four lines or more, or more complex rhyming patterns such as the fourteen-line sonnet.

Poetry is an ancient mode of expression; even before the development of writing, primitive societies seem to have achieved poetic renderings of their religious, historical, and cultural awareness and to have transmitted them to the next generation in hymns, incantations, and narrative poems. Something of this early association with the cultural traditions of the tribe has persisted in later theories of poetic inspiration and poetic privilege, though from the time of the Romantics the autonomous creative imagination has been regarded as the source of poetic energy and the guarantee of poetic authenticity. Some modern poets, such as the Surrealists, would claim that the poetic faculty is a mode of access to individual and collective unconscious experience.

In the 19th and 20th centuries Western poetry has responded more to the expressive possibilities of poetic idiom and convention in different traditions. Some poets have experimented with reviving or adapting the subject matter and the verse forms of other times and places. For other poets it has been important to break with tradition and convention and attempt a studied informality of manner, an approximation of the relaxed rhythms and colloquial vocabulary of ordinary speech, and a self-consciously "prosaic" imagery.

pogge (fish): *see* poacher.

Poggio Bracciolini, Gian Francesco (b. Feb. 11, 1380, Terranuova, Tuscany—d. Oct. 30, 1459, Florence), Italian humanist and calligrapher, foremost among scholars of the early Renaissance as a rediscoverer of lost, forgotten, or neglected classical Latin manuscripts in the monastic libraries of Europe.

While working in Florence as a copyist of manuscripts, Poggio invented the humanist script (based on the Caroline minuscule), a round, formal writing that, after a generation of polishing by scribes, served the new art of printing as prototype of "Roman" fonts. In 1403 he moved to Rome, where he became a secretary to Pope Boniface IX. In 1415, at Cluny, he brought to light two unknown orations of Cicero. At St. Gall in 1416 he found the first complete text of Quintilian's *Institutio oratoria,* three books and part of a fourth of Valerius Flaccus' *Argonautica,* and the commentaries of Asconius Pedianus on Cicero's orations. Various expeditions in 1417 to Fulda, St. Gall, and other monasteries produced P. Festus' *De significatu verborum;* Lucretius' *De rerum natura;* Manilius' *Astronomica;* Silius Italicus' *Punica;* Ammianus Marcellinus' *Res gestae;* Apicius' work on cooking; and other lesser works. He also found at Langres in 1417 Cicero's oration *Pro Caecina* and perhaps at Cologne seven other orations of Cicero. It is not known where and when he discovered the *Silvae* of Statius. Poggio made copies of the newfound works in his elegant script, several of which still survive.

He spent four years (1418–23) in England, where his hopes of continuing his discoveries were disappointed by the inadequacy of English libraries. In 1423 he was reappointed curial secretary in Rome and made further discoveries, including Frontinus' *De aquaeductibus* and Firmicus Maternus' *Matheseos libri,* the latter found at Montecassino in 1429. He translated into Latin Xenophon's *Cyropaedia,* the histories of Diodorus Siculus, and Lucian's *Onos.* His classical interests extended to the study of ancient buildings and the collecting of inscriptions and of sculpture, with which he adorned the garden of his villa near Florence. He succeeded Carlo Aretino as chancellor of Florence (1453). His last years were spent in exercising this office and in writing his history of Florence.

In his own writings, Poggio was gifted with a lively eloquence and a capacity for artistic representation of character and conversation that distinguish his moral dialogues from numerous similar contemporary works. The most important of these are *De avaritia* (1428–29), *De varietate fortunae* (1431–48), *De nobilitate* (1440), and *Historia tripartita disceptativa convivalis* (1450). A vein of sad-

ness and pessimism runs through some and appears strongly in his *De miseria humanae conditionis* (1455). His *Facetiae* (1438–52), a collection of humorous, often indecent tales, contains vigorous satires on monks, clerics, and rival scholars such as Francesco Filelfo, Guarino, and Lorenzo Valla, with whom Poggio engaged in some of the most notorious and vituperative polemics of a polemical age. This same spirit animates his dialogue *Contra hypocritas* (1447–48). Poggio's ability to handle Latin as a live idiom is best shown in his copious correspondence, which for its form as much as for its content stands out among the *epistolari* of the humanists.

Pogonia, genus of at least 10 species of orchids, family Orchidaceae, native to central and eastern Asia and North and South America. Some of them are variously known as ettercaps, beardflowers, and rose crest-lips.

Snakemouth (*P. ophioglossoides*), also known as rose pogonia and adder's mouth, is common in bogs and swamps of eastern North America. The plant is about 8 to 70 cm (3 to 28 inches) tall. It bears one leaf about halfway up the stem and several at the base. The pinkish flowers have an odour similar to red raspberries and usually are solitary. The lip of each flower is toothed and bearded.

pogonophoran (marine invertebrate): *see* beardworm.

pogrom (Russian: "devastation," or "riot"), a mob attack, either approved or condoned by authorities, against the persons and property of a religious, racial, or national minority. The term is usually applied to attacks on Jews in Russia in the late 19th and early 20th centuries.

The first extensive pogroms followed the assassination of Tsar Alexander II in 1881. Although the assassin was not a Jew, and only one Jew was associated with him, false rumours aroused Russian mobs in more than 200 cities and towns to attack Jews and destroy their property. In the two decades following, pogroms gradually became less prevalent; but from 1903 to 1906 they were common throughout the country. Thereafter, to the end of the Russian monarchy, mob action against the Jews was intermittent and less widespread.

The pogrom in Kishinev, in April 1903, although more severe than most, was typical in many respects. For two days mobs, inspired by local leaders acting with official support, killed, looted, and destroyed without hindrance from police or soldiers. When troops were finally called out and the mob dispersed, 45 Jews had been killed, nearly 600 had been wounded, and 1,500 Jewish homes had been pillaged. Those responsible for inciting the outrages were not punished.

The Russian central government did not organize pogroms, as was widely believed; but the anti-Semitic policy that it carried out from 1881 to 1917 made them possible. Official persecution and harassment of Jews led the numerous anti-Semites to believe that their violence was legitimate, and their belief was strengthened by the active participation of a few high and many minor officials in fomenting attacks and by the reluctance of the government either to stop pogroms or to punish those responsible for them.

Pogroms have also occurred in other countries, notably in Poland and in Germany during the Hitler regime. *See also* anti-Semitism; Kristallnacht.

pogy (fish): *see* menhaden.

P'ohang, city, Kyŏngsang-pukto (North Kyŏngsang Province), eastern South Korea. A fishing port, it lies on the eastern side of the Yŏngil Gulf, 51 miles (82 km) east-northeast of Taegu, the provincial capital. Formerly a small village, it began to develop after 1930 with the construction of a modern harbour by reclamation of the shoreline and diversion of the Hyŏngsan River to the south of the city. The surrounding plains produce various agricultural products, and the sea provides good fishing grounds. The city is at the intersection of rail and shipping lines. Traditional industries include wine and brandy making, but during the 1970s heavy industry, including iron and steel production, and shipbuilding were developed. Pop. (1980 prelim.) 201,355.

Pohjanmaa, Swedish ÖSTERBOTTEN, lowland plain covering about 70 percent of Vaasan *lääni* (Vaasa province), southwestern Finland, along the Gulf of Bothnia. Also known as the Ostrobothnian plain, Pohjanmaa is about 60 miles (100 km) wide and 160 miles (257 km) long. It consists of flat plains of sand and clay soil that are broken by rivers and bog areas. It is drained mainly by the Lapuan, Kyrön, and Iso rivers, which flow to the Gulf of Bothnia. The lowlands are divided between agricultural developments and forested areas. The Swedish-speaking farmers produce turnips, winter wheat, and hay and raise dairy cattle. Since the 1950s the raising of mink and fox and the exporting of furs have grown in importance. The pine forests, which cover approximately 65 percent of the region, have not been exploited to any great extent. The city of Vaasa is the primary port and economic centre for the area.

Pohjois-Karjala, in full POHJOIS-KARJALAN LÄÄNI, Swedish NORRA KARELENS LÄN, English NORTH KARELIA, *lääni* (province), east central Finland, bordering the Soviet Union to the east and southeast. Its land area is 6,866 square miles (17,782 square km). The province includes Lake Pielinen, which is the northeastern part of the Saimaa lake system. Lumbering of the province's softwood forests is the principal source of income, and there is some small-scale mixed farming. Joensuu, the administrative capital at the mouth of the Pielis River, is a lumber shipment centre with rail and lake port facilities. Other towns are Lieksa and Nurmes, both smaller market centres. Pop. (1986 est.) 177,565.

Pohnpei, also spelled PONAPE, also called ASCENSION, high coral-capped volcanic island, eastern Caroline Islands; it and nearby atolls constitute a state in the Federated States of Micronesia, in the western Pacific. Pohnpei island is roughly square in shape with a land area of 129 square miles (334 square km). It is well watered, hilly (rising to Mount Totolom, 2,595 feet [791 m]), and is surrounded by a barrier reef with many small islets. Its fertile soil and heavy rainfall have resulted in luxuriant tropical foliage, and it has been called the "garden of Micronesia." It has mangrove swamps along its coasts and rain forest in the central hilly area. Situated near Pohnpei are the low-lying coral atolls of Oroluk, Pakin, and Ant to the west; Ngatik, Nukuoro, and Kapingamarangi atolls to the southwest; and Mokil and Pingelap atolls to the east. Most of the coral atolls are wooded and support coconut palms. The native people, with the exception of the Polynesian inhabitants of Nukuoro and Kapingamarangi, are Micronesians.

In the lagoon on the eastern coast of Pohnpei is Nan Madol, a group of 92 prehistoric, artificial platform islands built in the lagoon and surrounded by man-made canals. Ruins of a town and ceremonial centre of the early 2nd millennium AD include tombs of former kings, belonging, according to tradition, to the Sau Deleur dynasty that once ruled the whole island.

Though Pohnpei was much visited by whalers and traders, it was not until the mid-19th century that missionaries established schools there. Spanish administration was followed by German possession after 1898. The Germans promoted the production of copra. After World War I, Japan was given mandate of Micronesia under the League of Nations, and Pohnpei was made one of the administrative centres. During World War II Pohnpei's Japanese garrison was bypassed by the Allies and isolated prior to its surrender. The island was part of the United Nations Trust Territory of the Pacific Islands from 1947 until the dissolution of the Trust Territory in 1986.

Pohnpei yields a wide variety of tropical products, including copra, breadfruit, taro, cacao, trochus, and tilapia. Rice is grown, pigs and poultry are raised, and fish are caught. Main coastal villages are Kolonia (capital of the Federated States of Micronesia and headquarters of Pohnpei State), Metalanim, and Ronkiti. Pohnpei has an international airport. The Community College of Micronesia is in Kolonia. Pop. (1985 est.) island (including Ant Atoll), 24,788.

poi, starchy Polynesian food paste made from the taro root. In Samoa and other Pacific islands, poi is a thick paste of pounded bananas or pineapples mixed with coconut cream; the word originally denoted the action of pounding the food to a pulp. In Hawaii, where poi is a staple of local cuisine, taro root is used almost exclusively for its preparation. The peeled roots are cooked, pounded, mixed with water to the desired consistency, and strained to remove fibres. The resultant bland, bluish-gray paste is eaten fresh or allowed to ferment for up to a week to develop a tangy taste. Hawaiians traditionally did not use eating utensils, and poi is still characterized as one-, two-, or three-finger, according to the technique necessary to scoop up a mouthful. The luau (*q.v.*), a Hawaiian banquet, is sometimes called a poi supper.

poikilothermy: *see* cold-bloodedness.

Poincaré, (Jules-)Henri (b. April 29, 1854, Nancy, Fr.—d. July 17, 1912, Paris), French mathematician, theoretical astronomer, and philosopher of science who influenced cosmogony, relativity, and topology and was a gifted interpreter of science to a wide public.

Poincaré was from a family distinguished by its contributions to government and administration. His first cousin was Raymond Poincaré, president of the French Republic during World War I. Poincaré was ambidextrous and was nearsighted; during his childhood he had poor muscular coordination and was seriously ill for a time with diphtheria. He received special instruction from his gifted mother and excelled in written composition in elementary school. He learned German during the Franco-German War—at which time he also witnessed the suffering of the soldiers and populace with his father, who was a physician. Becoming deeply interested in mathematics during adolescence, he attended in 1872–75 the École Polytechnique in Paris, where he easily won top honours in mathematics, but was undistinguished in physical exercise and

Henri Poincaré, 1909
H. Roger-Viollet

in art. He had an unusually retentive memory for everything he read; moreover, he could visualize what he heard, a useful faculty because he could not clearly see at a distance the mathematical symbols that were on the blackboard. Throughout his life he was able to perform complex mathematical calculations in his head and could quickly write a paper without extensive revisions. He received, in 1879, a doctorate from the École Nationale Supérieure des Mines with a thesis on differential equations.

Following a brief appointment in mathematical analysis at the Université de Caen, in 1881 Poincaré joined the Université de Paris, where, during the rest of his life, he lectured and wrote prolifically—almost 500 papers—on mechanics and experimental physics, in all branches of pure and applied mathematics, and in theoretical astronomy. Changing his lectures every year, he would review optics, electricity, the equilibrium of fluid masses, the mathematics of electricity, astronomy, thermodynamics, light, and probability. Many of these lectures appeared in print shortly after they were delivered at the university. In his extensive writings on probability, Poincaré anticipated the concept of ergodicity that is basic to statistical mechanics.

Applying his mastery of analysis to the question of the solvability of algebraic equations, Poincaré developed before age 30 the idea of the automorphic function—one that is invariant under a group of transformations that are characterized algebraically by ratios of linear terms. He showed how these functions can be used to integrate linear differential equations with rational algebraic coefficients and how to express the coordinates of any point on an algebraic curve as uniform functions of a single algebraic variable (or parameter). Some of these automorphic functions he called Fuchsian, after the German mathematician Immanuel Lazarus Fuchs, who was one of the founders of the theory of differential equations; he found that they were associated with transformations arising in non-Euclidean geometry. In recognition of his fundamental contributions to mathematics, he was elected, in 1887, to membership in the Académie des Sciences in Paris.

In celestial mechanics, Poincaré made substantial contributions to the theory of orbits, particularly the classical three-body problem (for example, the system involving the Sun, Moon, and Earth). This was part of the "problem of *n* bodies" (planets, stars, etc.), set for a prize by King Oscar II of Sweden: given the present masses, velocities, motions, and mutual distances of "*n* bodies," how long will they remain stable in their present spatial relationships, or will their orbits change at some future date? In his solution, Poincaré developed powerful new mathematical techniques, including the theories of asymptotic expansions and integral invariants, and made fundamental discoveries on the behaviour of the integral curves of differential equations near singularities. He was awarded the prize in 1889, even though his solution to the problem was only partially correct; in the same year he was also made a knight of the French Legion of Honour.

Poincaré summarized his new mathematical methods in astronomy in *Les Méthodes nouvelles de la mécanique céleste,* 3 vol. (1892, 1893, 1899; "The New Methods of Celestial Mechanics"). Another result of this work, his *Analysis situs* ("Positional Analysis") in 1895, was an early systematic treatment of topology, which deals with properties of a system that endure when metric distortion occurs—that is, topology deals with the qualitative characteristics of spatial configurations that do not vary during cumulative transformations. He also contributed to the theory of numbers by demonstrating how the conception of binary quadratic forms, which was developed by the German mathematician Carl Friedrich Gauss, could be cast in geometric form. In 1904 he lectured at the St. Louis Exposition.

In mathematical analysis, Poincaré made important contributions to the theory of equilibrium of rotating fluid masses. In particular, he described the conditions of stability of the pear-shaped figures that played so prominent a part in the researches of later cosmogony, with reference to the evolution of celestial bodies. He attempted an application of these ideas to the stability of Saturn's rings and to the origin of binary stars. In 1906, in a paper on the dynamics of the electron, he obtained, independently of Einstein, many of the results of the special theory of relativity. The principal difference was that Einstein developed the theory from elementary considerations concerning light signaling, whereas Poincaré's treatment was based on the full theory of electromagnetism and was restricted to phenomena associated with the concept of a universal ether that functioned as the means of transmitting light.

After Poincaré achieved prominence as a mathematician, he turned his superb literary gifts to the challenge of describing for the general public the meaning and importance of science and mathematics. Always deeply interested in the philosophy of science, he wrote *La Science et l'hypothèse* (1903; *Science and Hypothesis*), *La Valeur de la science* (1905; *The Value of Science*), and *Science et méthode* (1908; *Science and Method*), all of which reached a wide public of nonprofessionals. His works were translated into English, German, Hungarian, Japanese, Spanish, and Swedish. He emphasized the subconscious, while probing the psychology of mathematical discovery and invention. He was a forerunner of the modern intuitionist school in that he believed that some mathematical induction is a priori and independent of logic. In his view, sudden illumination, following long subconscious work, is a prelude to mathematical creation. But his greatest contribution to philosophy was to emphasize the role played in scientific method by convention—*i.e.,* by the arbitrary choice of concepts.

Poincaré's prestige and influence increased in French science, and in 1906 he was elected president of the Académie des Sciences and in 1908 to membership in the Académie Française, the highest honour accorded a French writer. (G.J.W.)

BIBLIOGRAPHY. There is no definitive biography of Henri Poincaré, but Eric T. Bell, *Men of Mathematics*, ch. 28 (1937, reprinted 1961), contains a biographical study of his work. A useful obituary notice is in the *Proc. R. Soc.*, series A, 91:5–16 (1915). The collected works, *Oeuvres de Henri Poincaré*, were published by the *Académie des Sciences de Paris*, 10 vol. (1916–54). His writings on the philosophy of science and of mathematics can be found in *The Foundations of Science*, containing *Science and Hypothesis, The Value of Science*, and *Science and Method*, trans. by George Bruce Halsted (1913); and in *Dernières pensées* (1913; *Mathematics and Science: Last* Essays, 1963).

Poincaré, Raymond (b. Aug. 20, 1860, Bar-le-Duc, Fr.—d. Oct. 15, 1934, Paris), French statesman who as prime minister in 1912 largely determined the policy that led to France's involvement in World War I, during which he served as president of the Third Republic.

Raymond Poincaré, 1913
H. Roger-Viollet

The son of an engineer, he was educated at the École Polytechnique. After studying law at the University of Paris, he was in 1882 admitted to the bar. Elected a deputy in 1887, he became six years later the youngest minister in the history of the Third Republic, holding the portfolio of education. In 1894 he served as minister of finance and in 1895 again as minister of education. In the Dreyfus affair (*q.v.*) he declared that new evidence necessitated a retrial.

Despite the promise of a brilliant political career, Poincaré left the Chamber of Deputies in 1903, serving until 1912 in the Senate, which was considered comparatively unimportant politically. He devoted most of his time to his private law practice, serving in the Cabinet only once, in March 1906, as minister of finance. In January 1912, however, he became prime minister, serving simultaneously as foreign minister until January 1913. In the face of new threats from Germany, he conducted diplomacy with new decisiveness and determination. In August 1912 he assured the Russian government that his government would stand by the Franco-Russian alliance, and in November he concluded an agreement with Britain committing both countries to consult in the event of an international crisis as well as on joint military plans. Although his support of Russian activities in the Balkans and his uncompromising attitude toward Germany have been cited as evidence of his being a warmongering revanchist, Poincaré believed that in the existing state of contemporary Europe war was inevitable and that only a strong alliance guaranteed security. His greatest fear was that France might be isolated as it had been in 1870, easy prey for a militarily superior Germany.

Poincaré ran for the office of president; despite the opposition of the left, under Georges Clemenceau, a lifelong enemy, he was elected on Jan. 17, 1913. Although the presidency was a position with little real power, he hoped to infuse new vitality into it and make it the base of a *union sacrée* of right, left, and centre. Throughout World War I (1914–18) he strove to preserve national unity, even confiding the government to Clemenceau, the man best qualified to lead the country to victory.

After his term as president ran out in 1920, Poincaré returned to the Senate and was for a time chairman of the reparations commission. He supported the thesis of Germany's war guilt implicit in the Versailles Treaty; and when he served again as prime minister and minister for foreign affairs (1922–24), he refused a delay in German reparation payments and in January 1923 ordered French troops into the Ruhr in reaction to the default. Unseated by a leftist bloc, he was returned as prime minister in July 1926 and is largely credited with having solved France's acute financial crisis by stabilizing the value of the franc and basing it on the gold standard. Under his highly successful economic policies the country enjoyed a period of new prosperity.

Illness forced Poincaré to resign from office in July 1929. He spent the remainder of his life writing his memoirs, *Au service de la France*, 10 vol. (1926–33).

Poinsat, Juan: *see* John of Saint Thomas.

Poinsett, Joel R(oberts) (b. March 2, 1779, Charleston, S.C., U.S.—d. Dec. 12, 1851, near Statesburg), U.S. statesman noted primarily for his diplomacy in Latin America. A fervent liberal, he frequently meddled in the affairs of Latin American nations, incurring their animosity by his misdirected good intentions.

The son of a prominent physician, Poinsett was educated in the U.S. and England and then travelled for seven years in Europe and western Asia. Returning home to serve in the approaching war with England, he was instead appointed the special agent for the U.S. in Buenos Aires and Chile in 1810. Although he initiated diplomatic and commercial relations with these Spanish territories, he also supported the nascent revolutionary forces there.

After serving in the South Carolina legislature (1816–20), Poinsett was elected to the U.S. House of Representatives in 1820. Interrupting his legislative career, he went on a special mission to Mexico in 1822 and 1823, publishing his *Notes on Mexico* in 1824. In 1825 he became the first U.S. minister to Mexico, a post he held until 1829. Deeply involved in Mexican politics, he finally became *persona non grata* to the government. The Mexicans even coined the word *poinsettismo* to characterize his officious and intrusive behaviour.

Poinsett, detail of a portrait by Thomas Sully; in the collection of the American Philosophical Society, Philadelphia
By courtesy of the American Philosophical Society, Philadelphia

In 1830 Poinsett became a leader of the Unionist Party in South Carolina, a group that opposed the doctrine of nullification, which held that the individual states have the right to set aside any federal law that violates their compact in the U.S. Constitution. As a reward for these services, Pres. Martin Van Buren appointed him secretary of war in 1837. He served until 1841 and then retired to South Carolina.

An accomplished amateur botanist, Poinsett brought a flower from Mexico that was renamed the poinsettia in his honour. He was instrumental in founding the National Institute for the Promotion of Science and the Useful Arts, a precursor of the Smithsonian Institution.

poinsettia (*Euphorbia pulcherrima*), best known member of the diverse spurge family, Euphorbiaceae. The poinsettia is native to Mexico and Central America, where it grows in moist, wet, wooded ravines and on rocky hillsides. It was named for Joel R. Poinsett, who popularized the plant and introduced it to floriculture while he was U.S. minister to Mexico in the late 1820s.

Poinsettia (*Euphorbia pulcherrima*)
Grant Heilman—EB Inc.

In warm climates the poinsettia grows outdoors as a winter-flowering leggy shrub about 5 metres (16 feet) high; as a potted plant in northern areas it rarely grows beyond 1 metre. What appear to be petals are actually coloured leaflike bracts that surround a central cluster of tiny yellow flowers. A milky latex in the stems and leaves can be irritating to persons or animals sensitive to it, but the claim that poinsettias are deadly poisonous is greatly exaggerated.

Cultivated varieties are available with white, pink, mottled, and striped bracts, but the solid red varieties, in several shades, remain in greatest demand during the Christmas season.

point appliqué: *see* application lace.

Point Barrow, northernmost point of Alaska, U.S., on the Arctic Ocean. It is connected with Anchorage and Fairbanks by regular air service. The headland was discovered in 1826 by Frederick W. Beechey and named for Sir John Barrow, promoter of Arctic exploration. Once important in Arctic aviation, it was the departure point of Sir George Hubert Wilkins' flight (1928) over the North Pole and was the site of the air crash (1935) that killed Will Rogers and Wiley Post. An Arctic research station was constructed by the U.S. Navy in the 1940s. The area has vast oil and gas deposits. The city of Barrow was incorporated in 1959. In June 1977 it was the site of the first international Inuit (Eskimo People's) Circumpolar Conference. Pop. (1980) Barrow city, 2,207.

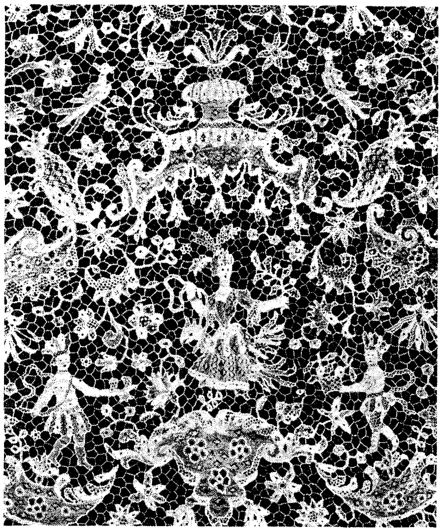
point Colbert (French: "Colbert lace"), needle-made lace developed at Bayeux in France in 1855, inspired by 17th-century Alençon lace (*q.v.*) and named after Louis XIV's minister Jean-Baptiste Colbert, who started Alençon's industry. Like Alençon, it had conventionalized flowers, stems, and the like on a background of bars, or brides, but new designs were also made.

point d'Alençon (lace): *see* Alençon lace.

point d'Angleterre (lace): *see* Angleterre.

point d'Argentan: *see* Argentan lace.

point de France (French: "French lace"), specifically, the 17th-century school of French lace set up by Louis XIV's minister Jean-Baptiste Colbert to curb the national extravagance in buying foreign lace. Colbert imported lace-



Point de France lace, end of the 17th century; in the Victoria and Albert Museum, London

By courtesy of the Victoria and Albert Museum, London

workers from Venice and Flanders and settled them in and around centres where lace was already being made, such as Sedan and Alençon; in 1665 they were granted a monopoly for 10 years to produce lace that was artistically and financially competitive with imported varieties.

Point de Galle (Sri Lanka): *see* Galle.

point de gaze (French: "gauze lace"), needle lace produced in Brussels, principally from 1851 to around 1900, though in the 1980s it was still being produced for the tourist trade. It was the last of the great laces to be devel-

Point de gaze lace from Brussels, 1870–90; in the Rijksmuseum, Amsterdam

By courtesy of the Rijksmuseum, Amsterdam

oped. Its gauzy appearance is the result of a delicate, needle-made mesh, created with one continuous thread forming a network of semicircular loops. In the solid parts of the design, shading is achieved by a combination of close and open stitches. The characteristic flowers sometimes have detached petals.

point de Paris (French: "Paris lace"), product of a lace industry known to have existed around 1634 in the Île de France. No authenticated examples of this lace have been found, however. In modern usage, *point de Paris* has come to mean any bobbin-made lace with a six-pointed star mesh that is twisted, as opposed to that of Chantilly, which is plaited.

point estimation, in statistics, the process of finding an approximate value of some parameter (mean, standard deviation, proportion) of a population from corresponding functions of random samples of the population. The accuracy of the approximation is not known, though probabilistic statements concerning such numbers as found over many experiments can be constructed.

It is desirable for an estimate to be: (1) Consistent. The larger the sample size, the more accurate the estimate. (2) Unbiassed. The expectation (*q.v.*) of the observed values of a function of many samples is the corresponding population parameter. (3) Most efficient or best unbiassed—of all consistent, unbiassed estimates, the one possessing the smallest variance.

Several methods are used to calculate the estimator. The most often used, the maximum likelihood method, uses differential calculus to determine the maximum of the probability function of a number of sample parameters. The moments method equates values of sample moments (functions describing the parameter) to population moments. The solution of the equation gives the desired estimate. The Bayesian method, named for the 18th-century English mathematician Thomas Bayes, differs from the traditional methods by introducing a frequency function for the parameter being estimated. The drawback to the Bayesian method is that sufficient information on the distribution of the parameter is usually not available. One advantage is that the estimation can be easily adjusted as additional information becomes available.

Point Four Program, U.S. policy of technical assistance and economic aid to underdeveloped countries, so named because it was the fourth point of Pres. Harry S. Truman's 1949 inaugural address. The first appropriations were made in 1950. The program was originally administered by a special agency of the Department of State, but in 1953 it was merged with other foreign-aid programs. The program was designed to promote U.S. influence by making modern technological and scientific knowledge available to underdeveloped areas, primarily in Asia, Africa, and Latin America.

point group, also called CRYSTAL CLASS, in crystallography, listing of the ways in which the orientation of a crystal can be changed without seeming to change the positions of its atoms. These changes of orientation must involve just the point operations of rotation about an axis, reflection in a plane, inversion about a centre, or sequential rotation and inversion. Only 32 distinct combinations of these point operations are possible, as demonstrated by a German mineralogist, Johann F.C. Hessel, in 1830. Each of the possible combinations is called a point group or crystal class. A crystal can be assigned to one of these point groups on the basis of its external shape, or morphology. The addition of translational changes will yield a total of 230 possible combinations; these are called space groups.

Point Pelee National Park, park in southeastern Ontario, Canada, lying southeast of Leamington, at the western end of Lake Erie. Established in 1918, it occupies an area of 6 sq mi (16 sq km) and comprises a wedge-shaped sandspit jutting into the lake. It lies astride a major flyway of wild ducks, Canada geese, swans, and other migratory birds, which find sanctuary in its marshland. The park has a variety of forest trees, shrubs, and fruit-bearing bushes and includes a large cattail marsh.

Point Pleasant, city, seat (1804) of Mason County, western West Virginia, U.S., on the Ohio River at the mouth of the Kanawha River, adjacent to Henderson (southwest). The settlement developed around Ft. Blair, built in 1774, and was chartered in 1794. On Oct. 10, 1774, at the confluence of the two rivers, Gen. Andrew Lewis and a band of Virginia frontiersmen defeated the allied Indian nations under Chief Cornstalk. That victory, which broke the strength of the warring Indians, is recognized by some historians as the first battle of the Revolution because the Indians were supposedly incited by the British; it is commemorated by Point Pleasant Battle Monument, an 84-ft (26-m) granite shaft in Tu-Endie-Wei Park. (In 1908 the U.S. Senate recognized the claim of the Battle of Point Pleasant as the first battle of the Revolution over the claim of Lexington, Mass.) Also in the park is the log Mansion House (1796), oldest building in the Kanawha Valley, now restored as a museum, and the graves of Chief Cornstalk and Ann Bailey, celebrated frontierswoman. Point Pleasant developed rapidly after a shipyard was built in 1849. Manufactures now include iron products and textiles.

On Dec. 15, 1967, Silver Bridge, spanning the Ohio River between Point Pleasant and Kanauga, Ohio, collapsed, dumping more than 50 cars into the river; the death toll exceeded 50. Inc. town, 1833; city, 1915. Pop. (1980) 5,682.

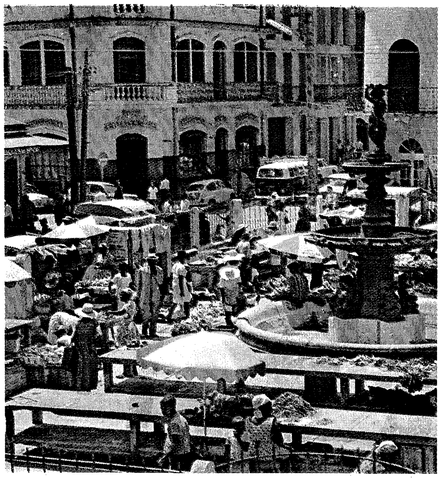
point-to-point, race run during the non-hunting season (February–May) by horses regularly hunted at fox hunts.

The races originated in England in the second half of the 19th century as a way to keep hunters fit and were first called hunt races. Each hunt had one such race. All riders are amateurs. The races are related to steeplechasing in that jumping is involved. At the turn of the 20th century, there were about 50 such races. In the second half of the 20th century there were nearly 200 throughout the British Isles. They came to be run on oval tracks set up on open ground rather than from one point to another crosscountry. The shortest distance is 3 miles (4.8 km) and the longest 4½ miles (7.2 km). There are races for novices and ladies. The major point-to-point is the Player's Gold Leaf Championship, for which the final is run at Newbury. The governing body is the National Hunt Committee.

Point-to-point raicng also began in the 19th century in the United States, mainly in fox hunting country along the Atlantic coast. There the governing body is the National Steeplechase and Hunt Association.

Pointe-à-Pitre, principal town and *arrondissement* of the French overseas *département* of Guadeloupe in the Caribbean Sea. The town lies on the southwestern coast of Grande-Terre island, on the eastern shore of the Mouillage (anchorage) de la Rivière Salée, a channel that connects two large bays to the north and south and separates Grande-Terre from Guadeloupe (Basse-Terre), the mountainous western island of Guadeloupe. Several islets in the southern bay guard the approach to the town's harbour, and there are extensive mangrove swamps in the vicinity of the town.

Pointe-à-Pitre was founded in the mid-17th century, soon after the French settlement of Guadeloupe, but it was eclipsed in importance until the late 18th century by Basse-Terre, which still remains the administrative capital. In 1906 a road bridge across the Rivière Salée replaced the existing ferry, and, favoured by its central position and harbour facilities, Pointe-à-Pitre became the chief commercial town. It

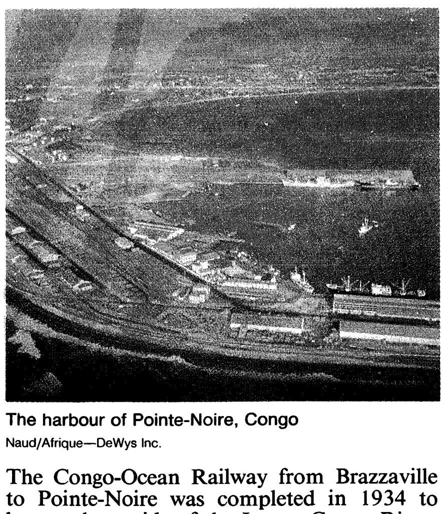


Pointe-à-Pitre market, Guadeloupe
Kurt Scholz—Shostal/EB Inc.

handles some 95 percent of Guadeloupe's imports. Near the town centre are many old houses with stone lower and wooden upper stories; in the mid-20th century there was extensive suburban development, particularly north toward Raizet Airport and the nearby town of Les Abymes. Pop. (1982) 25,151.

Pointe-Claire, city, Montréal region, southern Quebeç province, Canada, on the southern shore of Île-de-Montréal (Montreal Island), overlooking Lake Saint-Louis, a widening of the St. Lawrence River. Founded in 1713, it was a quiet agricultural settlement until after World War II, when the spread of metropolitan Montreal brought about its transformation into a modern residential and industrial suburb. Both national railways and the Trans-Canada Highway serve the city. Inc. town, 1911; city, 1958. Pop. (1986) 26,026.

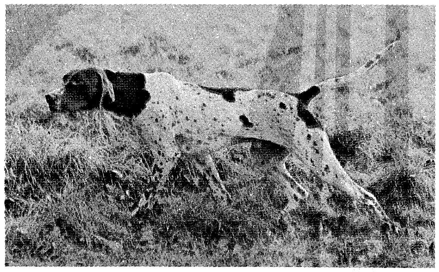
Pointe-Noire, commune (town), principal port of the Congo. It lies at the Atlantic coastal terminus of the Congo-Ocean Railway 95 miles (150 km) north of the Congo River and 245 miles (394 km) west of Brazzaville, the capital. Between 1950 and 1958 Pointe-Noire was the capital of the Moyen-Congo region of French Equatorial Africa. With independence in 1958, it was replaced by Brazzaville as the national capital, but Pointe-Noire remained the primary entrepôt and second largest city.



The harbour of Pointe-Noire, Congo
Naud/Afrique—DeWys Inc.

The Congo-Ocean Railway from Brazzaville to Pointe-Noire was completed in 1934 to bypass the rapids of the Lower Congo River. Although the city is situated on a calm bay, its port facilities were not completed until 1939; they were expanded during World War II. An international airport was built south of the town. Later, light industries and mineral-processing plants were established, but the city's chief importance remained its transit trade. In the 1970s, petroleum drilled offshore near Pointe-Noire and processed at a refinery in the town became a major national export. Pop. (1985 est.) 298,014.

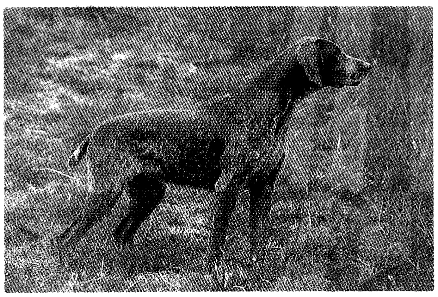
pointer, highly regarded breed of sporting dog of hound, spaniel, and setter ancestry. First recorded about 1650, in England, the pointer was originally used to point out hares for



English Pointer
Sally Anne Thompson—EB Inc.

greyhounds to track down. It was trained as a bird dog in the 18th century. Clean-cut, lithe, and powerful, it stands 58 to 64 cm (23 to 25 inches) and weighs 23 to 27 kg (50 to 60 pounds). It has a long muzzle, hanging ears, tapered tail, and a short, smooth coat, usually white with black, liver-coloured, yellowish brown, or reddish brown markings.

The German short-haired pointer is another sporting breed. Developed in Germany, it is



German short-haired pointer
Sally Anne Thompson

an all-purpose dog that can track game as well as point and retrieve game in water. It is about the size of a pointer and has a short coat of solid liver colour or liver and gray-white.

pointillism, in painting, the practice of applying small strokes or dots of colour to a surface so that from a distance they blend together. The technique is associated with the painting style known as Neo-Impressionism (*q.v.*).

pointing, in building maintenance, the technique of repairing mortar joints between bricks or other masonry elements. When aging mortar joints crack and disintegrate, the defective mortar is removed by hand or power tool and replaced with fresh mortar, preferably of the same composition as the original. Often an entire wall, or even a whole structure, is pointed because defective points cannot easily be detected, and adjacent joints may also be in need of repair. The mortar is packed tightly in thin layers and tooled to a smooth, concave, finished surface. Tuckpointing is a refinement of pointing, by which sharply defined points are formed for decorative purposes.

Poiré, Emmanuel: *see* Caran d'Ache.

Poiret, Paul (b. April 20, 1879, Paris, Fr.—d. April 30, 1944, Paris), French couturier, the most fashionable dress designer of pre-World War I Paris, who was particularly noted for his introduction of the hobble skirt, a vertical, tight-bottomed style that confined women to mincing steps.

After serving as a designer in the house of Parisian fashion designer Charles Frederick Worth, Poiret opened a small shop in Paris in 1903.

By placing a belt on the straight silhouette high under the bosom (1908), he revived the Empire style, popular in France during the reign of Napoleon I. Inspired by a widespread interest in Far Eastern art and Russian ballet, he added draped and belted knee-length tunics to his popular hobble skirt. Fringed and tasseled capes, multicoloured feathers, coils of pearls, and white-fox stoles imparted a flamboyant, theatrical look to Poiret's designs. His evening gowns appeared in brilliant shades of purple, red, orange, green, and blue. Poiret's simple, flowing Greek costumes were popular in the pre-World War I period, but his popularity waned in the 1920s.

Poiseuille, Jean-Louis-Marie (b. April 22, 1799, Paris, Fr.—d. Dec. 26, 1869, Paris), French physician and physiologist who formulated a mathematical expression for the flow rate for the laminar (nonturbulent) flow of fluids in circular tubes. Discovered independently by Gotthilf Hagen, a German hydraulic engineer, this relation is also known as the Hagen-Poiseuille equation.

Poiseuille received his medical degree in 1828 and established his practice in Paris. His interest in the circulation of the blood led him to conduct a series of experiments on the flow of liquids in narrow tubes, from which he determined the law that bears his name. This equation states that the flow rate is determined by the viscosity of the fluid, the drop in pressure along the tube, and the tube diameter. He also is believed to be the first to have used the mercury manometer to measure blood pressure.

poison, in biochemistry, a substance, natural or synthetic, that causes damage to living tissues and has an injurious or fatal effect on the body, whether ingested, inhaled, or absorbed or injected through the skin. Stated another way, a poison is a substance that, when consumed by an organism through an appropriate route of exposure at the correct dose, is capable of causing toxic effects or even death by its action on the tissues with which it comes into contact.

A brief treatment of poisons and poisoning follows. For full treatment, *see* MACROPAEDIA: Poisons and Poisoning.

A poison does not necessarily have an all-or-none effect. Degrees of poisoning are recognized, and some substances are more toxic than others. Potassium cyanide, of which as little as 0.25 gram may be lethal, is rated as highly toxic. Common salt, on the other hand, usually regarded as benign and as an item of the diet, can kill if a large enough single dose is taken. It has a relatively low toxicity.

Poisoning may be acute or chronic, defined mainly in reference to time. When a single dose is followed immediately by symptoms that imperil the victim, the poisoning is said to be acute. When the doses or exposures are repetitive or continuous, with either immediate or delayed toxic effects, the poisoning is called chronic. For example, in a delayed reaction, a person may consume extremely low doses of arsenic for weeks or months without symptoms; indigestion, skin rashes, and changes in the nerves of the arms and legs, all symptoms of arsenic poisoning, will appear only gradually and only as the rate of accumulation of the poison in the tissues exceeds the rate of excretion. Thus, although a normal person may harbour a small quantity of a chemical throughout life without any distress, and a somewhat higher level may even confer increased benefit, only when a still higher critical, toxic level is exceeded do adverse complications ensue. Consequently, it is sometimes difficult to classify a substance as a poison without information about such factors as the amount consumed and the duration and pattern of consumption.

Chronic poisoning can occur without the causal substance actually becoming stored in the body. The pain-relieving drug phenacetin, taken daily, even in large doses, is completely metabolized and eliminated. Yet a person who indulges in such self-medication excessively over months or years can sustain severe and irreversible kidney damage.

A peculiar variant of chronic toxicity is chemical carcinogenicity. Prolonged exposure to certain oils, to benzidine, to beta-naphthylamine, to asbestos, and to cigarette smoke can lead, after an interval, to the development of distinctive and characteristic cancers. No dose-response relationship has been worked out for this process; repeated contact seems to be the essential feature, together, possibly, with a particular chemical configuration.

Local effects of poisons include wheals, blisters, and violent inflammation, often followed by necrosis, muscle spasm, and disturbances in sensation. Systemic effects include local or widespread hemorrhages, destruction of blood cells, and abnormal clotting. Irritative effects on the various systems of the body may include excitement, convulsions, vomiting, diarrhea, or tetany; depressive symptoms include clouding of senses, paralysis, and weakening or arrest of respiration and heartbeat.

Agricultural and industrial chemicals. Most agricultural chemicals are pesticides, which include insecticides, fungicides, rodenticides, and fumigants. One well-known insecticide is chlorophenothane (DDT), which has been banned in many countries because it is thought to cause cancer and to have adverse environmental effects. Herbicides are chemicals used to kill plants. Milder symptoms of human toxicity from agricultural chemicals include skin and respiratory irritation. More severe effects include neurological symptoms, respiratory depression, clotting inhibition, birth defects, cancer, and even death.

Industrial chemicals include such agents as gasoline, paint strippers, spot removers, and chemicals used in industry. Human poisoning by such chemicals occurs most often either through the skin or through inhalation; irritation of the respiratory tract is common.

Drugs and health-care products. Drugs and health-care products include (1) pain killers, or analgesics, such as aspirin, acetaminophen, and morphine, (2) tranquilizers, such as benzodiazepines, (3) antiseptics, such as hydrogen peroxide, (4) vitamins and iron pills, such as vitamins A and C, (5) antidepressants, such as amitriptyline and imipramine, (6) drugs of abuse, such as amphetamines, cocaine, and heroin, and (7) cardiovascular drugs, such as digitalis and beta blockers. Most drug poisoning involves oral routes of exposure, resulting primarily in such gastrointestinal symptoms as anorexia, nausea, and vomiting. Many drugs also affect the nervous system, generally either depressing or stimulating the central nervous system.

Poisons of biological origin. Poisonous plants may cause various adverse physical effects, perhaps death, when eaten or touched by human beings or animals. Most plant species are harmless; a few are poisonous under ordinary conditions; others are poisonous under special conditions. Toxic materials are often very strictly localized in the plant.

Poisonous plants can be classified according to their effects on (1) the respiratory system, such as the ragweeds (*Ambrosia*) and cottonwood (*Populus trichocarpa*); (2) the nervous system, such as Jimson weed (*Datura stramonium*) and nightshade (*Solanum nigrum*); (3) the skeletal muscles, such as poison hemlock (*Conium maculatum*) and chinaberry (*Melia azedarach*); (4) the heart, such as foxglove (*Digitalis purpurea*) and mistletoe (*Phoradendron flavescens*); and (5) the skin, such as poison ivy (*Toxicodendron radicans*).

The poisons, or venoms, of animal origin are produced by specialized glands often associated with spines, teeth, or other piercing devices; some are skin, or cuticular, secretions. The poisonous apparatus may be primarily for killing or paralyzing prey or may be a purely defensive adaptation. Venoms of snakes, centipedes, and some marine invertebrates are also digestive fluids.

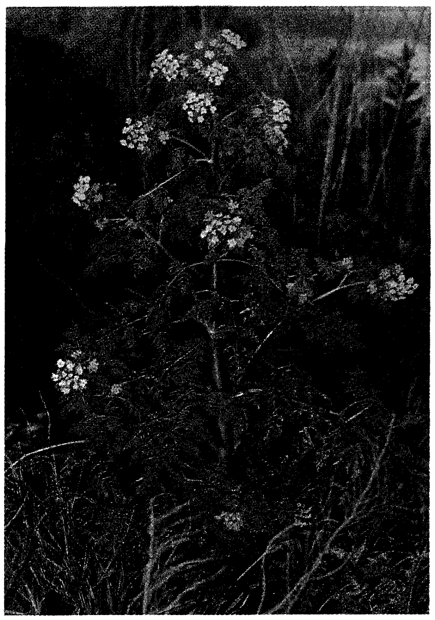
All major animal phyla except birds contain poisonous species, but relatively few are dangerous to humans. Among these are certain snakes (cobra, coral snake, rattlesnake, etc.), some scorpions, some spiders (black widow, brown recluse, etc.), some social insects (bee, wasp, ant, etc.), and a few jellyfish. Dangerous but causing few accidents because of habitat or habits are sea snakes (Hydrophidae), scorpion fish (*Synanceja*), and some cone shells. Poisonous animals that rarely or never cause human fatalities include sea anemones, fire corals, most jellyfish, some sea urchins, centipedes, most spiders and scorpions, certain ticks and mites, many insects, fishes with poisonous spines (sting rays, weever fish, certain catfish), and mildly venomous snakes.

Radiation. Most forms of radiation can be toxic. With ionizing radiation, human tissue is "poisoned" when it comes in contact with certain particulates (alpha particles, beta particles, neutrons, or positrons) or electromagnetic radiation (gamma rays or X rays). Ionizing radiation may produce nausea, vomiting, diarrhea, low production of blood cells, hair loss, and, more seriously, genetic mutations and cancer. Nonionizing radiation (*e.g.,* ultraviolet light, infrared radiation, and microwaves) can also be harmful, especially if exposure is prolonged or to large amounts. The areas chiefly affected are the eyes and skin.

poison, in nuclear physics, any material that can easily capture neutrons without subsequently undergoing nuclear fission. Examples of poisons are the naturally occurring elements boron and cadmium and the fission products xenon-135 and samarium-149. In nuclear reactors, poisons act as parasitic neutron absorbers and lower the rate of fission.

poison guava (plant): *see* manchineel.

poison hemlock, any of several poisonous herbaceous plants but especially *Conium maculatum,* which, according to tradition, was the plant used to kill Socrates. The water hemlocks (*Cicuta* species) are similar and also dangerous. They are members of the parsley family (Apiaceae). *Conium maculatum* is a tall biennial (living for two years) with green stems spotted with red or purple, large compound leaves, and white flowers. Coniine, the poison, is concentrated in the seeds, though the entire plant is dangerous to livestock when fresh. Of the water hemlocks, the European *Cicuta virosa* is perhaps the best known; it is a tall perennial herb that grows in marshy areas and is a deadly poison. The American *Cicuta maculata,* known as musquash root, or beaver poison, has potato-like tubers with a pleasant odour; the tubers as well as the leaves are poisonous. It grows to about 2.5 m (8 feet) and has divided leaves and clusters of white flowers resembling those of some nonpoisonous plants in the family.



Poison hemlock (*Conium maculatum*)
Ken W. Davis

Where the same name may denote a person, place, or thing, the articles will be found in that order

poison ivy, either of two species of white-fruited woody vines or shrubs of the cashew family (Anacardiaceae), native to North America. The species found in eastern North America (*Rhus toxicondendron*) is abundant; the western species (*R. radicans*) is less common.

Poison ivy (*Rhus toxicodendron*)
Walter Chandoha

(Some experts prefer to designate both as the genus *Toxicodendron.*) The plants are highly variable in growth habit. The leaves have three leaflets, which may be hairless and glossy or hairy, entire, toothed, or lobed.

The plant is poisonous to touch, producing in many persons a severe inflammation of the skin, or dermatitis. The toxic principle, urushiol, is produced in the resinous juice of the resin ducts of the leaves, flowers, fruits, and bark of stems and roots but not in the pollen grains. Being almost nonvolatile, the urushiol may be carried from the plant on clothing, shoes, tools, or soil or by animals or by smoke from burning plants to persons who never go near the poison ivy plants. Poisoning may occur if clothing is worn a year after contact with poison ivy.

poison wind: *see* samūm.

Poisons, Affair of the, one of the most sensational criminal cases of 17th-century France. In 1679 an inquiry revealed that nobles, prosperous bourgeois, and the common people alike had been resorting secretly to female fortune-tellers—at that time numerous in Paris—for drugs and poisons, for black masses, and for other criminal purposes.

Nicolas de La Reynie, whose diligent investigation took three years, headed the inquiry. A special tribunal for the trial of the accused, known as the *chambre ardente,* was created in April 1679. It held 210 sessions at the Arsenal in Paris, issued 319 writs of arrest, and sentenced 36 persons to death, including the poisoner La Voisin (Catherine Deshayes, Madame Monvoisin), who was burned on Feb. 22, 1680.

Among the many members of French society who were implicated was Madame de Montespan, the mistress of King Louis XIV. She was accused by Voisin's daughter and her accomplices of being a customer of La Voisin from 1667; of resorting to magic and philtres to win the King's love; of participating in black masses; and of attempting to poison her young rival, Mlle de Fontanges, and the King.

Louis suspended the public proceedings after the accusations against Madame de Montespan but ordered the continuation of the inquiry. Thus, most of the chief offenders, who had managed by their accusations to transform a criminal trial into an affair of state, escaped execution and ended their lives in various provincial prisons. The charges concerning black masses and attempted poisonings were never proved against Madame de Montespan.

Poisson, Jeanne-Antoinette: *see* Pompadour, Jeanne-Antoinette Poisson, marquise de.

Poisson, Siméon-Denis (b. June 21, 1781, Pithiviers, Fr.—d. April 25, 1840, Sceaux), French mathematician known for his work on definite integrals, electromagnetic theory, and probability.

His family coerced him into studying medicine, which he abandoned in 1798 in

Poisson, detail of a lithograph by François-Séraphin Delpech after a portrait by N. Maurin

By courtesy of the Archives de l'Academie des Sciences de Paris; photograph, J. Colomb-Gerard, Paris

favour of mathematics, studying at the École Polytechnique, Paris, under the mathematicians Pierre-Simon Laplace and Joseph-Louis Lagrange, who became his lifelong friends. His life was almost entirely engaged in mathematical research and in teaching. He became a deputy professor at the École Polytechnique in 1802 and a full professor in 1806. In 1808 he was made astronomer at the Bureau des Longitudes, and, when the Faculté des Sciences was instituted in 1809, he was appointed professor of pure mathematics.

Poisson's most important work concerned the application of mathematics to electricity and magnetism, mechanics, and other parts of physics. His *Traité de mécanique* (1811 and 1833; "Treatise on Mechanics") was the standard work in mechanics for many years. One of his publications (1812) contained many of the most useful laws of electrostatics and his theory that electricity is made up of two fluids, in which like elements repel and unlike attract.

Poisson contributed to celestial mechanics by extending the work of Lagrange and Laplace on the stability of planetary orbits and by calculating the gravitational attraction exerted by spheroidal and ellipsoidal bodies. His expression for the force of gravity in terms of the distribution of mass within a planet has been used in the late 20th century for deducing details of the shape of the Earth from accurate measurements of the paths of orbiting satellites.

Poisson's other works include *Théorie nouvelle de l'action capillaire* (1831; "A New Theory of Capillary Action") and *Théorie mathématique de la chaleur* (1835; "Mathematical Theory of Heat"). In *Recherches sur la probabilité des jugements . . .* (1837; "Researches on the Probability of Opinions . . ."), an important work on probability, the Poisson distribution, or Poisson law of large numbers, first appeared. Although originally derived as merely an approximation to Bernoulli's binomial law, it is now fundamental in the analysis of problems concerning radioactivity, traffic, and general distribution.

In pure mathematics his most important works were a series of papers on definite integrals and his advances in Fourier's series, which paved the way for the researches of Peter Dirichlet and Bernhard Riemann on the same subject.

Poissy, town, Yvelines *département,* Paris region, north central France, on the Seine River. It contains the 12th-century collegiate church of Notre-Dame, restored by the architect E.-E. Viollet-le-Duc, and the Savoye House (1929–30), a major work of the architect Le Corbusier. The town is the birthplace (1214) of Louis IX (St. Louis). Its former abbey was the scene of the Colloquy of Poissy (September 1561), at which French Catholics and Huguenots tried unsuccessfully to reconcile their differences. Manufactures include a variety of metal products (automobiles, kitchen equipment, cables, and razor blades). Pop. (1982) 35,938.

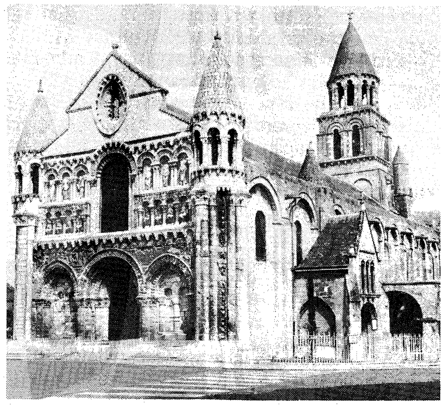
Poitier, Sidney (b. Feb. 20, 1924, Miami), Bahamian-American actor and motion-picture director. He was also a founder of First Artists Production Company in 1969.

Poitier grew up in the British West Indies. During World War II he served in a U.S. Army medical unit. After the war he decided to become an actor and applied at the American Negro Theatre (ANT) in New York City. He was refused because of his accent, spent six months listening to the radio and practicing enunciation, and applied again. He was accepted, studied acting, appeared in a series of ANT productions, and then in 1959 he won acclaim starring in Lorraine Hansberry's *A Raisin in the Sun* on Broadway.

Among Poitier's many film performances, the most notable include those in *No Way Out* (1950); *Blackboard Jungle* (1955); *The Defiant Ones* (1958); *Lilies of the Field* (1963), for which he won an Academy Award as best actor; *In the Heat of the Night* (1967); and *Guess Who's Coming to Dinner* (1967). Poitier is recognized as the actor who broke the colour barrier in the U.S. motion-picture industry and made the careers of other black actors possible. He directed such films as *Buck and the Preacher* (1972), *A Warm December* (1973), *Stir Crazy* (1980), and *Hanky Panky* (1982).

Poitiers, town, capital of Vienne *département,* Poitou-Charentes region, west central France, southwest of Paris. Situated on high ground at the confluence of the Clain and Boivre rivers, the town commands the so-called gate of Poitou, a gap 44 mi (71 km) wide between the mountains south of the Loire River and the Massif Central that serves as the connecting link between northern and southern France.

Poitiers derives its name from the Pictones, or Pictavi, a Gallic tribe that first settled there. It became a Christian centre in the 4th century in the time of Bishop St. Hilary of Poitiers. The Visigoths settled there in the 5th century but were driven out in 507 by the Frankish king Clovis. The city became a landmark in 732, when the Frankish ruler Charles Martel defeated the Saracens near the city, thus halting their invasion of France. The town and neighbouring provinces passed under English rule as the dowry of Eleanor of Aquitaine for her marriage (1152) to Henry Plantagenet (later Henry II of England). Poitiers was joined to the French crown during the 12th century,



Notre-Dame-la-Grande church, Poitiers, Fr.

Shostal—EB Inc.

but the English won it back at the Battle of Poitiers in 1356. The French reconquered the province and its capital between 1369 and 1374. The French national heroine St. Joan of Arc was interrogated there in 1429. The town suffered from the fighting during the 16th-century Wars of Religion. After a period of prosperity in the 16th century, it declined until the 19th century. Parts were destroyed during World War II.

The oldest part of the city has a maze of narrow, hilly streets encircled by boulevards that follow the line of the ancient fortifications. The great artistic wealth of Poitiers is not immediately noticeable, for its many old monuments are dispersed throughout the town. Notre-Dame-la-Grande church is a good example of Romanesque architecture, with a remarkable 12th-century facade containing a profusion of fine sculptures. The Saint-Pierre cathedral (12th–16th century), built largely in the local Gothic style known as Angevin (after the counts of Anjou and their descendants), has a great crucifixion window (12th century) that is said to be a gift of Henry II of England. The carved wooden pews in the choir are among the oldest in France. Nearby stands the 4th-century rectangular Baptistère Saint-Jean, probably the oldest Christian edifice in France; it now houses an archaeological museum containing a collection of tombs dating to the era of the Merovingians (5th–8th century). The Romanesque Saint-Hilaire-le-Grand church was built over the tomb of St. Hilary of Poitiers, the first known bishop of Poitiers, and was restored in the 19th century. The 12th-century former ducal palace has been incorporated into the 19th-century Hôtel de Ville, which houses the Musée des Beaux-Arts that contains a collection of Roman and medieval sculptures.

Poitiers has good road and rail communications and is a commercial and administrative centre. Recent industrial growth has been strong (printing and rubber) and electrical machinery and chemical industries have developed in the suburbs. Pop. (1982) 76,793.

Poitiers, Battle of, also called BATTLE OF TOURS (732), victory won by Charles Martel, Carolingian mayor of the palace and de facto ruler of the Frankish kingdoms, over Muslim invaders from Spain. The battlefield cannot be exactly located, and the battle may possibly have consisted of a series of running engagements. ʿAbd-ar-Raḥmān, governor of Córdoba, had invaded Aquitaine (present southwestern France) and defeated its duke, Eudes. Eudes appealed for help to Charles, who had already stationed his cavalry to defend the city of Tours. According to tradition, the Muslim attack was broken by Charles's cavalry near Poitiers. ʿAbd-ar-Raḥmān was killed, and the Arabs retired. There were no further Muslim invasions of Frankish territory, and Charles's victory has sometimes been regarded as decisive for world history. The Muslim advance, however, was really ended by internal dissensions and the revolt of the Berbers in North Africa. Charles derived profit as well as glory from the engagement; he was able to assert his authority in Aquitaine, where Eudes swore allegiance to him.

Poitiers, Battle of (Sept. 19, 1356), the catastrophic defeat sustained by the French king John II at the end of the first phase of the Hundred Years' War between France and England.

Edward, the Black Prince, son and heir to Edward III of England, with English troops under Sir John Chandos and with Gascon troops under the Captal de Buch (Jean III de Grailly), together rather less than 7,000 men, was conducting a raid from Bordeaux into central France but was turning westward and southward from the lower Loire River valley under pursuit from John II's probably superior forces. Contact between the enemy armies was made east of Poitiers on Sept. 17, 1356; but a truce for September 18, a Sunday, enabled the English to secure themselves on the Maupertuis (Le Passage), near Nouaillé south of Poitiers, where thickets and marshes surrounded the confluence of the Miosson and Clain rivers. Forgetful of the lessons of Crécy (1346), the French launched a series of assaults in which their knights, bogged down, became easy targets for the Black Prince's archers. John II himself led the last French charge and was taken prisoner. For his freedom he had to consent to the disadvantageous but inconclusive treaties of Brétigny and Calais (1360).

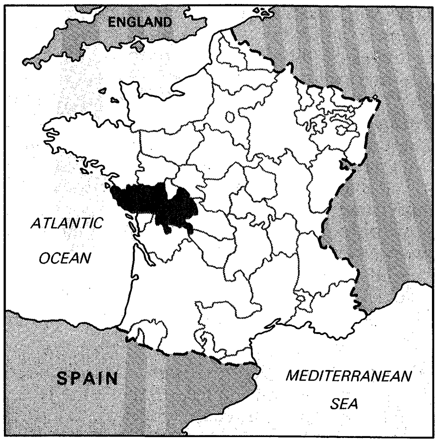
Where the same name may denote a person, place, or thing, the articles will be found in that order

Poitiers, University of, French UNIVERSITÉ DE POITIERS, coeducational, autonomous state institution of higher learning in Poitiers, Fr. Founded in 1970 under a law of 1968 reforming higher education, it replaced a university founded in 1431 by a Papal Bull of Eugene IV and confirmed by Charles VII in 1432. The university was suppressed by the French Revolution and was eventually replaced by separate faculties of law, letters, and science and by a school of medicine which was part of the University of France. In 1896 these faculties reconstituted as the University of Poitiers.

The modern university is organized into independent teaching and research units that include law and social sciences, exact and natural sciences, medicine and pharmacy, and languages and literature. Several institutes of technology offer two-year courses.

Poitou, historic and cultural region encompassing the western French *départements* of Vendée, Deux-Sèvres, and Vienne and coextensive with the former province of Poitou.

Poitou derives its name from the Gallic tribe of Pictones, or Pictavi, whose *civitas,* or community, formed part of Roman Aquitania. For centuries the northern part of Aquitaine, Poitou was a border country and a battlefield (Battle of Vouillé in 507, Charles Martel's victory over the Muslims in 732, the Anglo-French Battle of Poitiers in 1356, and the Battle of Moncontour in 1569) as well as the meeting place of northern and southern cultures. Its golden age (11th–12th century) is represented by a great school of Romanesque architecture, sculpture, and painting. The great counts of Poitiers (who also held the title duke of Aquitaine from the mid-10th century) were succeeded by the Angevin kings of England in the 12th century, but Philip II Augustus and



The *gouvernement* of Poitou in 1789

Louis VIII of France conquered the country early in the 13th century. Poitou was ceded to the English monarchy by the treaties of Brétigny and Calais (1360), but by 1375 the French had won it back. Poitou suffered in the Wars of Religion; its later history was quieter, apart from the Wars of the Vendée in the Revolutionary period.

Physiographically, Poitou consists of two smaller regions, Haut (High) Poitou at the southern end of the Massif Armoricain and Bas (Low) Poitou about the periphery. The Vendée is a northern section of the region. Small farms predominate in the north; the population tends to be dispersed. The rural population in the south tends to cluster in small villages surrounded by open fields. The *bourrine* is the traditional farmstead of Vendée and consists of one story roofed with thatch; the exterior is lime-washed.

Superstitions in the region include the *garou,* who is a person condemned by Satan to take the shape of an animal. The *cheval mallet* is a black stallion that wanders the roads at night and brings death to his rider. La Tranche-sur-Mer in Vendée hosts a festival of tulips over Easter; Les Sables-d'Olonne in Vendée features a festival of flowers the fourth week in June.

There are large Protestant enclaves in Vienne around Loudun and Châtellerault and in villages around Niort. Vendée is predominantly Roman Catholic, though there are sizable Protestant communities in Chantonnay and Pouzauges. The Petite Église ("Little Church") outside Courlay in Deux-Sèvres rejected the Concordat of 1801 and functions without a priest.

Regional cuisine features mussels cooked in cream or marinated in white wine, escargots prepared in wine, and a soup of fish and white wine.

Poitou-Charentes, *région de programme* ("planning region") encompassing the western French *départements* of Vienne, Charente, Charente-Maritime, and Deux-Sèvres. The capital is Poitiers. The region has an area of 9,965 square miles (25,809 square km) and is bounded by the *départements* of Vendée to the northwest, Maine-et-Loire and Indre-et-Loire to the north, Indre, Haute-Vienne, and Dordogne to the east, and Gironde to the south. The Bay of Biscay lies to the west. The Massif Armoricain extends into northwestern Deux-Sèvres; the Massif Central rises to the southeast. The centre of the region is low-lying and punctuated by the shallow valleys of Vienne, Clain, Charente, and Sèvre Niortaise. An oceanic climate prevails.

The region is sparsely populated. The population declined by more than 9 percent between 1901 and 1946, in common with most of rural France during that period, and has subsequently increased at a rate well below the national average. Vienne has benefited from its proximity to Paris.

Wheat, barley, and corn (maize) are widely cultivated. Cognac is produced in Charente and Charente-Maritime. Beef cattle are raised in the Massif Central and the Massif Armoricain; milk cows are raised in southern Deux-Sèvres and around Poitiers. Montmorillon in Vienne produces goat cheese. The mouth of the Seudre River in Charente-Maritime is a centre for oyster culture.

Industries must import raw materials and energy and are underdeveloped. Manufacturing is concentrated in Poitiers, Châtellerault, La Rochelle, Angoulême, and Niort, which produce electrical machinery, automobiles, and aeronautical equipment. Pop. (1988 est.) 1,599,600.

Poivre, Pierre (b. Aug. 23, 1719, Lyon, Fr.—d. June 6, 1786, near Lyon), French missionary-turned-entrepreneur whose enthusiasm for trade with Indochina stimulated French colonial expansion and whose many commercial schemes, had they been realized, might have established France securely in Indochina in the 18th instead of the 19th century.

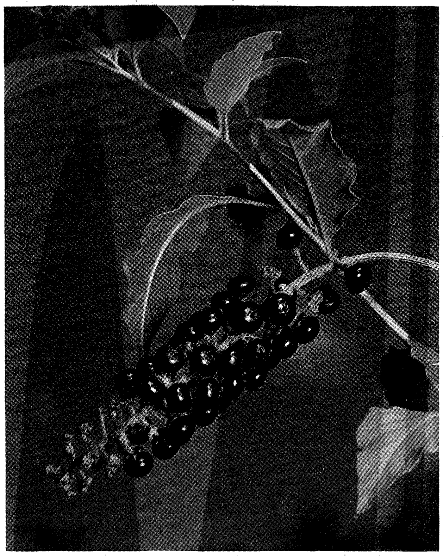
The son of a wealthy silk merchant, Poivre early developed an interest in the Far East and joined the Society of Foreign Missions as a seminary student, arriving in the Orient in 1740. His visits to India, China, and Indochina aroused his mercantile interests, and he became involved in trading ventures in China. After returning to Europe in 1747, he abandoned missionary work and persuaded the French East India Company to set up a bank in Cochinchina (southern Vietnam), to which he returned two years later as the company's representative. He obtained permission from the Vietnamese king Vo Vuong to set up temporary trading posts and a permanent one at Tourane but then alienated the king by kidnapping a young Vietnamese to serve as his interpreter. As a result, all European missionaries were expelled from the country and were not reinstated until the interpreter was returned two years later.

Poivre then made his way to the Moluccas, in the Dutch East Indies, despite the deceptive maps that the Dutch had drafted to delude other navigators. Landing at the island of Timor, he smuggled more than 3,000 nutmeg plants and other fruit trees and spices out to the French islands of Mauritius and Réunion, off the coast of eastern Africa. He returned to France in 1750 with samples of his goods and again tried to interest businessmen there in his ventures. In a brief respite from his continuing commercial pursuits, Poivre was appointed administrator of the French colony of Mauritius (1765), where he governed capably.

Poix, Charles I de Blanchefort, prince de (prince of): *see* Créquy, Charles I de Blanchefort, marquis de.

poke, also called POKEBERRY, or POKEWEED (species *Phytolacca americana*), strong-smelling shrublike plant with a poisonous root resembling that of a horseradish. It has white flowers and reddish black berries and leaves that often are red-veined or borne on red leafstalks. The berries contain a red dye used to colour wine, candies, cloth, and paper. Poke is native to wet or sandy areas of eastern North America.

Like the roots, mature stalks, which are red



Poke (*Phytolacca americana*)

or purplish in colour, are poisonous. Very young shoots—up to about 15 centimetres (6 inches)—are edible, however. The tender green stalks, stripped of leaves and peeled, may be simmered and eaten like asparagus. The leaves may be cooked with other greens.

poke bonnet, hood-shaped hat tied under the chin, with a small crown at the back and a wide projecting front brim that shaded the face. It became fashionable at the beginning of the 19th century and was worn by women and children of all ages. The size of the poke bonnet increased until, in 1830, a woman's face could not be seen except from directly in front.

After Queen Victoria's accession, in 1837, romantic dress designs were abandoned for more subdued and modest effects. The poke bonnet adorned with flowers and ribbons and fitting closely around the face came to mark the height of prudery. The fashion for small hats, which began in the 1860s, brought the era of the poke bonnet to an end.

Poker, a family of card games, almost invariably played as gambling games. Although played internationally, Poker is most popular in North America.

A Poker hand usually consists of five cards. Players try for combinations of two or more cards of a kind, five-card sequences, or five cards of the same suit. (*See below* Rank of Hands.)

Poker is played with a standard 52-card deck in which all suits are of equal value, the cards ranking from the ace high, downward through king, queen, jack, and the numbered cards 10 to the deuce. The ace may also be considered low to form a straight (sequence) ace through five as well as high with king–queen–jack–10.

Each deal is a separate game in which there is a pot, the aggregate of a preliminary ante and all bets made. There are one or more rounds of betting, and the pot is taken by the player with the best hand, or in some forms of the game it may be divided between two or more players.

History. The forerunner of Poker was a 16th-century European three-card game called *primera* (Spain) or *primero* (England). There was betting and valued hands were three of a kind, pairs, and three of the same suit: a flux (later flush). By the 18th century the betting and bluffing aspects of the game had been incorporated in such five-card games as Brag (England), Pochen (Germany), and Poque (France). The importance of bluffing (betting with a poor hand) is shown by the fact that pochen means "to bluff."

The game was carried to North America in the 18th century by French colonists to the Louisiana territory, the American term being a corruption of Poque. The game spread north up the Mississippi River and West as the country developed. By 1834 it was adapted to the 52-card deck and from the mid-19th century on it was described in books on card games. At first it was a game for men only, but by the mid-20th century it was played by women as well. It is the classic game in all Western films.

Poker was taken back to Europe when Robert C. Schenck, U.S. minister to Great Britain, introduced it to members of the court of Queen Victoria in the early 1870s. A set of rules written by Schenck was the first book on the game.

The rank of hands in the original European games was supplanted (in descending order) by four of a kind; full house (three of a kind and a pair); three of a kind; two pairs; one pair; and no pair (high card winning). Later the straight (five cards in sequence regardless of suit) and the flush were introduced, ranking, respectively, above three of a kind. Additional rounds of betting were also introduced.

Two principal forms of the game developed: (1) Closed (Straight or Draw Poker), in which all five cards are dealt face down; and (2) Open (Stud) Poker, in which one or two cards are dealt face down (five-card or seven-card) and the rest face up one at a time in five-card or the last card down, in seven-card. In Draw Poker, after the first round of betting, each player may draw from one to three cards to improve his hand. Six or seven players make the best game.

Rank of hands. The traditional ranking is (1) straight flush (five cards of the same suit in sequence, the highest ace–king–queen–jack–ten being called a royal flush; (2) four of a kind, plus any fifth card; (3) full house; (4) flush; (5) straight; (6) three of a kind; (7) two pair; (8) one pair; (9) no pair, highest card determining the winner.

To determine the winner in hands in which there are hands of the same rank, the one containing the highest card wins. If the high cards are identical, the second highest wins, and so on. With full houses, the higher three of a kind wins; with two pairs, the highest pair wins, or if the pairs are identical, the odd high card wins, as in the case of identical pairs. For the occasion when none of the above applies, *e.g.,* two flushes with identical cards in different suits, house rules may apply (the winning hand being the one in the higher bridge suit, or the two hands may split the pot). There is no universally accepted code of Poker rules. A code prepared by Oswald Jacoby in 1940 and a set of rules in the United States Playing Card Company's *Official Rules of Card Games*, published from 1945, are the ones usually adopted subject to house rules in the United States.

Wild cards. Most serious poker players decry the use of wild cards, but among the less serious, a wild card can be declared by the dealer (the deuce is most popular, but any rank can be used, or a distinguishable face card: the one-eyed jack). When there are wild cards in the game, the highest hand becomes five of a kind, though some house rules preserve the sanctity of the royal flush.

Betting. In each deal there are one or more betting rounds. In Draw Poker, the usual prerequisite to bet is holding a pair of jacks or better, though this requirement may be waived by the dealer, such a game being called "guts," *i.e.,* all that is required to open. In Stud Poker games, the highest card showing (or the first dealt if there are more than one) is the first to bet. Betting begins from the player to the left of the dealer. After a bet, a succeeding player may match the bet, "call," or raise. A player who declines to match a bet or a bet and raise drops out. Again, house rules may limit the size of bets and raises, and the number of raises. When all bets and raises have been matched by players still in the game, each player calls his hand, the player whose last bet has been matched, going first. The highest hand wins. Again, in serious games, a player who miscalls his hand (claiming a flush, say, when in fact he has a straight flush) is held to that call; in less serious games, the actual high hand may be allowed to win.

Playing the hand. A knowledge of probability ties is important. Chances are about 1 in 2 of receiving a hand of one pair or better, 1 in 5 for a pair of jacks or better, rising to 1 in 590 for a full house or better. Odds against improving the original hand in Draw Poker range from $2\frac{1}{2}$ to 1 (to improve a pair by drawing three cards) to 1,080 to 1 (to make a pair and an ace into four by drawing two cards). In Five-Card Stud, after 12 cards have been dealt face up, the odds against pairing an ace are 6 to 1 if none of the 12 was an ace and 10 to 1 if one was.

Betting decisions are based on the ratio of expected profit to the amount bet and on chances of winning. If a one chip bet can win ten chips (10 to 1 odds) and chances of winning appear to be 1 in 6, this is a good bet. It is important to know the mathematics of the game, but it is even more important to know the characteristic playing habits of other players. Such knowledge is best acquired through experience. (O.J.)

BIBLIOGRAPHY. See *Oswald Jacoby on Poker* (1947) for the game as played in the U.S.; M. Ellinger, *Poker* (1950), for the game as played in England. Other works include: A. Dowling, *Great American Pastime: Notes on Poker, the Game and the Players* (1970); Nesmith Askeny, *Poker Strategy: Winning with Game Theory* (1981).

Poker Dice, game involving five dice specially marked to simulate a playing-card deck's top six cards (ace, king, queen, jack, 10, 9); the dice may also be standard ones, one equalling an ace and the rest designated in descending order from 6. The object is to throw a winning Poker hand, with hands ranking as in Poker, (*see* Poker), except that five of a kind is high and there are no flushes. A player throws up to two times; after each throw, he elects either to stand pat or to draw, as in Draw Poker; in the latter case he separates out his best-showing dice and throws up to three of the dice again. In a version called Horses, a hand of five aces loses.

A variant, Liar Dice, as the name suggests, permits bluffing. Each player shields his throws and announces his hand, either truthfully or not. The second player, named the caller, or doubter, may either attempt a better hand or call the bluff. If the caller is correct in his call, he wins; if not, he loses.

The Puerto Rican game General is similar, with three throws instead of two. The English game Yacht is similar but with point values for various combinations and a game involving 12 throws. Trademarked variants called Yahtzee and Kismet, featuring other score categories and 13 rounds, are popular.

Pokomam (people): *see* Pocomam.

Pokorny, Julius (b. June 12, 1887, Prague, Austria-Hungary [now in Czechoslovakia]—d. April 8, 1970, Zürich, Switz.), European linguist known primarily for his work in Celtic studies and Indo-European etymological research.

Pokorny was a professor at the University of Berlin from 1920 until 1935 or 1936 and taught subsequently in Switzerland, holding lectureships at the University of Bern from 1944 to 1948 and at the University of Zürich from 1944 to 1958. He was named an honorary professor at the University of Munich in 1955. His major works include *Altirische Grammatik* (1925; "Old Irish Grammar"), *Altkeltische Dichtungen* (1944; "Old Celtic Poems"), and the monumental *Indogermanisches etymologisches Wörterbuch,* 2 vol. (1948–69; "Indo-European Etymological Dictionary").

Pokrovsky, Mikhail Nikolayevich (b. Aug. 29 [Aug. 17, Old Style], 1868, Moscow, Russia—d. April 10, 1932, Moscow), Soviet historian and government official, one of the most representative Russian Marxist historians.

Pokrovsky joined the revolutionary movement as a young man, becoming a member of the Bolshevik Party in 1905. Forced to leave Russia following the revolutionary disturbances of 1905–07, he lived abroad from 1908 until 1917, when he returned to take part in the Bolshevik seizure of power in the October Revolution.

Pokrovsky was active in the campaign against Leon Trotsky in the early 1920s and subsequently held several positions in the government, the Communist Party, and various academic institutions, becoming a member of the Academy of Sciences in 1929. He was instrumental in setting up new Marxist scholarly institutes and in subordinating historical writing to the political needs of the new state. Despite his rigid Marxism, his ideas were denounced by Joseph Stalin as anti-Marxist, pseudoscientific, and injurious. He was posthumously rehabilitated at the 22nd congress of the Communist Party of the Soviet Union in 1961.

In developing an orthodox Marxist interpretation of Russian history, Pokrovsky emphasized the socialist revolution and the dictatorship of the proletariat as the inevitable political consequences of class struggle and stressed the dialectical method in history. In the 1930s Stalinists attacked his "internationalist" insistence that the Russian Revolution was not necessarily the leading event in world revolution. His works include *Russkaya istoriya s drevneyshikh vremyon* (1911–12; "Russian History from the Earliest Times") and *Ocherk istorii russkoy kultury* (1915–18; "An Outline History of Russian Culture").

Pol Pot, also called POL PORTH, TOL SAUT, SALOTH SAR, or SALOT SAR (b. May 19, 1925/28, Kompong Thom province, Cambodia), Khmer political leader whose totalitarian regime (1975–79) imposed severe hardships on the people of Kampuchea (Cambodia). His radical communist government forced the mass evacuations of cities, killed or displaced millions of people, and left a legacy of disease and starvation.

Pol Pot was born into a peasant family and stayed in a Buddhist monastery, according to his own account, for six years, two of which he spent as a monk. He studied carpentry for a year in Phnom Penh at a technical school. In the 1940s he joined the anti-French resistance under Ho Chi Minh, and from 1946 he was a member of the Cambodian Communist Party.

He went to Paris in August 1949 to study radio electronics but spent more time on revolutionary activities than on his studies. His scholarship was cut short after he failed examinations, and he returned to Phnom Penh in January 1953.

Pol Pot taught at a private school in Phnom Penh from 1954 to 1963 but left the capital because his communist ties were suspected by the police. He spent the next 12 years building up the Communist Party that had been organized in Cambodia in 1960, and he served as the party's secretary. An opponent of the Norodom Sihanouk government and of the military government of General Lon Nol, he led the Khmer Rouge guerrilla forces in their overthrow of Lon Nol's regime in 1975. Pol Pot was prime minister of the new Khmer Rouge government from 1976 until he was overthrown in January 1979 by invading Vietnamese. Under the leadership of Pol Pot, it is estimated that from 1975 to 1979 his government caused the deaths of about 2 million people from forced labour, starvation, disease, torture, or execution.

Following the Vietnamese invasion of his country, Pol Pot withdrew to the mountains of the southwest to lead the Khmer Rouge forces against the new Hanoi-supported government in Phnom Penh, which refused to consider peace negotiations as long as he remained at the head of the party. Although officially removed from the military and political leadership of the Khmer Rouge in 1985, he apparently remained the guiding force of the organization.

Pola (Yugoslavia): *see* Pula.

Polab, member of the westernmost Slavs of Europe who dwelt in medieval times in the territory surrounded by the lower Elbe River in the west, the Baltic Sea in the north, the lower Oder River in the east, and Lusatia in the south. (This territory lay in what later became Germany.) Their name, derived from *po* and *Laba,* means "along the Elbe."

By the early 9th century the Polabs were organized into two confederations, or principalities, the Obodrites and the Lutycy, or Wilcy. The many Lutycy tribes, of which the Ratarowie and Stodoranie (Hawolanie) were the most important, were subdued by Lothar of Saxony and Albert the Bear of Brandenburg in the 12th century. The other Polab groups were also subjugated by the Germans in the 12th–13th century. Nevertheless, the Polab language, related to Kaszub and Polish, survived in what is now Lower Saxony until the beginning of the 19th century.

Poland, officially REPUBLIC OF POLAND, Polish POLSKA, or POLSKA RZECZPOSPOLITA, seventh largest country of Europe (excepting the European portion of the U.S.S.R.), covering an area of 120,727 square miles (312,683 square km). The capital is Warsaw. The country extends about 405 miles (650 km) from south to north and about 430 miles (690 km) at its widest from west to east. It is bordered on the east and northeast by the Soviet Union, on the south by Czechoslovakia, and on the west by Germany; it fronts the Baltic Sea on the northwest. The population in 1990 was estimated at 38,064,000.

A brief treatment of Poland follows. For full treatment, *see* MACROPAEDIA: Poland.

For current history and for statistics on society and economy, *see* BRITANNICA WORLD DATA ANNUAL.

Poland

The land. Except for its southern mountainous regions, Poland consists almost entirely of lowlands belonging to the North European Plain. More than 75 percent of its area lies below 650 feet (200 m) in elevation. The country can be divided into six physiographic zones from north to south: the swamps and sand dunes of the Baltic coast; the glacial outwash plain with thousands of lakes that marks the southern limit of the last ice sheet; the central lowlands—the heartland of Poland, where Warsaw, Wrocław, and Poznań cities are located; the Little Poland Uplands, including rounded, low-lying hills; the Sudeten, which includes the Giant Mountains (Karkonosze), in the southwest; and the Carpathian Mountains and their foothills in the extreme south, respectively. The highest point of the country, the peak of Rysy, at an elevation of 8,199 feet (2,499 m), is located in the Tatra Mountains of the Carpathians on the Czechoslovakian border. The Vistula (Wisła) and Oder (Odra) are the country's principal river systems and drain into the Baltic Sea.

Poland's climate is transitional between maritime and continental types, with cold, snowy winters and warm summers. Mean annual temperatures range from 46° F (8° C) in the southwestern lowlands to 43° F (6° C) in the colder northeast. The average annual precipitation is about 24 inches (600 mm).

Forests occupy more than one-fourth of the total land area; common tree species include pine, larch, beech, oak, and birch and, at higher elevations, spruce. Subalpine and alpine vegetation are found at higher elevations in the Carpathians. Large mammals include deer, wild pig, elk, brown bear, and wildcat.

Poland has relatively extensive natural mineral resources. It has among the world's largest reserves of bituminous coal (in Upper and Lower Silesia in the southwest), sulfur (near Tarnobrzeg in the southeast), and zinc and lead (near Katowice in the south) and other substantial reserves of lignite (brown coal), rock salt, natural gas, and copper.

The people. Poland's population is ethnically and linguistically very homogeneous, although minority groups include Germans, Ukrainians, and Belorussians. Polish is the predominant language, and about 95 percent of the population is Roman Catholic. During World War II a fifth of Poland's people, some 6 million in all, including almost the entire Jewish population of more than 3 million, were exterminated under the Nazi occupation.

Poland's population had one of the highest postwar rates of natural increase compared with other European countries. Between 1950 and 1990 the incidence of urban dwellers increased from 37 percent to 61 percent.

The economy. Poland's economy in the early 1990s was making the transition from a state-owned, centrally planned one to a more mixed economy relying on market pricing mechanisms and permitting private ownership and free enterprise in most spheres. In 1990 the government adopted a plan under which it lifted price controls and subsidies on many basic consumer items, allowed the exchange rate of the złoty, its currency, to be set freely on the international currency market, began converting many state-owned companies to private ownership, and permitted inefficient state-owned enterprises to go bankrupt. Under communist rule Poland's economic growth had been undermined by inefficient allocation of fuels and raw materials, low productivity, shortages of capital and consumer goods, and disaffection among workers and farmers. Consequently the country's gross national product (GNP) per capita is relatively low for an industrialized European country.

Agriculture accounts for more than one-seventh of the net material product (NMP) and employs more than one-fourth of the work force. About half of the land is arable. Poland traditionally exports food products and agricultural produce, but since the late 1970s it has often had to import fodder and grain to offset poor harvest years. Most farmland is privately owned, though the private agricultural sector suffers from a shortage of investment and a faulty distribution system. Major crops include potatoes, sugar beets, rye, wheat, and barley. Pigs are the leading livestock.

Sawn softwood taken mostly from state-owned forests is an important export. The fishing industry operates primarily in the Atlantic Ocean.

Coal (both bituminous and lignite), sulfur, copper, lead, and zinc are mined. Coal regularly accounts for about one-tenth or more of Poland's exports and is the country's chief source of electrical energy. Some natural gas is also produced, but about half of the natural gas consumed and most petroleum are imported from the Soviet Union, which has been Poland's chief postwar trading partner.

Manufacturing accounts for approximately one-third of the NMP and employs more than one-fourth of the work force. Major manufactures include steel, chemicals, household glass, cotton fabrics, paper, washing machines, refrigerators, television receivers, and motor vehicles. Poland's large shipbuilding industry is a major source of export earnings.

The private sector employs most of the country's farmers and a rapidly growing proportion of workers in industry and services. Many Polish workers belong to Solidarity (Solidarność), which was established as a labour union independent of the state in 1980, forcibly abolished by the government in 1981, and legalized again in 1989.

Poland owed a large public external debt to Western lenders by the early 1990s and, given the difficulties besetting the nation's economy, had little prospect of repaying it.

Government and social conditions. Poland's political system was in a state of transition in the early 1990s. From 1947 to 1989 the country had been ruled by the Polish United Workers' (communist) Party (PUWP). Poland was essentially a one-party state whose governmental structure and administration were patterned on the Soviet model. Ultimate political authority in the country was exercised by the Politburo of the PUWP's Central Committee and by the PUWP's first secretary.

In 1989 Poland's political system underwent a basic restructuring that converted the nation into the first multiparty parliamentary democracy among the Soviet-bloc nations of eastern Europe. The restructuring allowed the anticommunist opposition (*i.e.*, the Solidarity movement) to participate in free elections and, subsequently, to form a coalition government with the PUWP as its junior partner.

Under a historic agreement negotiated between the PUWP and Solidarity in April 1989, Poland's formerly unicameral Parliament was made into a bicameral National Assembly composed of a 460-member Sejm (lower house) and a 100-member Senate (upper house). The PUWP (now split into socialist or social democratic parties) and its former allies, the United Peasants' Party and the Democratic Party, henceforth competed with Solidarity factions in local and national elections. The April agreement also replaced the Council of State, which functioned as a collective presidency, with a strong executive president elected by the National Assembly. The president nominates as prime minister a member of that party that can command a voting majority in the Sejm. The prime minister then forms a cabinet, called the Council of Ministers, which must be approved by the Sejm.

Poland's social-welfare system provides health care for all workers, as well as pensioners, invalids, students, and the rural farm population.

Poland's high literacy rate reflects its comprehensive educational system. Education is compulsory between ages 7 and 14 and is free at all levels. Most print and electronic media were state-controlled until 1990, by which time an independent press had asserted itself.

Cultural life. Poland has produced many prominent artists and intellectuals. In literature the first half of the 19th century produced the Polish poet Adam Mickiewicz, and in the 20th century the Polish-born prose writers Henryk Sienkiewicz, Władysław Reymont, and Czesław Miłosz each won a Nobel Prize for Literature. Frédéric Chopin is the most famous Polish composer of music, while the pianists Ignacy Jan Paderewski and Artur Rubinstein headed a procession of famed musical performers in the late 19th and early 20th centuries. The 20th-century film director Andrzej Wajda has an international following.

History. Archaeological evidence supports the theory that Slavic tribes inhabited the Vistula River basin as early as the 2nd millennium BC. The tribes migrated in many directions from the Vistula basin and eventually formed differentiated groups referred to as East, South, and West Slavs. Several West Slavic tribes united to form small states between the years 800 and 960. One of these came to be ruled by the Piast dynasty (*q.v.*), which united the region around what is now modern Poznań, commonly called Great Poland. The year 966 is accepted as the founding date of Poland, when the Piast ruler Mieszko I (*c.* 963–992) adopted Christianity. A few decades later, the tribes of southern Poland united into Little Poland. In 1047 both Great Poland and Little Poland recognized the Piast ruler Casimir I the Restorer as their duke. The Piast dynasty continued to rule Poland until 1386, at which time Jogaila (Jagiełło), grand duke of Lithuania, married Jadwiga, the crown princess of the Piasts, and thus founded the ruling Jagiellon dynasty (*q.v.*) of Poland and Lithuania. Jagiellon heirs ruled over Poland and Lithuania until 1572. Poland's union with Lithuania enabled it to become the dominant power in east-central Europe during the 15th and early 16th centuries. The Jagiellon monarchs ruled Hungary and Bohemia for much of that time and repelled such powerful enemies as the (Germanic) Knights of the Teutonic Order, the Ottoman Turks, and the Grand Principality of Moscow. Poland's kings had to make growing concessions to the kingdom's landed gentry, however, who in turn used their powers to enserf the peasantry.

Following the end of the Jagiellon dynasty in 1572, the Polish nobility elected their kings from various royal houses of Europe, as well as from native Polish aristocratic families. The resulting succession of weak or inattentive rulers let power fall increasingly into the hands of the contentious and self-seeking Polish landed gentry, and thus the strength of the Polish-Lithuanian state was sapped just as powerful neighbours were once again reviving on the nation's borders.

Poland managed to suppress a great rebellion of Tatars and Cossacks on its southeastern frontier (the Ukraine) in the 1650s, but Sweden invaded Poland in 1655 and forced the cession of considerable territory in 1660. Poland then became embroiled in continuing conflicts with Russia and Sweden, while internally the Polish state succumbed to economic backwardness and social conflicts between Roman Catholic and Orthodox Poles.

In 1772 the first of three partitions of Poland occurred, and more than one-quarter of Poland's territory was seized by Russia (part of northeastern Poland), Austria (Galicia in the south), and Prussia (Polish Pomerania and Ermeland in the northwest). The second partition occurred in 1793 as Poland lost additional lands to Russia and Prussia. The third partition of Poland took place in 1795, and Poland was eradicated from the political geography of Europe and replaced by Austrian, Prussian, and Russian sectors.

In 1815 the Kingdom of Poland was established (with its own governmental system and army) within the Russian empire. The Polish people unsuccessfully revolted against tsarist oppression in 1830, 1846, and 1863. These revolts led to a policy of Russification in the educational system. Following the Russian example, the German chancellor Otto von Bismarck instituted a strict policy of Germanized education in the Prussian sector; only in the Austrian sector was Polish autonomy somewhat recognized.

Following World War I (1914–18) and the Russian Revolution (1917), an independent Poland was reestablished by the Allies in 1918 out of territories taken from Germany, Austria, and the Soviet Union. Between the world wars Poland's political life was dominated by Marshal Józef Piłsudski, who ruled Poland dictatorially from 1926 to 1935. Poland's uneasy coexistence with the Soviet Union to the east and Nazi Germany to the west ended in 1939 when Germany invaded and occupied the western two-thirds of Poland, while the Soviet Union occupied the remainder. When Germany invaded the Soviet Union in 1941, all of Poland came under Nazi rule. Germany's occupation policy in Poland was designed to eradicate Polish culture through mass executions and to exterminate the country's large Jewish minority.

In the winter of 1944–45, the Soviet Red Army drove the Germans from Polish soil. Under Red Army protection, a provisional Polish government headed by communists was established. (The Polish government-in-exile in London was ignored.) In 1945 Poland's boundaries were redrawn; the revived nation lost large territories in the east to the Soviet Union but gained significant territories in the west from defeated Germany. Meanwhile, the Soviet leader Joseph Stalin wanted to place Poland firmly into the Soviet orbit. To this end, the Polish communists under their leader, Bolesław Bierut, curtailed free elections, launched mass arrests of anticommunists, collectivized Polish farms, and nationalized the nation's industries. The communist Polish United Workers' Party was officially formed in 1948 to rule the country, and in 1952 a Soviet-style constitution was adopted. Poland was firmly in the grip of Stalinist totalitarianism.

In 1956, three years after the death of Stalin, Polish workers went on a general strike that was suppressed by force. In the ensuing crisis, Władysław Gomułka became the leader of the PUWP, and, under his rule (1956–70), Poland's farms were decollectivized and there was a mild relaxation of the regime's totalitarian controls. In 1970 Gomułka's failing economic policies provoked a new round of strikes by workers, and he was replaced as party leader by Edward Gierek. But Gierek similarly failed to make Poland's economy function effectively along Soviet lines, and by the late 1970s the Polish people again faced high prices and shortages of food and housing.

In 1979 Pope John Paul II, the former Karol Cardinal Wojtyła, archbishop of Kraków, made his first papal visit to his native country. He was received with great enthusiasm by the Roman Catholic faithful, for whom displaying loyalty to the church was an indirect means of protesting the Soviet political system.

In August 1980 strikes led by Lech Wałęsa, an electrician, erupted at the Gdańsk shipyards and quickly spread to other cities. The striking workers coalesced under Wałęsa's leadership into an illegal union, Solidarity, which won concessions from the government, notably legal status. Gierek was replaced as general secretary of the PUWP first by Stanisław Kania and then by the defense minister, General Wojciech Jaruzelski. Solidarity pressed for more concessions amid continuing strikes, and in response Jaruzelski declared martial law in December 1981. Solidarity's legal status was terminated, and its leadership was arrested. Martial law was lifted 18 months later, but the government continued to exercise tight control over its domestic opposition.

In the following years Poland's economy did not improve, and renewed labour unrest in 1988 prompted Jaruzelski to undertake a radical change of course and approve negotiations with the outlawed Solidarity movement. In April 1989 these negotiations resulted in far-reaching reforms of Poland's political system that allowed a newly legalized Solidarity to participate in free elections to a bicameral National Assembly. After Solidarity's overwhelming victory in these elections in June 1989, Solidarity formed a coalition government with the communists (who later converted to social democracy). The Cabinet was dominated by Solidarity members or supporters and was headed by the first noncommunist prime minister of Poland since the late 1940s. In subsequent months the new government enacted radical plans to transform Poland's centrally planned economy into a free-enterprise economy.

Poland, Congress Kingdom of: *see* Congress Kingdom of Poland.

Poland, Partitions of (1772, 1793, 1795), three territorial divisions of Poland, perpetrated by Russia, Prussia, and Austria, by which Poland's size was progressively reduced until, after the final partition, the state of Poland ceased to exist.

The First Partition occurred after Russia became involved in a war against the Ottoman Turks (1768) and won such impressive victories, particularly in the Danubian principalities, that Austria became alarmed and threatened to enter the war against Russia. Frederick II the Great of Prussia, however, in order to avoid an escalation of the Russo-Turkish War, determined to calm Austro-Russian relations by shifting the direction of Russia's expansion from the Turkish provinces to Poland, which not only had a structurally weak government but also, since 1768, had been devastated by a civil war and by Russian intervention and was, therefore, incapable of resisting territorial seizures.

On Aug. 5, 1772, Russia, Prussia, and Austria signed a treaty that partitioned Poland. Ratified by the Polish Sejm (legislature) on Sept. 30, 1773, the agreement deprived Poland of approximately half of its population and almost one-third of its land area. Russia received all the Polish territory east of the line formed roughly by the Dvina, Drut, and Dnepr rivers. Prussia gained the economically valuable province of Royal Prussia, excluding the cities of Gdańsk (Danzig) and Toruń, and also gained the northern portion of the region of Great Poland (Wielkopolska). Austria acquired the regions of Little Poland (Małopolska) south of the Vistula River, western Podolia, and the area that subsequently became known as Galicia.

Almost 20 years later Poland, which had made efforts to strengthen itself through internal reforms, adopted a new, liberal constitution (May 3, 1791). This action, however, resulted in the formation of the conservative Confederation of Targowica (May 14, 1792), which asked Russia to intervene to restore the former Polish constitution. Not only did Russia accept the confederates' invitation but Prussia also sent troops into Poland, and on Jan. 23, 1793, the two powers agreed upon the Second Partition of Poland. Confirmed in August and September 1793 by the Polish Sejm surrounded by Russian troops, the Second Partition transferred to Russia the major remnant of Lithuanian Belorussia and the western Ukraine, including Podolia and part of Volhynia, and allowed Prussia to absorb the cities of Gdańsk and Toruń as well as Great Poland and part of Mazovia.

In response to the Second Partition, the Polish officer Tadeusz Kościuszko led a national uprising (March–November 1794). Russia and Prussia intervened to suppress the insurgents, and on Oct. 24, 1795, they concluded an agreement with Austria that divided the remnants of Poland among themselves. By the Third Partition of Poland, which was not finally settled until Jan. 26, 1797, Russia incorporated Courland, all Lithuanian territory east of the Neman (Nieman) River, and the rest of the Volhynian Ukraine; Prussia acquired the remainder of Mazovia, including Warsaw, and a section of Lithuania west of the Neman; and Austria took the remaining section of Little Poland, from Kraków northeastward to the arc of the Northern Bug.

These territorial divisions were altered in 1807, when the emperor Napoleon of France created the duchy of Warsaw out of the central provinces of Prussian Poland, and in 1815, when the Congress of Vienna created the Congress Kingdom of Poland, but the main result of the partitions—*i.e.,* the elimination of the sovereign state of Poland—was in effect until after World War I, when the Polish Republic was finally restored (Nov. 11, 1918).

Polano, Pietro Soave (Italian theologian): *see* Sarpi, Paolo.

Polanski, Roman (b. Aug. 18, 1933, Paris, Fr.), motion-picture director, scriptwriter, and actor who was one of the more innovative filmmakers of the 1960s and '70s.

Shortly after the young Polanski's family resettled in Kraków, Pol., after having lived in France, his parents were interned in a Nazi concentration camp, where his mother subsequently died. At the age of 14, Polanski appeared on the stage, later acting in films directed by Andrzej Wajda, a leader in the Polish film revival of the 1950s. Polanski studied directing at the State School of Cinema in Łódź. By the time he graduated in 1959, he had already directed several award-winning short films. He made the French film *Le Gros et le maigre* (1961; *The Fat and the Lean*) and then returned to Poland to direct his first full-length feature, *Nóż w wodzie* (1962; *Knife in the Water*), a tense psychological study of sexual rivalry that brought him international fame.

After he left Poland in 1962, Polanski made several major films in Great Britain and the United States. *Repulsion* (1965) traces the psychotic breakdown of a young woman whose fear and loathing of sex drive her to commit several murders. *Rosemary's Baby* (1968) is a thriller about a young New York City matron who unwittingly bears a child by the devil. *Macbeth* (1971) is a gory but artistically effective adaptation of the play by William Shakespeare. *Chinatown* (1974) was one of the finest detective films made in the 1970s. These films were notable for their careful buildup of mood and suspense, their subtle handling of human psychology, and their fascination with evil in its various forms.

Polanski's second wife, the Hollywood actress Sharon Tate, was one of the victims of a horrible group murder in 1969. In 1977 Polanski was arrested and eventually pleaded guilty to a charge of unlawful intercourse with a minor. He subsequently jumped bail and fled to France, where he remained active in both the theatre and motion pictures. His subsequent films included *Tess* (1979), based on Thomas Hardy's novel *Tess of the D'Urbervilles,* and *Frantic* (1988), a suspense film.

Polanyi, John C(harles) (b. Jan. 23, 1929, Berlin, Ger.), chemist and educator who, with Dudley R. Herschbach and Yuan T. Lee, received the Nobel Prize for Chemistry in 1986 for his contribution to the field of chemical-reaction dynamics.

Born to an expatriate Hungarian family, Polanyi, whose father was also a noted chemist, was reared in England and attended Manchester University (Ph.D., 1952; D.Sc., 1964). He accepted a research position with the National Research Council of Canada in 1952 and began teaching at the University of Toronto in 1956, accepting the title of university professor in 1974.

Polanyi developed a technique that is known as infrared chemiluminescence based on the observation that molecules, when excited, emit infrared light. By means of spectroscopic analysis of the changes in emitted light that take place during a chemical reaction, he was able to trace the exchange of chemical bonds, thus helping to detail the disposal of excess energy that occurs during the process of chemical reaction.

Polanyi, Karl (Paul) (b. Oct. 25, 1886, Vienna, Austria—d. April 23, 1964, Pickering, Ont., Can.), economic anthropologist and former Hungarian political leader.

Polanyi qualified as a lawyer in Budapest in 1912. In college he had founded the radical Club Galilei, which would have far-reaching effects on Hungarian intellectual life. He served as a cavalry officer during World War I. Once back home he founded the Radical Citizens Party of Hungary. He then had to leave Hungary for political reasons. After working in Vienna as an economic journalist (1924–33), he moved to England and then, in 1940, to the United States. He was professor of economics at Columbia University (1947–53).

Polanyi was not a conventional economist but was instead concerned with the development of an overall view of the functioning of economic relationships within different social frameworks. This led him to detailed historical and anthropological studies. He produced three works based on the theme of the market economy as a special form of social organization. *The Great Transformation* (1944) concentrated on the development of the market economy in the 19th century, with Polanyi presenting his belief that this form of economy was so socially divisive that it had no long-term future. The second volume, *Trade and Markets in the Early Empires* (1957, written with others), concentrated on nonmarket forms of society. Polanyi had to develop a conceptual framework for what he regarded as nonmarket economies. His final work, published posthumously, was *Dahomey and the Slave Trade* (1966), which analyzed the economic structure of a slave-exporting state.

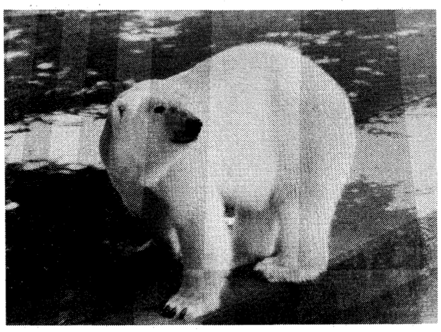
polar air mass, vast body of air that forms over land or water near either the North or the South Pole. *See* air mass; front.

polar anticyclone, wind system associated with a region in which high atmospheric pressure develops over the northern areas of continental landmasses during the colder half of the year. The Siberian anticyclone is an example of a polar anticyclone, as is the weaker high-pressure area that forms over Canada and Alaska during the winter.

Polar anticyclones are created by the cooling of surface layers of air over continental landmasses during the colder season. This cooling causes the air near the surface to become denser and, at the same time, causes an inflow of air at high levels to replace the denser, sinking air. These processes increase the mass of air above the surface, thus creating the anticyclone. The weather within the central regions of these anticyclones is typically clear and quite cold.

Polar anticyclones frequently migrate to the south and east in the winter season, bringing cold waves to more southerly latitudes. The boundary separating the cold polar air from the warmer air to the south is called the polar front, and along this frontal surface many of the mid-latitude extratropical cyclones, or wave cyclones, form. *See also* front.

polar bear, also called WHITE BEAR, WATER BEAR, SEA BEAR, or ICE BEAR (genus *Ursus maritimus,* formerly *Thalarctos maritimus*),



Polar bear (*Ursus maritimus*)
Roger Evans/Robert Harding Picture Library

semiaquatic northern bear, family Ursidae, found throughout Arctic regions, generally on drifting oceanic ice floes. The polar bear is sought for its trophy value and (especially by Eskimos) for its hide, tendons, fat, and flesh; the liver, however, is inedible and often poisonous because of its high vitamin A content. Since 1973 the polar bear has been protected by an international agreement that allows hunting of polar bears only by local populations using traditional weapons.

Camouflaged against ice and snow by its whitish fur, the polar bear is a swift and wide-ranging traveler. It swims very well and is often found many miles from land or ice packs. The polar bear stalks and captures its primary prey, the seal, whose southward migrations it may follow as far south as the Gulf of St. Lawrence in Canada and the mouth of the Amur River in the Soviet Union. It supplements its diet with fish, seaweed, grass, birds, caribou, and the occasional stranded whale.

The male polar bear, which is usually larger than the female, ranges in weight from about 410 to 720 kg (about 900 to 1,600 pounds). It grows to about 1.6 m (5.3 feet) at the shoulder and 2.2–2.5 m (about 7 feet) in length (also having a tail of 7–12 cm [3–4 inches]). The hairy soles of the polar bear's broad feet protect and insulate it from the cold and also facilitate movement across the ice. An elongated neck supports its relatively small head. The polar bear is usually shy but is dangerous when confronted or attacked.

One to four (usually two) cubs are born in winter, in a den of ice or snow, after a gestation period of 240–270 days. Cubs weigh about 1 kg (2 pounds) at birth and remain with their mother for 10 months to 2 years.

Polar Bear Provincial Park, wilderness park, northern Ontario, Canada, on Hudson and James bays. A huge undeveloped area of 11,233 square miles (29,093 square km), it is the largest of Ontario's provincial parks; it was established in 1970. Polar Bear Provincial Park is accessible only by plane or boat, and travel within the park is restricted in order to help preserve the abundant wildlife, which includes caribou, bearded seal, walrus, white whale, polar and black bear, red and Arctic fox, and moose. Birds include the Canada and snow goose, Arctic loon, and northern phalarope. The lowest 20 miles (32 km) of the Winisk River flow through the park.

polar biome, plant and animal community of either the Arctic or the Antarctic region, characterized by a cold, arid climate and a perpetual cover of snow or ice.

A brief treatment of the polar biome follows. For full treatment, *see* MACROPAEDIA: Biosphere.

Despite similarities of latitude, temperature, and barrenness, the Arctic and the Antarctic polar regions have markedly different plant and animal communities, or biomes. In both regions, the year is divided about equally between day (summer) and night (winter) owing to the continuous position of the Sun above or below the horizon during these seasons.

The polar ice caps are about 4.5 billion years old. It is probable, based on fossil discoveries, that before the ice froze over the poles both polar regions had temperate climates and were covered with forests. Variations in world climate and the poleward drift of landmasses have, over millions of years, rendered the Arctic and Antarctic largely barren, with only about 10 mm (0.4 inch) of yearly rainfall and permanently frozen subsoils. What flora exists is due to snow-melt water and the sunlight of the long summer day.

At the North Pole is the Arctic Ocean, lying in the midst of islands and landmasses (the

Gentoo penguins on Wiencke Island, Antarctica
Geoff Renner/ Robert Harding Picture Library

northernmost being Greenland) and the Canadian arctic archipelago. In all lowland areas the extreme cold is relieved with above-freezing temperatures for a month or more each year, allowing for a varied plant and animal life.

The South Pole is occupied by the continent of Antarctica, the mountains of which project through the world's greatest ice cap. No more than about 4 percent of the Antarctic's land is capable of sustaining life, while only the coast of Graham Land on the Antarctic Peninsula and several off-lying islands are warmed each year by above-freezing temperatures.

Plant life. In summer the Arctic is sprinkled with mosses and fields of grasses with brightly coloured flowers. There are many individual plants, and the number of species is fairly diverse. Lichens, fungi (850 species), liverworts (300 species), vascular plants, and nearly 2,000 species of algae take advantage of the short daylight period to fill the tundra with life, while nearly 1,000 species of ferns and flowers cover the landscape. Nourished by bird excrement, lichen and mosses spring up on the cliffs where birds dwell.

By contrast, there are only three native flowering plants in Antarctica: two grasses of the genus *Deschampsia* and a flower, *Colobanthus quitensis.* Besides some 70 species of mosses and a few liverworts, a large number (400 species) of lichens, because of their ability to live in extreme cold and dryness, inhabit the bare rock. On the coast the snow algae dapple the otherwise white expanse with a palette of yellow, red, and green. Life abounds in the Antarctic, primarily in the sea. Here, upward of 200 species of algae, mostly diatoms, populate the shallows, sometimes forming miniature underwater "forests."

Animal life. The Arctic is inhabited to its northernmost land reaches by the Arctic hare, wolf, fox, collared lemming, short-tailed weasel, caribou, musk-ox, and polar bear. The red fox, ermine, and brown bear, as well as some small rodents, the wolverine, shrew, and ground squirrel, also live in the south and mid-Arctic. In the sea are found seals, whales, walrus, and narwhals. Most of these species are threatened with extinction by human tampering with the ecosystem. Except for the Arctic ptarmigan and snowy owl, all Arctic birds migrate south for the winter. Ducks, geese, and swans come to nest in the Arctic in the summer. Terns, fulmar, puffins, guillemots, and little auk fill the cliffs and ground in vast numbers. There are also ravens and pipits, as well as falcons and other birds of prey. Waterbirds, such as loons, gulls, and skuas, fill the air with the sound of their calling, while the skies are sometimes clouded with masses of mosquitoes and other insects.

Animal life in Antarctica is limited to partially terrestrial species such as petrels, penguins, and seals. Although the sea contains some of the largest animals known (such as whales), small midges are the largest land creatures. There are also mites, springtales, worms, and a few microscopic fauna. In the seas of Antarctica, the blue, fin, and humpback whales feed on krill, a tiny, abundant crustacean. Zooplankton also provides food for mammals. In Antarctica the seas are rich in nutrients, and shallow marine waters feed much marine life, accounting for an overall biomass often greater than the otherwise more prolific Arctic.

Polar organisms have developed a remarkable ability to withstand their fiercely cold environment. Many green plants are capable of photosynthesis at temperatures slightly below freezing, and the Antarctic lichen can survive, in laboratory tests, at −324.4° F (−198° C). Differentials as great as 45–55° F (25–30°C) between plant and air temperatures have been recorded in both polar regions.

polar coordinates, system of locating points in a plane with reference to a fixed point (origin) and an axis through that point. The coordinates are written (r, θ), in which r is the distance from the origin to any desired point and θ is the angle made by the vector $\boldsymbol{r}$ and the axis. A simple relationship exists between Cartesian coordinates given in terms of two reference axes (x,y) and the polar coordinates (r, θ), namely: $x = r\cos\theta$, and $y = r\sin\theta$.

Polar coordinates, like Cartesian coordinates, may also be used to locate points in three-dimensional space. The system used involves again the radius vector $\boldsymbol{r}$, which gives distance from the origin, the angle θ, measured between r and the z axis, and a second angle φ, measured between the x axis and the projection of r in the x,y plane. This system is essentially identical to that of spherical coordinates; points on Earth, for example, are located in terms of latitude and longitude, which express angles measured with respect to the axis of the Earth's rotation and with respect to an arbitrary reference of longitude (the Greenwich meridian).

polar fox: *see* Arctic fox.

polar motion, a periodic rotation of the Earth's spin axis about a mean axis, somewhat like the wobble of a spinning top. Slight variations in latitude and longitude result from this wobble because the poles are displaced from their mean positions. The north pole of rotation rotates counterclockwise around its mean position.

Polar motion is primarily made up of two discrete periodic oscillations: one, called the Chandler Wobble, has about a 14-month period, and the other has a 12-month period. The combination of these two wobbles causes the poles to trace spiral paths out of, around, and eventually back into their mean positions over a period of about 6.5 years. The separation between the actual and mean poles was exceptionally large in about 1952, when they were separated by 12 m (37 feet), or 0.37 arc second (0.37″). Their maximum separation during the 6.5-year period averages about 0.25″.

Polar motion was first predicted by the Swiss physicist Leonhard Euler in 1765 using dynamical theory and a rigid model of the Earth; he predicted a 10-month oscillation period for the phenomenon. Observational proof for the postulated latitude variations was obtained in the mid-1880s, and about that time the American astronomer S.C. Chandler analyzed these data and obtained both the 14-month and the 12-month periods. The four-month difference between Euler's predicted period and the actual duration of the Chandler Wobble is due to the elasticity of the Earth's mantle and the mobility of the oceans, which together subtly affect the Earth's response to rotation and for which Euler had not provided in his calculations.

Astronomical observations of the Earth's rotational position in space, which are used in determining Universal Time, must be corrected for slight variations in longitude caused by polar motion.

polar wandering, the migration over the surface of the Earth of the magnetic poles of the Earth through geological time. It was long recognized that the directions of magnetization of many rocks do not correspond to the present direction of the geomagnetic field at their sites; but not until the 1950s was there sufficient paleomagnetic data to suggest that the poles had moved in a systematic way over the surface of the Earth. On the time scale of polar wandering, polarity reversals of the geomagnetic field are relatively frequent, and the field direction may be neglected. If this is done, the evidence clearly indicates that the magnetic poles have slowly wandered across the globe with respect to sections of the crust on which datable rock samples are found. Pole locations calculated from measurements on rocks younger than about 20 million years do not depart from the present pole locations by distances greater than the experimental uncertainties. Going back more than 30 million years, however, successively greater "virtual pole" distances are revealed, indicating that substantial deviations occurred.

If the continents had had fixed positions, it could be assumed that the path of a magnetic pole over the Earth would be a global phenomenon, independent of the location of the observer. That polar-wandering curves for different continents do not agree was one of the first important evidences for continental drift. Because the pole-location curves converge to the present pole location, it becomes possible to infer the relative movement of different continental blocks over different intervals of geologic time.

polarimetry, in analytic chemistry, measurement of the angle of rotation of the plane of polarized light (that is, a beam of light in which the vibrations of the electromagnetic waves are confined to one plane) that results upon its passage through certain transparent materials. Polarimetry is of interest to the chemist because the ability of a substance to affect polarized light in this way is closely related to its chemical structure. A compound that displays this ability is called optically active (*see* optical activity).

Polarimetric analysis is commonly used in the sugar industry, because the angle of rotation is related to the concentration of sucrose in a solution and can be used, in conjunction with other properties (such as density), in rapid and simple measurements of such concentrations. Many organic and some inorganic compounds are optically active; this property, easily determined by polarimetry, frequently is used as an indication of purity.

Polaris, also called ALPHA URSAE MINORIS, Earth's present northern polestar, or North Star, at the end of the "handle" of the so-called Little Dipper in the constellation Ursa Minor. Polaris is actually a triple star, the brighter of two visual components being a spectroscopic binary with a period of about 30 years and a Cepheid variable with a period of about 4 days. Its changes in brightness are too slight to be detected with the unaided eye. Apparent visual magnitude of the Polaris system is 2.04. *See also* polestar.

Polaris missile, first U.S. submarine-launched ballistic missile (SLBM) and the mainstay of the British nuclear deterrent force during the 1970s and '80s.

After four years of research and development, the U.S. Navy in 1960 began to deploy nuclear-powered submarines armed with 16 Polaris missiles each. Each missile was 31 feet (9.4 m) long and 4.5 feet (1.4 m) in diameter and was powered by two solid-fueled stages. Three models were developed: the A-1, with a range of 1,400 miles (2,200 km) and a one-megaton nuclear warhead; the A-2, with a 1,700-mile (2,700-kilometre) range and a one-megaton warhead; and the A-3, capable of delivering three 200-kiloton warheads a distance of 2,800 miles (4,500 km).

Between 1971 and 1978 the Polaris was replaced by the Poseidon missile in the U.S. SLBM force. The United Kingdom, after adopting the A-3 in 1969, refined it into the A-3TK, or Chevaline, system, which was fitted with such devices as decoy warheads and electronic jammers for penetrating Soviet ballistic-missile defenses around Moscow. In 1980 the United Kingdom announced plans to replace its Polaris force with the Trident SLBM in the 1990s.

polarization, property of certain electromagnetic radiations in which the direction and magnitude of the vibrating electric field are related in a specified way.

Light waves are transverse: that is, the vibrating electric vector associated with each wave is perpendicular to the direction of propagation. A beam of unpolarized light consists of waves moving in the same direction with their electric vectors pointed in random orientations about the axis of propagation. Plane polarized light consists of waves in which the direction of vibration is the same for all waves. In circular polarization the electric vector rotates about the direction of propagation as the wave progresses. Light may be polarized by reflection or by passing it through filters, such as certain crystals, that transmit vibration in one plane but not in others.

polarization, electric: *see* electric polarization.

polarography, also called POLAROGRAPHIC ANALYSIS, or VOLTAMMETRY, in analytic chemistry, an electrochemical method of analyzing solutions of reducible or oxidizable substances, invented by a Czech chemist, Jaroslav Heyrovský, in 1922.

The majority of the chemical elements can be identified by polarographic analysis, and the method is applicable to the analysis of alloys and to various inorganic compounds. Polarography is also used to identify numerous types of organic compounds and to study chemical equilibria and rates of reactions in solutions.

The solution to be analyzed is placed in a glass cell containing two electrodes. One electrode consists of a glass capillary tube from which mercury slowly flows in drops, and the other is commonly a pool of mercury. The cell is connected in series with a galvanometer (for measuring the flow of current) in an electrical circuit that contains a battery or other source of direct current and a device for varying the voltage applied to the electrodes from zero up to about two volts. With the dropping mercury electrode connected (usually) to the negative side of the polarizing voltage, the voltage is increased by small increments, and the corresponding current is observed on the galvanometer. The current is very small until the applied voltage is increased to a value large enough to cause the substance being determined to be reduced at the dropping mercury electrode. The current increases rapidly at first as the applied voltage is increased above this critical value but gradually attains a limiting value and remains more or less constant as the voltage is increased further. The critical voltage required to cause the rapid increase in current is characteristic of, and also serves to identify, the substance that is being reduced (qualitative analysis). Under proper conditions the constant limiting current is governed by the rates of diffusion of the reducible substance up to the surface of the mercury drops, and its magnitude constitutes a measure of the concentration of the reducible substance (quantitative analysis). Limiting currents also result from the oxidation of certain oxidizable substances when the dropping electrode is the anode.

When the solution contains several substances that are reduced or oxidized at different voltages, the current-voltage curve shows a separate current increase (polarographic wave) and limiting current for each. The method is thus useful in detecting and determining several substances simultaneously and is applicable to relatively small concentrations—*e.g.,* 10^{-6} up to about 0.01 mole per litre, or approximately 1 to 1,000 parts per 1,000,000.

Polaroid Corporation, major U.S. manufacturer of photographic equipment and supplies. Edwin Herbert Land, the founder, was the inventor of the instant camera. Headquarters are in Cambridge, Mass.

The company was founded in 1932 as the Land-Wheelwright Laboratories by Land and George Wheelwright to produce Land's first invention, an inexpensive plastics sheet light polarizer. By 1936 Land began to use polarized material in sunglasses and other optical devices, and in 1937 the company was incorporated under the Polaroid name.

During the 1930s and 1940s the corporation introduced a three-dimensional motion-picture process and polarized optical devices for military use. After World War II Land began to research an instantaneous developing film, and in 1947 the company brought out the Polaroid Land camera, which delivered a finished sepia-toned print 60 seconds after exposure. In the 1950s the cameras were refined to produce black-and-white prints in 15 seconds; in the 1960s a colour-developing process and film cartridges were introduced. The company introduced the compact Polaroid SX-70 in 1972. In addition to further technical refinements, the SX-70 combined the negative and positive prints in a single sheet. Instant motion pictures were introduced in 1977.

Polaroid's cameras and films are sold both to amateur photographers and professionals. The company also manufactures both specialty films used for scientific purposes and polarizing filters used in sunglasses and for a wide variety of technical applications.

polaron, electron moving through the constituent atoms of a solid material, causing the neighbouring positive charges to shift toward it and the neighbouring negative charges to shift away. This distortion of the regular position of electrical charges constitutes a region of polarization that travels along with the moving electron. After the electron passes, the region returns to normal. An electron accompanied by this kind of electrical displacement of neighbouring charges constitutes a polaron.

A polaron behaves as a negatively charged particle with a mass greater than that of an isolated electron because of its interaction with the surrounding atoms of the solid. The effect is most pronounced in ionic solids, composed of positively and negatively charged atoms called ions, because the forces between the electron and ions are strong. The strength of these forces is reflected in the mass of the polaron. In common table salt, or sodium chloride, the mass of a polaron is more than twice the mass of a free electron.

polder, tract of lowland reclaimed from a body of water, often the sea, by the construction of dikes roughly parallel to the shoreline, followed by drainage of the area between the dikes and the natural coastline. Where the land surface is above low-tide level, the water may be drained off through tide gates, which discharge water into the sea at low tide and automatically close to prevent re-entry of seawater at high tide. To reclaim lands that are below low-tide level, the water must be pumped over the dikes. If a sediment-laden stream can be diverted into the polder area, the sediment may serve to build up the polder bottom to a higher level, thus facilitating drainage.

Soil in areas newly reclaimed from the sea contains so much salt that most plants will not grow. Procedures for ridding the soil of salt, therefore, must be used along with diking and draining to develop agriculturally productive land.

The most notable example of polder construction is the system developed adjacent to the IJsselmeer (Zuiderzee) in The Netherlands.

Poldi Pezzoli, Museo (Italian: Poldi Pezzoli Museum), in Milan, museum in the former private house of G.G. Poldi-Pezzoli, housing fine examples of arms and armour from the 14th to the 17th centuries. There are also antique tapestries. The staircase is decorated with landscapes by Alessandro Magnasco. One room is devoted to works by Bernardino Luini and the Lombard school of painters. Other notable works include portraits of Martin Luther and his wife by Lucas Cranach, a madonna by Andrea Mantegna, a madonna by Botticelli, "St. Nicholas of Tolentino" by Piero della Francesca, and "Lady of the Bardi Family" by Antonio Pollaiuolo. The Dante hall is decorated in Art Nouveau style. The museum was founded in 1879; destroyed by bombs in World War II, it was subsequently rebuilt.

Polding, John Bede (b. Nov. 18, 1794, Liverpool—d. March 16, 1877, Sydney), first Roman Catholic bishop in Australia (from 1835), where eight years later he became the first archbishop of Sydney.

Polding joined the Benedictine Order in 1811 and was ordained priest in 1819. Consecrated bishop, he arrived at Sydney in 1835. There he divided his territory into missionary districts and swiftly provided them with priests, churches, and schools. He procured help for his bishopric through visits to Europe. Appointed archbishop in 1843, he became primate of the Catholic Church in Australia. In 1844 and 1859 he convoked synods in Melbourne and in Sydney, where he founded St. John's College.

Pole, Reginald (b. March 3, 1500, Stourton Castle, Staffordshire, Eng.—d. Nov. 17, 1558, London), English prelate who broke with King Henry VIII over Henry's anti-papal policies and later became a cardinal and a powerful figure in the government of the Roman Catholic queen Mary Tudor.

Reginald Pole, detail of a portrait attributed to Fra Sebastiano del Piombo; in a private collection
By courtesy of R.J.R. Arundell

His father, Sir Richard Pole, was a cousin of King Henry VII, and his mother, Margaret, countess of Salisbury, was a niece of Edward IV. In recognition of Pole's royal descent, his cousin, Henry VIII, paid for Pole's education at Oxford University and at Padua, Italy, and gave him minor offices in the church. Nevertheless, when Henry's attempts to obtain an annulment of his marriage to Catherine of Aragon encountered resistance from Pope Clement VII, Pole found himself unable to support the King's cause. He therefore withdrew to Padua in 1532 and immersed himself in theological studies. In 1536 Pole completed and sent to Henry a long treatise attacking his claim of royal supremacy over the English Church and strongly defending the Pope's spiritual authority. The document was later published, without Pole's consent, as *Pro ecclesiasticae unitatis defensione* ("In Defense of Ecclesiastical Unity").

Pole could no longer return to England. Remaining in Italy, he was made cardinal by Pope Paul III in December 1536, and he served on the commission that produced the important document *Consilium de emendanda ecclesia* (1537; "Plan for Church Reform"), a report on abuses in the church with recommendations for reforms. Between 1537 and 1539 the Pope sent Pole on two diplomatic missions to persuade Europe's Catholic monarchs to ally against Henry. Both endeavours were totally unsuccessful, and Henry, in revenge for Pole's treasonous activities, executed Pole's brother, Lord Montague, in 1538 and his mother in 1541. In August 1541 Pole was appointed papal governor of the Patrimony of St. Peter (the area around Rome). He took up residence at Viterbo and gathered around him a group of Humanists. Later, he was the presiding legate at the Council of Trent; and, upon the death of Paul III in November 1549, Pole, with backing from the Holy Roman emperor Charles V, was nearly elected pope. The office fell to Julius III only after the French and Italian prelates refused to endorse Pole's candidacy.

On the accession of Mary Tudor to the English throne in July 1553, the Pope at once appointed Pole legate for England. He landed at Dover on Nov. 20, 1554, and 10 days later formally received the country back into the Catholic fold. He then began to refound the monasteries, and in November 1555 he assembled at Westminster a synod that instituted a number of church reforms. Soon Pole was virtually running the government. Although he was not directly responsible for the burnings of Protestants that marked Mary's reign, he did not oppose them. Pole was made archbishop of Canterbury in March 1556, but as a result of a conflict between the papacy and England's ally Spain, Pope Paul IV cancelled his legatine authority in April 1557. Denounced by the Pope as a heretic, the demoralized Pole died 12 hours after the death of Queen Mary. Two biographies are K.B. McFarlane's *Cardinal Pole* (1924) and W. Schenk's *Reginald Pole, Cardinal of England* (1950).

Pole, Richard de la (d. Feb. 24, 1525, Pavia, Duchy of Milan), last Yorkist claimant to the English throne.

Pole was the youngest son of John de la Pole, 2nd duke of Suffolk (died 1491/92), and Elizabeth, sister to the Yorkist king Edward IV (ruled 1461–70, 1471–83). Since Edward IV's brother and successor, Richard III, died childless and since Edward's own sons disappeared in the Tower of London, the de la Poles inherited the Yorkist claim to the throne, a claim strengthened when Richard III named Suffolk's eldest son John, earl of Lincoln (d. 1487), as his successor. After the accession in 1485 of the first Tudor, Henry VII, the family therefore lived under suspicion; nor did it help that Lincoln joined Lambert Simnel's rebellion (1487), which cost him his life. The claim thus devolved upon the second brother, Edmund de la Pole, earl of Suffolk (1472?–1513). After years of waiting, Suffolk fled abroad in 1499; and though he returned briefly he fled again in 1501, this time accompanied by his brother Richard. The brothers tried to interest the emperor Maximilian in their cause, but in 1502 Maximilian agreed with Henry VII on terms that included dropping the Yorkist claimants. Suffolk, accused as a traitor in 1504, was imprisoned in Burgundy in that year and surrendered to Prince Henry (later Henry VIII) in 1506, on condition that his life be spared. He lived a prisoner in the Tower of London until Henry VIII carried out the old sentence against him in 1513.

Meanwhile, Richard had led an adventurous life, escaping (1504) the pressing attentions of his brother's creditors at Aachen, taking service with King Vladislas (Ulászló) II of Hungary, and establishing something of a reputation as a condottiere. After Edmund's death he took over the claim to the crown, calling himself duke of Suffolk. Although treated equivocally by Louis XII of France, he did find service with Louis's successor, Francis I, who saw fit to use him as a weapon in his complex diplomacy. In 1523 he encouraged an intrigue that was meant to restore the Yorkist claimant to England with the help of an exiled claimant to the Scottish throne. Though nothing came of this, Richard de la Pole remained in Francis' service, accompanied him to the war in Italy, and was killed in the Battle of Pavia (1525). His death terminated the claims of the main Yorkist line and ended a threat to the Tudor throne.

Pole, William: *see* Poel, William.

Pole, William de La: *see* Suffolk, William de La Pole, 1st duke of.

Pole of Inaccessibility, point on the Antarctic continent that is farthest, in all directions, from the surrounding seas, lying on the Polar Plateau in a vast territory claimed by Australia. The site, at an elevation of 12,198 feet (3,718 m) above sea level, is occupied by a meteorological research station set up by the Soviet Union during the International Geophysical Year (1957–58).

The term is also used occasionally in the Northern Hemisphere in conjunction with a point in the Arctic Ocean that is equidistant from the encircling landmasses; it lies 400 miles (640 km) from the North Pole in the direction of Alaska.

pole star: *see* polestar.

pole vault, track-and-field sport of jumping over an obstacle with the aid of a pole. Originally a practical means of clearing objects, such as ditches, brooks, and fences, pole-vaulting for height became a competitive sport in the mid-19th century. The sport is generally for men only.

In competition, each vaulter is given three chances to clear a specified height. A bar rests on two uprights so that it will fall easily if touched. It is raised progressively until a winner emerges by process of elimination. Ties are broken by a "count back" based on fewest failures at the final height, fewest failures in the whole contest, or fewest attempts throughout the contest. The pole may be of any material (glass fibre became the most effective and popular by the early 1960s) and of any length or diameter.

A slideway, or box, is sunk into the ground with its back placed directly below the crossbar. The vaulter thrusts his pole into this box as he leaves the ground. A pit at least 5 m (16.4 feet) square and filled with soft, cushioning material is provided behind the crossbar for his landing.

Requirements of the athlete include a high degree of coordination, timing, speed, and gymnastic ability. The modern vaulter makes a run of 30 to 45 m (100 to 150 feet) while carrying the pole and approaches the take-off with great speed. As the stride before the spring is completed, he performs the shift, which consists in advancing the pole toward the slideway and at the same time allowing the lower hand to slip up the pole until it reaches the upper hand, then raising both hands as high above his head as possible before leaving the ground. He is thus able to exert the full pulling power of both arms to raise his body and help swing up his legs.

As the vaulter plants his pole firmly in the box, he runs off the ground (he does not jump), leaving his body hanging by the hands as long as possible and not pulling too soon; the quick, catapulting action of the glass-fibre pole makes timing especially important. He lets his legs swing upward and to the side of the pole, then shoots his legs high above the crossbar and twists his body face downward. His body travels across the crossbar by "carry"—the forward speed acquired from the run. For winners in the pole-vault competition of the World Cup and world championships, *see* Sporting Record: *Athletics.* For Olympic champions, *see* Olympic Games.

polecat, any of several weasel-like carnivores of the family Mustelidae (which includes the weasel, mink, otter, and others). The pelt, especially of the European polecat, is called fitch in the fur trade.

The European, or common, polecat, also called foul marten for its odour (*Mustela,* sometimes *Putorius, putorius*), occurs in wood-

European polecat (*Mustela putorius*)
Russ Kinne—Photo Researchers

lands of Eurasia and North Africa. It weighs 0.5–1.4 kg (1–3 pounds) and is 35–53 cm (14–21 inches) long exclusive of the bushy tail, which is 13–20 cm (5–8 inches) long. Its long, coarse fur is brown above, black below, and marked with yellowish patches on the face. Much lighter fur distinguishes the masked, or steppe, polecat (*M. p. eversmanni*) of Asia.

Principally terrestrial, the polecat hunts at night, feeding on small mammals and any birds it can catch. It also eats snakes, lizards, frogs, fishes, and eggs. The polecat is more powerful than the marten but less active, and it rarely climbs trees. Its litters of three to eight young are born in the spring after about two months' gestation. The domestic, albino variety of the European polecat is known as the ferret (*q.v.*).

The marbled polecat (*Vormela peregusna*) of Eurasian foothills and steppes is similar to the European species in habits, appearance, and size. It is mottled reddish brown and yellowish above, blackish below.

The zorille (*q.v.*), a related African carnivore, is also called striped, cape, or African polecat. In the United States the name polecat is often applied to skunks (*see* skunk), particularly the spotted and striped species.

Polemoniaceae, phlox, or Jacob's ladder, family of plants; there are about 18 genera and at least 300 species, mostly in North America but found in temperate parts of western South America and Eurasia. The family includes many popular garden ornamentals. A few species are woody, but most are herbaceous annuals or perennials.

The tubular, five-lobed, funnel-shaped or flaring flowers are gathered into clusters or heads. They usually have three-chambered ovaries with styles topped by three narrow stigmas.

Polemoniales, order of flowering plants that includes some of the most handsome and favoured garden flowers and wildflowers. Most of the order's 8 families, 208 genera, and more than 4,000 species are annual, biennial, or perennial herbs. There are also, however, woody trees, shrubs, and vines and two families of nonphotosynthetic parasites.

A brief treatment of Polemoniales follows. For full treatment, *see* MACROPAEDIA: Angiosperms.

The only member of Polemoniales that is of economic importance is the sweet potato (*Ipomoea batatas*) of the Convolvulaceae family; its tuberous roots are used as a food. Other members of *Ipomoea,* such as the heavenly blue morning glory (*I. violacea*), are of interest for their seeds, which contain hallucinogenic alkaloids similar to the drug LSD. Known to the Aztecs, the seeds are traditionally used by the Zapotec Indians of Mexico for ceremonial and curative purposes. The common morning glory (*I. purpurea*), cypress vine (*I. quamoclit*), bush morning glory (*I. leptophylla*), and morning glory tree (*I. arborescens*) are ornamentals prized for their flowers.

The bindweed (*Convolvus* and *Calystegia*) of the Convolvulaceae are low, twining plants that produce small white, pink, or blue funnel-shaped flowers. Bellbine (*Calystegia sepium*) creeps along hedges and roads in North America and Eurasia, while sea bindweed (*C. soldanella*) is found along the beaches of Europe. Field bindweed (*Convolvus arvensis*) is a flowering weed. Other species of *Convolvus* are the sources of rosewood oil and scammony, a purgative.

The Convolvulaceae family also includes several species of lawn-leaf (*Dichondra*), used in tropical and subtropical regions as a ground cover. The low plants, with round green leaves, spread along the ground by runners and make an excellent substitute for grass.

The largest family of the Polemoniales is the Boraginaceae, or borage family, containing about 2,000 species. Most of its members are tropical or temperate herbs, although some are shrubs or trees. The flowers of this family are known for their bright blue colours and some, such as the forget-me-not (*Myosotis* species), the borage (*Borago officinalis*), the Virginia bluebell (Virginia cowslip; *Mertensia virginica*), the heliotropes (*Heliotropium*), and the lungworts (*Pulmonaria*), are grown as ornamentals.

Of the family Polemoniaceae, the 65 *Phlox* species are much admired as garden flowers and wildflowers. The group includes the perennials summer phlox (*P. paniculata*), blue phlox (*P. divaricata*), and perennial phlox (*P. pilosa*). The 50 species of *Polemonium,* especially Jacob's ladder (Greek valerian; *Polemonium caeruleum*) are also prized for their flowers.

The waterleaf family (Hydrophyllaceae) of about 250 species is best known for its garden annuals. These include *Hydrolea spinosa, Wigandia caracasana,* the Virginia waterleaf (*Hydrophyllum virginianum*), the California bluebell (wild Canterbury bell; *Phacelia whitlavia*), and baby blue-eyes (*Nemophila menziesii*).

Many members of the family Loasaceae (Particularly *Loasa, Caiophora,* and *Mentzelia*) have nettle-like stinging hairs, in addition to beautiful, unusual flowers of red, orange, yellow, or white.

The dodder (Cuscutaceae) and sand food (Lennoaceae) families within the Polemoniales order are composed of totally parasitic plants. The dodders (*Cuscuta*) are nearly leafless and without chlorophyll; they twine about the host plant, withdrawing both water and nutritive substances. The sand foods send out roots that attach to the roots of a host plant, thereby establishing parasitism.

Polenta FAMILY, Italian noble family, named for its castle of Polenta (located in the Romagna, southwest of Cesena), which dominated the city-state of Ravenna from the end of the 13th century to the middle of the 15th. The family's ascendancy began with Guido da Polenta (d. 1310), known as Guido Minore, or Guido the Old, who led the Guelf, or propapal, faction in Ravenna against the Ghibelline, or pro-emperor, faction. Ravenna, traditionally Ghibelline, had fallen to the Guelfs in 1239. When the emperor Frederick II reconquered the city in the following year, Guido's father, Lamberto, was imprisoned and executed. In 1275 Guido, with the aid of the Malatesta family of nearby Rimini, seized the town, driving out rival factions.

After the Romagna (the territory of Ravenna) fell under direct papal administration in 1278, Guido consolidated his power and after 1285 began to resist papal encroachment. In 1290, when Guido was in Florence serving as chief magistrate, the papal official Stefano Colonna arrived in Ravenna to demand that the town surrender to his authority. Guido's sons Lamberto and Bernardino imprisoned him, kindling a revolt against papal power in the Romagna. Elected chief magistrate of Ravenna from 1286 to 1290 and again in 1292 and 1293, Guido was a strong ruler, repelling outside enemies and suppressing factions within the town.

Guido's grandson Guido Novello da Polenta, a patron of the arts known as the host of Dante during his final years of exile (*c.* 1318–21), was himself a scholar and poet. In 1322 Guido Novello was chosen captain of the people in Bologna and left his brother Rinaldo, the archbishop, to govern Ravenna in his place; but his cousin Ostasio da Polenta assassinated Rinaldo and made himself lord of the city. With Bolognese aid, Guido Novello tried to recover Ravenna the following year but was defeated and ended his life in exile.

Ostasio was also a patron of letters, befriending Boccaccio in 1345–46, but his politics were violent. In 1326 he had seized Cervia, south of Ravenna, killing his uncle and cousin. The tradition was continued by his descendants. His son Bernardino punished a conspiracy of his brothers by starving them to death (1347). In 1390 Bernardino's son Guido was deposed by his own sons and starved to death; one of the sons, Obizzo, then killed the others. During Obizzo's rule, Ravenna began to fall under the power of Venice, and he was forced in 1410 to accept a Venetian chief magistrate. In 1441 the da Polenta family yielded the city to Venice, Obizzo's son and grandson taking refuge in Crete, where they died not long after, the last of their line.

polestar, also spelled POLE STAR, also called (Northern Hemisphere) NORTH STAR, the brightest star that appears nearest to either celestial pole at any particular time. Owing to the precession of the equinoxes, the position of each pole describes a small circle in the sky over a period of 25,800 years. Each of a succession of stars has thus passed near enough to the north celestial pole to serve as the polestar. At present the polestar is Polaris; Thuban (α Draconis) was closest to the North Pole *c.* 2700 BC, and the bright star Vega (α Lyrae) will be the star closest to the pole in AD 14000. The location of the northern polestar has made it a convenient object for navigators to use in determining latitude and north–south direction in the Northern Hemisphere. There is no bright star near the south celestial pole; the present southern polestar, σ Octantis, is only of the 5th magnitude.

A list of the abbreviations used in the MICROPAEDIA *will be found at the end of this volume*

Polesye (Soviet Union): *see* Pripet Marshes.

Polevskoy, city, Sverdlovsk *oblast* (administrative region), western Russian Soviet Federated Socialist Republic, located near the Chusovaya River in the mid-Urals. Founded in 1724 in connection with copper mining, it was called Polevskoy Zavod until 1928; it became a city in 1942. Copper is still mined and refined there; ferrous metallurgy, hoisting and transport equipment production, and a chemical industry based on Siberian fluorspar are located in the city. Pop. (1985 est.) 69,000.

police, body of civil officers charged with maintaining public order and safety and enforcing the law, including preventing and detecting crime. In addition, it is usually entrusted with various inspectional, licensing, and regulatory activities.

A brief treatment of police follows. For full treatment, *see* MACROPAEDIA: Police.

Police administration in most countries has six major aspects: uniformed patrol, criminal investigation (detection of criminals), traffic regulation, special measures for controlling commercial "vice" (narcotics, prostitution, and gambling), regulation of the sale and consumption of intoxicating liquor, and procedures and facilities for dealing with juvenile delinquents.

The internal organization of police departments varies from country to country, but a general pattern can be detected. A uniformed patrol is distributed over cities on beats or territories as a first line of defense and protection against crime and disorder. The detective bureau is organized as a separate unit having to do with detection of the more serious crimes and apprehension of offenders. Special units of plain-clothes operatives devote their attention chiefly to suppression of gambling, prostitution, illegal sale of narcotics, and liquor law violations. Traffic regulation is a pressing problem in cities, and requirements in this direction have called for the employment of a large number of officers. Most large cities have training schools for instruction of new recruits, and in some cases advanced instruction is given to older members of the force. Considerable progress has been made in the keeping of records, installation of systems of telecommunication, and the use of land, sea, and air equipment in patrol and emergency service. Laboratories for scientific criminal investigation and identification have become common.

Many governments permit much local autonomy in police administration, whereas others tend to centralize police control. England, Wales, and Scotland have scores of local police forces, whereas the Republic of Ireland and the government of Northern Ireland each maintains a single police establishment. Belgium has dual police systems for the national and local levels, with municipal forces that are almost completely autonomous, whereas in Denmark all police activities are administered by functionaries of the crown. For the most part, western European countries follow the French pattern of a national police charged with the maintenance of public order, the investigation of all major crimes, and the full policing of the larger cities, together with locally recruited forces, which are concerned with routine law enforcement duties such as local traffic control in the smaller places. In some countries, such as France and Italy, a branch of the national police force also performs routine police duties in rural districts. Japan, under a law of 1954, centralized all police forces under the National Defense Force; even so, a certain degree of autonomy in matters of authority, administration, and finance is left to the prefectural and larger municipal departments. In the United States and Canada, national and state (or provincial) police parallel the local police systems.

A special use of the word police is involved when authoritarian states set up secret political police organizations that operate independently of the regular civil police establishments. Political police are always highly centralized agencies. The Nazi Gestapo and *Schutzstaffel*, the tsarist Okhrana, and the Soviet KGB all shared characteristics sharply distinguishing them from other civil police. Their governments may be called police states. Under democratic governments, police authority is carefully limited and numerical strength is held within modest bounds. Under some systems the police officer bears a heavy responsibility for the manner in which he or she performs law-enforcement functions and is personally answerable in the criminal and civil courts for abuses of authority.

Police Gazette, The, daily publication of the London Metropolitan Police that carries details of stolen property and of persons wanted for crime. It is distributed without charge to British and certain European police forces.

The original *Gazette,* the *Quarterly Pursuit,* was founded in 1772 by John Fielding, chief magistrate of the Bow Street Police Court, then seat of London's police forces. The name was changed to *The Police Gazette* in 1828, and responsibility for the publication was transferred to Scotland Yard in 1883. Wood engravings of stolen valuables, photographs of criminals, and a classified system of descriptions all became features of the publication under Sir Howard Vincent, first director of the Criminal Investigation Division. The *Gazette* became a daily publication in 1927.

police power, in U.S. constitutional law, the permissible scope of federal or state legislation so far as it may affect the rights of an individual when those rights conflict with the promotion and maintenance of the health, safety, morals, and general welfare of the public. When the U.S. Supreme Court has considered such cases, it has tended to use a doctrine called "balance of interests," to determine whether a state has the right to exercise its implied police powers although that exercise may be in conflict with a federal law, either statutory or constitutional. The court has held, in these instances, that if a state does enact legislation for the protection and maintenance of the health, safety, or welfare of its citizens, such laws "fall within the most traditional concept of the state's police power." Therefore, even in matters where federal laws take precedence over those of the state, the court has decided in favour of the state. For example, a state's police power may be employed to ban the export of immature citrus fruits on the grounds that such shipments would adversely affect the reputation of the grower state in the marketplace. Although it would seem to be a clear impediment to the free exercise of interstate commerce, the court, in *Sligh* v. *Kirkwood* (1915), upheld the measure as legitimate police power exercise on behalf of its citizenry. However, if the statute were intended to discriminate against another state's market or resource, rather than (as in *Sligh*) to protect its own resource, then it is not a legitimate exercise of police power.

Even where the balance of interests may well lie in favour of the state's apparent right to enact legislation under its police powers privilege, the burden on other factors, *e.g.,* interstate commerce, may be too great to permit such enactment. In *Bibb* v. *Navajo Freight Lines Inc.* (1959), an Illinois law requiring special mudguards on trucks using its highways was found to be too cumbersome a requirement although it had been enacted in behalf of the safety of its citizens.

State courts also render decisions on the validity of contested legislation that enables a state to exercise its police powers.

Periodically, state courts have had to deal with matters involving private concepts of health in contention with the public's health. One example is the insistence on immunizing school children against certain communicable diseases, or prohibiting children from entering school without such immunization. The private concerns of the parent who may feel that only he or she has a right to decide what medical treatment the child should have—

or the convictions of a person who feels that medication is an infringement on his or her religious practice—are matters that do come to state courts from time to time. Again, the court usually finds that the public's right to health tends to outweigh private or individual concerns.

In general, the courts tend to uphold laws exercising what it considers bona fide concerns for the public's well-being, on the ground that the legislature has the discretion to discern public need and to enact legislation in protection of the public interest.

Police Zone, southern two-thirds of South West Africa (now Namibia) in which the German and later South African colonial administrations were able to establish effective European-style police control beginning in the early 20th century. The name of the area and its original boundary were adopted in 1919 by the South Africans from a 1911 German map of the territory on which the area was marked *Polizei-Zone.*

Spanning the north-central sector of what became the mandated territory of South West Africa, the Police Zone's boundary (often called the Red Line because it was printed on maps in red ink) extended from the Atlantic Ocean to Botswana in a generalized northward-arcing semicircle. The boundary separated indigenous African groups to the north, including the numerically significant Owambo (Ovambo) as well as other Bantu-speaking peoples, from white settlement areas to the south. Not all indigenous groups of South West Africa, however, lived north of the Police Zone. The numerically less significant Herero, together with groups of Khoikhoin (Hottentots) and other groups of mixed origin, lived mostly within the Police Zone.

The Police Zone boundary was long inviolate. Whites were prohibited from entering the north, and the indigenous groups of the north were generally prohibited from entering the Police Zone except when hired as a "labour unit" contracted for a prescribed period. Many successive demarcation changes of the boundary between the 1920s and '60s usually reflected the increasing white control of better farming areas. The name Police Zone was used less after the South African Odendaal Commission defined the geographic, economic and political aspects of apartheid in South West Africa. The commission's directive in 1964 led to the establishment of 10 reserves (homelands) in the 1970s for South West Africa's African peoples and groups of mixed origin; the eastern, southern, or western boundaries of the 6 reserves for the indigenous African groups to the north of the Police Zone followed the Police Zone boundary with slight alterations.

The 1977 South African agreement to create an interim government in Namibia until independence was achieved led to the Rural Areas Proclamation (1977), which revoked the regulations previously used to control the movement of black Africans and permitted all ethnic groups to take employment and residence wherever they chose. By the time of independence in 1990, even the effects of a Police Zone had ceased.

policy, form of lottery in which pellets usually numbered 1 to 78 are deposited in a drum-shaped wheel and players wager that certain numbers will appear among the pellets—usually 12 pellets—that are selected at the drawing.

Policy, a true lottery initiated in the United States by Italian-Americans, derives its name from the Italian *polizza* ("receipt," or "ticket") and retains only occasional and local popularity. It has been substantially replaced by the numbers game (*q.v.*).

Polidoúri, Maria, Polidoúri also spelled POLYDOÚRE (b. 1905, Kalámai, Greece—d. 1930, Athens), Greek poet known for her impassioned, eloquent farewell to life.

Polidoúri was orphaned as a small child, and in 1921 she went to Athens to study law. There she began a friendship with another poet, Kóstas Kariotákis. In 1926 she went to Paris, returning two years later, fatally ill. In 1930 she entered a sanatorium near Athens, where she died.

Her two books of poems reflect her awareness of impending death. The tone alternates between bitter questioning and a cold resignation in which she seems to contemplate her own pain from outside herself.

Polignac FAMILY, French noble house important in European history.

From the 1050s and perhaps even from 860, the first viscounts of Polignac (in the modern *département* of Haute-Loire) were practically independent rulers of Velay, where the Loire River rises. Their ultimate heiress, Valpurge, was married in 1349 to Guillaume III de Chalençon, whose descendants assumed the Polignac name in 1421. The actual power of the house declined as feudalism broke down, but it maintained its exalted rank in the nobility; and in the ninth generation after Guillaume of Chalençon it emerged into political prominence with Melchior (b. Oct. 11, 1661, Puy, Fr.—d. April 3, 1742, Paris), known first as the abbé, then as the cardinal de Polignac. Early experienced in diplomatic affairs between France and Rome, the Abbé was sent as King Louis XIV's ambassador to Poland in 1693. There he procured the abortive election of François Louis de Bourbon, Prince de Conti, as king of Poland in 1697. After a temporary disgrace, Melchior was elected to the French Academy in 1704. During the War of the Spanish Succession he played a major part in the negotiations at Gertruydenberg (1710) and at Utrecht (1712) before becoming a cardinal (creation *in petto* 1712, published 1713). He was exiled for participation in the Cellamare plot of 1718 but was French chargé d'affaires in Rome from 1724 to 1732 and was made archbishop of Auch in 1726. His long Latin poem, *Anti-Lucretius,* first printed in 1747, largely against Pierre Bayle's philosophy, went through many editions and translations.

The cardinal's grandnephew, Armand-Jules-François, Count de Polignac (b. 1743, Claye, Fr.—d. 1817, St. Petersburg [now Leningrad], Russia), was married in 1767 to Yolande Martine Gabrielle de Polastron (1749–93). She became a great favourite of Queen Marie-Antoinette, and he was created Duke de Polignac (1780). Their influence was savagely denounced in pamphlets during the Revolution.

Auguste-Jules-Armand-Marie de Polignac (b. May 14, 1780, Versailles, Fr.—d. March 2, 1847, Paris), the first duke's second son, went from England back to France, with his elder brother Armand-Jules-Marie-Héraclitus (b. Jan. 17, 1771, Paris, Fr.—d. March 30, 1847, Saint-Germain-en-Laye), to conspire against Napoleon in 1804, but they were arrested. Released in 1813, Auguste-Jules was made a peer at the Bourbon Restoration (1815) but refused at first to take the constitutional oath because he thought it derogatory to the Holy See's rights. For this the Holy See granted him the Roman title of prince (1820; recognized in France 1822). His ultramontanism and extreme royalism appealed to King Charles X, who appointed him minister of foreign affairs on Aug. 8, 1829, and prime minister on November 17. Responsible for the ordinances that provoked the July Revolution of 1830, he was arrested and, in December 1830, sentenced to life imprisonment. Released but banished in November 1836, he finally returned to France in 1845. The Bavarian monarchy in 1838 extended the title of prince to all his descendants; and, because his elder brother died childless, he inherited the ducal title as well just before his own death the same month. The counts de Polignac descend from the first duke's third son, Camille-Melchior-Henri (1781–1855). One of them, Count Pierre (1895–1964), was the father of Prince Rainier III of Monaco.

Prince Edmond-Melchior (1834–1901), fifth son of Jules, was a composer. In 1893 he married Winnaretta Singer (1865–1943), who, as Princess Edmond de Polignac, was the outstanding Parisian patroness of avant-garde music in the first half of the 20th century.

polio vaccine, preparation of poliomyelitis virus given to prevent infection with the disease. The virus is grown in kidney tissue from rhesus monkeys. There are two types of vaccine: one with killed virus, which is injected, and the other with live, attenuated (weakened) virus, which is given orally. Vaccines, whether killed or live, must contain strains of all of the three poliovirus types, and three doses are required, as the body develops immunity to only one type at a time.

poliomyelitis, also called INFANTILE PARALYSIS, acute infectious viral disease characterized by symptoms that range from a mild nonparalytic infection to an extensive flaccid paralysis of voluntary muscles.

Severe epidemics of poliomyelitis have been reported in many parts of the world. In the United States the greatest recorded sustained incidence was in 1942–53; in 1950 there were 33,344 cases. In 1952 severe epidemics occurred in Denmark, Germany, and Belgium. In Asia outbreaks were reported in Bombay, Singapore, Japan, Korea, and the Philippines.

Since the 1960s, however, poliomyelitis has been more or less under control in the developed world. Control is based on community- or area-wide use of the attenuated live polio vaccine, given orally (Sabin), and the inactivated (killed) injectable vaccine (Salk).

The poliovirus is believed to enter the body through the throat. From the alimentary tract it is absorbed into the blood and lymphatics, whence it is widely disseminated throughout the body and ultimately reaches the central nervous system.

The most common early symptoms of poliomyelitis are mild headache, fever, sore throat, nausea, vomiting, diarrhea, restlessness, and drowsiness. Temperature rises slowly, and fever peaks in two to three days and then rapidly subsides. More than 80 percent of all patients who develop poliomyelitis recover within three to four days without the development of paralysis. When the disease is severe, the patient becomes irritable and develops pain in the back and limbs, muscle tenderness, and stiff neck.

Paralytic poliomyelitis results from the destruction of the anterior horn (motor nerve) cells of the spinal cord. Cells that are destroyed are not replaced because nerve cells cannot regenerate. Cells that are not severely injured recover their normal function in time; to the extent that they do recover, a corresponding restoration of muscle function may be expected. The paralysis may range in severity from transient weakness that soon disappears to complete permanent paralysis, with associated progressive atrophy of the unused muscles.

In respiratory poliomyelitis the virus injures the upper part of the spinal cord, with resulting difficulties in breathing.

In bulbar poliomyelitis the virus attacks the bulb, or brainstem, situated just above the spinal cord, and the nerve centres that control swallowing and talking are injured. Secretions collect in the throat and may lead to suffocation by blocking the airway.

Treatment during the preparalytic stages includes complete bed rest, isolation, and careful observation. If paralysis occurs, passive movement of the limbs can be used to avoid deformities. As muscle strength returns, exercises are increased. Breathing requires mechanical aids such as the iron lung or the positive pressure ventilator, which pumps air into the patient's lungs through a tracheotomy tube inserted in the windpipe. Accumulated secretions in the throat may be removed by a mechanical suction machine.

There seem to be individual differences in the degree of natural susceptibility to the disease. Many persons have acquired antibodies to the polio virus in their blood without having had any symptoms of infection. It is generally held that a lasting immunity follows recovery from the disease; but second attacks are known to occur, caused, at least in some cases, by viral strains differing immunologically from those responsible for the first attack. Among the predisposing factors, age is the most important, children and young adults being most often affected. Other predisposing factors include strenuous exercise, sudden chilling, and pregnancy.

Polioptilidae (bird family): *see* gnatcatcher.

polis, plural POLEIS, ancient Greek city-state. The small state in Greece originated probably from the natural divisions of the country by mountains and the sea and from the original local tribal (ethnic) and cult divisions. There were several hundred poleis, the history and constitutions of most of which are known only sketchily if at all. Thus, most ancient Greek history is recounted in terms of the histories of Athens, Sparta, and a few others.

The polis centred on one town, usually walled, but included the surrounding countryside. The town contained a citadel on raised ground (acropolis) and a marketplace (agora). Government was centred in the town, but citizens of the polis lived throughout its territory. The citizens governed in varying degrees, depending upon the form of government; usually there was an assembly of citizens, a council, and magistrates. Each polis also contained substantial numbers of noncitizens (women, minors, resident aliens, and slaves).

In the Hellenistic Age the political freedom of most poleis was curtailed, since they came under the ascendancy of the large territorial monarchies of Macedonian origin. But they continued to manage local affairs, and some, such as Athens, were flourishing intellectual centres. The Hellenistic kings founded numerous new cities, bringing in Greek and Macedonian settlers who Hellenized part of the local population; in this way the institutions characteristic of the polis spread through much of the Middle East.

Polisario, abbreviation of POPULAR FRONT FOR THE LIBERATION OF SAGUIA EL HAMRA AND RÍO DE ORO, Spanish FRENTE POPULAR PARA LA LIBERACIÓN DE SAGUIA EL HAMRA Y RÍO DE ORO, politico-military organization striving to end Moroccan control of the former Spanish territory of Western Sahara (*q.v.*), in northwestern Africa, and win independence for that region. Polisario is composed largely of the indigenous nomadic inhabitants of the Western Sahara region, the Saharawis. Polisario began as an insurgency (based in neighbouring Mauritania) against Spanish control of the Western Sahara. After Spain withdrew and Morocco and Mauritania partitioned Western Sahara between them in 1976, Polisario relocated to Algeria, which henceforth provided the organization with bases and the military hardware with which to try to wrest control of the region. Mauritania made peace with Polisario in 1979, but Morocco then unilaterally annexed Mauritania's portion of the Western Sahara. During the 1980s the Polisario guerrillas, numbering some 20,000 motorized and well-armed troops, harassed and raided Moroccan outposts and defenses in the Western Sahara. Polisario also mounted a diplomatic campaign, and by the late 1980s more than 60 countries had recognized the government-in-exile that Polisario had formed for what it called the Saharan Arab Democratic Republic.

Polish Corridor, strip of land, 20 to 70 miles (32 to 112 km) wide, that gave the newly reconstituted state of Poland access to the Baltic Sea after World War I. The corridor lay along the lower course of the Vistula River and consisted of West Prussia and most of the province of Posen (Poznań), which the Treaty of Versailles (1919) transferred from defeated Germany to Poland. Perhaps no provision of the treaty caused so much animosity and resentment among Germans than this arrangement, for the corridor ran between Pomerania and East Prussia and separated the latter province from the main body of the German Reich to the west. On the other hand, it should be noted that (1) the territory was historically Polish (that is, before the partitions of Poland in the late 18th century) and was inhabited by a Polish majority; (2) the provision accorded with the 13th of U.S. President Woodrow Wilson's Fourteen Points, for giving Poland "a free and secure access to the sea" and indeed its only access; and (3) the territory ceded did not include Danzig (Gdańsk), then a purely German town, which was established as a free city under the sovereignty of the League of Nations. Poland developed the corridor port of Gdynia as an alternative to Danzig. Free German transit was permitted across the corridor.

The Polish Corridor was the issue, or at least the apparent pretext, over which World War II began. In March 1939 the Nazi dictator of Germany, Adolf Hitler, demanded the cession of Danzig and the creation of extraterritorial German highways across the corridor connecting to East Prussia. Poland refused these demands and secured French and British guarantees against German aggression. In September Germany invaded Poland, thus beginning the war. Hitler annexed the Polish Corridor, Danzig, Posen, and districts along the Silesian frontier and placed the rest of the conquered Polish territory under a German governor. But after World War II the whole area was remapped, with great shifts of German and Polish populations, and the issue disappeared as the Polish Corridor, along with Gdansk and East Prussia, became part of postwar Poland.

Polish language, Polish JĘZYK POLSKI, West Slavic language belonging to the Lekhitic subgroup and closely related to Czech, Slovak, and the Sorbian language of eastern Germany; it is spoken by the majority of the present population of Poland.

The modern literary language, written in the Roman (Latin) alphabet, dates from the 16th century and was originally based on the dialects of the area around Poznań, in western Poland. The first written Polish consists of a list of names in the Papal Bull issued in 1136 by Pope Innocent II to the Archbishop of Gniezno; the oldest recorded sentence is a gloss translating a quotation in a document from 1270. Extant manuscripts containing any appreciable amount of connected Polish text date back no earlier than the 14th century.

Polish contains a great number of words borrowed from Latin, Czech, German, Belorussian, and Ukrainian and also some words from Italian, French, and English. Along with the other West Slavic languages, it has a fixed stress accent. In contrast to the others, however, the language has nasalized vowels (spelled *ę* and *ą*), indirectly continuing the nasalized vowels of Church Slavonic. Among the major dialects are Great Polish and Pomeranian, Silesian, Little Polish, and Mazovian. Kashubian (Cassubian), often classified as a Polish dialect, is, historically, a separate language.

Polish literature, body of writing in Polish, one of the Slavic languages. The Polish national literature holds an exceptional position in the life of the country. Over the centuries it has mirrored the turbulent events of Polish history and at times sustained Poland's cultural and political identity.

A brief account of Polish literature follows. For full treatment, *see* MACROPAEDIA: Polish Literature.

Poland's early literature was slow to emerge. The oldest documents, written in Latin, date from the 12th century, but the development of vernacular writing in the 14th and 15th centuries, hampered by internal disorders and destructive invasions, was late, and extant records are few. Although probably written in the 13th century, the earliest copy of a poetic text to have survived dates from 1407.

The Golden Age of Polish literature occurred during the 16th century. The spread of Italian Renaissance influences, closer contacts with other countries, and a period of relative peace and stability encouraged a varied and confident expression. The first original Polish writer is Mikołaj Rej. The date of his verse debate (1543), belonging in content and style to the earlier period, conveniently marks the beginning of the new age. His contemporary, the poet Jan Kochanowski, a man truly of the Renaissance, is the outstanding early Polish writer. The richness of the literature of the period is represented by prose (Lukasz Górnicki), sermons (Piotr Skarga), political writings (Andrzej Modrzewski), idylls (Simonides), and sonnets (Mikołaj Sęp Szarzyński).

The stylistic tensions of 17th-century Baroque writing, with its exotic colour and textures, its vigorous, sharp contrasts, and unexpected twists, mirror those of a century plagued by religious discord and war. Courtly lyrics (Jan Andrzej Morsztyn), religious poetry (Zbigniew Morsztyn), historical epics (Samuel Twardowski), and the memoirs of the boisterous Jan Chryzostom Pasek exemplify the literature of this troubled age.

Following a period of debility in the first part of the 18th century, the Age of Enlightenment during the reign of the last Polish king, Stanisław II August Poniatowski, brought a vigorous revival in all areas of Poland's cultural, political, and intellectual life. Literature, journalism, publishing, political and educational reform, and the opening of a national theatre (1765) attest to the progressive attitudes of the age. Its best representative is Ignacy Krasicki. The poetry of Franciszek Karpiński and Franciszek Dionizy Kniaźnin, the plays of Wojciech Bogusławski and Franciszek Bohomolec, and the writings of Julian Ursyn Niemcewicz are among the best examples of 18th-century Polish literature.

The enthusiasm and passions that stirred the 19th-century Romantics were common everywhere, but in Poland they were soon charged by the drama of events. After the failure of the 1830 insurrection, Polish Romanticism assumed the guilt and the tragic sorrows of an oppressed and martyred nation. Written in exile, the bardic tones of Adam Mickiewicz's work (with its Promethean anguish and Messianic visions) and that of Juliusz Słowacki and Zygmunt Krasiński became an expression of the national spirit. These writers' major works—with their quest for self-identification, individual liberty, and questioning of history—are an enduring part of the Polish consciousness.

The unsuccessful uprising of 1863 marked the end of earlier Romantic dreams. In the aftermath of a bitter defeat, the old idealism gave way to a new positivism with an emphasis on practical endeavour and social and political realism. The novels of Henryk Sienkiewicz, Bolesław Prus, and Eliza Orzeszkowa (ranging from historical themes to social and contemporary problems) dominated the literature of the second part of the 19th century.

Reacting against the constrictions of positivism, the Young Poland movement (1890–1918) vibrated with new names and new ideas. European and provokingly modernistic in its early, enthusiastic manifestos, it contained a wide variety of currents and styles. Its best examples embrace poetry (Kazimierz Tetmajer), symbolist drama (Stanisław Wyspiański), and the novel (Stefan Żeromski).

The short period of restored independence during the interwar years (1918–39) produced a literature of freshness and diversity. Apart from the work of the older writers such as Bolesław Leśmian and Leopold Staff, the period witnessed the noisy inventions of the Futurists, the avant-garde poetry of Tadeusz Peiper and Julian Przyboś, and the confident optimism of the Skamander poets. In prose there were the works of some of the major modern Polish writers: Maria Dąbrowska, Witold Gombrowicz, Jerzy Andrzejewski, and Bruno Schulz; in the theatre were the plays of Jerzy Szaniawski and the innovative surrealism of Stanisław Ignacy Witkiewicz.

After 1945 the experiences of war and occupation produced new topics for Polish writers, particularly since the lifting of Soviet-inspired Stalinist cultural controls in 1956. Whether distilling the tragedies of war or depicting the traumas of contemporary Polish life in the Soviet bloc, the works of Zbigniew Herbert, Tadeusz Konwicki, Tadeusz Różewicz, Sławomir Mrożek, and Stanisław Lem, and of the older Czesław Milosz, mirror the modern Polish condition.

Polish National Catholic Church of America, Old Catholic church that arose in the late 19th and early 20th centuries among Polish immigrants in the United States who left the Roman Catholic church. Polish immigrants were unhappy with the Roman Catholic church in the United States for several reasons, including various internal disputes and dissatisfaction with pastors, the absence of a bishop of Polish birth or descent in the American hierarchy, and the 1884 ruling that gave bishops the title to all diocesan properties.

In 1896–97 members of the Sacred Hearts of Jesus and Mary parish in Scranton, Pa., founded an independent parish under the leadership of their former curate, Reverend Francis Hodur. They launched a petition calling for ownership by Polish parishes of property built by their members, parish-wide elections of administrators of such property, and no appointment by bishops of non-Polish pastors to such parishes without the consent of the parishioners. Excommunication followed. Father Hodur's parish became the nucleus of a movement that took in other seceded congregations. In 1904 a synod, in Scranton, of independent parishes voted to form one body and chose its present name. It also adopted a constitution, elected a lay-clerical Supreme Council, and unanimously elected Hodur bishop. On Sept. 29, 1907, he was consecrated in Utrecht, Neth., by bishops of the Old Catholic church.

Liturgically, the Polish National Catholic Church resembles the Roman Catholic church. From 1900 masses were in Polish, but in the 1960s English masses were permitted if the parishes desired them. Doctrinally, the church is based on the Scriptures, tradition, decrees of the first four ecumenical councils, and decrees of its own synods. In 1922 the requirement of clerical celibacy was abolished. General rather than private confession is made by adults. Between synods, executive power in the church rests with the prime bishop and Supreme Council, which consists of all bishops and the seminary rector, and a lay and a clerical representative from each of the church's five dioceses. Synods, consisting of all the clergy as well as lay delegates, are held every four years. Headquarters and a seminary are in Scranton. In the late 20th century the membership was reported to be about 270,000.

Polish People's Republic: *see* Poland.

Polish Succession, War of the (1733–38), general European conflict waged ostensibly to determine the successor of the king of Poland, Augustus II the Strong. The war resulted mainly in a redistribution of Italian territory and an increase in Russian influence over Polish affairs.

After Augustus died (Feb. 1, 1733), Austria and Russia supported the election of his son Frederick Augustus II of Saxony as king of Poland. Most Poles, however, preferred Stanisław I Leszczyński, who had been their king (1704–09) when the Swedes had temporarily forced Augustus II to be deposed and who also had become the father-in-law of Louis XV of France. France and Spain both opposed the Austro-Russian position and supported Leszczyński, who was elected king of Poland by a *sejm* (Diet) of 12,000 delegates in Warsaw on Sept. 12, 1733. But when a Russian army of 30,000 approached Warsaw, Leszczyński fled to Gdańsk, and another *sejm* of 3,000 delegates named Frederick Augustus as Poland's new king, Augustus III (Oct. 5, 1733). France consequently formed anti-Habsburg alliances with Sardinia-Savoy (September 26) and Spain (November 7) and declared war on Austria (October 10).

Don Carlos, the Spanish infante, led a Spanish army of 40,000 across Tuscany and the Papal States to Naples, defeated the Austrians at Bitonto (May 25, 1734), conquered Sicily, and was crowned king of Naples and Sicily as Charles III. The French, however, after overrunning Lorraine, were effectively checked in southern Germany by Austria's prince Eugene of Savoy. Furthermore, the French and Savoyard forces that invaded Lombardy were unable to take Mantua, and the small French contingent sent by sea to relieve the Russian siege of Gdánsk was ineffective. Gdánsk fell in June 1734.

Leszczyński escaped to Prussia, and to support him the Poles organized the Confederation of Dzików (November 1734), which, however, failed to defeat the Russians and Augustus. Furthermore, dissension between the Spaniards and the Savoyards made the Italian campaign of 1735 inconclusive; and, because the French feared that the British and the Dutch would enter the war as Austria's allies, France signed a preliminary peace with Austria (Peace of Vienna; Oct. 3, 1735). It provided for Augustus to remain king of Poland. In addition, Don Carlos was to retain Naples-Sicily but had to give Austria both Parma and Piacenza, which he had inherited in 1731, and to renounce his claims to Tuscany. Sardinia-Savoy also acquired Novara and Tortona from Lombardy, which remained a Habsburg possession. Following the settlement, Leszczyński renounced the crown (Jan. 26, 1736), and the Dzików Confederation recognized Augustus as king (July 1736).

Three years later, on Nov. 18, 1738, France and Austria signed the final Treaty of Vienna, in which the provisions of the preliminary agreement were confirmed and in which France also conditionally guaranteed the Pragmatic Sanction, by which Holy Roman emperor Charles VI named his daughter, the Austrian archduchess Maria Theresa, as the heiress to his Habsburg lands. The other outstanding belligerents acceded to the peace in 1739.

Politburo, the supreme policy-making body of the Communist Party of the Soviet Union. The Politburo until July 1990 exercised supreme control over the Soviet government; in 1990 the Politburo was enlarged and was separated to a certain degree from control over the Soviet government. Central party organs comparable to the Soviet Politburo are found in China and other communist countries.

The first Politburo was created in Russia by the Bolshevik Party Central Committee in late October 1917 to provide continuous and flexible leadership in that year's uprising. The seven Politburo members included Vladimir Lenin, Leon Trotsky, and Joseph Stalin. The Bolshevik coup accomplished, the Politburo was dissolved. The 8th Party Congress in March 1919 instructed the Central Committee to elect a new Politburo of five from its ranks; its formal role would be to decide on questions too urgent to await Central Committee deliberation. The Politburo soon assumed a major position in party and state administration, and it eventually came to overshadow the role of the Central Committee. Because the party secretariat planned the agenda, provided all documentation for debate, and transmitted Politburo decisions to the lower echelons, the general secretary of the Communist Party (Stalin) became the Politburo's most influential member. Following the power struggles after Lenin's death in 1924, Stalin achieved a controlling position on the Politburo, exercising complete dominance over it and the party in general.

In 1952 the Politburo was abolished and was replaced by a larger Presidium of the Central Committee. More stress was laid on "collective leadership" within this body after the tyrannical excesses of Stalin (d. 1953), and the Presidium was actually strong enough to remove Nikita Khrushchev from the party's leadership in 1964. The old name of Politburo was revived for the body in 1966, and so it has remained.

The Politburo's membership is nominally elected by the Central Committee of the Communist Party, but in truth the Politburo has been a self-perpetuating body that itself decides which new members it will admit and which it will expel from its ranks. Until mid-1990 it consisted of about 12–15 members and 5–8 candidate members. With the changes made in 1990, the body grew to include a representative from each of the Soviet republics. Several top government officials were dropped from the Politburo; though they remained party members, they were to concentrate on their responsibilities as members of the presidential council. The chairman of the Politburo is the general secretary of the Communist Party and, traditionally, was in effect the leader of the Soviet Union. (The Politburo formerly included the minister of defense, the head of the KGB [the Soviet secret police], and the heads of the most important republic or urban party organizations.) The Old Bolshevik ideologues who sat in the early Soviet Politburo have been replaced by party members with some technical training and records of long and loyal service in the bureaucracy.

The politburos of the eastern European communist countries were similar in form and function to the Soviet model. The politburo of China is also similar, but it contains a Standing Committee of about 7 members who exercise great power within the party and the politburo itself.

Politian, Italian in full ANGELO POLIZIANO, also called ANGELO AMBROGINI (b. July 14, 1454, Montepulciano, Tuscany [Italy]—d. Sept. 28/29, 1494, Florence), Italian poet and humanist, the friend and protégé of Lorenzo de' Medici, and one of the foremost classical scholars of the Renaissance. He was equally

Politian, detail from "Zaccharias and the Angel" by Ghirlandajo, 1490–94; in Sta. Maria Novella, Florence
Alinari—Art Resource/EB Inc.

fluent in Greek, Italian, and Latin and was equally talented in poetry, philosophy and philology.

The murder of Politian's father in May 1464 left the family poverty-stricken, and not later than 1469 Politian was sent to Florence. He started to write Latin and Greek epigrams and attracted the attention of Lorenzo de' Medici, to whom Politian dedicated the first two books of his Latin translation of the *Iliad.* In about 1473 he entered the Medici household and was able to study in the Medici library until, in 1475, he was entrusted with the education of Lorenzo's eldest son, Piero, then aged three. In 1477 he was given as a benefice the priory of San Paolo. His translation of the *Iliad,* books ii–v, into Latin hexameters (1470–75) brought him his first renown. Between 1473 and 1478 he produced Latin and Greek verses that are among the best examples of humanist poetry: they include elegies, odes, and epigrams (of particular merit are the elegies *In violas* ["In Violets"] and *In Lalagen* and the ode *In puellam suam* ["In Regard to One's Daughters"]). To the same period belong the strange and poetically experimental *Sylva in scabiem* (1475; "Trees with Mildew"), in which he describes realistically the symptoms of scabies.

His poetic masterpiece of this period is, however, a vernacular poem in ottava rima, *Stanze cominciate per la giostra del Magnifico Giuliano de' Medici* ("Stanzas Begun for the Tournament of the Magnificent Giuliano de' Medici"), composed between 1475 and 1478, which is one of the great works of Italian literature. In it he was able to synthesize the grandeur of classical literature with the spontaneity of Florentine vernacular poetry. The poem describes the love of "Julio" (*i.e.,* Giuliano de' Medici), for "Simonetta" (*i.e.,* Simonetta Cattaneo; d. 1476) by means of a poetic transfiguration in which beauty is glorified according to humanist ideals. Stylistically it is influenced by Latin epic and encomiastic poems and reveals the author's taste for refined poetry. It was interrupted at book ii, stanza 46, probably because of Giuliano's death in 1478.

Politian was, with Lorenzo de' Medici, one of those mainly responsible for the revaluation of vernacular literature. It is generally believed that it was he who wrote the dedicatory letter, tracing the history of vernacular poetry and warmly defending it, that accompanied the so-called *Raccolta Aragonese* ("The Aragon Collection"), a collection of Tuscan verse sent by Lorenzo de' Medici to Federico d'Aragona in about 1477.

Politian was with Lorenzo and Giuliano when the latter was killed by the Pazzi on April 26, 1478; on this episode he wrote the dramatic report *Pactianae coniurationis commentarium* (1478). In May 1479, as a result of a quarrel with Lorenzo's wife, Clarice Orsini, he was expelled from the Medici household. In December, instead of accompanying Lorenzo on a difficult diplomatic mission to Naples, he undertook a series of journeys in northern Italy. After visiting Venice and Verona he was attracted to Mantua, where, in the Gonzaga court, he found a new patron in Cardinal Francesco Gonzaga. It was for a court occasion that he wrote in Mantua *Orfeo* (1480; "Orpheus"), a short dramatic composition in the vernacular, based on the myth of Orpheus and Eurydice and inspired by the same humanist ideal of beauty that pervades his *Stanze. Orfeo* is less refined than the *Stanze,* but it nevertheless reveals the author's poetic genius. During his stay in Mantua, Politian repeatedly wrote to Lorenzo asking to be recalled to Florence, and in August 1480 he was at last invited to return and was again entrusted with Piero's education. Thanks to Lorenzo he was appointed to the Florentine chair of Latin and Greek (autumn 1480) but was not readmitted to the Medici household and went to live outside of Florence.

At the Florentine university he gave four inaugural lectures in verse, known collectively as the *Sylvae* ("The Trees"): *Manto* (1482; "The Cloak"), on Virgil's poetry; *Rusticus* (1483; "The Countryside"), on the bucolic poems of Hesiod and Virgil; *Ambra* (1485; "Amber"), on Homer; and *Nutricia* (1486; "The Foster Mother"), on the different genres of Greek and Latin literature.

In 1488 he took part in a diplomatic mission to Pope Innocent VIII; and in 1491 he traveled to Bologna, Ferrara, Padua, and Venice to trace manuscripts for the Medici library. Otherwise he spent the last years of his life in Florence. His writings of this last period include a Latin translation of Epictetus' *Manual* (1479); a collection of *Detti piacevoli* (witty sentences), composed in the vernacular between 1477 and 1479; Greek epigrams; a number of vernacular *canzoni a ballo* ("songs for dancing") and *rispetti* ("regards"), which show his taste for popular poetry; and Latin letters on problems of style and literature.

His most important work on classical philology is the *Miscellanea* (1489), two collections, each consisting of about 100 notes (*centuria*) on classical texts: these and other works laid the foundations for subsequent scholarly studies in classical philology.

political action committee (PAC), in U.S. politics, an organization whose purpose is to raise and distribute campaign funds to candidates seeking political office. PACs are formed by corporations, labour unions, trade associations, or other organizations to solicit voluntary campaign contributions from individuals and channel the resulting funds to candidates for elective offices in the federal government, primarily in the House of Representatives and the Senate. PACs rose to prominence after the Federal Election Campaign Act of 1971 set strict limits on the amount of money a particular corporation, union, or private individual could give to a candidate. By soliciting smaller contributions from a much larger number of individuals, PACs circumvent these limitations and manage to provide substantial funds for candidates. By the late 20th century, the vast amounts of money raised by PACs had greatly escalated the cost of running for federal office in the United States.

political convention, in U.S. politics, a meeting of party delegates at the local, state, or national level to select candidates for office and to decide on party policy. The conventions, as representative organs of the parties, may also elect executive committees of the parties and adopt rules governing party organization. In practice they also act as rallies for the election campaigns that follow.

Before the institution of conventions in the 1830s, parties decided on candidates and policies in informal caucuses. Conventions were introduced to eliminate the abuses of the caucus system; they were expected, by their open and public conduct of business, to be more democratic and less amenable to control by party bosses and machines. However, most of the real business of conventions has been conducted in informal meetings of various delegates and leaders; activity on the floor of the convention has usually been merely a reflection of behind-the-scenes decisions and compromises. In order to lessen this control by party oligarchies, candidates for most elective offices at the state and local levels are now nominated by direct primaries rather than conventions, although conventions still play an important role in endorsing party candidates.

National party conventions are held every four years to nominate candidates for president and vice president and to adopt a national platform. At first, voting strength in both conventions was apportioned among the states according to their electoral-college vote, usually two convention votes for each of the state's electors. For its 1916 convention, the Republican Party adopted rules curtailing the representation of congressional districts in which the Republican vote was light. Both parties later began giving "bonus" votes to the states carried by the party in a previous election.

Each convention begins by electing a convention chairman and a rules committee, adopting convention rules, and checking delegate credentials through a credentials committee. Thereafter, party platforms, prepared by a special committee, are debated and voted upon by the delegates.

Although nominations of candidates are the work of the convention as a whole, the growth of presidential primaries increasingly limits conventions to ratifying the candidate already selected by the voters. Candidates are nominated in eulogistic speeches; noisy demonstrations are then staged, with bands and marchers hired for the occasion parading up and down the aisles; and eventually the convention votes. The roll of states is called alphabetically, and the vote of each state delegation is reported by its chairman; if necessary, the delegation is polled, each delegate being asked to openly declare his vote. Although many contests have been settled on the first ballot, the taking of several ballots is common.

In the late 20th century the great majority of Republican and Democratic delegates have been selected through primaries. Most of the delegates elected in primaries are bound to vote in a way that reflects the voters' choice, at least on the first ballot. A candidate who has won enough delegate votes in the primaries can be certain of nomination on the first ballot. This reduces the power of party leaders and favourite-son candidates to broker delegate votes to candidates in exchange for political favours. Their bargaining strength has also been lessened by the public-opinion polls that measure the strength of the candidates and show their support by regions and demographic groups. The convention seeks to run a candidate who can win, and the polls are persuasive assessments of a candidate's viability. If primaries and polls do not make the nomination a foregone conclusion, they at least eliminate all but the serious contenders before the convention.

The nomination of a vice-presidential candidate, frequently one chosen by the presidential nominee in consultation with party leaders, follows the selection of the presidential standard bearer. At the final convention session the nominees make acceptance speeches that usually spell out the major campaign platforms.

The national conventions are nationally televised and receive a great deal of attention. Local and state conventions perform similar functions, but the rules governing their composition and proceedings vary from state to state. The tendency has been toward greater uniformity in such procedures.

The national conventions have been criticized throughout their history as undemocratic spectacles. Critics have proposed replacing them with some form of national presidential primary. Defenders argue that, besides promoting party unity and enthusiasm, conventions allow compromise, and they tend to nominate candidates and take positions that represent the political mean rather than the extremes. Because a president must be able to win-over party leaders as well as the public to function in office, supporters of the system claim that it is a better test of how a candidate will perform.

political economy, branch of social science, which later developed into economics, concerned with the raising of revenue by the state and the increase of the state's general resources. The term was introduced about the beginning of the 17th century to describe the study of the problems of the princely states, which at the close of the Middle Ages in Europe replaced the feudal-ecclesiastical political order. Adam Smith, the first to present a comprehensive systematized study, seemed to equate political economy with the treatment of "the nature and causes of the wealth of nations."

After the nationalistic epoch gave way to individualism or liberalism in the late 18th century, the older state-oriented literature came to be called mercantilism. Works in this period, including David Ricardo's *Principles of Political Economy and Taxation* (1817) and John Stuart Mill's *Principles of Political Economy* (1848), gave increased attention to problems of value and distribution.

The term economics replaced political economy in general usage during the 20th century; the change of name accompanied the expansion of the discipline itself, which had become subdivided into a number of specialties.

political machine, in U.S. politics, a party organization, headed by a single boss or small autocratic group, that commands enough votes to maintain political and administrative control of a city, county, or state.

The rapid growth of American cities in the 19th century, owing to both immigration and migration from rural areas, created huge problems for city governments, which were often poorly structured and unable to provide services. In these conditions, political machines, such as Tammany Hall, run by boss William Marcy Tweed (1823–73) in New York City, were able to build a loyal voter following, especially among immigrant groups, by performing such favours as providing jobs or housing.

Political machines are characterized by a disciplined and hierarchical organization, reaching down to neighbourhood and block organizers, that enables the machine to respond to the problems of individual neighbourhoods, or even families, in exchange for loyalty at the polls. The term refers to their ability to elect candidates or enact measures with mechanical efficiency and predictability.

Although the primary goal of a political machine is keeping itself in power rather than providing good government, machines have been responsible for restructuring city governments to centralize authority, improving facilities and services, helping to assimilate immigrant groups, and encouraging the growth of business and industry. Supporters of political machines say that they "work" and that consolidating power in the hands of a boss, like Mayor Richard J. Daley (1902–76) of Chicago, guarantees city governments the power and authority that they need to cope with urban problems effectively. However, because political machines in such cities as Boston, Philadelphia, New York, Pittsburgh, Chicago, and Kansas City have also been responsible for many abuses of power, the term carries a pejorative sense.

Organizers who "deliver" the votes are often rewarded with patronage jobs. However, patronage can result in poorer service to the citizens because appointees may be neither qualified for their jobs nor interested in performing them. Control of both elective and appointed posts also gives a machine control of government salaries and revenues, which can be used to enrich the party at the public's expense. For example, the machine may accept donations or kickbacks from businesses in return for such favours as tax or zoning concessions or the award of lucrative public-works contracts. In some cities, machine business dealings have included accepting money from organized-crime syndicates in exchange for protection from legal interference.

In cities whose neighbourhoods are divided along ethnic or racial lines, machine patronage may aggravate hostilities by awarding most jobs and services to those people of the same background as the city's power elite. In practice, this made machine politics the last defense of white neighbourhoods against growing black populations, while black politicians who anticipated power viewed their constituents as merely the latest in a series of ethnic or racial groups that had benefited from the machine.

Since the 19th-century heyday of machine politics, civil-service reforms limiting the number of patronage jobs, the institution of direct primaries rather than party nomination of candidates, the municipal operation of public utilities, and judicial review by state and federal courts have all reduced the power of political machines. The steady exodus of city residents to the suburbs since World War II and a more mobile population with fewer ties to particular neighbourhoods have also weakened the social base that once made political machines synonymous with city government.

political party, a group of persons organized to acquire and exercise political power through election or revolution. Political parties are a product of the 19th century, when they developed in Europe and the United States alongside modern electoral political systems.

A brief treatment of political parties follows. For full treatment, *see* MACROPAEDIA: Political Parties and Interest Groups.

Structurally, political parties fall into one of two categories: the cadre party, with a membership confined to an active elite, and the mass-based party. In practice most parties combine features of each type. Cadre parties promoting the interests of the landed classes and the established church (conservative) or of the commercial and industrial bourgeoisie (liberal) developed in 19th-century England from earlier cliques and factions. American parties were from their beginning less ideological and less centralized than those in Europe, and, because of a high degree of economic mobility and the early adoption of broad-based suffrage in the United States, they were not so distinctly based on class.

By the late 19th century complaints that existing parties did not truly represent their constituencies led in the United States to the adoption of various reforms, notably the primary system of nominating candidates, which promoted the democratization of parties in the direction of the mass-based model. Truly mass-based parties arose in Europe with the organization of socialist parties in several countries. These differed from cadre parties in their efforts to enroll as many individual members as possible, in their financing by numerous small contributions, and in the election of party leaders by the membership. Parties may seek political power by electoral or revolutionary means, or sometimes by both. There is a strong tendency for a party that has gained power by revolution to decree a one-party state, a special case considered below. The two- or multiparty state with an electoral system is more common.

After an election all parties exercise some degree of power, either as the governing majority party, as one party in a governing coalition, or as an opposition. In parliamentary systems the continuance of the government depends on its ability to obtain a majority vote of the legislature on important measures, and all parties therefore exercise strong discipline over their members. In the American presidential system, party discipline is less necessary and is rarely applied because both president and Congress serve definite terms. Whether a country has a two-party or a multiparty system depends partly on tradition and partly on the structure of the electoral system. Systems of proportional representation encourage the proliferation of parties, while the winner-take-all systems of English-speaking countries make it difficult for new parties to succeed.

The single-party system prevails in countries where revolutionary parties have come to power or where leaders believe that political conflict and criticism of the government serve only to divide a society. The most notable examples are the communist regimes, in which the party bureaucracy, chosen from a small elite, has in effect become the state, and facist regimes, where the party is even more of a closed corporation but is usually subordinated to a charismatic leader or to the army. Variations of the single-party system are also found in many developing countries.

political philosophy, branch of philosophy that is concerned, at the most abstract level, with the concepts and arguments involved in political opinion. The meaning of "political" is itself one of the major problems of political philosophy. Broadly, however, one may characterize as political all those practices and institutions that are concerned with government.

A brief treatment of Western political philosophy follows. For full treatment, *see* MACROPAEDIA: Political Philosophy, The History of Western.

Of first importance in political philosophy is the analysis of the state and related institutions. The question of the state leads to those of sovereignty (the power and authority assumed by the ruler) and political obligation (the duty and submission assumed by the ruled). Under what conditions, if any, can political obligation arise, and what is its extent? Political obligation tends to be upheld on grounds either of utility or of justice. But what is justice? This question was regarded by Plato and Aristotle as the fundamental question of political theory, and it remains high on the agenda of modern liberal philosophers. No political philosophy is complete without an account of law and constitution. What is a law, how are laws justified, and how far should they extend? Are there forms of reasoning that are special to law? Finally, the concept of a constitution is one of the major inventions of Western thought and describes the condition of "limited government"—government that is circumscribed by its own procedures.

The first major work of political philosophy in the Western tradition was Plato's *Republic,* defending a well-ordered, authoritarian state presided over by a "philosopher king." Aristotle's *Politics* rejected Plato's approach in favour of a detailed consideration and step-by-step justification of existing political institutions, including both the family and private property. Both philosophers influenced the Roman tradition of civil thought, which is best exemplified by Cicero and Polybius. They also profoundly influenced St. Augustine, whose *City of God* began the long tradition of Christian political thinking, in which a concept of natural law is used to describe and to circumscribe the rights and duties of the sovereign. Medieval thinkers such as St. Thomas Aquinas further developed that idea, while philosophers of the Italian Renaissance—of whom Francesco Guicciardini and Niccolò Machiavelli were the most prominent—concerned themselves with the problem posed by the need for both the existence of power and its limitation.

The seminal work of modern political philosophy—the *Leviathan* (1651) of Thomas Hobbes—raised the problem of political obligation in its modern form and tried to give a theory of sovereignty that would incorporate the conclusions of Machiavelli. Hobbes was followed by Baruch de Spinoza, John Locke, and Jean-Jacques Rousseau in the exposition of a social-contract theory of political obligation. This theory was rejected by David Hume and also by Friedrich Hegel, whose *Philosophy of Right* (1821) set the stage for 19th-century political thought by making the questions of private property and individual freedom central to the analysis of political order. Hegel's defense of private property stimulated Karl Marx's critique of it; J.S. Mill meanwhile developed Jeremy Bentham's utilitarian theory of law and political institutions, so as to reconcile them with a demand for individual liberty.

By the beginning of the 20th century, political philosophy had become so diversified that few philosophers recognized a single set of problems that they shared with their competitors. Recent work has been characterized by a division between Marxists (concerned with sociological analysis and the "class struggle") and more traditional liberal thinkers, who remain attached to the problems posed by the concepts of liberty and right. Such a division is by no means exhaustive—there are also pragmatic conservatives in the tradition of Edmund Burke, and latter-day Hegelians—yet, it accounts for one of the major existing barriers of comprehension.

political science, academic discipline concerned with the study of government and politics.

A brief treatment of the discipline of political science follows. For full treatment, *see* MACROPAEDIA: Social Sciences, The.

For a description of the place of political science in the circle of learning and for lists of both MACROPAEDIA and MICROPAEDIA articles on the subject, *see* PROPAEDIA: Part Five, Division IV.

Political science studies the functions performed by governments—*e.g.*, legislation and administration of the law—as well as the behaviour of voters, the operation of political parties, the influence of political organizations, and other factors in the functioning of the state. The discipline, which is concerned with observing patterns in political behaviour and deriving principles from the data, is generally distinguished from political philosophy, a normative field that is concerned with such concepts as "right," "justice," and "obligation."

Speculation on political subjects is found in the thought of many ancient cultures, but it is generally agreed that the roots of political science are found in the works of Plato and Aristotle. The scientific character of the discipline was developed by the Christian Socialist Henri de Saint-Simon and by Auguste Comte and other 19th-century Positivists. During this period political science became allied with other disciplines that were beginning to study human behaviour by using scientific techniques, and scholars began to examine actual human behaviour as reflected in political life. A pioneer in this development was Ludwig Gumplowicz, who drew upon ideas from anthropology and from Charles Darwin's theory of evolution and who focused attention on the interactions that take place between groups within the state.

During the last three decades of the 19th century, institutions dedicated specifically to the study of political science were established. The first such institution was the Free School of Political Sciences (now the Institute for Political Studies, of the University of Paris), founded in 1871. Although a chair in history and political science had been created in 1857 at Columbia University, it was not until 1880 that John W. Burgess, who had studied at the Free School of Political Sciences, established a separate school of political science at Columbia. The London School of Economics and Political Science was founded in 1895, and the University of Oxford established a separate chair in politics in 1912.

One of the most influential books in American political science was Arthur F. Bentley's *The Process of Government* (1908). Following Gumplowicz, Bentley made the concept of the group central to his thought, and he considered how governmental actions could be understood in terms of human activities. In the 1920s and '30s, the so-called Chicago school, which later influenced the development of behavioralism, assumed preeminence in political science. Charles E. Merriam and Harold D. Laswell, leading members of the school, emphasized the role of psychological factors in political life, though Merriam was also interested in the use of mathematical techniques such as statistics in the analysis of politics.

Since World War II the techniques of systems analysis have become increasingly important in political science. This approach, particularly as developed by David Easton in *The Political System* (1953), studies politics as that part of the overall social system whose activities involve the making of social policy and the distribution of social goods. Systems analysis also provides a broad framework for other topics of study, such as the interactions of interest groups, elite classes, and political parties.

Politis, Nikolaos Sokrates (b. Feb. 7, 1872, Corfu, Greece—d. March 4, 1942, Cannes, Fr.), Greek jurist and diplomat, a champion of disarmament and the peaceful settlement of disputes. He was president of the Institute of International Law (1937–42) and was largely responsible for the founding of the Academy of International Law at The Hague.

After holding law professorships at Aix-en-Provence, Poitiers, and Paris, Politis was summoned in 1914 to reorganize the Greek Ministry of Foreign Affairs, of which he became director general. After becoming Greece's minister of foreign affairs in 1916, he attended the Paris Peace Conference in 1919 as the Greek delegate. Later, as the representative of Greece in the League of Nations, he wrote the report on the Geneva Protocol (1924), and, as vice president of the Disarmament Conference, he framed the official League definition of aggression. Among Politis' published works on jurisprudence are *La Justice internationale* (1924) and *Les Nouvelles Tendances du droit international* (1927; *New Aspects of International Law*).

Politis
H. Roger-Viollet

Polivanov, Aleksey Andreyevich (b. March 16 [March 4, Old Style], 1855—d. Sept. 25, 1920, Riga, Latvia), general in the imperial Russian army who, during World War I, was appointed minister of war in 1915 to revitalize the sagging Russian war effort. A capable administrator of liberal sympathies, he was dismissed after less than a year.

Having fought in the Russo-Turkish War of 1877–78, Polivanov served on the army's general staff (1899–1904), during which time he edited several journals. He was chief of the general staff from 1905 to 1906 and was assistant minister of war from 1906 to 1912, but he was dismissed from the latter post for being too cooperative with liberal elements in the Duma. From 1912 to 1915 he served on the State Council. As minister of war from June 1915 to March 1916, Polivanov reorganized the army's training program as well as the military production and supply system. He also unsuccessfully tried to dissuade Tsar Nicholas II from personally assuming supreme command of Russia's armed forces in September 1915. Nicholas eventually dismissed Polivanov from his ministry at the instigation of the empress, Alexandra.

Polivanov offered his services to the Red Army in February 1920 and was a military expert at the Soviet–Polish peace talks in 1920 at Riga, where he died of typhus.

Poliziano, Angelo (Renaissance scholar): *see* Politian.

polje (Serbo-Croatian: "field"), elongated basin having a flat floor and steep walls; it is formed by the coalescence of several sinkholes. The basins often cover 250 square km (about 100 square miles) and may expose "disappearing streams." Most such basins have steep enclosing walls that range from 50 to 100 m (165 to 330 feet) in height, giving rise to the name "blind valley." The flat floor of a polje is characteristically covered with a soil composed of the residues of limestone solution. These areas may constitute the only arable part of the rock wasteland in a karst region. *See also* karst.

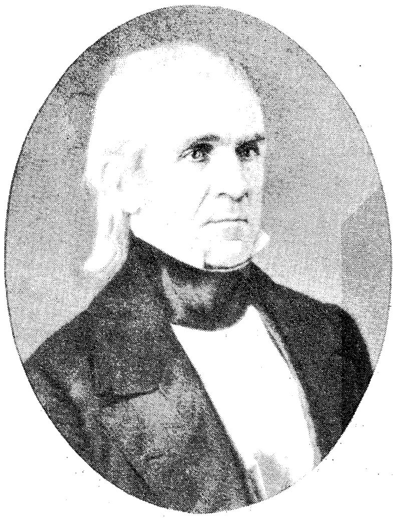
Polk, James K(nox) (b. Nov. 2, 1795, Mecklenburg County, N.C., U.S.—d. June 15, 1849, Nashville, Tenn.), 11th president of the United States (1845–49). Under his leadership the United States fought the Mexican War (1846–47) and acquired vast territories along the Pacific coast and in the Southwest.

Early life and career. At the age of 11 Polk accompanied his family to Tennessee, where his father operated a prosperous farm in Maury County. Though ill health made formal schooling impossible during his childhood, at the age of 20 he successfully passed the entrance requirements for the second-year class of the University of North Carolina. He was "correct, punctual, and industrious," and as a graduating senior in 1818 he was the Latin salutatorian of his class—the preeminent scholar in both the classics and mathematics.

After graduation he returned to Tennessee and began to practice law in Nashville. His interest in politics, which had fascinated him even as a young boy, was encouraged by his association with leading public figures in the state. In 1820 he was admitted to the bar. Because he was a confirmed Democrat and an unfailing supporter of Andrew Jackson and because his style of political oratory became so popular that he was characterized as the "Napoleon of the stump," his political career was assured.

His rapid rise to political power was furthered by his wife, Sara Childress Polk (1803–91), whom he married Jan. 1, 1824, while serving in the state house of representatives (1823–25). The social prominence of her family and her personal charm were distinct assets for a politically ambitious lawyer. As an official hostess she won the admiration and esteem of the leading figures of the day, and for 25 years she was her husband's close companion in state and national politics.

James K. Polk was by nature a student of government, by experience a legislator, and by force of circumstance an administrator. He was not an easy man to know or to like. Even



James K. Polk, daguerreotype by Mathew Brady, 1849

close companions did not relish his austerity, and associates tolerated but did not approve his inflexible living standards. Among his few close friends was Andrew Jackson, who encouraged and advanced Polk and whose influence carried him from the Tennessee House of Representatives to the United States House of Representatives, where he served from 1825 to 1839.

As speaker of the House during that time, Polk acquired a reputation as an undeviating supporter of Jacksonian principles. In 1839 he left the House to become governor of Tennessee. Two defeats for a second term (1841, 1843) by small majorities convinced him that to strengthen his party he should return to Washington in some capacity.

Polk's nomination as the Democratic candidate for president in 1844 was unsought by him, for the party had more prominent sons in Martin Van Buren, Lewis Cass, and James Buchanan. But the Democrats could not reconcile their differences, and a compromise candidate had to be found because the campaign was to be run on issues and not on personalities; it was decided that Polk would do. He is regarded as the first "dark horse" nominee in the history of the presidency.

It was thought that Polk, as a party man from what was then the West, and a former member of the House of Representatives, would bring about legislative and executive cooperation and understanding in the functioning of the national government. While speaker of the House he had decided many procedural questions and had usually been sustained by majorities composed of the leaders of both parties. His party feeling was intense, but his integrity was unquestioned; he knew the rights and privileges of the House, and he also knew its responsibilities.

During his campaign Polk surprised the country by taking a positive stand on two burning issues of the day. Whereas other candidates hedged on the question of whether to annex Texas, which had been independent of Mexico since 1836, he demanded annexation. Whereas other candidates evaded the problem of joint occupancy of Oregon with England, he openly laid claim to the whole territory that extended as far north as 54°40′ with the campaign slogan "Fifty-four Forty or Fight." His election was close, but it was decisive—a popular plurality of about 38,000 and 170 electoral votes against 105 for Henry Clay.

Presidency. Not yet 50 years of age, Polk was the youngest successful presidential candidate up to that time. He entered the presidency full of vigour and with an expressed zeal to serve his country to the best of his ability. He left it four years later exhausted and enfeebled by his efforts. In office he demonstrated remarkable skill in the selection and control of his official advisors, and in his formal relations with Congress his legislative experience served him well. When his party was firmly united behind a policy he himself opposed, he yielded to the wishes of Congress. When he disagreed strongly with congressional policy and decided to make an issue of it, he fortified his position with recognized executive precedent and practice. His formal disapprovals (in the form of two message vetoes and one pocket veto, by which legislation is killed by the failure of the president to sign a bill before the adjournment of Congress) were questioned, but the two returned measures failed to command the necessary two-thirds majority in order to override his vetoes.

The Polk administration was marked by large territorial gains. The annexation of Texas as a state was concluded and resulted in a two-year war with Mexico. As a consequence of that war the Southwest and far West (California), partly by conquest and partly by purchase, became part of the U.S. domain. During this period the northwestern boundary became fixed by treaty, and the continental United States emerged a recognized reality.

Additional achievements included a treaty with New Granada (Colombia) resolving the problem of right-of-way for U.S. citizens across the Isthmus of Panama; establishment of a warehouse system that provided for the temporary retention of undistributed imports; and the passage of the Walker Tariff Act of 1846, which lowered import duties and did much to pacify British public opinion that had been inflamed over the Oregon compromise of 1846 that established the international frontier at the 49th parallel. As these measures helped foreign trade, so the reenactment of the independent treasury system in 1846 helped in the solution of domestic financial problems.

The expansion of the country westward led to the creation of a new agency, the Department of the Interior. The Polk administration should also be credited with the establishment of the United States Naval Academy at Annapolis and the authorization of the Smithsonian Institution, a national foundation for all areas of science.

Assessment. Polk's influence over his Congresses may be gauged from the results of the recommendations of 4 annual messages and 10 significant special messages to one or both houses. His control of legislative policy in bitterly partisan Congresses must be judged in terms of results, not oratory or parliamentary delay. He recommended with a high degree of success settlement of a trade dispute with Great Britain, an increase in U.S. armed forces, war with Mexico, peace with Great Britain over Oregon, making available finances to expedite peace conclusions, organization of the Oregon Territory, peace with Mexico providing for limited conquest, and a revised treasury system. He refused information desired by Congress (on the ground that it was incompatible with the public interest), recognized a new French revolutionary government, and proclaimed the validity of the Monroe Doctrine. Succeeding presidents recognized these pronouncements.

A diary kept by Polk during his term of office stressed the presidential burden. Day after day, week after week, he recounted in his diary his experiences with the hosts of office seekers who infested Washington and who occupied so much of his public time. Again and again there is evident in his writings a note of despair. He knew from experience what an evil an unlimited executive patronage can become, but he felt powerless to change its obligations and too conscientious to avoid its duties. At the close of his term, March 4, 1849, Polk retired to his Nashville home, where he died three months later.

The office of chief executive under Polk was well filled—maintained with dignity, integrity, and an extraordinary sense of duty. His great influence over Congress was due to the justness of his policies and his persistence in having the members see questions not as interests of district or section but as matters of national welfare. His sturdy character and unblemished reputation gave weight to his counsels and strengthened his pleas. History may not rate him as one of the greatest U.S. presidents, but his successes in office made his influence considerable. (G.C.R.)

BIBLIOGRAPHY. James D. Richardson, *Messages and Papers of the Presidents,* vol. 4 (1897), includes a noteworthy biographical sketch in its Polk section. The restricted accounts on aspects of his life before the presidency, E.I. McCormac, *James K. Polk: A Political Biography* (1922, reprinted 1965); and C.G. Sellers, *James K. Polk, Jacksonian, 1795–1843* (1957), are highly selective. M.M. Quaife (ed.), *The Diary of James K. Polk During His Presidency, 1845 to 1849,* 4 vol. (1910), is a reliable, almost complete printing of the manuscript and a revelation of a president's mind.

Polk, Leonidas (b. April 10, 1806, Raleigh, N.C., U.S.—d. June 14, 1864, Pine Mountain, Ga.), U.S. bishop of the Protestant Episcopal Church, founder of the University of the South, and lieutenant general in the Confederate Army during the U.S. Civil War.

After two years at the University of North Carolina (1821–23), Polk entered the U.S. Military Academy at West Point, from which he was graduated in 1827. But during his final year there, Polk underwent a profound religious experience and resigned his commission at the end of 1827 to enter the Virginia Theological Seminary.

In 1830 Polk was ordained a deacon in the Protestant Episcopal Church, and in May 1831 he was advanced to the priesthood. He was appointed missionary bishop of the Southwest in 1838 and was made bishop of Louisiana in 1841. Polk attempted to combine his religious duties with life as a benevolent and paternalistic planter, since by marriage he acquired a large number of slaves. Polk also turned his energies toward creating an Episcopal university in the South, dedicated to training Southern aristocrats in their responsibilities toward blacks, who Polk anticipated would be gradually emancipated. In 1856 he began to raise funds and acquire land for the school, and on Oct. 9, 1860, he laid the cornerstone for the University of the South at Sewanee, Tenn.

With the coming of the Civil War, Polk, after some hesitation, accepted a commission as major general in the Confederate Army. Put in charge of defending the Mississippi River, Polk performed well despite his lack of practical military experience. On Nov. 7, 1861, he defeated Ulysses S. Grant's smaller force at Belmont, Mo., and he personally led four charges at Shiloh while in command of the Confederate right flank. In October 1862 he was promoted to lieutenant general. Polk sustained fatal wounds in fighting at Pine Mountain, Ga., in June 1864—four years before classes opened at the University of the South.

polka, lively courtship dance of Bohemian folk origin. It is characterized by three quick steps and a hop and is danced to music in $\frac{2}{4}$ time. The couples cover much space as they circle about the dance floor. Introduced in Paris in about 1843, it became extraordinarily

"The Original Polka," coloured lithograph by J. Brandard, 1844; Jules Perrot and Carlotta Grisi are the dancers

popular in ballrooms and on the stage, sweeping across Europe and the Americas from Scandinavia to Latin America and developing many varieties. Still popular in the 20th century both as a folk dance and as a ballroom dance, polkas also appear in stage works—*e.g.*, in Jaromir Weinberger's opera *Schwanda the Bagpiper* and in Bedřich Smetana's opera *The Bartered Bride.*

poll tax, tax of a uniform amount levied on each individual, or "head."

Of the poll taxes in English history, the most famous was the one levied in 1380, a main cause of the peasant's revolt of 1381 led by Wat Tyler. In the United States, most discussion of the poll tax centred on its use as a voting prerequisite in the Southern states. The origin of the tax is associated with the agrarian unrest of the 1880s and 1890s, which culminated in the rise of the Populist Party in the West and the South. The Populists, a low-income farmers' party, gave the Democrats in these areas the only serious competition that they had experienced since the end of Reconstruction. The intensity of competition led both parties to bring blacks back into politics and to compete for their vote. Once the Populists had been defeated, the Democrats amended their state constitutions or drafted new ones to include various disfranchising devices. When payment of the poll tax was made a prerequisite to voting, impoverished blacks and often poor whites, unable to afford the tax, were denied the right to vote.

Poll taxes of varying stipulations lingered in Southern states into the 20th century. Some states abolished the tax in the years after World War I, while others retained it. Its use was declared unconstitutional in federal elections by the Twenty-fourth Amendment to the U.S. Constitution, effective in 1964. In 1966 the Supreme Court, going beyond the Twenty-fourth Amendment, ruled that under the "equal protection" clause of the Fourteenth Amendment, states could not levy a poll tax as a prerequisite for voting in state and local elections.

Pollaiuolo, Antonio del and Piero del, Pollaiuolo also spelled POLLAJUOLO, original names ANTONIO E PIERO DI JACOPO D'ANTONIO BENCI (respectively b. Jan. 17, 1432/33, Florence—d. Feb. 4, 1498, Rome; b. 1443, Florence—d. 1496, Rome), Italian brothers who, as sculptors, painters, engravers, and goldsmiths, produced myriad works together under a combined signature. The Pollaiuolo brothers had significant influence on the development of Florentine art, and their workshop is regarded as one of the most important in Florence during the late 15th century.

The brothers received the name of Pollaiuolo because their father was alleged to have been a poulterer (from *pollaio,* "hen coop"), though he was probably a goldsmith. Antonio learned goldsmithing and metalworking from either his father or Andrea del Castagno. Piero probably learned painting from Andrea del Castagno and became his brother's associate in goldsmithing, painting, sculpture, and engraving.

After 1460 the two collaborated consistently, and the individual contributions of each are frequently difficult to determine. Their Florentine commissions included the altarpiece in the Chapel of the Cardinal of Portugal in S. Miniato al Monte and the "Martyrdom of St. Sebastian" (1475) for the Pucci Chapel in the church of SS. Annunziata. In 1484 they went to Rome, where their works included the tomb of Pope Sixtus IV (1484–93) in the Vatican Grottoes of St. Peter's and, in the final years of their lives, the tomb of Pope Innocent VIII (1493–97), also in St. Peter's.

Antonio Pollaiuolo is recognized individually as a superb draftsman whose mastery of line is best exemplified in his renderings of the human figure in motion; he was among the first artists to practice anatomical dissection in the study of the human form. His contri-

"Hercules and Antaeus," bronze statuette by Antonio Pollaiuolo; in the Bargello, Florence
Alinari—Art Resource/EB Inc.

butions to landscape representation were also significant. Notable works include his engraving "Battle of the Nudes" (*c.* 1470) and the bronze statuette "Hercules and Antaeus" (*c.* 1475).

The individual works of Piero are regarded as less artistically significant than those of his brother. His principal works were his "Coronation of the Virgin," an altarpiece painted in 1483 (in the choir of the cathedral at San Gimignano); his "Three Saints," an altarpiece; and "Prudence" (both at the Uffizi Gallery).

Pollaiuolo, Simone del: *see* Cronaca, Il.

Pollard, A(lbert) F(rederick) (b. Dec. 16, 1869, Ryde, Isle of Wight, Hampshire, Eng.—d. Aug. 3, 1948, Milford-on-Sea, Hampshire), English historian who was the leading Tudor scholar of the early 20th century.

He was educated at Felsted School and at Jesus College, Oxford. In 1893 he was appointed to the editorial staff of the *Dictionary of National Biography,* to which he contributed about 500 entries, mainly on figures in the Tudor period. During that period, before the *Dictionary* was completed (through the first supplement), he completed two biographical volumes, *England Under Protector Somerset* (1900) and *Henry VIII* (1902).

Quitting the *Dictionary of National Biography* in 1901, he was elected to the chair of constitutional history at University College, London, in 1903; he held that position until his retirement in 1931. At the University of London he firmly established the history degree course and strove to promote postgraduate research. In 1906 he founded the Historical Association, which served teachers of history and which, from 1916, published the periodical *History.* The Institute of Historical Research, of which he was chairman (1921–31) and honorary director (1931–39), was largely his achievement.

Pollard's works on English history under the Tudor dynasty—including his volume *The History of England from the Accession of Edward VI to the Death of Elizabeth (1547–1603)* (1910) in "The Political History of England" series and his books on *Thomas Cranmer and the English Reformation* (1904), *The Elizabethans and the Empire* (1921), and *Wolsey* (1929)—were models of careful and enduring work. On more modern subjects he wrote *The Commonwealth at War* (1917), *A Short History of the Great War* (1920), and *Factors in American History* (1925). He also wrote *The Evolution of Parliament* (1920; 2nd ed. 1926).

Pollard, Marjorie (b. 1899, Peterborough, Northamptonshire, Eng.—d. March 21, 1982), field hockey player who became one of England's greatest players. She was also editor of *Hockey Field* magazine from 1946 to 1970.

Pollard competed in her first hockey match at school as a goalkeeper, but when her team was beaten 17–0, she opted to become a forward. She won her first cup for England in 1921 and, except for two short periods, played regularly for the national team until 1933.

Her goal-scoring feats were extraordinary, including eight goals that she scored against Germany in 1926 and 13 in the 20–0 defeat of Wales in 1928. Pollard spent most of her career with the Peterborough club before founding North Northants, for whom she played her last match in 1949. After her retirement Pollard became acting president of the All England Women's Hockey Association and a sports journalist.

pollarding, cutting of top tree branches back to the trunk, leaving club-headed stems that grow a thick head of new branches. The purpose in some areas is to limit the area of top growth or to create an annual harvest of boughs for basket weaving, securing thatch, and the like. In cities such as London it is done to prevent branches from tangling with overhead wires and from overhanging streets and to promote growth of a denser foliage.

pollen, a mass of microspores in a seed plant appearing usually as a fine dust. Each pollen grain is a minute body, of varying shape and structure, formed in the anther, or male apparatus, in seed-bearing plants and transported by various means (wind, water, insects, etc.) to the pistil, or female structure, where fertilization occurs. The pollen grain of flowering plants (angiosperms) consists of three distinct parts. The central cytoplasmic part is the source of nuclei responsible for fertilization. The other parts constituting the wall of the grain are an inner layer, the intine, and an outer layer, the exine. The intine consists, at least in part, of cellulose. The outer and most durable layer, the exine, is very resistant to disintegration; treatment with intense heat, strong acids, or strong bases has little effect upon it. The composition of the exine is uncertain; its constituents have been termed sporopollenins. The internal parts of the pollen grain are easily broken down, whereas the exine layer, and thus the general form of the pollen grain, is easily preserved in various kinds of sediments; the quality of preservation may vary with different environments.

Because of their remarkably symmetrical structure and surface patterns, pollen grains are readily recognizable under the microscope. The structure of the wall of a pollen grain is oftentimes so characteristic that in some cases species may be identified by pollen grains alone. On the other hand, there are cases in which pollen grains of very like structure occur in quite unrelated plant families.

Because of their high resistance to decay, their widespread dispersal by wind and water, and their abundant production by plants, pollen grains are very common constituents of geologic sediments, both recent and ancient. Because of these features pollen grains have provided much information on the origin and geologic history of terrestrial plant life.

Pollen is produced in such quantities that it is a significant component of the airborne constituents of the Earth's atmosphere, especially in areas over continents. The proteinaceous substance in many pollen grains (namely, ragweed and many grasses) induces an allergic reaction commonly known as hay fever (*q.v.*). Frequently local governmental authorities publish pollen counts, estimates of the concentration of pollen grains in the air, for the purpose of indicating the relative discomfort that may be experienced by sufferers from hay fever and similar allergies.

The study of pollen and spores is known as palynology (*q.v.*). *See also* pollination.

Consult the INDEX *first*

Pollen, Daniel (b. June 2, 1813, Dublin—d. May 18, 1896, New Zealand), Irish-born physician, prime minister of New Zealand (1875–76), and a public figure who combined business and politics with his profession and worked for such liberal causes as the enfranchisement of women and the rights of the Maori.

Pollen settled in New Zealand in the 1840s, purchased land, practiced medicine, and contributed articles to the *New Zealander* in support of such issues as temperance, libraries, and responsible government. Appointed to the Auckland superintendent's office (1852, 1854) and elected to the Provincial Council (1856, 1857–61), he accepted appointment as commissioner of crown lands for Auckland (1858–62) and began his life-long support of the Maori cause. Pollen served on the Legislative Council (1861–62, 1868–70), and in 1870, after attempting to resign in protest at the government's censure of his approval of a truce offer to a Maori guerrilla leader, he not only was agent for Auckland but also became receiver of land revenue, commissioner of confiscated lands, commissioner under the native land Act of 1870, and immigration officer.

Recalled by the government of Sir Julius Vogel to the Legislative Council, Pollen joined this ministry as colonial secretary until he formed his own ministry for a few months (1875–76). He remained a member of the "continuous ministry" of Vogel and Sir Harry Atkinson as colonial secretary and native minister (1876–77), and he served on the Legislative Council until his death.

Pollentia, modern POLLENZA, ancient town in the territory of the Statielli in Liguria, northern Italy, located 10 miles north of Augusta Bagiennorum (Vagienna) on the Tenarus (Tanaro) River. Its position on the road from Augusta Taurinorum (Turin) to Hasta (Asti) gave it military importance in ancient Roman times.

Decimus Brutus checked Mark Antony's retreat at Pollentia in 43 BC. The Roman general Stilicho on Easter Sunday, April 6, AD 402, fought a battle there with the Goths. Though it was indecisive, the leader of the Goths, Alaric, afterward withdrew them from Italy. Pollentia was noted for its pottery and its dark-coloured wool. Remains survive at the village of Pollenza.

pollex: *see* thumb.

pollination, the transfer of pollen grains in seed plants from the stamens, where they are formed, to the ovules or ovule-bearing organs. Pollination is a prerequisite for fertilization and the production of seeds.

A brief treatment of pollination follows. For full treatment, *see* MACROPAEDIA: Reproduction and Reproductive Systems.

In flowering plants the ovules are contained at the base of a hollow pistil, and the pollen is deposited on the pistil's surface, the stigma. There the pollen grains germinate and form pollen tubes that grow downward toward the ovules. Fertilization takes place as a sperm cell in a pollen tube fuses with the egg cell of an ovule, giving rise to the plant embryo. The ovule then grows and becomes a seed.

Since the pollen-bearing parts of the stamens are rarely in contact with the stigma, plants commonly rely on external agents for pollen transport. Insects and wind are the most important pollinators; other agents include birds and a few mammals. Water transport of pollen is rare. Very ancient flowering plants apparently developed odours and mechanical traps to attract and hold beetles, which would scatter stray grains after they fed on the pollen. More advanced species began to produce nectar, a concentrated sugar solution found in modern flowers, and developed patterns of colour as guides for insects to the presence of nectar. Insects acquired sucking mouthparts capable of feeding on the nectar.

Fertilization of an egg cell may take place by self-pollination, when the sperm cell derives from pollen produced by the same flower or by another flower on the same plant; or by cross-pollination, when the sperm comes from the pollen of a different plant. Cross-pollination, producing seeds that contain the hereditary traits of two parent plants, tends to result in a species that is sturdier and more adaptable to environmental changes.

Many plants have developed mechanisms that prevent self-pollination. Some species produce only male (staminate) flowers on some plants and only female (pistillate) flowers on other plants. Species with staminate and pistillate flowers on the same plant and those with flowers having both stamens and pistils often avoid self-pollination by shedding their pollen either before or after the stigmas on the same plant are receptive to it. Another preventive device is chemical self-incompatibility; the pollen either fails to grow on a stigma of the same plant or fails to produce pollen tubes that reach the ovules. Self-pollination is sometimes advantageous, however, and may take place when external pollinators are scarce, when plants are widely scattered, or when cross-pollination has not occurred at the end of a flower's life span. It is common among annual plants, which often produce an abundance of seed to ensure species survival.

The most important insect pollinators are the bees, which live on nectar and feed their larvae on pollen and honey, a modified nectar. Bees have long tongues that can reach the nectar; hairy bodies that pick up sticky pollen grains, facilitating their transport to another flower; and a sensitivity to colours and aromas that helps guide them to nectar-producing flowers. Bee flowers are brightly coloured, fragrant, and open in the daytime. Many have a broad lower lip on which the bee can land before pushing its way inside the flower.

Pollination by wind, although prevalent in the conifers and cycads, is less common in flowering plants. Plants that depend on wind pollination produce copious quantities of light, powdery pollen that can be blown a considerable distance; but even so, an individual stigma is likely to be hit by only one or two grains. To facilitate exposure to the wind, the flowers often bloom before the leaves come out in the spring, or they may grow high up on the tree or plant. Stigmas tend to be long and lobed to provide a large area for catching pollen grains, and plants of one species frequently grow in dense populations. Wind flowers are usually inconspicuous and devoid of the fragrance, colours, and nectar that attract insects.

Birds are important as pollinators, especially in tropical regions. Many species have adapted to feeding on nectar, pollen, or flower-inhabiting insects or spiders by developing slender beaks and brushlike or tubelike tongues. Birds rely on their powerful vision and colour sense in their quest for food, and bird-pollinated flowers often display vivid colours. They generally lack the fragrance of most insect flowers, are bigger and more sturdily built, and produce greater quantities of nectar. The stamens are usually numerous and protruding so that they touch the bird as it feeds. Some bird flowers provide a landing platform or a perch of twigs near the flower. A few species of small mammals, notably certain bats, also help to pollinate plants as they feed on the flowers.

Pollio, Gaius Asinius (b. 76 BC, Italy—d. AD 4, Tusculum, near Rome), Roman orator, poet, and historian who wrote a contemporary history that, although lost, provided much of the material for Appian and Plutarch.

Pollio moved in the literary circle of Catullus and entered public life in 56. In 54 he impeached unsuccessfully the tribune C. Cato, incurring Pompey's displeasure. In the Civil War he joined Caesar at the Rubicon and campaigned in Africa with Curio and (49–45) in Greece, Africa, and Spain with Caesar, for whom he held a praetorian command in Spain against Sextus Pompey (44). On Caesar's death he followed Antony, for whom he governed Cisalpine Gaul. There he was friendly with Virgil and in distributing land to veterans saved the poet's property from confiscation. He stood aloof in the Perusine War but held his army firmly in Antony's interests, and he shared in the negotiations leading to the pact of Brundisium between Antony and Octavian in 40. In that year he was consul, and Virgil addressed his Fourth Eclogue to him. In 39 Pollio subdued the Parthini, an Illyrian people. From the booty he built the first public library in Rome, in the Atrium Libertatis, which he restored. With full honours he then retired from public life. Unwilling to join Antony in the east, hoping for nothing from Octavian, he took no part in the Actium campaign (31) and subsequently maintained a position of republican dignity and independence. He gave hospitality to the rhetorician Timagenes, when the latter was in disgrace with Augustus. This was the main period of his activity as an advocate, and he devoted himself to the support of literature, organizing public recitations.

Pollio was a distinguished orator, combining, according to Tacitus and Seneca, careful composition and dry Atticist elegance in strict presentation of his argument. His style displeased Ciceronian critics, and his speeches are lost. As a poet he was accepted by Catullus, Helvius Cinna, and Virgil. He also wrote tragedies, which Virgil and Horace praised, but he ceased to write serious verse when he turned to history shortly after 35. His *Historiae* (*History of the Civil Wars*) covered the period from 60 probably to 42; that is, from the First Triumvirate to Philippi—the period in which the Roman republic fell. A stern critic of men and style, he corrected Caesar, attacked Cicero, and praised Brutus; he reprimanded Sallust for archaism and Livy for a quality of provincialism that Pollio termed *Patavinitas*. Above all, he defended Roman *libertas* under the *principatus* of Augustus.

Pollio, Marcus Vitruvius: *see* Vitruvius.

Pollitt, Harry (b. Nov. 22, 1890, Droylsden, Lancashire, Eng.—d. June 27, 1960, at sea en route from Australia to England), British Communist, general secretary (1929–39, 1941–56) and chairman (1956–60) of the Communist Party of Great Britain (CPGB).

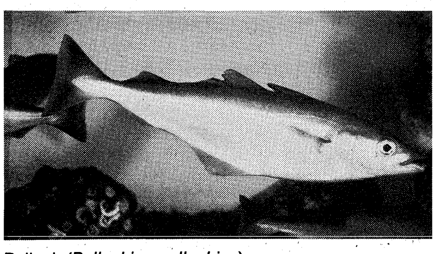
Pollitt's father was a factory worker and trade unionist and his mother a weaver in a textile manufacturing village. At age 13 (1903) he left school to work in the local textile mill and eventually became a boilermaker and a leader in the boilermakers union. He helped found the CPGB in 1920 and went to Moscow in 1921 to attend a congress of the Third International, where he met Lenin. In 1925 he was sentenced to a year's imprisonment for seditious libel and incitement to mutiny. (In 1934 he was acquitted in another sedition trial.) In 1929 he became head of his party as general secretary.

Pollitt enthusiastically supported Britain's declaration of war against Germany on Sept. 3, 1939; but when Russia invaded Poland two weeks later, the official Moscow line changed, and Pollitt was caught in an embarrassing contradiction. He was removed from the secretaryship. Following the outbreak of war between Germany and the Soviet Union in June 1941, however, Pollitt was returned to leadership of the party.

He was caught again in a contretemps in 1956, when, while he was praising Stalin, the secret 20th Party Congress in Moscow was condemning the former Soviet leader. Pollitt was again set aside, this time given the nominal post of chairman of the British Communist Party. His autobiography, *Serving My Time*, appeared in 1940.

polliwog: *see* tadpole.

pollock (*Pollachius*, or *Gadus, virens*), North Atlantic fish of the cod family, Gadidae, known as saithe, or coalfish, in Europe. The pollock is an elongated fish, deep green with a



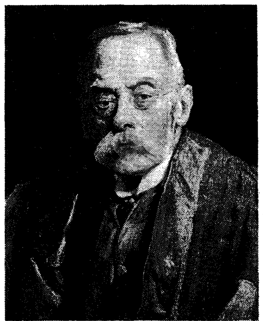
Pollock (*Pollachius pollachius*)
Ingmar Holmasen

pale lateral line and a pale belly. It has a small chin barbel and, like the cod, has three dorsal and two anal fins. A carnivorous, lively, usually schooling fish, it grows to about 1.1 metres (3½ feet) in length and 16 kilograms (35 pounds) in weight. It is caught commercially for food and also affords sport for anglers.

The pollock classified as either *Gadus* or *Pollachius pollachius* is a related species of no commercial value found inshore in European waters.

Pollock, Sir Frederick, 3RD BARONET (b. Dec. 10, 1845, London—d. Jan. 18, 1937, London), English legal scholar, noted for his *History of English Law Before the Time of Edward I* (with F.W. Maitland, 2 vol., 1895) and for his correspondence over 60 years with U.S. Supreme Court Justice Oliver Wendell Holmes.

Pollock was called to the bar in 1871, taught jurisprudence at Oxford (1883–1903), succeeded his father in the baronetcy in 1888,



Sir Frederick Pollock, portrait by R.G. Eves; in the National Portrait Gallery, London
By courtesy of the National Portrait Gallery, London

and was made a king's counsel in 1920. He was a founder and the first editor (1885–1919) of the *Law Quarterly Review* and also edited the *Law Reports* (1895–1935). Three of Pollock's textbooks remained in use for many years: *Principles of Contract* (1876), *Digest of the Law of Partnership* (1877), and *The Law of Torts* (1887). The *Holmes-Pollock Letters*, edited by Mark De Wolfe Howe, were published in 1941.

Pollock's son, Frederick John Pollock (1878–1963), a noted historian, succeeded to the baronetcy.

Pollock, (Paul) Jackson (b. Jan. 28, 1912, Cody, Wyo., U.S.—d. Aug. 11, 1956, East Hampton, N.Y.), American painter, one of the leading exponents of a loose movement called Abstract Expressionism, particularly the form known in the United States as Action Painting (or *tachisme* in France). After considerable stylistic experimentation, he developed about 1947 the radical "drip painting" technique that became his hallmark.

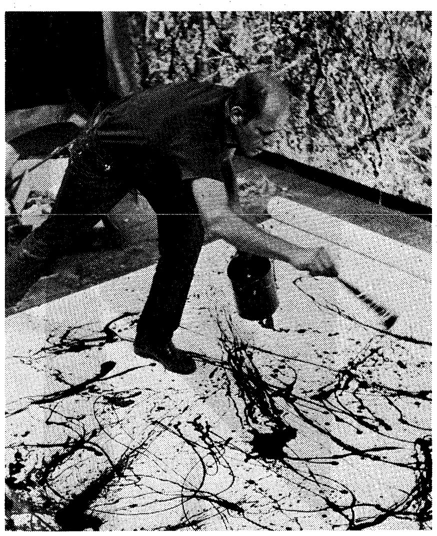
Pollock's family left Cody, Wyo., 11 months after his birth, and he grew up in California and Arizona. In Los Angeles in the late 1920s he was taught and influenced by Frederick John de St. Vrain Schwankovsky, a painter and illustrator who was also a member of the Theosophical Society, a mystical religious sect. Pollock was also drawn to an exploration of unconscious imagery espoused by adherents of Surrealism.

In the fall of 1930 Pollock followed a brother to New York City, where he enrolled at the Art Students League under his brother's teacher, the regionalist painter Thomas Hart Benton. In the fall of 1935 he came to be employed on the WPA Federal Art Project as an easel painter. This provided economic security during the years of the Great Depression and the opportunity to develop his art through early 1943. In 1937 he began psychiatric treatment for alcoholism, and he briefly suffered a nervous breakdown in 1938. In 1943, after the liquidation of the Federal Art Project, he was given a contract by Peggy Guggenheim at her Art of This Century Gallery in New York City, and his first one-man show was held there in November. Thereafter he had one-man shows of new work nearly every year. In 1945 he married the painter Lee Krasner and moved to East Hampton, Long Island, N.Y., where he lived until his death in an automobile accident.

Pollock's artistic development went through a number of evolutions. From his years with Benton to 1938, his work was strongly influenced by the methods and subject matter of his teacher and consisted mostly of small landscapes and figurative scenes such as "Going West." After his breakdown and hospitalization in 1938 until the time of his first one-man show in 1943, his work was semi-abstract and shows the assimilation of motifs from the modern Spanish artists Pablo Picasso and Joan Miró as well as the Mexican muralist José Clemente Orozco. Jungian symbolism and Surrealist theory also influenced the works of this period. Paintings such as "Bird," "Male and Female," and "Guardians of the Secret" reflect these influences in their powerful and seething imagery.

Late in 1943 or early in 1944, Pollock painted his first wall-size work, called "Mural." This painting is his breakthrough into a totally personal style in which Benton's compositional methods and energetic linear invention are fused with Surrealist free-association of motifs or unconscious imagery. His evolution from this point through the 1940s shows a struggle to find a process by which he could translate his entire personality into painting. In 1947 he first used the process of pouring or dripping enamel or aluminum paint onto a flat canvas in stages, often taking weeks of alternating periods of painting and contemplating to finish a canvas. The results were huge areas covered with complex and dynamic linear patterns. A whole series of paintings—beginning with "Full Fathom Five" and proceeding through "Summertime" and "Number Ten, 1949" to the mural-size canvases of 1950 such as "One," "Autumn Rhythm," "Lavender Mist," and the black and white "Number Thirty-two, 1950"—display the infinite variety of effect and expression that this method—poured painting—permitted him. In 1951 and 1952 he painted almost exclusively in black and white. In 1952 he returned to colour and mural-scale in "Convergence" and "Blue Poles." In 1953 he created his last series of major works. "Portrait and a Dream," "Easter and the Totem," "Ocean Greyness," and "The Deep," among other works, recapitulate many aspects of his former styles and images. Though his production waned and his health deteriorated after 1953, Pollock did produce important paintings such as "White Light" and "Scent" in his last years.

From the early 1940s on, Pollock created numerous works on paper, ranging from drawings to mixed-media paintings that parallel the development of his work on canvas. He created few prints, however, and only experimental sculpture.



Pollock painting in his studio on Long Island, New York, 1950
Hans Namuth

His critical reception ranged from the favourable art criticism of Clement Greenberg in *The Nation* during the 1940s to *Time* magazine's reference to him as "Jack the Dripper" a few months before his death in 1956. Despite occasional attempts in the art press to treat his work seriously, his name became synonymous with extreme artistic caprice, since the novelty of his "drip" technique overshadowed his obsession with the personal expression which that technique may have permitted. Ironically, he did not profit financially from his fame. He never sold a painting for more than $10,000 in his life and often was hard-pressed for cash.

BIBLIOGRAPHY. The definitive biography to date, along with all known statements by the artist, a detailed history of his exhibitions and their critical reception, and a comprehensive bibliography, is Francis V. O'Connor, *Jackson Pollock* (1967). Interpretative monographs have been written by Frank O'Hara, *Jackson Pollock* (1959); Bryan Robertson, *Jackson Pollock* (1960); Italo Tomassoni, *Pollock* (1968; Eng. trans. 1969); and Alberto Busignani, *Pollock* (1979).

Pollock v. Farmers' Loan and Trust Company (1895), U.S. Supreme Court case in which the court voided portions of the Wilson–Gorman Tariff Act of 1894 that imposed a direct tax on the incomes of U.S. citizens and corporations, thus declaring the federal income tax unconstitutional. The decision was mooted (unsettled) in 1913 by ratification of the Sixteenth Amendment to the federal Constitution, giving Congress the power "to lay and collect taxes on incomes."

The 1894 act provided (for a five-year term) that "gains, profits and incomes" in excess of $4,000 would be taxed at 2 percent. In compliance with the Tariff Act, the Farmers' Loan and Trust Company, a New York financial institution with vast holdings, announced to its shareholders that it intended to pay the tax and also to provide the U.S. collector of internal revenue a list of all persons for whom the company was acting in a fiduciary capacity who were liable for tax under the act.

Charles Pollock, a citizen of Massachusetts who owned 10 shares of the company's stock, filed a lawsuit seeking to enjoin the company from carrying out its stated intention to comply with the act. He lost in the lower courts, but the Supreme Court ruled in his favour. It declared that a direct income tax was a breach of the constitutional provision requiring that direct taxes be apportioned among the states according to population.

A highly unpopular decision, *Pollock* v. *Farmers' Loan and Trust Company* spurred the Democratic Party to include an income tax plank in its 1896 platform and to charge the court with "judicial usurpation." Farmers and workers saw the decision as one designed to protect wealthy individuals and corporations from paying their fair share of the cost of government. Sen. Norris Brown of Nebraska declared that the Supreme Court was wrong in its interpretation of the Constitution and proposed the explicit language permitting an income tax that was incorporated into the Sixteenth Amendment. He said it was imperative that Congress "give the court a Constitution that cannot be interpreted in two ways." The Senate and House of Representatives approved the amendment in 1909, and it was ratified in 1913.

pollution, the addition to the environment of any substance or energy form (*e.g.,* heat, sound) at a rate that results in higher than natural concentrations of that substance or energy form.

A brief treatment of pollution follows. For full treatment, *see* MACROPAEDIA: Conservation of Natural Resources.

Pollutants commonly are classified according to the part of the environment primarily affected by them; either the air, water, or land. Subgroupings depend on characteristics of the pollutants themselves: chemical, physical, thermal, and others. Many pollutants affect more than one resource.

Some pollutants, such as noise, produce only local and short-lived effects. Others, such as smelter slag, affect limited areas but may persist for many years. Some substances, such as radioactive dusts and certain pesticides (*e.g.,* DDT), can be relatively long lasting and can disperse readily to the point that they become virtually worldwide in distribution. Such pollutants, which include many chlorinated hydrocarbon insecticides and several toxic mercury compounds, may enter biological food chains by becoming concentrated in the bodies of microorganisms (algae and protozoans) and move upward as successively larger organisms prey upon smaller ones. The concentration of the pollutant may increase 100-fold at each stage of the chain, so that the predator at the top of the chain is the organism most seriously affected.

The control of pollution has provided many of the most difficult economic, legislative, and administrative questions of the 20th century. Many serious pollutants are closely and fundamentally bound to vital agricultural or industrial systems or products. Abatement of a given pollutant may involve the total redesign of an industry or its product.

pollution and purification, in Hinduism, twin concepts central to the ritual and social order. The notions of pollution and purification are based on Hindu beliefs that each caste group can maintain its status by regulating its contact with lower caste groups (that is, by avoiding their "polluting" effects) and by regulating its contact with objects thought to be inherently impure.

Important delimiters of caste pollution include: (1) occupational association with the destruction of cows (considered sacred), typified by some leatherworkers and shoemakers; (2) occupational destruction of living things, typified by slaughterers; (3) occupational association with death and decay, typified by funeral officiators and scavengers; (4) occupational association with human emissions, typified by barbers, washermen, midwives, and lavatory attendants. The participants in such occupations are deemed polluted in varying degrees, and physical contact with either their persons or their bodily emissions—*i.e.,* external pollution—is thought to be contaminating.

The notion of pollution by physical contact also includes the conception that a person is vulnerable to internal pollution (as by ingesting impure foodstuffs). While external pollution can be washed off with water, internal pollution requires another means of purification, normally imposed by tradition but on occasion by decision of the caste assembly (sabha).

Because castes are normally endogamous and commensal (*i.e.,* members intermarry and dine together), a polluted individual could, by association, pollute other caste members. Purification rites could include a fine or penalty paid by giving a feast for caste members or Brahmans. A common purification rite is the consumption of a cleansing agent the constituents of which include cow's milk, butter, curds, dung, and urine.

A woman's sexual alliance with a lower ranking male (*anuloma,* or hypergamous, marriage) would normally mean excommunication from the caste. *Pratiloma,* or hypogamous, marriage (an alliance between a male and a lower ranking female) also carries with it a lowering of social rank, but not to the same degree as *anuloma* marriage.

Pollution is therefore a relative term describing the degree to which a caste allows practices that a ritually and socially superior caste group does not permit its members. There is a code of prescriptions, ultimately based on the texts of the traditional Hindu code (dharmashastra), which lays down, in theory at least, the proper standards of conduct for a pure group.

In fact, there are many regional and sectarian differences. Each caste maintains its own standards, infractions of which are adjudicated and punished by the caste itself. An upwardly mobile caste may aim for a higher degree of purity and eventually higher social rank by abstaining from earlier polluting practices, typically by restricting the groups with which it allows intermarriage and commensality or by increasing its observance of vegetarianism.

In all, the concepts of pollution and purity have reinforced the hierarchical nature of the Hindu caste system. At the top are the Vedic Brahmans (those families continuing the practice of Vedic study and ritual); at the bottom are the "untouchables," whose very shadows were once thought to pollute a superior group. This extremism is receding, and untouchability is in fact officially outlawed (*see* untouchable). Other factors in lessening the abuses of caste discrimination are movement from the villages to the cities, increased literacy and education, and new occupational opportunities. Nonetheless, caste, as the basic means of distinguishing between social groups, persists.

Pollux (Roman deity): *see* Dioscuri.

Pollux, also called BETA GEMINORUM, brightest star in the zodiacal constellation Gemini (*q.v.*). A reddish giant star, it has an apparent visual magnitude of 1.15. The stars Castor and Pollux are named for the mythological twins. Pollux is about 40 light-years from the Earth.

Pollux, Julius (fl. last half of the 2nd century AD), Greek scholar and rhetorician from Naukratis, Egypt. The emperor Commodus appointed him to a chair of rhetoric in Athens. He is author of an *Onomasticon,* a Greek thesaurus of terms. The 10-volume work, which has survived incomplete, contains rhetorical material and technical terms relating to a wide variety of subjects, as well as citations from literature. It is especially interesting in discussion of music and the theatre.

polo, game played on horseback between two teams of four players each who use mallets with long flexible handles to drive a wooden ball down a grass field and between two goal posts. It is the oldest of equestrian sports.

History. A game of Central Asian origin, polo was first played in Persia (Iran) at dates given from the 6th century BC to the 1st century AD. Polo was at first a training game for cavalry units, usually the king's guard or other elite troops. To the warlike tribesmen, who played it with as many as 100 to a side, it was a miniature battle.

In time polo became a Persian national sport played extensively by the nobility. Women as well as men played the game, as indicated by references to the Queen and her ladies engaging King Khosrow II Parvīz and his courtiers in the 6th century AD.

From Persia the game spread to Arabia, then to Tibet (the English word polo is the Balti word meaning "ball"), to China, and to Japan. In China (910) the death of a favoured relative in a game prompted Emperor A-pao-chi to order the beheading of all surviving players.

Polo was introduced into India by the Muslim conquerors in the 13th century; but, although the game had been described in Sir Anthony Sherley's *Travels to Persia* (1613), the first Europeans to play the game were British tea planters in Assam, who formed the first European polo club in 1859 at Silchar. The Calcutta Polo Club was formed in the early 1860s. Polo spread rapidly after a captain in the 10th Hussars stationed in India saw a match early in 1866 and immediately formed a team from among his fellow offi-

Persian princes playing polo, miniature from an illuminated manuscript, 1472; in the British Library
Reproduced by permission of the British Library

cers. Before the year ended, informal matches were held between British cavalry units stationed in India. In 1870 a challenge round was held between the 10th Hussars and the 9th Lancers in England. At this time there were eight men to a side and almost no rules. Polo grew rapidly in England, with matches at Richmond Park and Hurlingham attracting more than 10,000 spectators by 1875. After it had been introduced by the military, the sport of polo remained popular with them but also spread to the universities and was popular with the nobility and royalty.

In 1876, the sportsman and newspaper publisher James Gordon Bennett saw his first polo game and introduced it in the United States. Later that year informal games were being played in New York City and by 1877 at Jerome Park racetrack in Westchester County, N.Y., where the Westchester Polo Club was founded the same year. In 1881 the Meadow Brook Club was formed in Long Island, N.Y., by such early outstanding players as Thomas Hitchcock, Sr., August Belmont, and Benjamin Nicoll. The size of the team was reduced to five and then, in 1881 in the United States and in 1883 in England, to four, the present number. Though the rules devised by the Hurlingham Club of England (founded 1886) were at first used in the United States, in 1888 a system of handicapping players (see below) was devised to equalize tournament play. The Polo Association (later the United States Polo Association) was founded in 1890 and standardized the rules. Polo spread throughout the country, though the game long remained one for the rich because of the expense of acquiring and maintaining a stable of polo ponies. Outside the United States, the governing body is the Hurlingham Polo Association, which maintains relations with many national bodies.

International competition. The first international competition took place in 1886 when the United States unsuccessfully challenged the English, then the undisputed world leaders in polo, for the Westchester Cup. England defended the Cup successfully in 1902, but the United States won in 1909. The Cup was contested nine additional times (the last in 1939), with the Americans winning each time except in 1914. The next international meeting was in 1971, when the United States defeated England for the first Coronation Cup, a single-game rather than a three-game match, thereafter held annually.

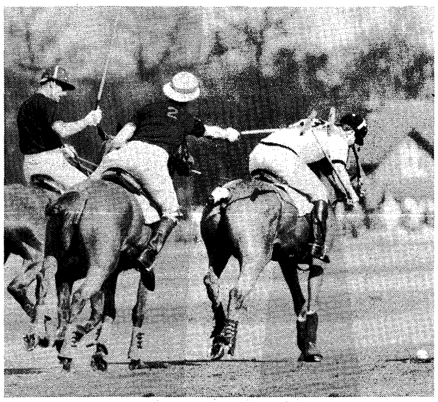
After 1909 the style of the game changed from the relatively slow English form of play characterized by short, controlled hitting. American polo players used a long-hitting, fast-moving, wide-open style that revolutionized the sport. The rules of the two countries were eventually assimilated, the United States adopting the English rule permitting a player to hook an opponent's stick with his mallet, while the English abandoned their offside rule that forbade players preceding the ball.

From 1909 to 1950 the United States was supreme in polo. Through the 1920s and 1930s polo became increasingly popular in Argentina, and in 1928 the first Copa de las Americas (Cup of the Americas) was contested between the United States and Argentina. Since then Argentina has become the uncontested master of international polo. Polo became the Argentine national game, and crowds exceeded 60,000. International matches commercially sponsored (mainly at Boca Raton, Fla.) were held in the 1970s, and European championships were inaugurated in 1980.

Although in the 20th century it is far from common, British and American women also play polo. In the United States, women compete against women on the collegiate level, and there is a women's National Handicap competition. Occasionally a woman also acts as the fourth member of an otherwise all-male team.

The game. Polo is played on an outdoor grass field 300 yards (274.3 metres) long by 160 yd wide. Centred at each end are lightweight goal posts 8 yd apart. A score is made by hitting the ball between the goal posts. Play begins with the two teams of four lined up facing each other in the centre of the field. One of the umpires (there are two mounted umpires on the field and a referee on the sidelines) bowls the ball between the teams. Then, with passes to teammates, speed, and maneuvering, each team tries to score as the opponents try to prevent a score. A game consists of six periods of 7½ minutes each, called chukkers, chukkars, or chukkas. Eight chukkers are played in Argentina, and four is a common number in England and on the Continent.

The players. Each player is assigned a position with certain responsibilities, but the positions are numbered, not named. The basic duties of the players are as follows: Number One is usually the novice or weakest player



Centre player trying to prevent a shot by hooking his stick under the stick of the player at right
UPI/EB Inc.

on the team, though the position is one of the most difficult to play. Number One needs anticipation, determination, and self-control, being theoretically responsible for scoring goals and neutralizing the opposing Number Four (defensive player). Number Two is the "hustler" or "scrambler," always scrapping for the ball. He needs extremely maneuverable, fast ponies, a keen eye, and an optimistic, aggressive nature. Number Three, who plays quarterback, is a kind of pivot man. He must be a long, powerful hitter and is the tactical leader. He must feed balls up to Number One and Number Two, but he must also help maintain a solid defense. Number Three is usually the best player on the team. Number Four is primarily a defensive player, who, though he may move anywhere on the field, mainly functions to prevent scoring.

Polo ponies. Restrictions on size having been removed after World War I, the term pony is purely traditional. The mount is a full-sized horse and should have docility, speed, endurance, and intelligence. The pony is judged to be 60 to 75 percent of a player's ability. At first only Thoroughbreds were used, but horses of mixed breeding are now common. Most of the best ponies are bred in Argentina or in Southwestern or Rocky Mountain ranches in the United States, where they are broken early and are worked as cow ponies. A training period beginning at about age five lasts from six months to two years. Ponies reach their peak at about age 9 or 10 but, barring accidents, may play until age 18 or 20.

Handicaps. Each player is rated from 0 to 10 according to his ability in competition. Minus ratings such as −1 and −2 are also used. Rating is based on horsemanship, hitting ability, knowledge of the game, quality of horses, and sportsmanship. The number of 10-goal players has not increased, though the total number of players has. Argentine dominance is reflected in a virtual monopoly of active 10-goal players.

Equipment. Each player wears a protective helmet, riding boots to just below the knees, and a coloured shirt bearing the number of his position. He may also wear knee pads and spurs (not sharp) and carry a whip. The ball for outdoor polo is made of bamboo or willow root about 3¼ inches (8.3 centimetres) in diameter and weighing about 4 ounces (113.4 grams). The mallet has a rubber-wrapped grip with a webbed thong for wrapping around the hand and a flexible bamboo-cane shaft with a bamboo head 9½ in. in length, the whole weighing about 7 oz and varying from 48 to 53 in., depending on pony size and length of a player's arm. The ball is struck with the side of the mallet, not the end.

Saddles are English-style with deep seats like jumping saddles. The pony's front legs are bandaged from just below the knee to the ankle to prevent injury, and the pony's mane is clipped and its tail braided to prevent interference with the mallet swing.

Indoor, or arena, polo. The indoor game was introduced in the United States and is played predominantly there, thus allowing polo in winter. The field is 100 yd long and 50 yd wide, with wooden boards 4–4½ ft (1.2–1.4 m) high to keep the ball in play. The ball is inflatable leather, 4½ in. in diameter and weighing at least 6 oz. A team has three players instead of four as in the outdoor game. Except for some minor rule changes, the indoor game is basically the same as the outdoor. (R.C.L./Ed.)

Polo, Marco (b. *c.* 1254, Venice, or Curzola, Venetian Dalmatia—d. Jan. 8, 1324, Venice), Venetian merchant, adventurer, and outstanding traveler, who journeyed from Europe to Asia in 1271–95, remaining in China for 17 of those years, and whose *Il milione* ("The Million"), known in English as the *Travels of Marco Polo,* became a geographical classic.

Travels of the Polo family. Marco found his way paved by the pioneering efforts of his ancestors and especially of his father, Niccolò, and his uncle Maffeo. The family had traded with the Middle East for a long time, apparently reaching a position of considerable wealth and prestige. Although it is not quite clear if the family was actually of the nobility, the point lost much of its typically medieval relevance in a city of republican and mercantile traditions such as Venice.

The Polos appear to have been shrewd, alert, and courageous; in about 1260 they foresaw a political change in Constantinople, liquidated their property there, invested it in jewels, and set off for the Volga River, where Berke Khan, sovereign of the western territories in the Mongol Empire, held court at Sarai or Bulgar, according to the season. The Polos seem to have managed their affairs well at this provincial Mongol court, doubling their assets. When political events prevented their return to Venice, they travelled eastward to Bokhara, eventually ending their journey four years later (1265) at the capital of the Mongol Empire, probably the summer residence of the Grand Khan—called Shang-tu (the Xanadu of the English poet Samuel Taylor Coleridge).

Marco Polo, title page of the first printed edition of *The Travels of Marco Polo,* 1477
By courtesy of the Columbia University Libraries, New York

Establishing friendly relations with the great Kublai Khan himself, they were eventually sent back to Europe as Kublai's ambassadors to the Pope, carrying letters asking the Pope to send Kublai one hundred intelligent men "acquainted with the Seven Arts"; they also bore gifts and were asked to bring back some oil from the lamp burning at the Holy Sepulchre in Jerusalem.

Marco himself had meanwhile been born in or around 1254. (This date, like nearly all the others concerning major events in his life, is conjectural.) Nothing is known of his early years in Venice, although it seems fairly certain that he learned little or no Latin. He was a lad of 15 or 16 when he first met his father, on the latter's return from the East in 1269.

Marco's journey to Asia. When Niccolò and Maffeo returned, they found that the Pope (Clement IV) had recently died. They waited patiently in Venice for a new pontiff to be elected, but after two years a successor had not yet been chosen. Becoming restive, the Polos started off on their journey, taking the young Marco with them (1271). In Palestine the papal legate, Teobaldo of Piacenza, gave them letters for the Mongol emperor; the Polos had been only a few days on the road when they heard that their friend Teobaldo had been elected pope (Gregory X). They went back to Acre, where they were given proper credentials and the company of two friars. The small expedition departed once more; the two friars, however, soon lost heart, and the Polos continued alone.

From Acre the travellers proceeded to Ayas ("Laiazzo" in Marco's writings, now Yumurtalik, on the Gulf of İskenderun, also called Gulf of Alexandretta, in southeastern Turkey). During the early part of 1272 they probably passed through Erzurum, in what is now eastern Turkey, and Tabriz, in what is now northern Iran, later crossing inhospitable deserts infested with brigands, before reaching Hormuz on the Persian Gulf. There the Polos decided not to risk a sea passage to India and beyond but to proceed overland to the Mongol capital.

Soon they were on the road again, travelling through deserts of "surpassing aridity" toward the Khorasan region in what is now eastern Iran. Turning gradually to the northeast they reached more hospitable lands; Badakhshān ("Balascian"), in Afghanistan, in particular, pleased the travellers. Marco seems to suggest that they remained here for a year; long illness (possibly malaria) was cured by the benign climate of the district. It has also been supposed that Marco, during this period, visited territories to the south (other parts of Afghanistan, Kafiristan in the Hindu Kush, Chitral in what is now Pakistan, and perhaps Kashmir); it is, however, difficult to establish which districts he traversed and which he may be describing from information gathered en route.

Leaving Badakhshān, the Polos proceeded up the Vākhān ("Vocan") valleys toward the Pamirs, which were eventually crossed by an itinerary that has long been a subject of discussion and conjecture. Descending on the northeastern side of the chain, they reached Kashgar ("Cascar") in what is now the Sinkiang Uighur Autonomous Region of China. By now the Polos were on the main Silk Road, and their advance can be followed along the oases to the south and east of the Takla Makan Desert—Yarkand ("Yarcan"), Khotan ("Cotan"), Charchan ("Ciarcian"), and Lop Nor (Lop Lake)—stepping-stones on the way to Sha-chou ("Saciu") on the borders of China, a place now called Tun-huang (Kansu province).

Before reaching Sha-chou, the Polos had travelled primarily among Muslim peoples—also encountering sprinklings of Nestorian Christians, Buddhists, Manichaeans, and Zoroastrians; now, however, they entered the vast province of Kansu (called "Tangut" by Marco), where an entirely different civilization, mainly Buddhist in religion but partly Chinese in culture, prevailed. Their itinerary most probably took the travellers to Su-chou ("Sukchu") and Kan-chou ("Campiciu") before entering the Ning-hsia area. It is not clear whether the Venetians reached the Mongol summer capital of Shang-tu ("Ciandu") directly or after a detour; at all events, some time in 1275 (1274, according to recent researches by a Japanese scholar, M. Otagi), the Polos were again at the Mongol court, presenting the sacred oil from Jerusalem and the papal letters to their patron, Kublai Khan.

Marco's sojourn in China. For the next 16 or 17 years the Polos lived in the Emperor's dominions—which included, among other countries, Cathay (now North China) and Mangi, or "Manzi" (now South China). Possibly they moved with the court from the summer residence, Shang-tu, to the winter one, Ta-tu or "Taidu"—modern Peking.

Unfortunately Marco's book *Il milione* is only incidentally a biography and autobiography; it is therefore exceedingly difficult to ascertain where the Polos went and what they did during these years. It is well known that many foreigners were in the employ of the Mongol state, since Chinese were mistrusted; it was therefore natural for the Polos to fit in most honourably and successfully with this motley society.

But precisely how successfully? In what specific capacities did they make themselves useful? These and similar points have been discussed for centuries without definite conclusions being reached. The elder Polos were probably employed in some technical role. Once and very abruptly, a glimpse is obtained of them acting as military advisers during the siege of "Saianfu" (historically and presently Hsiang-yang), a city that was finally taken, says Marco, thanks to some "great mangonels" (missile-throwing engines) built according to their specifications. The whole episode is, however, dubious.

Marco himself reached Cathay very young (at the age of 20 or so). Although he knew little or no Chinese, he spoke some of the many languages then used in East Asia—most probably Turkish (in its Coman dialect) as spoken among the Mongols, Arabized Persian, perhaps Mongol, and Uigur Turkish. Marco was noticed very favourably by Kublai Khan, who took great delight in hearing of strange countries; the Emperor repeatedly sent him on fact-finding missions to distant parts of the empire. One such journey took Marco to southwestern China, to Yunnan, and perhaps as far as Tagaung in Burma; on another occasion he visited southeastern China, later giving an enthusiastic description of the city of "Quinsay" (now Hang-chou) and of the populous regions recently conquered by the Mongols. There is ample evidence that Marco considered himself an adoptive son of his new country.

Marco's reticence concerning personal matters has left a void that has been eagerly filled in by romantic hero-worshippers, who see him as a brilliant young courtier enamouring princesses and governing provinces: indeed, a Marco Polo myth has been current for centuries and has often provided a theme for novelists, filmmakers, or dramatists. On the other hand, more sober critics point out that contemporary Chinese records show no trace of Marco. (But under what name was he known: who would recognize the 16th- and 17th-century Italian missionary Matteo Ricci under Li Matou or the 18th-century painter Giuseppe Castiglione under Lang Shih-ning?) They also observe that his reports sound more like echoes of bazaar gossip than gleanings from inner councils. The truth probably lies somewhere in between. Apart from the missions he undertook for the Emperor, Marco's evident competence in matters pertaining to salt and the administration of its monopoly suggest that he may have held some responsibility in this branch of government. According to some texts of *Il milione,* Marco governed the city of Yang-chou (in Kansu) for three years, sometime between 1282 and 1287; but this seems hardly credible and hinges entirely on the reading of one word.

The return to Venice. Some time around 1292 (1290 according to Otagi), a Mongol princess was to be sent by sea to Persia, there to become the consort of Arghun Khan, and the Polos offered to accompany her. It seems that Kublai Khan was unwilling to let them go but finally granted permission. Kublai Khan was then nearing his 80th year, and his death (and the consequent change in regime) might well have been dangerous for a small group of isolated foreigners. They also, naturally, longed to see once more their native Venice and their families.

The Princess, with some 600 courtiers and sailors, and the Polos boarded a fleet of 14 ships, which left the port of Ch'uan-chou ("Zaiton") and sailed southward. The fleet touched Champa ("Ciamba," modern Vietnam), as well as a number of islands and the Malay Peninsula. On the island of Sumatra ("Lesser Giaua") a stop of five months was made to avoid monsoon storms. There, Marco was much impressed by the fact that the North Star appeared to have dipped below the horizon. The fleet then passed near the Nicobar Islands ("Necuveran"), touching land again in Ceylon ("Seilan"). The Chinese ships subsequently followed the west coast of India and the southern reaches of Persia, finally anchoring at Hormuz. The expedition then proceeded to Khorasan, handing over the Princess not to Arghun, who had died, but to his son Maḥmūd Ghāzān.

The Polos eventually departed for Europe, but their movements at this point are not clear; possibly they stayed for a few months in Tabriz. Unfortunately, as soon as they left the Mongol dominions and set foot in a Christian country, at Trebizond in what is now Turkey, they were robbed of most of their hard-won earnings. After further delays, they reached Constantinople and finally Venice (1295). The story of their dramatic recognition by relatives and neighbours, who had thought them long since dead, is a part of Polo lore that is universally known.

Compilation of Il milione. Soon after his return to Venice, Marco was taken prisoner by the Genoese—great rivals of the Venetians at sea—during a skirmish or battle in the Mediterranean; Marco was then sent to Genoa and locked in one of the local prisons. There a most felicitous encounter occurred. The Venetian traveller met a prisoner from Pisa, who had possibly lost his liberty some 10 years earlier at the Battle of Meloria—one Rustichello (or Rusticiano), a fairly well-known writer of romances and a specialist in chivalry and its lore, then a fashionable subject. Marco may have had it in mind to write a report of his 25 years in Asia but possibly did not feel sufficiently at home in either Venetian or Franco-Italian; but now Rustichello was at hand, and the traveller began dictating his tale. The language employed was Franco-Italian—a strange composite tongue fashionable during the 13th and 14th centuries. Page by page the great book was compiled.

Fortunately Marco was soon freed and returned to Venice. His subsequent life can be reconstructed, in part, through the testimony of some legal documents that have reached us. He seems to have led a somewhat retired life, managing a not too conspicuous fortune, and died at the age of 70. A famous story relates how Marco was asked on his deathbed to retract the "fables" he had invented in his book; his answer was that he barely told half of what he actually saw. It is known that in his will he set free a "Tatar slave," who may possibly have followed him all the way from East Asia.

Nature and content of Il milione. The actual personality of Marco is somewhat elusive. Practically all that is known about him derives from the text of his book; the traditional view is that Marco dictated the text, and certainly many portions sound like transcriptions from a tape recording. But was Rustichello always such a passive intrument? Scholarly research has shown that he often asserted his personality and familiar phraseology, especially in the somewhat standardized description of battles.

The book itself was an instant success. "Tutta Italia in pochi mesi ne fu piena" ("In a few months it spread throughout Italy"), wrote Giovanni Battista Ramusio, the 16th-century Italian geographer. Unfortunately, however, people read the book for the wrong reasons—not as history, geography, or travel but as a fantastic romance in which Kublai Khan was ranked with King Arthur and Cathay became a new province in the dreamy topography of chivalry.

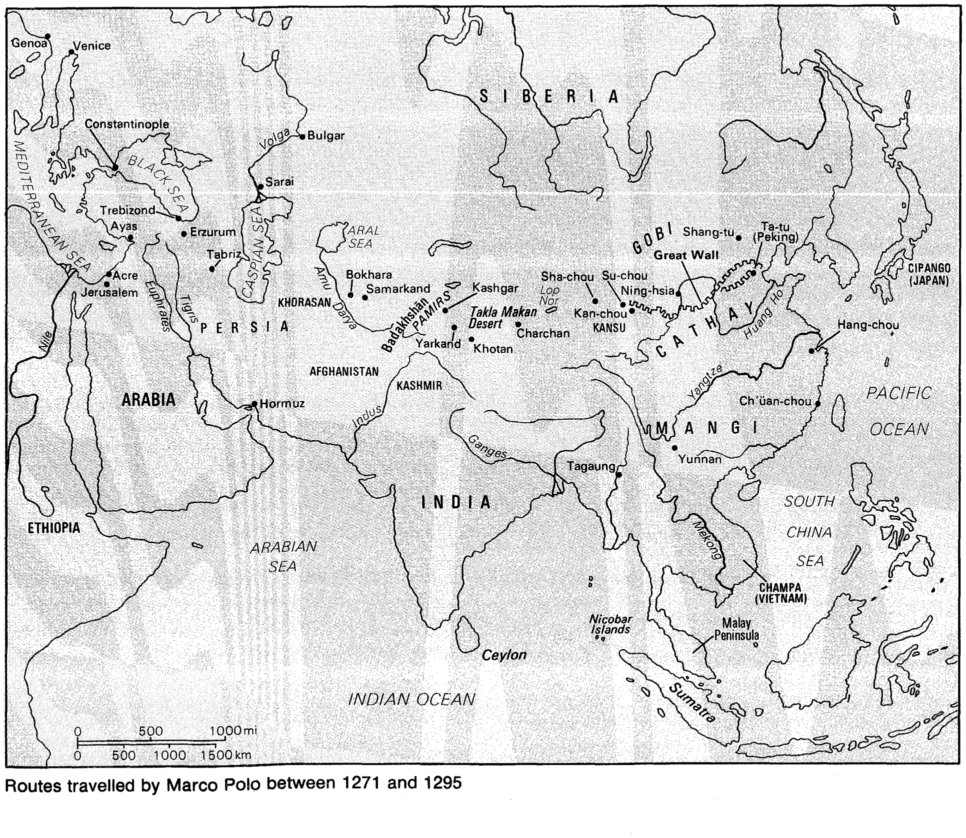
Since all this happened long before the invention of printing, professional scribes or amateurs made dozens of copies of the book, as well as free translations and adaptations—often adding to or subtracting from the text with little or no respect for authenticity. There were also many unfamiliar names that rarely passed unharmed from one copy to another; as a result, modern commentators throw up their hands in despair when confronted with the task of reconstruction. In fact, an authentic and original copy of *Il milione* does not exist; there are some 140 different manuscript versions of the text, in a dozen different languages and dialects—an immensely complex and controversial body of material representing one of the most obdurate philological problems inherited from the Middle Ages.

Marco seems to have made additions and corrections himself, on various copies of the work, during the last 20 years or so of his life. Some editors—for instance, the friar Pipino, who made a good Latin translation of the original—found many of Marco's descriptions or interpretations impious or dangerously near to heresy and therefore heavily bowdlerized the text.

The book seems to have been conceived by Marco as a vast cosmography based on first-hand experience—the book to end all books on Asia. The original title—*Divisament dou Monde* ("Description of the World") is significant; Marco all too often sacrifices personal recollections to doctrinal ambitions. Details concerning travel, stages (*i.e.,* distances covered), and seasons are rarely stated; the panorama is observed from an impersonal distance with a powerful wide-angle lens. In *Il milione* Marco follows a definite itinerary but often branches off into descriptions of places probably visited not by himself but by his relatives or people he knew. Typical digressions are those on Mesopotamia, the Assassins and their castles, Samarkand, Siberia, Japan, India, Ethiopia, and Madagascar. *Il milione* is better understood if considered as forming a part of the vernacular didactic literature, of which the Middle Ages offer many examples.

The origin of the popular title, *Il milione,* is not quite clear; it may have source relation with the idea of a "tall story," but it may also derive from a nickname running in the family, possibly traceable back to a corruption of Aemilione (Big Emil). The complete silence of the poet Dante Alighieri regarding his illustrious contemporary seems to be significant; he evidently considered the book a fable, an invention, and a dangerously heretical one at that. Marco's descriptions of peoples living under the Equator, where according to the orthodox views of the times there should have been nobody, may have appeared particularly alarming.

Marco Polo's subsequent reputation. As a result of such controversies, which have continued for nearly seven centuries, Marco's reputation has suffered dramatic ups and downs. For some he was a genius, a man of prodigious memory, a most conscientious observer,



Routes travelled by Marco Polo between 1271 and 1295 and a successful official at the Khan's court—a man at home in the cosmopolitan Asia of the great Mongol rulers. For others he was a braggart, who made too much of himself; a drifter ready to believe the gossip of ports and bazaars; a man with little culture, scant imagination, and a total lack of humour; a man who failed, among other things, to mention the Great Wall of China, the use of tea, and the ideographic script of the Far East.

A more balanced view must take into account many factors, especially the textual problem and medieval ideas of the world. Modern scholarship and research have, however, given a new depth and scope to his work. It is now generally conceded that he reported faithfully what he saw and heard, even though much of what he heard was fabulous or distorted. In any case, Marco's account opened new vistas to the medieval mind. As Western horizons expanded, Marco's influence became greater and greater. His description of Japan set a definite goal for Columbus in his journey toward the setting sun in 1492, while his detailed localizations of spices encouraged Western merchants to seek out these areas and break the age-old Arab trading monopoly. The wealth of new geographical information recorded by Marco Polo was widely used in the late 15th and the 16th centuries, during the age of the great European ocean voyages. (F.M.)

BIBLIOGRAPHY. A Franco-Italian text of Marco Polo's book, generally considered very near to the lost original, has been edited, collated with many other early manuscripts, and published by L.F. Benedetto, *Il Milione, prima edizione integrale* (1928). This work is fundamental; a long and detailed introduction (in Italian) deals with the complex problems related to the text and its tradition. The works by Sir Henry Yule, now somewhat dated, have been standard texts for decades: *Cathay and the Way Thither: Being a Collection of Medieval Notices on China,* new and enlarged ed., 4 vol. (1913–16, reprinted 1967), and *The Book of Ser Marco Polo, the Venetian, Concerning the Kingdoms and Marvels of the East,* 3rd ed. rev. and enlarged by H. Cordier (1903, reprinted many times). A modern, readable, and dependable translation in English is *The Travels of Marco Polo,* trans. and with introduction by Ronald Latham (1958). The itineraries of the Polos are critically examined in Milton Rugoff, *Marco Polo's Adventures in China* (1964), which follows Marco Polo's tale brilliantly step by step with illustrations from many different sources. A scholarly and very readable introduction to the subject of Marco Polo, his journeys, his book, and his times is L. Olschki, *L'Asia di Marco Polo* (1957; *Marco Polo's Asia,* 1960). Eileen Power, *Medieval People,* 10th ed. (1963), contains a first-rate chapter dealing with Marco Polo and his times.

Polochic River, Spanish RÍO POLOCHIC, river in eastern Guatemala. Its major headstreams arise in the Sierra de Chamá and in the Sierra de las Minas. Flowing eastward for 150 miles (240 km), it forms a delta south of the town of El Estor. The Polochic is navigable as far upstream as Panzós; its principal traffic consists of coffee and lumber. Except for some nickel mining, the river's valley is undeveloped. The unpaved highway linking El Estor with Huehuetenango follows the Polochic Valley.

Polock (Belorussian S.S.R.): *see* Polotsk.

polonaise, also spelled POLONESE, in clothing, a coatlike dress, originally worn by Polish women, that was extremely popular in the 1770s and 1780s in western Europe and North America. It consisted of a fitted bodice with a full skirt, draped in front from the waist and caught up on either side at the back, so that it fell in three large loops.

The underskirt, or petticoat, which showed prominently, was elaborately decorated, quilted, or embroidered. In the 19th century the polonaise gave its name to a short over-

coat, usually fur-trimmed, worn by men and, somewhat later, by women.

polonaise, Polish POLONEZ, in dance, dignified ceremonial dance that from the 17th to 19th century often opened court balls and other royal functions. Likely once a warrior's triumphal dance, it was adopted by the Polish nobility as a formal march as early as 1573 for the coronation of Henry of Anjou as king of Poland. In its aristocratic form the dancers, in couples according to their social positions, promenaded around the ballroom with gliding steps accented by bending the knees slightly on every third step. Polonaise music is in $\frac{3}{4}$ time. The dance was used as a musical form

Polonaise

by such prominent composers as Beethoven, Handel, Mussorgsky, and Chopin.

polonium (Po), a radioactive, silvery-gray or black metallic element of the oxygen family (Group VIa in the periodic table). The first element to be discovered by radiochemical analysis, polonium was discovered in 1898 by Pierre and Marie Curie, who were investigating the radioactivity of a certain pitchblende, a uranium ore. Polonium is a very rare element (its abundance in the Earth's crust is about one part in 10^{15}) that occurs in nature as a radioactive decay product of uranium, thorium, and actinium. The half-lives of its isotopes range from a fraction of a second up to 103 years; the most common natural isotope of polonium, polonium-210, has a half-life of 138.4 days.

Polonium usually is isolated from by-products of the extraction of radium from uranium minerals. It can be produced artificially by bombarding bismuth or lead with neutrons or with accelerated charged particles.

Chemically, polonium resembles the elements tellurium and bismuth. Because polonium is highly radioactive—it disintegrates to a stable isotope of lead by emitting alpha rays, which are streams of positively charged particles—it must be handled with extreme care. When contained in such substances as gold foil, which prevent the alpha radiation from escaping, polonium is used industrially to eliminate static electricity generated by such processes as paper rolling, the manufacture of sheet plastics, and the spinning of synthetic fibres. It is also used on brushes for removing dust from photographic film and in nuclear physics as a source of alpha radiation. Mixtures of polonium with beryllium or other light elements are used as sources of neutrons.

atomic number	84

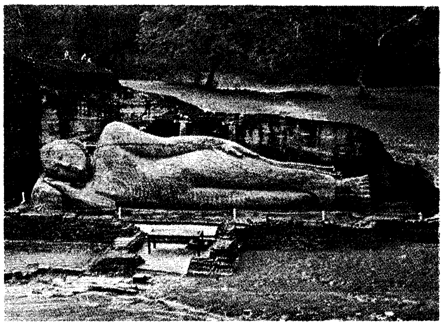
Polonnaruwa, town, north-central Sri Lanka (Ceylon), near the Mahaweli River. It is an ancient Ceylonese capital that was long deserted but has been revived in modern times. Polonnaruwa (Polonnaruva) became the residence



Reclining Buddha, Polonnaruwa, Sri Lanka

Richard Abeles

of Ceylon's kings in AD 368 and succeeded Anuradhapura as the capital in the 8th century when the latter was captured by Tamils. The modern town arose in the 20th century after the restoration nearby of an ancient irrigation reservoir to serve the needs of the surrounding agricultural region, in which rice and tobacco are grown. There is also a rail station. The town contains numerous temples and other Buddhist structures, most of them dating from the 12th century. The most imposing remaining structure is a building 170 feet (52 m) long with walls about 80 feet (24 m) high and 12 feet (3.5 m) thick. Many other great ruins have been carefully excavated and preserved. Pop. (1981 prelim.) 11,793.

Polotsk, also spelled POLOCK, city, Vitebsk *oblast* (administrative region), Belorussian Soviet Socialist Republic. It is situated on the Western Dvina River at its confluence with the Polota. Polotsk, first mentioned in 862, has always been a major trading centre and an important fortress with a remarkably stormy history. Modern Polotsk and its satellite town, Novopolotsk, are railway junctions and industrial centres, with oil-refining, petrochemical, glass-fibre, wood-working, and food-processing industries, as well as a teacher-training institute. Pop. (1985 est.) 79,000.

Polovtsy (Euro-Asian tribal confederation): *see* Kipchak.

Polska: *see* Poland.

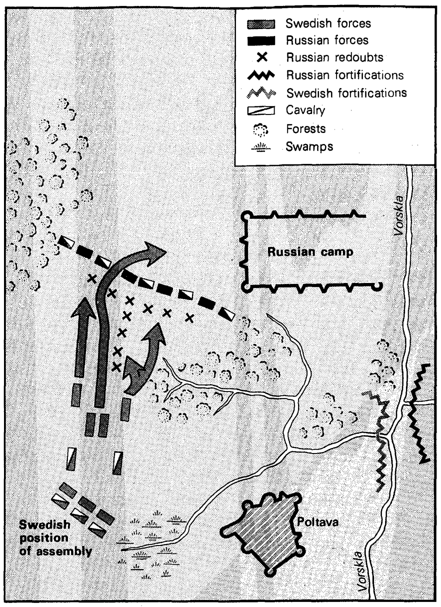
polska (Swedish: Polish), Scandinavian folk dance originating in the 16th century, possibly influenced by Polish courtly dances. Polska in Finland refers nonspecifically to many dances in $\frac{3}{4}$ time, both for individual couples and for sets of several couples. In Sweden the polska is a turning dance in $\frac{3}{4}$ time, usually for couples, who grasp each other firmly and pivot around and around with a smooth, carefully coordinated step. Among its varieties, the *gammal polska,* or old polska, is the simplest and probably the oldest. The lively and very popular *hambo* is a 19th-century offshoot of the *gammal polska.* The Norwegian dance analogous to the Swedish polska is the *pols.*

Poltava, *oblast* (administrative region) in the Ukrainian Soviet Socialist Republic, occupying an area of 11,100 sq mi (28,800 sq km) along the left bank of the middle Dnepr River. It is almost wholly within the forest-steppe zone, only the extreme south lying in true steppe. Except on the meadows of the Dnepr floodplain, soils are fertile. The natural grass and forest vegetation have been very largely removed by plowing, and soil erosion is serious. Surviving groves of oak or pine cover only 6 percent of the surface. Nearly half of the population is rural, reflecting the agricultural importance of the *oblast.* Communities, except Poltava, the administrative centre, and Kremenchug, are small and concerned chiefly with processing farm produce. Agriculture is dominated by wheat, corn (maize), sugar beets, and sunflowers. Natural gas and petroleum are found in several areas, oil is refined at Kremenchug, and iron ore is mined at Komsomolskoye near Kremenchug. Pop. (1983 est.) 1,727,000.

Poltava, city and administrative centre of Poltava *oblast* (region), Ukrainian Soviet Socialist Republic, located on the Vorskla River. Archaeological evidence dates the city from the 8th–9th century, although the first documentary reference is from 1174, when it was variously known as Oltava or Ltava. Destroyed by the Tatars in the early 13th century, it was the centre of a Cossack regiment by the 17th century. In 1709 Peter I the Great inflicted a crushing defeat on Charles XII of Sweden outside Poltava after Charles had laid siege to the town for three months. In 1802 it became a provincial centre.

The modern city of Poltava is largely new, having been reconstructed after it suffered severe damage during World War II. It is the focus of a fertile agricultural region and has a range of industries processing farm produce. Its textile and clothing industries include the largest cotton mill in the Ukraine. There are also important engineering works engaged in diesel-locomotive repair and machine building. Poltava has teacher-training, medical (dealing with mouth diseases), agricultural, and agricultural-engineering institutes and several research establishments. Pop. (1983 est.) 290,000.

Poltava, Battle of (July 8 [June 27, old style], 1709), the decisive victory of Peter the Great of Russia over Charles XII of Sweden in the Great Northern War, ending Sweden's status as a major power and marking the beginning of Russian supremacy in eastern Europe. It was fought north and west of Poltava, west of the Vorskla River, in the Ukraine, between 80,000 Russian troops under Peter the Great and the general Prince Aleksandr Danilovich Menshikov and 17,000 Swedes under Charles XII. The Swedish invasion of Russia had already failed the previous winter, with the loss of their major supply column to the Russians and their failure to receive expected reinforcements. Despite the severe shortages of men, artillery, and powder, Charles continued the war and besieged Poltava in May 1709. The Russians assembled their forces to raise the siege. They set up entrenchments (a countersiege) within a few hundred yards of the Swedish siege lines, thus forcing the Swedes to attack. Charles planned to charge past the Russian line of redoubts, without stopping to subdue them, and directly assault the main Russian defensive position. This called for extreme mobility and daring. But Charles himself lacked mobility because he had been injured a few days before, and his secondary commanders either lacked daring or failed to understand his plan. The Swedish attack faltered; the Russian counterattack, with 40,000 troops, killed or captured the entire Swedish army, except for Charles and 1,500 followers, who escaped south into Turkish territory.



Poltava, the initial Swedish attack

poltergeist (German *Polter,* "noise" or "racket"; *Geist,* "spirit"), in occultism, a disembodied spirit or supernatural force credited with certain malicious or disturbing phenomena, such as inexplicable noises, sudden wild movements, or breakage of household items. Poltergeists are also blamed for violent actions—throwing stones or setting fire to clothing and furniture. Such events are said to be sporadic, unpredictable, and often repetitive.

A poltergeist's activity appears to concentrate on a particular member of a family, often an adolescent, its object being harassment or, rarely, physical harm. When strangers are present, the unusual phenomena often cease. A large portion of those reported to be victimized suffer from hysteria. In many instances, the activities attributed to poltergeists have been explained as natural phenomena—*e.g.,* the normal creaking of boards in an old house. *See also* kobold.

Poltoratsk (Turkmen S.S.R.): *see* Ashkhabad.

poludnitsa, in Slavic mythology, female field spirit, generally seen either as a tall woman or a girl dressed in white. The *poludnitsa* customarily appears in the field at noon, when the workers are resting from their labours. Any human who dares upset her traditional visit risks his health and his life.

The *poludnitsa* is related to the *polevoy,* the male field spirit, who is seldom seen and then only at noon in the fields. Some describe him as a man black as the earth, with grass instead of hair growing out of his head. Others say he dresses in white. In some areas offerings are made to the *polevoy* at night to insure fertility.

Polwarth, Patrick Hume, Lord: *see* Hume, Sir Patrick.

polyacrylonitrile, any of a class of resinous, fibrous, or rubbery substances belonging to the family of organic polymers based on acrylonitrile. Almost all polyacrylonitrile resins are copolymers (*q.v.*), made from mixtures of monomers, with acrylonitrile (*see* nitrile) usually making up the major portion; other monomers often present include butadiene, styrene, vinylidene chloride, or other vinyl compounds.

Acrylic fibres, such as Orlon, contain at least 85 percent acrylonitrile; modacrylics contain 35–85 percent. The inclusion of other monomers confers desirable properties upon the fibres, such as increased affinity for dyestuffs. Acrylonitrile, butadiene, and styrene polymerize together to form the so-called ABS resins, which are hard, tough, strong, and resistant to impact; they are easily fabricated into pipe, structural panels, housewares, and the like. Mixtures of butadiene and acrylonitrile, containing 15–40 percent of the latter, form elastomers called NBR or Buna N rubber, which are highly resistant to abrasion and to attack by hydrocarbon solvents such as gasoline. Saran N is a resin made from acrylonitrile and vinylidene chloride (*q.v.*).

Polyaenus (fl. 2nd century AD), Macedonian rhetorician and pleader living in Rome, the author of a work entitled *Strategica* (or *Strategemata*), which he dedicated to the emperors Marcus Aurelius and Lucius Verus on the outbreak of the Parthian War (162–165).

Strategica, still extant, is a historical collection of stratagems and maxims of strategy written in Greek and strung together in the form of anecdotes; it also includes examples of wisdom, courage, and cunning from civil and political life. Comprising eight books (parts of the sixth and seventh are lost), it originally contained 900 anecdotes, of which 833 are extant. Despite its many errors of judgment and fact, its contents have some historical value. Evidently highly esteemed by the Roman emperors, it was handed down by them as a sort of heirloom and passed to Constantinople, where it was diligently studied by Leo VI, who himself wrote a work on tactics.

polyandry, marriage of a woman to two or more men at the same time; the term is derived from the Greek *polys,* "many," and *anēr, andros,* "man." When the husbands in a polyandrous marriage are brothers or are said to be brothers, the institution is called adelphic or fraternal polyandry. Sometimes in the latter form of union the children are said to be descended from the eldest brother only, whereas in other instances the role of father is established by special ceremony, or the children are said to belong to all brothers equally.

A related form of marital union, sometimes called secondary marriage, obtains when a woman cohabits with a man other than her first husband but without having terminated the first marriage by annulment or divorce.

Polyandry must be distinguished from the privileged sexual access to a woman by several men, a practice not uncommon and often associated with customs of kinship or hospitality. True polyandry is, in fact, so rare a phenomenon as to be considered a curiosity and a response to peculiar localized conditions, but not a survival of an earlier polyandrous stage of civilization, as was contended by the early cultural evolutionists.

polyarteritis nodosa, also called PERIARTERITIS NODOSA, inflammation of blood vessels and surrounding tissue; it may affect functioning of adjacent organs. The word nodosa ("knotty") forms part of the name because of the fibrous nodules along the medium-sized arteries that are affected.

The course and symptoms of the disease vary. Men are more susceptible to it than women. It often follows other illnesses, particularly bronchial asthma, and hypersensitivity to drugs is a suspected cause. The condition is diagnosed by microscopic examination of inflamed tissue. Treatment involves corticosteroid therapy.

polybasite, heavy, black sulfosalt mineral, a sulfide of the elements silver, copper, and antimony ($[Ag, Cu]_{16}Sb_2S_{11}$), that occurs as monoclinic crystals and masses in silver veins, sometimes in large amounts.

Polybasite is found in Chile, Peru, Czechoslovakia, and many localities in Mexico and in the states of Colorado, Montana, Idaho, and Nevada. For detailed physical properties, *see* sulfosalt (table).

Polybius (b. *c.* 200 BC, Megalopolis, Arcadia—d. *c.* 118), Greek statesman and historian who wrote of the rise of Rome to world prominence.

Early life. He was the son of Lycortas, a distinguished Achaean statesman, and he received the upbringing appropriate for a son of rich landowners. His youthful biography of Philopoemen reflected his admiration for that great Achaean leader, and an interest in military matters found expression in his lost book, *Tactics.* He enjoyed riding and hunting, but his knowledge of literature was rather specialized (apart from the historians) and his acquaintance with philosophy superficial. Before 170/169, when he was hipparch (cavalry commander) in the Achaean Confederation, almost nothing is known of his career. But he then became involved in critical events. Encumbered by their war with Perseus of Macedonia, the Romans were watching for disloyalty in the Greek states. Although Polybius declared for open support of Rome and was sent as an envoy to the consul Quintus Marcius Philippus, Achaean help was rejected. After Perseus' defeat at Pydna in 168, Polybius was one of 1,000 eminent Achaeans who were deported to Rome and detained in Italy without trial.

Residence in Rome. At Rome, Polybius had the good fortune to attract the friendship of the great Roman general Scipio Aemilianus; he became Scipio's mentor and through his family's influence was allowed to remain in Rome. It is probable that Polybius accompanied Scipio to Spain in 151, went with him to Africa (where he saw the Numidian king Masinissa), and crossed the Alps in Hannibal's footsteps on his way back to Italy. Shortly afterward, when his political detention had ended, Polybius joined Scipio at Carthage and was present at its siege and destruction in 146; and it is likely that he then undertook a voyage of exploration in the Atlantic, which is related in Pliny the Elder's *Natural History.* Meanwhile, hostilities had broken out between Achaea and Rome, and Polybius was in Corinth shortly after its destruction, in 146. He devoted himself to securing as favourable a settlement as possible for his countrymen and to reestablishing order; and, as the geographer Pausanias states, Achaean gratitude found expression in the erection of statues in his honour at Tegea, Pallantium, Mantineia, Lycosura—where the inscription declared that "Greece would never have come to grief, had she obeyed Polybius in all things, and having come to grief, she found succour through him alone"—and Megalopolis, where it was recorded that "he had roamed over all the earth and sea, had been the ally of the Romans, and had quenched their wrath against Greece." Of Polybius' life after 146 little is known. At some date he visited Alexandria and Sardis. He is known to have discussed political problems with Scipio and Panaetius of Rhodes. He wrote a history of the Numantine War, evidently after 133 BC, and also a treatise on the habitability of the equatorial region; but when he composed the latter is unknown.

Polybius' history of Rome. The Histories on which his reputation rests consisted of 40 books, the last being indexes. Books I–V are extant. For the rest there are various excerpts, including those contained in the collection of passages from Greek historians assembled in the 10th century and rediscovered and published by various editors from the 16th to the 19th century.

Polybius' original purpose was to narrate the history of the 53 years (220–168 BC)—from Hannibal's Spanish campaign to the Battle of Pydna—during which Rome had made itself master of the world. Books I–II form an introduction covering Roman history from the crossing into Sicily against the Carthaginians in 264 and including events in various other parts of the world (especially Achaea) between 264 and 220. In Book III, Polybius sketches a modified plan, proposing to add an account of how the Romans exercised their supremacy down to the destruction of Carthage, in 146.

The events of 168–146 were related in Books XXX–XXXIX. Polybius probably conceived his revision after 146, having by this date completed his narrative down to the end of the Second Punic War. At least Books I–VI seem to have been published by about 150; there is no information as to when the rest of the work, including the revised plan in Book III, appeared.

Conception of history. "All historians," according to Polybius,

> have insisted that the soundest education and training for political activity is the study of history, and that the surest and indeed the only way to learn how to bear bravely the vicissitudes of fortune is to recall the disasters of others.

Practical experience and fortitude in facing calamity are the rewards of studying history and are stressed repeatedly throughout the work. History is essentially didactic. Pleasure is not to be wholly excluded, but the scale comes down sharply on the side of profit. To be really profitable, history must deal with political and military matters; and this is *pragmatikê historia,* in contrast to other sorts of history (IX, 1–2)—genealogies and mythical stories, appealing to the casual reader, and accounts of colonies, foundations of cities, and ties of kindred, which attract the man with antiquarian interests. Its nature is austere, though it may include contemporary developments in art and science. He stands in contrast to the sensationalism of many of his predecessors, who confuse history with tragedy.

In Book II, in which he attacks the Greek historian Phylarchus for practices that might be called unprofessional today, Polybius states:

> . . . A historian should not try to astonish his readers by sensationalism, nor, like the tragic poets, seek after men's probable utterances and enumerate all the possible consequences of the events under consideration, but simply record what really happened and was said, however commonplace. For the object of history is the very opposite of that of tragedy. The tragic writer seeks by the most plausible language to thrill and charm the audience temporarily; the historian by real facts and real speeches seeks to instruct and convince serious students for all time. There it is the probable that counts, even though it be false, the object being to beguile the spectator; here it is the truth, the object being to benefit the student.

This attack on Phylarchus is not isolated. Similar faults are castigated in other historians judged guilty of sensationalism (*cf.* II, 16, 13–15; III, 48, 8; VII, 7, 1–2; XV, 34, 1–36). Nor are these their only weaknesses. Many historians are prone to exaggeration—and that for a special reason. As writers of monographs whose subjects are simple and monotonous, they are driven "to magnify small matters, to touch up and elaborate brief statements and to transform incidents of no importance into momentous events and actions" (XXIX, 12, 3). In contrast to such practices, Polybius stresses the universal character of his own theme, which is to narrate "how and thanks to what kind of constitution the Romans in under 53 years have subjected nearly the whole inhabited world to their sole government—a thing unique in history" (I, 1, 5).

Polybius believed that he had a particular reason for adopting a comprehensive view of history, apart from his own predilection for such a view. He wrote:

> Hitherto the affairs of the world had been as it were dispersed . . .; since this date [220 BC] history has formed an organic whole, and the affairs of Italy and Africa have been interlinked with those of Greece and Asia, all tending towards one end (I, 3, 3–4).

Indeed, only universal history is capable of adequately treating Rome's rise to world power—the historian's synoptic view matches the organic character of history itself:

> What gives my work its peculiar quality, and is nowadays most remarkable, is this. Tyche [Fortune] having guided almost all the world's affairs in one direction and having inclined them to one and the same goal, so the historian must bring under one conspectus for his readers the operations by which she has accomplished her general purpose. For it was chiefly this consideration, coupled with the fact that none of my contemporaries has attempted a general history, which incited and encouraged me to undertake my task (I, 4, 1–2).

The role here allotted to Fortune is somewhat unusual. For clearly the value of history as a source of practical lessons is diminished if cause and effect are at the mercy of an incalculable and capricious power. Usually, although Polybius uses Fortune to cover a variety of phenomena, ranging from pure chance to something very like a purposeful providence, much of the apparent inconsistency springs from his use of purely verbal elaboration or the careless adoption of current Hellenistic terminology, which habitually made Fortune a goddess. Here, however, Fortune seems to be a real directive power, which raised Rome to world dominion—because Rome deserved it. Normally, Polybius lays great emphasis on causality, and his distinction (III, 6) between the causes of an event (*aitiai*) and its immediate origins (*archai*) is useful up to a point, though it is more mechanical than that of the great Greek historian Thucydides and allows nothing for the dialectical character of real historical situations.

An important place in Polybius' work is occupied by his study of the Roman constitution and army and the early history of the city in Book VI. His analysis of the mixed constitution, which had enabled Rome to avoid the cycle of change and deterioration to which simple constitutional forms were liable, is full of problems, but it has exercised widespread influence, from Cicero's *De republica* down to Machiavelli and Montesquieu.

Sources of information. Polybius defines the historian's task as the study and collation of documents, acquaintance with relevant geographical features, and, finally, political experience (XII, 25e); of these the last two are the most essential. And he practiced what he preached, for he possessed good political and military experience and had travelled widely throughout the Mediterranean and beyond. Nor did he neglect written sources; indeed, for his introductory books, covering the period from 264 to 220, they were essential. For the main part of his history, from 220 onward, he consulted many writers, Greek and Roman, but, following precedent, he rarely names them.

He had access to private sources; for example, Publius Cornelius Scipio's letter to Philip V of Macedonia describing the capture in Spain, in 209 BC, of New Carthage (X, 9, 3), and a letter of Scipio Nasica to some Hellenistic king about the campaigns of the Third Macedonian War (XXIX, 14, 3). He almost certainly consulted the Achaean record office and must have drawn on Roman records for such material as the treaty between Carthage and Philip V (VII, 9). It has not been proved that he had access to the Rhodian records. His detailed figures for Hannibal's troop formations in Italy came from an inscription left by Hannibal, which he found in the Temple of Juno on the Lacinian promontory.

Polybius regarded oral sources as his most important, and the questioning of witnesses as the most vital part of a historian's task; indeed, this is one reason why he chose to begin his main history at the year 220. Anything else would be "hearsay at one remove," a safe foundation for neither judgments nor statements.

Style and qualities as a historian. Writing in the 1st century BC, Dionysius of Halicarnassus reckons Polybius among those who "have left behind them compositions which no one endures to read to the end"; that his successors shared this view of Polybius' style is confirmed by the failure of his works to survive except in an incomplete form. The infelicity of Polybius' Greek (which frequently reproduces the conventional phrases of the Hellenistic chancelleries familiar from contemporary inscriptions) lies in its awkward use of long and cumbersome circumlocutions, vague abstract nouns, and pedantic repetitions. To the scholar his style is, however, no great obstacle; and, though in his anxiety to improve his reader he moralizes and belabours the obvious, the perennial interest and importance of his theme will always ensure him a following among those who can enjoy a historian who is accurate, serious, and sensible, who understands the events of which he writes, and, above all, who asks the right questions.

(F.W.W.)

BIBLIOGRAPHY. Two works by Frank W. Walbank, *A Historical Commentary on Polybius,* 2 vol. (1957–67), and *Polybius* (1973), contain both general and detailed discussion and comprehensive bibliographies. The standard text is that of Theodorus Buttner-Wobst, 5 vol. (1866–1904); but Fridericus Hultsch, 4 vol. (1870–92), gives a fuller description of manuscript variants; for the history of the text, John M. Moore, *The Manuscript Tradition of Polybius* (1965), is invaluable. There is a Greek text with an English translation by W.R. Paton, "Loeb Classical Library," 6 vol. (1922–27); and a translation by E.S. Shuckburgh, 2 vol. (1889, reprinted 1962). A *Polybios-Lexicon* (1956–) by Arno Mauersberger is being published.

Polycarp, SAINT (fl. 2nd century; feast day February 23), Greek bishop of Smyrna who was the leading 2nd-century Christian figure in Roman Asia by virtue of his work during the initial appearance of the fundamental theological literature of Christianity. Historically, he formed a link between the apostolic and patristic ages.

By his major writing, *The Letter to the Philippians,* and by his widespread moral authority, Polycarp combated various heretical sects, including certain Gnostic groups that claimed religious salvation exclusively through their arcane spiritual knowledge. Polycarp's *Letter to the Philippians* contains a classic formulation in which he refutes the Gnostics' argument that God's incarnation in, and the death and Resurrection of, Christ were all imaginary phenomena of purely moral or mythological significance.

More important, however, is the way in which Polycarp referred to the apostle Paul in *The Letter to the Philippians.* Not only does he repeatedly quote from Paul's writings but he also stresses the personal importance of Paul as a primary authority of the Christian church. It must be remembered that at that time Paul had been adopted as a primary authority by the Gnostic heretics. Polycarp, in response, reclaimed Paul as a treasured figure of the orthodox church. It is apparently thus partly due to Polycarp that Paul, the disputed apostle, became a theologically respectable part of the Christian church's tradition. Furthermore, Polycarp's orthodox use of the Pauline texts marked a crucial advance in the Christian theology of biblical interpretation. According to certain scholars, Polycarp may even have composed or directly influenced some of the letters traditionally ascribed to St. Paul, the so-called Pastoral Letters (I and II Timothy, Titus). These letters possess a 2nd-century vocabulary and style that are characteristic of Polycarp.

Polycarp's *Letter to the Philippians* is doubly important for its early testimony to the existence of various other New Testament texts. It probably is the first to quote passages from the Gospels of Matthew and Luke, the Acts of the Apostles, and the first letters of St. Peter and St. John. Other immediate postapostolic writers employed a more oral tradition.

Toward the end of his life Polycarp visited Bishop Anicetus of Rome to discuss with him the date at which the Easter festival was to be celebrated, a controversy that threatened to provoke a schism between Rome and Asia Minor. The two men could not reach agreement on a common date on which to celebrate Easter, so they agreed that Rome and Asia Minor would follow different practices in this regard. On his return to Smyrna, Polycarp was arrested by the Roman proconsul and burned to death when he refused to renounce Christianity. This event has been eulogized in the *Martyrdom of Polycarp,* one of the earliest-known Christian documents of this nature.

Polycarp, Martyrdom of (letter): *see* Martyrdom of Polycarp.

polychaete, any worm of the class Polychaeta (phylum Annelida). About 5,400 living species are known. Polychaetes, which include rag worms, lugworms, bloodworms, sea mice, and others, are marine worms notable for well-defined segmentation of the body. They vary in size from a few millimetres to about 3 m (10 feet) and are divided informally into two groups; the errantia, or free-moving forms, and sedentaria, or tube-dwelling forms.

Most body segments bear a pair of parapodia—flat, lobelike outgrowths—with setae, or tiny bristles. The head has short sensory projections (palps) and tentacles. The body is often brightly coloured. The diet consists of minute aquatic plants and animals.

The sexes are usually separate; sperm and eggs are discharged directly into the water, where fertilization occurs. Larvae are free-swimming. Some species are hermaphroditic; *i.e.,* the functional reproductive organs of both sexes are present in one individual. Other species reproduce by budding, in which a portion of an adult's body breaks away to form a new individual.

Polychaetes play an important role in turning over bottom sediments in the sea. The palolo worm (*q.v.*) is used as human food in areas of the South Pacific where it swarms in great abundance at breeding time.

polychaete hypothesis, theory that conodonts (minute toothlike structures found as fossils in marine rocks) are parts of the jaw apparatus of polychaete worms, a class of the annelid, or segmented, worms. Conodonts resemble the jaws (scolecodonts) of polychaete worms in form, and they are found in left and right pairs, as are scolecodonts. Polychaete teeth are known as early as the Ordovician period (about 505 million to 438 million years ago), but conodonts have their first undisputed occurrence earlier, in the Late Cambrian epoch (about 523 million to 505 million years ago). Arguments against the conodont–polychaete relationship include the fact that scolecodonts change little with time, whereas conodonts exhibit great variation and evolution over time. Scolecodonts are composed of chitin, a resistant, horny material similar to fingernails in composition. Conodonts, however, are composed of calcium phosphate, as in the skeletons of vertebrates. Some unknown group of polychaetes may have been able to secrete structures of calcium phosphate, but the large differences in manner of growth between conodonts and polychaete jaws constitute a convincing argument against the polychaete hypothesis.

polychlorinated biphenyl (PCB), any of a class of highly stable organic compounds that are prepared by the reaction of chlorine with biphenyl. A commercial mixture of such chlorinated isomers of biphenyl provides a colourless, viscous liquid that is relatively insoluble in water, does not degrade under high temperatures, and is a good dielectric. Because of these qualities, PCBs are particularly useful as lubricants, heat-transfer fluids, and fire-resistant dielectric fluids in transformers and capacitors. They also are good plasticizers and have found application in points, paper coatings, and certain packaging materials.

PCBs came into widespread industrial use during the 1930s and '40s, but since the mid-1970s the production and application of these chemicals have been restricted because they have been found to be injurious to living organisms. PCBs were never intended to be released into the environment, but they found their way into the air, water, and soil via industrial and municipal waste disposal and leaks from mechanical equipment. The high resistance of PCBs to decomposition ensures that they remain in soils and bodies of water for many years, enabling them to accumulate and enter the food chain. PCBs are particularly toxic to fishes and invertebrates and are fatal to these animals even in small concentrations. PCBs cause liver dysfunction, dermatitis, and dizziness in humans exposed to them. The chemicals are also suspected of being carcinogenic. PCB concentration levels in the environment have dropped since the manufacture and use of the compounds were curtailed in several countries.

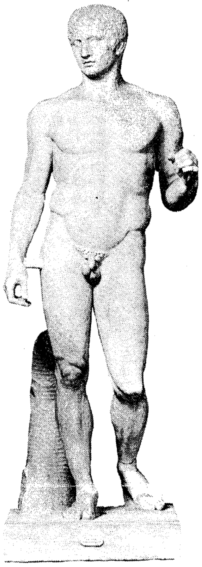
polychlorotrifluoroethylene, synthetic resin belonging to the family of organic polymers, prepared by treatment of an aqueous suspension of chlorotrifluoroethylene with a catalyst composed of a mixture of sodium persulfate and sodium hydrogen sulfite. Polychlorotrifluoroethylene, sometimes abbreviated to CTFE resin, is similar to polytetrafluoroethylene; although it is slightly less resistant to chemical attack, it has the important advantage that it can be shaped by molding or extrusion into solid articles such as gaskets, linings for containers, and parts for valves and pumps. Dispersions of the resin in organic liquids can be used to form protective coatings on surfaces.

polychondritis, disease characterized by inflammation and destruction of cartilages. The disease begins in middle age and most often affects the external ear and the nose; there is painful swelling of the joints when their cartilage is affected. Involvement of the trachea may obstruct breathing or lead to pneumonia. Relapsing polychondritis may affect the inner ear and cause deafness, or it may cause inflammation of the eyes. Corticosteroid drugs are administered to moderate the symptoms of the disease, but the effects on the cartilage cannot be reversed.

Polyclitus, also spelled POLYCLEITUS, or POLYKLEITOS (fl. late 5th century BC), Greek sculptor from the school of Argos, known for his masterly bronze sculptures of young athletes; he was also one of the most significant aestheticians in the history of art.

Polyclitus' two greatest statues were the "Diadumenus" (430 BC; "Man Tying on a Fillet") and the "Doryphorus" (*c.* 450–440 BC;

"Spear Bearer"), the latter work being known as the "Canon" (Greek: Kanon) because it was the illustration of his book by that name. The *Canon* is a theoretical work that discusses ideal mathematical proportions for the parts of the human body and proposes for sculpture of the human figure a dynamic counterbalance—between the relaxed and tensed body parts and between the directions in which the parts move. In Greece this concept was called *symmetria,* and Polyclitus' statues of young athletes, balanced, rhythmical, and finely detailed, were the best demonstration of his principles. His freer use of contrapposto (depiction of the human body with twistings in its vertical axis) helped liberate Greek sculpture from its tradition of rigid frontal poses.



"Doryphorus" ("Spear Bearer"), Roman marble copy of Greek bronze by Polyclitus, about 450–440 BC; in the Museo Archeologico Nazionale, Naples
Hirmer Fotoarchiv, Munchen

Another outstanding work by Polyclitus was his gold and ivory statue of the goddess Hera. As a contemporary of Phidias, Polyclitus was considered by the Greeks of the period to be that sculptor's equal. His "Hera" was ranked with Phidias' gold and ivory statues of "Athena" and "Zeus," and Polyclitus' entry in a competition to make an Amazon for the Temple of Artemis at Ephesos was selected over that of Phidias, among others. None of Polyclitus' original works survive, and the "Doryphorus" and "Diadumenus" are known only through Roman copies.

Polycrates (fl. 6th century BC), tyrant (*c.* 535–522 BC) of the island of Samos, in the Aegean Sea, who established Samian naval supremacy in the eastern Aegean and strove for control of the archipelago and mainland towns of Ionia.

Polycrates seized control of the city of Samos during a celebration of a festival of Hera outside the city walls. After eliminating his two brothers, who had at first shared his power, he established a despotism, and ships from his 100-vessel fleet committed acts of piracy that made him notorious throughout Greece. He made an alliance with Egypt, but, when the Persians advanced against Egypt in 525 BC, he abandoned his ally and sent a squadron of 40 ships to join the Persian fleet. He took the opportunity to send his main political opponents with the squadron; they deserted, however, and, supported by Spartans, attempted unsuccessfully to dislodge the tyrant. He maintained his ascendance until about 522, when Oroetes, Persian governor of Sardis, lured him to the mainland and had him crucified.

In addition to the political and commercial preeminence that his reign brought to Samos, Polycrates was also a patron of letters; the poet Anacreon lived at his court.

polycrystal, any solid object composed of randomly oriented crystalline regions, called crystallites, especially as distinguished from a single crystal (*q.v.*). Polycrystalline materials result when a substance solidifies rapidly; crystallization commences at many sites (*see* nucleation), and the structurally ordered regions growing from each site intersect each other. The random arrangement of the boundaries between individual crystallites in a polycrystal causes them to scatter a beam of light instead of reflecting or refracting it uniformly, so that even colourless polycrystals are opaque. Other mechanical, electrical, or magnetic properties of single crystals are similarly altered by the absence of long-range order in polycrystals.

polycythemia, abnormal increase in red blood cells and hemoglobin in the circulation, a situation that results in thickened blood, retarded flow, and an increased danger of clot formation within the circulatory system. Polycythemia may be relative (*e.g.,* after blood-plasma loss), transient (as when a large number of red blood cells suddenly enter the circulation from storage), or absolute (*i.e.,* reflecting an increase in actual mass of red cells in the body). Relative and transient, or secondary, polycythemia disappear when the condition to which they are secondary is eliminated. Absolute polycythemia, when the cause is known, is called erythrocytosis; this may accompany congenital heart disease, some hemoglobin defects, pulmonary disease (*e.g.,* emphysema, silicosis), the Pickwickian syndrome (a form of obesity), and living at high altitudes.

The situation in which excess red blood cells occur without known cause is called erythremia, primary polycythemia, or polycythemia vera. Symptoms include headache, dizziness, difficulty in breathing, skin changes (*e.g.,* tendency to bruise), an enlarged spleen, and red discoloration of the face and sometimes the extremities. Certain blood-clotting factors are not produced in adequate amounts, and consequently hemorrhages may occur from ulcers or minor wounds. Duodenal ulcer and gout occur with increased frequency in persons with erythremia. The disease is relatively common in Jews, affects men more often than women, and usually appears at middle age or later. Treatment is aimed at reducing the volume of red blood cells.

Polydoûre, Maria: *see* Polidoúri, Maria.

polyembryony, a condition in which two or more embryos develop from a single fertilized egg, forming what in humans is known as identical twins. A common phenomenon in many plant and animal species, polyembryony occurs regularly in the nine-banded armadillo, which usually gives birth to four identical young. Striking examples may be found among parasitic insects of the order Hymenoptera; *Copidosoma truncatellum,* a parasite of certain cutworms, lays a single egg in the body of the host worm from which may develop as many as 2,000 individuals.

polyester, any of a class of organic substances composed of large linear (chainlike) or cross-linked (network) molecules, or polymers, formed from a large number of smaller molecules, or monomers, by establishment of ester linkages between them. Polyesters most commonly are prepared from equivalent amounts of glycols (organic compounds containing two hydroxyl groups) and dibasic acids (containing two carboxyl groups).

The long-chain polyester made from ethylene glycol and terephthalic acid is the basis of the fibre called Dacron, Fortrel, or Terylene and the film Mylar. The polycarbonate resin Lexan is also a long-chain polyester.

The polyester fibres are generally similar in performance and properties. They recover quickly after extension and absorb very little moisture. They melt at about 260° C (500° F). Prolonged exposure to light reduces their strength but does not affect their colour. Polyesters have good resistance to chemicals. They can be washed or dry-cleaned with most common cleaning solvents; they are resistant to attack by insects and microorganisms. Their low moisture content makes them likely to accumulate static charges unless treated with antistatic agents.

Polyesters are made into both woven and knitted fabrics, either alone or blended with other fibres. Industrial applications include ropes, filters, conveyor belts, and tire cords. In surgery, polyester is used to replace or reinforce damaged body tissue.

Liquid linear polyesters made from unsaturated dibasic acids, especially maleic and fumaric acids, can be used to impregnate materials such as glass fabrics, then cured, or converted by cross-linking, into durable, resinous polymers; such composite materials have been widely used for hulls of small boats, patches for automobile bodies, and the like.

Alkyd resins, used in paints, varnishes, and other kinds of coating materials, are cross-linked polyesters of which the principal components are glycerol and phthalic acid.

polyether, any of a class of organic substances prepared by joining together or polymerizing many molecules of simpler compounds (monomers) by establishing ether links between them; polyethers, which may be either chainlike or networklike in molecular structure, comprise an unusually diverse group of polymers.

Polyethylene glycols are water-soluble liquids or waxy solids used in cosmetic and pharmaceutical preparations and in the manufacture of emulsifying or wetting agents and lubricants. Polypropylene glycols are liquids, mostly insoluble in water, used to suppress foaming in industrial processes and for making polyurethane resins, hydraulic fluids, and various other materials.

Epoxy resins, widely used as coatings and adhesives, are prepared by converting liquid polyethers into infusible solids by connecting the long-chain molecules into networks, a process called curing. Phenoxy resins are polyethers similar to those used in epoxies, but the polymers are of higher molecular weight and do not require curing; they are used mostly as metal primers. Polyphenylene oxide resins, such as Noryl, possess great resistance to water and to high temperatures (175°–300° C; 350°–575° F). Penton, a chlorine-containing polyether unaffected by many chemicals, is fabricated into sheets used for lining storage tanks and the like.

Polygalales, the milkwort order of dicotyledonous flowering plants comprising five families, with 26 genera of herbs, shrubs, small trees, and vines. They are characterized by the presence in most species of simple leaves and bilaterally symmetrical, bisexual flowers of distinctive structure that superficially resemble those of the pea family (Fabaceae). Despite this resemblance, the order is related instead to the geranium order (Geraniales), which is considered to be its evolutionary ancestor.

The milkwort family (Polygalaceae), with 12 genera and about 1,000 species, is the largest, most typical, and most important of the order; its members are found throughout the world except in New Zealand, Polynesia, and the far northern parts of North America and Asia. The chief genera are *Polygala* (500 to 600 species, mostly herbs, with the distribution of the family), *Monnina* (150 species, Mexico to

Chile), *Muraltia* (115 species, South Africa), *Securidaca* (80 species, vines and climbers of the tropics excepting Australia), and *Xanthophyllum* (60 species, trees of the Indo-Malayan region that accumulate aluminum in their leaves). The genus *Salomonia* (8 species, Indo-Malayan region and Australia) contains saprophytic (deriving nutrients from decaying matter) plants with scalelike leaves. The seeds of many milkworts (*Polygala* species) have a fleshy appendage (aril) that attracts ants, which carry the seeds about for food and thus distribute them.

The milkwort family is important for the Seneca snakeroot (the root of *Polygala senega*), which is used medicinally. The only genus with any horticultural importance is *Polygala*, with about two dozen species grown as ornamentals—*e.g.*, the bastard box (*P. chamaebuxus*), used in rock gardens; the orange milkwort (*P. lutea*), with showy yellow flowers and used in bog gardens; and the flowering wintergreen or fringed milkwort (*P. paucifolia*), which has purple flowers and is grown in wildflower gardens. All are small herbs less than 30 centimetres (one foot) tall. The common milkwort (*P. vulgaris*) produces showy white, pink, or bluish flowers, usually on separate plants but sometimes on the same plant.

The family Vochysiaceae, mostly consisting of trees and shrubs of Central America and tropical South America, contains six genera and 200 species, of which the most important are *Vochysia* (105 species), *Qualea* (60 species), *Erisma* (20 species), and *Callisthene* (10 species).

The family Trigoniaceae, with four genera and 35 species, consists mostly of shrubs and climbers of Central America and tropical South America. The genera are *Trigonia* (30 species), and *Lightia, Trigoniastrum,* and *Humbertiodendron,* which have only one or two species each.

The family Tremandraceae is a group of small herbs and heather-like shrubs of Australia that have small leaves. Unlike the other families of the order, which have irregular (bilaterally symmetrical) flowers, those of this family are regular (radially symmetrical). The genera are *Tetratheca* (20 species), *Tremandra* (2 species), and *Platytheca* (one species).

The family Krameriaceae (of doubtful inclusion) comprises the genus *Krameria,* 15 species of shrubs that occur in warm regions from the southern United States to Chile. They are little-known parasites on the roots of other plants.

polygamy, marriage to more than one spouse at a time—either polygyny, marriage with more than one woman, or polyandry (*q.v.*), marriage with more than one man. The term polygamy is often used, however, as a synonym for polygyny, which appears once to have been common in most of the world. Nowhere, however, has it been the exclusive form of marriage. Among most peoples who permit or prefer it, the large majority of men live in monogamy either because of a limited number of eligible women or because only the well-to-do can afford to support several wives and households.

From the male viewpoint polygyny may be preferred for several reasons: the economic contributions of the wives to the wealth of the household; the availability of sexual companionship, especially in those cultures where pregnancy and lactation dictate abstinence for the married couple; and the enhanced social status and prestige that accrue to the head of a large household. Polygyny also offers certain advantages to women. Particularly in societies that provide no institutionalized role for the unmarried woman, a surplus of women may make polygyny a preferred way of life. Shared labour is also a factor, as it lightens the woman's economic burdens. Despite certain advantages to both sexes, the polygynous family is commonly fraught with bickering and sexual jealousy. To preserve harmony, one wife, usually the first, is accorded seniority, and each wife and her children have separate living quarters or compounds.

The practice of polygyny in developing countries is becoming increasingly unfeasible, as a result of economic changes, urbanization, and mass education. The general prestige of Western ways and the influence of the Western women's movement have also contributed to the decline of polygyny.

polyglot Bible, any of several editions of the Bible in which the text consists of translations in various languages arranged in parallel columns. This arrangement allows scholars to compare ancient and modern versions, as well as to examine closely the translation from one language to another.

The first and best known polyglot Bible is the Complutensian, begun in 1502 under the sponsorship of the archbishop of Toledo, Cardinal Francisco Jiménez de Cisneros, printed in 1514–17 at the University of Alcalá de Henares near Madrid, and published in 1522. The Old Testament in the Complutensian contained a revised Masoretic Hebrew text and translations in Aramaic (the Targum of Onkelos), Latin (the Vulgate), and Greek (the Lucianic recension of the Septuagint, printed in full for the first time). The Complutensian New Testament presented the original Greek version together with the Latin translation.

The *Biblia Regia,* or Antwerp Polyglot (1569–72), is another important polyglot. The work, paid for by Philip II of Spain, was supervised by the Spanish scholar Benedictus Arias Montanus and printed in Antwerp by a well-known printer, Christophe Plantin.

One of the most comprehensive and generally considered the finest is the London Polyglot, also called the Londoninesis or Waltonian (1657), compiled by Brian Walton, with the aid of many contemporary scholars; the Waltonian was one of the first English books assembled under public subscription. Its six volumes contain a total of nine languages: Hebrew, Samaritan, Aramaic, Greek, Latin, Ethiopic, Syriac, Arabic, and Persian.

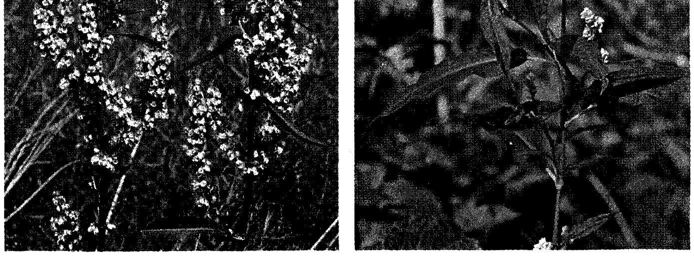
polygnathiform, conodont, or small toothlike fossil of uncertain relationship found widely in ancient marine rocks, that resembles or may be derived from the genus *Polygnathus,* a genus found in rocks of Early Devonian to Early Mississippian age (the Devonian Period ended 345,000,000 years ago, when the Mississippian Period began). *Polygnathus* is clearly a key conodont genus; from this form a wide variety of distinct conodont genera evolved, including many forms that are important index, or guide, fossils.

Polygnotus (b. *c.* 500 BC, Thasos, Thrace—d. *c.* 440 BC, Athens), painter famed for his large monumental wall paintings in a severely classical style, none of which is extant. He lived in Athens and eventually acquired citizenship.

The Greek traveler Pausanias left an account of two paintings in the hall of the Cnidian at Delphi: the "Iliupersis" ("Sack of Troy") and the "Nekyia" ("Ulysses Visiting Hades"). Idealized figures approximately life size were freely distributed within the composition: in Greek painting of the first half of the 5th century BC this method represents an innovation, though precedents existed elsewhere, notably in Assyrian art. It constitutes a break with the ancient Greek principle of arranging figures on a single base line; Polygnotus replaced the horizontal base lines by irregular mounting or descending terrain lines. Comparable representations can be found in contemporary vase paintings, perhaps under his influence. There was no unifying perspective in the modern sense; the individual figure remained the focus of interest even when several figures were grouped together. Stateliness was paired with subtlety of detail: delicate headdresses of women, transparent garments, mouths with parted lips uncovering the teeth. Polygnotus employed sharp foreshortening and four basic colours: black, white, red, and ochre. The "ethos," which later critics, including Aristotle (*Poetics*, ch. 6), valued so highly in his work, indicates a concept of character as an innate disposition, governing the actions and manifest in a person's outward bearing.

Polygonales, the buckwheat order of dicotyledonous flowering plants comprising the family Polygonaceae, with about 40 genera of herbs, shrubs, and trees.

The plants are characterized by the presence in most species of leaves that have an appendage (ochrea) that clasps the stem just above the base of the leafstalk. The flowers are radially symmetrical and bisexual and have a single-chambered ovary with one basally positioned ovule. The flowers are variable in the structure and number of their petallike parts and stamens (the male pollen-producing structures). The perianth (petallike parts) consists of three, four, five, or six members that are not differentiated into sepals and petals.



Polygonales
(Left) Dock (*Rumex*) and (right) knotweed (*Polygonum aviculare*)
(Left) Jeanne White—The National Audubon Society Collection/EB Inc., (right) Peter L. Ames—EB Inc.

The fruits are nearly always small, triangular, one-seeded, nutlike structures with membranous wings formed from the persistent perianth. The seeds are distributed by wind.

The largest genera include *Polygonum* (300 species); *Eriogonum* and *Rumex* (200 species each); *Coccoloba* (150 species); *Calligonum* (80 species); *Chorizanthe* (50 species); *Rheum* (25 species); and *Oxygonum* (30 species). Some botanists classify the Polygonaceae as a family of the order Caryophyllales.

The order is not of great economic importance, though there are some notable species. Buckwheat (*Fagopyrum esculentum*) is cultivated for its edible seeds and as an animal-feed plant and honey plant. The leafstalks of rhubarb (*q.v.*; *Rheum rhaponticum*) are edible, but the leaf blades are poisonous. The sea grape (*Coccoloba uvifera*), growing on beaches, produces edible fruit. Ornamental plants include the sea grape; the sacaline (*Polygonum sachalinense*); the silver-lace vine (*P. aubertii*); the fleeceflower (*P. reynoutria*, or *P. cuspidatum compactum*), an aggressive ground cover; the ribbonbush or tapeworm plant (*Homocladium platycadum*); and the coral vine (*Antigonon leptopus*). A number of common weeds and pasture plants belong to this order, for example, the common sorrel, or dock (*Rumex acetosa*), and sheep's sorrel (*R. acetosella*), both of which are sometimes used in dried flower arrangements.

polygraph: *see* lie detector.

polygyny, marriage of a man to two or more women at the same time. *See* polygamy.

polyhalite, a sulfate mineral in evaporite deposits that often occurs with anhydrite and halite. Its name, from the Greek words meaning "many salts," reflects its composition, hydrated sulfates of potassium, calcium, and magnesium. It makes up 7 percent of the rock in the salt deposits at Stassfurt, Ger., and is also abundant in the salt deposits of the Saratov region of the Soviet Union, where certain beds consist of 85 percent polyhalite. The Texas–New Mexico potash region is another noteworthy locality. For detailed physical properties, *see* sulfate mineral (table).

Polyhistor, Alexander: *see* Alexander Polyhistor.

polyhydramnios (medicine): *see* hydramnios.

Polyhymnia (Greek religion): *see* Polymnia.

polymer, any of a class of natural or synthetic substances composed of very large molecules that are multiples of simpler chemical units called monomers. Polymers make up many of the materials in living organisms, as, for example, proteins, cellulose, and nucleic acids. Moreover, they constitute the basis of such minerals as diamond, quartz, and feldspar and such man-made materials as concrete, glass, paper, plastics, and rubbers.

A brief treatment of polymers follows. For full treatment, *see* MACROPAEDIA: Chemical Compounds.

The word polymer designates an unspecified number of monomer units. When the number of monomers is very large, the compound is sometimes called a high polymer. Polymers are not restricted to monomers of the same chemical composition or molecular weight and structure. Some natural polymers, such as the proteins, are composed of one kind of monomer. Most natural and synthetic polymers, however, are made up of several different monomers.

Organic polymers play a crucial role in living things, providing basic structural materials and participating in vital life processes. For example, the solid parts of all plants are made up of polymers. These include cellulose, lignin, and various resins. Cellulose is a polysaccharide, a polymer composed of sugar molecules. Lignin consists of a complicated three-dimensional network of polymers. Wood resins are polymers of a simple hydrocarbon—a structure of carbon atoms with hydrogen atoms attached—called isoprene. Another familiar isoprene is rubber.

Other important natural polymers include the proteins, which are polymers of amino acids, and the nucleic acids, which are polymers of nucleotides—complex molecules composed of nitrogen-containing bases, sugars, and phosphoric acid. The nucleic acids carry genetic information in the cell. Starches, important sources of food energy derived from plants, are natural polymers composed of glucose.

Many inorganic polymers also are found in nature, including diamonds and graphite. Both are composed of carbon. In diamond, carbon atoms are linked in a three-dimensional network that gives the material its hardness. In graphite, used as a lubricant and in pencil "leads," the carbon atoms link in planes that can slide across one another.

Synthetic polymers are produced in different ways. Many simple hydrocarbons, such as ethylene and propylene, can be transformed into polymers by adding one monomer after another to build the polymer chain. Polyethylene, the polymer of ethylene, is an addition polymer. It may have as many as 10,000 monomers joined to form in long, coiled chains.

Polyethylene is crystalline, transluscent, and thermoplastic—*i.e.,* it softens when heated. It is used for coatings, packaging, molded parts, and for the manufacture of bottles and containers. Polypropylene is also crystalline and thermoplastic. Its molecules may consist of from 50,000 to 200,000 monomers. This compound is used in the textile industry and to make molded objects.

Other addition polymers include polybutadiene, polyisoprene, and polychloroprene, which are all important in the manufacture of synthetic rubbers. Some polymers, such as polystyrene, are glassy and transparent at room temperature, as well as being thermoplastic. Thus, polystyrene, which can be coloured any shade, is used in the manufacture of toys and other plastic objects.

Replacing one hydrogen atom in ethylene by a chlorine atom makes vinyl chloride. This polymerizes to polyvinyl chloride, a colourless, hard, tough, thermoplastic material that can be manufactured in a number of forms films, including foams, films, and fibres. Vinyl acetate, produced by the reaction of ethylene and acetic acid, polymerizes to amorphous, soft resins used as coatings and adhesives. It copolymerizes with vinyl chloride to produce a large family of thermoplastic materials.

Many important polymers have oxygen or nitrogen atoms, along with those of carbon, in the backbone chain. Among such macromolecular materials with oxygen atoms are polyacetals. The simplest polyacetal is polyformaldehyde. It has a high melting point and is crystalline and resistant to abrasion and the action of solvents. Acetal resins are more like metal than are any other plastics and are used in the manufacture of machine parts such as gears and bearings.

A linear polymer characterized by a repetition of ester groups—carbon and oxygen—along the backbone chain is called a polyester. Open-chain polyesters are colourless, crystalline, thermoplastic materials. Those with high molecular weights (10,000 to 15,000 molecules) are employed in the manufacture of films, molded objects, and fibres such as Dacron.

The polyamides include the naturally occurring proteins casein, found in milk, and zein, found in corn (maize), from which plastics, fibres, adhesives, and coatings are made. Among the synthetic polyamides are the urea-formaldehyde resins, which are thermosetting. They are used to produce molded objects and as adhesives and coatings for textiles and paper. They are also utilized in plywood and various other laminated products. Also important are the polyamide resins called nylons. They are strong, resistant to heat and abrasion, noncombustible, nontoxic, and can be coloured. Their best known use is as textile fibres, but they have many other applications.

Another important family of synthetic organic polymers is formed of linear repetitions of the urethane group. Polyurethanes are employed in making elastomeric fibres known as spandex and in the production of coating bases and soft and rigid foams.

A different class of polymers are the mixed organic–inorganic compounds. The most important representatives of this polymer family are the polysiloxanes, also called silicones. Their backbone consists of alternating silicon and oxygen atoms with organic groups attached to each of the silicon atoms. Polysiloxanes with low molecular weight are oils and greases. Higher molecular-weight species are versatile elastic materials that remain soft and rubbery at very low temperatures. They are also relatively stable at high temperatures.

Where the same name may denote a person, place, or thing, the articles will be found in that order

---

polymerization, any process in which relatively small molecules, called monomers, combine chemically to produce a very large chainlike or network molecule, called a polymer. The monomer molecules may be all alike, or they may represent two, three, or more different compounds. Usually at least 100 monomer molecules must be combined to make a product that has certain unique physical properties—such as elasticity, high tensile strength, or the ability to form fibres—that differentiate polymers from substances composed of smaller and simpler molecules; often, many thousands of monomer units are incorporated in a single molecule of a polymer. The formation of stable covalent chemical bonds between the monomers sets polymerization apart from other processes, such as crystallization, in which large numbers of molecules aggregate under the influence of weak intermolecular forces.

Two classes of polymerization usually are distinguished. In condensation polymerization, each step of the process is accompanied by formation of a molecule of some simple compound, often water. In addition polymerization, monomers react to form a polymer without formation of by-products. Addition polymerizations usually are carried out in the presence of catalysts, which in certain cases exert control over structural details that have important effects on the properties of the polymer.

Linear polymers, composed of chainlike molecules, may be viscous liquids or solids with varying degrees of crystallinity; many of them can be dissolved in certain liquids, and they soften or melt upon heating. Cross-linked polymers, in which the molecular structure is a network, are thermosetting resins (they form under the influence of heat but, once formed, do not melt or soften upon reheating) that do not dissolve in solvents. Both linear and cross-linked polymers can be made by either addition or condensation polymerization.

Polymnia, also called POLYMNIS, or POLYHYMNIA, in Greek religion, one of the nine Muses, patron of dancing or geometry. She was said in some legends to have been the mother of Triptolemus, the first priest of Demeter and the inventor of agriculture, by Cheimarrhus, son of Ares, god of war, or by Celeus, king of Eleusis. In other versions, she was the mother of Orpheus, the legendary lyre-playing hero, or of Eros, the god of love.

polymorphism, in biology, any of several structural or functional variations among members of a single species. Such variations may be determined by genetic differences or by differences in the circumstances under which individual organisms live and are able to adapt. In a few characters, such as the blood groups, the differences are wholly genetic in origin, and no external influence can change them. Most characters, however, show both genetically and environmentally determined variation simultaneously. Furthermore, variation arising from genetic causes cannot be distinguished by inspection from that determined by environment. Thus an animal may be smaller than others of its species because of the genes it has received or because it is undernourished.

Genetic variation can be classified as discontinuous or continuous. In principle, discontinuous and continuous variation have the same genetic basis. Discontinuous variation is usually controlled by unit genetic determiners (alleles) of one gene or a cluster of genes; continuous variation, on the other hand, is the result of the cumulative effects of many genes, each exerting small but similar effects.

A discontinuous variation divides the individuals of a population into two or more sharply distinct forms. If the frequency of both forms is too high to be explained by mutation, the variation—as well as the population displaying it—is said to be polymorphic. The most obvious example of a discontinuous variation is the separation of most higher organisms into males and females; another is the human blood types.

In continuous, or multifactorial, variation the individuals do not fall into sharp classes but are almost imperceptibly graded between wide extremes. A familiar example is the smooth graduation of height among individuals of human populations. The relationship between polymorphic and multifactorial variation is important. In the latter, numbers of genes having small, similar, and cumulative effects operate, as in the genetic component of human height. This may allow a change to develop more easily than in the case of polymorphism, since most of the genes concerned in multifactorial variation are generally scattered in the normal population.

A specific character may, however, show both discontinuous and continuous variation within a population. Thus a human population, while showing continuous variation in height among its normal members, may simultaneously include sharply distinct dwarf or giant individuals.

Several types of nongenetic variation can be distinguished. One type occurs in adults of animal species that undergo seasonal changes in phenotype (outward, observable characteristics); the plumage of certain birds and the fur of some mammals, for example, change colour with the season. The effects of physical environment are particularly pronounced in plants. Composition of the soil, amount of sunlight, water, and other factors can affect height; size, shape, and colour of leaves; number and appearance of flowers; and other physical traits. The phenotype of some freshwater fishes is dependent upon certain physical and chemical properties of the water they inhabit—*e.g.,* temperature, acidity. The formation of genetically identical but morphologically different castes among social insects such as ants and bees is regulated by the nutrition of the larvae and other environmental conditions. Similarly, among a few butterfly species, temperature or moisture differences may give rise to highly dissimilar spring and summer forms or dry- and wet-season forms.

Because no two individuals are genetically identical in sexually reproducing species, genetic variation is important with regard to variations of the phenotype. Thus, almost any feature, be it morphological, physiological, or cytological, may vary. When the differences among individuals within a population can be divided into several classes based on the presence of certain characters, the variation, called polymorphism, is frequently controlled by one gene; however, the genetic requirements for polymorphism may be met by the segregation of a gene, a super-gene (a section of a chromosome containing more than one gene and acting as a unit), or a specialized pair of chromosomes.

polymorphism, in crystallography, the condition in which a solid chemical compound exists in more than one crystalline form; the forms differ somewhat in physical and, sometimes, chemical properties, although their solutions and vapours are identical. The existence of different crystalline or molecular forms of elements is called allotropy, although it has been suggested that the meaning of allotropy should be restricted to different molecular forms of an element, such as oxygen (O_2) and ozone (O_3), and that polymorphism be applied to different crystalline forms of the same species, whether a compound or an element. Differences in the crystalline forms of many elements and compounds were discovered during the 1820s by Eilhardt Mitscherlich, a German chemist.

Among polymorphs of certain compounds, one is more stable than the others under all conditions; in the cases of other compounds, one polymorph is stable within a particular range of temperature and pressure while another is stable under a different set of conditions. In either circumstance, the rate at which a less stable polymorph becomes more stable often is so low that an intrinsically unstable form may persist indefinitely. As an example of the first class, calcium carbonate has an orthorhombic form (*i.e.,* having three unequal crystalline axes at right angles to each other) called aragonite and a hexagonal form (having three equal axes intersecting at angles of 60 degrees and a fourth axis at right angles to these three) called calcite. Calcite is the stabler form; aragonite changes into calcite rapidly at temperatures around 470° C (about 880° F) but very slowly at room temperatures. The second class is represented by silica, which has three forms—quartz, tridymite, and cristobalite—each of which is stable only in its particular range of temperature and pressure, the others slowly changing into the stable modification.

The conditions under which synthetic crystalline substances are prepared often dictate the formation of one or another polymorph; in the manufacture of pigments, particular care is required because the colour, reflectivity, and opacity frequently vary among the polymorphic modifications of a single substance.

polymyositis, connective-tissue disease characterized by inflammation and degeneration of skeletal muscle, especially the muscles of the shoulder and pelvic girdles. In dermatomyositis, a closely related disorder, polymyositis is accompanied by an inflammation of the skin.

Polymyositis occurs in all age groups (though it is most common in the fifth and sixth decades of life) and is slightly more common in women. Involvement of the muscles of the esophagus and the larynx causes difficulty in swallowing and in uttering sounds. Heart muscle may be affected. The skin changes, which occur in approximately half the persons affected and are highly variable, include a characteristic puffiness around the eyes, with lavender discoloration of the upper eyelids and sharply demarcated reddened patches overlying the small joints of the fingers, which heal with atrophy and whitening of the skin; a rash also may occur over parts of the face, neck, shoulders, chest, and back. Calcium deposits under the skin, around the joints, and in the muscles are a common sequel to the inflammation in skin and muscle; when extensive, the condition is called calcinosis universalis.

The cause of polymyositis is unknown. Corticosteroids are used with some success, but treatment is generally long-term, and the disease may recur or reappear if the drug is discontinued.

polymyxin, any of several polypeptide antibiotics that are active against gram-negative bacteria. Polymyxins act on the cell membranes of bacteria, interrupting their function by causing a loss of intracellular material.

Only polymyxins B and E are used clinically; others damage the kidneys. Polymyxin B is somewhat toxic and therefore mostly used for severe infections. Polymyxin E, also known as colistin, is used frequently for diarrhea in children. The chief therapeutic use of the polymyxins is treating infections of gram-negative bacteria that are resistant to penicillin and aminoglycosides. They work particularly well against *Pseudomonas.*

Polynesia, ethnogeographic grouping of islands scattered across a huge triangular area of the east-central Pacific Ocean; the triangle has its apex at the Hawaiian Islands and its base angles at New Zealand and Easter Island. Polynesia (from Greek *poly,* "many," and *nēsoi,* "islands") comprises the island groups of Samoa (American Samoa and Western Samoa), the Cook Islands, French Polynesia (Tahiti and the other Society Islands, the Marquesas Islands, the Tubuai Islands, and the Tuamotu Archipelago), the island of Niue, the islands of Tokelau, Tuvalu (formerly the Ellice Islands), the islands of Tonga and of Wallis and Futuna, the Hawaiian Islands, and Pitcairn Island. New Zealand's original inhabitants, the Maori, are also Polynesian; Fiji is sometimes included in Polynesia because of the proportion of its population that is Polynesian.

A brief treatment of Polynesia follows. For full treatment, *see* MACROPAEDIA: Pacific Islands.

On the basis of both archaeological evidence and relative linguistic homogeneity, authorities believe that central Polynesia was settled by migration from Melanesia beginning some 3,000 to 4,000 years ago. Secondary migrations then occurred from the central island groups to the more remote areas of Polynesia. Samoan peoples are believed to have settled the Marquesas perhaps as early as AD 300, and Easter Island may have been settled from the Marquesas as early as AD 400. Hawaii also was settled by voyagers from the Marquesas some time in the second half of the 1st millennium AD; centuries later explorers from the Society Islands arrived. The Societies were probably the point of origin for the Polynesians who later settled the Cook Islands. Either the Marquesas or the Societies were the point of origin for the people who settled New Zealand sometime before AD 1000. The closely related Polynesian languages, spread over a vast area of the Pacific Ocean, tend to support the archaeological indication of relatively recent dispersal of Polynesian culture.

Prior to European contact, settlement of the Polynesian islands was of two types, the hamlet and the village. The larger volcanic islands in general were settled in hamlets, because food resources were diversified and spread over many environmental zones. Houses were clustered in groups of four or five, with gardens, taro patches, coconut trees, and breadfruit growing in the immediate vicinity. Village-type settlements of 30 or more houses were found, especially along the coasts, in Samoa and New Zealand. Such settlements were often fortified by walls of stone or wooden palisades. The most elaborate and impressive of fortified villages were built by the Maori of New Zealand.

Both hamlet and village settlement depended upon kinship patterns and family descent for organization. The usual Polynesian kinship pattern is based on an extended patrilineal, patrilocal family. Adoption, however, was common and social custom was flexible. In certain societies (those of Tahiti and Hawaii, for example), kinship could be traced through the female line if it conferred greater advantage; though male descent lines were preferred, in practice descent was bilateral.

The most common type of kinship-based descent group in Polynesian society was the "ramage" type, in which descent passed from firstborn son to firstborn son and was traceable back to the mythological past. The ruling chief of an independent district or island was supposed to be the most direct descendant in the senior line from the head of the family that had established itself on the land by virtue of first occupancy or conquest. Another major type of kinship-based organization, the "descent line," seems to be the result of a breakdown in the lower levels of "ramage" organization. Descent line is unconcerned with ranking based on relative position tc a particular male line of descent and with genealogical relationship of one descent line to another.

In ancient Polynesian societies, the chief, though highest in social status and clearly the repository of sacred power for the group, was regarded as the first among equals. In some Polynesian societies—such as those of Hawaii, Tahiti, and Tonga—this system gave way to a new order in which the families of the chiefs (sometimes determined by prestige or greater force) established themselves as a class apart from commoners and their position became hereditarily fixed. Their genealogies provided connections with creator gods from whom they derived their mana (superior and supernatural power). Rigid taboos, the infringement of which often involved the death penalty, were laid down to protect the chief from being familiarly approached by those not of his blood or rank and to uphold the religious system that supported him. In these societies social stratification was clear-cut, and warfare was frequent. It is also notable that in societies of this type, Christian missionaries succeeded in overthrowing ancient religious practices only after they had converted the chiefs. Because chiefly powers were deeply rooted in religious belief and made effective through religious taboos, the chiefs lost much of their hold on the people through this change. Those who let their land be taken over by foreigners lost even more power and prestige.

Religion and magic played an important role in traditional Polynesian culture. The gods of Polynesia were a complex assortment, including malevolent as well as benevolent beings, and they varied in rank and importance from those of the pantheon (who had a part in the cosmogony) to strictly local gods. Each of these beings had its own ritual requirements, and often schools of priests were required to carry them out. Among the religious practices were sacrifice (sometimes human sacrifice), chanting, great feasting, and fertility rites.

One of the key beliefs of the culture was that all things animate and inanimate possess mana. This mana was dynamic and could be damaged, sapped, or nullified by improper actions. Women especially were considered powerful (though unclean) creatures, capable of defiling the sacredness of certain tracts of land or groves and any number of inanimate objects with which they came into contact. An elaborate system of social rules was established on the principle of mana, both to protect mana and to avoid violations of taboo (tapu). Magic was also prevasive, and countless rituals regarding love, war, revenge, agriculture, and fishing were practiced.

Polynesian culture had a largely marine-based way of life, though horticulture and arboriculture were not disdained in Polynesia as they were among many other marine-based cultures. In addition to fish, mollusks and crustaceans were an important source of food. Fishing was often a group activity, with a line of men driving fish and even porpoises and whales toward shore or spreading and drawing enormous nets. Bays and lagoons were not the only source of fish; Polynesian fishermen explored vast expanses of ocean around their island homes, taking grouper, schools of tuna, and sometimes sharks and rays, which were a delicacy.

Other dietary staples and condiments were generally provided by gardens and groves. Crops of sweet potatoes, taro, breadfruit, bananas, sugarcane, and coconuts were cultivated and, depending on the particular society and growing conditions, achieved dietary importance. Kava, a nonalcoholic, euphoria-producing beverage made from the root of the pepper plant, was a favourite drink of the elders and was used ceremonially.

Food plants also provided raw material for much of Polynesian material culture. Breadfruit wood was used in canoe-making, and its sap served as caulking; the inner bark, or bast, of the breadfruit tree (as well as that of the paper mulberry plant) was soaked and beaten into cloth called tapa. Leaves of some plants were used in weaving mats, clothing, sails, and other household goods. In what they fashioned, Polynesians showed themselves consummate craftsmen and artists. The outrigger canoe, which could negotiate shallow lagoons, land over reefs, and be easily hauled ashore, was essential to island life. When a second canoe was substituted for the outrigger float, the craft became a double canoe. Both the single canoe and the double canoe were often equipped with mat sails. Very large double canoes for interisland communication or for settlement expeditions were vessels 100–150 feet (30–45 m) long, decked over and supporting a thatched house. These were capable of transporting families, domesticated animals, and plants over great stretches of ocean.

Over the course of time, each island group developed distinctive artistic skills. The ruined stone temples of the Society Islands, Easter Island, and the Marquesas indicate a fine grasp of masonry and architecture. Functional goods—canoes, war clubs, dance shields, fish hooks—were elegantly designed and meticulously decorated. In Hawaii single whale teeth were fashioned into pendants to be worn by chiefs. Bark cloth was decorated by means of bamboo stamps. Feather cloaks represented a phenomenal amount of effort in the gathering of thousands of small, rare feathers, arranging them in tufts, and tying them in overlapping rows onto a fabric of extremely fine netting. These and other objects—some of which have survived into the late 20th century—bear eloquent witness to Polynesian craftsmanship and artistry.

The exchange of goods and services among Polynesian societies was characterized by redistribution and reciprocity. This system, evident even in the late 20th century, is exemplified in early land-holding practices. In traditional Polynesian societies, land was corporately held, and sections were apportioned to various family groups. As social organization evolved, however, each island group began to develop its own methods of land distribution, some of which were determined by social class.

Contact with European culture that began in the late 1700s radically altered life in Polynesia. Spanish explorers searching for riches and eager to spread Christianity were the first Europeans to explore Polynesia. Álvaro de Mendaña de Neira landed on the Marquesas in 1595, and in 1606 Pedro Fernández de Quirós sighted the Tuamotu Archipelago and the northern Cook Islands. The Dutch arrived soon thereafter. In 1642 Abel Tasman sighted New Zealand and later Tonga. British and French exploration in Polynesia began in 1766 with the British navigator Samuel Wallis, who explored Tahiti; in the same year, the French navigator Louis-Antoine de Bougainville reached Tahiti and later the Samoan islands. The British naval officer and explorer Captain James Cook circumnavigated and charted the two major islands of New Zealand in 1769 and 1770 and later reached Tahiti. In 1778 Cook landed on the Hawaiian Islands, which he named the Sandwich Islands in honour of the earl of Sandwich. Resistance to European intervention occurred in almost all of the Polynesian islands, but such movements were brief.

Hawaii was annexed by the United States in 1898; France annexed the Marquesas and Society Islands in 1880; Chile claimed Easter Island in 1888; the British annexed New Zealand in 1840 and the Cook Islands in 1901; and Tonga remained an independent kingdom but came under British protection from 1900. By the end of the 19th century, all of Polynesia was under the control of European powers and the United States.

During the 20th century, Western Samoa achieved its independence (1962); American Samoa became a U.S. territory (1929); Hawaii became the 50th state of the United States (1959); New Zealand achieved independence (1947) within the Commonwealth; the Cook Islands became politically dependent on New Zealand; and the Marquesas Islands, Society Islands, and Tuamotu Archipelago were made the French overseas territory of French Polynesia.

Colonizers and, especially, Christian missionaries, in imposing Western belief systems and cultural ways, effectively wiped out Polynesian local traditions and customs. Most of the traditional ways were lost or amalgamated with Western ways. Of the Polynesian islands, Western Samoa and Tonga retain more of traditional culture than the others. Elsewhere, Western influence is evident nearly everywhere, particularly in the conspicuous presence of consumer goods.

The Polynesian way of life had considerable romantic appeal for many Western artists and writers because it represented to them a simple, natural way of life, free of "civilization" and bourgeois attitudes. The French painter Paul Gauguin lived and worked for several years toward the end of his life in Tahiti and the Marquesas, taking Polynesian people and culture as subjects for his paintings. Another example of this phenomenon is Herman Melville, who as a young man worked aboard a number of Pacific-bound whaling ships and wrote about his experiences in the South Seas in *Typee: A Peep at Polynesian Life* (1846) and *Omoo: A Narrative of Adventures in the South Seas* (1847).

Polynesian geographic race, a group of human populations inhabiting islands in the southern Pacific Ocean within the area bounded by Hawaii, New Zealand, and Easter Island. Characteristic of the Polynesian race are light to medium skin pigmentation, medium stature and rather stocky body build, straight to curly hair, little body hair, low incidence of blood type B (ABO system), and rather high incidence of blood type N (MNSs blood-group system). In the past, the Polynesians were thought to be a mixture of at least three racial stocks, European Caucasoid, Asian Mongoloid, and Pacific Melanesian. Though their light skin, wavy hair, and full beards suggest European ties, and their facial features sometimes suggest Mongoloid affinities, they are more or less typically Pacific in blood type, with high N and little B, no Rh-negative blood type or type A_2 in the ABO system (European traits), and not high enough B, M, or Duffy-positive blood types for close Mongoloid ties.

Polynesian languages, group of about 30 languages belonging to the Eastern, or Oceanic, branch of the Austronesian (Malayo-Polynesian) language family and most closely related to the languages of Micronesia and Melanesia. Spoken by fewer than 1,000,000 persons spread across a large section of the Pacific Ocean, the Polynesian languages show a relative homogeneity indicating that they have dispersed only in the last 2,500 years from an original centre in the Tonga-Samoa area.

The best-known Polynesian languages are Samoan, with about 200,000 speakers; Maori, spoken in New Zealand by about 100,000 persons; Tahitian, with an unknown number of native speakers but widely used as a lingua franca in French Polynesia; and Hawaiian, with only a few remaining native speakers but formerly spoken by perhaps 100,000 persons. Samoan is the national language of Western Samoa, and Tongan is the official tongue of the Kingdom of Tonga.

The Polynesian languages are notable for their scarcity of consonants; they make heavy use of vowels, distinguishing long and short forms of all vowels. One of the major features of Polynesian grammar is the reliance on particles, small separate words that function as grammatical markers of various sorts, standing before or after the words they modify, in some ways similar to English prepositions, conjunctions, and articles.

polyneuritis, also called MULTIPLE PERIPHERAL NEURITIS, inflammation of serveral peripheral nerves at the same time. A great variety of toxic and metabolic disorders can cause polyneuritis, including alcoholism, ingestion of toxic substances (such as lead or buckthorn), infectious disease, vitamin deficiency (as in beriberi), thyroid-gland disorders, and cancer. Symptoms may range from mild to severe; in general, with treatment, recovery is complete. *See also* neuritis.

polynya, also spelled POLYNIA, a semipermanent area of open water in sea ice. Polynyas are generally believed to be of two types. Coastal polynyas characteristically lie just beyond landfast ice, *i.e.,* ice that is anchored to the coast and stays in place throughout the winter. They are thought to be caused chiefly by persistent local offshore winds, such as the foehn, or katabatic (downward-driving), winds typically found off Greenland's coast. Open-ocean polynyas, the larger and longer-lasting of the two types, form within the ice cover and are believed to be caused by the upwelling of deep warmer water. This type is best exemplified by the vast Weddell Polynya in the antarctic Weddell Sea.

Polynyas are as yet incompletely understood. Early explorers who ventured into open waters often mistakenly believed they had discovered a new ocean. Since the 1970s, satellites containing microwave sensors have enabled scientists to closely observe changes in polar ice cover. Many hypotheses about the formation of polynyas have been put forward. Among the other factors thought to influence their formation are cyclones (which pile up ice on some portions of the landfast ice while drawing ice away from other boundary areas), eddies and local gyres, and swift surface currents.

Polynyas vary in size, some being as large as inland seas. One of the larger arctic polynyas, known as North Water, is centred on Smith Sound, at the northern end of Baffin Bay on the Greenland coast; it has an area of approximately 85,000 square km (33,000 square miles). Some polynyas, like that found in the Weddell Sea, have been measured at 350 by 1,000 km (215 by 620 miles); some remain open for a number of years at a time. Smaller polynyas, often recurring at the same place and time each year, may slowly get smaller and close, or they may dramatically reopen at any point in the seasonal cycle.

Polynyas support a significant ecosystem as the source of plankton, krill, and cod, and large colonies of arctic birds (including murres, kittiwakes, black guillemots, and Ross's gulls) breed nearby. Many marine mammals (walruses, seals, whales, and polar bears) also depend on the polynyas as feeding grounds and overwintering areas. Scientists also are studying the effects of polynyas on atmosphere and the processes involved in the circulation of the Earth's oceans.

polyolefin, any of a class of organic substances prepared by the addition polymerization of olefins (hydrocarbons containing one double bond per molecule), especially ethylene and propylene.

In textiles, polyolefin denotes synthetic fibre composed of at least 85 percent by weight of polyethylene or polypropylene. Trademarked fibres in this group include DLP, Herculon, Polycrest, and Vectra. Polyolefins were originally used for various plastic items and films; the fibres were not developed until the mid-1950s.

The strength of polyethylene fibres varies with type, ranging from that of nylon-6,6 to somewhat less. Polypropylenes can withstand about the same range of loads, again varying with type. Polyethylenes can be stretched about 10–40 percent beyond their original length and polypropylenes from about 15 to 30 percent, with some types having elongation up to 50 percent. Fibres can return to about 90–98 percent of their original length when stretched by about 5 percent.

The polyolefins absorb very little moisture. Polyethylenes melt at 110°–140° C (230°–280° F) and polypropylenes at about 165°–175° C (330°–350° F). Most polyolefins lose some strength upon prolonged exposure to sunlight.

The fibres are not usually affected by age, provided moderate temperatures are maintained, and they have high resistance to most chemicals. They can be washed in strong alkaline solutions and can be dry-cleaned with most common cleaning solvents. Resistance to attack by insects and microorganisms is high, and the fibres are good electrical insulators.

The polyolefins are used, alone or in blends, in hosiery, sportswear, and undergarments and in pile fabrics. They are also used in such home furnishings as upholstery, outdoor furniture, and rugs and carpeting, particularly indoor-outdoor types for both residential and public area use. Industrial applications include filters, marine cordage, automobile seat covers, electrical insulation, and carpet backing.

polyoma virus, minute infectious agent normally present in extremely small amounts in wild mice and causing no obvious ill effects. There is evidence that the virus may induce malignant tumours if grown in tissue culture and injected in sizable quantities into newborn mice or young hamsters, guinea pigs, and rabbits. The virus is highly antigenic; *i.e.,* all animals bearing its tumours also have virus-neutralizing antibodies in their blood. The virus is also capable of clumping red blood cells and affecting deoxyribonucleic acid (DNA) synthesis.

Polyoma virus is one of the infectious oncogenic (tumour-forming) viruses and belongs to the papova group of viruses. Another oncogenic virus of the same group is simian virus 40 (SV-40). Great care has to be taken to make sure that vaccine viruses grown on monkey (simian) kidney cells are not contaminated with SV-40.

polyp, in medicine, any growth projecting from the wall of a cavity lined with a mucous membrane. A polyp may have a broad base, in which case it is called sessile; or it may be a pedunculated polyp, *i.e.,* one with a long, narrow neck. The surface of a polyp may be smooth, irregular, or multilobular. The most common locations of polyps in the human body are the nose, the urinary bladder, and the gastrointestinal tract, especially the rectum and colon.

Symptoms of polyps depend upon their location and size. There may be no symptoms, or there may be symptoms resulting from pressure or from mechanical obstruction of all or part of a channel, such as that of the nose or a bowel. Polyps occasionally may bleed. Usually polyps are simple, benign growths, but a small percentage may be either precursors to cancers or may actually contain cancers. For that reason, it is advisable, when possible, to have all polyps removed and examined microscopically.

Consult the INDEX *first*

polyp, in zoology, one of two principal body forms occurring in members of the animal phylum Cnidaria. The polyp may be solitary, as in the sea anemone, or colonial, as in coral, and is sessile (attached to a surface). The upper, or free, end of the body, which is hollow and cylindrical, typically has a mouth surrounded by extensible tentacles that bear stinging structures called nematocysts. The tentacles capture prey, which is then drawn into the mouth. The lower end of the polyp typically is adapted for attachment to a surface. The body wall consists of an ectodermal, or outer, layer and an endodermal, or inner, layer.

Hydroid polyp (*Pennaria*)
William H. Amos—Helen Wohlberg, Inc.

One class of cnidarians, anthozoans, is polypoid; most species of the other three classes (hydrozoans, scyphozoans, and cubozoans) alternate in their life cycles between polypoid and medusoid (free-swimming) body forms. *Compare* medusa.

The term polyp also is sometimes applied to an individual in a colony of invertebrate aquatic animals belonging to the phylum Bryozoa.

Polypemon (in Greek mythology): *see* Procrustes.

Polyphemus, in Greek mythology, the most famous of the Cyclops (one-eyed giants), son of Poseidon, god of the sea, and the nymph Thoösa. According to some accounts, Polyphemus loved Galatea, a Sicilian Nereid. When the Greek hero Odysseus was cast ashore on the coast of Sicily, he fell into the hands of Polyphemus, who shut him up with 12 of his companions in his cave and blocked the entrance with an enormous rock. Odysseus at length succeeded in making Polyphemus drunk, blinded him by plunging a burning stake into his eye while he lay asleep, and, with six of his friends (the others having been devoured by Polyphemus), made his escape by clinging to the bellies of the sheep let out to pasture.

polyphony, in the broadest sense, music comprising two or more relatively autonomous voices or parts (*compare* monophony, music consisting of only a single melodic line), in contrast to homophony (*q.v.*; music emphasizing chordal textures.) In polyphony the different voices are heard as separate entities and are rhythmically more or less independent of each other. Counterpoint, the combination of simultaneous lines of melody, is sometimes equated with polyphony; but the technique of counterpoint can be applied within either polyphony or homophony. Palestrina's textures are typically polyphonic, Mozart's are basically homophonic; yet both use counterpoint. More specifically, therefore, polyphony refers to multipart textures animated by the dynamic interplay of usually closely related, complementary parts. The energies thus generated (for example, in canons and fugues) are not easily brought to a halt; hence the intrusion of homophony and functional harmonic forces, especially toward the end of polyphonic compositions. In the fugues of J.S. Bach, in which polyphony and functional harmony are uniquely matched, the concluding cadence is often presaged by a pedal point, which serves as a kind of ground to which the extended polyphonic flight can return.

Purely vocal polyphony had its heyday in the 16th century, prior to the reign of functional harmony. With the latter's decline, in the first quarter of the 20th century, polyphonic textures regained much of their former prominence, especially in the dodecaphonic compositions of Arnold Schoenberg and his followers.

polyploidy, the condition in which a normally diploid cell or organism acquires one or more additional sets of chromosomes. In other words, the polyploid cell or organism has three or more times the haploid chromosome number. Polyploidy arises as the result of total nondisjunction of chromosomes during mitosis or meiosis.

Polyploidy is common among plants and has been, in fact, a major source of speciation in the angiosperms. Particularly important is allopolyploidy, which involves the doubling of chromosomes in a hybrid plant. Normally a hybrid is sterile because it does not have the required homologous pairs of chromosomes for successful gamete formation during meiosis. If through polyploidy, however, the plant duplicates the chromosome set inherited from each parent, meiosis can occur, because each chromosome will have a homologue derived from its duplicate set. Thus, polyploidy confers fertility on the formerly sterile hybrid, which thereby attains the status of a full species distinct from either of its parents. It has been estimated that up to half of the known angiosperm species arose through polyploidy, including some of the species most prized by man. Plant breeders utilize this process, treating desirable hybrids with chemicals, such as colchicine, that are known to induce polyploidy.

Polyploid animals are far less common, and the process appears to have had little effect on animal speciation.

Polypodiaceae, one of several families in the fern order Polypodiales. The family contains 30 to 50 genera (depending on the authority consulted) and more than 1,000 species of diverse and widely distributed medium-sized and small ferns. Some earlier classification systems have recognized as many as 170 genera and 7,000 species in the family, most of which are now placed in other families. This entire larger group is still often referred to as polypodiaceous ferns, however, because all exhibit certain characteristics considered to be evolutionarily advanced; *i.e.,* long-stalked, spore-producing structures (sporangia) characterized by the presence of an incomplete, vertically arranged band of thick-walled cells (annulus). In addition, members of the presently recognized family are mostly tropical and subtropical epiphytes (plants not rooted in soil but growing upon other plants) with a rootlike creeping stem (rhizome) covered with distinctive scales. The lower surfaces of the leaves bear round or oblong clusters of sporangia (sori) that usually lack the protective membranous covering (indusium) found in many other fern families. The genera are distinguished by numerous characteristics such as presence and type of plant hairs on stems and leaves, arrangement of sori, rhizome type, growth habit, and others. The limits of the family and many of its included genera are still in need of study. Some of the chief genera include *Polypodium* (true polypodies, 75 species), *Platycerium* (staghorn ferns [*q.v.*], 17 species), *Pleopeltis* (40 species), *Loxogramme* (40 species), *Microsorium* (60 species), and *Pyrrosia* (100 species).

Polypody (*Polypodium*)
Leonard Lee Rue III

The dwarf polypodies (*Grammitis,* about 150 species; *Ctenopteris,* about 200 species; and 7 other genera) are sometimes included in the family Polypodiaceae, but recent opinion favours their separation into a closely related family, Grammitidaceae.

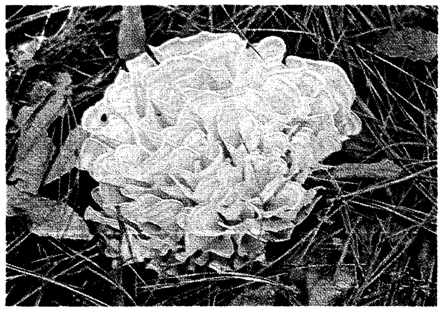
Economically, the family is of little importance except for the few grown as ornamentals, the most popular of which are the staghorn ferns and true polypodies.

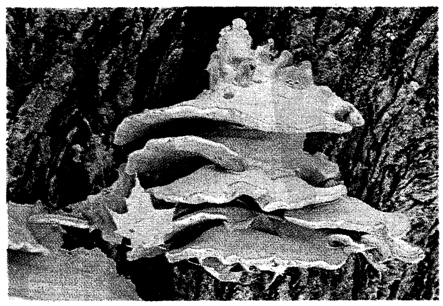
Polyporales, the large pore fungus order of fungi (division Mycota) within the class Basidiomycetes. (It is sometimes relegated to family rank, Polyporaceae, in the order Agaricales.) The 1,000 known species have conspicuous sporophores (fruiting bodies), sometimes mushroomlike, the spore-bearing layer (hymenium) appearing either tube-shaped, gill-like, rough, smooth, or convoluted. Many species are found on the ground or on decaying wood. Some species are edible; others cause diseases of trees.

The order includes the coral (club) fungi (Clavariaceae), shelf, or bracket, fungi (Polyporaceae), and the cantharelles (Cantharellaceae). About 500 widely distributed species of coral fungi are known. They are edible, but not delectable, and have an upright growth habit with branches. Coral fungi are found mostly in late summer and autumn on soil or decaying wood. Representative genera include *Clavaria* (25 species), *Pistillaria* (50 species), *Pterula* (50 species), *Rumaria,* and *Typhula* (40 species).

Shelf, or bracket, fungi produce a shelf-like fruiting structure on many trees. They cause decay of birch and other hardwoods and of structural timbers (certain *Poria* species); conifer rot, heart rot, and root rot of rubber plants (*Fomes*); wood decay and root rot of cacao, coffee, rubber, and other trees (*Ganoderma*); and diseases of birch and conifers (*Polyporus*). The white undersurface of artist's fungus (*Fomes applanatus*), which darkens when cut, has been used for etching.

The inedible birch fungus *Polyporus betulinus* causes decay on birch trees in the northern United States. Dryad's saddle (*P. squamosus*) produces a fan- or saddle-shaped mushroom. It is light coloured with dark scales, has a strong odour, and grows on many deciduous trees. The edible hen of the woods (*P. frondosus*), which grows on old trees and stumps, produces a cluster of grayish mushrooms with two or three caps on a stalk; the undersides of the caps are porous. The sulfur mushroom, *P.* (*Laetiporus*) *sulphureus,* a common, shelf-like fungus that grows on dead wood, derives its name from its sulfur-yellow colour; only the younger portions of the fruiting body are edible.





Polyporales
(Top) sponge fungus (*Sparassis herbstii*) and (bottom) artist's fungus (*Fomes applanatus*)
(Top) L.N. and Anella Dexter, (bottom) Mary W. Ferguson

The hedgehog fungus is the common name for species of the genera *Dentinum* (*Hydnum*) and *Hericium. Hydnum repandum,* an edible, whitish mushroom with toothlike structures hanging from the cap, occurs on decaying organic matter in autumn.

The horn of plenty (*Craterellus cornucopioides*), also called the trumpet of death, is a member of the family Cantharellaceae. Common in the woods in late summer, it is edible when young and turns black with age and when cooked. Another cantharelle, the chanterelle (*Cantharellus cibarius*), an edible mushroom yellow-orange in colour and with a pleasant odour, is found in woods during summer and autumn.

The genus *Schizophyllum* of the family Schizophyllaceae consists of five species. *S. commune* is a very common and widespread whitish mushroom that grows on decaying wood. The cap has split edges. Sponge fungus is the common name for five species of the genus *Sparassis* (family Sparassidaceae). *S.*

crispa and *S. radicata* produce at the base of trees in autumn a large (up to 20 kilograms, or about 44 pounds), edible fruiting body like a gray to buff cluster of lettuce.

Beefsteak fungus (*Fistulina hepatica*) of the family Fistulinaceae is an edible species found on oaks and other trees in the autumn. Its name derives from its colour, which resembles that of raw beef. It causes a stain on oaks called brown oak.

polyrhythm, also called CROSS-RHYTHM, the simultaneous combination of contrasting rhythms in a musical composition. Rhythmic conflicts, or cross-rhythms, may occur within a single metre (*e.g.*, two eighth notes against triplet eighths) or may be reinforced by simultaneous combinations of conflicting metres. The latter effect is characteristic of numerous non-Western musical forms (*e.g.*, Indonesian gamelan) and of certain Western, especially American, compositions.

Polyrhythmic and polymetric textures are in fact among the stylistic earmarks of such American composers as Charles Ives and his disciple Elliott Carter. Polyrhythm is also prevalent in American jazz and related Afro-American phenomena, including rock music.

polysaccharide, also called GLYCAN, the form in which most natural carbohydrates occur. Polysaccharides may have a molecular structure that is either branched or linear. Linear compounds such as cellulose often pack together to form a rigid structure; branched forms (*e.g.*, gum arabic) generally are soluble in water and make pastes.

Polysaccharides composed of many molecules of one sugar or one sugar derivative are called homopolysaccharides (homoglycans). Homopolysaccharides composed of glucose include glycogen and starch, the storage carbohydrates of animals and plants respectively; and cellulose (*q.v.*), the important structural component of most plants. Preparations of dextran, a glucose homopolysaccharide found in slimes secreted by certain bacteria, are used as substitutes for blood plasma in treating shock. Other homopolysaccharides include pentosans (composed of arabinose or xylose) from woods, nuts, and other plant products; and fructans (levans) composed of fructose, such as inulin from such roots and tubers as the Jerusalem artichoke and dahlia. Mannose homopolysaccharides occur in ivory nuts, orchid tubers, pine trees, fungi, and bacteria. Pectins, found in fruits and berries and used commercially as gelling agents, consist of a derivative of galacturonic acid (itself a derivative of the sugar galactose). The repeating unit of chitin, a component of the outer skeleton of arthropods (*e.g.*, insects, crustaceans) is *N*-acetyl-D-glucosamine, a compound derived from glucose; shells of arthropods such as crabs and lobsters contain about 25 percent chitin. It is also found in certain structures of annelid worms, mollusks, and other invertebrate groups (*e.g.*, jellyfishes, bryozoans, nematodes, and acanthocephalans). The cell walls of most fungi also are chitin. Chitin in nature is linked to protein.

Polysaccharides consisting of molecules of more than one sugar or sugar derivative are called heteropolysaccharides (heteroglycans). Most contain only two different units and are associated with proteins (glycoproteins; *e.g.*, gamma globulin from blood plasma, acid mucopolysaccharides) or lipids (glycolipids; *e.g.*, gangliosides in the central nervous system). Acid mucopolysaccharides are widely distributed in animal tissues. The basic unit is a so-called mixed disaccharide consisting of glucuronic acid linked to *N*-acetyl-D-glucosamine. The most abundant mucopolysaccharide, hyaluronic acid from connective tissue, is also the major component of joint fluid (synovia) and occurs in the soft connective tissue (Wharton's jelly) of the umbilical cord of mammals. Glucuronic acid linked to *N*-acetyl-D-galactosamine is the repeating unit of chondroitin sulfate, a heteropolysaccharide found in cartilage. Heparin, a heteropolysaccharide related to the acid mucopolysaccharides, has anticoagulant properties and is present in connective and other tissues.

Complex heteropolysaccharides occur in plant gums such as gum arabic from *Acacia* and gum tragacanth from *Astragalus.* Most contain glucuronic acid and various sugars. Produced after either mechanical damage to bark (a method used in commercial production) or an attack on the bark by certain bacteria, insects, or fungi, plant gums are used in the arts (gum arabic) and as an adhesive agent and emulsifying agent (gum tragacanth). Heteropolysaccharides also occur in bacterial cell walls.

polysiloxane: *see* silicone.

polystyrene, an important member of the class of synthetic organic polymers, composed of long-chain molecules prepared by a chemical reaction in which many (usually 2,000–3,000) molecules of the aromatic hydrocarbon styrene become linked together.

Large-scale manufacture of polystyrene was begun in the late 1930s; usually the styrene is dispersed in water with the aid of soap, and the polymerization reaction is initiated by free-radical catalysts. The product, an inexpensive, strong, thermoplastic (softened by heat) resin that resists attack by acids, alkalies, and many solvents, does not absorb water and is an excellent electrical insulator.

Addition of rubber latex to the suspension in which polystyrene is made greatly increases its resistance to impact. By the mid-1960s, more than half the polystyrene made in the United States was produced by this process. Polystyrene has numerous uses, as in making housings for such large household appliances as refrigerators and air conditioners.

polysulfide, any member of a class of chemical compounds containing one or more groups of atoms of the element sulfur linked together by covalent bonds. In inorganic compounds belonging to this class, these groups are present as ions having the general formula S_n^{2-}, in which *n* is a number from 3 to 10 or more; these compounds usually are prepared by dissolving sulfur in solutions containing the sulfide ion, S^{2-}. Sodium polysulfides are used in the tanning industry to remove hair from hides; lime-sulfur and sulfurated potash, prepared by heating sulfur with lime and potash, respectively, are mixtures containing polysulfides, used as insecticides and pesticides.

Sodium polysulfide, in which *n* has a value around 4, has been used as a starting material in the preparation of rubbery or resinous synthetic organic substances called Thiokols. The molecules of these products consist of long chains in which polysulfide groups alternate with small organic groups capable of forming two covalent bonds. They can be converted by heating with zinc oxide to tough, resilient materials used to make hoses and linings for storage tanks and in other applications requiring resistance to chemical and physical attack; they also have been used as solid fuels for rockets. Thiokols also can be prepared as aqueous dispersions useful for forming protective coatings on surfaces such as wood, metal, or concrete or for preparing caulking compositions.

polysulfone, any of a class of resinous organic chemical compounds belonging to the family of polymers in which the main structural chain most commonly consists of benzene rings linked together by sulfonyl ($-SO_2-$), ether ($-O-$), and isopropylidene ($-C(CH_3)_2-$) groups.

The polysulfone resins, introduced in the 1960s, are tough, strong, stiff, and resistant to decomposition by heat or chemical attack. They retain their mechanical properties over a wide temperature range (−70° to 150° C, or about −95° to 300° F) and are used as wire coatings, for fabricating household and plumbing items, and for automotive parts.

Polytechnical Museum, Russian POLITEKHNICHESKY MUZEY, in Moscow, museum of science and technology that emphasizes the history of Soviet science and technology and contemporary developments and inventions. The museum was founded in 1872 after the first Russian technical exhibition on the bicentennial anniversary of the birth of Peter the Great. The building housing the museum was completed in 1877. It includes some foreign exhibitions.

polytetrafluoroethylene (PTFE), a strong, tough, waxy, nonflammable resin belonging to the family of organic polymers, substances composed of large molecules formed by chemical combination of many small ones (monomers) into chains or networks. Known by the abbreviation PTFE or the trade name Teflon, it is distinguished by its complete indifference to attack by almost all chemicals and by its slippery surface; it retains its physical properties over a wide temperature range (−270° to 250° C, or −450° to 480° F). These qualities suit polytetrafluoroethylene to uses in gaskets, bearings, linings for containers and pipes, and parts for valves and pumps that must operate in corrosive environments and for protective coatings on cooking utensils, saw blades, and other articles.

Polytetrafluoroethylene forms upon treating tetrafluoroethylene with oxygen; the monomer is made by heating chlorodifluoromethane at about 600°–750° C (about 1,100°–1,400° F). The chemical and physical properties of PTFE necessitate a special technique for fabricating it into solid articles: a suspension of the powder in a diluent is molded into the desired shape, the diluent is removed by evaporation, and the object is consolidated by sintering (heating to a temperature sufficient to cause the particles to adhere to each other without actually melting).

Polymerization of mixtures of tetrafluoroethylene and hexafluoropropylene yields rubbery products that have high resistance to heat and chemical attack; these substances, called Viton, are used in gaskets and sealing devices.

polytheism, the belief in many gods, which, as opposed to the monotheism of Judaism, Christianity, and Islām, has characterized nearly all other religions throughout history. The many gods may be subordinate to a supreme god and object of devotion (as in some stages of Hinduism), or subordinate to some higher state, end, or saviour (as in Buddhism), or subordinate to one god that is dominant though not supreme (as in Greek religion). In addition to belief in many gods, polytheistic cultures generally also include belief in many other malevolent or benevolent spiritual forces or powers, which are unlike the gods in that they are usually unnamed and conceptually indefinite.

A brief treatment of polytheism follows. For full treatment, *see* MACROPAEDIA: Religious and Spiritual Belief, Systems of.

The gods and powers of polytheism appear in many different forms. Religions often identify the forces and objects of nature as deities. The common threefold breakdown of these nature-deities as celestial, atmospheric, and earthly is exemplified by the Indo-Aryan triad of Sūrya (sun), Indra (rain and battle), and Agni (fire). In hunting and agrarian cultures, religious fertility rites usually acknowledge the vitality of the sun in the rhythm of growth and decay. Furthermore, the sun is frequently viewed as all-knowing, just as the sky is associated with creation; thus sky gods tend to be very powerful and knowledgeable, and mythic thought often associates creation with light. The divine mother who gives birth to plant life is a primary earthly god. Particular features of a religious group's environment also often take on divine significance; thus, the sacred mountains, such as Mt. Olympus in Greece, and the sacred rivers, such as the Ganges in India.

Plants and animals figure prominently in most polytheistic schemes, either explicitly deified or in association with deities in other forms. Trees have commonly been regarded as having a symbolic relation to earth and heaven. Most important plant gods are associated with cultivated plants, such as corn (maize) in Central America and the vine of the Mediterranean world; in the Dionysian cult of the classical period, for instance, ecstasy and agriculture were symbolically united in the vine. Animals may be represented in the divine scheme on the basis of their importance to the livelihood of the culture or, more commonly, attributes associated with their appearance or behaviour.

In addition to the forces and objects of nature, various social and other functions, such as healing, seafaring, war, learning, or love, may be divinized. Of special importance are the gods concerned with death and judgment after death, such as Osiris in ancient Egypt, Yama in India, Hades in Greece, and Hel in Norse religion.

Anthropomorphism, or the modelling of the gods in the form of human beings, is a widespread phenomenon in polytheism. This is evident especially in the religious tradition of the Greeks, in which the gods are fully human in their thoughts and emotions. In some cases, human beings may take on the attributes of divinity, either through their manifestation of power or through their identification with deities; divine kingship was a characteristic feature of the ancient Middle East, the Roman world, Japan, and China. Cultural heroes have frequently been elevated to a semidivine status, and sages in the Buddhist and Jain traditions have become objects of cults.

polytonality, in music, the simultaneous occurrence of two or more different tonalities or keys (the interrelated sets of notes and chords used in a composition). If only two keys are employed, the term bitonality is sometimes used.

Polytonality first appeared in music of the early 20th century. Stravinsky's *Petrushka* (1911) employs "black keys against white" (in terms of the piano keyboard), combining C major and F♯ major. Sergey Prokofiev's *Sarcasms for piano* juxtaposes the keys of F♯ minor in the right hand and B♭ minor in the left, while Darius Milhaud's *Saudades do Brasil* combines a melody in C with an accompaniment in A♭ major. Such combinations of tonalities may be reviewed as 20th-century extensions of diatonic harmonic practices, following logically from post-Wagnerian chromaticism.

polyurethane, any of a class of synthetic resinous, fibrous, or elastomeric compounds belonging to the family of organic polymers made by the reaction of diisocyanates (organic compounds containing two functional groups of structure −NCO) with other difunctional compounds such as glycols. The best known polyurethanes are flexible foams—used as upholstery material, mattresses, and the like—and rigid foams—used for such lightweight structural elements as cores for airplane wings.

Foamed polyurethanes result from the reaction of diisocyanates with organic compounds, usually polyesters, containing carboxyl groups; these reactions liberate bubbles of carbon dioxide that remain dispersed throughout the product. Use of polyethers or polyesters containing hydroxyl groups in preparing polyurethanes results in the formation of elastomeric fibres or rubbers that have outstanding resistance to attack by ozone but are vulnerable to the action of acids or alkalies.

In textiles the synthetic fibre known generically as spandex is composed of at least 85 percent polyurethane by weight. Such fibres are generally used for their highly elastic properties. Trademarked fibres in this group are Lycra, Numa, Spandelle, and Vyrene. Such fibres have, for many textile purposes, largely replaced natural and synthetic rubber fibres.

Although somewhat weak in the relaxed state, spandex fibres can be stretched about 500–610 percent beyond their original length without breaking and quickly return to their original length. The fibre, usually white with dull lustre, is readily dyed. It absorbs very little moisture. It melts at about 250° C (480° F) and yellows upon prolonged exposure to heat or light. Items made of spandex can be machine washed and dried at moderate temperatures. Use of chlorine bleach can produce yellowing. Spandex fibres are frequently covered with other fibres such as nylon.

Spandex is used in such apparel as foundation garments, support hosiery, and swimsuits. It is light in weight and cool; it is resistant to deterioration from body acids; and it is easily laundered and quick-drying.

polyvinyl acetate, a colourless, water-insoluble resin belonging to the family of organic polymers, prepared by treating its monomer, vinyl acetate, with peroxide catalysts. In its most important application, polyvinyl acetate comprises the film-forming ingredient of water-based (latex) paints; it also is used in adhesives, lacquers, and cements and as the starting material for making polyvinyl alcohol (*q.v.*).

Polyvinyl acetate resins are thermoplastic (they soften upon heating) and flammable; they dissolve in certain organic compounds, including methanol, benzene, butyl acetate, and methyl ethyl ketone.

polyvinyl alcohol, a colourless, water-soluble, flammable resin belonging to the family of organic polymers. The resin is used in sizing agents that confer resistance to oils and greases upon paper and textiles, to make films resistant to attack by solvents or oxygen, as a component of adhesives and emulsifiers, and as a starting material for the preparation of other resins.

Polyvinyl alcohol is made by treating polyvinyl acetate (*q.v.*) with acids or alkalies, which remove the acetate groups without disrupting the long-chain structure of the molecule. If this reaction is allowed to proceed to completion, the product is highly soluble in water and insoluble in practically all organic solvents. Incomplete removal of the acetate groups yields resins less soluble in water and more soluble in certain organic liquids.

The chemical properties of polyvinyl alcohol resemble those of simpler alcohols; the reactions with aldehydes are particularly useful in the preparation of additional resinous substances. Polyvinyl formal, made by the reaction with formaldehyde, and polyvinyl acetal, from acetaldehyde, are employed in making lacquers, coatings, and films; polyvinyl butyral, from butyraldehyde, is produced as a tough, clear, adhesive, and water-resistant film widely used in laminating glass to make it shatterproof (safety glass) and for similar applications.

polyvinyl chloride (PVC), a synthetic resin belonging to the family of polymeric organic compounds, manufactured by treating vinyl chloride (*q.v.*) with a peroxide catalyst, usually in aqueous suspension or emulsion. After mixing with plasticizers, stabilizers, and pigments, the resin may be fabricated by techniques such as calendering, molding, or extrusion into flexible articles such as raincoats, shower curtains, and packaging films. The resin is not plasticized for use in making rigid products such as water pipe, plumbing fittings, and phonograph records.

For use in making piping or structural panels that require high resistance to impact, polyvinyl chloride often is blended with small proportions of rubbery synthetic polymers. Resins more easily plasticized than polyvinyl chloride can be prepared by adding various proportions of vinyl acetate to vinyl chloride before polymerizing the mixture; stiffer resins result from treatment of polyvinyl chloride with chlorine.

polyvinyl fluoride, a synthetic resin belonging to the family of organic polymers. It is a tough material resistant to attack by chemicals or by weathering, produced by treating vinyl fluoride (*q.v.*) under pressure in the presence of oxygen and peroxide catalysts. It is commonly manufactured in the form of films for use in coating such surfaces as siding for buildings or pipes used for transporting corrosive chemicals.

polywater: *see* anomalous water.

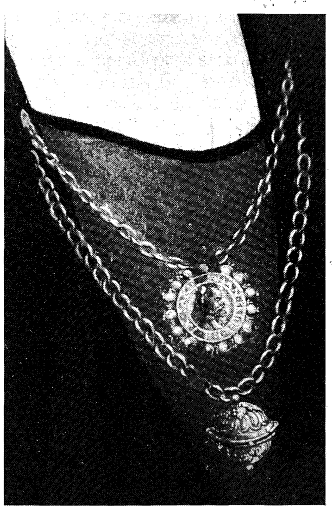
Polyxena, in Greek mythology, a daughter of Priam, king of Troy, and his wife, Hecuba. After the fall of Troy, she was claimed by the ghost of Achilles, the greatest of the Greek warriors, as his share of the spoils and was therefore put to death at his tomb. In post-classical times the story was elaborated to include a love affair between Polyxena and Achilles before his death.

polyzoan (aquatic invertebrate): *see* moss animal.

Polzone, Scipio: *see* Pulzone, Scipione.

pomace fly: *see* vinegar fly.

pomander, small metal (sometimes china) container designed to hold a ball of aromatic spices or herbs. Worn suspended from neck or girdle or attached to the finger by a ring, it was believed to be a protection against infections and noxious smells. As fashionable jew-



Pomander (bottom), detail from "Portrait of a Man," oil painting by Lucas Cranach the Younger, 1543; in the Staatsgalerie Stuttgart, Germany

elry in the late Middle Ages, pomanders were decorative objects often enriched with gems and enamels. Late in the 16th century, the original sphere shape was divided into several segments in order to accommodate a variety of powdered spices, and soon afterward pomanders in the form of dice, skulls, and books appeared.

They were succeeded in the 18th century and 19th century by the vinaigrette. In the 20th century, inexpensive pomanders are made by encrusting an orange with whole dried cloves. *See also* pouncet-box.

Pomare, Sir Maui, in full SIR MAUI WIREMU PITA NAERA POMARE (b. Jan. 13, 1876, Pahou Pa, N.Z.—d. June 27, 1930, Los Angeles), Maori statesman and physician whose public-health work helped revive New Zealand's Maori population, which had declined nearly to extinction by the late 19th century.

Pomare was educated at Te Aute College in Hawkes Bay, where he helped form the Young Maori Party. He became a Maori health officer in 1900 and worked to improve medical care and hygiene in Maori settlements in an effort to overcome resistance to European medical practices. Largely through Pomare's efforts, the Tohunga Suppression Act (1907) was passed, which prohibited unqualified medical treatment in native communities.

As a member of Parliament from 1911 to 1930 and minister for the Maori race (1912–28), Pomare helped form two royal commissions that allowed the Taranaki Maori to buy back their ancestral lands and compensated tribes that had lost land in the Waitara district. His term as minister of health (1923–26) under William F. Massey was noted for the reorganization of New Zealand's mental hospitals. As minister for the Cook Islands (1916–28), Pomare helped to improve the islands' educational and legal systems and fought monopoly trading interests. After his health declined in 1928, he collaborated with James Cowan in writing *The Legends of the Maori.*

He was knighted in 1922.

Pomatorhinidae, scimitar babbler family of noisy birds, based on the genus *Pomatorhinus*—in this encyclopaedia classified as part of the babbler family (Timaliidae, *q.v.*).

Pombal, Sebastião de Carvalho, marquês de (marquess of), in full SEBASTIÃO JOSÉ DE CARVALHO E MELLO, MARQUÊS DE POMBAL, also called (1759–69) CONDE (count) DE OEIRAS (b. May 13, 1699, Lisbon—d. May 8, 1782, Pombal, Port.), Portuguese reformer

Pombal, engraving by João S. Carpinetti, 1759
By courtesy of the Biblioteca Nacional, Madrid

and virtual ruler of his country from 1750 to 1777.

Sebastião was the son of Manuel de Carvalho e Ataíde, a former cavalry captain and former nobleman of the royal house. The elder Carvalho died relatively young, and Sebastião's mother remarried. Sebastião's uncle, Paulo de Carvalho, who was professor at the Universidade de Coimbra, archpriest of the patriarchal see, and a person of political influence, enrolled his nephew in that institution. But Sebastião abandoned his studies to enlist in the army, in which he reached the humble rank of corporal. Disillusioned with the army, he quit and dedicated himself to the study of history and law and was later admitted, at the age of 34, to the Academia Real da História Portuguesa.

In 1733 he married Teresa Maria de Noronha e Almada, a widow, niece of the Conde de Arcos. They moved to the village of Soure, near Coimbra, where he had property. There he dedicated himself to his studies and to agriculture. In 1738 he returned to Lisbon. His uncle now recommended him to João da Mota, prime minister for King John V, who appointed him Portuguese ambassador to England. His wife, in poor health, was unable to accompany him; she died in 1739.

His diplomatic career opened wider political horizons for him. He distinguished himself by the zeal with which he conducted several negotiations. And, for the seven years he stayed in London, Carvalho carefully studied English political, social, and economic practices.

After returning to Lisbon in 1745, Carvalho was immediately appointed ambassador plenipotentiary to Vienna, with the mission of serving as mediator in the solution of a serious quarrel between the Holy Roman empress Maria Teresa and the Vatican. The probabilities of success were very slight, but he overcame all obstacles, winning the sympathy of the Empress and the love of Eleonora von Daun, daughter of the Graf von Daun, whom he married in December 1745. The Austrian climate was bad for his health, however, and he submitted his resignation and returned to Lisbon at the end of 1749.

As King John V did not like him, Carvalho's progress was temporarily halted. But soon after John's death on July 31, 1750, he was called by Queen Maria Ana, the King's widow, of whom he was a favourite, and was appointed to one of the royal councils. The heir to the throne, Prince Joseph, on being crowned king, made him a minister, along with two other favourites. He soon came to dominate Portuguese politics and the new monarch gave him a free hand. Thus began what may be termed the reign of the Marquês de Pombal.

Carvalho instituted domestic administrative reforms and succeeded in elevating Portugal's prestige in external politics. He granted England privileges that entitled it to receive large amounts of gold in exchange for manufactured articles. On the other hand, he stimulated national industry, forbidding the exportation of certain raw materials and developing the manufacture of silk, woollens, ceramics, and glass. Aiming at the development of commerce in the Orient, he founded a company for trade with India, similar to England's but which, however, was unsuccessful. But he was successful in another, similar enterprise—the Companhia do Grão-Pará—aimed at stimulating trade with Brazil.

His reforming activity was interrupted by a catastrophe, the earthquake of Nov. 1, 1755. Two-thirds of Lisbon was reduced to rubble. Carvalho mobilized troops, obtained supplies, and had shelters and hospitals improvised. The day after the catastrophe, he was already outlining ideas for reconstruction. With architect Eugênio dos Santos' plans, old medieval Lisbon was changed into one of the most beautiful European cities.

Carvalho's firm and effective handling of the crisis enhanced his prestige and strengthened even further his position with the King. But his ascendancy had from the beginning created envy and animosity among two very powerful and influential groups: the high nobility and the Society of Jesus. On the night of Sept. 3, 1758, an unsuccessful attempt was made on the King's life. This served as a pretext for Carvalho to rid himself of his enemies among the nobility and Jesuits, whom he accused of conspiracy. The court, influenced by him, attributed the crime to the Duque de Aveiro and to other members of the Távora family. On Jan. 12, 1759, they were tortured to death. Carvalho then began persecuting members of the Society of Jesus. Almost all were deported to Rome, but some were imprisoned, along with many noblemen who were confined without proof of guilt.

Sebastião de Carvalho's power had become absolute. He was created conde de Oeiras in 1759 and continued to enact reforms, including the reform of university education, the initiation of commercial education, the creation of trading companies, and the reorganization of the army. In September 1769 the King conferred on him the title of Marquês de Pombal.

Upon the death of King Joseph on Feb. 24, 1777, however, all the Marquês' power vanished. Under the new queen, Maria I, political prisoners were freed, and Pombal was accused of having abused his powers. He was found guilty by a judicial tribunal that subjected him to severe interrogation from October 1779 to January 1780. Queen Maria then banished him from Lisbon, and he retired to Pombal, where he died in 1782. (M.J.D.)

pomegranate, fruit of *Punica granatum,* a bush or small tree of Asia, which with a little-known species from the island of Socotra constitutes the family Punicaceae. The plant, which may attain 5 or 7 metres (16 or 23

Pomegranate (*Punica granatum*)
Walter Dawn

feet) in height, has elliptic to lance-shaped, bright-green leaves about 75 millimetres (3 inches) long and handsome axillary orange-red flowers borne toward the ends of the branchlets. The calyx is tubular and persistent and has five to seven lobes; the petals are lance-shaped, inserted between the calyx lobes. The ovary is embedded in the calyx tube and contains several compartments in two series, one above the other.

The fruit is the size of a large orange, obscurely six-sided, with a smooth, leathery skin that ranges from brownish yellow to red; within, it is divided into several chambers containing many thin, transparent vesicles of reddish, juicy pulp, each surrounding an angular, elongated seed. The fruit is eaten fresh, and the juice is the source of grenadine syrup, used in flavourings and liqueurs.

Throughout the Orient, the pomegranate has since earliest times occupied a position of importance alongside the grape and the fig. According to the Bible, King Solomon possessed an orchard of pomegranates, and, when the children of Israel, wandering in the wilderness, sighed for the abandoned comforts of Egypt, the cooling pomegranates were remembered longingly. Centuries later, the prophet Muḥammad remarked, "Eat the pomegranate, for it purges the system of envy and hatred."

While the pomegranate is considered indigenous to Iran and neighbouring countries, its cultivation long ago encircled the Mediterranean and extended through the Arabian Peninsula, Afghanistan, and India. It is commonly cultivated in the Americas from the warmer parts of the United States to Chile.

Though the pomegranate grows in a wide range of climates, good fruit is produced only where high temperatures and dry atmosphere accompany the ripening period. Deep, rather heavy loams appear to be the best soils. Seeds can readily be grown, but choice varieties are reproduced by cutting and layerings. Commercial propagation is performed by taking hardwood cuttings 250–300 mm (10–12 inches) long and rooting them in the open ground.

pomelo: *see* grapefruit.

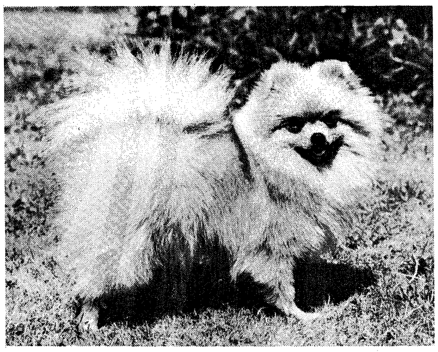
Pomerania, Polish POMORZE, German POMMERN (from Slavic *po,* "along"; *morze,* "sea"), historic region of northeastern Europe lying along the Baltic coastal plain between the Oder and the Vistula rivers. Politically, the name also came to include the area west of the Oder as far as Stralsund, including the island of Rügen (Rugia). Most of Pomerania is now part of Poland, but its westernmost section is in eastern Germany, as reflected in the name of Mecklenburg-West Pomerania *Land* (state). The region is generally flat, and there are numerous small rivers and, along the east coast, many lakes.

Pomerania was inhabited successively by Celts, Germanic tribes, and, by the 5th century AD, the Slavic Pomeranians (Pomorzanie) and Polabs. Mieszko I, prince of Poland (d. 992), mastered it, and in 1000 his successor, Bolesław I the Brave, organized a diocese in Pomerania with its seat at Kołobrzeg. A local dynasty then ruled Pomerania and also the region to the west, later called Mecklenburg. On the death of Duke Swiatobor in 1107, his three sons each inherited a district: Bogusław I received the eastern area, later called Hinterpommern (Pomerania Ulterior, or Eastern Pomerania), including Gdańsk (Danzig); Warcisław I received the western area, Vorpommern (West Pomerania) including Wołogoszcz (Wolgast); and Ratibor obtained the central area including Szczecin (Stettin). German immigration into the western and central regions of Pomerania began in the late 12th century. This resulted in the Germanization of the towns and later of the nobility and the countryside.

Until the 17th century, Polish dukes ruled western and central Pomerania (the duchies of Wolgast and Stettin) under the suzerainty of the Holy Roman Empire. The elector of Brandenburg acquired these duchies in 1637, when the last Polish duke, Bogusław XIV, who had united them, died without issue. Sweden received Western Pomerania by the Peace of Westphalia (1648); part of it was returned to Brandenburg-Prussia in 1720, and the remainder (Stralsund and Rügen) was recovered by Prussia in 1815. Prussia united western and central Pomerania into one province called Pommern.

Eastern Pomerania was held by the Teutonic Knights from 1308 to 1454, when it was reconquered by Poland. In 1772 it was annexed by Prussia and made into the province of West Prussia. Part of it was restored to Poland after World War I; and the remainder, together with central Pomerania, became Polish in 1945. The German population of eastern and central Pomerania was expelled westward and replaced by Poles. Western Pomerania was incorporated into the German Democratic Republic.

Pomeranian, breed of toy dog that can be traced back, like the related Keeshond, Samoyed, and Norwegian elkhound, to early



Pomeranian
Sally Anne Thompson—EB Inc.

sled-dog ancestors. The breed is named for the duchy of Pomerania, where, in the early 19th century, it is said to have been bred down in size from a 30-pound (13.5-kilogram) sheep dog. Characteristically spirited but docile, the Pomeranian is a compactly built dog with a foxlike head and small, erect ears. Its long coat, especially full on the neck and chest, may be any of a variety of colours, including white, black, brown, and reddish brown. The Pomeranian stands about 6 to 7 inches (14 to 18 cm) high and weighs about 3 to 7 pounds (1.5 to 3 kg).

Pomeranian Lakeland, Polish POJEZIERZE POMORSKIE, lake district, northwestern Poland. Located immediately south of the Baltic coastal plain, the 20,000-square-mile (52,000-square-kilometre) lakeland is bounded by the lower Oder River on the west, the ancient river valley occupied by the modern Warta and Noteć rivers on the south, and the lower Vistula River on the east. Owing to the gentle descent of the land to the west as well as northward to the Baltic, the drainage pattern of the district is characterized by rivers that drain alternately from south to north and from east to west. As a result, a trellised, or grid, pattern of valleys dissects the region into rectangular blocks. The region abounds with marshes and streams and has considerably more than 1,000 lakes. Consequently, it is covered with sandy deposits consisting of postglacial outwash, morainal hills, and fluvial material.

The soil of the area is rather acidic and is deficient in humus. In the western part, brown forest soils have developed on the glacial till. In the eastern part, near the Vistula River delta, there are heavier and more fertile soils yielding rye, potatoes, and fodder crops. Important urban centres of the district are Szczecin, Piła, and Bydgoszcz.

pomerium (from Latin *post-moerium,* "behind the wall"), in ancient Rome, a sacred open space located just inside the wall surrounding the four hills—the Esquiline, the Palatine, the Quirinal, and the Capitoline—of the early city. In most Italian walled cities, such spaces, which ran along the complete length of the city walls, were originally left clear to facilitate the maneuvering of defenders in times of attack. This space was later invested with religious significance, being dedicated to the gods in gratitude for their protection, and building and planting upon it remained forbidden. Rome rapidly expanded beyond its pomerium, but the legendary date of its demarcation—April 21—continued to be celebrated as the anniversary of the city's foundation.

pomfret, any of the approximately 35 species of marine fishes constituting the family Bramidae (order Perciformes), with representatives occurring in the Atlantic, Pacific, and Indian oceans. Most are relatively rare. Members of the family are characterized by a single dorsal fin, extending the length of the body in some species. Most species are deep-bodied and have deeply forked tails. Young pomfrets often differ markedly in body and fin form from adults of their species. The blunt-headed Pacific pomfret (*Brama japonica*) ranges abundantly throughout the north Pacific. The bigscale pomfret (*Taractichthys longipinnis*) of the Atlantic Ocean, the largest species in the family, reaches a length of 90 cm (35 inches).

Pomigliano d'Arco, town, in Napoli *provincia,* Campania *regione,* southern Italy, at the northern foot of Vesuvius. It is an agricultural centre with a castle dating from the 15th century. An air-force flight-training establishment is nearby. The town is the site of an automobile factory established in 1970, one of the most important development projects in the Mezzogiorno. Pop. (1987 est.) mun., 41,358.

Pommern: *see* Pomerania.

Pomo, Hokan-speaking Californian Indians of the west coast of the United States. Their territory was centred in the Russian River valley some 50 to 100 miles (80 to 160 km) north of what is now San Francisco. The Pomo's territory also included the adjacent coastlands and the interior highlands near Clear Lake. A small, detached group lived in the Sacramento River valley surrounded by Wintun (*q.v.*).

The Pomo were a wealthy people, well-supplied with food and other natural resources. Fish, waterfowl, deer, acorns, bulb plants, and other food were plentiful. Northeastern settlements held a lucrative salt deposit. Southeastern settlements had magnesite, a substance that, along with ground shells, was made into beads used as standard currency in north-central California. Pomo basketry, considered by some to be the finest in California, was exceptionally well twined and intricately ornamented, using various woody materials, beads, and coloured feathers. Their housing depended on locale: coastal people constructed dwellings of heavy timber and bark; inland peoples built various types of dwellings out of such materials as poles, brush, grass, and tule mats.

The Pomo practiced the Kuksu cult, a ceremonial religion involving secret societies, esoteric dances and rituals, and impersonations of spirits. There were also ceremonies for such things as ghosts, coyotes, and thunder.

There were probably about 900 Pomo remaining in the late 20th century, living in some 20 communities in their original territory.

were introduced by Madame de Pompadour, mistress of Louis XV of France, and imitated by members of his court.

Dressing the hair with a pompadour was favoured in the opening years of the 20th century. Men brushed the front hair back, and women used pads or other devices to create the raised pompadour, thus giving the illusion of a mass of puffy hair.

Pompadour, Jeanne-Antoinette Poisson, marquise de (marchioness of), byname MADAME DE POMPADOUR, also called (1741–45) JEANNE-ANTOINETTE LE NORMANT D'ÉTIOLES (b. Dec. 29, 1721, Paris—d. April 15, 1764, Versailles, Fr.), influential mistress (from 1745) of the French king Louis XV and a notable patron of literature and the arts.

Early years. Her parents were on the fringes of a class gaining in importance, speculators in the world of finance. Some of these people made immense fortunes, but many ended in the gutter if not in prison. Her father, François Poisson, involved in a black-market scandal, had to flee the country in 1725; his beautiful wife and two small children were then looked after by a more fortunate colleague, Le Normant de Tournehem. Both children were clever, and the girl was fascinating; she was educated to be the wife of a rich man. In those days rich men, even if they came from a low class, were interested in art and literature, and they expected their wives to share these interests.

By the time Mademoiselle Poisson was of an age to marry, she could hold her own in any society and had made friends with many distinguished men, including Voltaire. Le Normant de Tournehem arranged a match for her with his own nephew, Charles-Guillaume

Madame de Pompadour, detail of a portrait by François Boucher; in the National Gallery of Scotland, Edinburgh

By courtesy of the National Galleries of Scotland, Edinburgh

Le Normant d'Étioles, a rising young man; they had a little girl, Alexandrine. Madame d'Étioles became a shining star of Parisian society and was admired by the King himself. In 1744 Louis XV's young mistress, the Duchesse de Châteauroux, died suddenly. She was soon replaced by Madame d'Étioles, who obtained a legal separation from her husband and was created marquise de Pompadour.

Nineteenth-century historians thought that Madame de Pompadour had complete ascendancy over Louis XV. These post-Revolution writers were concerned with portraying the Bourbon monarchs as poor creatures; it is now generally admitted that Louis XV was a much more able man than he has been painted. Shy and introspective, he had difficulty in communicating with people whom he did not know well. Madame de Pompadour acted as his private secretary, but, although she gave the orders, the decisions were made by the King.

She began her reign at Versailles modestly. She was lodged in a few rooms under the roof; she set out to make herself agreeable to all those who counted for anything in the palace, beginning with Queen Marie (Maria Leszczyńska). Marie could hardly have been a more unsuitable wife for the handsome, artistic, sensual, and pleasure-loving Louis XV. Eight years older than he, she was preoccupied with the welfare of her father (a deposed king of Poland), with childbearing, and with religion. After giving birth to an heir to the throne (and eight or nine other children between 1727 and 1737), she let the King understand that she had no wish to remain sexually intimate with him.

After five romantic years in her attic, Madame de Pompadour moved downstairs to a regal apartment. Louis XV now began to take other mistresses, but Madame de Pompadour was more firmly established than ever before; favours, promotions, and privileges could be obtained only through her good offices.

Artistic and political collaboration with Louis. Her collaboration with the King was twofold, artistic and political. The artistic side was wholly successful. On her suggestion, her brother was appointed director of the King's buildings and created marquis de Marigny; the brother, the sister, and Louis XV, working in perfect harmony, planned and built the École Militaire and the Place Louis XV (now the Place de la Concorde) in Paris, most of the palace of Compiègne, the Petit Trianon Palace at Versailles, a new wing at the palace of Fontainebleau, and the exquisite Château de Bellevue, as well as many pavilions and summer houses. He and his mistress patronized all forms of decorative art: painters, sculptors, cabinetmakers, and craftsmen worked under the royal eye; the famous porcelain factory was built at Sèvres. Madame de Pompadour's 20 years of power marked the very apogee of taste in France. The protector of most of the authors and the editor of the *Encyclopédie,* she would have liked to do for literature what she did for the arts, but the King had no literary interests and disliked the intellectuals whom he knew.

The political collaboration between the King and his mistress was much less successful than the artistic, mainly because the French politicians and generals of the day were of such poor calibre. The Duc de Choiseul, by far the ablest of the ministers, was Madame de Pompadour's protégé. He was brought in to implement the famous Reversal of Alliances, which allied France with its old enemy Austria against the German Protestant principalities. This was a statesmanlike conception, but it was unpopular and led to the Seven Years' War, disastrous to France. Frederick the Great crushed the huge, incompetently led French and Austrian armies, while the English were driving the French out of Canada. All these defeats were laid at the door of Madame de Pompadour. She fell prey to melancholy, and soon after the end of the war she died, in the spring of 1764, probably of cancer of the lung, in her apartment at Versailles. One of her last actions was to get Louis XV's support for the revision of the Calas case, a gross miscarriage of justice in which Voltaire was interested. Voltaire said of her:

> I mourn her out of gratitude . . . Born sincere, she loved the King for himself; she had righteousness in her soul and justice in her heart; all this is not to be met with every day.

(Na.M.)

Perciformes). Pompanos, some of which are highly prized as food, are deep-bodied, toothless fishes with small scales, a narrow tail base, and a forked tail. They are usually silvery and are found along shores in warm waters throughout the world. The Florida, or common, pompano (*T. carolinus*), considered the tastiest, is a valued commercial food fish of the American Atlantic and Gulf coasts and grows to a length of about 45 centimetres (18 inches) and weight of 1 kilogram (2 pounds). The blue and silver great pompano (*T. goodei*), or permit, is found off Florida and the West Indies.

The African pompano, or threadfish, also of the family Carangidae, is *Alectis crinitis* of the Atlantic and eastern Pacific oceans. It is about 90 centimetres (35.5 inches) long and, especially when young, has very long, threadlike rays extending from the dorsal and anal fins.

The Pacific pompano (*Peprilus simillimus*) is a food fish of the butterfish (*q.v.*) family.

Pompeii, ancient city of Campania, Italy, 14 miles (23 kilometres) southwest of Naples, near Mt. Vesuvius, built on a spur formed by a prehistoric lava flow to the north of the mouth of the Sarnus (modern Sarno) River. Pompeii was destroyed, together with Herculaneum and Stabiae (*qq.v.*), by the violent eruption of Mt. Vesuvius in AD 79; the circumstances of their preservation make their remains a unique document of Greco-Roman life. The modern town of Pompei (pop. [1981 prelim.] 22,896) lies to the east; it contains the basilica of Santa Maria del Rosario, a pilgrimage centre.

History. It seems certain that Pompeii, Herculaneum, and Stabiae were first settled by the Oscans, who were descendants of the Neolithic inhabitants of Campania. Archaeological evidence indicates that the Oscan village of Pompeii, strategically located near the mouth of the Sarnus River, soon came under the influence of the cultured Greeks who had settled across the bay in the 8th century BC. Greek influence was challenged, however, when the Etruscans came into Campania in the 7th century. The Etruscans' influence remained strong until their sea power was destroyed by King Hieron I of Syracuse in a naval battle off Cumae, in 474 BC. A second period of Greek hegemony followed.

Then, toward the end of the 5th century, the warlike Samnites, an Italic tribe, conquered Campania, and Pompeii, Herculaneum, and Stabiae became Samnite towns. Coinage suggests that a century later the city of Nuceria was the head of a league to which Pompeii, Herculaneum, and Stabiae may have belonged.

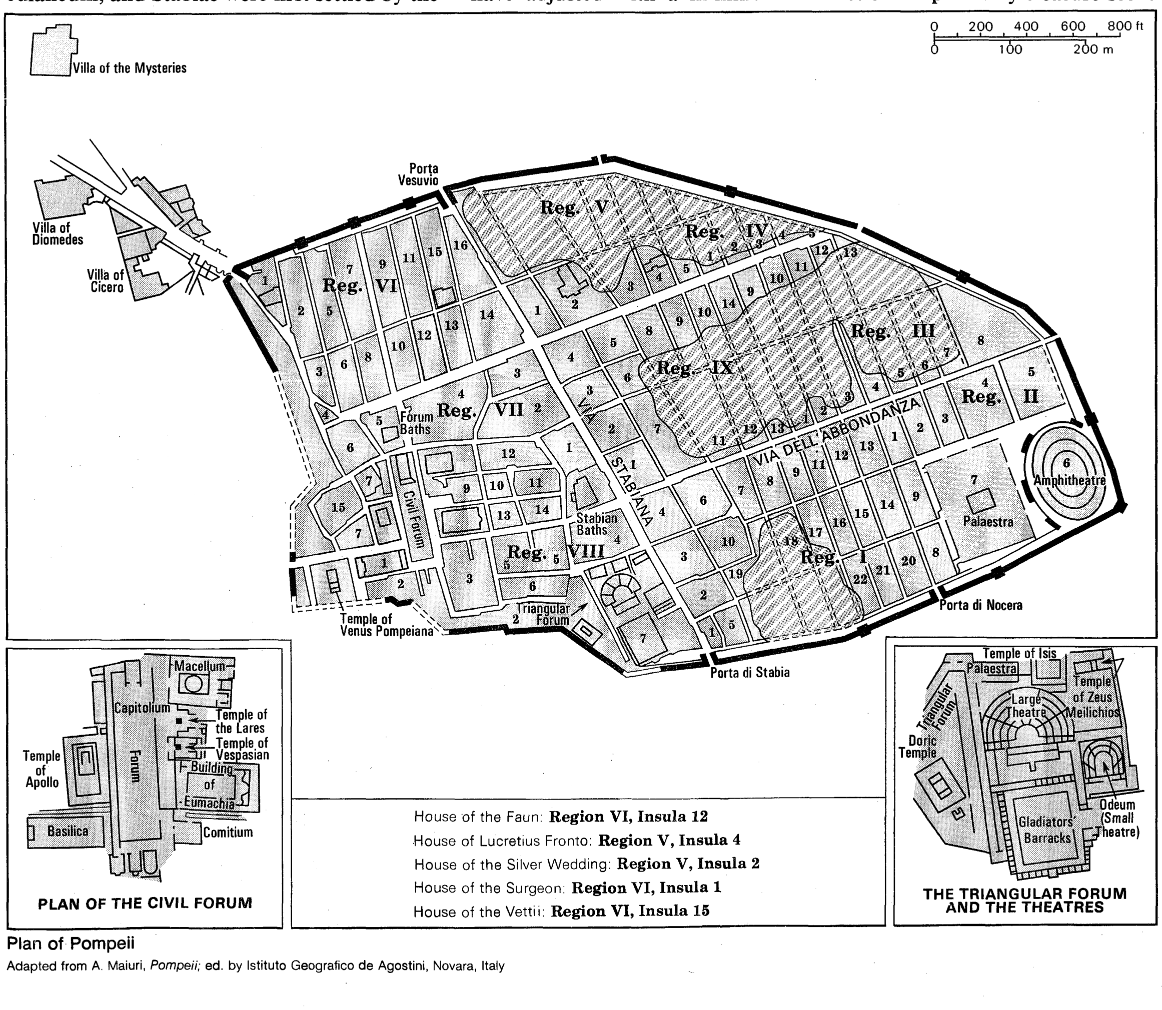
Pompeii is first mentioned in history in 310 BC, when, during the Second Samnite War, a Roman fleet landed at the Sarnus port of Pompeii and from there made an unsuccessful attack on Nuceria. At the end of the Samnite Wars, Campania became a part of the Roman confederation, and the cities became "allies" of Rome. But they were not completely subjugated and Romanized until the time of the Social War (the war of the *socii,* or "allies"). Pompeii joined the Italians in their revolt against Rome in this war and was besieged by the Roman general Lucius Cornelius Sulla in 89 BC. After the war, Pompeii, along with the rest of Italy south of the Po, received Roman citizenship. As a punishment for Pompeii's part in the war, a colony of Roman veterans was established there under Publius Sulla, the nephew of the Roman general. After initial difficulties, Pompeians and colonists seem to have adjusted with a minimum of friction. Latin now replaced Oscan as the official language, and the city soon became Romanized in institutions, architecture, and culture.

A riot in the amphitheatre at Pompeii between the Pompeians and the Nucerians, in AD 59, is reported by the Roman historian Tacitus. An earthquake in AD 62 did great damage in both Pompeii and Herculaneum. The cities had not yet recovered from this catastrophe when final destruction overcame them 17 years later.

Mt. Vesuvius erupted on Aug. 24, AD 79. A vivid eyewitness report is preserved in two letters written by Pliny the Younger to Tacitus, who had inquired about the death of Pliny the Elder, commander of the Roman fleet at Misenum. Pliny the Elder had died at Stabiae while trying to rescue friends. When the eruption ceased on the second day, Pompeii was covered with lapilli (volcanic debris) and ashes to a depth of 19 to 23 feet (6 to 7 metres). The villas at Stabiae, at a greater distance from Vesuvius, did not have as deep a covering. At Herculaneum the avalanche of volcanic materials carried along by torrents of water hardened into a kind of mud-lava that penetrated everywhere and covered the city up to a depth of 65 feet.

History of excavations. The ruins at Pompeii were first discovered late in the 16th century by the architect Domenico Fontana, who tunnelled under the hill known as La Cività to bring water from the Sarno River to the town of Torre Annunziata. Excavation of the buried cities began first at Herculaneum, in 1709, during Austrian occupation. Work did not begin at Pompeii until 1748, and in 1763 an inscription ("*rei publicae Pompeianorum*") was found that identified the site as Pompeii.

Excavations have continued intermittently until the present. Earlier digging was haphazard and often irresponsible; excavators were primarily treasure seekers, hunting for impos-



Plan of Pompeii

Adapted from A. Maiuri, *Pompeii;* ed. by Istituto Geografico de Agostini, Novara, Italy ing buildings or museum objects. Haphazard digging was brought to a stop in 1860, when the Italian archaeologist Giuseppe Fiorelli became director of the excavations. Areas lying between excavated sites were cleared and carefully documented. Pompeii was divided into nine Regions; the insulae (blocks) in each Region were numbered, and each door on the street was given a number so that each house could be conveniently located by three numbers (*see* plan). Fiorelli also developed the technique of making casts of bodies by pouring cement into the hollows formed in the volcanic ash when the bodies disintegrated. This technique is also used to make casts of ancient doors, furniture, and roots.

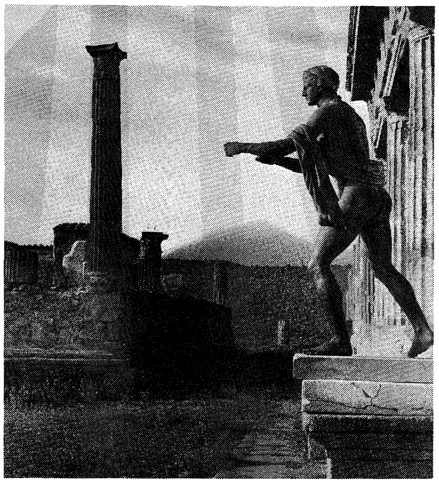
In 1951, after the interruption caused by World War II, intensive excavation was resumed under Amedeo Maiuri, who was in charge of the excavations from 1924 to 1961. Large areas to the south of the Via dell'Abbondanza in Regions I and II were uncovered, and the debris piled outside the city walls was cleared away. This revealed the Porta (Gate) di Nocera and an impressive stretch of cemetery lining each side of the road leading from the gate to Nuceria. By the late 20th century, about three-fourths of the city had been excavated.

In the vicinity of Stabiae and Gragnano, excavations initiated by Charles IV discovered 12 villas between 1749 and 1782. Work was not resumed again until the present century, and it is still in progress. The Villa of San Marco, with its two large peristyle gardens and bath, is the best preserved. Other villas have been found near Gragnano, in the vicinity of Pompeii, and at nearby Scafati, Domicella, Torre Annunziata, and on the lower slopes of Vesuvius near Boscoreale and Boscotrecase. Many of these villas were reburied after excavation, but a few can be seen, notably the Villa of the Mysteries.

Description of the remains. The city of Pompeii was shaped irregularly because of the prehistoric lava flow on which it was built. Excavations indicate that the southwestern part of the town was the oldest, but scholars are not agreed as to the stages by which the walls were expanded, or by whom. The walls are two miles (three kilometres) in circumference, and they enclose an area of about 155 acres (63 hectares). They were probably given their final boundaries after the Samnites took over Pompeii, but there is evidence of Greek influence. Seven city gates have been excavated. The chief street running in a southeast–northwest direction was the Via Stabiana; it connected the Porta Vesuvio (144 feet [44 metres] above sea level), in the highest part of the city, with the Porta di Stabia (26 feet [8 metres]), in the lowest part of town. Through this gate came traffic from the Sarnus River and Stabiae. This street was crossed by two other main streets, the Via dell' Abbondanza and the Via di Nola.

The public buildings are for the most part grouped in three areas: the Forum (elevation 110 feet [34 metres]), located in the large level area on the southwest; the Triangular Forum (82 feet [25 metres]), standing on a height at the edge of the south wall overlooking the bay; and the Amphitheatre and Palaestra, in the east.

The Forum was the centre of the religious, economic, and municipal life; it was a large rectangular area surrounded by a two-storied colonnaded portico. Dominating the Forum on the north was the temple dedicated to the Capitoline triad of deities: Jupiter, Juno, and Minerva. To the east was the Macellum, or large provision market; to the south were the small sanctuary of the city Lares (guardian deities), built after the earthquake in AD 62; the Temple of Vespasian; and the imposing headquarters of the woollen industry, erected by the wealthy patroness Eumachia. Opposite the Capitolium on the southern end of the Forum were the meeting place of the city council and the offices of the magistrates of the city. The large basilica, with its main room surrounded on four sides by a corridor, is the most architecturally significant building in the city and of considerable importance in studying the origin and development of the Christian basilica. It served as a covered exchange and as a place for the administration of justice. To the west was the Temple of Venus Pompeiana, patron deity of Pompeii.



Temple of Apollo, Pompeii, with Mt. Vesuvius in the background
Edwin Smith

Across from the basilica was the Temple of Apollo, one of the oldest in the city. Subsoil excavations here give evidence for Greek and Etruscan influence.

The Triangular Forum is the site of the Doric Temple, the oldest temple in the city. Between the 3rd and the 1st century, a theatre, a palaestra, and a small covered theatre were built to the east of the Triangular Forum. The temples of Zeus Meilichius and of Isis, and the old Samnite palaestra, were nearby. In the east corner of Pompeii was the Amphitheatre; the oldest so far known, it was built after the Roman colony was established at Pompeii. To the west a large palaestra was built to replace the old Samnite palaestra. Baths were scattered throughout the town: the Stabian Baths (which date before the Roman period), the Forum Baths, the Central Baths—still under construction at the time of the eruption—and many baths in luxurious private homes.

But more significant than the public buildings, which have been excavated at other sites, are the hundreds of private homes. These are unique, for only at Pompeii is it possible to trace the history of domestic architecture for at least four centuries. The earliest houses date from the First Samnite period (4th–3rd century BC). The House of the Surgeon is the best known example of the early atrium house built during this period.

The most luxurious houses were built during the Second Samnite period (200–80 BC), when increased trade and cultural contacts resulted in the introduction of Hellenistic refinements. The House of the Faun occupies an entire city block, has two atria (chief rooms), four triclinia (dining rooms), and two large peristyle gardens. Its facade is built of fine-grained gray tufa from Nuceria, the chief building material of this period. The walls are decorated in the Incrustation, or First Pompeian, style of painting, which imitates marble-veneered walls by means of painted stucco. The famous Alexander the Great mosaic found in the House of the Faun is probably a copy of a lost Hellenistic painting. Many of the houses from this period were decorated with elaborate floor mosaics. The House of the Silver Wedding, with its imposing high-columned atrium, was also built during this period, but it underwent later alterations. The handsome banquet hall and the exedra, which served as a schoolroom for children of the family, were decorated in the Second Pompeian, or Architectural, style, which was popular from 80 BC to AD 14.

The large number of houses built during the Samnite period made it necessary to build fewer houses in the Roman period. Those that were built were usually less imposing, with lower atria, but with more elaborate decoration. The House of Lucretius Fronto is a small but elegant house of the Roman Imperial period. The tablinum (master's office) is decorated in especially fine Third Pompeian, or Egyptianizing, style, usually dated from the early empire to the earthquake. The House of the Vettii is typical of the homes of the prosperous merchant class of the Roman period. Some of its rooms are decorated in the Fourth Pompeian, or Ornamental, style.

The atrium-peristyle house, with its handsome paintings, elegant furniture, beautiful gardens with fountains and bronze and marble sculptures, is not as typical as has generally been supposed. There are also numerous small homes throughout the city, many of them shop houses. Excavators now preserve as completely as possible all aspects of ancient life. The homes of the humble are as informative as those of the wealthy. Roofs, second stories, and balconies can now be restored.

Influence on European culture. The discoveries at Pompeii and other sites buried by the Vesuvian eruption had a profound influence on European taste. News of the excavations kindled a wave of enthusiasm for antiquity that spread throughout Europe. The laudatory pronouncements of the eminent German classicist Johann Joachim Winckelmann, who made his first trip to Naples in 1755, and the etchings of Giambattista Piranesi did much to popularize the excavations. Naples, Pompeii, and Herculaneum became important stops on the European Grand Tour made by English visitors, who found an enthusiastic guide and a well-informed amateur archaeologist in Sir William Hamilton, ambassador to the Naples court from 1764 to 1800, and a captivating hostess in his second wife, Lady Emma Hamilton.

Artists, architects, potters, and even furniture makers drew much inspiration from Pompeii. Contemporary painted interiors were inspired by the frescoed walls found in the excavations. The stucco work popularized in England by the 18th-century architects Robert and James Adam used the same motifs. The famed potter Josiah Wedgwood changed the style of his work and named his factory "Etruria," sharing the mistaken belief that Pompeii was Etruscan. In France, the Louis XVI style incorporated Pompeian motifs, and the apartment of Louis's queen, Marie Antoinette, at Fontainebleau was decorated in this style, which became popular throughout Europe. Jacques-Louis David and his student Jean-Auguste-Dominique Ingres drew inspiration for their paintings from the excavations. Indeed, the Neoclassic style stimulated by the discoveries at Pompeii completely replaced the Rococo and became the artistic style of the French Revolution and of the Napoleonic period.

Importance as historical source. The extent of the archaeological sites makes them of the greatest importance, for they provide a unique source of information about so many aspects of social, economic, religious, and political life of the ancient world. The many well-preserved house shrines give a hitherto unexpected picture of the vitality of religion in the family. The bakeries, complete with mills, kneading machines, and ovens, some still containing loaves of bread, show how this staple of everyday life was produced. Numerous fulleries (processing and cleaning plants for wool) make it possible to study this important industry. The shops of the sculptor, toolmaker, and gem cutter, as well as the *garum* (fish sauce) and the lamp factories and the many wine and food shops, document other aspects of ancient life. Pompeii was a busy port town that exported products throughout the Mediterranean. Merchants and tradesmen found food and lodging near the city gates and the Forum. Some restaurants and inns were quite attractive and served food to guests who reclined in the garden; in the cheaper places, the rooms were small and dark and customers sat on stools.

Inscriptions provide further information. They include monumental inscriptions on public buildings, tombs, and statue bases; the business transactions recorded in the famous wax tablets of the banker Lucius Caecilius Jucundus; announcements of gladiatorial combats; and many election notices, echoes of hotly fought contests. Preserved in the graffiti are accounts, lists of market days, the exchanges of lovers, quotations from Virgil, and even the scratched alphabets of children. Epigraphical and archaeological evidence makes it possible to study the stratification of society and learn more of the freedmen, slaves, small businessmen, and aristocrats of the ancient Roman world.

Further, Pompeii offers the best opportunity for the study of city planning and land use in an ancient city. Recent excavations have revealed an unexpected amount of open land. The large insula across from the Amphitheatre was not the Foro Boario (Cattle Market), as had been long supposed, but a vineyard. Many vineyards, fruit trees, and gardens have been found, indicating less intensive land use and a smaller population than had been thought.

Unfortunately, the excavations are constantly endangered by the ravages of weather and destructive vegetation. Of first importance is the preservation, restoration, and study of the valuable evidence already uncovered before it is lost forever.

BIBLIOGRAPHY. August Mau, *Pompeji in Leben und Kunst* (1900; rev. Eng. trans. by F.W. Kelsey, *Pompeii: Its Life and Art,* 2nd ed., 1902), still the most comprehensive treatment, but now outdated; Matteo Della Corte, *Case ed abitanti di Pompei,* 3rd ed. (1965), a thorough, scholarly treatment of the houses and places of business, and their owners as identified from the inscriptions and the graffiti; Robert Etienne, *La Vie quotidienne à Pompéi* (1966), a good discussion of daily life; H.H. Tanzer, *The Common People of Pompeii: A Study of the Graffiti* (1939), brief but interesting; Wilhemina Jashemski, *Letters from Pompeii* (1963), actual letters written from Pompeii, with descriptions of new excavations, coloured photos of excavated sites, and paintings by M. Sasek showing how the sites looked in antiquity, and her *Gardens of Pompeii: Herculaneum and the Villas Destroyed by Vesuvius* (1979), a comprehensive discussion of these sites, for almost every house and many public buildings had gardens; Amedeo Maiuri, *Pompeii,* 14th ed. (1970), the best brief treatment available.

Pompeius Magnus, Gnaeus: *see* Pompey the Great.

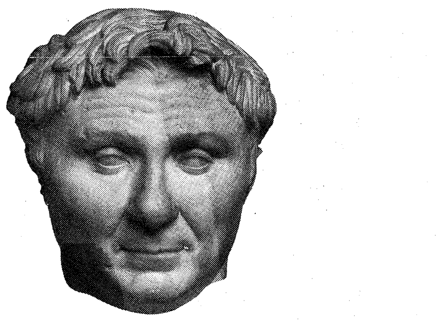
Pompeius Magnus Pius, Sextus (b. *c.* 67 BC—d. 35 BC, Miletus), younger son of the Roman general Pompey the Great, and a vigorous opponent of Pompey's Caesarian rivals.

After his father was killed in the Civil War (49–45 BC) against Julius Caesar, Pompeius fled to Spain, where he continued the struggle against Caesar's forces. Following the assassination of Caesar in 44, Pompeius came to terms with Mark Antony and was given a naval command, but in August 43 he was outlawed. For the next several years he ravaged the coast of Italy with his fleet. Occupying Sicily and blockading Italy, he helped Mark Antony against Octavian and, after they renewed their agreement, forced them to make a formal treaty with him, appointing him governor of Sicily and other islands and of Achaea (39). When these promises were not carried out, Pompeius renewed the war and, after some striking successes against Octavian, was decisively defeated by Octavian's friend Agrippa at Naulochus (near Messina, Sicily, 36). He fled to Asia Minor but was captured and executed by the Roman general Marcus Titius.

Pompe's disease, also called GLYCOGENOSIS TYPE II, hereditary defect in the body's ability to metabolize glycogen, resulting in a muscle disorder that is usually fatal during the first year of life. The defect responsible, absence of the enzyme alpha-1,4-glucosidase, is extremely rare, occurring in fewer than one in every 150,000 births, and is transmitted as an autosomal recessive trait. In Pompe's disease, glycogen accumulates in all body tissues, but especially in the muscles, causing enlargement of the heart, cardiac muscle failure, and breathing difficulties. Accumulation of glycogen in other tissues causes mental retardation and enlargement of the liver and spleen. Death usually results from cardiorespiratory failure. Juvenile and adult forms, with similar but milder symptoms, are also known.

Pompey THE GREAT, Latin in full GNAEUS POMPEIUS MAGNUS (b. Sept. 29, 106 BC, Rome—d. Sept. 28, 48 BC, Pelusium, Egypt), one of the great statesmen and generals of the late Roman Republic, a triumvir (61–54 BC), the associate and later opponent of Julius Caesar. He was initially called Magnus (the Great) by his troops in Africa (82–81 BC).

Early career. Pompey belonged to the senatorial nobility, although his family first achieved the office of consul only in 141.



Pompey, bust *c.* 60–50 BC; in the Ny Carlsberg Glyptotek, Copenhagen
By courtesy of Ny Carlsberg Glyptotek, Copenhagen

Fluent in Greek and a lifelong and intimate friend of Greek literati, he must have had the normal education of a young Roman nobleman; but his early experience on the staff of his father, Pompeius Strabo, did much to form his character, develop his military capabilities, and arouse his political ambition. The family possessed lands in Picenum, in eastern Italy, and a numerous body of clients, which Strabo greatly enlarged in the year of his consulship. In a civil war (88–87) between the rival generals Lucius Sulla and Gaius Marius, Strabo defied Sulla and favoured the Marians and a fellow general.

After his father's death, however, Pompey detached himself from the Marians. A report that he was "missing" in Cinna's army, when it was embarking for the Balkans to deal with Sulla, led to the lynching of Cinna by his troops (84). Pompey's part in this mutiny is unclear; he next appears with three legions recruited in Picenum, joining Sulla as an independent ally in the campaign to recover Rome and Italy from the Marians (83). Sulla made ample use of his youthful ally's military abilities. Pompey married Sulla's stepdaughter. On Sulla's orders the Senate gave Pompey the job of recovering Sicily and Africa from the Marians—a task he completed in two lightning campaigns (82–81). Pompey ruthlessly executed Marian leaders who had surrendered to him. To his enemies he was Sulla's butcher; to the troops he was "Imperator" and "Magnus." From Africa Pompey demanded that a triumph be given him in Rome; he refused to disband his army and appeared at the gates of Rome, obliging Sulla to yield to his demand. After Sulla's abdication, Pompey supported the renegade Sullan Marcus Lepidus for the consulship of 78. Once in office Lepidus attempted revolution, and Pompey promptly joined the forces of law and order against him. The rising crushed, however, Pompey refused to disband his army, which he used to bring pressure on the Senate to send him with proconsular power to join Metellus Pius in Spain against the Marian leader Sertorius.

The reconquest of Spain taxed Pompey's military skill and strained his own and the state's resources to the utmost. In the end it was he, not Metellus, who imposed on Spain a settlement reflecting and promoting his own political aims. His policy was one of reconciliation and rehabilitation. His personal authority and patronage now covered Spain, southern Gaul, and northern Italy. Unlike Metellus, Pompey took his army back to Italy with him, ostensibly to assist in putting down a slave revolt led by Spartacus, but in reality to secure a triumph and election to the consulship for 70. The nobles whom Sulla had restored to power had proved to be more corrupt and incompetent than ever. Pompey promised reforms at home and abroad. A bargain was struck with his rival Marcus Licinius Crassus, the two were jointly elected consuls, and Pompey was given another triumph.

Reorganization of the East. Although the nobles were to continue to dominate the consular elections in most years, the real sources of power henceforth lay outside of Italy. Extraordinary commands would have to be created if Rome was to recover control of the sea from pirates. It was Pompey who benefitted most from the restoration of tribunician initiative. After his consulship, he waited in Rome while rival nobles undermined the position of Lucius Licinius Lucullus, who was campaigning against Mithradates in Anatolia, and made halfhearted attempts to deal with the pirates. Finally, in 67, the tribune Aulus Gabinius forced a bill through the popular assembly empowering Pompey to settle the pirate problem.

Pompey was still in the East, resettling pirates as peaceful farmers, when in Rome another tribune, Gaius Manilius, carried through, against weakened opposition, a bill appointing Pompey to the command against Mithradates, with full powers to make war and peace and to organize the whole Roman East (66). Pompey displaced Lucullus and lost no time defeating Mithradates in Asia Minor. After the death of Mithradates in 63, Pompey was free to plan the consolidation of the eastern provinces and frontier kingdoms. For 6,000 talents he set up King Tigranes in Armenia as a friend and ally of Rome—and as his own protégé. Pompey rejected the Parthian king's request to recognize the Euphrates as the limit of Roman control and extended the Roman chain of protectorates to include Colchis, on the Black Sea, and the states south of the Caucasus. In Anatolia, he created the new provinces of Bithynia-Pontus and Cilicia. He annexed Syria and left Judaea as a dependent, diminished temple state. The organization of the East remains Pompey's greatest achievement. His sound appreciation of the geographical and political factors involved enabled him to impose an overall settlement that was to form the basis of the defensive frontier system and was to last, with few important changes, for more than 500 years.

Pompey's power and prestige were at their height in December 62, when he landed at Brundisium (Brindisi) and dismissed the army. His third triumph (61) trumpeted the grandeur of his achievement. The following decade was the period of his ascendancy in Italy, an ascendancy that was to be eroded through Caesar's growing military power and gradual capture of Pompey's worldwide *clientelae,* from the power base Caesar, in turn, created in northern Italy and Gaul. Pompey's inveterate enemies in Rome were the Optimates, the inner ring of nobles, not Crassus or Caesar, who had merely tried to steal the limelight in Pompey's absence and to manoeuvre into a better position for bargaining with their former political ally. The nobles meanwhile had gradually reasserted their dominance in Rome and hampered attempts to alleviate the condition of Italy and the Roman populace. Once back in Italy, Pompey avoided siding with popular elements against the Optimates. He was no revolutionary. He wanted all classes to recognize him as first citizen, available for further large-scale services to the state. He had divorced his third wife, Mucia, and now proposed to ally himself by marriage to the party of the young senatorial leader Marcus Porcius Cato the Younger. But the nobles were closing their ranks against him, and his offer was rebuffed. Lucullus and others were determined to prevent the en bloc ratification of Pompey's eastern settlement and to reject his demand for land for his veterans.

The First Triumvirate. Help came only when Caesar returned from his governorship in Spain. Pompey, Crassus, and Caesar formed the unofficial and at first secret First Triumvirate. It was to become more than a mere election compact. It would strain all the resources of the triumvirs to wrest one consulship from the Optimates; their continued solidarity was essential if they were to secure what Caesar gained for them in 59. Caesar, for his part, wanted a long-term command. Pompey, who now married Caesar's daughter, Julia, saw Caesar as his necessary instrument. Caesar, once consul, immediately forced through a land bill and, shortly after, another appropriating public lands in Campania. Once he had secured a five-year command in Illyria and Gaul he could be relied on to take off a large proportion of Pompey's discharged troops and give them further opportunities for profitable employment.

Pompey solved the problem of Rome's grain supply with his usual efficiency, but the nobles kept up their opposition. The year 56 was a critical one for the triumvirs. The nobles concocted religious impediments to prevent the dispatch of Pompey on a military mission to Egypt, while Publius Clodius contrived to persuade Pompey that Crassus had designs on his life. An attempt was made to suspend Caesar's law for the distribution of Campanian land.

Alarmed at Pompey's suspicions and truculence, Crassus set off to meet Caesar at Ravenna, and Caesar in turn came to the limit of his province at Luca to meet Pompey. The Luca conference (56) prepared the ground for the next phase of triumviral cooperation: Pompey and Crassus were to secure election to the consulship for 55, for they, too, wanted five-year commands in the provinces, while Caesar's command was to be renewed for another five years. The three secured their ends by violence and corruption after a prolonged struggle. Early in 55 Pompey and Crassus were at last elected consuls, with most of the lesser magistracies going to their supporters. Caesar obtained the extension of his command, while Pompey and Crassus received commands in Spain and Syria, respectively. Pompey could stay on in Italy and govern his provinces by deputies. But the triumvirate was coming to an end. The death of Julia (54) destroyed the strongest bond between Pompey and Caesar, and Crassus suffered disastrous defeat and death in Mesopotamia. The triumvirate existed no longer; but Pompey as yet showed no inclination to break with Caesar.

Civil war. Meanwhile, from outside the walls of Rome, Pompey watched the anarchy in the city becoming daily more intolerable. He was prepared to wait without committing himself until the Optimates found an alliance with him unavoidable. He refused further offers from Caesar of a marriage alliance. There was talk in Rome as early as 54 of a dictatorship for Pompey. Street violence made it impossible to hold the elections. In January 52 Clodius was killed by armed followers of Titus Annius Milo, whose candidacy for the consulship was being bitterly opposed by both Pompey and Clodius. Now both factions exploded into even greater violence. The senate house was burnt down by the mob. With no senior magistrates in office, the Senate had to call on Pompey to restore order. It was the hour he had waited for. He speedily summoned troops from Italy. The nobles would not have him as dictator; they thought it safer to appoint him sole consul.

Pompey's legislation of 52 reveals his genuine interest in reform and the duplicity of his conduct towards Caesar. He reformed procedure in the courts and produced a panel of respectable jurors. A severe law against bribery at elections was made retrospective to 70 and, for all Pompey's protests, was rightly taken by Caesar's friends as aimed at him. Another useful law enforced a five-year interval between tenure of magistracies in Rome and assumption of provincial commands. But this law and another, which prohibited candidature in absence, effectively destroyed the ground of Caesar's expectation that he should become designated consul, and so safe from prosecution, before he had to disband his army in Gaul. Several attempts were made in the years 51–50 to recall Caesar before the expiration of his second term in Gaul. They were frustrated by the assertiveness of Caesar's faction and agents in Rome. Pompey, for all his growing fear and suspicion of Caesar's ambitions, did not come out openly against Caesar until late in 51, when he suddenly made clear his intentions. He declared that he would not consider the suggestion that Caesar should become designated consul while still in command of his army. His proposals for a compromise date for Caesar's recall were unacceptable to Caesar, whose sole resource now was to use the wealth he had accumulated in Gaul to buy men who could obstruct his enemies in the Senate. When war came, the Senate was evenly divided between Caesar and Pompey. The consulars were solidly for Pompey, although they saw him simply as the lesser evil. Late in 50 the consul Gaius Marcellus, failing to induce the Senate to declare Caesar a public enemy, visited Pompey with the consuls designate and placed a sword in his hands. Pompey accepted their invitation to raise an army and defend the state. Caesar continued to offer compromise solutions while preparing to strike. On Jan. 7, 49, the Senate finally decreed a state of war. Four days later Caesar crossed the Rubicon.

Pompey's strategic plan was to abandon Rome and Italy to Caesar and rely on his command of the sea and the resources of the East to starve out the Caesarians in Italy; but he did not have the disciplined loyalty and full cooperation of his Optimate allies, and Caesar's swift advance southward only just failed to prevent his withdrawal from Italy. Across the Adriatic at Dyrrhachium the wisdom of Pompey's strategy became clear. Caesar, after a hazardous crossing in pursuit, found himself cut off from his base in Italy by sea and facing superior land forces. Pompey, however, eventually had to abandon his naval blockade of the rest of Caesar's forces in Brundisium and failed to prevent their crossing to join Caesar. Caesar's army was repulsed in an assault on Pompey's camp at Dyrrhachium and, failing a quick decision in the West, Caesar was obliged to move eastwards into Thessaly. Pompey followed and joined forces with the Senate's army there under Scipio, rendering Caesar's position untenable. At this juncture, Pompey, under pressure from his Optimate allies, decided for battle, a sensible enough decision if his opponent had not been a commander of genius. Pompey suffered a disastrous defeat on the plain of Pharsalus (48). He fled from his camp as the enemy stormed it and made his way to the coast. His supporters were to rally and involve Caesar in strenuous fighting in Africa, Spain, and the East for three more years; but Pompey did not live to play a part in this struggle. Hurried on by Caesar's rapid pursuit, he lost contact with his own fleet. He moved on southward to Cilicia, Cyprus, and Egypt. He decided to land at Pelusium and seek the assistance of Ptolemy, his former client. The King marched down to the coast, ostensibly to welcome him; but he and his counsellors had chosen not to risk offending the victorious Caesar. Pompey's small squadron lay offshore while Pompey, bidding farewell to his wife, Cornelia, complied with an insidious invitation to enter, with several companions, a small boat sent to bring him to land. As he prepared to step ashore he was treacherously struck down and killed (Sept. 28, 48 BC).

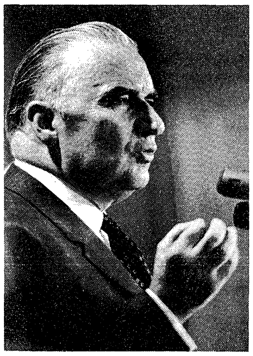
Assessment. Pompey's name cast a lasting shadow. His end inspired some of Lucan's finest verses. In the empire he acquired official respectability, and the greatness of his achievement was fully appreciated by the great writers. But there are few clear-headed or unbiassed accounts of Pompey by his own contemporaries. Caesar would have his readers believe that he wrote of Pompey more in sorrow than in anger; his propaganda was discreet and subtly damaging to his rival's reputation. Cicero's veering, day-to-day judgments of Pompey reveal his inability to see clearly through the distorting medium of his own vanity. The inflated eulogies of Pompey in Cicero's speeches are punctured by his persistent sniping at him in his letters. Yet he looked up to him for leadership and, in the moment of decision, joined him. But Pompey was neither a revolutionary nor a reactionary, willing to wreck the fabric of the commonwealth for the advantage of self or class. He expected a voluntary acceptance of his primacy but was to discover that the methods he had used to get his commands had permanently alienated the dominant nobility. So year after year he had to play a passive role, covertly intriguing or waiting for successive occasions to arise that would force them to accept his leadership. Some thought his waiting game duplicity, others, sheer political incompetence. He was an ineffective politician, not from incapacity for intrigue or ruthless action but from lack of candour and consistency in speech and action.

As a military leader, Pompey fell short of real greatness, lacking Caesar's genius, his dynamism and panache, and his geniality in personal relationships. He was circumspect and thorough—the perfect administrator. His vision of empire was no narrower than Caesar's. Like many a more recent imperialist, he was satisfied with the ideal of efficient and clean-handed administration and justice, and many of his contemporaries believed that he went far to achieve that aim in his own practice. Pompey, the wealthiest man of his age, invested his millions prudently; his landed estates were distributed throughout Italy in manageable units. For all the extravagance of his triumphal shows and the inexcusable heartlessness of the contests in slaughter with which he entertained the populace, he was a plain-living man, friend and admirer of the Stoic Panaetius. His third wife, Mucia, bore him two sons, Gnaeus and Sextus, and a daughter, Pompeia, before he divorced her for infidelity (62). Julia was the wife he loved most dearly; Cornelia outlived him and mourned his death. (E.W.G./Ed.)

BIBLIOGRAPHY. Of ancient sources, Plutarch's *Lives* (of Pompey and his Roman contemporaries) are invaluable; also the *Histories* of Cassius Dio (books 36–42); Appian's *Civil Wars*, books I and II; and Caesar's *Civil War;* but Cicero's speeches and letters throw most light on Pompey's role in the public life of his day. Peter A.L. Greenhalgh, *Pompey: The Roman Alexander* (1980), and *Pompey: The Republican Prince* (1981), constitute a substantial biography; John D. Leach, *Pompey the Great* (1978), is an introduction for the general reader; Robin Seager, *Pompey: A Political Biography* (1979), assesses his political life. For background to his career, see *The Cambridge Ancient History*, vol. 9 (1932); or, more briefly, Ronald Syme, *The Roman Revolution*, ch. 2–5 (1939, reissued 1960), a masterly analysis. Matthias Gelzer, *Pompeius*, 2nd ed. (1959), is a balanced and realistic political biography. Jules Van Ooteghem, *Pompée le grand* (1954), breaks little new ground, but is useful for its overall coverage, its brief discussion of the iconography of Pompey, and its bibliography of articles on points of detail. See also, for Pompey's operations in the East, David Magie, *Roman Rule in Asia Minor*, vol. 1, ch. 15–16 (1950, reprinted 1975).

Pompidou, Georges (-Jean-Raymond) (b. July 5, 1911, Montboudif, Fr.—d. April 2, 1974, Paris), French statesman, bank director, and teacher who was premier of the Fifth French Republic from 1962 to 1968 and president from 1969 until his death.

The son of a schoolteacher, Pompidou graduated from the École Normale Supérieure and then taught school in Marseilles and Paris. During World War II he fought as a lieutenant and won the Croix de Guerre. In late 1944 he



Pompidou
Dennis Brack—Black Star/EB Inc.

was introduced to Charles de Gaulle, who was then head of the provisional French government. At this time Pompidou was a complete stranger to politics, but he soon proved adept at interpreting and presenting de Gaulle's policies. Pompidou served from 1944 to 1946 on de Gaulle's personal staff and remained a member of his "shadow Cabinet" after de Gaulle's sudden resignation from the premiership in January 1946. He then was assistant to the general commissioner for tourism (1946–49) and also held the post of *maître des requêtes* at the Conseil d'État, France's highest administrative court (1946–57).

In 1955 he entered the Rothschild bank in Paris where, again without professional qualifications, he rose rapidly to become director general (1959). De Gaulle had never lost touch with Pompidou, and, on his return to power at the time of the Algerian crisis (June 1958), he took Pompidou as his chief personal assistant (June 1958–January 1959). Pompidou played an important part in drafting the constitution of the Fifth Republic and in preparing plans for France's economic recovery. When de Gaulle became president (January 1959), Pompidou resumed his private occupations. In 1961 Pompidou was sent to conduct secret negotiations with the Algerian Front de Libération Nationale (FLN), a mission that finally led to a cease-fire between the French troops and Algerian guerrillas in Algeria.

The Algerian crisis resolved, de Gaulle decided to replace Michel Debré as premier and appointed Pompidou, then virtually unknown to the public, in his place (April 1962). Defeated in a vote of censure in the National Assembly (October 1962), Pompidou resumed office after de Gaulle's victory that same month in the plebiscite on the election of the president by universal suffrage. The second Pompidou administration (December 1962–January 1966) was succeeded by the third (January 1966–March 1967) and the fourth (April 1967–July 1968). Pompidou had thus been premier for six years and three months, a phenomenon that de Gaulle noted had been unknown in French politics for four generations.

Pompidou's standing was probably highest at the time of the French student–worker revolt of May 1968, at which time he participated in negotiations with workers and employers, persuaded de Gaulle to make the necessary reforms, and concluded the Grenelle Agreement (May 27) that finally ended the strikes. Pompidou's campaign calls for the restoration of law and order enabled him to lead the Gaullists to an unprecedented majority in the National Assembly elections of June 30, 1968. Although he was unexpectedly dismissed from the premiership by de Gaulle in July 1968, Pompidou retained his prestige and influence in the Gaullist party. When de Gaulle abruptly resigned the presidency in April 1969, Pompidou campaigned for the office and was elected on June 15, 1969, receiving more than 58 percent of the second-round votes.

During his term as president, Pompidou was largely successful in continuing the policies initiated by de Gaulle. He maintained friendship and economic ties with Arab states, but he was less successful with West Germany and did not significantly improve relations with the United States. For almost five years he provided France with a stable government and strengthened its economy. He also supported Great Britain's entry into the EEC. His death was unexpected despite the growing evidence of his rapidly failing health.

Pompidou Centre, French CENTRE POMPIDOU, in full CENTRE NATIONAL D'ART ET DE CULTURE GEORGES POMPIDOU ("Georges Pompidou National Art and Cultural Centre"), French national cultural centre on the Rue Beaubourg and on the fringes of the historic Marais section of Paris. It is named after the French president Georges Pompidou, under whose administration the museum was commissioned.

The Pompidou Centre was formally opened on Jan. 31, 1977, by the French president, Valéry Giscard d'Estaing. Its overpowering industrial-looking exterior, which dwarfs its surroundings, attracted notoriety for its brightly coloured exterior pipes, ducts, and other exposed services. The architects were Renzo Piano of Italy and Richard Rogers of Britain. The Pompidou Centre quickly became an enormous popular attraction and was reckoned to be the most frequently visited cultural monument in the world.

Primarily a museum and centre for the visual arts of the 20th century, the Pompidou Centre houses many separate services and activities. Its museum of modern art brought under one roof several public collections of modern art previously housed in a number of other Paris galleries. There are also frequent temporary exhibitions devoted to modern themes. In addition there is a large public library, a centre for industrial design, a film museum, and an important musical centre associated with the French conductor and composer Pierre Boulez, known as the Centre for Musical and Acoustical Research (Ircam). The music centre comprises rehearsal rooms, studios, and a concert hall and presents concerts devoted primarily to modern music.

Pompilius, Numa (8th–7th-century-BC traditional Roman king): *see* Numa Pompilius.

Pomponazzi, Pietro (b. Sept. 16, 1462, Mantua, Marquisate of Mantua—d. May 18, 1525, Bologna), philosopher and leading representative of Renaissance Aristotelianism, which had developed at Italian universities after the close of the 13th century.

Pomponazzi was educated in philosophy and medicine at the University of Padua, and he taught philosophy there intermittently from 1487 to 1509. He also taught at Ferrara and at Bologna until his death. Thoroughly versed in Aristotle and his commentators, particularly Thomas Aquinas and Averroës, Pomponazzi interpreted Aristotle in the light of the Humanism of his own time. His treatise on the immortality of the soul, *Tractatus de immortalitate animae* (1516), was attacked but not officially condemned; and he was allowed to publish a defense of his position in his *Apologia* (1518) and *Defensorium* (1519).

He contended that the immortality of the individual soul cannot be demonstrated on the basis of Aristotle or of reason, but must be accepted as an article of faith. In developing this view, he maintained that moral action is the only proper goal of human life. Appealing to the Stoic philosophers, rather than to Aristotle, he declared that virtue is its own reward and vice its own punishment. In Pomponazzi's typically Humanist view, man's special dignity consists in his moral virtue. A master of the Scholastic treatise, which formulates objections to its thesis and proceeds to overcome them, Pomponazzi was also the author of the lengthy treatises *De incantationibus* (1556; "On Incantations"), which proposed a natural explanation of several reputedly miraculous phenomena, and *De fato* (1567; "On Fate"), which discusses predestination and free will.

Ponca, North American Indian people of the Dhegiha branch of the Siouan linguistic stock. Under pressure of settlement by whites, the Ponca migrated westward from the Atlantic coast, settling first in Virginia and the Carolinas. After a time they moved to what is now western Missouri. The Ponca then moved north to present-day Minnesota, where they lived until the late 17th century, when they were driven farther west by the Dakota. They then settled in villages in southwestern Minnesota and the Black Hills of South Dakota.

In their semipermanent villages the Ponca lived in earth-covered lodges and engaged in farming. In spring and autumn they moved into portable tepees for the hunting season.

The Ponca were never a large tribe; an early estimate places their number at 800. By 1804, when they were encountered by Lewis and Clark, a smallpox epidemic had reduced the tribe to about 200. In 1865 they were guaranteed a reservation on their homelands, but, after tragic bureaucratic blundering, the land was awarded to the Dakota, and the Ponca were forcibly removed to Indian Territory (present-day Oklahoma). The tribe found living conditions unbearable, and, led by their chief, Standing Bear, they traveled north on foot for 600 miles (965 km) to eastern Nebraska, where they were given asylum by the

Omaha. They were arrested, but after a court battle sponsored by whites sympathetic to their cause and by a young Omaha woman named Susette La Flesche (*q.v.*), they were freed. They settled in Oklahoma. In the late 20th century they numbered somewhat fewer than 1,000.

Ponca City, city, Kay County, northern Oklahoma, U.S. It lies along the Arkansas River, near the Kansas border. Founded overnight in 1893 with the opening of the Cherokee Strip, it was named for the Ponca Indians, who moved in 1879 to a reservation south of the townsite. Surrounded by farm and ranch lands, the city boomed with the oil discoveries of the 1920s. Its diversified industries include oil refining, manufacture of petrochemicals and metal products, and servicing of diesel engines. Its "Pioneer Woman" statue, honouring the courage of the women who helped settle

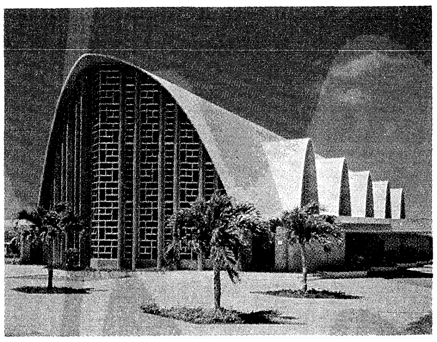
the West, is at the Pioneer Woman Museum. Kaw Lake, immediately northeast, is a major reservoir on the Arkansas River. Inc. village, 1895; city, 1899. Pop. (1984 est.) 28,616.

Ponce, major city and principal port of southern Puerto Rico. The third most populous centre of the island, after San Juan and Bayamón, the city is situated 3 miles (5 km) north of its port, Playa de Ponce. Founded in either 1670 or 1680 as Nuestra Señora de Guadalupe de Ponce, it was raised to the status of town in 1692, to that of *villa* in 1848, and to that of city in 1877. In 1897 Spain's overseas minister designated Ponce as the capital of the southern region, one of the island's two major districts. In 1898 Ponce fell with the rest of



The church of Santa María Reina on the campus of the Catholic University of Puerto Rico, Ponce, Puerto Rico
Arthur Griffin—EB Inc.

the island to the United States, which made extensive harbour improvements to it.

Among the major industries of Ponce are canning, sugar refining, and the production of cement, paper, iron, shoes, textiles, and rum; there is also diamond cutting and the manufacture of ball bearings, electrical devices, tools and dies, and aluminum windows. The city is linked to Mayagüez and Guayama by rail and to San Juan by regular air service. Cultural facilities include the Catholic University of Puerto Rico (1948), a regional college of the University of Puerto Rico, and the Museum of Art. The city has also preserved many old Spanish homes and churches.

Sugarcane, coffee, cocoa, fruits, and grazing flourish in the area around Ponce despite a rainfall that varies from only 15 to more than 40 inches (375 to 1,000 mm) annually. Pop. (1980) city, 161,739 (1984 est.) mun., 190,-900.

Ponce de León, Juan (b. 1460, Tierra de Campos Palencia, Leon—d. 1521, Havana), Spanish explorer who founded the oldest settlement in Puerto Rico and later discovered Florida (1513) while searching for the mythical fountain of youth.

Born into a noble family, Ponce de León was a page in the royal court of Aragon and later fought in a campaign against the Moors in Granada. It is possible that he began his career of exploration in 1493 as part of Christopher Columbus' second expedition to the New World. In 1502 he was in the West Indies as a captain serving under Nicolás de Ovando, governor of Hispaniola. As a reward for suppressing an Indian mutiny, Ponce de León was named by Ovando to be the provincial governor of the eastern part of Hispaniola. Hearing persistent reports of gold to be found on Puerto Rico, Ponce de León in 1508–09 explored and settled that island, founding the colony's oldest settlement, Caparra, near what is now San Juan. He then returned to Hispaniola and was named governor of Puerto Rico but was soon displaced from the governorship through the political maneuvering of rivals.

The Spanish crown encouraged Ponce de León to continue searching for new lands. He learned from Indians of an island called Bimini (in the Bahamas) on which there was a miraculous spring or fountain that could rejuvenate those who drank from it (the fountain of youth). In search of this fountain, he led a privately outfitted expedition from Puerto Rico in March 1513 and in April of that year landed on the coast of Florida near the site of modern St. Augustine. At the time he did not realize that he was on the mainland of North America and instead supposed he had landed on an island. He named the region Florida because it was discovered at Easter time (Spanish: Pascua Florida) and because it abounded in lush, florid vegetation. He coasted southward, sailing through the Florida Keys and ending his search near Charlotte Harbor on Florida's west coast. He then returned to Puerto Rico and thence to Spain, where he secured the title in 1514 of military governor of Bimini and Florida with permission to colonize those regions.

In 1521 Ponce de León sailed again for Florida with two ships and 200 men, landing near Charlotte Harbor. On this occasion he was wounded by a Seminole arrow during an Indian attack, and he died after being returned to Cuba. Puerto Rico's third largest city, Ponce, is named in his honour.

Ponce de León, Pedro (b. 1520?—d. 1584) Spanish Benedictine monk believed to have been the first person to develop a method for teaching deaf-mutes.

Ponce achieved his first success with Gaspard Burgos, who, because of his affliction, had been denied membership in the Benedictine order. Under Ponce's tutelage, Burgos learned to speak so that he could make his confession; Burgos later wrote a number of books. Ponce taught several other deaf-mutes to speak and write, although details of his methods either were never recorded or have been lost. He apparently traced letters and indicated pronunciation with lip movements to introduce and develop speech among his students.

Poncelet, Jean-Victor (b. July 1, 1788, Metz, Fr.—d. Dec. 22, 1867, Paris), French mathematician and engineer who was one of the founders of modern projective geometry.

Poncelet, detail of a lithograph by Patout, 1849
By courtesy of the Bibliotheque Nationale, Paris

As a lieutenant of engineers in 1812, he took part in Napoleon's Russian campaign, in which he was abandoned as dead at Krasnoy and imprisoned at Saratov. He returned to France in 1814.

During his imprisonment Poncelet studied projective geometry and wrote *Applications d'analyse et de géométrie*, 2 vol. (1862–64; "Applications of Analysis and Geometry"). This work was originally planned as an introduction to his celebrated *Traité des propriétés projectives des figures* (1822; "Treatise on the Projective Properties of Figures"), for which Poncelet is regarded as one of the greatest projective geometers. His development of the pole and polar lines associated with conics led to the principle of duality and a dispute over priority for its discovery. His principle of continuity, a concept designed to add generality to synthetic geometry, led to the introduction of imaginary points.

From 1815 to 1825 Poncelet was occupied with military engineering at Metz, and from 1825 to 1835 he was professor of mechanics at the *école d'application* there. He applied mathematics to the improvement of turbines and waterwheels. Although the first inward-flow turbine was not built until 1838, he proposed such a turbine in 1826. From 1838 to 1848 he was professor to the faculty of sciences at Paris, and from 1848 to 1850 he was commandant of the École Polytechnique, with the rank of general.

Poncet, Charles-Jacques (b. Franche-Comté—d. 1706, Persia), French resident pharmacist in Cairo known for the account of his travels in Ethiopia, which was closed to Europeans after about 1630.

Poncet was summoned to Gonder, the Ethiopian capital, to treat the emperor Iyasu I and his son for leprosy. His account of the journey, *A Voyage to Ethiopia in the Years 1698, 1699 and 1700,* is the only European source for the history of Ethiopia in this period. Poncet, who had lived in Egypt since 1687, departed for Ethiopia in May 1698. He ascended the Nile River and turned south through the Nubian Desert, reaching Gonder in July 1699. He cured the Emperor and his son and made a detailed description of the country during his nine-month stay.

An attempt to establish diplomatic relations between the Emperor and Louis XIV of

France came to nothing, and Poncet's account of his voyage was unfairly discredited. In 1702 Poncet left France to return to Ethiopia, but a civil war in Ethiopia prevented his return.

Ponchielli, Amilcare (b. Aug. 31 or Sept. 1, 1834, Paderno Fasolaro, near Cremona, Lombardy [Italy]—d. Jan. 16, 1886, Milan), Italian composer, best-known for his opera *La gioconda.*

Ponchielli studied at Milan and produced his first opera, *I promessi sposi* (after Manzoni), in 1856; its revised version was popular in Italy and abroad. Between 1873 and 1875 he wrote two ballets and four operas. *La gioconda* (1876), on a libretto by Arrigo Boito based on Victor Hugo's *Angelo,* achieved wide success at the end of the 19th century. Later remembered chiefly for its ballet, *Dance of the Hours,* it returned to the repertory of Italian opera houses in the 1950s. From 1881 to 1886 Ponchielli was music director at Bergamo Cathedral; there he wrote several sacred works.

poncho, cloak worn by men or women, made of a square or rectangle of cloth with a hole in the middle for the head. The original poncho, consisting of a rough, brightly coloured, handloomed woolen cloth, was worn by Latin-American Indians. Ponchos, with the edges hanging either parallel or diagonally, forming

Mexican charro wearing a poncho
Dick Davis—Photo Researchers/EB Inc.

a diamond shape, became fashionable in the second half of the 20th century. The poncho can also be a similarly designed garment made of a waterproof material, often hooded, worn chiefly as a raincoat.

Pond, John (b. 1767, London—d. Sept. 7, 1836, Blackheath, Kent, Eng.), sixth astronomer royal of England, who organized the Royal Greenwich Observatory to an efficiency that made possible a degree of observational precision never before achieved.

Pond was elected a fellow of the Royal Society in 1807 and served from 1811 to 1835 as astronomer royal. During Pond's term, obsolete and worn-out instruments at Greenwich were replaced and the staff increased from one to six, enabling him to complete in 1833 a catalog of positions of 1,112 stars with an ac-

pond turtle, any of several freshwater turtles of the family Emydidae: two of the best known are the Pacific, or western, pond turtle (*Clemmys marmorata*) and the European pond turtle (*Emys orbicularis*). The term is

European pond turtle (*Emys orbicularis*)
Joe B. Blossom—Photo Researchers/EB Inc.

sometimes used collectively to refer to members of the genus *Clemmys* (*see* spotted turtle; wood turtle).

The Pacific pond turtle is one of the few turtles native to the western coast of North America. It is found from southern Canada to southern California and usually inhabits ponds and other quiet waters. It has been widely sold for food in California. The smooth, broad upper shell of the Pacific pond turtle reaches a length of about 15–25 cm (6–10 inches) and is brown or blackish with yellow spots and streaks. The lower shell is yellow and black. The Pacific pond turtle is a highly aquatic, wary reptile. It feeds on both plant and animal material, basks in the sun, and is frequently hooked by fishermen.

The European pond turtle, also known as the swamp turtle, or swamp tortoise, is found in Europe, northern Africa, and western Asia. It is primarily aquatic and is said to be carnivorous. The upper shell, which reaches a length of about 12–13 cm (5 inches), is brownish or blackish with yellow speckling and sometimes resembles that of the Pacific pond turtle.

Pondicherry, union territory of India, formed in 1962 from the four former French colonies of Pondicherry, Kārikāl, Yanam, and Mahe. Pondicherry, Kārikāl, and Yanam are scattered along the southeastern coastal region known as the Coromandel Coast, and Mahe lies opposite Pondicherry on the southwestern shoreline known as the Malabar Coast. The total area of the union territory is 190 square miles (492 square km), and the town of Pondicherry is the administrative capital.

A brief treatment of Pondicherry follows. For full treatment, *see* MACROPAEDIA: India.

One of the smallest of the union territories, Pondicherry is united by little other than the Hindu religion; the Tamil language predominates in Pondicherry and Kārikāl, while Malayālam is spoken in Mahe and Telugu in Yanam. All of the former colonies are noted seaside tourist resorts. Agriculture—including the growing of rice, peanuts (groundnuts), sugarcane, and cotton—and some industries (mainly in Pondicherry) provide the territory's economic basis. Pop. (1981) 604,471.

Pondicherry, town and capital of Pondicherry union territory, surrounded by Tamil Nādu state, southeastern India.

The town of Pondicherry lies on the Coromandel Coast 105 miles (170 km) south of Madras. It originated as a French trade centre in 1674, when it was purchased from a local ruler. Now a seaside tourist resort, Pondicherry contains the Hindu ashram (religious retreat) of Sri Aurobindo, now an international study centre, and several colleges affiliated with the University of Madras. The colony of Pondicherry was the scene of frequent fighting among the French and Dutch in the late 17th century, and by 1761 the British had driven the French from the region. Pop. (1981) 162,639.

Pondo (people): *see* Mpondo.

Pondoland, region on the African coast of the Indian Ocean, located in the republic (not internationally recognized) of Transkei, South Africa, between the Mtamvuna and Umtata rivers, bordering Natal province in the north. Settled by the Mpondo (Pondo) peoples at the end of the 16th century AD, it is divided by the Umzimvuhu River into East Pondoland and West Pondoland. The region was annexed to the Cape Colony by Sir Henry George Elliot in 1894.

Pondoland occupies a narrow strip about 30 miles (50 km) wide, extending from the coast across the thornveld (thorn trees, bushes, and grasses) to the interior plateaus in the west. The vegetation of the coastal areas is mainly subtropical evergreens. Interior Pondoland is regarded as the richest cattle country in Transkei and has the most fertile lands in the republic; corn (maize), tobacco, sugarcane, tea, coffee beans, cotton, and tropical fruits are grown. In the deep forests and other remote areas, the narcotic *dagga* (Indian hemp) is cultivated. The region is served by good roads, and the rivers also provide inland transport.

pondweed, any of several cosmopolitan freshwater plants sometimes grown in ponds or aquariums. They belong to two families: the Potamogetonaceae (pondwood family) and the Aponogetonaceae (lattice plant family), both of which have species that develop submerged or floating leaves but frequently have emergent flowering shoots. The former group includes frog's lettuce (*Potamogeton densus*), of Europe and southern Asia, and *P. crispus,* of Europe but naturalized in the eastern United States and in California. Cape pondweed (*Aponogeton distachyus*), of the family Aponogetonaceae, has several varieties grown for ornament in pools or greenhouses. Many species of these families serve as food for waterfowl and as cover for fishes.

Ponferrada, city, León province and region, Castile-León *comunidad autónoma* ("autonomous community"), northwestern Spain, at the confluence of the Sil and Boeza rivers, west of the city of León. Identified with the Roman Interamnium Flavium, Ponferrada was refounded in the 11th century as a station on the pilgrimage route to Santiago de Compostela. The city's historic monuments include the castle of the Knights Templars (12th–14th centuries), a fine example of medieval military architecture; the 10th-century Mozarabic church of Santo Tomás de las Ollas; and the Gothic church of Santa María de la Encina. Located in a coal- and iron-mining district, Ponferrada has steel mills and manufactures coal briquettes. Pop. (1981) 52,499.

Poṅgal, important Hindu festival in South India marking the beginning of the Tamil New Year. It is celebrated on the winter solstice, when, according to the traditional Hindu system of reckoning, the Sun, having reached its southernmost point, turns to the north again and reenters the sign of *makara* (Capricorn).

The month preceding Poṅgal is considered to be made up entirely of inauspicious days and the month following Poṅgal of auspicious days. The name of the festival comes from the Tamil word meaning "to boil"; rice is boiled in milk and offered first to the gods, then to the cows, and then to family members. During the exchange of visits that mark all Hindu festivals, the anticipated greeting, "Has the rice boiled?" is answered, "It has boiled." Cows are especially venerated during Poṅgal: their horns are painted, and they are garlanded with flowers and fruit, taken in procession, and allowed to graze freely.

Pongidae, family of anthropoid primates including the orangutan, chimpanzee, and gorilla (*qq.v.*); Hylobatidae, the family of apes that includes the gibbon and siamang (*qq.v.*), is sometimes considered to be a subfamily of Pongidae. The Pongidae inhabit tropical Africa and Southeast Asia. *See also* ape.

Poniatowski, Józef Antoni (b. May 7, 1763, Vienna—d. Oct. 19, 1813, Leipzig), Polish patriot and military hero, who became a marshal of France.

Initially an officer in the Austrian army, Poniatowski was transferred to the Polish army in 1789 at the request of his uncle, King Stanisław II August Poniatowski of Poland. He distinguished himself against the Russians in 1792 and took part in Tadeusz Kościuszko's anti-Russian revolt in 1794. Poniatowski retired in 1795, after the Third Partition of Poland, but he was named commander in chief of the Duchy of Warsaw by Napoleon in 1807. He led a Polish corps in Napoleon's Russian campaign of 1812 and during the Battle of Leipzig (Oct. 16–19, 1813) was made a marshal of France. On the last day of the battle the wounded marshal died in an attempt to cross the Elster River on horseback.

Poniatowski, Stanisław (b. Sept. 15, 1676—d. Aug. 3, 1762, Ryki, Pol.), Polish soldier and state official who supported the Swedes against the Poles in the Great Northern War (1700–21) and was later a reconciled leader in Polish military and political affairs.

Grandson of Jan Ciołek Poniatowski (d. *c.* 1676), founder of the princely family of Poniatowskis, he was the first of the family to distinguish himself politically and militarily. At the outbreak of the Great Northern War, he joined the powerful Sapieha family in siding with the Swedes against the Saxon king of Poland, Augustus II the Strong. He was a major general in the Swedish army and a strong supporter of Stanisław Leszczyński, installed on the Polish throne by the Swedes in 1704 as Stanisław I. After the war Poniatowski reconciled himself with the restored Augustus II and became grand treasurer of Lithuania in 1722. From 1728 he was commander in chief of the Polish army, and in 1731 he became palatine of Mazovia. His son Stanisław August was king of Poland as Stanisław II August Poniatowski (reigned 1764–95).

Poniatowski, Stanisław (king of Poland): *see* Stanisław II August Poniatowski.

Ponnaiyār River, river in southern India, rising as the Southern Pinakim on the eastern slope of Nandidrug Mountain, in the Chennakaseva Hills of Karnātaka state. It flows southward for 50 miles (80 km) through Karnātaka to Tamil Nādu state, where it turns southeastward and flows 200 miles (320 km) to enter the Bay of Bengal at Cuddalore. Major tributaries are the Chinnār, Mārkanda, Vaniar, and Pamban.

Heavy rains at the river's source cause sudden, but short-lived, floods. The river is extensively dammed for irrigation, especially in Tamil Nādu. There are also reservoirs at Krishnagiri and Sathanur. The Ponnaiyār is considered sacred by Hindus, and festivals are held during the Tamil month of Tai (January–February).

Ponnāni River, river in central Kerala state, southwestern India. The Ponnāni rises in the Western Ghāts range northeast of Pālghāt town. Flowing first southwest and then west across the coastal plain, the river empties into the Arabian Sea at Ponnāni after a course of about 100 miles (160 km).

pons, plural PONTES, a portion of the mammalian brain lying above the medulla oblongata and below the cerebellum and the cavity of the fourth ventricle. The pons is a broad, horseshoe-shaped mass of transverse nerve fibres that connect the medulla with the cerebellum. It is also the point of origin or termination for four of the cranial nerves that transfer sensory information and motor impulses to and from the facial region and the brain. The pons also serves as a pathway for nerve fibres connecting the cerebral cortex with the cerebellum.

Pons, Lily, byname of ALICE JOSÉPHINE PONS (b. April 12, 1904, Draguignan, near Cannes, Fr.—d. Feb. 13, 1976, Dallas, Texas, U.S.), American coloratura soprano known for her vocal range, musical skill, and warmth of expression. She was associated with the Metropolitan Opera in New York City for more than 30 years.

Pons studied piano at the Paris Conservatoire but later studied voice with Albert di Gorostiaga. In 1928 she made her opera debut at the Mulhouse Opera in Alsace in the title role of Léo Delibes' *Lakmé,* subsequently appearing in a series of French provincial houses. She auditioned for Giulio Gatti-Casazza, general director of the Metropolitan Opera, who asked her to sing the title role in Gaetano Donizetti's *Lucia di Lammermoor* there in 1931. She remained with the Metropolitan for more than three decades as a principal soprano famed for French and Italian coloratura parts, including those in Donizetti's *La figlia del reggimento* and Vincenzo Bellini's *La sonnambula.* She was the first soprano in 50 years who could reach the high F that Delibes wrote in the "Bell Song" in *Lakmé.*

Pons sang on radio and on television and also appeared in several motion pictures. During World War II she performed on North African and Asian battlefronts, and a community in Maryland was named Lilypons in her honour.

Ponselle, Rosa, original name ROSA MELBA PONZILLO (b. Jan. 22, 1897, Meriden, Conn., U.S.—d. May 25, 1981, Baltimore), American coloratura soprano of great breadth of range and expressive ability, who is probably best-known for her performance in the title role of Vincenzo Bellini's *Norma.*

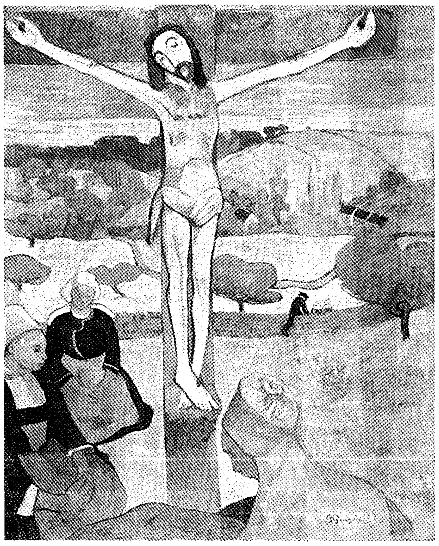
As a teenager Ponselle played the piano for silent motion pictures and at the age of 16 began singing in vaudeville. At the age of 21 she came to the attention of Enrico Caruso and made her first operatic appearance at the Metropolitan Opera in New York City in the challenging role of Leonora in Giuseppe Verdi's *La forza del destino.* She studied for the role with Romano Romani, who remained her principal vocal coach and teacher for the rest of her career.

Most of Ponselle's career was spent at the Metropolitan, although she sang at Covent Garden in London (1929–30) and also at the Maggio Musicale in Florence (1933). During her 19 seasons at the Met, she sang a total of 22 dramatic and dramatic-coloratura roles. She retired from the opera stage in 1937. After retiring she taught and served as artistic director for the Civic Opera of Baltimore.

Pont-Aven school, group of young painters that espoused the style known as Synthetism and united under Paul Gauguin's tutelage at Pont-Aven, Brittany, Fr., in the summer of 1888. The artists included Émile Bernard, Charles Laval, Maxime Maufra, Paul Sérusier, Charles Filiger, Meyer de Haan, Armand Séguin, and Henri de Chamaillard.

Gauguin and Bernard were the first to reject Impressionist and Pointillist techniques in favour of Synthetist methods. The paintings executed by these artists in the years between 1886, when they first met at Pont-Aven, and 1888 show an overall simplification, a highly expressive use of colour, and an intensely spiritual subject matter. In their Breton landscapes, Gauguin and Bernard employed bright areas of colour surrounded with heavy, dark outlines that give the painted surface the appearance of medieval enamel and stained-glass work. Gauguin's emulation of the simpler, more religious life practiced by the Breton peasants served as an example to the rest of the Pont-Aven school. The content of their paintings was often derived in abstracted form from the everyday life of the Breton people.

Gauguin's disciples, enthusiastically accepting his advice not to paint exclusively from nature, gradually abandoned the Neo-Impressionist styles that they had adopted originally. In their revolt against Naturalism, the early Synthetist painters emphasized the decorative potentials of colour and line: a painting was to be primarily a flat surface upon which colour was laid ornamentally. "Landscape at the Bois d'Amour at Pont-Aven," painted by Paul Sérusier under the direct guidance of Gauguin, became the talisman of the young disciples. Gauguin had instructed Sérusier not only to paint the landscape from memory but to be certain to paint the different-coloured areas as intensely as possible. Upon the return of the Pont-Aven school to Paris in the fall of 1888, the members met regularly to discuss new developments in French art, particularly Symbolism. In 1889 Gauguin arranged an important exhibition of Impressionist and Synthetist art that featured his own and other works.



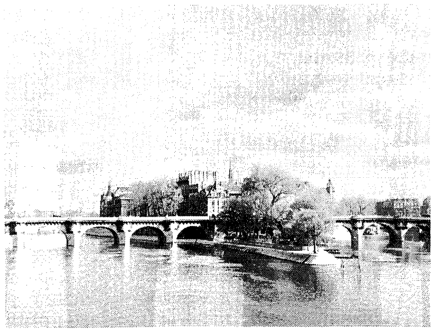
"The Yellow Christ," Pont-Aven school painting by Paul Gauguin, oil, 1889; in the Albright-Knox Art Gallery, Buffalo
By courtesy of the Albright-Knox Art Gallery, Buffalo

At one point in the existence of the Pont-Aven school, the idea of an artistic and communal society had seemed feasible, but once Gauguin decided to leave for Tahiti, hopes for this to materialize were abandoned. The members of the original Pont-Aven school became increasingly involved in the development of Symbolist art theories and techniques. Artists such as Sérusier eventually became active in the Académie Julian and in the Nabis.

Pont-l'Évêque, one of the classic cow's-milk cheeses of Normandy, France, named for the eastern Normandy village in which it is produced. The traditional form of Pont-l'Évêque is a small, approximately four-inch (10-centimetre) square, with a golden-brown rind crisscrossed by marks from the straw mats on which it is ripened.

The finely holed, golden-yellow interior is semisoft when young but after six to eight weeks softens, becoming almost, but not quite, runny. The aroma becomes increasingly pungent as the cheese ripens, and the rind becomes sticky. It should not, however, be rank or discoloured.

Pont Neuf, second-oldest bridge across the Seine River via the Île de la Cité in Paris, built, with interruptions in the work, from 1578 to 1607. It was designed by Baptiste Du Cerceau and Pierre des Illes, who may have made use of an earlier design by Guillaume Marchand.



Pont Neuf, Paris
Ewing Galloway

For centuries the Pont Neuf, filled with shops and traffic, was the centre of Paris life. Its "long arm" consisted of seven arches from the right bank of the Seine to the western end of the Île de la Cité; its "short arm" of five arches from the island to the left bank. The foundations were completely rebuilt under Napoleon III, together with the arches of the long arm, which were made elliptical. At the same time the shops were removed from the roadway.

Ponta Delgada, capital and largest city of the *região autónoma* (autonomous region) of the Azores, consisting of the three districts (one of which is Ponta Delgada) of the Azores archipelago of Portugal in the North Atlantic. The city, on the south coast of Ilha (island) de São Miguel, became São Miguel's second capital (Vila Franca do Campo was the first) in 1540. It was severely damaged in 1839 by a tidal wave and has since been rebuilt. The Holy Christ of the Miracles Church is a noted place of pilgrimage. A mild climate and lush vegetation have made the city an important winter tourist resort. Its harbour has a breakwater nearly a mile long and serves as a fuelling supply station and offers minor repair facilities to transatlantic ships. Ponta Delgada is the Azores' leading commercial centre, exporting pineapples, oranges, tea, wine, cereals, vegetables, and dairy products. Sugar refining and liquor distilling are its primary industries. Sperm whale oil is also produced. The University of the Azores was founded in the city in 1976. A local shipping line maintains regular services with continental Portugal, northern Europe, and the United States.

Avenue Infante Henrique along the harbour at Ponta Delgada, Azores
Gianni Tortoli—Photo Researchers

Ponta Delgada district comprises the islands of São Miguel and Santa Maria and the unpopulated Rocas (rocks) Formigas. Apart from Ponta Delgada city, it is basically agricultural. Pop. (1981) city, 22,200; district, 203,914.

Ponta Grossa, town, east central Paraná state, southeastern Brazil, located on a plateau at an altitude of 2,930 ft (893 m). It serves as a commercial centre, exporting maté (tea), timber, tobacco, rice, bananas, and *xarque* (jerked beef) through the Atlantic ports of Antonina (100 mi [160 km] east) and Paranaguá, and as a distribution centre for the interior of the state. It is also a rail and road centre for hog raising and lumbering activities. Industries include meat-packing; lard, coffee, and maté processing; and sawmilling and woodworking. Ponta Grossa is the site of the Universidade Estadual de Ponta Grossa (1970) and of a government agricultural experimental station. Pop. (1980 prelim.) 171,111.

Pontano, Giovanni, Latin JOVIANUS PONTANUS (b. May 7, 1426, Cerreto di Spoleto, near Perugia, Papal States—d. September 1503, Naples), Italian prose writer, poet, and royal official, whose works reflect the diversity of interests and knowledge of the Renaissance. His supple and easy Latin style is considered, with that of Politian, to be the best of Renaissance Italy.

He studied language and literature in Perugia. From 1447 to 1495 he served the Aragonese kings of Naples as adviser, military secretary, and, after 1486, as chancellor, an office he handled with great distinction. He was dismissed in 1495 for negotiating peace with the French and, though pardoned, he did not return to power.

Pontano became a major literary figure in Naples after 1471 when he assumed leadership of the city's Humanist academy. Called the Accademia Pontaniana, it became one of the major Italian literary academies of the 15th century. Pontano's writings, all in Latin, include a historical work (*De bello neapolitano*); philosophical treatises (*De prudentia, De fortuna*); an astrological poem (*Urania*); dialogues on morality and religion, philology and literature; and many lyrical poems, of which the most important are *Lepidina,* a charming account of the wedding between a river god and a nymph, with a distinctly Neapolitan flavour, and a collection called *De amore coniugali,* a warm and personal series of poems on the joys and sorrows of family life.

Pontardawe, locality, Lliw Valley district, West Glamorgan County, Wales. Located in the Tawe Valley 8 mi (13 km) north of Swansea, Pontardawe originated as a mining community and grew rapidly during the 18th- and 19th-century exploitation of the South Wales coalfield. There are several stone circles and cairns in the area, and to the west in a pre-Roman earthworks.

In addition to coal mining, copper smelting was an important industry during the 18th century, succeeded by tinplate manufacture in the late 19th and early 20th centuries. With the decline of mining, new industries have been introduced as part of a government attempt to shield the valley communities from its impact.

Pontchartrain, Lake, lake, southern Louisiana, U.S., 40 mi (64 km) long and 25 mi wide, with an area of 625 sq mi (1,619 sq km) and a mean depth of 10 to 16 ft (3 to 5 m). More a tidal lagoon than a lake, since it connects eastward with the Gulf of Mexico by a narrow passage called the Rigolets, Lake Pontchartrain is brackish and teems with game fish. It was discovered by Pierre Le Moyne,

Lighthouse on Lake Pontchartrain in southern Louisiana
Alan Pitcairn from Grant Heilman—EB Inc.

sieur d'Iberville, in 1699. Fontainebleau State Park and many small resorts are around the lakeshore. Pontchartrain Causeway, a 24-mi multispan concrete bridge completed in 1956, crosses the lake north from New Orleans. The lake receives floodwaters from the Mississippi via the Bonnet Carré Spillway (*q.v.*).

Ponte, Antonio da (b. 1512, Venice—d. *c.* 1595), architect-engineer who built the Rialto Bridge, Venice.

Though he was undoubtedly the builder of many previous structures, Antonio's earlier works are entirely unknown. He won a competition in 1587 for a design for a permanent bridge over the Grand Canal at the busy Rialto. His broad, single-arch span, covered with arcaded shops, at once became one of the city's foremost monuments. Two years later Antonio built another Venetian landmark, the famed Bridge of Sighs, to replace a span that had been destroyed by a fire.

Ponte-Corvo, Jean-Baptiste Bernadotte, prince de: *see* Charles XIV John *under* Charles (Sweden).

Ponte Vecchio, first segmental arch bridge built in the West (the first of which the

Ponte Vecchio, Florence
J. Allan Cash

arches describe an arc smaller than a semicircle), crossing over the Arno River, Florence, and an outstanding engineering achievement of the European Middle Ages. Its builder, Taddeo Gaddi, completed the bridge in 1345. Requiring fewer piers in the stream than the Roman semicircular-arch design, the segmental arch offered less obstruction to navigation and freer passage to floodwaters. The Ponte Vecchio roadway carries a two-story gallery, the upper gallery connecting the neighbouring Pitti, Uffizi, and other palaces, the lower providing space for shops. During World War II the Ponte Vecchio bridge over the Arno River was the only one spared from destruction by the retreating German army.

Pontecorvo, Guido (b. Nov. 29, 1907, Pisa), Italian geneticist who discovered the process of genetic recombination in the fungus *Aspergillus*.

Pontecorvo was educated at the universities of Pisa (doctorate in agricultural sciences, 1928), Edinburgh (Ph.D., 1941), and Leicester (D.Sc., 1968). Influenced in 1938 by U.S. geneticist Hermann Muller, he designed a method for studying genetic differences among species that ordinarily produce sterile hybrids when interbred. That method permitted him to study evolutionary divergence in the fruit fly *Drosophila*. The conviction that research in microbial genetics could lead to increased production of the drug penicillin, much needed in World War II, led him in 1943 to the genetics of fungi. In 1950 he found that recombination of genes can occur in the filamentous fungus *Aspergillus nidulans* without sexual reproduction. Nonsexual gene recombination became a useful technique in probing the nature of gene action.

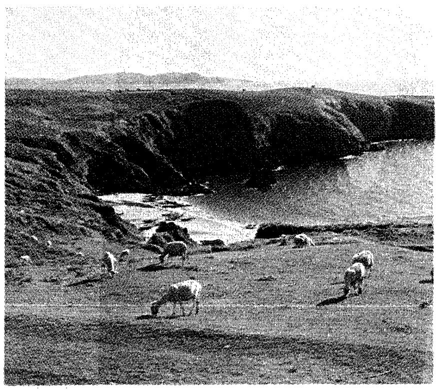
Pontecorvo was elected a fellow of the Royal Society of Edinburgh (1946) and the Royal Society of London (1955). He received honorary degrees from several universities, and he was awarded the Hansen Foundation prize for microbiology (1961) and the Royal Society's Darwin Medal (1978). Pontecorvo was appointed to the first chair of genetics at the University of Glasgow in 1955 after serving for ten years as the head of that university's newly created genetics department. In 1968 he moved to London to work at the Imperial Cancer Research Fund Laboratories where he remained until his retirement in 1975.

Pontedera, Andrea da: *see* Pisano, Andrea.

Pontefract, locality and historic market town (1194), Wakefield district, county of West Yorkshire, England. It lies east of the Pennine foothills, 4 mi (6 km) south of the Calder River above its confluence with the Aire. It grew around a Norman castle (1069) as the market centre of a rich agricultural area. The castle, an important stronghold, sustained three sieges in the mid-17th-century English Civil War before the Royalists surrendered.

With the development of coal mining in the locality in the 19th century, it acquired industries, especially engineering. Still a market and service centre, it manufactures licorice confectionery (Pomfret cakes) and has a well-known racecourse. Pop. (1981) 29,047.

Pontevedra, province, northwestern Spain, smallest of the four provinces of the autonomous community (region) of Galicia, with an area of 1,729 sq mi (4,477 sq km). It is mountainous, with an Atlantic coastline deeply indented by the picturesque *rías bajas* (inlets) of Arosa, Pontevedra, and Vigo. Numerous traditional fiestas held throughout the province contribute, with the scenic beauty and fine beaches, to its attractions for tourists. Cattle, timber, agricultural produce, fish, and shellfish are exported. Vigo, with one of the best harbours in Europe, is a port of call for transatlantic shipping and is also Spain's most important fishing port. Other ports are Villagarcía (also a resort), Marín (with a naval aca-



Goats grazing along the coast in Pontevedra province, Spain
G. Mairani

demy), and Pontevedra, the provincial capital. Pop. (1982 est.) 915,152.

Pontevedra, city, capital of Pontevedra province, in the autonomous community (region) of Galicia, northwestern Spain, on the Río Lérez at its entry into the Ría (inlet) de Pontevedra, an Atlantic inlet. The city's port and shipyards were important in the Middle Ages, and it is probable that Columbus' ship, the "Santa Maria," was built there. It has also been claimed as the birthplace of Columbus. Legend says that it was founded by a Greek, Teukro, who called it Helenes; but more likely it was of Roman origin, hence its old name Pons Vetus ("old bridge"), from the 11-arch bridge that, with modifications, still spans the Lérez. Noteworthy buildings include the Plateresque church of Santa María la Mayor (1520–59), a national monument; the 14th-century Gothic convents of San Francisco (also a national monument) and Santa Clara; the Rococo Santuario de La Peregrina (1778–92); and the ruins of the 14th-century convent of Santo Domingo, now an archaeological museum.

Industries include the manufacture of cloth, hats, leather, pottery, fertilizers, timber, and cellulose; and there is an active trade in grain, wine, and fruit. Pop. (1982 est.) 70,223.

Consult the INDEX *first*

Ponti, Gio(vanni) (b. Nov. 18, 1891, Milan—d. Sept. 15, 1979, Milan), Italian architect and designer associated with the development of modern architecture and modern industrial design in Italy.

Ponti graduated in 1921 from the Milan Polytechnic. From 1923 to 1938 he did industrial design for the Richard-Ginori pottery factory. In 1928 he founded the magazine *Domus*, which influenced interior decoration, serving as its editor until 1946.

In 1933 Ponti was appointed to the executive committee of the Fifth Milan Triennale, an international exhibition stressing the work of young Milanese avant-garde architects. Among his important buildings of the 1930s were the Institute of Mathematics, University of Rome (1934); the Catholic Press Exhibition, Vatican City (1936); and the first office block of the Montecatini company, Milan (1936). Thereafter he carried out a series of projects in various parts of the world. His best known architectural work, the Pirelli Building, Milan (1955–59, with Pier Luigi Nervi and others), is notable for its hexagonal plan.

Simultaneously with his architecture, Ponti was active in painting, the graphic arts, design for the theatre—including costumes and scenery for Milan's La Scala opera—and motion pictures, and interior design.

Pontiac (b. *c.* 1720, on the Maumee River, in Ohio—d. April 20, 1769, Cahokia, Ill.), Ottawa Indian chief who became a great intertribal leader when he organized a combined resistance—known as Pontiac's War (1763–64)—to British power in the Great Lakes area.

Little is known of Pontiac's early life, but by 1755 he had become a tribal chief. His commanding manner and talent for strategic planning also enabled him to become the leader of a loose confederacy among the Ottawa, the Potawatomi, and the Ojibwa. In 1760 he met Maj. Robert Rogers, a British colonial ranger on his way to occupy Michilimackinac (St. Ignace, Mich.) and other forts surrendered by the French during the French and Indian War of 1754–63. Pontiac agreed to let the British troops pass unmolested on condition that he be treated with respect.

He soon came to realize, however, that under the British rule his people would no longer be welcome in the forts and that they would ultimately be deprived of their hunting grounds by aggressive settlers encroaching upon their ancestral lands. Thus, in 1762 Pontiac enlisted support from practically every Indian tribe from Lake Superior to the lower Mississippi for a joint campaign to expel the British. In what the English called "Pontiac's Conspiracy," he arranged for each tribe to attack the nearest fort (May 1763) and then to combine to wipe out the undefended settlements.

The shrewd and daring leader elected to capture Detroit himself, and it is for this military action that he is particularly remembered. When his carefully laid plans for a surprise attack (May 7) were betrayed to the commanding officer, he was forced to lay siege to the fort. On July 31 Pontiac won a brilliant victory at the Battle of Bloody Run, but the besieged fort was nevertheless able to receive reinforcements, and on October 30 Pontiac withdrew to the Maumee River.

Pontiac's larger plan was more successful. Of the 12 fortified posts attacked by the united tribes, all but 4 were captured; most of the garrisons were wiped out, several relief expeditions were nearly annihilated, and the frontier settlements were plundered and laid desolate. By 1764 continuing British action began to take its toll, however, and Pontiac finally agreed to conclude a treaty of peace in July 1766.

Three years later, while he was visiting in Illinois, a Peoria Indian stabbed and killed him. His death occasioned a bitter war among the tribes, and the Illinois group was almost annihilated by his avengers.

Pontiac, city, seat (1847) of Livingston County, central Illinois, U.S., on the Vermilion River. Settled *c.* 1830, it was laid out in 1837 and named for the famous Ottawa Indian chief. A state reformatory, established there in 1871, is now the Pontiac Correctional Center. The community's basically agricultural economy—corn and soybeans—is supplemented by light industry, including the manufacture of furniture, industrial storage equipment, lawn mowers, gloves, and shoe heels, and by commercial printing. Inc. village, 1856; city, 1872. Pop. (1980) 11,227.

Pontiac, city, seat (1820) of Oakland County, southeastern Michigan, U.S., on the Clinton River, 25 mi (40 km) northwest of Detroit. Named for the Ottawa Indian chief, it was located on the Saginaw Trail and became an important wagon and carriage production centre in the 1880s. It later turned to the manufacture of automobiles, auto parts, buses, and trucks. The Oakland Pioneer and Historical Society is headquartered in the Governor Moses Wisner House (1845). Oakland University (1959) in nearby Rochester is the site of the summer Meadow Brook Music Festival. Pontiac is the site of the Silverdome, a sports arena, that seats 80,600 persons. Inc. village, 1837; city, 1861. Pop. (1980) 76,715.

Pontian, SAINT, Latin PONTIANUS (b. Rome—d. *c.* 236, Sardinia; feast day November 19), pope from 230 to 235 who summoned the Roman synod that confirmed the condemnation of Origen, one of the chief theologians of the early Greek Church. At the beginning of the persecution of Christians under the Roman emperor Maximinus in 235, Pontian was exiled to the mines of Sardinia with St. Hippolytus, who had opposed both Pope St. Urban I and Pontian.

While sharing their exile, Pontian and Hippolytus became reconciled. On Sept. 28, 235, Pontian abdicated to St. Anterus, who was quickly executed. Pontian died a short while afterward with Hippolytus. Their deaths are traditionally thought to have been the result of ill treatment. His epitaph in the catacomb of St. Calixtus, Rome, was found in 1909; the inscription of the date of his resignation is noted as the first specific date in papal history.

Pontian Stage, major division of Miocene rocks and time (the Miocene Epoch began about 26,000,000 years ago and lasted about 19,000,000 years). It was named for deposits near the Black Sea (Latin: Pontus Euxinus). The Pontian deposits are representative of a freshened lagoonal environment, in contrast to the preceding Sarmatian Stage, in which inland, salt-sea deposits dominate.

The Pontian faunal assemblage is the ancestral fauna of the present Caspian Sea. It is of limited variety, though it is locally abundant. Mollusks are dominant, especially clams.

Pontian rocks were deposited in a series of basins that were exposed at first to a period of extensive flooding by a transgressing sea and then to more pronounced isolation and freshening as the seas withdrew and the basins became freshwater or brackish-water lakes.

Pontianak, *kotamadya* (city), *kabupaten* (regency), and capital, Kalimantan Barat *propinsi* (West Borneo province), Borneo, Indonesia, just inland from the western coast on the Sungai (river) Kapuas-ketjil. Founded in 1772, the city was formerly the capital of the sultanate of Pontianak, a trading station that later became the chief gold city of Borneo. Houses are built on piles to avoid the regular flooding of the river; the hinterland is tropical forest and swampland, and the area is one of great humidity. A major industry is shipbuilding, and palm oil, rubber, and sugar are processed. Other products of the region include pepper, rice, corn (maize), cassava, and tobacco. Air service is from nearby Supadio airport. Pop. (1980) city, 304,778; regency, 608,893.

Pontic Mountains, mountains rising out of the northern side of the Asia Minor peninsula, Turkey, in an area once occupied by the ancient country of Pontus. The range reaches a maximum height of 12,917 ft (3,937 m) and makes a gentle double bend, reflected in the outline of the southern shore of the Black Sea.

Dense pine forests cover the hills. On the cultivated land near the sea, tobacco, hazelnuts, tea, and citrus fruits predominate.

pontifex (Latin: "bridge builder"), plural PONTIFICES, member of a council of priests in ancient Rome. The college, or *collegium*, of the *pontifices* was the most important Roman priesthood, being especially charged with the administration of the *jus divinum* (*i.e.,* that part of the civil law that regulated the relations of the community with the deities recognized by the state), together with a general superintendence of the worship of gens and family. Whether the literal meaning of the name indicates any special connection with the sacred bridge over the Tiber (Pons Sublicius) cannot now be determined.

The college existed under the monarchy, when its members were probably three in number; they may be considered as having been legal advisers of the *rex* in all matters of religion. Under the republic they emerge into prominence under a *pontifex maximus*, or supreme priest, who took over the king's duties as chief administrator of religious law. During the republican period the number of *pontifices* increased until by the time of Julius Ceasar there were 16. Included in the *collegium* were also the *rex sacrorum*, the *flamines*, three assistant *pontifices* (*minores*), and the Vestal Virgins, who were all chosen by the *pontifex maximus.* Vacancies in the body of *pontifices* were originally filled by co-optation; but from the second Punic War onward the *pontifex maximus* was chosen by a peculiar form of popular election, and in the last age of the republic this was true for all the members. They all held office for life.

The immense authority of the *collegium* centred in the *pontifex maximus*, the other *pontifices* forming his *consilium*, or advising body. His functions were partly sacrificial or ritualistic, but these were the least important; the real power lay in the administration of the *jus divinum*, the chief departments of which may briefly be described as follows: (1) the regulation of all expiatory ceremonials needed as the result of pestilence, lightning, etc.; (2) the consecration of all temples and other sacred places and objects dedicated to the gods by the state through its magistrates; (3) the regulation of the calendar both astronomically and in detailed application to the public life of the state; (4) the administration of the law relating to burials and burying places and the worship of the Manes, or dead ancestors; (5) the superintendence of all marriages by *confarreatio* (*i.e.,* originally, of all legal patrician marriages) (6) the administration of the law of adoption and of testamentary succession. They had also the care of the state archives and of the lists of magistrates and kept records of their own decisions (*commentarii*) and of the chief events (*annales*).

It is obvious that a priesthood with such functions and holding office for life must have been a great power in the state, and for the first three centuries of the republic it is probable that the *pontifex maximus* was in fact its most powerful member. The office might be combined with a magistracy, and, though its powers were declaratory rather than executive, it may be described as quasi-magisterial. Under the later republic it was coveted chiefly for the great dignity of the position; Julius Caesar held it for the last 20 years of his life, and Augustus took it after the death of Lepidus in 12 BC, after which it became inseparable from the office of the reigning emperor.

Pontine Islands (Italy): *see* Ponza Islands.

Pontine Marshes, Italian AGRO PONTINO, reclaimed area in Latina province, Lazio (Latium) region, south central Italy, extending between the Alban Hills (Colli Albani), the Monti (mountains) Lepini, and the Tyrrhenian Sea, and traversed by the Appian Way. Two tribes, the Pomptini and the Ufentini, lived in this district in early Roman times, but the region was already marshy and malarial during the later years of the Roman Republic. Several emperors and popes made unsuccessful attempts at reclamation, but throughout modern history the marshes remained unhealthy, inhabited by a handful of shepherds, with small fields on the higher eastern edge where peasants from towns high on the Monti Lepini cultivated wheat. Rough pasture and *maquis* (a tough scrub) covered most of the area.

In 1928 the Fascist government of Benito Mussolini launched a drive to drain the marshes, clear the vegetation, and settle several hundred families. Towns were built in the former wilderness: Littoria (now Latina) in 1932, Sabaudia in 1934, Pontinis in 1935, Aprilia in 1937, and Pomezia in 1939. On the eve of World War II the only areas in which the original vegetation remained were in the Monte Circeo National Park. Damage done to the farms and drainage works and canals during World War II was later repaired, and the Agro Pontino (area about 300 sq mi [777 sq km]) is now one of the most productive in Italy, yielding cereals, sugar beets, fruit, vegetables, and livestock. Light industry was established in the area from 1960 onward with subsidies from a regional development program, the Cassa per il Mezzogiorno (Fund for the South).

Pontoise, town, capital (since 1964) of Val-d'Oise *département*, Paris region, northern France, on the right bank of the Oise River, northwest of Paris. In 1966 it became an episcopal see, and its cathedral, formerly Saint-Maclou church, dates from the 12th century. It has a Flamboyant Gothic facade and a tower with a Renaissance dome. The double northern aisle is a Renaissance masterpiece. Pontoise was acquired by Philip I in 1064 and became the capital of the French Vexin region. It played a conspicuous part in the Hundred Years' War (1337–1453) and was twice in English hands in the first half of the 15th century. The Parliament of Paris met there several times in the 16th and 17th centuries. It was occupied by the Germans in 1870–71 and was damaged in World War II. Metallurgical and chemical industries form part of the city's economic base. Just south of the city the new town of Cergy is being developed. Pop. (1982) 27,885.

pontoon bridge, floating bridge, used primarily but not invariably for military purposes. A pontoon bridge was constructed in 480 BC by

Persian engineers to transport Xerxes' invading army across the Hellespont (Dardanelles). According to Herodotus, the bridge was made of 676 ships stationed in two parallel rows with their keels in the direction of the current. Alexander the Great is said to have crossed the Oxus by rafts made of his soldiers' tents of hide stuffed with straw.

More modern armies, such as Napoleon's, carried prefabricated pontoons of wood, copper, or other material either closed or open. The U.S. Army in the 19th century experimented with pneumatic rubber pontoons and discarded them as less serviceable than wood or metal but returned to their use in an improved form serviced by air compressors during World War II.

Because they obstruct navigation, floating bridges are limited in non-military applications, yet several long-span floating bridges have been built in modern times. Notable examples are concrete-pontoon bridges over Lake Washington (Seattle, Wash.), 6,560 feet (2,000 metres) long; over the Derwent (Tasmania), 3,165 ft long; and over the Golden Horn (Istanbul), 1,500 ft long.

Pontoppidan, Henrik (b. July 24, 1857, Fredericia, Den.—d. Aug. 21, 1943, Ordrup, near Copenhagen, Den.), Realist writer who shared with Karl Gjellerup the Nobel Prize for Literature in 1917 for "his authentic descriptions of present-day life in Denmark."

Pontoppidan, 1917
By courtesy of the Nobel Foundation, Stockholm

Pontoppidan's novels and short stories—informed with a desire for social progress but despairing, later in his life, of its realization—present an unusually comprehensive picture of his country and his epoch.

The son of a clergyman, Pontoppidan partly revolted against his environment by studying engineering in Copenhagen in 1873. In 1879 he broke off his studies and became for several years a teacher. His first collection of stories, *Stækkede Vinger*, was published in 1881, and thereafter he supported himself by writing, until 1900 partly as a journalist with various Copenhagen papers.

Pontoppidan's output—mainly novels and short stories written in a cold, aloof, epic style—stretches over half a century and covers most aspects of Danish life.

His first books were about country-town life. *Landsbybilleder* (1883), *Fra Hytterne* (1887), and *Skyer* (1890) are all characterized by social indignation though also by ironic appreciation of the complacency and passivity of country people. The trilogy *Det Forjættede Land*, 3 vol. (1891, 1895; *The Promised Land*, 1896) describes the religious controversies in country districts. In the 1890s Pontoppidan wrote short novels on psychological, aesthetic, and moral problems (*e.g., Nattevagt,* 1894; *Den Gamle Adam*, 1895; and *Højsang*, 1896). These were followed by a major work, the novel *Lykke-Per* (1898–1904), in which the chief character bears some resemblance to Pontoppidan himself. He is a clergyman's son who rebels against the puritanical atmosphere of his home and seeks his fortune in the capital as an engineer. The book's theme is the power of environment, and national tendencies toward daydreaming and fear of reality are condemned.

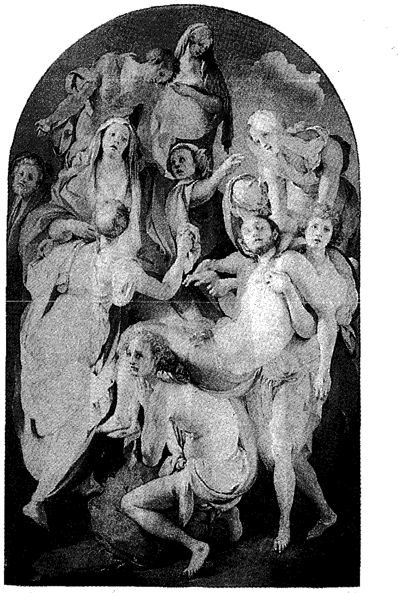
Pontoppidan's third great novel cycle, *De dødes rige*, 5 vol. (1912–16; "The Empire of Death"), shows dissatisfaction with political developments after the liberal victory of 1901, and anxiety over the barrenness of the new era. The bitter novel *Mands Himmerig* (1927) describes neutral Denmark during World War I and attacks carefree materialism. His last important work was the four volumes of memoirs that he published between 1933 and 1940 and that appeared in a collected and abridged version entitled *Undervejs til mig selv* (1943).

Pontormo, Jacopo da, original name JACOPO CARRUCCI (b. May 24, 1494, Pontormo, near Empoli, Republic of Florence—buried Jan. 2, 1557, Florence), Florentine painter who broke away from High Renaissance Classicism to create a more personal, expressive style that is sometimes classified as early Mannerism.

Pontormo was the son of Bartolommeo Carrucci, a painter. According to Vasari he was apprenticed to Leonardo da Vinci and afterward to Albertinelli and Piero di Cosimo. At the age of 18 he entered the workshop of Andrea del Sarto, and it is this influence that is most apparent in his early works. In 1518 he completed an altarpiece in the church of S. Michele Visdomini, Florence, that reflects in its agitated—almost neurotic—emotionalism a departure from the balance and tranquillity of the High Renaissance. His painting of "Joseph in Egypt" (*c.* 1515; National Gallery, London), one of a series for Pier Francesco Borgherini, suggests that the revolutionary new style appeared even earlier.

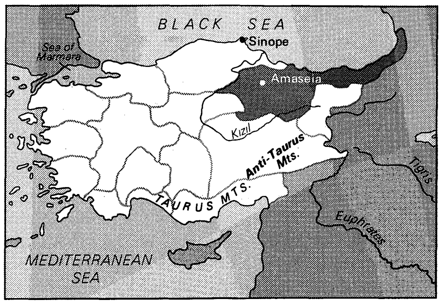
Pontormo was primarily a religious painter, but he painted a number of sensitive portraits and in 1521 was employed by the Medici family to decorate their villa at Poggio a Caiano with mythological subjects. In the Passion cycle (1522–25) for the Certosa near Florence (now in poor condition), he borrowed ideas from Dürer, whose engravings and woodcuts were circulating in Italy. His mature style is best exemplified in the "Deposition" painted soon after this for Sta. Felicità, Florence.

Pontormo became more and more of a recluse in later life. A diary survives from 1554 to 1557, but the important frescoes in S. Lorenzo on which he worked during the last decade of his life are now known only from drawings; in these the influence of Michelangelo is apparent. Numerous drawings survive, and paintings are to be found in various galleries in Europe and America, as well as in Florence.



"Deposition," oil on panel by Jacopo da Pontormo, 1525–28; in the church of Sta. Felicità, Florence
SCALA—Art Resource/EB Inc.

Pontus, ancient district in northeastern Anatolia adjoining the Black Sea; in the 1st century BC it briefly contested Rome's hegemony in Anatolia. An independent Pontic kingdom with its capital at Amaseia (modern Amasya)



Pontus
From W. Shepherd, *Historical Atlas*, Harper & Row, Publishers (Barnes & Noble Books), New York City; revision copyright © 1964 by Barnes & Noble, Inc.

was established at the end of the 4th century BC in the wake of Alexander's conquests. Superficially Hellenized, the kingdom retained its Persian social structure, with temple priests and Persianized feudal nobles ruling over a heterogeneous village population. In the 3rd and 2nd centuries BC Pontus gradually asserted itself among the petty Hellenistic states of Anatolia, annexing Sinope (modern Sinop; *q.v.*) as its new capital (183 BC). The Pontic kingdom reached its zenith under Mithradates VI Eupator (*c.* 115–63 BC), whose program of expansion brought him into disastrous conflict with Rome, resulting in the virtual extinction of the Pontic kingdom and its incorporation into the Roman Empire (63–62 BC).

Pontypool, town, seat of Torfaen district, Gwent county, Wales, in the valley of the Afon Lwyd. Lying on the eastern edge of the South Wales coalfield, it was an early metalworking centre, with iron smelting (from 1577) and also tinplate manufacture; in the 18th century it produced lacquered ironware known as Pontypool ware. Today it has both steel and glass industries, some rubber manufacturing, and a large nylon factory. Pop. (1981) 36,301.

Pontypool ware, japanned (varnished) tinplate produced in Wales at the Allgood family factory in Pontypool and later in Usk, Monmouthshire. It is distinguished from other japanned tinware by its distinctive lustre and unique durability. These features are the results of the experiments by craftsmen of the Allgood family, who also developed their own tinplating technique. The Pontypool factory was established by Edward Allgood in about 1732. Thin sheets of iron were dipped into molten tin, then worked into domestic utensils, such as teapots, trays, and dishes, or into ornaments. The pieces were japanned with a preparation made from linseed oil, umber (a brown oxide of iron), litharge (a lead monoxide), and, for the dark ground on which the colourful decoration is based, asphalt, or coal-tar pitch. When the pieces had been decorated with several coats, they were fired repeatedly at a low temperature, often over periods of up to three weeks, leaving the finish almost totally resistant to heat. The Allgood partnership broke up in 1761, another factory being established at Usk and producing a similar ware.

The decorative subjects used on Pontypool ware were largely Chinese scenes and figures, but those on the Usk ware included sporting and rustic scenes. The Pontypool factory had closed by 1822, and the Usk factory continued only for another 40 years. The most comprehensive collections of Pontypool ware are to be seen at the National Museum of Wales, Cardiff, and the Newport Museum and Art Gallery, Gwent.

Pontypridd, town, seat of Taff-Ely district, Mid Glamorgan county, Wales, at the confluence of the rivers Rhondda and Taff. Pontypridd is a shopping centre for the Rhondda and middle Taff valleys. Industrially, its coal-mining and chain-making interests have been largely superseded by a variety of light engineering and other factories, especially on the Treforest Industrial Estate (1937). A single-span, 140-ft (43-m) bridge over the Taff, no longer in use, was constructed in 1756 by William Edwards, a local stonemason. Pop. (1981) 29,796.

pony, any of several breeds of small horses standing less than 14.2 hands high (a hand equals 4 inches, or about 10 centimetres) and noted for gentleness and endurance. Among the common pony breeds are the Shetland, whose docile nature and good endurance make it desirable as a pack animal and a riding horse for children; the Welsh, a hardy breed with fine endurance and style; the Welsh Cob, noted for its high-stepping action; the Exmoor and Dartmoor, native to the moors of Somerset, Devon, and Cornwall, England, and now used to breed polo ponies; and the Highland, a thick, gray saddle animal.

Pony Express, in U.S. history, system of mail delivery by continuous horse and rider relays between St. Joseph, Mo., and Sacramento, Calif. (April 1860–October 1861). Although a financially disastrous, brief enterprise for the sponsoring firm of Russell, Majors, and Waddell, the Pony Express and its most famous riders, William ("Buffalo Bill") Cody and "Pony Bob" Haslam, gave rise to one of the most colourful episodes of the American West.

The approximately 1,800-mile (2,897-kilometre) route normally required about 10 days to cover, with riders changing horses six to eight times between stations, of which there were 157. The service ceased with the completion of the transcontinental telegraph system.

Ponza Islands, also called PONTINE ISLANDS, Italian ISOLE DI PONZA, Latin INSULAE PONTIAE, volcanic island group in the Tyrrhenian Sea off the west coast of south central Italy, part of Latina province. The islands include Ponza (the largest), Palmarola, and Zannone in a western cluster and Ventotene and Santo Stefano in an eastern group, with a total area of 4.2 sq mi (10.9 sq km). The highest point of the island of Ponza is Monte Guardia (928 ft [283 m]).

Regular steamer services connect Ponza with Naples and, in the summer, with Anzio and Formia. Kaolin and bentonite are mined on the islands, which have become popular as summer resorts. Used since ancient times as places of exile, Ventotene has a prison and Ponza was used as a place of banishment for political prisoners under the Fascist regime. Pop. (1981 prelim.) 3,653.

Ponzillo, Rosa (singer): *see* Ponselle, Rosa.

poodle, breed of dog thought to have originated in Germany. It grew so popular in France, however, that it became the national dog of that country. The poodle was developed as a water retriever, and the distinctive clipping of its heavy coat was initiated to increase the animal's efficiency in the water. The dog has been used as a performer and as a truffle hunter, whose job it was to scent and dig up the edible fungus.

An elegant-looking dog, often ranked as one of the most intelligent of all breeds, the poodle has been bred in three size varieties—

Standard poodle
Sally Anne Thompson—EB Inc.

standard, miniature, and toy. All three are judged by the same standard of appearance, which calls for a well-proportioned dog with a long, straight muzzle, heavily haired, hanging ears, a docked pompon tail, and a characteristic springy gait and proud manner of carrying itself. The coat consists of a woolly undercoat and a dense, wiry topcoat; if allowed to grow, the hair forms ropelike cords, and the dog is called a corded poodle. The coat should be solid, not variegated, and may be any of a number of colours, among them gray, white, black, brown, apricot, and cream. The standard poodle stands more than 15 inches (38 centimetres); the miniature is 10 to 15 inches (25.5 to 38 centimetres); the toy is under 10 inches (25.5 centimetres). Weight variations range from as much as 55 pounds (25 kilograms) to as little as 7 pounds (3 kilograms). The standard and miniature poodles are classed by the American Kennel Club as nonsporting dogs, the toy as a toy dog.

Pool, *région* of southern Congo, west central Africa, bordered by Zaire (south and east). It covers an area of 13,100 sq mi (34,000 sq km) and includes seven districts: Kinkala, Boko, Mindouli, Kindamba, Mayama, Ngamaba, and Ngabé. The capital is Kinkala.

The Djoué River bisects the *région* from northwest to southeast and joins the Congo River just below Brazzaville (the national capital, an administratively distinct commune within the boundaries of Pool). Northeast of the Djoué River, the Plateau Batéké is comparatively empty and undeveloped except near Brazzaville. Southwest of the Djoué, by contrast, a dense rural population supplies meat, dairy products, fruits, and vegetables for the Brazzaville market. Pool's savanna grassland supports one-quarter to one-third of the Congo's goats, pigs, sheep, cattle, and poultry. Truck farming is widespread around Kinkala in the Plateau des Cataracts, between the Congo River and the Brazzaville–Pointe-Noire railway. Further north, around Kindamba in the upper Niari River basin, paddy rice and tobacco are cultivated. Because of the proximity of the capital, transportation networks are among the most highly developed in the country. Pop. (1980 est.) 208,420.

pool, British billiards game in which each player uses a cue ball of a different colour and tries to pocket the ball of a particular opponent, thus taking a "life." Players have three lives and pay into a betting pool at the start of the game. The last player with a life wins the pool. During play, a player who takes a life wins a stake from that opponent. There are also a number of other forfeits paid into the pool for such errors as pocketing one's own ball or knocking a ball off the table.

Pool was a forerunner of the game snooker. *See also* Sporting Record: *Billiards.*

pool (U.S. billiards): *see* pocket billiards.

pool, method of gambling in which all money bet on the result of a particular event by a number of people is awarded to one or more winners according to conditions established in advance (taxes, operating expenses, and other charges may be deducted from the total pool before prizes are awarded).

Pools on football and other professional sports are popular in various forms throughout the world, including areas where they are illegal. In Great Britain and several other countries, football pools are in effect a national lottery, with the government taking more than 30 percent of total receipts. Prizes have been as high as £100,000 on a shilling bet, and gambling winnings by citizens are not taxed. Usually the bettor's task is to select the winning teams or tie games, to predict the correct score in several specified games, or, in baseball, to predict the number of hits or runs each named team will make during a week. A baseball pool called "13" has players taking one of 26 teams, the pool going to the holder of the first team that scores 13 runs in one game.

In U.S. football pools, illegal in most states, selection of winners is made more difficult by handicapping—inferior teams are allotted a certain number of points (point spread), which the other team's winning margin must surpass to score a win in the pool. Payoffs range from 3 to 1 when the actual odds are 15 or 16 to 1 and up to 100 to 1 when the actual odds are 300 to 1. The largest payoffs are made when the odds are as much as 250,000,000 to 1 against the bettor. Such winnings have occurred in Great Britain only as often as might mathematically be expected, considering that about 150,000,000 such bets are made each year.

Pool Checkers (game): *see* Spanish Checkers.

Poole, district (borough), county of Dorset, England, adjoining the major British resort of Bournemouth. The old town occupies a site on the north shore of an extensive, almost landlocked tidal harbour. Extending 25 sq mi (64 sq km), the harbour is a major English yachting centre, and Poole still functions as a small port, mainly for British coastal traffic. There is an old-established pottery, and other industries include boatbuilding, the making of chemicals, and engineering. On the east the town has been greatly extended by modern residential growth in the communities of Parkstone and Branksome to coalesce with its modern larger neighbour, Bournemouth. Largest of the islands in Poole Harbour is Brownsea, a bird sanctuary given to the National Trust in 1962. Pop. (1981) 119,316.

Poole, Elijah: *see* Muhammad, Elijah.

Poole, William Frederick (b. Dec. 24, 1821, Salem, Mass., U.S.—d. March 1, 1894, Evanston, Ill.), U.S. bibliographer and library administrator whose indexing of periodicals became authoritative.

As a student at Yale, Poole learned the principles of indexing from John Edmands (1820–1915), afterward librarian of the Philadelphia Mercantile Library, whom Poole succeeded as librarian of a college literary society. While still in college, Poole prepared *An Alphabetical Index to Subjects Treated in the Reviews and Other Periodicals* . . . (1848), which was revised and enlarged as *Poole's Index to Periodical Literature* (1887–1908).

After directing successively two libraries in Boston (1852–69), Poole organized and served as chief librarian of the public libraries of Cincinnati (1871–73) and Chicago (1874–87),

Poole

building the circulation of the Chicago library to the largest in the United States in its time. Subsequently he organized the Newberry Library, Chicago.

Poona (India): *see* Pune.

Poona Pact (Sept. 24, 1932), agreement between Hindu leaders in India granting new rights to untouchables. The pact resulted from the communal award of Aug. 4, 1932, made by the British government on the failure of the India parties to agree, which allotted seats in the various legislatures of India to the different communities. Mahatma Gandhi objected to the provision of separate electorates for the "scheduled castes" (untouchables), which in his view separated them from the whole Hindu community. Though in prison, Gandhi announced a fast unto death, which he began on September 18.

B.R. Ambedkar, the untouchable leader, who felt that his group's special interests might be advanced by the government's system, resisted concessions until Gandhi was near death. He and the Hindu leaders then agreed to the pact, which withdrew separate electorates but gave increased representation to the scheduled castes for a 10-year period. Ambedkar complained of blackmail, but the pact marked the start of movement against untouchability within the Indian nationalist movement.

Poonch (India): *see* Pūnch.

Poopó, Lake, Spanish LAGO POOPÓ, lake in Oruro department, west central Bolivia, occupying a shallow depression in the Altiplano, or high plateau, at 12,090 ft (3,686 m) above sea level. It is the country's second largest lake and covers approximately 1,000 sq mi (2,600 sq km) at low stage. It is about 56 mi (90 km) long and 20 mi wide but only 8 to 10 ft deep.

The Desaguadero and del Márquez rivers feed the lake, and its only visible outlet is the Río Lacajahuira. During floods (high stage) it spills into the Salar de Coipasa, a salt flat 50 mi to the southwest. Salt content of the water is heavy because of excessive evaporation. Settlement on its shores, made marshy by filtration of water into the lake bed, is sparse.

poor house: *see* almshouse.

Poor Knights of Christ and of the Temple of Solomon: *see* Templar.

Poor Law, body of laws undertaking to provide relief for the poor, developed in 16th-century England and maintained, with various changes, until after World War II. The Elizabethan Poor Laws, as codified in 1597–98, were administered through parish overseers, who provided relief for the aged, sick, and infant poor, as well as work for the able-bodied in workhouses. Late in the 18th century, this was supplemented by the so-called Speenhamland system of providing allowances to workers who received wages below what was considered a subsistence level. The resulting increase in expenditures on public relief was so great that a new Poor Law was enacted in 1834, based on a harsher philosophy that regarded pauperism among able-bodied workers as a moral failing. The new law provided no relief for the able-bodied poor except the misery of the workhouse, with the object of stimulating workers to seek regular employment rather than charity. The growth of humanitarian feeling in the 19th century helped to mitigate the harshness of the law in practice, and the phenomenon of industrial unemployment in the 20th century showed that poverty was more than a moral problem. The social legislation of the 1930s and 1940s replaced the Poor Laws with a comprehensive system of public welfare services. *See also* workhouse.

poor-me-one, bird also known as the common potoo. *See* potoo.

Poor Richard, unschooled but experienced homespun philosopher, a character created by Benjamin Franklin and used as his pen name for the annual *Poor Richard's* almanac, edited by Franklin from 1732 to 1757. Although the Poor Richard of the early almanacs was a dim-witted and foolish astronomer, he was soon replaced by Franklin's famous Poor Richard, a country dweller, dutifully pious, quiet, and rather dull, who is a rich source of prudent and witty aphorisms on the value of thrift, hard work, and the simple life. Among his practical proverbs are "God helps those who help themselves" and "Early to bed and early to rise, makes a man healthy, wealthy, and wise."

The Way to Wealth (1757) is a collection of Poor Richard's advice on getting ahead in business and public life. Poor Richard is the precursor of later horse-sense characters such as Sam Slick, Josh Billings, and Davy Crockett, who belong to a tradition of typically American humour.

poorwill (*Phalaenoptilus nuttallii*), nocturnal bird of North America belonging to the nightjar family (Caprimulgidae). The poorwill, named for its call, is about 20 centimetres (8 inches) long and has mottled gray plumage, a short tail with a bit of white at the corners, and a narrow bib, white in the male, buffy in the female. This bird catches flying insects at night. It breeds in arid country west of the Mississippi River, north to British Columbia, laying two white eggs on the ground. It winters from California to central Mexico.

The poorwill is one of the few examples of hibernators among birds. It clings to the walls of rock crevices in a torpid state during the unfavourable winter months.

Pop art, largely British and American cultural phenomenon from the late 1950s, named by the art critic Lawrence Alloway in reference to the prosaic iconography of its painting and sculpture. Pop art, according to Richard Hamilton, one of its exponents in England, was "Popular/Transient/Expendable/Low-Cost/Mass-Produced/Young/Witty/Sexy /Gimmicky/Glamorous/Big Business . . . ." Works by such Pop artists as the Americans Roy Lichtenstein, Andy Warhol, Claes Oldenburg, Tom Wesselman, James Rosenquist, and Robert Indiana and the Englishmen David Hockney and Peter Blake, among others, were characterized by their portrayal of any and all aspects of popular culture that had a powerful impact on contemporary life; their iconography—taken from television, comic books, movie magazines, and all forms of advertising—was presented emphatically and objectively, without praise or condemnation but with overwhelming immediacy, and by means of the precise commercial techniques used by the media from which the iconography itself was borrowed. Pop art represented an attempt to return to a more objective, universally acceptable form of art after the dominance in both the United States and Europe of the highly personal American Abstract Expressionism (*q.v.*). It was also iconoclastic, rejecting both the supremacy of the "high art" of the past and the pretensions of other contemporary avant-garde art. Pop art became a cultural event because of its close reflection of a particular social situation and because its easily comprehensible images were immediately accepted and exploited by the mass media. Although Pop art has been described as vulgar, sensational, nonaesthetic, and a joke, it has also been seen as an art directly responsive to life, an art that is democratic and nondiscriminatory, bringing together both connoisseurs and untrained viewers.

Pop art is a descendant of Dada (*q.v.*), a nihilistic movement current in the 1920s that ridiculed the seriousness of contemporary Parisian art and, more broadly, the political and cultural situation that had brought war to Europe. Marcel Duchamp, the champion of Dada in the United States, who tried to narrow the distance between art and life by celebrating the mass-produced objects of his time, was the most influential figure in the evolution of Pop art. Other 20th-century artists who influenced Pop art were Stuart Davis, Gerard Murphy, and Fernand Léger, all of whom depicted in their painting the precision, mass-production, and commercial materials of the machine-industrial age. The immediate predecessors of the Pop artists were Jasper Johns, Larry Rivers, and Robert Rauschenberg, American artists who in the 1950s painted flags, beer cans, and other similar objects, though with a painterly, expressive technique.

Some of the more striking forms that Pop art took were Roy Lichtenstein's faithful reproductions, down to the colour dots used in commercial printing, of comic-strip pictures; Andy Warhol's meticulously literal paintings and silk-screen prints of soup can labels, soap cartons, and rows of soft drink bottles; Claes Oldenburg's soft plastic sculptures of objects such as bathroom fixtures, typewriters, and gigantic hamburgers; Tom Wesselman's "Great American Nudes," flat, direct paintings of faceless sex symbols; and George Segal's constructed tableaux featuring life-sized plaster-cast figures placed in actual environments (*e.g.,* lunch counters and buses) retrieved from junkyards.

Most Pop artists aspired to an impersonal, urbane attitude in their works. Some examples of Pop art, however, were subtly expressive of social criticism—for example, Oldenburg's drooping objects and Warhol's monotonous

"Brillo Box," silk screen ink on wood by Andy Warhol, Pop art, 1964; in the Leo Castelli Gallery, New York City

By courtesy of Leo Castelli Gallery, New York City repetitions of the same banal image have an undeniably disturbing effect—and some, such as Segal's mysterious, lonely tableaux, are overtly expressionistic.

American Pop art tended to be emblematic, anonymous, and aggressive; English Pop, more subjective and referential, expressed a somewhat romantic view of Pop culture fostered perhaps by England's relative distance from it. English Pop artists tended to deal with technology and popular culture primarily as themes, even metaphors; some American Pop artists actually seemed to live these ideas. Warhol's motto, for example, was, "I think everybody should be a machine," and he tried in his art to produce works that a machine would have made.

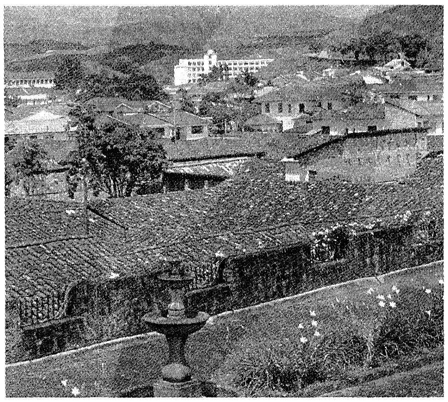
Pop art was not taken seriously by the public, but it found critical acceptance as a form of art suited to the highly technological, mass-media oriented society of Western countries.

Pop Warner Football, in full POP WARNER JUNIOR LEAGUE FOOTBALL, American football program in which boys aged 8 to 15 compete under safety-first rules. Teams are matched by age and weight and must comply with strict equipment standards. The program was founded in 1929 and named for Glenn Scobey ("Pop") Warner, a prominent and innovative coach of the early 1900s. By the late 20th century several thousand teams in local leagues were participating in the United States and Mexico. League headquarters are in Philadelphia.

Popa, Mount, also called POPA HILL, extinct volcano, central Myanmar (Burma), at the northern end of Pegu Mountain Range. It rises to 4,985 feet (1,519 m), has a mile-wide crater, and is the highest point in the range. Mount Popa is believed to be the home of the 37 nats, or spirits, that are a part of Burmese animist religion.

Popayán, capital of Cauca *departamento,* southwestern Colombia, at the base of Puracé Volcano (15,603 feet [4,756 m]) on a tributary of the Cauca River, 5,702 feet (2,241 m) above sea level. Founded in 1535, the city has always been an administrative centre. During the colonial era, landowners and mining entrepreneurs resided there, giving it major cultural and religious importance and its architecture a distinctive Spanish flavour. Its various educational institutions include the University of Cauca (1827).

The changing pattern of development in Colombia since independence has reduced



Popayán, Colom.
Carl Frank

Popayán's economic significance. Its industrial activity is focused largely on the processing of food and beverages and the manufacture of clothing and building materials. Popayán is the southern terminus of the railway running north to Cali and Medellín and is on the Simón Bolívar Highway and a part of the Pan-American Highway connecting the Cauca valley with Ecuador. It is the node of an extensive departmental road network. Indian peoples make up a large part of the population. Pop. (1985) 141,964.

popcorn, a variety of corn (maize), the kernels of which, when exposed to heat or microwaves, are exploded into large fluffy masses. The corn used for popping may be any of about 25 different varieties of *Zea mays;* the two major types are rice popcorn, in which the grains are pointed at both base and apex, and pearl popcorn, in which the grains are rounded and compact. A popcorn kernel has an extremely hard hull and hard outer endosperm, and within there is a mass of moist, starchy, white endosperm. The moisture is optimally about 13.5 percent. When such kernels are heated to about 400° F (about 200° C), the moisture in the starch turns into steam and builds up pressure until the kernel explodes inside out into a white fluffy, irregular mass, about 20 to 40 times the original size.

Popcorn is native to the Western Hemisphere. Thousand-year-old kernels of popcorn have been found by archaeologists in Peru and Utah. The first European explorers of the New World described the toasting of popcorn by the Indians for food, for scattering in religious ceremonies, and for wearing as decoration in the hair. Today the United States grows almost all the world's popcorn.

As a snack food, popcorn is commonly buttered and salted. It may instead be glazed with variously flavoured and coloured candy syrups that harden, or be mixed with peanuts or almonds, or be coated with melted cheese.

Popé (d. 1692, San Juan Pueblo New Spain [now in New Mexico, U.S.]), Tewa Pueblo medicine man who led an all-Indian revolt in 1680 against the Spanish invaders in what is now the southwestern United States, driving them out of Santa Fe and temporarily restoring the old Pueblo way of life.

Little is known of Popé's life before 1675. In that year he was imprisoned by Spanish authorities on suspicion of witchcraft and of killing several missionaries. After his release from prison, he hid in Taos Pueblo to plan and organize what came to be known as the Pueblo Revolt. Popé believed that he was commanded by tribal ancestral spirits (kachinas) to restore traditional native customs, and other villages enthusiastically responded to news of the planned uprising.

On Aug. 10, 1680, Popé led a united attack of almost all the Pueblo Indian tribes on the Spanish capital of Santa Fe, killing nearly 500. After 10 days nearly 1,000 besieged residents abandoned the city and fled to El Paso del Norte. Popé immediately set about erasing all vestiges of Spanish culture and the Christian religion. Restoring ancestral ways, he traveled from one pueblo to another in ceremonial dress. For a time he was accorded great honour, but success made him despotic; and after a few years, drought, enemy tribe forays, and internal dissension combined to depose him. He was, however, reelected Pueblo leader in 1688, shortly before his death. Although Spanish rule was reestablished in 1692, the alien domination was never as strong as before the time of Popé.

pope (Latin *papa,* from Greek *pappas,* "father"), an ecclesiastical title expressing affectionate respect, formerly given, especially from the 3rd to the 5th century, to any bishop and sometimes to simple priests. The title is still used in the East for the Orthodox patriarch of Alexandria and for Orthodox priests, but, since about the 9th century, it has been reserved in the West exclusively for the bishop of Rome. (*See also* papacy. The article contains a list of popes and antipopes.)

The *Annuario Pontificio* (official directory of the Holy See) describes the office of the pope by the following titles: Bishop of Rome, Vicar of Jesus Christ, Successor of the Prince of the Apostles, Supreme Pontiff of the Western Church, Patriarch of the West, Primate of Italy, Archbishop and Metropolitan of the Province of Rome, Sovereign of the State of Vatican City. The title pope or *papa* (abbreviated PP.) is officially used only as a less solemn style.

Doctrinally, in Catholic churches, the pope is regarded as the successor of St. Peter, who was head of the Apostles. The pope, as bishop of Rome, thus is seen to have full and supreme power of jurisdiction over the universal church in matters of faith and morals, as well as in church discipline and government.

The twofold basis of this doctrine of papal primacy is the place of Peter in the New Testament (in which there are various metaphors expressing his prerogatives) and the place of the Roman church in history. The understanding of papal primacy developed as the church developed, two notable factors being the role of Rome as the imperial city until the 5th century and the religious and political role of the bishop of Rome afterward.

The teaching of the Second Vatican Council (1962–65) on the role of bishops counterbalanced the emphasis on papal prerogatives while maintaining the view that the authority of the bishops as a body cannot be separated from that of the pope as its head. Although the Eastern Orthodox have long been willing to give the bishop of Rome the primacy of honour accorded to patriarchs, and, although many Protestants have appreciated the moral leadership shown by some recent popes, the Catholic doctrine was still a major obstacle to ecumenical efforts in the 20th century.

Pope, Alexander (b. May 21, 1688, London, Eng.—d. May 30, 1744, Twickenham, near London), poet and satirist of the English Augustan period, best known for his poems *An Essay on Criticism* (1711), *The Rape of the Lock* (1712–14), *The Dunciad* (1728), and *An Essay on Man* (1733–34). He is one of the most quotable of all English authors.

Pope's father, a wholesale linen merchant, retired from business in the year of his son's birth and in 1700 went to live at Binfield in Windsor Forest. The Popes were Roman

Alexander Pope, portrait by Thomas Hudson; in the National Portrait Gallery, London

Catholics, and at Binfield they came to know several neighbouring Catholic families who were to play an important part in the poet's life. Pope's religion procured him some lifelong friends, notably the wealthy squire John Caryll (who persuaded him to write *The Rape of the Lock,* on an incident involving Caryll's relatives) and Martha Blount, to whom Pope addressed some of the most memorable of his poems and to whom he bequeathed most of his property. But his religion also precluded him from a formal course of education; he was trained at home by Catholic priests for a short time and attended Catholic schools at Twyford, near Winchester, and at Hyde Park Corner, London, but he was mainly self-educated. He was a precocious boy, eagerly reading Latin, Greek, French, and Italian, which he managed to teach himself, and an incessant scribbler, turning out verse upon verse in imitation of the poets he read. The best of these early writings are the "Ode on Solitude" and a paraphrase of St. Thomas à Kempis, both of which he claimed to have written at the age of 12.

Early works. Windsor Forest was near enough to London to permit Pope's frequent visits there. He early grew acquainted with former members of John Dryden's circle, notably William Wycherley, William Walsh, and Henry Cromwell. By 1705 his "Pastorals" were in draft and were circulating among the best literary judges of the day. In 1706 Jacob Tonson, the leading publisher of poetry, had solicited their publication, and they took the place of honour in his *Poetical Miscellanies* in 1709.

This early emergence of a man of letters may have been assisted by Pope's poor physique. As a result of too much study, so he thought, he acquired a curvature of the spine and some tubercular infection, probably Pott's disease, that limited his growth and seriously impaired his health. His full-grown height was four feet six inches; but the grace of his profile and fullness of his eye gave him an attractive appearance. He was a lifelong sufferer from headaches, and his deformity made him abnormally sensitive to physical and mental pain. Though he was able to ride a horse and delighted in travel, he was inevitably precluded from much normal physical activity, and his energetic, fastidious mind was largely directed to reading and writing.

When the "Pastorals" were published, Pope was already at work on a poem on the art of writing. This was *An Essay on Criticism,* published in 1711. Its brilliantly polished epigrams (*e.g.,* "A little learning is a dangerous thing," "To err is human, to forgive, divine," and "For fools rush in where angels fear to tread"), which have become part of the proverbial heritage of the language, are readily traced to their sources in Horace, Quintilian, Boileau, and other critics, ancient and modern, in verse and prose; but the charge that the poem is derivative, so often made in the past, takes insufficient account of Pope's success in harmonizing a century of conflict in critical thinking and in showing how nature may best be mirrored in art.

The well-deserved success of the *Essay on Criticism* brought Pope a wider circle of friends, notably Richard Steele and Joseph Addison, who were then collaborating in *The Spectator.* To this journal Pope contributed the most original of his pastorals, "The Messiah" (1712), and perhaps other papers in prose. He was clearly influenced by its policy of correcting public morals by witty admonishment, and in this vein he wrote the first version of his mock-epic, *The Rape of the Lock* (two cantos, 1712; five cantos, 1714), to reconcile two Catholic families. A young man in one family had stolen a lock of hair from a young lady in the other. Pope treated the dispute that followed as though it were comparable to the mighty quarrel between Greeks and Trojans, which had been Homer's theme. Telling the story with all the pomp and circumstance of epic made not only the participants in the quarrel but also the society in which they lived seem ridiculous. Though it was a society where

> . . . Britain's statesmen oft the fall foredoom
> Of foreign tyrants, and of nymphs at home;

as if one occupation concerned them as much as the other; and though in such a society a young lady might do equally ill to

> . . . Stain her honour, or her new brocade;
> Forget her pray'rs, or miss a masquerade;

Pope managed also to suggest what genuine attractions existed amid the foppery and glitter. He acknowledged how false the sense of values was that paid so much attention to external appearance, but ridicule and rebuke slide imperceptibly into admiration and tender affection as the heroine, Belinda, is conveyed along the Thames to Hampton Court, the scene of the "rape":

> But now secure the painted vessel glides,
> The sunbeams trembling on the floating tides:
> While melting music steals upon the sky,
> And soften'd sounds along the waters die;
> Smooth flow the waves, the zephyrs gently play,
> Belinda smil'd, and all the world was gay.

A comparable blend of seemingly incompatible responses—love and hate, bawdiness and decorum, admiration and ridicule—is to be found in all Pope's later satires.

Pope had also been at work for several years on "Windsor-Forest." In this poem, completed and published in 1713, he proceeded, as Virgil had done, from the pastoral vein to the georgic and celebrated the rule of Queen Anne as the Latin poet had celebrated the rule of Augustus. In another early poem, "Eloisa to Abelard," Pope borrowed the form of Ovid's "heroic epistle" (in which an abandoned lady addresses her lover) and showed imaginative skill in conveying the struggle between sexual passion and dedication to a life of celibacy.

Homer and "The Dunciad." These poems and other works were collected in the first volume of Pope's *Works* in 1717. When it was published, he was already far advanced with the greatest labour of his life, his verse translation of Homer. He had announced his intentions in October 1713 and had published the first volume, containing the *Iliad,* Books I–IV, in 1715. The *Iliad* was completed in six volumes in 1720. The work of translating the *Odyssey* (vol. i–iii, 1725; vol. iv and v, 1726) was shared with William Broome, who had contributed notes to the *Iliad,* and Elijah Fenton. The labour had been great, but so were the rewards. By the two translations Pope cleared about £10,000 and was able to claim that, thanks to Homer, he could " . . . live and thrive/Indebted to no Prince or Peer alive."

The merits of Pope's Homer lie less in the accuracy of translation and in correct representation of the spirit of the original than in the achievement of a heroic poem as his contemporaries understood it; a poem Virgilian in its dignity, moral purpose, and pictorial splendour, yet one that consistently kept Homer in view and alluded to him throughout. Pope offered his readers the *Iliad* and the *Odyssey* as he felt sure Homer would have written them had he lived in early 18th-century England.

Political considerations had affected the success of the translation. As a Roman Catholic his affiliations were Tory rather than Whig; and though he retained the friendship of such Whigs as William Congreve, Nicholas Rowe, and Charles Jervas the painter, his ties with Steele and Addison grew looser owing to the political animosity at the end of Queen Anne's reign, and he found new and lasting friends in Tory circles—Jonathan Swift, John Gay, John Arbuthnot, Thomas Parnell, the Earl of Oxford, and Viscount Bolingbroke. With the first five he was associated (1713–14) in the Scriblerus Club to write joint satires on pedantry, later to mature as *Peri Bathouse, Or the Art of Sinking in Poetry* (1728) and the "Memoirs of Martinus Scriblerus" (1741); and these were the men who encouraged his translation of Homer. The Whigs, who associated with Addison at Button's Coffee-House, put up a rival translator in Thomas Tickell, who published his version of *Iliad,* Book I, two days after Pope's. Addison preferred Tickell's manifestly inferior version; his praise increased the resentment Pope already felt owing to a series of slights and misunderstandings; and when Pope heard gossip of further malice on Addison's part, he sent him a satirical view of his character, published later as the character of Atticus, the insincere arbiter of literary taste in the "Epistle to Dr. Arbuthnot" (1735).

Even before the Homer quarrel, Pope had found that the life of a wit was a perpetual warfare. There were few years when either his person or his poems were not objects of attacks from the critic John Dennis, the bookseller Edmund Curll, the historian John Oldmixon, and other writers of lesser fame. The climax was reached over his edition of Shakespeare. He had emended the plays, in the spirit of a literary editor, to accord with contemporary taste (1725); but his practice was exposed by the scholar Lewis Theobald in *Shakespeare Restored* (1726). Though Pope had ignored some of these attacks, he had replied to others with squibs in prose and verse. But he now attempted to make an end of the opposition and to defend his standards, which he aligned with the standards of civilized society, in the mock-epic *The Dunciad* (1728). Theobald was represented in it as the Goddess of Dullness' favourite son, a suitable hero for those leaden times; and others who had given offense were preserved like flies in amber. Pope dispatches his victims with such sensuousness of verse and imagery that the reader is forced to admit that if there is petulance here, as has often been claimed, it is, to parody Wordsworth, petulance recollected in tranquility. Pope reissued the poem in 1729 with an elaborate mock-commentary of prefaces, notes, appendixes, indexes, and errata; this burlesque of pedantry whimsically suggested that *The Dunciad* had fallen a victim to the spirit of the times and been edited by a dunce.

Life at Twickenham. Pope and his parents had moved from Binfield to Chiswick in 1716. There his father died (1717), and two years later he and his mother rented a villa on the Thames at Twickenham, at that time a small country town where several Londoners had retired to live in rustic seclusion. This was to be Pope's home for the remainder of his life. There he entertained such friends as Swift, Bolingbroke, Oxford, and Jonathan Richardson the painter. These friends were all enthusiastic gardeners, and it was Pope's pleasure to advise and superintend the laying out of their landscape grounds on the best contemporary principles, formulated in his "Epistle to the Right Honourable Richard Earl of Burlington" (1731). This poem, one of the most characteristic works of his maturity, is a rambling discussion in the manner of Horace on false taste in architecture and design, with some suggestions for the worthier employment of a nobleman's wealth.

Pope now began to contemplate a new work on the relations of man, nature, and society that would be a grand organization of human experience and intuition, but he was destined never to complete it. *An Essay on Man* (1733–34) was intended as the introductory book discussing the overall design. The poem has often been charged with shallowness and philosophical inconsistency, and there is indeed little that is original in its thought, almost all of which can be traced in the work of the great thinkers of Western civilization. Subordinate themes were treated in greater detail in "Of the Use of Riches, An Epistle to Bathurst" (1732), "An Epistle to Cobham, Of the knowledge and characters of men" (1733), and "Of The Characters of Women: an Epistle to a Lady" (1735). He was deflected from this "system of ethics in the Horatian way" by the renewed need for self-defense. Critical attacks drove him to consider his position as satirist. He chose to adapt for his own defense the first satire of Horace's second book, where the ethics of satire are propounded, and after discussing the question in correspondence with Dr. John Arbuthnot, he addressed to him an epistle in verse (1735), one of the finest of his later poems, in which were incorporated fragments written over several years. His case was the satirist's traditional case, that depravity in public morals had roused him to stigmatize outstanding offenders beyond the reach of the law, concealing the names of some and representing others as types, that he was innocent of personal rancour and habitually forbearing under attack.

The success of his "First Satire Of the Second Book Of Horace, Imitated" (1733) led to the publication (1734–38) of 10 more of these paraphrases of Horatian themes adapted to the contemporary social and political scene. Pope's poems followed Horace's satires and epistles sufficiently closely for him to print the Latin on facing pages with the English; but whoever chose to make the comparison would notice a continuous enrichment of the original by parenthetic thrusts and compliments, as well as by the freshness of the imagery. The series was concluded with two dialogues in verse, republished as the "Epilogue to the Satires" (1738), where, as in the "Epistle to Dr. Arbuthnot," Pope ingeniously combined a defense of his own career and character with a restatement of the satirist's traditional apology. In these imitations and dialogues Pope directed his attack upon the materialistic standards of the commercially minded Whigs in power and upon the corrupting effect of money, while restating and illustrating the old Horatian standards of serene and temperate living. His anxiety about prevailing standards was shown once more in his last completed work, *The New Dunciad* (1742), reprinted as the fourth book of a revised *Dunciad* (1743), in which Theobald was replaced as hero by Colley Cibber, the poet laureate and actor-manager, who not only had given more recent cause of offense but seemed a more appropriate representative of the degenerate standards of the age. In *Dunciad,* Book IV, the Philistine culture of the city of London was seen to overtake the court and seat of government at Westminster, and the poem ends in a magnificent but baleful prophecy of anarchy. Pope had begun work on *Brutus,* an epic poem in blank verse, and on a revision of his poems for a new edition, but neither was complete at his death.

Assessment. Pope's favourite metre was the 10-syllable, iambic pentameter rhyming (heroic) couplet. He handled it with increasing skill and adapted it to such varied purposes as the epigrammatic summary of the *Essay on Criticism,* the pathos of "Verses to the Memory of an Unfortunate Lady," the mock-heroic of *The Rape of the Lock,* the discursive tones of the *Essay on Man,* the rapid narrative of the Homer translation, and the Miltonic sublimity of the conclusion of *The Dunciad.* But his greatest triumphs of versification are found in the "Epilogue to the Satires," where he moves easily from witty, spirited dialogue to noble and elevated declamation, and in the "Epistle to Dr. Arbuthnot," which opens with a scene of domestic irritation suitably conveyed in broken rhythm:

> Shut, shut the door, good John! fatigu'd, I said:
> Tie up the knocker, say I'm sick, I'm dead.
> The Dog-star rages! nay 'tis past a doubt,
> All Bedlam, or Parnassus, is let out:
> Fire in each eye, and papers in each hand,
> They rave, recite, and madden round the land;

and closes with a deliberately chosen contrast of domestic calm, which the poet may be said to have deserved and won during the course of the poem:

> Me, let the tender office long engage
> To rock the cradle of reposing age,
> With lenient arts extend a mother's breath,
> Make languor smile, and smooth the bed
> of death,
> Explore the thought, explain the asking eye,
> And keep a while one parent from the sky!

Pope's command of diction is no less happily adapted to his theme and to the type of poem, and the range of his imagery is remarkably wide. He has been thought defective in imaginative power, but this opinion cannot be sustained in view of the invention and organizing ability shown notably in *The Rape of the Lock* and *The Dunciad.* He was the first English poet to enjoy contemporary fame in France and Italy and throughout the Continent and to see translations of his poems into modern as well as ancient languages.

(J.E.Bu./Ed.)

Pat Rogers, *An Introduction to Pope* (1976), is a study of the poetry; Howard Erskine-Hill and Anne Smith (eds.), *The Art of Alexander Pope* (1979), is a collection of critical essays. A standard bibliography of Pope's own writings is R.H. Griffith, *Alexander Pope: A Bibliography,* 2 vol. (1922–27). A valuable list of modern studies of the poet and his works is contained in J.E. Tobin, *Alexander Pope: A List of Critical Studies Published from 1895 to 1944* (1945); and in C.L. Lopez, *Alexander Pope: An Annotated Bibliography, 1945–67* (1970). J.V. Guerinot, *Pamphlet Attacks on Alexander Pope, 1711–1744: A Descriptive Bibliography* (1969), gives a memorable account, with quotations, of the hostility that the poet's success generated among the lesser writers of his time and so has biographical as well as bibliographical value.

Pope, John (b. March 16, 1822, Louisville, Ky., U.S.—d. Sept. 23, 1892, Sandusky, Ohio), Union general in the American Civil War who was relieved of command following the Confederate triumph at the Second Battle of Bull Run.

A graduate of the U.S. Military Academy at West Point in 1842, Pope served as a topographical engineer with the Army throughout most of the 1840s and 1850s. He did, however, see combat during the Mexican War, serving with distinction in the campaigns of General Zachary Taylor.

Following the outbreak of the Civil War, Pope was appointed brigadier general of volunteers in 1861 and was promoted to major general in 1862. After securing the Mississippi River for the Union almost as far south as Memphis, Pope attracted the admiration of President Abraham Lincoln. He was made a brigadier general of the regular army and transferred to Washington, D.C., where he was given command of the Army of Virginia.

In August 1862 a Confederate force under General Stonewall Jackson moved toward Pope's army. Jackson's force was reinforced by troops under generals James Longstreet

John Pope

and Robert E. Lee, and Pope—misgauging the number and location of the enemy—issued muddled and confusing orders. The result was the decisive defeat at the Second Battle of Bull Run, August 29–30, and the loss of about 15,000 Union troops. Pope attempted to blame his subordinate officers—especially General Fitz-John Porter—for the debacle, but in September Pope was relieved of his command and sent to Minnesota to quell a Sioux uprising.

After the Civil War, Pope served in various posts, notably as commander of the Department of the Missouri (1870–83), in which he was primarily engaged in protecting settlers in the Northwest and Southwest from Indian attacks. On Oct. 26, 1882, he was promoted to major general of the regular army, a rank he held until he retired in 1886.

Pope, John R(ussell) (b. April 24, 1874, New York City—d. Aug. 27, 1937, New York City), American architect whose most important design was the National Gallery of Art (completed in 1941 and since 1978 known as the West Building of the National Gallery) in Washington, D.C.

Trained at the American Academy at Rome and later at the École des Beaux-Arts (Paris), Pope became a leading exponent of academic eclecticism—the duplication of historic architectural styles through painstaking scholarship. Following his studies, Pope began practice in New York City in 1900. His designs included the Scottish Rite Temple in Washington, D.C., the Baltimore Museum of Art, and the Richmond, Va., Terminal Station.

Immensely popular as a designer, he also was chosen architect of many memorials throughout the country, including memorials for Theodore Roosevelt in Washington, D.C., and New York City and the Lincoln Memorial in Hodgenville, Ky.

Popish Plot (1678), in English history, a totally fictitious but widely believed plot in which it was alleged that Jesuits were planning the assassination of King Charles II in order to bring his Roman Catholic brother, the duke of York (afterward King James II), to the throne. The allegations were fabricated by Titus Oates (*q.v.*), a renegade Anglican clergyman who had feigned conversion to the Roman Catholic Church the year before and spent a few months as a student at two English seminaries abroad, from both of which he was expelled.

Encouraged by a fanatically anti-Catholic acquaintance, Israel Tonge, Oates informed the government of the imagined plot and eventually gained access to the Privy Council, where the king's questioning showed Oates to be lying. But meanwhile, Oates also made a sworn deposition of his "evidence" (Sept. 28, 1678) to a Westminster justice of the peace, Sir Edmund Berry Godfrey, and when the latter was found murdered in October, a popular panic was engendered. Ramifications of the plot were imagined everywhere, and in all about 35 innocent people were executed. Eventually, Oates was discredited, and the panic died down.

poplar, any of several shrubs and trees belonging to the genus *Populus,* family Salicaceae. The trees are mostly native to north temperate areas and are valued for their pulp, quick shade, and beauty. They have alternate, oval- or heart-shaped leaves, drooping catkins, seeds with silky hairs, and buds usually sticky with resin.

Two well-known species of Eurasia are the white and the black poplar, both naturalized in North America. White poplar (*P. alba*)—also known as silver poplar, for its white, felted leaves and twigs, and as maple leaf poplar, for its lobed leaves—is widely spreading in form, reaching 30 metres (100 feet) in height. Bolle's poplar (*P. alba* variety *bolleana*) is a colum-

Bolle's poplar (*Populus alba* variety *bolleana*)
Miles C. Labrum

nar variety. Black poplar (*P. nigra*) with oval, fine-toothed leaves, is long trunked and 35 m tall. Lombardy poplar is a columnar form (*P. nigra* variety *italica*).

Balsam poplar, or tacamahac (*P. tacamahaca* or *P. balsamifera*), native throughout northern North America in swampy soil, is distinguished by its aromatic, resinous buds. The buds of the similar balm of Gilead poplar (*P. candicans* or *P. gileadensis*) are used to make an ointment. Western balsam poplar, or black cottonwood (*P. trichocarpa*), 60 m tall, is one of the largest deciduous trees of northwestern North America.

poplin, strong fabric produced by the rib variation of the plain weave and characterized by fine, closely spaced, crosswise ribs. It is made with heavier filling yarns and a greater number of warp yarns and is similar to broadcloth, which has even finer, more closely spaced ribs.

Though originally made with a silk warp and a heavier wool filling, poplin is now made of a variety of fibres, including silk, cotton, wool, and man-made types, and with combinations of such fibres. It is used for shirts, pajamas, women's wear, and sportswear and also as a decorative fabric.

Popocatépetl, dormant volcano, México–Puebla state line, central Mexico. On Mexico's volcanic axis at the southern edge of the Mexican Plateau, 10 mi (16 km) south of its twin, Iztaccíhuatl, and 45 mi southeast of Mexico City, the perpetually snowcapped, symmetrical cone of Popocatépetl (Nahuatl: "smoking mountain") rises to a height of 17,930 ft (5,465 m). The only higher Mexican volcano is Citlaltépetl.

The first Spanish ascent of Popocatépetl is thought to have been made by one of Cortés' men in 1519. Although the volcano has not erupted since 1802, it emits large clouds of smoke from time to time.

Popol Vuh, Maya document, an invaluable source of knowledge of ancient Mayan mythology and culture. Written in Quiché (a Guatemalan Mayan language) with Spanish letters by a Mayan author or authors between 1554 and 1558, it chronicles the creation of man, the actions of the gods, the origin and history of the Quiché people, and the chronology of their kings down to 1550.

The original book was discovered at the beginning of the 18th century by Francisco Jiménez (or Ximénez), parish priest of Chichicastenango in highland Guatemala. He both copied the original Quiché text (now lost) and translated it into Spanish. His work is now in the Newberry Library, Chicago.

Popolare, plural POPOLARI, member of PARTITO POPOLARE ITALIANO (PPI; Italian Popular Party), an Italian political party organized in 1919 and inspired by Christian Socialist principles. The formation of the party marked the entrance of Catholics, alienated since the government's seizure of papal lands in 1860–70, into Italian political life as an organized force.

Led by the Sicilian priest Don Luigi Sturzo, the Popolari espoused a program of local administrative autonomy, agricultural reform, recognition of the right of workers to organize, election (rather than appointment) of the Senate, and extension of suffrage to women. In the general election of 1919, they scored a major victory, winning more than 100 seats and becoming the second largest party in the Chamber of Deputies. The party, however, was weakened by lack of internal unity and so failed to exert the influence on government that its numbers deserved. During the period of crisis for Italian democracy in the early 1920s, the Popolari were unwilling to cooperate with either the Socialists on the left or the liberals on the right to block the rise of Fascism. With the Fascist suppression of parliamentary government in the mid-1920s, the party was dissolved. Its principles were revived after World War II in the Christian Democratic Party, led by the former Popolare Alcide De Gasperi.

popolo (Italian: "people"), in the communes (city-states) of 13th-century Italy, a pressure group instituted to protect the interests of the commoners (actually, wealthy merchants and businessmen) against the nobility that up to then had exclusively controlled commune governments. It was one of a number of groups competing for power in the commune and in some cities succeeded in dominating the government in the late 13th century.

The *popolo* was organized either on a territorial basis (by quarters or districts) or on a corporative basis (by guilds); in some cities, notably Florence, a combination of both types developed. It gradually developed its own officials, who paralleled those of the commune. In the mid-13th century the office of *capitano del popolo* ("captain of the people") became prominent. This official was charged with leading the military forces of the *popolo* and ensuring justice to injured members; like the communal officer the *podestà,* he was usually a native of another city. The effective leaders of the *popolo* were the local representatives, the *anziani,* or "elders" (sometimes known as priors).

In Florence the organization of the *popolo* developed early and became quite powerful. From 1250 to 1260 it controlled the government (in the regime known as *il primo popolo*), and after the seizure of power in 1282 its power was firmly established. By the beginning of the 14th century, its priors, chosen from among guild members, formed the supreme executive of the commune.

In the writings of medieval chroniclers and modern historians, the term *popolo grasso* ("fat people") refers to the wealthy middle class of merchants and businessmen that dominated the economic and political life of the Italian communes. The term *popolo minuto* ("small or common people") refers to the lower middle class of proprietors of small shops and small merchants denied direct participation in government; it is sometimes extended to include the wage-earning proletariat, the most economically deprived group.

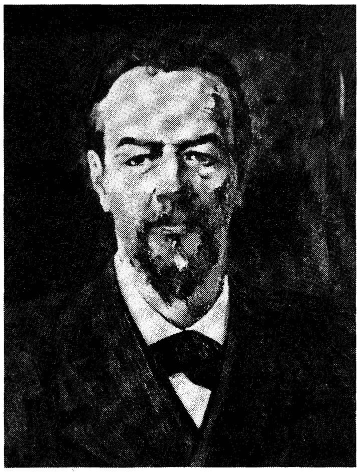
Popoloca, Middle American Indians of southern Puebla in central Mexico (not to be confused with the Popoluca of southern Mexico). The Popoloca language is most closely related to Ixcatec and Chocho, and to Mazatec, all spoken nearby in northern Oaxaca. The territory of the Popoloca is mostly flat and dry; vegetation is the semidesert type. The people are agricultural, growing corn and black beans as staples, supplemented by grains and fruit. Settlements are loosely congregated around village centres; houses are typically built of vertically placed poles or of lumber, with thatched roofs. A few are built of mud blocks. Characteristic crafts are ceramics and palm-fibre weaving; a limited amount of textile weaving is also done. Traditional costume has almost entirely disappeared, replaced by commercially made clothing.

Religion is Roman Catholic, with few remaining pagan elements. Belief in witchcraft persists, and there are fertility rituals. The social institution of the *compadrazgo,* or godparent ritual, is widespread and occurs in several forms. The godparent takes economic responsibility for the baptismal ceremony of the godchildren.

Popondetta, town, administrative headquarters of Northern province, Papua New Guinea.

The town, on a tributary of the Girua River, was a U.S. air base during World War II; the field now allows regular air service. In addition, Popondetta is the focus of a road network 300 mi (500 km) long, extending from the port of Oro Bay to Kokoda, in the Owen Stanley Range of the central highlands. The area produces cocoa, coffee, rubber, and palm oil. There is some tourism centred on the nearby peaks, one of which, Mt. Lamington (20 mi south) erupted in 1951, killing 3,000 persons and destroying the town of Higaturu. Popondetta has a high school, vocational institute, and agricultural college. Pop. (1984 est.) 7,400.

Popov, Aleksandr Stepanovich (b. March 16 [March 4, old style], 1859, Turinskiye Rudniki, Perm, Russia—d. Jan. 13, 1906 [Dec. 31, 1905, O.S.], St. Petersburg), physicist and electrical engineer acclaimed in the Soviet Union as the inventor of radio. Evidently he built his first primitive radio receiver, a lightning detector (1896), without knowledge of the contemporary work of the Italian inventor Guglielmo Marconi. The genuineness and the value of Popov's successful experiments are not seriously doubted, but Marconi's priority is usually conceded outside the Soviet Union.



Aleksandr Popov, detail of a painting by P.D. Korin
Sovfoto

Popov was the son of a village priest. He received his early education in an ecclesiastical seminary school and planned to enter the priesthood. But in 1877 his interests changed to mathematics, and he entered the University of St. Petersburg, from which he was graduated with distinction in 1883. Joining the teaching faculty of the university, he lectured in mathematics and physics in preparation for a professorship.

Popov's main interest soon changed to electrical engineering, however; and because Russia in that period lacked colleges that taught the subject, he became an instructor at the Russian Navy's Torpedo School at Kronstadt (presently Kronshtadt), near St. Petersburg (presently Leningrad), where students were trained to take charge of electrical equipment on warships. Popov took advantage of the school's library, which was stocked with foreign books and periodicals, and also of its well-equipped laboratory to follow scientific developments abroad and carry out experiments. Recognizing the importance of German physicist Heinrich Hertz's discovery of electromagnetic waves, Popov began to work on methods of receiving them over long distances.

Popov constructed an apparatus that could register atmospheric electrical disturbances and, in July 1895, installed it at the meteorological observatory of the Institute of Forestry in St. Petersburg. In a paper published a few months later, Popov suggested that such an apparatus could be used for the reception of signals from a man-made source of oscillations, provided a sufficient power source became available. In March 1896, he appeared before the St. Petersburg Physical Society and demonstrated the transmission of Hertzian waves—as they were then termed—between different parts of the University of St. Petersburg buildings. Evidence suggests that on that occasion the words "Heinrich Hertz" were transmitted in Morse code and that the aural signals received were transcribed on a blackboard by the society's president, who was the chairman of the meeting.

During the academic year 1895–96 at the Torpedo School, however, Popov became interested in setting up experiments on Röntgen rays (X-rays), which had just been discovered. Therefore, he discontinued for a time the further development of his lightning, or thunderstorm, detector. During the summer of 1896, Popov worked as electrical engineer in charge of the power plant at the annual fair in Nizhnii Novgorod (presently Gorky), where the demonstration of his storm detector won him a prize. He then read the first newspaper accounts of Marconi's demonstrations in September 1896. It seems clear that neither Marconi nor Popov was aware of the close similarity between their experiments.

The news of Marconi's work, as disclosed in his patent of June 1896, aroused Popov to fresh activity. Working in conjunction with the Russian Navy, he effected ship-to-shore communication over a distance of 6 miles (10 kilometres) by 1898. The distance was increased to about 30 miles (50 kilometres) by the end of the following year, during which he had also visited wireless stations in operation in France and Germany.

Popov was given remarkably little support by the Russian government until 50 years later, when national attitudes and enthusiasms had changed. On May 7, 1945, the Bolshoi Theatre was packed with a distinguished audience to celebrate the 50th anniversary of the "invention of the radio" by A.S. Popov. On the stage sat scientists, marshals, admirals, commissars, leaders of the Communist Party, and Popov's daughter. It was announced that in the future, the 7th of May would be celebrated as the day of the radio.

Although it is agreed that Popov's experimental work in connection with Hertzian waves is deserving of recognition, it has not been generally accepted that radio communication was actually invented by Popov. Thus, while it is true that historical research has brought to light indirect evidence that Popov demonstrated the transmission of intelligible signals in March 1896, there is comparable evidence that Marconi demonstrated the transmission of intelligible signals at an even earlier date, though not before an audience of scientists.

In 1901 Popov returned to St. Petersburg as a professor at the electrotechnical institute, of which he was later elected director. He died five years later. (R.L.S.-R.)

Radio Engrs.*, 50:2036–2047 (1962), a comprehensive and critical review of the early days of wireless communication, with special reference to the Soviet claim that Popov invented radio; R.L. Smith-Rose, "Marconi, Popov, and the Dawn of Radiocommunication," *Electronics and Power*, 10:76–79 (1964), a review of the claims of the two pioneers, G. Marconi and A.S. Popov, with an assessment of credits as the founders of practical radio communications.

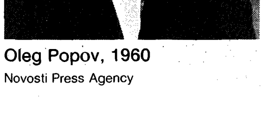
Popov, Alexey Dmitriyevich (b. March 12, 1892, Nikolavsk, Russia—d. Aug. 18, 1961, Moscow), Soviet director and prominent exponent of Socialist Realism whose monumental productions were notable for their meticulous attention to naturalistic detail.

Popov began his career as an actor with the Moscow Art Theatre and then moved to Kostroma to be managing director of a studio formed to follow the ideas of Konstantin Stanislavsky. At Kostroma he directed standard plays from the world repertoire, such as Charles Dickens' *The Cricket on the Hearth*, as well as the type of Soviet propaganda piece for which he would become noted, such as *An Evening Dedicated to the Paris Commune.* Popov returned to Moscow to direct, with few exceptions, new Soviet plays at the Vaktangov Theatre (1923–30) and the Theatre of the Revolution (1930–35). He introduced Lydia N. Seifullina and V.P. Pravdukhin's *Virineia* (1925), Boris Lavrenev's *The Break* (1927), and, most especially, Nikolay F. Pogodin's *Poem of the Ax* (1931), *My Friend* (1932), and *After the Ball* (1934). Popov was made head of the Central Theatre of the Red Army in 1935, a position he held until 1960. Although Popov did a few Shakespearean plays and also revived Russian classics, his productions invariably were monumental in scope and shaded to teach moral lessons regarding class struggle from the Soviet viewpoint. Popov's principal interest was in staging more overtly propagandistic pieces. Among the new plays that he directed were *The Year Nineteen* by Eosif L. Prut (1936), *The Men of Stalingrad* by Yury Chepurin (1944), *The Wide Steppe* by Nikolay G. Vinnikov (1949), and *Virgin Soil Upturned*, in a dramatized version of the novel by Mikhail Sholokhov (1957). Popov, honoured as a People's Artist of the U.S.S.R. in 1948, received a doctorate of art studies in 1957, as well as many other prizes and medals in his later years.

Popov, Oleg Konstantinovich (b. July 3, 1930, Vyrubovo, near Moscow), member of the Moscow Circus, the most popular clown in the Soviet Union.

Popov studied at the Moscow Circus School (1944–49) and then joined the circus as an eccentric tightrope walker. In 1952 he first appeared as a clown when the regular clown was injured. Using the film comedian Charlie Chaplin's tramp character as a model, Popov portrayed a gentle little man baffled by the big, precarious world; his act also incorporated his skills as an acrobat, juggler, and animal trainer.

He first appeared abroad in 1955 at Warsaw; toured France, Belgium, and England in 1956; appeared in 1958 at the Brussels Exposition; in 1957 appeared on American television from Moscow; and in 1963 and 1972 toured the United States with the Moscow Circus.



Oleg Popov, 1960

popover, in American cuisine, light muffin that puffs up into a nearly hollow bubble as it bakes (hence the name). Popovers are made from a thin unleavened batter that is poured into individual cups and placed in a very hot oven to ensure the rising of the batter. The baking is sometimes completed at a lower temperature. The batter for popovers is nearly identical to that for Yorkshire pudding (*q.v.*), the traditional British accompaniment to roast beef.

Popovich, Pavel Romanovich (b. Oct. 5, 1930, Uzin, Ukrainian S.S.R.), Soviet cosmonaut who piloted the Vostok 4 spacecraft, launched Aug. 12, 1962. He and Andriyan G. Nikolayev, who was launched a day earlier in Vostok 3, became the first two men to be in space simultaneously.

Popovich, a herdsman in his early youth, graduated from a technical school in Magnitogorsk, Russian S.F.S.R., in 1951, when he entered the Army. He quickly transferred to the Air Force and in 1954 was graduated from the Stalingrad Air Force College. He became a pilot, and in 1960 he was among the first to enter cosmonaut training.

Popovich was also the command pilot of the Soyuz 14 mission (July 3–19, 1974), on which he was accompanied by Yury P. Artyukhin. The cosmonauts docked their craft with Salyut 3, a space station that had been placed in orbit on June 25, and engaged in a 15-day program of scientific experiments. Popovich wrote an autobiographical book, *Vyletayu utrom* (1974; "Takeoff in the Morning.").

Pöppelmann, Matthäus Daniel (b. May 3, 1662, Herford, Westphalia—d. Jan. 17, 1736, Dresden, Saxony), German architect, best known for his design of the Zwinger, an open-air arena in Dresden that is considered one of the most successful realizations of the Baroque aesthetic. He was one of the first indigenous Baroque architects of central Europe.

Pöppelmann was a student of Wolf Caspar von Klengel, who participated in rebuilding Alt-Dresden after a fire in 1685. Pöppelmann carried on the work following von Klengel's death and in 1691 was put in charge of the project. In 1704 he became sculptor-architect to the court of Augustus II (Augustus the Strong) of Saxony, for whom he made a series of plans to rebuild the Royal Palace in Dresden.

The Zwinger in Dresden (begun 1709), originally planned as part of a large palace, is an outdoor theatre intended for opera, dance, tournaments, and other royal entertainments. The basic element of the structure is a square court, with U-shaped extensions of the transverse axes, bounded by airy, glass-enclosed pavilions. At one end of the main axis is the celebrated Kronentor (Crown Gate). *Langgalerien*, or galleries, extending from its sides to meet the pavilions, were probably inspired by the Grand Trianon at Versailles, which Pöppelmann visited in 1715.

Among Pöppelmann's works outside of Dresden are the Joachimstein Castle near Zittau (begun 1713); two bridges, the Niedertorbrücke and Frauentorbrücke, in Zwickau; and the castle on the Elbe at Pillnitz. After the mid-1720s he worked mainly in Dresden. His Augustusbrücke (1727-31) is considered among the most beautiful bridges in Europe.

Popper, Sir Karl (Raimund) (b. July 28, 1902, Vienna), Austrian-born British philosopher of natural and social science who subscribed to antideterminist metaphysics, believing that knowledge evolves from experience of the mind.

Although his first book, *Logik der Forschung* (1934; *The Logic of Scientific Discovery*), was published by the Vienna Circle of logical positivists, he rejected their inductive empiricism and developmental historicism. After studying mathematics, physics, and psychology at the University of Vienna, Popper taught philosophy at Canterbury University College, New Zealand (1937–45). In 1945 he became a reader in logic at the London School of Economics, and he served there as professor of logic and scientific method from 1949 until his retirement in 1969.

Popper's principal contribution to the philosophy of science rests on his rejection of the inductive method in the empirical sciences. According to this traditional view, a scientific hypothesis may be tested and verified by obtaining the repeated outcome of substantiating observations. As the Scottish empiricist David Hume had shown, however, only an infinite number of such confirming results could prove the theory correct. Popper argued instead that hypotheses are deductively validated by what he called the "falsifiability criterion." Under this method, a scientist seeks to discover an observed exception to his postulated rule. The absence of contradictory evidence thereby becomes proof of his theory. According to Popper, such pseudo-sciences as astrology, metaphysics, Marxist history, and Freudian psychoanalysis are not empirical sciences, because of their failure to adhere to the principle of falsifiability.

Popper's later works include *The Open Society and Its Enemies* (1945), *The Poverty of Historicism* (1957), and *Postscript to the Logic of Scientific Discovery,* 3 vol. (1981–82). He was knighted in 1965.

Poppo (pope): *see* Damasus II.

poppy, any of several ornamental flowering plants of the poppy family (Papaveraceae), especially species of the *Papaver* genus, which have lobed or dissected leaves, milky sap, nodding buds on solitary stalks, and four- to six-petaled flowers with numerous stamens surrounding the ovary. The two sepals drop off as the petals unfold. The ovary develops into a short, many-seeded capsule that opens in dry weather, permitting the small seed to escape when it is shaken by the wind.

Opium, from which morphine, heroin, codeine, and papaverine are derived, comes from the milky fluid in the capsule of the opium poppy (*Papaver somniferum*), native to Anatolia. An annual plant, it bears 12.7-centimetre- (5-inch-) wide blue-purple or white flowers on plants 1 to 5 m (about 3 to 16 feet) tall, with lobed or toothed silver-green foliage. The opium poppy also is grown for its nonnarcotic seeds, used for seasoning, oil, and birdseed. Red-flowered and double and semidouble strains are garden ornamentals.

About 50 other species of *Papaver* are grown for their attractive papery flowers or interestingly cut foliage. The Oriental poppy (*P. orientale*), native to the Middle East, has 15.2-centimetre scarlet, salmon, pink, white, or red blooms on 1.2-metre-tall, long-lived perennial plants. The white and red or white and pink Shirley poppy is an annual variety developed from the corn poppy (*P. rhoeas*). The Iceland poppy (*P. nudicaule*), from Arctic North America, is a short-lived perennial with fragrant white, orange, reddish, or bicoloured 7.6-centimetre flowers that are 30 cm tall. Peacock poppy (*P. pavoninum*), an annual with dark-spotted, scarlet, 2.5-centimetre blooms on 30-centimetre-tall plants, is from Afghanistan. The poppy family is well represented in western North America, especially in California, where about 20 native species are found. The best-known of these is the California poppy (*Eschscholtzia californica*), an annual with brilliant orange-coloured flowers, extensively naturalized in California, Australia, and India.

Poppy (*Papaver dubium*)
Ingmar Holmasen

Other ornamental members of the poppy family include the matilija poppy (*Romneya coulteri*) with 15.2-centimetre, white, fragrant flowers on a 2.4-metre-tall perennial herbaceous plant, native to southwestern North America; the plume poppies, members of the oriental genus *Macleaya,* grown for their giant, interestingly lobed leaves and 2-metre-tall flower spikes; plants of the tropical America genus *Bocconia,* woody, mild-climate shrubs prized for their large, cut leaves; the snow poppy (*Eomecon chionantha*), a perennial from China, with white, cuplike flowers in sprays; and the flaming poppy (*Stylomecon heterophylla*), a purple-centred, brick-red annual plant from western North America. Meconopsis (*q.v.*) includes the Welsh poppy.

Consult the INDEX *first*

poppy seed, tiny dried seed of the opium poppy, used as food, food flavouring, and the source of poppy-seed oil. Poppy seeds have no narcotic properties, because the fluid contained in the bud that becomes opium is present only before the seeds form. The plant, *Papaver somniferum,* is an herbaceous annual native to Greece and the Orient. Poppy seed is an ancient spice; the seed capsules have been found in Switzerland in the remains of prehistoric lake dwellings.

The seeds are small (about 1 mm in length), kidney-shaped, and grayish blue to dark blue in colour. They have a faint nutlike aroma and a mild, nutty taste especially popular in breads and other baked goods. Poppy seed contains from 44 to 50 percent fixed oil, the principal components of which are linoleic and oleic acids.

Poprad, city, Poprad *okres* (district), western Východoslovenský *kraj* (region), Slovakia, eastern Czechoslovakia. Located in the Poprad River valley between the Vysoké Tatra Mountains, the Nizké Tatry Mountains, and the Levočské Mountains, it is a centre for the valley's agricultural area, where potatoes, barley, oats, and flax are grown and sheep are reared. Lumbering is an important local industry. The city also has automobile assembly and food-processing plants and a brewery. More industry is located in Svit, 4 miles (7 km) to the west, where there are chemical, textile, meat-packing, and food-processing plants.

Poprad is the regional transportation centre and also a starting point for tours into the Vysoké Tatra Mountains; it is a rail and road junction and has an airport. The Tatra Museum, with natural history exhibits of the mountain area, is located in Poprad. Spišská Sobota, a small town and now a suburb of Poprad, is noted for its 13th-century Gothic church of St. Egidius, which has a 14th-century fresco showing the Vysoké Tatra Mountains; the church is located on a square surrounded with Renaissance and Baroque houses with steeply pitched shingle roofs. Pop. (1988 est.) 50,375.

popular art, any dance, literature, music, theatre, or other art form intended to be received and appreciated by the largest possible audience. Popular art in the 20th century is usually dependent on such reproductive technology as printing, photography, phonograph and tape recording, films, radio, and television, as well as on large, concentrated populations that occur in societies dominated by urban culture.

Popular art in general tends to be narrative, to reinforce uncontroversial beliefs and sentiments, to support popular institutions, and to create identity in a social group. It is distinguished by the rapidity of its changes of style, by its revivals from earlier periods, and by its constant borrowings from elite art, folk art, foreign cultures, and modern technology for its song tunes and lyrics, radio and television broadcasts, novels, dances, and many other current entertainments, objects, trends, and fads.

Popular dance. Dancing performed in public or in private solely for the enjoyment of the participants is known as popular dance, or as social dance. It was practiced as early as 3,000 years ago at both community and family levels. Dancers arranged themselves in circles, or sometimes lines, which gradually developed into chain dances. From the Middle Ages in Europe there was a widening gap between country dances, which subsequently tended to survive in a folk tradition, and the genteel court variety, which influenced social developments in recreation from the Industrial Revolution onward.

In 16th-century Europe the stately pavane and energetic galliard were popular in Renaissance court circles. Such dances by then were performed in couples, side by side, and utilized swaying movements, hops, and complex capers. At the 17th-century French court of Louis XIV, new dances were notated for the first time. Such measures as the minuet and gavotte emerged, and in England Charles II imported many such dances after 1660. The cotillion, originally a lively measured square dance from the French court, became popular in the late 18th century. It was performed by four couples arranged in a square facing inward, with pairs of couples alternately executing various geometric figures.

The main century of the waltz lasted from the Napoleonic period to World War I. The waltz—performed by turning couples in a step–slide–step pattern—originated in central Europe and was popular in Vienna and Paris during the Napoleonic Wars. Ultimately the whole of western Europe adopted the measure, and it became socially acceptable for a man publicly to hold a woman in his arms while dancing.

"Cheek-to-cheek" dancing became popular in the second decade of the 20th century. Such exotic numbers as the turkey trot, the bunny hug, and the maxixe were popularized by the exhibition dancers Vernon and Irene Castle. The tango, purged of its more erotic elements, became acceptable to the clientele of the *thé dansant* (tea dance), and the charleston epitomized the Jazz Age. When the quickstep and the slow fox-trot emerged, competitions began to be held, reflecting dancing's wide attraction as a leisure activity.

During the Great Depression in the United States the dance marathon flourished—a ghastly parody of enjoyment, with couples struggling to be the last competitors left upright. Large public ballrooms flourished in the 1930s and '40s, especially in Britain and North America, while private dances grew relatively infrequent. It also became fashionable to go to hotels, nightclubs, restaurants, and wherever else there were large dance floors.

The late 1930s, the early '40s, and World

War II (with its large population dislocations) saw the spread of American cultural influence. The jive, jitterbug, and many such dances that were virtually improvisational originated in the United States, often among the black population, and were subsequently adopted in Europe.

Mainstream popular dance in the 1950s adopted Latin rhythms—including the rumba, samba, and cha-cha-cha. In general from about 1960, starting with the twist, popular dance among the young became more of a solo performance. White and black ethnic music created soul and reggae, and dancing partners no longer touched. By the late 1970s and early '80s, discotheques had taken the place of the old fashioned *palais de danse*, or ballroom. Echoes of many styles could be seen in disco dances, but popular dancing had become essentially improvisatory and eclectic.

Popular literature. Popular literature includes those writings intended for the masses, those that find favour with large audiences, and those that originate from the masses. It can be distinguished from artistic literature in that it is designed primarily to entertain. Popular literature, unlike high literature, generally does not seek a high degree of formal beauty or subtlety, and is not intended to endure. The growth of popular literature has paralleled the spread of literacy through education and has been facilitated by technological developments in printing. With the Industrial Revolution, works of literature, which were previously produced for consumption by small, well-educated elites, became accessible to large sections and even majorities of the members of a population.

The boundary between artistic and popular literature is murky, with much traffic between the two categories according to current public preference and later critical evaluation. While he was alive Shakespeare could be thought of as a writer of popular literature, but he is now regarded as a creator of artistic literature. Indeed, the main, though not invariable method of defining a work as belonging to popular literature is whether it is ephemeral, that is, losing its appeal and significance with the passage of time.

The most important genre in popular literature is and always has been the romance, extending as it does from the Middle Ages to the present. The most famous type of romance describes the obstacles encountered by two people (usually young) engaged in a forbidden love. Another common genre is that of fantasy, or science fiction. Novels set in the western frontier of the United States in the 19th century, and called Westerns, are also popular. Finally, the detective story or murder mystery is a widely read form of popular literature. Popular literature has also come to include such genres as comic books and cartoon strips.

In Communist countries popular literature encounters obstacles to its development not normally met in the West. Literature must be approved by the government to be published, and decisions to publish or not to are made by bureaucrats, sometimes without reference to public taste and preferences. This leads to a situation in which the government can exclude certain works from circulation if it is felt that they are inimical to the interests of the state, even though they may be of interest to the population.

Popular music. Unlike folk music, popular music is written by known individuals, usually professionals, and does not evolve through the process of oral transmission. In the West, since the 1950s, "pop" music has come to mean the constantly changing styles derived from the electronically amplified music form known as rock 'n' roll.

Historically, popular music was any non-folk form that acquired mass popularity—from the songs of the medieval minstrels and troubadours to those elements of fine art music originally intended for a small, elite audience but that became widely popular. After the Industrial Revolution, true folk music largely disappeared, and the popular music of the Victorian era and the early 20th century was that of the music hall and vaudeville, later replaced by songs from stage musicals.

Western popular music of the past century has been dominated by developments in the United States, particularly in the music of black Americans, who incorporated elements of African folk music and rhythms into the most important new musical style of the century, jazz.

In the late 1930s the swing style of the big bands dominated the larger record market, and in the 1940s the bands' vocalists, developing what became known as crooning, attracted attention. Meanwhile, the exclusively black American musical form known as the blues was also changing: black singers from the South moved north to industrial cities to seek work, and their music was transformed to the harsher style of urban blues or rhythm and blues. The blues bands that emerged in Chicago in the 1940s used amplified electric guitars, often backed with electric bass and drums—the instruments borrowed later by many rock 'n' roll bands.

Developing alongside these black styles was a white rural music—country, a dance and narrative style partly derived from the Anglo-Celtic ballads of white immigrants from Europe. Country music was sometimes influenced by black jazz styles (as with the Texas fusion "western swing"), and in the 1950s country singers meshed their music with black rhythm and blues to form "rockabilly."

Rock 'n' roll, which emerged in the 1950s, adapted the slow and powerful rhythms and melancholy vocalizations of urban blues to a quicker tempo and an exuberant emotional tone. In the 1960s more complex forms of rock 'n' roll became known simply as rock. Styles varied from gentle, vocal-harmony songs (soft rock) to new songs written in a traditional style and given amplified backing (folk rock), and a secular black ballad style influenced by gospel music (soul).

British rock became influential in the 1960s, through the work of four- or five-piece pop groups rather than solo performers. At first the British groups copied black rhythm and blues styles, but then developed their own more experimental styles, which in turn became popular in the United States. The Beatles, the most influential group, were partly responsible for rock music's growing intellectual respectability in the 1960s and '70s.

Popular theatre. The term popular theatre denotes live performances—in the tradition of the music hall, vaudeville, burlesque, follies, revue, circus, musical comedy, and musical performance—as distinguished from legitimate, high, or artistic theatre. The singers, dancers, comedians, clowns, puppeteers, jugglers, acrobats, conjurers, and ventriloquists of popular theatre make up much of what is known as "show business."

Music, movement, and humour are all essential ingredients used by popular theatre throughout its history. The physical element most often presents itself through eroticism, exaggeration, or acrobatics. England's traditional music hall, virtually identical to vaudeville, originated in working-class alehouses but became a standard entertainment for all classes of society. As with revue and vaudeville, it generally offered a variety of short pieces—sentimental and patriotic songs, dances, comic turns, and magicians, jugglers, and acrobats.

Humour itself may distort reality—crudely, as in slapstick, or corrosively, as in the mockery of a stand-up comic. Its effect—earthy, ribald laughter—has been sought in all kinds of theatre, and the greatest playwrights have blended both laughter and tears in their interpretations of life. Sometimes a popular performer has managed to achieve an interpretation of wider significance so as to bridge the gap between popular theatre and elite art. Charlie Chaplin and Buster Keaton are outstanding examples.

The effect of music as a form of communication has always been highly valued in popular theatre, whether with a large orchestra in a gilded auditorium or in a crowded taproom with only an upright piano. Music aids the suspension of disbelief and joins performer and viewer more closely in a shared event in which there is no pretense of realism. Musical comedy evolved from a wide variety of musical, dramatic, and dance styles going back to the Elizabethan dramatists, who used simple ballads to reinforce their narratives, through the tradition of Viennese operetta and the comic operas of Gilbert and Sullivan in England. The 20th century saw these traditions, although Americanized, flowering again in the United States in a seemingly endless procession of popular Broadway musicals.

Popular Democratic Front for the Liberation of Palestine (PDFLP), Arabic AL-JABHA AL-SHAʿBĪYAH AL-DIMUQRĀṬĪYAH LI-TAḤRĪR FILASṬĪN, one of several organizations associated with the Palestine Liberation Organization (*q.v.*), which has engaged in terrorist activities in addition to maintaining a Marxist-Leninist orientation which asserts that the peasants and working classes should be educated in socialism in order to bring about a democratic state of Jews and Arabs free of Zionism and imperialism.

Originating in the leftist swing of the 1960s and founded by a Jordanian Orthodox Christian, Naʾif Hawatimah, in 1969, the PDFLP was envisioned as a political movement distinct from the Popular Front for the Liberation of Palestine (*q.v.*), which had been founded to provide a front for diverse militant Palestinian groups. The PDFLP stood ideologically to the left of the PFLP and claimed that its enemies were Zionist upper-class imperialists, although in 1974 it took credit for the terrorist attacks in Maʿalot and Beth Shean. The PDFLP is also wary of Arab governments and critical of other pro-Palestine groups for ignoring "reactionary" forces within the Arab world.

popular front, any coalition of working-class and middle-class parties united for the defense of democratic forms against a presumed Fascist assault. In the mid-1930s European Communist concern over the gains of Fascism, combined with a Soviet policy shift, led Communist parties to join with Socialist, liberal, and moderate parties in popular fronts against Fascist conquest. In France and Spain, popular front governments were formed.

The early successes of Fascism in Italy and Germany had been regarded with equanimity by the Soviet Communist leadership. In the 1930s, when the Stalinist purges were in progress and deviations from current Stalinist norms were officially deemed more dangerous to the ultimate success of the proletarian revolution than the assaults of the far right, the Soviet attitude was shared by European Communists; in Germany, for instance, the Communists joined with the Nazis in bringing down the Weimar Republic.

In time, however, the clear Fascist determination to annihilate Communist cadres, coupled with the Communist realization that the divided state of the left had greatly facilitated the achievements of the right, aroused among European Communists considerable sentiment favouring alliance with at least the non-Communist left to combat Fascism.

For a time the Soviet leadership, consistently placing Soviet national interests above other considerations in its foreign policy, maintained cordial diplomatic relations with Fascist states, refusing in each case to let a government's domestic persecution of Communists affect the Soviet Union's relations with that government. Growing awareness of the danger of a German attack on the U.S.S.R., however, led the Soviets to seek allies among the Western capitalist nations. This policy shift, which saw the Soviets join the League of Nations in 1934, was a decisive factor in bringing the Soviet leadership to its advocacy of the popular front. At the same time, Stalin began to pursue a clandestine policy of seeking an alliance with Hitler—which bore fruit in August 1939.

The seventh and last congress of the Comintern (*see* International, Third), meeting in 1935, proclaimed the new policy, which went beyond the concept of a "united front" of Communists and Socialists to advocate the formation of popular fronts comprising not only leftists but also liberals, moderates, and even conservatives opposed to Fascism. The goal of revolution was deferred until the immediate battle at hand was won, and Communists were urged not to frighten away the non-Communists in the coalition with revolutionary rhetoric.

In France, for example, the Communist Party joined in the forming of a popular front in 1934. In 1936 a popular front government, led by the Socialist Léon Blum, was elected. Though the Communists refused ministerial appointments, they pledged full parliamentary support and cooperation. The regime succeeded in implementing an extensive program of social reform, including the institution of the 40-hour work week. The financial situation deteriorated, however, and Blum was replaced in June 1937, whereupon the liberals began to exclude other members of the coalition, including the Communists, from the government. In 1938 Blum once again attempted, unsuccessfully, to establish a popular front ministry. Though it may have prevented socio-economic conditions in France from becoming fertile ground for any domestic Fascist movement, the French Popular Front did little in the international arena to stop the march of Fascism.

A broad-based popular front government was elected in Spain in February 1936. Considerable turmoil followed, however, and in July 1936 Gen. Francisco Franco led a Fascist insurrection against the legal government. At first the Soviets, and indeed Léon Blum's French Popular Front, advocated non-intervention in the conflict. Eventually the Soviets did intervene, supplying limited military aid to the republican forces. Soon Stalin, however, for reasons that are unclear, conducted a violent purge of the Spanish extreme left, including Anarchists, Syndicalists, and Trotskyites.

Ironically, the effect of the popular fronts in the West was the opposite of Stalin's intention. The social changes that they tried to institute and the unrest that occurred while they held power combined to exacerbate Western capitalists' fear and distrust of the Soviets.

Popular Front for the Liberation of Palestine (PLFP), Arabic AL-JABHA AL-SHAʿBĪYAH LI-TAḤRĪR FILASṬĪN, organization providing an institutional framework for militant organizations associated with the Palestine Liberation Organization (*q.v.*), notable for its internal conflicts between ideology and military action.

It was established as the Arab Nationalist Movement (ANM) by George Habash, who was born into a Greek Orthodox family in Jerusalem and attended medical school at the American University in Beirut, at about the same time as Yāsir ʿArafāt was co-founding al-Fatah in the early 1950s. The PLFP was an amalgamation of several groups, each of which had its own aims, and between which little compromise was possible, although all were engaged in militant activities. By the late 1970s some of these groups, such as the Popular Front for the Liberation of Palestine–General Command (PFLP-GC), were being supported by Libya and Syria in their acts of terrorism on an international scale, and the PFLP was still promoting a Marxist-Leninist line of a liberated Palestine of progressive Israelis and Jews uniting with the Arabs.

Popular Republican Movement, French MOUVEMENT RÉPUBLICAIN POPULAIRE (MRP), French social reform party whose policies correspond largely to the European Christian Democratic tradition.

Founded on Nov. 26, 1944, just after the German occupation of France during World War II, the MRP consistently won some 25 percent of the vote in the elections of the remainder of the 1940s, and it served as a bulwark of the early governments of the Fourth Republic. As a centre party, however, the MRP lost votes to both the right and the left as political opinions began to polarize during the East–West Cold War; in the 1951 elections it won only 12.6 percent of the votes cast and never regained its former popularity.

In October 1965 the MRP joined other right-centre parties to support the presidential candidacy of Jean Lecanuet, who came in a poor third to Gen. Charles de Gaulle and the candidate of the left, François Mitterrand. Lecanuet attempted to solidify the parties that supported him, including the MRP, into a centre party, the Centre Démocrate, founded in February 1966. Legislative elections in 1967 and 1968, however, brought fresh defeats for the centre, which failed to win more than 13 percent of the vote in either election. By the end of 1967 the MRP had become little more than a political club.

popular sovereignty, also called SQUATTER SOVEREIGNTY, in U.S. history, a controversial political doctrine that the people of federal territories should decide for themselves whether their territories would enter the Union as free or slave states. Its enemies, especially in New England, called it "squatter sovereignty."

It was first applied in organizing the Utah and New Mexico territories in 1850; its most crucial application came with the passage of Sen. Stephen A. Douglas' Kansas–Nebraska Act of 1854, which repealed the prohibition of slavery north of latitude 36°30′ (established in the Missouri Compromise of 1820). The violent struggle that followed for control of the Kansas Territory (*see* Bleeding Kansas) illustrated the failure of popular sovereignty as a possible ground for agreement between proslavery and anti-slavery factions in the country. *See also* Dred Scott decision.

Populares (ancient Roman political group): *see* Optimates and Populares.

population, in biology, the number of individuals of a species living in a restricted area, or the total number or combined weight of members of a plant species present in a given area.

A brief treatment of biological populations follows. For full treatment, *see* MACROPAEDIA: Biosphere.
